REPORT

OF THE

COMMISSIONER OF PATENTS.

UNITED STATES PATENT OFFICE,
January, 1851.

SIR:—I have the honor to submit the Report of the proceedings of this bureau for the year 1850. [Part I., Arts and Manufactures.]

Most respectfully,
Your obedient servant,
THOMAS EWBANK.

To Hon. HOWELL COBB,
Speaker of the House of Representatives.

I.

FINANCIAL, STATISTICAL, &c.

The number of applications for patents received during the year ending December 31st, 1850, is twenty-one hundred and ninety-three; the number of caveats filed during the same period is six hundred and two.

The number of patents issued during the year 1850, is nine hundred and ninety-five; including twenty-seven re-issues, three additional improvements, and eighty-six designs. Three disclaimers have been entered during the year.

Within the year 1850, six hundred and eighty-four patents have expired, a list of which is annexed marked F. There were seventeen applications to extend patents, the terms of which were about to expire; seven of which were granted, and five rejected. Five are still pending. None have been extended by act of Congress within the year.

The receipts of the Office for the year 1850, on account of applications for patents, caveats, additional improvements, re-issues, extensions, recording assignments, powers of attorney, &c., and for copies, amount to $86,927.05, as per statement marked A. The expenses of the Office for the year 1850, are as follows, viz:

For salaries $29,260.94; contingent expenses $13,430.19; books for the library, $767.47; temporary clerks, $13,361.67; agricultural statistics, $3,-859.35; refunding money paid by mistake, $258.00; analysis of breadstuffs, $500.00; compensation of librarian, $500.00; Chief Justice of District of Columbia, sitting on appeals from Commissioner of Patents, $100; on applications withdrawn, $18,013.33; and restoring models, $50; amounting in the whole sum to $80,100.95, as per statement marked B:—leaving a balance to be carried to the credit of the Patent Fund of $6,826.10 as per statement C.

On the first day of January, 1850, the amount of money in the Treasury to the credit of the Patent Fund was $169,505.17. Of this sum, $90,000 was appropriated by Congress by the act approved May 15th, 1850, "towards the completion of the "east wing of the Patent Office," which has been drawn out and expended. By the act of Congress approved September 30th, 1850, the further sum of $110,000 was appropriated "for completing the east wing of the Patent Office building, &c., to be paid out of the Patent Fund, if so much of said fund remains unappropriated, and if not, the excess out of any money in the Treasury not otherwise appropriated." Of the amount last appropriated, $71,000 has been drawn from the Patent Fund, leaving a balance in the Treasury to the credit of the Patent Fund on the first day of January, 1851, of $15,331.27, as per statement D.

There were nine cases on the examiners' desks January 1st, 1850; the number of applications received during the year, twenty-one hundred and ninety-three; making the whole number of applications before the Office during the year, twenty-two hundred and two. Of this number, one hundred and sixty-nine cases remained unexamined on the 1st day of January, 1851.

The business of the Office for the past year shows the examination of two thousand and thirty-two applications, resulting in the issue of nine hundred and ninety-five patents, and ten hundred and thirty-eight rejections and suspensions as exhibited per statement E.

A statement is also appended showing the amount of fees received, applications and caveats filed, during each month in the year, marked F.

[A.]

Statement of receipts for patents, caveats, additional improvements, recording assignments, &c., and for copies.

Amount received for patents, caveats, re-issues, and additional improvements, ...	$80,750 00
Amount received for recording assignments, &c., and for copies, ...	6,177 05
Total, ...	$86,927 05

[B.]

Statement of expenditures and payments made from the Patent Fund by the Commissioner of Patents from January 1st, 1850, to December 31st, 1850 inclusive, under the act of March 3d, 1837, and subsequent acts of Congress making provision for the expenses of the Patent Office, viz:

For salaries, ...	$29,260 94
" Contingent Expenses, ...	13,430 19
" Books for Library, ...	767 47
" Temporary Clerks, ...	13,361 67
" Agricultural Statistics, ...	3,859 35
" Refunding money paid by mistake, ...	258 00
" Withdrawals, ...	18,013 33
" Compensation of Librarian, ...	500 00
" " District Judge, ...	100 00
" Analysis of breadstuffs, ...	500 00
" Restoring models, ...	50 00
	$80,100 95

[C.]

Statement of Receipts and Expenditures of the Patent Office for the year 1850.

Amount received from all sources, ...	$86,927 05
" of expenditures of all kinds, ...	80,100 95
Amount carried to the credit of the Patent Fund for 1850,	$6,826 10

[D.]

Patent Fund, January 1st, 1850.

Amount of fund January 1st, 1850, . . .	$169,505 17	
Amount drawn out per acts of Congress approved May 15th, and September 30th, 1850, . .	161,000 00	
		$8,505 17
Amount carried to the credit of the Patent Fund for 1850, .		6,826 10
Amount remaining in the Treasury to the credit of the Patent Fund, January 1st, 1851, ...		$15,331 27

The books of the Treasury show the balance to the credit of the Patent Fund, January 1st, 1851, to be somewhat less, which is explained by the following letter received from the 1st Comptroller, viz:

Treasury Department,
Comptroller's Office, January 21st, 1851.

Thomas Ewbank, Esq., Commissioner of Patents:

Sir:—In answer to your letter of inquiry of the 16th inst., I state that the balance in the Treasury to the credit of the Patent Fund at different periods has been as follows:

On the 31st December, 1842,	$170,559 39
" 30th June, 1849,	210,315 05
" 30th June, 1850,	106,224 89
There has come into the Treasury, funds deposited between the 1st July and 31st December, 1850, amounting to	40,807 22
	147,032 11
Amount drawn out from 1st July to 31st December, 1850,	131,925 00
Balance due the Patent Fund December 31, 1850,	$15,107 11

as appears now by the books of the Treasury. It is very likely, however, that some of the deposites made with depositories previous to December 31st, have not come in yet, which may, when they come in, swell the balance belonging to that fund on the 31st of December last, an hundred or two dollars, and possibly more than that.

Most sincerely yours,
ELISHA WHITTLESEY.

[E.]

Statement of applications on hand January 1st, 1850, and number received during the year and acted upon.

No. of cases on examiners' desks January 1st, 1850,		9
" applications received in 1850,		2,193

Statement showing amount of fees received, and number of applications and caveats filed during each month of the year 1850.

1850.	Cash Received.	Certificates Received.	Small Fees Received.	Total Received.	Applicat's Filed.	Caveats Filed.
January,	$3,780	$4,595	$402.47	$8,777.47	239	60
February,	3,705	3,070	464.26	7,239.26	176	60
March,	2,765	4,895	459.43	8,119.43	196	38
April,	2,990	3,095	598.72	6,683.72	177	48

1850.	Cash Received.	Certificates Received.	Small Fees Received.	Total Received.	Applicat's Filed.	Caveats Filed.
May,	3,465	3,450	674.43	7,589.43	196	60
June,	3,515	4,890	442.88	8,847.88	191	44
July,	2,820	2,695	673.23	6,188.23	161	31
August,	2,835	2,910	542.93	6,287.93	174	49
September,	2,375	4,065	544.00	6,984.00	151	34
October,	2,615	3,000	480.57	6,095.57	166	61
November,	3,060	2,865	467.81	6,392.81	165	52
December,	2,840	4,455	426.32	7,721.32	199	65
	$36,765	$43,985	$6,177.05	$86,927.05	2,193	602

Table exhibiting the business of the Office for the last ten years, and the necessity of an increase of clerical force.

Years.	Applications Filed.	Caveats Filed.	Patents Issued.	Amount of Cash Received.	Amount of Cash Expended.
1841	847	312	495	$40,413.01	$23,065.87
1842	761	291	517	36,505.68	31,241.48
1843	819	315	531	35,315.81	30,776.96
1844	1045	380	502	42,509.26	36,344.73
1845	1246	452	502	51,076.14	39,395.65
1846	1272	448	619	50,264.16	46,158.71
1847	1531	533	572	63,111.19	41,878.35
1848	1628	607	660	67,576.69	58,905.84
1849	1955	595	1076	80,752.78	77,716.44
1850	2193	602	995	86,927.05	80,100.95

During the first entire year (1840) after two assistants were added to the examining force (previously consisting of two examiners) the number of applications received was 765, and of caveats 228. By the act approved May 27th, 1848, two more examiners and two assistants were added to the corps, based upon the business of the Office for the year 1847, during which year there were 1531 applications and 533 caveats received.

Thus *the present* examining force of the Office was deemed necessary for the transaction of that amount of business.

From the foregoing table it will be observed that in 1848 there were received 1628 applications and 607 caveats; in 1849, 1955 applications and 595 caveats; and in 1850, 2193 applications and 602 caveats; an increase over 1847 of *six hundred and sixty-two applications* for Patents and sixty-nine caveats; and an increase over 1840 of *fourteen hundred and twenty-eight applications and three hundred and seventy-four caveats.* Thus the business of the Office has nearly trebled within the last ten years, while the corps of examiners has only been doubled during that period.

The foregoing facts clearly indicate that two chief and two assistant examiners are necessary to meet the present demands of the Office, and prevent the business, now two months behindhand, from falling still further in arrears.

[G.]

CLASSIFIED LIST OF PATENTS

THAT HAVE EXPIRED DURING THE YEAR 1850.

CLASS I.—AGRICULTURE, *including Instruments and Operations.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.

Gin, cotton	James McCreight	Winsborough, S. C.	July 2, "
Gin, cotton, grates	Edwin Keith	Bridgewater, Mass	Mar. 4, "
Hats, blocking	W. W. Jemeson	Wheeling, Ohio	Mar. 30, "
Hats, bodies, stiffening	J. P. Kettell and J. Wright	Worcester Co., Mass	June 11, "
Hats, bodies, stiffening	E. P. Spear	Lexington, Mass	July 2, "
Hats, elastic, ventilating	Daniel Greenleaf	Vicksburg, Miss	Nov. 26, "
Hats, napping	L. Lyon, 2d	Needham, Mass	Apr. 13, "
Hats, palm leaf	Frederick Groening	Brooklyn, N. Y	June 25, "
Hats, water proof, silk	George B. Dexter	Boston, Mass	Jan. 6, "
Hemp, breaking	John Pursell	Perryville, Ky	Mar. 18, "
Loom, harness for	John Blackmar	Killingly, Conn	Oct. 20, "
Loom, power	F. C. Lewis	Grafton, Mass	Mar. 30, "
Loom, power	Benjamin Lapham	Waterford, N. Y	June 28, "
Loom, power, and taking up motion	H. Hendrick	Killingly, Conn	Sep. 22, "
Loom, power, and taking up motion	John P. Comins	Killingly, Conn	Oct. 20, "
Loom, reeds, machine for making.	Jeptha A. Wilkinson	Providence, R. I	May 23, "
Loom, weaving	Cullen Whipple	Douglass, Mass	June 11, "
Loom, weaving cloth for stocks	Conrad Kile	Philadelphia, Pa	Oct. 11, "
Napping cloth	Stephen Marsh	Jericho, Vt	Jan. 11, "
Oakum and hair picking	R. B. Lewis	Hallowell, Maine	June 25, "
Paper, cylinders for drying	H. P. Howe	Shirley, Mass	Sep. 20, "
Paper, drying	Henry Howe	Shirley, Mass	Mar. 12, "
Paper, making	Charles Forbes	East Hartford, Conn.	Feb. 20, "
Picking and breaking wool	John Shly	Augusta, Ga	Oct. 27, "
Rags, cleaning	William Debit	Hartford, Conn	July 1, "
Rags, dusting	E. Burt and Geo. Carriel	Manchester, Conn.	Nov. 28, "
Silk, winding	Adam Brooks	South Scituate, Mass	June 20, "
Silk, winding, gimp or cord	Adam Brooks	South Scituate, Mass	June 20, "
Spinning cotton	William P. Brayton	New York City	June 25, "
Spinning, fliers	Samuel Ladd	Waltham, Mass	Feb. 20, "
Spinning, fliers	Samuel Ladd	Waltham, Mass	May 6, "
Spinning, fliers, cotton	John Morse	Newton, Mass	June 25, "
Spinning hemp, &c.	Moses Day	Roxbury, Mass	June 2, "
Spinning machine	John Morgan	Manayunk, Pa	May 14, "
Spinning, roping, cotton	William Fowler	Fishkill, N. Y	Mar. 23, "
Spinning, spindle, and flier	W. T. Eddy	Ithica, N. Y	Feb. 10, "
Spinning wool	Sykes and Conradt	Fredericktown, Md.	Mar. 3, "
Spinning wool	J. Withered	Baltimore, Md	Mar. 30, "
Wool, combing	S. Couillard's assignees.	Boston, Mass	June 16, "
Wool, or flax, comber	William W. Calvert	Lowell, Mass	July 2, "
Wool, hair, &c., forming web without spinning, &c.	J. Arnold & G. G. Bishop	Norwalk, Conn	Oct. 20, "
Yarn, woollen	William B. Walker	Hillsborough Bridge, N. H	July 1, "

CLASS IV.—CHEMICAL PROCESSES, MANUFACTURES, AND COMPOUNDS, *including Medicine, Dying, Color-making, Distilling, Soap and Candle making, Mortars, Cements, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Blood, equalizing the	S. R. Terrell	Burton, Miss.	Feb. 5, 1836
Candles, moulds	Jefferson Dunlap	New Holland, Pa.	Mar. 8, "
Caoutchouc, application to cloths	E. M. Chaffee	Roxbury, Mass	Aug. 31, "
Caoutchouc, dissolving	Patrick Mackie	New York City	Mar. 23, "
Cement, hydraulic	Levi Kidder	New York City	Jan. 15, "
Cement, hydraulic	John White	Syracuse, N. Y.	Jan. 23, "
Distilling	Peter Swartz, jr.	Muncey, Pa	June 25, "
Distilling	A. R. Kerr & H. Hoover	Waynesborough, Pa.	July 1, "
Distilling, cold	A. V. H. Webb	Utica, N. Y.	May 14, "
Distilling, still for	John Wright	New York	Feb. 20, "
Dying hats	Aaron Gould	Washington, Conn	Jan. 11, "
Extracts, making	T. Close & J. C. Sanford	Rye, N. Y.	Mar. 18, "
Fermenting and distilling spirits	Isaiah Stowell	Manchester, N. H.	Feb. 5, "
Gypsum, applied to cisterns	J. Flint and Clark Mills	New York, N. Y.	Mar. 4, "
Lead, white	Homer Holland	Westfield, Mass	Mar. 18, "
Lead, white	Edward Clark	Saugerties, N. Y.	June 20, "
Lead, white	Joseph Richards	Philadelphia, Pa	Dec. 2, "
Light, and heat, generating	H. L. Barnum	New York	June 2, "
Matches, friction	Alonzo D. Phillips	Springfield, Mass	Oct. 24, "
Medicine, botanic	Samuel Thompson	Boston, Mass	May 6, "
Mineral water, soda fountain	Jos. Boston & T. Bryant	New York	Apr. 11, "
Ointment, for cancer	Elias Gilman	Licking, Ohio	Mar. 31, "
Paint, composition	H. Hibbard	Darien, N. Y.	Sep. 20, "
Pearl ash	J. and N. Paree	Linklean, N. Y.	May 14, "
Pitch, composition	Thomas H. Sherman	Scriba, N. Y.	Mar. 4, "
Pitch, making	Henry Ruggles	New York	Mar. 19, "
Potash, and pearl ash	Elijah Williams	Erie, Pa	Mar. 8, "
Salt, manufacturing	Richard K. Cralle	Lynchburg, Va	Mar. 18, "
Salt, supplying	Peter Cooper	New York	Feb. 20, "
Sores, curing	Reuben Rood	Centre Lisle, Brown county, N. Y.	Feb. 20, "
Starch, rice	W. and T. Liversidge	Dorchester, Mass	Feb. 17, "
Turpentine, spirits, extracting	J. Jennings	New York	July 1. "

CLASS V.—CALORIFIC, *comprising Lamps, Fire-places, Stoves, Grates, Furnaces for heating Buildings, Cooking Apparatus, Preparation of Fuel, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Baker, reflecting	L. B. Olmstead	Binghampton, N. Y.	Jan. 20, 1836
Chimneys, ovens, &c.	Elihu Smith	Ithica, N. Y.	July 1, "
Cooking stove	R. G. Cochran	Francistown, N. H.	Feb. 3, "
Cooking stove	Daniel Williams	Scaghticoke, N. Y.	Feb. 3, "
Cooking stove	B. and A. Titus	Marshall, N. Y.	Feb. 25, "
Cooking stove	John Liddle	Schoharie, Ohio	Mar. 12, "
Cooking stove	Charles Vale	Newark, N. J.	Mar. 18, "
Cooking stove	O. Wilson	Concord, Mass	Mar. 23, "
Cooking stove	B. H. Pearson	Warner, N. H	Mar. 31, "
Cooking stove	Charles Vale	Newark, N. J.	April 13, "
Cooking stove	Jonas Kendall, assignee of J. Perkins	Ipswich, Mass	April 28, "
Cooking stove	E. G. Currier	Warner, N. H	June 2, "
Cooking stove	E. G. Currier	Warner, N. H	June 2, "
Cooking stove	Charles Higgins	Turner, Me.	June 2, "
Cooking stove	William A. Arnold	Northampton, Mass.	June 1[illegible], "
Cooking stove	Gould Thr[illegible]	New York city	June 25, "
Cooking stove	Thomas Sh[illegible]	N. Yarmouth, M[illegible]	Jun. 25. "
Cooking stove	Seb[illegible]n H. Lacter	M[illegible]y, Pa.	June 28, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Cooking stove	P. F. Perry	Rockingham, Vt.	June 28, 1836
Cooking stove	Beriah Douglas	Albany, N. Y.	June 30, "
Cooking stove	Asahel Lear	Wendall, N. H.	July 1, "
Cooking stove	E. Andrews and S. Austin	Bradford, N. H	July 1, "
Cooking stove	Elisha N. Pratt	Albany, N. Y.	July 1, "
Cooking stove	Chester Granger	Pottsford, Vt.	July 2, "
Cooking stove	P. C. Traver	West Troy, N. Y.	July 2, "
Cooking stove	Elisha Lyman	E. Hampton, Mass.	July 2, "
Cooking stove	John Whiting	Boston, Mass.	Oct. 20, "
Cooking stove	S. B. Spalding	Brandon, Vt.	Nov. 17, "
Cooking stove, and parlor	Nicholas Smith	New Hampton, N.H.	Oct. 27, "
Fire, extinguishing	Isaac Clowes	Norfolk, Va.	July 2, "
Fire place	Elijah Skinner	Sandwich, N. H.	Mar. 12, "
Fire place	William Burgess	Middleboro', Mass.	Mar. 12, "
Fire place	William R. Prescott	Hallowell, Me.	Mar. 19, "
Fire place	Reuben Buck	Acton, Me.	July 1, "
Fire place, or stoves	Foster Stevens	Springfield, Mass.	Mar. 2, "
Fuel, saw-dust, drying, &c.	William Avery	Syracuse, N. Y.	Oct. 11, "
Furnaces and boiler combined	Alexander Harrison	New Haven, Conn.	Mar. 2, "
Furnaces for warming buildings	F. A. Fickhardt	Easton, Pa.	Sept. 8, "
Grates	James Bennett	New York	May 14, "
Grates, cooking	John James Giraud	Baltimore, Md.	Feb. 10, "
Grates, parlor	William Anderson	New York	June 25, "
Grates, pendulum	Nathan Winslow	Portland, Me.	July 2, "
Grates, portable	James Williamson	Washington, D. C.	Nov. 8, "
Grates, sliding	John C. Howard	Hampton, Conn.	Feb. 13, "
Gridirons and spider	A. and George Sizer	Meriden, Conn.	Nov. 14, "
Heat, applying from lime, &c.	Peter Wenn	Philadelphia, Pa.	Mar. 8, "
Heat, evolution and management of	Lovell Lewis	Lewistown, N. Y.	Mar. 2, "
Heating chocolate ingredients	G. W. Waite	Baltimore, Md.	June 25, "
Heating water machines	D. B. Barnum	New Fairfield, Conn.	June 25, "
Kitchen ranges	George Johnson	Philadelphia, Pa.	May 23, "
Lamps	Isaiah Jennings	New York city	Sept. 22, "
Lamps, hanging, (antedated August 13, 1836)	Alonzo Platt	Middletown, Conn.	Oct. 8, "
Lamps, light-house burner	Isaac Dunham	Bristol, Me	June 20, "
Lamps, reflecting	John C. Fletcher	Springfield, Ohio	Mar. 30, "
Ovens	Samuel Pollard	Orono, Maine	Feb. 3, "
Ovens	William H. Akins	Berkshire, N. Y.	June 2, "
Ovens, baker	Eben B. Strong	Buffalo, N. Y.	April 11, "
Ovens, heating by anthracite	F. C. Treadwell	Brooklyn, N. Y.	June 16, "
Ovens, heating rooms	J. A. Pitts	Winthrope, Maine	July 2, "
Ovens, reflecting	C. D. Van Allen	Pen Yan, N. Y.	Mar. 31, "
Ovens, reflecting	Benjamin Ames	Ithica, N. Y.	June 25, "
Smoke, consuming	Nathan Lockling	Sparta, N. Y.	Mar. 4, "
Stoves	William M. Carmichael	Hempstead, N. Y.	Mar. 23, "
Stoves	John H. B. Swanzey	Lynn, Mass	Mar. 30, "
Stoves	Frazier, Blanchard & Gill	New York	April 28, "
Stoves	Frederick A. Fickhardt	Eaton, Pa.	April 28, "
Stoves	Nathaniel Russell	Waterville, Maine	May 14, "
Stoves	Howell Parmelee	Watervleit, N. Y.	July 2, "
Stoves, air-tight	Isaac Orr	Washington, D. C.	Jan. 20, "
Stoves, air warmer	J. J. Heintzelman	Philadelphia, Pa.	June 16, "
Stoves, anthracite coal	Adrian Jones	Hartford, Conn	June 2, "
Stoves for carriages	Alexander McWilliams	Washington, D. C.	April 21, "
Stoves, conical	Robert Robertson	Albany, N. Y.	June 16, "
Stoves, and fire place	C. Hendricks and W. Elwell	Gardner, Maine	Feb. 25, "
Stoves, and fire place	Jordan L. Mott	New York	Oct. 11, "
Stoves, foot	Ezekiel Daboll	Canaan, Conn.	July 1, "
Stoves, Franklin	John Harryman	Haverhill, Mass.	Sept. 29, "
Stoves, parlor	Beriah Douglas	Albany, N. Y.	June 30, "
Stove pipes	Ezra Ripley	Albany, N. Y.	Jan. 23, "
Stoves, rotary caps	Maynard French	Albany, N. Y.	Mar. 2, "
Stoves, ventilating	Clement Woodward	Washington, D. C.	July 2, "
Ventilating and supplying houses with cold or hot air	R. Mayo and Robt. Mills	Washington, D. C.	Oct. 24, "

CLASS VI.—STEAM AND GAS ENGINES, *including Boilers and Furnaces therefor, and parts thereof.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Boilers, steam	J. W. and E. Strange	Taunton, Mass.	Sept. 29, 1836
Boilers, steam, purifying water	Moody Park	Madison, Indiana	Oct. 4, "
Spark catcher	A. McDonough	Philadelphia, Pa.	Feb. 17, "
Spark catcher	Francis Milo	New York city	Feb. 26, "
Spark catcher	William Shultz	Philadelphia, Pa.	Mar. 31; "
Spark catcher	James F. Curtis	Boston, Mass.	Apr. 13, "
Spark catcher	A. Whitney & L. L. Burr	Albany, N. Y.	May 23, "
Spark catcher	Gabriel Winter	Donaldsonville, Pa.	July 1, "
Steam engine	A. S. Dawley	Boston, Mass.	May 23, "
Steam engine, safety	Edward D. Tippet	Washington, D. C.	Nov. 23, "
Steam engine, locomotive	H. R. Campbell	N. L. Philad'a, Pa.	Feb. 5, "
Steam engine, locomotive, for inclined planes, (ante dated July 13, 1836)	John Ruggles	Thomaston, Maine	July 28, "
Steam engine, locomotive and rail roads	Isaac W. Edgar	Wayne county, Ohio	July 2, "
Steam engine, rotary	Aaron Clark	Bangor, Maine	Feb. 16, "
Steam engine, rotary	David Ulard	Greenburg, Pa.	Mar. 23, "
Steam engine, rotary	Shepherd Whitman	New Albany, Ind.	June 25, "
Steam engine, rotary	F. Carpenter	Cazenovia, N. Y.	July 2, "
Steam engine, rotary reacting	John Ingham	Apulia, N. Y.	Nov. 28, "
Steam, generating	Job Carr	Springborough, Ohio	Mar. 12, "
Steam, generating	John Ames	Springfield, Mass.	Mar. 12, "
Steam, generating	E. Nott	Schenectady, N. Y.	Mar. 19, "
Steam, generating	J. Jennings	New York	July 1, "
Steam, generating	M. W. Baldwin	Philadelphia, Pa.	Oct. 15, "
Valve, puppet, raising, &c	Wm. Duff & T. Murphy	Baltimore, Md.	Feb. 17, "
Valve, slide	A. McCausland, Jr.	Philadelphia, Pa.	Feb. 10, "

CLASS VII.—NAVIGATION *and Maritime Implements, comprising all Vessels for conveyance on water, their construction, rigging and propulsion, Diving Dresses, Life Preservers, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Anchor, cast iron	James S. Stoddard	Palmyra, N. Y.	July 2, 1836
Blocks, sheaves of	Cyrus Alger	Boston, Mass.	July 1, "
Blocks, ships', cutting sheaves, &c.	Thomas Blanchard	New York	Aug. 31, "
Blocks, ships', and dead eyes, &c.	Thomas Blanchard	New York	Aug. 10, "
Blocks, ships', finishing wooden sheaves	Thomas Blanchard	New York	Aug. 1, "
Blocks, ships', forming end pieces &c	Thomas Blanchard	New York	Aug. 10, "
Blocks, ships', forming or shaping cheeks, &c	Thomas Blanchard	New York	Aug. 31, "
Blocks, ships', mortising and boring, &c	Thomas Blanchard	New York	Aug. 10, "
Blocks, ships', riveting plank, &c.	Thomas Blanchard	New York	Aug. 10, "
Blocks, ships', rounding edges, &c.	Thomas Blanchard	New York	Aug. 10, "
Blocks, ships', tackle, countersinking, &c	Thomas Blanchard	New York	Aug. 31, "
Boats, passing over dams	Stephen Underwood	Bath, N. H.	Mar. 19, "
Boats, and rafts, passing, &c	Benning Sanbord	Lyman, N. H.	Apr. 11, "
Boats to be used under water	Edward Fitzpatrick	Mount Morris, N.Y.	Feb. 12, "
Capstan	Andrew Morse	Boston, Mass.	Mar. 12, "
Constructing vessels	Daniel Gerrish	Boston, Mass.	July 2, "
Dead eyes, for cutting and boring laniard scores	Thomas Blanchard	New York	Aug. 10, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Ice breaker	Michael Freytag	Philadelphia, Pa.	July 2, 1836
Ice cutting machine	Samuel Trask	Hallowell, Maine	Apr. 21, "
Propelling boats, &c.	Gideon Hotchkiss	Windsor, N. Y.	June 2, "
Propelling boats	Philander Noble	Westfield, Mass.	Jan. 20, "
Propelling paddles for boats	John Cochran	Baltimore, Md.	Apr. 28, "
Raising vessels	Tobias Cook	Scituate, Mass.	June 30, "
Rudders	Samuel Kepner	Harrisburg, Pa.	Mar. 4, "
Sails for ships, &c. making and furling	John Wade	Boston, Mass.	Dec. 6, "
Thimbles, ships'	Prentiss White	Yarmouth, Mass.	July 2, "

CLASS VIII.—MATHEMATICAL, *Philosophical and Optical Instruments, including Clocks, Chronometers, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Clocks	Joseph Ives	Bristol, Conn.	July 1, 1836
Compass, quadrant, and protractor	Francis Whiteley	Standardsville, Va.	Dec. 6, "
Compass, surveying	Nathan Basset	Wilmington, Del.	June 28, "
Distance, measuring	Rufus Porter	Billerica, Mass.	June 11, "
Glasses, for spectacles	Isaac Schnaitman	N. L. Philadel'a, Pa	Feb. 20, "
Maps, charts, &c., apparatus for exhibition	Nathaniel K. Lombard	Boston, Mass.	Oct. 27, "
Spring for clocks	James S. Ives	Bristol, Conn.	May 23, "
Time piece	William Pardie	Poughkeepsie, N.Y.	Feb. 20, "
True meridian, finding, &c	William A. Burt	Mount Vernon, Mich	Feb. 25, "

CLASS IX.—CIVIL ENGINEERING *and Architecture, comprising works on Rail and Common Roads, Bridges, Canals, Wharves, Docks, Rivers, Wiers, Dams, and other Internal Improvements, Buildings, Roofs, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bridges, frame	Stephen H. Long	U. S. Topograph Eng	Jan. 23, 1836
Buildings, constructing	Lewis Knapp	New York	June 28, "
Buildings, stores, &c.	Isaac Knight	Baltimore, Md.	May 23, "
Canals, locks	David Wilkinson	Cahoes, N. Y.	May 14, "
Canals, locks, gate	Valentine Brown	Clifton Park, N. Y.	May 14, "
Canals, locks, indicator	Valentine Brown	Clifton Park, N. Y.	May 14, "
Dock, dry	J. Houston, A. Hinman and J. Ingraham	Buffalo, N. Y.	June 22, "
Dock, hydraulic	Zebedee Ring	New York	Feb. 13, "
Drilling stone	Andrew Turney	Reading, Conn.	Mar. 3, "
Excavating from rivers	Sylvanus Russell	Buffalo, N. Y.	Apr. 28, "
Marsh drainer	Jean Blanc	New Orleans, La.	July 2, "
Railroad	Nathan Reed	Belfast, Maine	Mar. [illegible], "
Railroad plates, jointing	A. M. McCaine	Montgomery, Ala.	Mar. 31, "
Railroad, turn out	John Talbot	Portsmouth, Va.	Oct. 11, "
Roads, constructing	John S. Williams	Fulton, Ohio	July 1, "
Sewer, of hydraulic cement	Obadiah Parker	New York city	July 2, "
Tunnelling rivers	J. B. Bucklin & J. Jacobs	West Troy, N. Y.	July 11, "
Wharves, piers, &c., constructing	John G. Pray	Brooklyn, N. Y.	Jan. 6, "
Window frieze and covering	William Woolley	New York	July 1, "

CLASS X.—LAND CONVEYANCE, *comprising Carriages, Cars, and other Vehicles used on roads, and parts thereof.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Axletrees for carriages and cars..	Spencer Coleman........	Mount Pleasant, Va.	Mar. 2, 1836
Breakers, cylindrical, for retarding machinery	Smith Cram........	New York........	June 2, "
Car, door fastening............	John K. Smith	Port Clinton, Pa.....	Feb. 12, "
Car, railroad............	J. Davis and W. Ashdown	Baltimore, Md......	Mar. 4, "
Car, railroad, attaching..........	L. Pickering & J. Lightner	Boston, Mass........	June 28, "
Car, taking over elevators..........	Smith Cram........	New York city......	June 11, "
Springs, carriage..........	Newel Hungerford......	Ithica, N. Y.......	Mar. 31, "
Sulkey seat............	O. H. Capron and G. Barton, jr.........	Shaftsbury, Vt.....	Jan. 23, "
Tire for wheels..........	James H. Rogers	Mount Morris, N.Y.	Feb. 17, "
Wagon, coaches, and breaks for..	Henry West	Quincy, Mass......	Sept. 29, "
Wagon, hanging..........	Henry Mellish........	Walpole, N. Y......	Jan. 11, "
Wagon, tilting..........	Stephen Beebe........	Norwich, Conn......	June 22, "
Wheels, boxes fitting to..........	J. & C. Putnam........	Hallowell, Maine....	April 28, "
Wheels, cart and carriage..........	William Woodbridge....	Kennebec, Maine....	May 17, "
Wheels, confining carriage to.....	Clark Force..........	Baltimore, Md......	April 28, "
Wheels, horse detaching..........	Philip T. Share	Baltimore, Md......	Mar. 18, "
Wheel hubs..........	John Atherton........	Philadelphia, Pa....	June 2, "

CLASS XI.—HYDRAULICS AND PNEUMATICS, *including Water-wheels, Windmills, and other implements operated on by air or water, or employed in raising and delivery of fluids.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Blow-pipe for furnace..........	J. Barker..........	Baltimore, Md......	Feb 12, 1836
Faucets, molasses..........	Charles W. Peckham....	New Haven, Conn..	Feb. 10, "
Gate, flume..........	Harvey Frink........	Chautauque co, N.Y.	Feb. 25, "
Hydrants..........	S. T. Walker........	Baltimore, Md......	July 1, "
Hydrants..........	S. T. Walker........	Baltimore, Md......	July 2, "
Hydrants..........	David Horne........	Baltimore, Md......	Mar. 31, "
Hydrostatic press..........	Thomas Baxter........	Petersburg, Va......	April 13, "
Pumps..........	J. F. Walker........	Easton, Pa........	May 6, "
Pumps..........	Abner T. Mixwell......	Oxford, N. J......	June 30, "
Pump, forcing, double..........	Levi Newton........	Alexander, N. Y....	Mar. 8, "
Pump, forcing, double..........	John G. White........	Dryden, N. Y......	July 1, "
Pump, forcing..........	Benjamin Egbert........	Lansing, N. Y......	Jan. 23, "
Pump, forcing..........	W. W. Lesner........	Venice, N. Y......	Mar. 12, "
Pump, forcing..........	John F. Rodgers........	Waterford, N. Y....	Mar. 30, "
Pump, forcing..........	Nathan Chapin........	Penn Yan, N. Y....	Mar. 30, "
Pump, frictionless..........	Edward Whitfield........	New York........	June 2, "
Pump, frictionless..........	Charles V. Card........	New Bedford, Mass.	Nov. 26, "
Pump, suction..........	Thomas C. Barton........	Washington, N. J..	Feb. 20, "
Pump, vibrating..........	Sampson Davis........	Derby, Vt........	Feb. 25, "
Raising water..........	Joseph Turner........	Poland, Maine......	May 6, "
Raising water..........	Jesse C. Wood........	Ephrata, N. Y......	June 22, "
Raising water by weight..........	David Hess........	Shepardstown, Va..	July 1, "
Water, applying..........	J. Hinds, M. B. Ball, and S. Pike........	Troy, N. Y........	May 14, "
Water, conveying..........	Samuel Hant........	Baltimore, Md......	Mar. 31, "
Water-wheel..........	William L. Elgar........	Winchester, N. H..	Feb. 10, "
Water-wheel..........	Frederick Wingate........	Augusta, Maine....	Mar. 4, "
Water-wheel..........	Abraham Straub........	Milton, Pa........	Mar. 12, "
Water-wheel..........	Carey S. Mercer........	Franklin, Md......	Mar. 30, "
Water-wheel..........	J. T. Towne........	Mount Morris, N.Y.	April 11, "
Water-wheel..........	William Hitchcock........	Spencer, N. Y......	May 23, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Water-wheel..........	Henry Allen..........	Fayetteville, Tenn..	June 2, 1836
Water-wheel..........	Orson Waldo..........	Newark, N. Y......	June 25, "
Water-wheel..........	Charles Kenzie..........	Troy, N. Y........	July 1, "
Water-wheel..........	Samuel Garrett..........	Loudonville, Ohio..	July 2, "
Water-wheel..........	William F. Brown......	Augusta, Maine....	July. 2, "
Water-wheel, propelling..........	Aretas A. Wilder......	Warsaw, N. Y......	Mar. 8, "
Water-wheel, &c., regulating the motion of..........	Nathan Scholfield......	Norwich, Conn......	May 17, "
Wells, covers of..........	Levi Kidder..........	New York city......	Jan. 15, "
Wind wheel..........	Job Wilbur..........	Fall River, Mass...	Mar. 30, "

CLASS XII.—LEVER, SCREW, AND OTHER MECHANICAL POWER, *as applied to Pressing, Weighing, Raising and Moving Weights.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Balance..........	Jirah Vaughn..........	Rutland, Vt........	May 6, 1836
Balance, platform..........	C. P. Ladd..........	Strasburg, Vt......	May 17, "
Balance, platform..........	James M. Peck..........	Lyndon, Vt........	May 23, "
Balance, platform..........	John Horton..........	Madrid, N. Y......	July 2, "
Condensing cotton..........	Arlon Man..........	Smithfield, R. I....	April 28, "
Crane..........	Elias Marsh..........	Oswego, N. Y......	Feb. 12, "
Crane..........	Gilbert Sherwood..........	Erie, Pa........	June 30, "
Lever power, sawing, &c. by	Jeremiah Walker..........	Phillips, Maine....	Feb. 25, "
Packing flour..........	Jonathan F. Barrett....	Granville, N. Y....	Jan. 23, "
Packing screw, inverted..........	Stephen Terry..........	Decatur, Geo......	June 11, "
Packing tobacco..........	J. B. Allen..........	Richmond, Va......	Jan. 15, "
Press, cotton..........	J. Mitchell..........	Rutherford, Tenn..	Mar. 12, "
Press, hay..........	A. R. Chamberlin and A. Cleflin..........	Richmond, Va......	Mar. 30, "
Press, lever..........	H. G. Guyon..........	New York........	July 2, "
Press, tobacco..........	A. M. McLean..........	Russellville, Ky....	Feb. 5, "

CLASS XIII.—GRINDING MILLS, *and Mill-gearing, containing Grain Mills, Mechanical Movements and Horse-Powers, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Chocolate, grinding..........	Geo. W. Waite..........	Baltimore, Md......	June 25, 1836
Chocolate, moulding..........	James Mathews..........	Baltimore, Md......	June 25, "
Cider mill..........	Christian Sheaffer..........	Lebanon, Pa......	Mar. 19, "
Cider mill..........	Elias Jenkins..........	Harmony, Pa......	May 17, "
Coffee mill..........	C. W Peckham..........	New Haven, Ct....	April 13, "
Cooler, flour..........	Josiah Pope..........	Windham, Me......	Feb. 5, "
Grist mill..........	W. and J. McCreight....	Winnsborough, S.C.	Feb. 5, "
Grist mill..........	Oliver Wyman..........	Watertown, Mass..	July 1, "
Grist mill, for cutting..........	William Gerrish..........	Portsmouth, N. H..	Jan. 11, "
Horse power..........	Daniel Fitzgerald..........	New York city......	Oct. 19, "
Horse power..........	Samuel Newton..........	Dayton, Ohio......	Jan. 20, "
Horse power..........	Dudley Marvin..........	New York city......	Feb. 5, "
Horse power..........	Joseph Musten..........	Franklin county, Vt.	Feb. 12, "
Horse power..........	Richard Skinner..........	Williamson, N. Y....	Mar. 31, "
Horse power..........	Amos Adams..........	Augusta, Maine....	May 6, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Horse power	Isaac Straub	Lewistown, Pa	May 14, 1836
Horse power	C. Coster and D. Pennypacker	Upper Providence, Penn	May 23, "
Horse power	Rufus Porter	Billerica, Mass	June 11, "
Horse power	Wm. Whitman	Haverhill, N. H	June 20, "
Horse power	John Abbott	S. Reading, Mass	June 30, "
Horse power	Charles G. Gilbert	Leeds, Maine	July 2, "
Horse power	Daniel Fitzgerald	New York city	Oct. 19, "
Horse power, endless chain, &c	O. Badger	Cooperstown, Conn.	Oct. 15, "
Mill	John Harman, jr	New York	Mar. 30, "
Mill, metallic	Joseph C. Gentry	Dayton, Ohio	Mar. 18, "
Mill stones, cooling	Autin Taylor	Littleton, N. H	Mar. 31, "
Mill stones, picks	Samuel Etheridge	Tecumseh, Mich	Mar. 2, "
Mill wheel, dresser	John Turk	Columbus, Pa	July 1, "
Motion, reciprocating, &c	Benjamin Babbet	Bangor, Maine	Oct. 11, "
Power, endless chain propeller	Lewis Chevrier	Philadelphia, Pa	July 11, "
Power, alternate motion, by contraction and expansion of metals	Hazard Knowles	Hartford, Conn	Sept. 8, "
Power, self-motive	J. J. Giraud	Baltimore, Md	Mar. 31, "
Regulating speed, wheel for grist mills	S. H. Freeman	Cecilton, Md	May 17, "

CLASS XIV.—LUMBER, *including Machines and Tools for Preparing and Manufacturing; such as Sawing, Planing, Mortising, Shingle and Stave, Carpenters and Coopers' Implements.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bit stocks	Jeremy Taylor	Hebron, Conn	June 30, 1836
Boring wood	John B. Pell	New York	Mar. 2, "
Casks, machine	Sumner King	Suffield, Conn	Mar. 23, "
Casks and barrel headings	Hiram Andrews	Canaan, Conn	Mar. 2, "
Drawing knife	Edward Richards	Hingham, Mass	June 28, "
Dye woods, cutting and shaving	B. Swift	Washington, N. Y	Aug. 10, "
Fence pickets, cutting	J. Tichenor, S. Goodrich, and G. A. Hart	Ithica, N. Y	June 22, "
Gimlet, forging	De Grass Fowler	Wallingford, Conn	July 2, "
Gimlet, &c	William M. Fowler	N. Brandford, Conn	April 28, "
Joint, of wood work	S. C. Batchelor and N. S. Thomas	Watertown, N. Y	Mar. 30, "
Lathe	Enos and Nelson Avord	Westfield, Mass	Oct. 2, "
Lathe, gripe chuck for	David Peeler	Boston, Mass	Mar. 31, "
Laths, machine	Elihu Smith	Ithica, N. Y	April 28, "
Mortising machine	George Page	Keene, N. H	Mar. 18, "
Mortising machine	Erastus M. Shaw	Wilbraham, Mass	Mar. 23, "
Mortising machine	J. C. Channell	Dunstable, N. H	June 16, "
Mortising machine	Samuel B. Babcock	Oldstead, N. H	June 16, "
Mortising machine	John Hawkins	Stockbridge, Mass	June 20, "
Mortising machine	David Clark	Brooklyn, Conn	Sept. 14, "
Mortising and boring machine	George Page	Keene, N. H	Mar. 13, "
Mortising timber	George Page	Keene, N. H	Mar. 21, "
Pegs, shoe	R. H. Thompson	Rochester, N. Y	Mar. 23, "
Plane	J. T. Jones	Philadelphia, Pa	May 14, "
Plane, revolving	Lemuel Hedge	Brattleboro', Vt	June 28, "
Planing machine	Melzer Tuells	Milo, N. Y	Feb. 10, "
Planing machine	Lorrain Curtis	Sherburne, N. Y	June 16, "
Planing machine	P. M. Martz	Marion county, Ia	June 25, "
Planing machine	Ira Gay	Dunstable, N. H	June 25, "
Planing machine	William Woodworth	New York	Nov. 15, "
Saw belt	William Carey	Poughkeepsie, N. Y	Feb. 17, "
Saw belt, for timber	Benjamin Barker	Ellsworth, Me	Jan. 6, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Saw for felling trees	Walter Hunt	New York city	Jan. 6, 1836
Saw, rotary	Robert S. Thomas	Rockingham, N. C.	July 1, "
Saw, straightening	E. Rathbun and W. Tinker	Conneaut, Ohio	July 1, "
Sawing machine	Joseph Peevy	Levant, Maine	May 14, "
Sawing timber	Joshua Webb	Brooklyn, Conn	May 14, "
Sawing wood	Joseph Pinno, jr	Hanover, N. H	April 21, "
Saw-mills	G. W. Black	Montgomery co., Te.	Feb. 3, "
Saw-mills	David Washington	Peru, Mass	Feb. 25, "
Saw-mills	Isaac Read	Marshfield, Mass	Mar. 2, "
Saw-mills	Daniel Gerrish	Boston, Mass	April 11, "
Saw-mills	James Sanders	Alleghany co., Md	April 28, "
Saw-mills	W. J. McGhee	Columbus, Geo	May 14, "
Saw-mills	T. B. Naylor	Jonesville, N. C	June 2, "
Saw-mills	Simon Willard	New York city	June 30, "
Saw-mills	Samuel Gondy	Greensburg, Ky	July 2, "
Saw-mill, blocks for	Erastus Rathburn	Conneaut, Ohio	April 11, "
Saw-mill, crank	Benjamin F. Snyder	Elmira, N. Y	Sept. 29, "
Saw-mill, cross-cutting	Rufus Riker	Dexter, Maine	Feb. 20, "
Saw-mill, dogs	Martin Rich	Ithica, N. Y	Feb. 25, "
Saw-mill, dogs	Phineas Bennett	Ithica, N. Y	Feb. 25, "
Saw-mill, endless side chain, carriages for	James Murray	Baltimore, Md	Oct. 11, "
Saw-mill, saw	B. K. Barker	Johnsbury, N. Y	Feb. 5, "
Screws, cutting wooden	Joseph Peevy	Levant, Mo	Jan. 6, "
Shingles, dressing	N. P. Hawk and J. Keyes	Union, N. Y	April 21, "
Shingle machine	Tunis J. Burhyte	Barton, N. Y	July 1, "
Shingles, sawing	Jonathan Hobbs, jr	Falmouth, Maine	Sept. 14, "
Slitting timber	R. Beale and M. Bucklin	Grafton, N. H	May 23, "
Staves, sawing	Charles M. Keller	Washington, D. C.	June 30, "
Staves, sawing	A. Bard and S. Heywood	Lunenburg, Mass	Feb. 20, "
Staves, sawing for barrels	Cyrus McGregor	Newport, N. H	July 2, "
Veneers, cutting	James Hamilton	New York city	Nov. 10, "
Veneers, laying on ogee and other mouldings	John Soule	New Bedford, Mass.	Aug. 31, "

CLASS XV.—STONE AND CLAY MANUFACTURES, *including Machines for Pottery, Glass making, Brick making, Dressing and Preparing Stone, Cements, and other Building Materials.*

INVENTIONS OR DICOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Brick machine	John Moffatt	Buffalo, N. Y	Mar. 8, 1836
Brick machine	Nathaniel Adams	Newburg, N. Y	April 13, "
Brick machine	Gooding Halloway	Montgomery co., Pa.	April 21, "
Brick machine	Calvin Waterman	Bath, Maine	July 2, "
Brick moulding	James Coppuck	Louisville, Ky	July 1, "
Brick press	Phineas Ball	Mount Vernon, O.	Mar. 2, "
Glass cases	Thomas W. Whitley	Paterson, N. J	April 21, "
Granite, cutting and dressing	John D. Buzzell	Cape Elizabeth, Me.	June 2, "
Granite, hammering and dressing	William Morse	Corinna, Maine	Sept. 5, "
Gypsum, applied to cisterns	J. Flint and Clark Mills.	New York city	Mar. 4, "
Moulding pottery	J. C. Mendall and R. B. Ricketts	Masonville, Ky	June 30, "
Stone, cutting	J. and J. Sutton	Reading, N. Y	June 20, "
Stone, cutting and planing	A. Clark and C. H. Boynton	West Stockbridge, Mass	June 20, "

CLASS XVI.—LEATHER, *including Tanning and Dressing, Manufacture of Boots, Shoes, Saddlery, Harness, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Boots, crimping, clamps for	E. G. Pomeroy	Newark, Ohio	Oct. 4, 1836
Boots, crimping, cramp for	Hubbard L. Pierce	St. Johnsbury, Vt.	June 25, "
Boots, crimping legs	William Gerrish	Poland, Maine	Feb. 10, "
Boots, machine for turning boot legs	Thomas N. Saddler	Spencer, Mass	Nov. 8, "
Boots, trees	M. Matthews	Wayne, Ohio	Feb. 25, "
Boots, tucking machine	Sherburne C. Blodget	Rowley, Mass	June 11, "
Boots, turning	Peletiah Stevens	Stoughton, Mass	Mar. 4, "
Boot and shoe soles, cutting	Jonathan Hill	Billerica, Mass	Mar. 31, "
Glazed leather	E. G. Adams	Decatur, Ga	June 30, "
Harness, horse collars	John Hopkinson	Warren county, O.	Jan. 23, "
Harness, horse collars, forming	G. Warner and Robinson	Canajoharie, N. Y.	June 22, "
Harness, nets, fly for horses	Henry Korn	Philadelphia, Pa	July 2, "
Harness, pad, elastic water proof	A. Deitz	Albany N. Y.	Oct. 14, "
Harness, riveting	William Dukehart	Baltimore, Md	Mar. 30, "
Hides, unhairing	James Banks	Dixmont, Maine	June 30, "
Mail bags, bolt for	Ira Atkins	Hanover, N. H	Feb. 17, "
Rolling leather	J. M. Laughlin & H. Hill	Sunderland, Vt	April 28, "
Saddles	Benjamin Kraft	Reading, Pa	June 20, "
Saddles	Otho W. S. Callihan	Staunton, Va	July 1, "
Saddles and collars	Ebenezer Hale	New York, N. Y	Jan. 29, "
Saddles, elastic	William McCormick	Bath county, Ky	June 20, "
Saddles, ladies'	M. Jenkins	Attica, N. Y	July 1, "
Saddles, side	E. Bridewell	Bardstown, Ky	Nov. 26, "
Saddles, spring	Peter Crim	Waynestown, Pa	April 28, "
Saddles, spring	William Duchman	Morgantown, Pa	Aug. 31, "
Saddles, trees	Andrew R. McBride	Williamson co., Te.	Feb. 5, "
Shaving leather	Herkimer Johnson	Brooklyn, Conn	June 16, "
Shoe making machine	J. Hall	N. Bridgewater, Mass	May 6, "
Shoe, over	Daniel H. Bond	Canterbury, Conn.	June 30, "
Tanning	Henry Lochier	Lancaster, Pa	Mar. 18, "
Tanning	Laban Emery	New York	Mar. 17, "
Tanning	Simeon Heath	Pike, N. Y	May 23, "
Tanning, bark for	Daniel Williams	Boston, Mass	Feb. 5, "
Trunks, travelling	Washington Sweetzer	Portsmouth, N. H.	July 1, "
Trunks, valises, &c	James W. Noble	Pittsfield, Mass	Jan. 15, "
Trunks, valises, &c	William Brown	Brooklyn, N. Y	July 1, "

CLASS XVII.—HOUSEHOLD FURNITURE, *Machines and Implements for Domestic Purposes including Washing Machines, Bread and Cracker Machines, Feather Dressing, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bed-bug, destroying	Britain Garrand	Marysville, Tenn	Mar. 12, 1836
Beds, spring, spiral	M. F. Moody and B. Eastman	Northampton, Mass.	April 13, "
Bedsteads	Jonas Maguire	Philadelphia, Pa	Jan. 15, "
Bedsteads	Christian Kniseley	Meadville, Pa	June 16, "
Bedstead, cot	Samuel Clarke	New York	Mar. 23, "
Bedstead fastenings	Ira McLaughlin	Sunderland, Vt	April 28, "
Chairs, easy	Andrew Wood	Charlestown, Va	June 28, "
Crackers and biscuit, cutting	Eph. Treadwell	New York	May 18, "
Crackers, cutting and rolling	W. R. Nivens	New York	Mar. 2, "
Cutting apples, and paring	John W. Hatcher	Bedford county, Va.	Feb. 3, "
Cutting meat	J. Masser and S. Smith	Megentown, Pa	June 2, "
Cutting sausage meat	Ambrose Henkel	New Market, Va	Feb. 13, "
Cutting vegetables	Austin H. Robbins	Denmark, N. Y	May 6, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Cutting vegetables	Henry Mellish	Walpole, N. H	June 25, 1836
Dough machine	D. and T. Shackford	Westbrook, Conn.	Mar. 2, "
Feathers, cleaning	Daniel K. Hall	New York	Feb. 12, "
Feathers, dressing	Samuel Keplinger	Baltimore, Md	Feb. 12, "
Feathers, dressing	Elam Wilbur	Geneva, N. Y	Mar. 18, "
Feathers, dressing	Billy and Alanson Todd	Marietta, Ohio	May 6, "
Feathers, dressing	George Reynolds	East Hartford, Ct	May 23, "
Feathers, dressing	Benton P. Coston	Philadelphia, Pa	June 28, "
Feathers, dressing	F. P. Knowlton	Clermont, N. H	July 2, "
Feathers, renovator	J. W. Post and R Collier	Baltimore, Md	Mar. 2, "
Mattresses, bolsters, &c	A. Salisbury and J. Uram	Troy, N. Y	July 1, "
Sacking bottom	L. L. Wells	Middletown, Conn.	April 13, "
Washing machine	Joab H. Hubbard	Bloomfield, Conn.	Jan. 6, "
Washing machine	Luther Davis	Norwich, Conn	Feb. 12, "
Washing machine	John S. Geer	Norwich, Conn	Mar. 2, "
Washing machine	Albion P. Arnold	Readfield, Maine	Mar. 12, "
Washing machine	E. Y. Watson	Albany, N. Y	Mar. 23, "
Washing machine	Charles Merriman	Middletown, Conn.	April 21, "
Washing machine	Henry Souder	Strasburg, Pa	April 21, "
Washing machine	L. R. Prince	Beverly, Mass	May 14, "
Washing machine	Amory Davidson	Littleton, "	June 11, "
Washing machine	Amos Larcum	Troy, N. Y	June 16, "
Washing machine	William Newton	Warren county, O.	July 1, "
Washing machine	James H. Little	Skaneateles, N. Y.	July 2, "
Water, pressing from clothes	Caleb Angevine	New York city	Feb. 25, "

CLASS XVIII.—ARTS, POLITE, FINE, AND ORNAMENTAL, *including Music, Painting, Sculpture, Engraving, Books, Paper, Printing, Binding, Jewelry, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Pencil case and pen	Henry Withers	New York city	Mar. 19, 1836
Pencil, everpointed, open case	Jacob J. Lounds	Philadelphia, Pa	Sept. 22, "
Piano-forte	John Pethick	Mt. Morris, N. Y	Feb. 12, "
Piano-forte	Isaac Clark	Cincinnati, Ohio	Mar. 2, "
Piano-forte	H. Hartye	Baltimore, Md	Mar. 12, "
Printing press	J. Lemuel Kingsley	New York	Mar. 2, "
Printing press	Hezekiah Camp	Trenton, Ohio	Mar. 4, "
Printing press, hand	F. J. Austin	New York	Oct. 8, "
Printing press, power	Isaac Adams	Boston, Mass	Mar. 2, "

CLASS XIX.—FIRE-ARMS *and Implements of War, and parts thereof, including the Manufacture of Shot and Gunpowder.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Cannon for chain shot	Edwin Gordon	Hingham, Mass	Feb. 17, 1836
Cannon, malleable iron	George W. Chapman	New York	June 16, "
Cannon, traverse board	William H. Bell	Washington, D. C.	May 14, "
Cannon, vent	John W. Cochran	Lowell, Mass	Mar. 23, "
Fire-arms	Samuel Colt	Hartford, Conn	Feb. 25, "
Lock, gun	Samuel Morrison	Milton, Pa	Feb. 10, "
Lock, gun and pistol	Johnson Marsh	East Dorset, Vt	July 1, "
Pistols	B. and B. M. Darling	Bellingham, Mass.	April 13, "
Stock, gun, lathe for	Abner Town	Woodbury, Vt	Feb. 25, "

CLASS XX.—SURGICAL AND MEDICAL INSTRUMENTS, *including Trusses, Dental Instruments, Bathing Apparatus, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bones, setting, apparatus for	James H. Willard	Brown Elm, Ohio	June 11, 1836
Lancet, revolving	T. H. Harrison	New Egypt, N. J.	June 20, "
Splints, for fractures	Enoch Thomas	New Athens, Ohio	Mar. 8, "
Syringe, injecting	Joseph Ralph	New York	Feb. 25, "
Thigh, fractured, apparatus for	Samuel Walston	Vincentown, N. J.	July 2, "
Tooth extractor	Moses R. Hanson	Bangor, Maine	Mar. 12, "
Truss	F. H. Newman	Huntsville, Ala.	Feb. 25, "
Truss	John W. Newson	New York	June 20, "
Truss for hernia	Wm. Adair	Pleasant Hill, Ky.	Feb. 17, "
Truss for hernia	Isaac Thompson	Brattleborough, Vt.	July 1, "

CLASS XXI.—WEARING APPAREL, *Articles for the Toilet, &c., including Instruments for Manufacturing.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Combs, metallic	H. Durell	New York	June 20, 1836
Combs, metallic	Richard A. Ives	Bristol, Conn	July 1, "
Corsets, rings, &c., grooves in	Charles Buckland	Middletown, Conn.	June 2, "
Razor case and sharpener	E. M. Pomeroy	Wallingsford, Conn.	Oct. 19, "
Shears, tailors'	Richard Fitzgerald	Elizabethtown, N. J.	April 28, "
Stock, for the neck, shaping	Thomas Goodrum	New York	July 1, "
Suspenders, manufacturing, gum-elastic	Ransom Warner	New York city	Mar. 18, "
Tailoring, art of	James Twisler, jr	Hagerstown, Md.	July 1, "

CLASS XXII.—MISCELLANEOUS.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Coffins, metallic	James A. Gray	Richmond, Va.	June 11, 1836
Corn husks, slitting	Asa Barrett	Baltimore, Md.	April 21, "
Traps, for rats, &c	Thomas Neill	Herkersville, Ohio	Jan. 23, "

[H.]

ALPHABETICAL LIST

OF PERSONS WHOSE PATENTS HAVE EXPIRED DURING THE YEAR 1850, WITH THEIR INVENTIONS OR DISCOVERIES AND CLASS.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Abbot, John	Horse power	XIII.
Adams, Amos	Horse power	XIII.
Adams, Nathaniel	Brick machine	XV.
Adams, E. G.	Glazed leather	XVI.
Adams, Isaac	Printing press, power	XVIII.
Adair, William	Truss for hernia	XX.
Akins, William H.	Ovens	V.
Allen, Henry	Cutting grass	I.
Allen, Adna	Hoe	I.
Allen, Henry	Seeding, cotton planter	I
Alger, Cyrus	Blocks, sheaves of	VII.
Allen, Henry	Water wheel	XI
Allen, J. B.	Packing tobacco	XII
Ames, Benjamin	Ovens, reflecting	V.
Ames, John	Steam, generating	VI.
Andrews, Solomon	Lock, door	II.
Andrews, E. and S. Austin	Cooking stove	V.
Anderson, William	Grate, parlor	V.
Andrews, Hiram	Casks and barrel headings	XIV.
Angevine, Caleb	Water, pressing from clothes	XVII.
Arnold, J. and G. G. Bishop	Wool, hair, &c., forming web, &c	III.
Arnold, Wm. A.	Cooking stove	V.
Arnold, Albion P.	Washing machine	XVII.
Atherton, John	Wheel hubs	X.
Atkins, Ira	Mail bags, bolt for	XVI.
Austin, F. J.	Printing press, hand	XVIII
Averill, Isaac	Garden hoe	I.
Avery, William	Fuel, saw-dust	V.
Avord, Enos and Nelson	Lathe	XIV.
Baldwin, J. C.	Corn shelling	I.
Barnett, Ezra	Cutting scythe	I.
Baldwin, Cyrus B.	Hulling clover seed	I.
Barclay, Hugh	Thrashing machine	I.
Baily, J. and J. Sprinkle	Thrashing machine	I.
Bacon, Jonathan	Window spring, fastener	II.
Barnum, H. L.	Light and heat, generating	IV.
Barnum, D. B.	Heating water machines	V.
Baldwin, M. W.	Steam, generating	VI.
Bassett, Nathan	Compass, surveying	VIII.
Barker, J.	Blowpipe, for furnace	XI.
Baxter, Thomas	Hydrostatic press	XI.
Barton, Thomas C.	Pump, suction	XI.
Barrett, Jonathan F.	Packing flour	XII.
Badger, O.	Horse power, endless chain, &c.	XIII.
Babbet, Benjamin	Motion, reciprocating	XIII.
Batchelor and Thomas	Joint of wood work	XIV.
Babcock, Samuel F.	Mortising machine	XIV
Barker, Benjamin	Saw, belt for timber	XIV
Barker, B. K.	Saw-mill saw	XIV.
Bard & Heywood	Staves, sawing	XIV
Banks, James	Hides, unhairing	XVI
Barrett, Asa	Corn husks, slitting	XXII.
Belt, Chas. R.	Seeding, corn planter	I

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Beam, Michael	Seeding, cotton planter	I.
Bedee, Thomas	Thrashing Machine	I.
Beaumont, George	Thrashing Machine	I.
Beane, Jonathan	Winnowing Machine	I.
Bennett, James	Grates	V.
Beebe, Stephen	Wagon, tilting	X.
Bennett, Phineas	Saw-mills, dogs	XIV.
Beale & Bucklin	Slitting timber	XIV.
Bell, William H.	Cannon, traverse board	XIX.
Blair, Henry, (colored man)	Seeding, cotton planter	I
Blake, P. and E. W.	Locks, mortise	II.
Blackmar, John	Loom, harness for	III.
Blanchard, Thomas	Blocks, ship's, cutting sheaves, &c.	VII.
Blanchard, Thomas	Blocks, ship's, and dead eyes, &c.	VII.
Blanchard, Thomas	Blocks, ship's, finishing wooden sheaves	VII.
Blanchard, Thomas	Blocks, ship's, forming end pieces, &c.	VII.
Blanchard, Thomas	Blocks, ship's, forming or shaping, &c.	VII.
Blanchard, Thomas	Blocks, ship's, mortising, &c.	VII.
Blanchard, Thomas	Blocks, ship's, riveting plank, &c.	VII.
Blanchard, Thomas	Blocks, ship's, rounding edges, &c.	VII.
Blanchard, Thomas	Blocks, ship's, tackle, &c.	VII.
Blanchard, Thomas	Dead eyes, &c.	VII.
Blanc, Jean	Marsh drainer	IX.
Black, G. W	Saw-mills	XIV.
Blodget, Sherburne C.	Boots, tucking machine	XVI.
Boyden, Benjamin F.	Hoe, cast iron	I.
Boyd, George C.	Seeding, corn planter, &c.	I.
Boyden, Wm. P.	Iron and steel, making	II.
Boston & Bryant	Mineral water, soda fountain	IV.
Bond, Daniel H.	Shoe, over	XVI.
Briggs & Carpenter	Cutting and thrashing	I.
Brown, Eleazer	Thrashing machine	I
Brainard, M. M.	Gouges, making	II.
Brockway, J.	Spoons, silver, mill	II.
Brooks, Adam	Silk, winding	III.
Brooks, Adam	Silk, winding, &c.	III.
Brayton, William P.	Spinning cotton	III.
Brown, Valentine	Canals, locks, gates	IX.
Brown, Valentine	Canals, locks, indicator	IX.
Brown, William F.	Water wheel	XI.
Bridewell, E.	Saddles, side	XVI.
Brown, William	Trunks, valises	XVI.
Burt & Carriel	Rags, dusting	III.
Burgess, William	Fire-place	V.
Buck, Reuben	Fire-place	V.
Burt, William A.	True meridian, finding	VIII.
Bucklin & Jacobs	Tunneling rivers	IX.
Burkhyte, Tunis, J.	Shingle machine	XIV.
Buzell, John D.	Granite, cutting and dressing	XV.
Buckland, Charles	Corsets, rings, &c.	XXI
Carpenter, Warren	Corn, hulling	I.
Carpenter, Warren	Corn, sheller	I
Cannon, William P.	Plough	I.
Campbell, William	Awl haft	II.
Calvert, William W.	Wool or flax, comber	III
Carmichael, William M.	Stoves	V.
Campbell, H. R.	Steam engine, locomotive	VI
Carpenter, F.	Steam engine, rotary	VI.
Carr, Job	Steam, generating	VI.
Capron, O. H., and G. Barton, jr	Sulky seat	X.
Card, Charles V.	Pump, frictionless	XI.
Carey, William	Saw, belt	XIV.
Callihan, Otho W. S.	Saddles	XVI.
Camp, Hezekiah	Printing press	XVIII.
Chandler & Ranger	Plough	I.
Chaffee, E. M.	Caoutchouc, application, &c.	IV
Chapin, Nathan	Pump, forcing	XI

PATENTEES.	INVENTIONS OR DISCOVERIES	CLASS.
Chamberlain & Cleffin	Press, hay	XII.
Chevrier, Lewis	Power, endless chain, &c.	XIII.
Channel, J. C.	Mortising machine	XIV.
Chapman, George W.	Cannon, malleable iron	XIX.
Cleaveland, Porter	Thrashing machine	I.
Clark, Henry	Gin, cotton	III.
Close & Sanford	Extracts, making	IV.
Clark, Edward	Lead, white	IV.
Clowes, Isaac	Fire, extinguishing	V.
Clark, Aaron	Steam engine, rotary	VI.
Clark, David	Mortising machine	XIV.
Clark & Boynton	Stone, cutting and planing	XV.
Clark, Samuel	Bedstead, cot	XVII.
Clark, Isaac	Piano forte	XVIII.
Concklin, John C	Harrow, press	I.
Cole, Lewis	Hulling rice	I.
Cooper, James	Thrashing machine	I.
Cockran, J.	Andirons, bars	II.
Coover, William	Latch, mortise	II.
Conant, Abel	Lock, door	II.
Couillard, S., jr.	Flax and hemp, &c., combing	III.
Comins, John P.	Loom, power, and taking up motion	III.
Couillard's, S., assignees	Wool, combing	III.
Cooper, Peter	Salt, supplying	IV.
Cochran, R. G.	Cooking stove	V.
Cochran, John	Propelling paddles for boats	VII.
Cook, Tobias	Raising vessels	VII.
Coleman, Spencer	Axletrees for carriages, &c.	X.
Coster & Pennypacker	Horse power	XIII.
Coppuck, James	Brick, moulding	XV.
Coston, Benton P.	Feathers, dressing	XVII.
Cochran, John W.	Cannon, vent	XIX.
Colt, Samuel	Fire-arms	XIX.
Cram, H.	Screws, cutting wood, &c	II.
Cralle, Richard K.	Salt, manufacturing	IV.
Cram, Smith	Breakers, cylindrical	X.
Cram, Smith	Car, taking over elevations	X.
Crim, Peter	Saddles, spring	XVI.
Currier, E. G.	Cooking stove	V.
Currier, E. G.	Cooking stove	V.
Curtis, James F.	Spark catcher	VI.
Curtis, Lorrain	Planing machine	XIV.
Dalkener, John	Plough	I.
Davis, William	Ores, screening and washing	II.
Day, Moses	Spinning hemp, &c.	III.
Daboll, Ezekiel	Stoves, foot	V.
Dawley, A. S	Steam engine	VI.
Davis & Ashdown	Car, rail-road	X.
Davis, Sampson	Pumps, vibrating	XI.
Davis, Luther	Washing machine	XVII.
Davidson, Amory	Washing machine	XVII.
Darling, B. and B. M.	Pistols	XIX.
Dennison, Rufus	Smut machine	I.
Dexter, George B.	Hats, water-proof, silk	III.
Debit, William	Rags, cleaning	III.
Deitz, A.	Harness pad, elastic water-proof	XVI.
Douglass, Beriah	Cooking stove	V.
Douglass, Beriah	Stoves, parlor	V.
Dunlap, Jefferson	Candles, moulds	IV.
Dunham, Isaac	Lamps, light-house burner	V.
Duff & Murphy	Valve, puppet, raising	VI.
Dukehart, William	Harness, riveting	XVI.
Duchman, William	Saddles, spring	XVI.
Durell, H.	Combs, metallic	XXI.
Drummond, John	Cutting grass	I.
Eastman, J. S.	Cultivator	I.
Echols, James H.	Cordage, rope yarns, &c.	III.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Edgar, H. and J. W.	Thrashing machine	I.
Eddy, W. T.	Spinning, spindle and flier	III.
Edgar, Isaac W.	Steam engine, locomotive and rail-roads	VI.
Egbert, Benjamin	Pump, forcing	XI.
Elgar, William L.	Water wheel	XI.
Emery, Laban	Tanning	XVI.
Eagle, Robert	Smut machine	I.
Etheridge, Samuel	Mill stones, picks	XIII.
Everett, Joseph	Straw cutter	I.
Farlee, John	Plough	I.
Fanning, William	Cordage and rope	III.
Ferguson, J. C	Plough, wheel	I.
Fickhardt, F. A.	Furnaces, for warming buildings	V.
Fickhardt, F. A.	Stoves	V.
Fitzpatrick, Edward	Boats, to be used under water	VII.
Fitzgerald, Daniel	Horse power	XIII.
Fitzgerald, Daniel	Horse power	XIII.
Fitzgerald, Richard	Shears, tailors'	XXI.
Flanders & Rathburn	Winnowing wheat	I.
Flint & Mills	Gypsum, applied to cisterns	IV.
Fletcher, John C.	Lamps, reflecting	V
Flint & Mills	Gypsum, applied to cisterns	XV.
Forbes, Charles	Paper making	III.
Fowler, William	Spinning, roping, cotton	III.
Force, Clark	Wheels, confining carriage to	X.
Fowler, De Grasse	Gimlet, forging	XIV.
Fowler, Wm. M	Gimlets, &c.	XIV.
French, Maynard	Stoves, rotary caps, &c.	V.
Freytag, Michael	Ice breaker	VII.
Frazier, Blanchard and Gill	Stoves	V.
Frink, Harvey	Gate flume	XI.
Freeman, S. H.	Regulating speed wheel for grist mills	XIII.
Garnett, James M	Cultivator	I.
Garrett, Samuel	Water wheel	XI.
Gay, Ira	Planing machine	XIV.
Garrand, Britain	Bedbug, destroying	XVII.
Gerrish, Daniel	Constructing vessels	VII.
Gerrish, Wm.	Grist mill, for cutting	XIII.
Gentry, Joseph C.	Mill, metallic	XIII.
Gerrish, Daniel	Saw, mills	XIV.
Gerrish, Wm.	Boots, crimping legs	XVI.
Geer, John S.	Washing machine	XVII.
Gibbs, Joshua	Plough	I.
Gilman, Elias	Ointment for cancer	IV.
Giraud, John J.	Grates, cooking	V.
Gilbert, Charles G.	Horse power	XIII.
Giraud, J. J.	Power, self-motive	XIII.
Goodyear, John	Thrashing and cleaning cloverseed	I.
Goldsborough, Nicholas	Thrashing machine	I.
Greening, Frederick	Hats, palm leaf	III.
Gould, Aaron	Dying hats	IV.
Goody, Samuel	Saw mills	XIV.
Gordon, Edwin	Cannon for chain shot	XIX.
Goodrum, Thomas	Stock for neck	XXI.
Gray, Albert W.	Corn sheller	I.
Greenleaf, Wm. C.	Cutting grass	I.
Granger, John L.	Milk, preserving	I.
Greenleaf, Wm. C.	Seeding grain, sowing	I.
Greenleaf, Daniel	Hats, elastic, ventilating	III.
Granger, Chester	Cooking stove	V.
Gray, James A.	Coffins, metallic	XXII.
Guyon, H. G.	Press, lever	XII.
Hanson, Amos	Churn	I.
Haynes, Richard	Bolt and spike, drawing	II.
Harrington, Daniel	Fire-proof, safe	II.
Hall & Chase	Window shutter, fastening	II.
Harrison, Alexander	Furnaces and boiler combined	V

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Harryman, John	Stoves, Franklin	V.
Hant, Samuel	Water conveying	XI.
Harman, John, jr.	Mill	XIII.
Hawkins, John	Mortising machine	XIV.
Hawk & Keyes	Shingles, dressing	XIV.
Hamilton, James	Veneers, cutting	XIV.
Halloway, Gooding	Brick machine	XV.
Hale, Ebenezer	Saddles and collars	XVI.
Hall, J.	Shoe making machine	XVI.
Hatcher, J. W.	Cutting apples, &c.	XVII.
Hall, Daniel K.	Feathers, cleaning	XVII.

Harrison, T. H.	Lancet, revolving	XX.
Hanson, Moses R.	Tooth extractor	XX.
Hedges, Isaac A.	Corn sheller	I.
Hendrick, H.	Loom, power, and taking up motion	III.
Heintzelman, J. J.	Stoves, air warmer	V.
Hendricks & Elwell	Stoves and fire-place	V.
Hess, David	Raising water by weight	XI.
Hedge, Lemuel	Plane, revolving	XIV.
Heath, Simeon	Tanning	XVI.
Henkel, Ambrose	Cutting sausage meat	XVII.
Hibbard, H.	Paint, composition	IV.
Higgins, Charles	Cooking stove	V.
Hinds, Ball & Pike	Water, applying	XI.
Hitchcock, Wm.	Water wheel	XI.
Hill, Jonathan	Boot and shoe soles, cutting	XVI.
Hopper & Doughty	Hulling cloverseed	I.
Howe, H. P.	Paper, cylinders for drying	III.
Howe, Henry	Paper drying	III.
Holland, Homer	Lead, white	IV.
Howard, John C.	Grates, sliding	V.
Hotchkiss, Gideon	Propelling boats, &c.	VII.
Houston, J. A. Hinman, and J. Ingraham	Dock, dry	IX.
Horne, David	Hydrants	XI.
Horton, John	Balance, platform	XII.
Hobbs, Jonathan, jr	Shingles, &c., sawing	XIV.
Hopkinson, John	Harness, horse collars	XVI.
Hubbard, J. M.	Beehive	I.
Hull, Alonzo G.	Wrench, screw	II.
Hungerford, Newell	Springs, carriage	X.
Hunt, Walter	Saw for felling trees	XIV.
Hubbard, Joab H.	Washing machine	XVII.
Hyde, James	Straw cutter	I.
Ingham, John	Steam engine, rotary, reacting	VI.
Ives, Joseph	Clocks	VIII.
Ives, James S.	Spring for clocks	VIII.
Ives, Richard A.	Combs, metallic	XXI.
Jackson, Samuel	Churn dash	I.
Jemeson, W. W	Hats, blocking	III.
Jennings, Isaiah	Turpentine, spirits, extracting	IV.
Jennings, Isaiah	Lamps	V.
Jennings, Isaiah	Steam, generating	VI.
Jenkins, Elias	Cider mill	XIII.
Jenkins, M.	Saddles, ladies'	XVI.
Jones, William R.	Drills for metal	II.
Jones, J. T.	Plane	XIV.
Johnson, Herkimer	Shaving leather	XVI.
Johnson, George	Kitchen ranges	V.
Jones, Adrian	Stoves, anthracite coal	V.
Keane, William	Screw, manufacturing	II.
Kelsey, Mellville	Wire cap	II.
Keith, Edwin	Gin, cotton, grates	III.
Kettell & Wright	Hats, bodies, stiffening	III.
Kerr & Hoover	Distilling	IV.
Kendall, Jonas, assignee of J. Perkins	Cooking stove	V.
Kepner, Samuel	Rudders	VII.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Kenzie, Charles	Water wheel	XI.
Keller, Charles M	Staves, sawing	XIV.
Keplinger, Samuel	Feathers, dressing	XVII.
Kile, Conrad	Loom, weaving stocks	III.
Kidder, Levi	Cement, hydraulic	IV.
Kidder, Levi	Wells, covers of	XI.
King, Sumner	Casks, machine	XIV.
Kingsley, J. Lemuel	Printing press	XVIII.
Knapp, Lewis	Buildings, constructing	IX.
Knight, Isaac	Buildings, stores, &c.	IX.
Knowles, Hazard	Power, alternate motion, by contraction and expansion of metals	XIII.
Knisely, Christian	Bedsteads	XVII.
Knowlton, F. P.	Feathers, dressing	XVII.
Korn, Henry	Harness, nets, fly, for horses	XVI.
Kraft, Benjamin	Saddles	XVI.
Kugler, Benjamin	Furnace, blast	II.
Lamson, S	Cutting scythe	I.
Lapham, Benjamin	Loom, power	III.
Ladd, Samuel	Spinning, fliers	III.
Ladd, Samuel	Spinning, fliers	III.
Lacier, Sebastian H	Cooking stove	V.
Ladd, C. P	Balance, platform	XII.
Laughlin & Hill	Rolling leather	XVI.
Larcum, Amos	Washing machine	XVII.
Leonard, William B	Loom, power	III.
Lewis, R. B.	Oakum and hair picking	III.
Lear, Asahel	Cooking stove	V.
Lewis, Lovell	Heat, evolution and management of	V.
Lesner, W. W	Pump, forcing	XI.
Liversidge, W. and T.	Starch, rice	IV.
Liddle, John	Cooking stove	V.
Little, James H	Washing machine	XVII.
Locklin, Nathan	Plough	I.
Loomis, Wm	Thrashing cloverseed	I.
Lockling, Nathan	Smoke, consuming	V.
Lombard, Nathaniel K.	Maps, charts, &c., apparatus for	VIII.
Long, Stephen H	Bridges, frame	IX.
Lochier, Henry	Tanning	XVI.
Lounds, Jacob J.	Pencil, ever-pointed, open case	XVIII.
Lyon, 2d. L	Hats, napping	III.
Lyman, Charles	Cooking stove	V.
Marshall, Mallory M	Straw cutting, box	I.
Mans, Lewis H	Thrashing machine	I.
Manning, James	Winnowing clover seed	I.
Mathews, James	Fire-proof chest	II.
Mans, L. H	Patterns for casting	II.
Marsh, Stephen	Napping cloth	III.
Mackie, Patrick	Caoutchouc, dissolving	IV.
Mayo & Mills	Ventilating houses	V.
Man, Arlon	Condensing cotton	XII.
Marsh, Elias	Crane	XII.
Mathews, James	Chocolate, moulding	XIII.
Marvin, Dudley	Horse power	XIII.
Martz, P. M	Planing machine	XIV.
Matthews, M	Boots, trees	XVI.
Maguire, Jonas	Bedsteads	XVII
Masser & Smith	Cutting meat	XVII
Marsh, Johnson	Lock, gun and pistol	XIX.
McClory, James	Lock, door	II.
McClory, James	Lock, door	II.
McCreight, W. & J	Gin, cotton	III.
McCreight, James	Gin, cotton	III.
McWilliams, Alexander	Stoves for heating carriages	V.
McDonough, A	Spark catcher	VI.
McCausland, A. jr	Valve, slide	VI.
McCain, A. M	Rail-road, plates, jointing	IX.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
McLean, A. M	Press, tobacco	XII.
McCreight, W. and J.	Grist mill	XIII.
McGhee, W. J	Saw mills	XIV.
McGregory, Cyrus	Staves, sawing for barrels	XIV.
McCormick, William	Saddles, elastic	XVI.
McBride, Andrew R.	Saddles, trees	XVI.
McLaughlin, Ira	Bedstead fastenings	XVII.
Merriman, Charles	Churn	I.
Merriman, Samuel G.	Saw teeth, cutting	II.
Merriman, Marcus, jr.	Window fastening	II.
Mellish, Henry	Wagon, hanging	X.
Mercer, Carey S	Water wheel	XI.
Mendall & Ricketts	Moulding pottery	XV.
Mellish, Henry	Cutting vegetables	XVII.
Merriman, Charles	Washing machine	XVII.
Miller, Timothy	Plough	I.
Mix, William	Spoons, casting	II.
Milo, Francis	Spark catcher	VI.
Mixwell, Abner T.	Pumps	XI.
Mitchell, J.	Press, cotton	XII.
Moore & Hascall	Cutting grain, &c.	I.
Mott, Jordan L.	Columns, cast iron, &c.	II.
Montgomery, Adam	Cordage, rope, serving	III.
Morse, John	Spinning fliers	III.
Morgan, John	Spinning machine	III.
Mott, Jordan L.	Stoves and fire place	V.
Morse, Andrew	Capstan	VII.
Moffatt, John	Brick machine	XV.
Morse, William	Granite, hammering, &c.	XV
Moody & Eastman	Beds, spring, spiral	XVII.
Morrison, Samuel	Lock, gun	XIX.
Mudge, Abraham	Smut machine	I.
Musten, Joseph	Horse power	XIII.
Murry, James	Saw mill, endless side chain, &c.	XIV.
Naylor, T. B	Saw mills	XIV.
Neal, Henry G	Corn sheller	I.
Newton, Levi	Pump, forcing	XI.
Newton, Samuel	Horse power	XIII.
Newton, William	Washing machine	XVII.
Newman, F. H	Truss	XX.
Newson, John W	Truss	XX.
Neill, Thomas	Traps for rats	XXII.
Nicholson, Thomas	Churn	I.
Nivens, W. R.	Crackers, cutting and rolling	XVII.
Nott, Eliphalet	Steam, generating	VI.
Noble, Philander	Propelling boats	VII.
Noble, James W	Trunks, valises, &c.	XVI.
Olmstead, L. B.	Baker, reflecting	V.
Orr, Isaac	Stove, air tight	V.
Parsons, Aaron	Thrashing machine	I.
Page, George	Bit, spiral, &c.	II.
Parke, Charles	Cordage, rope, serving	III.
Paree, J. & N.	Pearl ash	IV.
Parmalee, Howell	Stoves	V.
Park, Moody	Boilers, steam, purifying water	VI.
Pardie, William	Time piece	VIII.
Parker, Obadiah	Sewer of hydraulic cement	IX.
Page, George	Mortising machine	XIV.
Page, George	Mortising and boring machine	XIV.
Page, George	Mortising timber	XIV.
Perry, P. F	Cooking stove	V.
Peckham, Charles W	Faucets, molasses	XI.
Peck, James M	Balance, platform	XII.
Peckham, C. W	Coffee mill	XIII.
Pell, John B	Boring wood	XIV.
Peeler, David	Lathe, gripe chuck for	XIV.
Peevy, Joseph	Sawing machine	XIV.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Peavy, Joseph	Screws, cutting wooden	XIV.
Pethick, John	Piano-forte	XVIII.
Philbrick, John	Cotton, drying, &c.	I.
Phillips, Alonzo D	Matches, friction	IV.
Pitts, Harvey W	Plough	I.
Pierson, J. H	Screws, cutting, &c	II.
Pierson, J. H	Screws, cutting, &c	II.
Pitts, J. A	Ovens, heating rooms	V.
Pickering & Lightner	Car, rail-road, &c	X.
Pinno, Joseph, Jr	Sawing wood	XIV.
Pierce, Hubbard L	Boots, crimping, cramp for	XVI.
Plank, Jacob	Plough	I.
Platt, Alonzo	Lamps, hanging	V.
Poague, J. B. and W. F	Hulling clover seed	I.
Pollard, Samuel	Ovens	V.
Porter, Rufus	Distance, measuring	VIII.
Pope, Josiah	Cooler, flour	XIII.
Porter, Rufus	Horse power	XIII.
Pomeroy, E. G	Boots, crimping, clumps for	XVI.
Post & Collier	Feathers, renovator	XVII.
Pomeroy, E. M	Razor case and sharpener	XXI.
Prouty & Mears	Plough	I.
Pratt, Jonas	Smut machine	I.
Prutzman, Augustus	Locks, &c	II.
Pratt, Elisha N	Cooking stove	V.
Prescott, William R	Fireplace	V.
Pray, John G	Wharves, &c., constructing	IX.
Prince, L. R	Washing machine	XVII.
Pursell, John	Hemp, breaking	III.
Putnam, J. and C	Wheels, boxes, &c	X.
Quimby P. B	Locks	II.
Rathburn & Tinker	Saw, straightening	XIV.
Rathburn, Erastus	Saw mill, blocks for	XIV.
Ralph, Joseph	Syringe, injecting	XX.
Reading, Pierson	Hulling cotton seed	I.
Reoff, Almon	Lock, door	II.
Reading, Pierson	Gin, cotton	III.
Reed, Nathan	Rail-road	IX.
Read, Isaac	Saw mills	XIV.
Reynolds, George	Feathers, dressing	XVII.
Richardson, Samuel	Smut machine, and hulling	I.
Richardson, J. S	Door plates	II.
Richardson, Charles	Forge, blacksmith,	II.
Richards, Joseph	Lead, white	IV.
Ripley, Ezra	Stove pipes	V.
Ring, Zebedee	Dock, hydraulic	IX.
Richards, Edward	Drawing knife	XIV.
Riker, Rufus	Saw mill, cross cutting	XIV.
Rich, Martin	Saw mill dogs	XIV.
Roberts, Hezekiah	Churn	I.
Robbins, Hildreth	Hulling clover seed	I.
Root, Erastus S	Rake, horse	I.
Rollins, Jacob S	Thrashing machine	I.
Root, Elisha K	Axes	II.
Rouse, James	Hinges, butt	II.
Robinson, Draper & Lord	Knobs, glass, &c	II.
Robinson, Draper & Lord	Knobs, glass, &c	II.
Rood, Reuben	Sores, curing	IV.
Robertson, Robert	Stoves, conical	V.
Rogers, James H	Tire for wheels	X.
Rodgers, Jno. F	Pump, forcing	XI.
Robbins, Austin H	Cutting vegetables	XVII.
Ruggles, Henry	Pitch, making	IV.
Russell, Nathaniel	Stoves	V.
Ruggles, John	Steam engine, locomotive, for inclined planes	VI.
Russell, Sylvanus	Excavating from rivers	IX.
Ryan, W. B	Smut machine	I.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Sanborn, Benning	Boats and rafts, passing, &c	VII.
Sanders, James	Saw mills	XIV.
Sadler, Thomas N	Boots, machine for turning, &c	XVI.
Salisbury & Uram	Mattresses, bolsters, &c	XVII.
Schmutman, Isaac	Glasses for spectacles	VIII.
Scholfield, Nathan	Water wheel, &c., regulating, &c	XI.
Shull, N. J	Cultivator or hoe harrow	I.
Shugert, John	Tew iron	II.
Shly, John	Picking and breaking wool	III.
Sherman, Thomas H	Pitch, composition	IV
Shaw, Thomas	Cooking stove	V
Shultz, William	Spark catcher	VI.
Share, Philip T	Wheels, horse, detaching	X
Sherwood, Gilbert	Crane	XII
Sheaffer, Christian	Cider mill	XIII.
Shaw, Erastus M	Mortising machine	XIV
Shackford, D. and T	Dough machine	XVII.
Sizer, A. and George	Gridiron and spider	V.
Skinner & Kead	Straw cutter	I.
Skinner, Elijah	Fire place	V.
Skinner, Richard	Horse power	XIII.
Smith, Ira	Corn shelling	I.
Smith, David M	Awl haft	II.
Smith, Benjamin	Lock, door	II.
Smith, Elihu	Chimneys ovens, &c	V.
Smith, Nicholas	Cooking stove, and parlor	V.
Smith, Jno. K	Car, door fastening	X.
Smith, Elihu	Laths, machine	XIV.
Snider, Isaac	Plough	I.
Snyder, Benjamin F	Saw mill crank	XIV.
Soule, John	Veneers, laying on ogee, &c	XIV.
Souder, Henry	Washing machine	XVII.
Spafford, M. B	Smut machine	I.
Spear, E. P	Hats, bodies, stiffening	III.
Spalding, S. B	Cooking stove	V.
Stoker, Elijah	Saw, filing teeth of	II.
Stowell, Isaiah	Fermenting and distilling spirits	IV.
Stevens, Foster	Fireplace or stoves	V.
Strong, Eben B.	Ovens, baker	V.
Strange, J. W. and E	Boilers, steam	VI.
Stoddard, James S	Anchor, cast iron	VII.
Straub, Abraham	Water wheel	XI.
Straub, Isaac	Horse power	XIII.
Stevens, Peletiah	Boots, turning	XVI.
Sutton, J. and J	Stone cutting	XV.
Swartz, Peter, Jr	Distilling	IV.
Swainzey, Jno. H. B	Stoves	V.
Swift, Beriah	Dye woods, cutting and shaving	XIV.
Sweetzer, Washington	Trunks, travelling	XVI.
Sykes & Conradt	Spinning wool	III.
Tarbox & Kneeland	Straw cutter	I.
Talbot, Jno	Rail-road turn out	IX.
Taylor, Antin	Mill stones, cooling	XIII.
Taylor, Jeremy	Bit stocks	XIV.
Terrell, S. R	Blood, equalising the	IV.
Terry, Stephen	Packing screw, inverted	XII.
Thomas, Jno. E	Churn	I.
Thompson, Samuel	Medicine, botanic	IV.
Throp, Gould	Cooking stoves,	V.
Thompson, R. H	Pegs, shoe	XIV.
Thomas, Robert S	Saw, rotary	XIV.
Thomas, Enoch	Splints for fractures	XX.
Thompson, Isaac	Truss for hernia	XX.
Tilford, T. M	Plough	I.
Tiers, Arunthus	Furnace, smelting	II.
Titus, B. and A	Cooking stove	V
Tippet, Edward D	Steam engine, safety	VI.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Tichenor, J. S. Goodridge, and J. A. Hart	Fence, Pickets, cutting	XIV.
Town, J. T	Smut machine	I.
Towne, J. T	Water wheel	XI.
Todd, Billy and Alanson,	Feathers, dressing	XVII.
Town, Abner	Stock, gun, lathe for	XIX.
Traver, P. C	Cooking stove	V.
Treadwell, F. C	Ovens, heating by anthracite	V.
Trask, Samuel	Ice cutting machine	VII.
Treadwell, Ephraim	Crackers and biscuit, cutting	XVII.
Turney, Andrew	Drilling stone	IX.
Turner, Joseph	Raising water	XI.
Turk, John	Mill wheel, dresser	XIII.
Tuells, Melzer	Planing machine	XIV.
Tyler, Samuel	Churn	I.
Ulam, David	Steam engine, rotary	VI.
Underwood, Stephen	Boats, passing over dams	VII.
Variel, Davis	Churn	I.
Van Tiers, S	Anvil block	II.
Vale, Charles	Cooking stove	V.
Van Allen, C. D	Ovens, reflecting	V.
Vaughn, Jirah	Balance	XII.
Walker, Wm. B	Yarn, woollen	III.
Waite, G. W	Heating chocolate ingredients	V.
Wade John	Sails for ships, &c	VII.
Walker, S. T	Hydrants	XI.
Walker, S. T	Hydrants	XI.
Walker, J. F	Pumps	XI.
Waldo, Orson	Water wheel	XI.
Walker, Jeremiah	Lever power, sawing, &c., by	XII.
Waite, Geo. W	Chocolate, grinding	XIII.
Washington, David	Saw mills	XIV.
Waterman, Calvin	Brick machine	XV.
Warner & Robinson	Harness, horse, collars, &c	XVI.
Watson, E. Y	Washing machine	XVII.
Walston, Samuel	Thigh, fractured, apparatus for	XX.
Warner, Ransom	Suspenders, manufacturing, gum, &c	XXI.
Weeks, James M	Bee hive	I.
Webb, Jas. W	Rake, horse	I.
Webb, A. V. H	Distilling, cold	IV.
Wenn, Peter	Heat applying, from lime, &c	V.
West, Henry	Wagon, coaches, and breaks for	X.
Webb, Joshua	Sawing timber	XIV.
Wells, L. L	Sacking bottom	XVII.
Whittier, Simon	Churn	I.
Wharff, Amasa	Churn	I.
Whittaker, Welcome	Hinges, butt, &c	II.
Whiteman, J	Cordage, rope, making	III.
Whipple, Cullen	Loom, weaving	III.
White, John	Cement, hydraulic	IV.
Whiting, John	Cooking stove	V.
Whitney & Burr	Spark catcher	VI.
Whitman, Shepherd	Steam engine, rotary	VI.
White, Prentiss	Thimbles, ships	VII.
Whiteley, Francis	Compass, quadrant, &c	VIII.
White, John G	Pump, forcing, double	XI.
Whitfield, Edward	Pump, frictionless	XI.
Whitman, Wm	Horse power	XIII.
Whitley, Thomas W	Glass cases	XV.
Witherow, Samuel	Plough	I.
Wilson, David	Winnowing machine	I.
Wilkinson, Arnold	Polishing iron and brass wire for, &c	II.
Wilkinson, Jeptha A	Loom reeds, machine for making	III.
Withered, J	Spinning wool	III.
Williams, Elijah	Pot ash and pearl ash	IV.
Williams, Daniel	Cooking stove	V.
Winslow, Nathan	Grates, pendulum	V.
Williamson, James	Grates, portable	V.

PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
Winter, Gabriel	Spark catcher	VI.
Wilkinson, David,	Canals, locks	IX.
Williams, John S	Roads, constructing	IX.
Wingate, Frederick	Water wheel	XI.
Wilder, Aretas A	Water wheel, propelling	XI.
Wilbur, Job	Wind wheel	XI.
Willard, Simon	Saw mills	XIV.
Williams, Daniel	Tanning, bark for	XVI.
Wilbur, Elam	Feathers, dressing	XVII.
Withers, Henry	Pencil case and pen	XVIII.
Willard, James H	Bones, setting, apparatus for	XX.
Woodcock, B	Plough	I.
Wolfolk, Jas. M	Straw cutter	I.
Woodward, Clement	Stoves, ventilating	V.
Woolley Williams	Window frieze and covering	IX.
Woodbridge, William	Wheels, cart and carriage	X.
Wood, Jesse C	Raising water	XI.
Woodworth, William	Planing machine	XIV.
Wood, Andrew	Chairs, easy	XVII.
Wright, Isaac S	Straw cutter	I.
Wright, John	Distilling, still for	IV.
Wyman, Oliver	Grist mill,	XIII.
Zwisler, James, Jr	Tailoring art of	XXI.

[I.]

CLASSIFIED LIST OF PATENTS,

GRANTED DURING THE YEAR 1850, WITH THE NAMES OF PATENTEES, PLACES OF RESIDENCE AND DATES OF PATENTS.

CLASS I.—AGRICULTURE, *including Instruments and Operations.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bee hives, entrance to	John E. Dalton and Thomas Stevens	New Vienna, O	April 9, 1850
Bee hive, working the doors of a	Jarvis Case	Selma, O	Nov. 19, “
Bee moth traps	George Fletcher, sr.	Greensburg, Ind	Mar. 26, “
Churns	Zenas C. Robbins	St. Louis, Mo	Jan. 8, “
Churns	Robert W. Davis	Rodgersville, N. Y.	April 2, “
Churns	John Andrews	Woburn, Mass	April 23, “
Churns, atmospheric	John Young	West Galway, N. Y.	Jan. 22, “
Churns, atmospheric	Simon F. Emerson	Canaan, O	April 2, “
Churns, atmospheric	Peter F. Ellicott	Philadelphia, Pa	June 25, “
Churns, atmospheric	John O'Neil	Xenia, O	July 30, “
Churn dashers	Isaac D. Garlic	Lyons, N. Y	Feb. 26, “
Churn dashers	Nathaniel Routzahn	Middletown, Md	Mar. 19, “
Churn dashers	Joseph Marsh	Petersburg, Ill	July 30, “
Churn dashers	Robert S. Sherman	Napanock, N. Y	Aug 6, “
Churn dashers	William and Matthew C. Walker	Lancaster, Pa	Aug. 6, “
Churn dashers, spiral	Cornelius R. and John Hight	Geneva, Ill	July 9, “
Churn dasher, working a rotary and vertical	William R. Nash	Bridgeport, Conn	May 7, “
Churns, rotary	Osbert B. Loomis	Windsor, Conn	Apr. 2, “
Clevises, plough	John B. Stoner	Southampton, Pa	Sept. 10, “
Clevis, plough	Gerrett Erkson	Hobart, N. Y	Sept. 17, “
Clevis, substitute for the	John and Wm. D. Howell and Joseph Sipe	Clark co., O	Jan. 15, “
Cotton, picking from the bowls in the field	Saml. S. Rembert & Jedediah Prescott	Memphis, Tenn	Sept. 10, “
Cotton stalks, cutting in the field	Fields Bradshaw	Clinton, Ala	Feb. 12, “
Coulters to ploughs, fastenings of	Austin and Austin K. Whittlesey	Springport, N. Y	Sept. 22, “
Cream, processes of preparing	Charles D. Birdseye	New York, N. Y	Sept. 17, “
Cultivators	Ashley Crafts and Ebenezer Weeks	Auburn, O	Jan. 8, “
Cultivator teeth	Lewis Lamborn	Kennett Square, Pa	Mar. 26, “
Cultivator, weed cutters of a	Charles Rodger	Montpelier, Vt	June 25, “
Drills, grain*	William Bullock	Philadelphia, Pa	Jan. 8, “
Fanning mills	Jesse Roberts	Penn's square, Pa	May 28, “
Fanning mills	John Weidman	Littlestown, Pa	May 28, “
Fanning mills	Eleazer Bless	Minerva, Ky	Dec. 17, “
Forks, hay	Alanzor Clark	Southfield, N. Y	Oct. 8, “
Forks, hay and manure, fastening for	Alanzor Clark	Southfield, N. Y	Mar. 5, “
Forks, hay, shanks of	David Anthony, sr.	Springport, N. Y	Oct. 8, “
Grain cleaning machine	Geo. W. Bowers	Leitersburg, Md	Sept. 24, “
Grain cradle	Isaac T. Grant and Daniel H. Viall	Schaghticoke, N. Y	Oct. 15, “
Grain cradle fingers	Joel Houghton	Ogden, N. Y	Dec. 17, “

* Antedated Oct. 8, 1849.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Grain, machine for raking and binding	John E. Heath	Warren, O	July 22, 1850
Grain screens, rotary	Dan Pease, jr	Floyd, N. Y	Oct. 29, “
Harvester, cutters and rakes of a grain and grass	Hazard Knowles & Henry C. Bevington	Washington, D. C. Holmes, O	July 2, “
Harvester, arrangement of cutters in a grain and grass	Jacob Pierson	Wilmington, Del	July 2, “
Harvesters, grain	Ebenezer Danford	Geneva, Ill	Sept. 17, “
Harvesters, grain and maize	Edmund Quincy	Lacon, Ill	Oct. 8, “
Harvester, maize	William Watson	Chicago, Ill	Oct. 15, “
Harvesters, hemp	William B. Coates	Big Lick, Va	Oct. 15, “
Harvesters, rice	John J. Herndon	Bonneetsville, S. C	Oct. 1, “
Harvesters, cotton stalk	Stephen Bowerman	Detroit, Mich	Oct. 1, “
Harvesting machines	John E. Heath	Warren, O	Jan. 15, “
Hay, machines for raking and loading	Benj. M. Townsend	Quincey, Ill	April 9, “
Hullers, clover	Robert Staddon	Milton, Pa	
Hulling clover seed	Joseph Pollock, Allen R. McGriff, adm'r of the estate of	Richmond, Ind	Feb. 19, “
Manure, carts for spreading	Joel K. Holland	Washington, N. C	July 9, “
Manure, preparation of animal and other	Robert Hare	Philadelphia, Pa	Jan. 29, “
Mowing machines	Homer Adkins	Round Prairie, Ill	Jan. 15, “
Mowing machines, mounting the cutters of a	Geo. Hart	Dillsborough, Ind	Oct. 8, “
Planting barrows, seed	Chas. A. Wakefield	Essex co., N. Y	Feb. 19, “
Planters, seed	William B. Willis	Charlestown, Va	Jan. 22, “
Planter, seed	Chas. A. Wakefield	Essex co., N. Y	Feb. 19, “
Planter, cultivating, seed	Wm. Flory & Geo. Grove	Chambersburg, Pa	Mar. 12, “
Planters, seed	John P. Groshon	Yonkers, N. Y	Mar. 19, “
Planter, seed, the seed roller of a	Edward Wicks	Bart Township, Pa	Mar. 26, “
Planters, seed	George Fletcher, sr. and Turner Barnes	Greensburg, Ind	Mar. 26, “
Planters, seed, construction of drill teeth in	Levi Haverstick	Manor Top, Pa	April 2, “
Planters, seed, gearing for	Jacob Pierson	Wilmington, Del	April 9, “
Planters, seed, attachment of harrow to	Marcus & Silas S. Sage	Windsor, N. Y	April 16, “
Planters, seed, gearing of	Anthony Sandoe	Mifflintown, Pa	April 16, “
Planters, seed, seeding apparatus of	Lewis Moore	Bart, Pa	July 2, “
Planters, seed, seeding apparatus of	Sam'l & Morton Pennock	Kennett Square, Pa	July 9, “
Planters, seed, seeding apparatus of	Geo. Rohr	Charlestown, Va	July 16, “
Planters, seed	Edson Hart	New Albany, Ind	Aug. 6, “
Planters, seed, seeding, roller of a	Aaron Palmer	Brockport, N. Y	Sept. 10, “
Planters, seed	Sam'l Cannon	New Richmond, Pa	Nov. 12, “
Planters, seed	Sam'l & Morton Pennock	Kennett Square, Pa	Dec. 10, “
Planters, seed	Deeter B. Rhodes	Concord, N. Y	Dec. 10, “
Planters, seed	John Signer and Thomas N. Shipton	Kishacoquillas valley Pa	Dec. 10, “
Planters, seed	Joseph W. Fawkes	Bart, Pa	Dec. 17, “
Plants, machines for fumigating	David S. Brown	Surry, England	Sep. 27, “
Ploughs, corn	Robert J. King	Lancaster, Pa	Mar. 25, “
Plough and clevis	Ira Reynolds	West Liberty, O	Mar. 26, “
Plough cleaners	James F. Reasin	Darlington, Md	Apr. 9, “
Plough, corn, adjustable shares of	David Wolf	North Lebanon, Pa	Apr. 23, “
Plough cleaners	Daniel D. Gitt	Butler Township, Pa	May 7, “
Ploughs, gang	Joseph D. Hope	Philadelphia, Pa	June 4, “
Ploughs, hill side	Mark L. Chase, ass'or to Wm. L. Chase	Frankfort, Me. Boston, Mass	July 16, “ July 16, “
Ploughs, fastening the shoes of hill side	Wm. L. Chase	Boston, Mass	July 22, “
Plough cleaner	David Warren	Gettysburg, Pa	Sept. 10, “
Ploughs, spring beams to	William Morrison	Carlisle, Pa	
Ploughs, sub-soil	Wm. C. Pagett	Xenia, O	Oct. 22, “
Ploughs, gang	Henry Cowing	New Orleans, La	Nov. 26, “
Rakes, hay, spring teeth of	Zephaniah Breed	Ware, N. H	June 18, “

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Rakes, hay fastenings of	Orange W. Hogle	Somerset, N. Y.	Sep. 3, 1850
Rakes, horse	Alvan Hovey	Brookfield, Vt.	Feb. 12, "
Rakes, horse	Harry W. Sabin	Canandaigua	Dec. 3, "
Seed planters, sliders for	Robert J. Colvin	Lancaster, Pa.	Oct. 1, "
Seed planters	David Eberly	Strasburg, Pa.	Oct. 8, "
Seeding apparatus, gearing and ungearing	David Eberly	Strasburg, Pa.	Jan. 22, "
Seeding, apparatus for, seed planter	Gervis S. Gardner, ass'or to G. S. Gardner & G. Rohr	Charlestown, Va.	Oct. 8, "
Seeding cylinders, oscillating	David E. Rohr	Charlestown, Va.	Dec. 17, "
Straw carriers	Wm. Pierpont	Salem, N. J.	May 7, "
Straw cutters	Reuben Daniels	Woodstock, Vt.	July 2, "
Straw cutters	Isaac Woodward	Mechanicsburg, O.	Oct. 1, "
Straw cutters	A. S. Macomber	Bennington, Vt.	Nov. 5, "
Straw cutters, mounting the knife of	John R. Nelson	Knoxville, Tenn.	June 25, "
Straw cutters, feeders of a	John E. Erb	Baltimore, Md.	July 21, "
Straw cutters, feeding apparatus of	David Stiles, jr.	Middleton, Mass	July 16, "
Straw machines, for cutting	Harry Camp	Newton, Ga.	Aug. 27, "
Straw cutters, adjustment of knives in	Joseph W. Webb, ass'or to Benj. Gould	Aurora, N. Y.	Oct. 8, "
Straw cutters, feeding apparatus for	Henry W. Berthoif	Sugar Loaf, N. Y.	Oct. 22, "
Thrasher, clover, setting the teeth on the concave of a	Jonathan Hibbs	Bristol, Pa.	July 2, "
Thrashers, endless for	Adkins Nash	Logansport, Ind.	Apr. 9, "
Thrashing harvesters	Samuel S. Renfwert	Memphis, Tenn.	Mar. 26, "
Thrashing machines	A. S. Pelton	Clinton, Conn.	May 14, "
Thrashing machines	Elisha S. Snyder	Charlestown, Va.	June 11, "
Thrashing machine	Darius W. Harris	Yorkshire, N. Y.	Sept. 24, "
Thrashing, machine, and grain cleaners, endless aprons for	Ashley Townsend	Pavilion, N. Y.	Oct. 1, "
Tobacco, stems, curing—see class XXII			
Vegetable cutter	Reuben Daniels	Woodstock, Vt.	Oct. 1, "
Winnowing machines	Abraham Straus	Milton, Pa.	Jan. 15, "
Winnowing machines	J. G. Goshen	Shirleysburg, Pa.	Oct. 29, "

CLASS II.—METALLURGY, *and Manufacture of Metals and Instruments therefor.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Alloys for points of lightning rods—see class IV			
Amalgamator, reimmersing	Joseph R. Miller	Fredericksburg, Va.	July 2, 1850
Auger, handle	Gideon Sanford	Ellenville, N. J.	Oct. 1, "
Blast pipes, for conveying heated air and gases to furnaces	Ransom Cook	Saratoga springs, NY	Mar. 26, "
Blind and shutter opener and fastener	Jabez F. Lawrence and Luke A. Farnsworth	Claremont, N. H.	April 2, "
Blind and slat operator	David R. Williams	Prospect, Conn.	Mar. 19, "
Blowers, hydraulic, for furnaces, &c.—see class XI, "Hydraulic, &c."			
Bolts, rivets, &c., machines for heading	John Van Bocklin	Middleport, N. Y.	Aug. 20, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bolt and rivet machine	William E. Ward	Port Chester, N. Y.	July 30, 1850
Buckles—see class XVI			
Car wheels, apparatus for regulating the construction of	Samuel Truscott	Columbia, Pa.	July 16, "
Casting large kettles, metallic flask for	William Kelly	Edyville, Ky.	Dec. 3, "
Casting rolls, method of giving rotary motion to fluid iron in	John C. Parry	Pittsburg, Pa.	May 21, "
Castings, hollow, method of loosening metallic cores from	John C. Parry	Pittsburg, Pa.	Dec. 24, "
Cores for castings, composition for making	Edward Rees	Cincinnati, O.	Dec. 17, "
Cores for casting, machines for making and holding	Luther H. Crocker	Cincinnati, O.	Oct. 22, "
Cutters, machines for forming rotary	Andrew Jennings	Fall River, Mass.	Mar. 26, "
Door spring	Amos Westcott	Syracuse, N. Y.	Oct. 1, "
Door springs, adjustable cord hook for	William B. Barnard	Bristol, Conn.	Mar. 5, "
Door springs and levers, arrangement of	William B. Barnard	Bristol, Conn.	April 9, "
Drilling machine, self-acting adjustable feed gear for	Allen R. Morrill and Hiram Baldwin	Nashville, N. H.	Aug. 27, "
Eaves, trough and gutter machine	John Lee	Wellsville, O.	Oct. 8, "
Eylets, machine for making	Lucien E. Hicks, ass'nor to Wm. A. Churchill and James Stanley	Berlin, Conn.	Dec. 17, "
Fastener and mover, blind and shutter	Wm. Maguire	Cincinnati, O.	Jan. 1, "
Fasteners, and window shutter openers, method of bolting in	Samuel B. Snedaker	Cincinnati, O.	Feb. 12, "
Fastener, combined shutter and sash	Thomas Harvey	Baltimore, Md.	April 16, "
Fastener, sash	William H. Lazell	Hartford, Conn.	Dec. 17, "
Gold, bullion, process of reducing	Richard S. McCulloh	Princeton, N. J.	Sep. 24, "
Gold, machine for beating	Wm. Vine and James H. Ashmead	Hartford, Conn.	Aug. 6, "
Gold, processes for amalgamating; see class IV			
Gold, process for refining	James C. Booth	Philadelphia, Pa.	Sep. 24, "
Gold washer, cylinder and trough	Thomas M. Collins	Marion, Ark.	May 14, "
Gold, washers, method of constructing the sections of	Russel Burton	Rome, N. Y.	Mar. 26, "
Gold washing, double acting rocker for	Arnold Buffum and Philip Thorpe	New York	Oct. 1, "
Hammer, direct action, steam	John H. Towne, ass'nor to S. V. Merrick	Philadelphia, Pa.	Sep. 3, "
Hammer, forge, attachment of the to its helve	Daniel Hicks	Duncansville, Pa.	April 2, "
Horse shoe, machinery	Samuel S. Greene	Lowell, Mass.	Nov. 12, "
Iron, coating with copper or its alloy	Ebenezer G. Pomeroy	St. Louis, Mo.	Jan. 8, "
Iron, wrought, method of making directly from the ore	Alexander Dickerson	Newark, N. J.	July 22, "
Jack, chains, machine for making	Charles Atwood and Geo. Kellogg	Birmingham, Conn.	Nov. 12, "
Knives, spiral, machine for grinding	Silas Stevens, ass'nor to Geo. Forbes	E. Brookfield, Mass.	May 21, "
Lathe for turning a peculiar species of curve	Henry G. Thompson	New York, N. Y.	Apr. 23, "
Lock, bolt for shutters	Joseph Nock	Philadelphia, Pa.	July 2, "
Locking, portable safes to the floor—see class XXII			
Lock, revolving plate and tumbler	Lewis Jennings	New York, N. Y.	April 2, "
Locks, prison, attachment of	Edward Kershaw	Boston, Mass.	July 30, "
Metal, sheet, &c., machine for cutting	Stephen P. Ruggles	Boston, Mass.	Aug. 20, "

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Metal, sheet, machinery for cutting and bending	Joseph F. Flanders	Newburyport, Mass.	Dec. 17, 1850
Nail plate, feeder and turner	Melville Otis	E. Bridgewater, "	Dec. 3, "
Nail plate, machines for feeding	Frederick J. Ayers	St. John, N. B.	Nov. 26, "
Nails, method of making by rolling*	Elisha H. Collier	London, England	June 16, "
Punching between rollers	Richard Montgomery	New York, N. Y.	Feb. 5, "
Rocker, submerged for separating ores	Oliver Edes	Plymouth, Mass.	April 23, "
Sash, balancing	Hiram C. Brown	Xenia, Ohio	May 14, "
Sash, bearer elastic roller	Julius A. Pease	Philadelphia, Pa.	April 9, "
Sash stopper	George H. Gray, Sr.	Clinton, Miss	April 2, "
Sash stopper	Charles C. Cameron	Harper's Ferry, Va.	July 2, "
Sash stopper, arrangement of	Nathaniel Myers & Frederick C. Smith	Charlestown, Va. Harper's Ferry, Va.	June 25, "
Sash, stopper, spiral spring	William R. Barnard	Bristol, Conn.	Mar. 12, "
Sash, stopper, spring inclined plane and roller	Seth E. Winslow	Kensington, Pa.	Apr. 2, "
Sash stopper, friction roller	Joseph Haynard	Philadelphia, Pa.	Feb. 5, "
Screws, machines for cutting	Thos. J. Sloan	New York, N. Y.	July 9, "
Screws, wood, machines for nicking the heads of	Thos. J. Sloan	New York, N. Y.	Oct. 29, "
Screw threading machines	Thos. J. Sloan	New York, N. Y.	Nov. 26, "
Shafts, etc., of sheet iron, method of making	Chas. F. Fisher	New Orleans, La.	June 4, "
Shutters, the hinge of rolling iron	A. Livingston Johnson	Baltimore, Md	June 25, "
Shutters, window chain and flanges apparatus for opening and closing	George Welsh	Washington, D. C.	Jan. 22, "
Smiths, strikers	Melchi Scott	Claysville, Pa.	Sept. 10, "
Spike machine	Ammi M. George	Nashua, N. H	June 18, "
Spike machines	Moore Hardaway	Troy, N. Y.	July 16, "
Spike machines	William Blake	Boston, Mass	Sept. 17, "
Spike machines	Horatio N. Swift	Boonton, N. J.	Oct. 29, "
Spike machines, movement of the pointing die in	Edmund Sawyer	Boston, Mass.	Mar. 19, "
Steel cast, process for making	Joseph Dixon	Jersey City, N. J.	April 9, "
Tacks, carpet, machine for forming washers and attaching them to	Jason G. Howard	North Easton, Mass.	June 25, "
Tin cutting and bending machines, arrangement of the bending rollers in	William H. Horton	Newbury	
Tubes, copper, machinery for making	Edward Hamilton	Bridgeport, Conn	May 28, "
Tubes, method of forming sheet metal	Wm. Ostrander and Wm. Webster	New York, N. Y.	Mar. 17, "
Tubes, of sheet metal, machine for forming	Joseph Stout and Jas. T. Staunton	Waynesville, O.	July 30, "
Tuyere	John Pawling	Morgantown, Pa.	Jan. 22, "
Tuyers, devices for discharging ashes from	James A. Maynerd	Boston, Mass	May 21, "
Vises, parallel method of working the pawl in	Jasper Johnson	Genesee, N. Y	April 9, "
Window blinds and their slats, apparatus for operating	John Jones	Clyde, N. Y.	Dec. 24, "
Wrench, revolving jaw	Nathl. Colver ass'or to N. Colver and William S. Damrell	Boston, Mass. Dedham, Mass	May 14, "

* In England, September 11, 1845.

CLASS III.—MANUFACTURES OF FIBROUS AND TEXTILE SUBSTANCES, *including Machines for Preparing Fibres of Wool, Cotton, Silk, Fur, Paper, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Bobbins upon spindles, driving	Oliver Pearl	Essex Co., Mass.	Jan. 29, 1850
Carding and mixing wool and cotton	Stephen H. Adams and John A. Wood	Cohoes, N. Y.	June 11, "
Carding and drawing wool, engines for	Charles Jackson and Jas. Moir	Cazenovia, N. Y.	Feb. 5, "
Carding, machines for preparing bats for felting	Samuel G. Blackman	Norwalk, Conn.	Feb. 5, "
Carpets, manufacture of two and three ply	Alexander Smith	West Farms, N. Y.	Dec. 10, "
Cloth, apparatus for stretching and smoothing	John Butcher	Lowell, Mass	Nov. 5, "
Cloth, instruments for measuring	E. F. Whiton	West Stafford, Conn.	April 23, "
Cloth, machinery for folding	Augustus C. Carey and Dan'l C. Bagley	Amesburg, Conn.	Feb. 12, "
Cloth, machines for shearing	Amasa Woolson	Springfield, Vt.	May 28, "
Cloth, measuring on looms	John G. Webster, ass'r to John W. Robertson and John G. Webster	Lowell, Mass	Feb. 19, "
Cloth, wide machinery for double folding	Zachariah Allen	Providence, R. I.	July 16, "
Cordage, cotton, machinery for making	Franklin Slaughter and David Perry	Fredericksburg, Va.	Jan. 1, "
Cordage, cotton, machinery for making	Franklin Slaughter and David Perry	Fredericksburg, Va.	Jan. 8, "
Cordage, processes for rendering uninflammable	M. Y. Johnson, adm'r of James H. Johnson	Galena, Ill	Nov. 26, "
Cotton batting, apparatus for sizing and drying	Elias P. Rider	New York, N. Y.	July 30, "
Cotton, machinery for ginning or picking	Francis A. Calvert	Lowell, Mass	Sept. 17, "
Drawing rollers, regulators for	Whiting Hayden	Windham, Conn.	Mar. 12, "
Electricity, removing from wool in the process of manufacture	Joseph Metcalf	Worcester, Mass	Sept. 24, "
Flax and hemp, machinery for dressing	William W. Grant	Providence Co., R.I.	Mar. 5, "
Fliers and spindle, arrangement of	John Dermond,	Paterson, N. Y.	Feb. 12, "
Fulling cloth, machinery for	Chas. A. Reed and Thos. Cotter	Wash'n Mills, N. Y.	Sept. 24, "
Fulling mills	John C. Millar	Springfield, Mass	Aug. 20, "
Gins, cotton	John Du Bois	Greensboro', Ala.	Jan. 8, "
Gins, cotton	Stephen R. Parkhurst	New York, N. Y.	April 23, "
Harness, weavers, machinery for dressing	Kasimir Vogel	Westbrook, Me.	Aug. 6, "
Heddles, wire, machinery for making	Milton Finkle	Utica, N. Y.	April 9, "
Hemp brakes	Jonathan Crane and F. H. Hamilton	Schenectady, N. Y.	Jan. 1, "
Hemp, drawing and parting fibres of	O. S. Leavitt	Maysville, Ky	Sept. 24, "
Hemp, machines for cutting	J. Locke Hardeman	Arrow Rocke, Me	Aug. 20, "
Hemp, scutchers	Farwell H. Hamilton and Thos. Bullock	Schenectady, N. Y.	Jan. 1, "
Knitting machines	Joseph Hollen	White township, Pa.	July 16, "
Loom	Halvor Halvorson, ass'or to Wm. M. Chase	Northampton, Mass.	Oct. 1, "
Loom, power	Enoch Burt	Hartford, Conn.	
Looms	Amos H. Boyd	Saco, Me.	Oct. 15, "
Looms for figured fabrics*	Samuel Eccles	Kensington, Pa.	Mar. 5, "
Looms for piled fabrics	James Turnbull, Jr., and John Turnbull	Simsbury, Conn.	Jan. 29, "
Looms for weaving out pile fabrics	Mertown C. Bryant	Lowell, Mass	June 25, "

* Antedated Dec. 22, 1849.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Looms for weaving figured fabrics	Samuel T. Thomas and Edwd. Everett	Lowell, Mass; Lawrence, Mass	Dec. 24, 1850
Looms for weaving figured goods	Avery Babbett	Auburn, N. Y	Oct. 8, "
Looms for weaving piled fabrics*	John Johnson, ass'or to Elias Johnson	Troy, N. Y	Mar. 12, "
Looms for weaving piled fabrics	Mertown C. Bryant	Lowell, Mass	Mar. 19, "
Looms for weaving tapestry and Brussels carpets	Erastus B. Bigelow	Clinton, Mass	Sept. 24, "
Looms, hand	John G. Garretson	Salem, Iowa	May 21, "
Looms, let off motion of	Jonathan Knowles	Buffalo, N. Y	April 30, "
Looms, operating shuttle boxes in	Robert Burns Goodyer & Benj. Twist, ass'or to Alfred Jenks	Philadelphia, Pa; Manayunk, Pa; Bridesburgh, Pa	Jan. 1, "
Looms, power	John Shuttleworth	Frankford, Pa	May 21, "
Looms, shuttle motion of	Oliver A. Kelly	Woonsocket, R. I	June 4, "
Looms, shuttle motions in	Thomas T. Wilcox	Norwich, Conn	Nov. 26, "
Looms, stop motion for	Elijah Hall	Cabotsville, Mass	Sept. 24, "
Paper, machinery for measuring pulp in the manufacture of	Henry Pohl	Paterson, N. J	July 9, "
Pile for rugs, &c., preparation of†	James Taylor, ass'or to John Joseph and Francis Crossley	Loch Winnock, Scotland; Halifax	May 28, "
Ropes, machinery for making	Henry Evans	N. Bedford, Mass	Sep. 24, "
Sewing machines	David M. Smith, ass'or to Thomas Chadbourne	Springfield, Vt; Concord, N. H	April 16, "
Sewing machines	O. L. Reynolds	Dover, N. H	May 14, "
Sewing machines	Bartholomy Thimonnier, Sr., ass'or to Philip May	France; London, England	Sept. 3, "
Sewing machine	John Bacheider	Boston, Mass	Sept. 24, "
Sewing machines	Allen B. Wilson	Pittsfield, Mass	Nov. 12, "
Sewing machines	Frederick R. Robinson	Boston, Mass	Dec. 10, "
Shuttle, weavers'	Wm. Markland and Jos. Milner	Lowell, Mass	Oct. 1, "
Silk, &c., machinery for doubling and twisting	Joseph Conant & Lucius Dimmock	Northampton, Mass	Dec. 17, "
Speeder, counter twist	Jesse Whitehead	Manchester, Va	July 30, "
Spindles and bobbins for spinning	Josiah G. Reed	Paterson, N. J	Jan. 15, "
Spinners cop, operating the coping rail of	Warren Rouse	Taunton, Mass	Nov. 5, "
Spinners, hand	David Current	Crittenden, Ky	Sep. 3, "
Spinning machines, preventing fibres from winding on drawing rollers in	John C. Dodge	Dodgeville, Mass	May 14, "
Spooling, machinery for	Avery Babbett	Auburn, N. Y	Feb. 5, "
Temples used in weaving double cloth	Stephen Everett	Biddeford, Me	April 2, "
Yarn, machinery for doubling and twisting	Moses Hey	Springfield, Pa	Oct. 8, "

* In England, Mar. 9, 1849. † In England, Oct. 10, 1845.

CLASS IV.—CHEMICAL PROCESSES, MANUFACTURES, AND COMPOUNDS, *including Medicine, Dying, Color-making, Distilling, Soap and Candle making, Mortars, Cements, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Alloys for points and lightning rods	James Spratt	Cincinnati, O	Jan. 8, 1850
Alum, process for manufacturing	Jacob H. Wurtz	New York, N. Y	Oct. 22, "
Candles, mould apparatus	Herman Camp	Dunkirk, N. Y	Jan. 22, "
Candles, manufacture of	James G. Davis, ass'or to A. B. Warner and Jas. G. Davis	Buffalo, N. Y	Aug. 13, "
Composition of, covering hams	Hosea Billings	Beardstown, Ill	April 9, "
Composition for enamelling hollow ware*	Chas. E. & Chas H. Paris	Paris, France	Mar. 5, "
Compound for imparting a gloss to cloths†	Wm. D. Beaumont	Baltimore, Md	Oct. 8, "
Compounds for sizing, for warps on yarns	Wm. Mallerd	Providence, R. I	July 16, "
Curing meat, process for	George Starkweather	Hartford, Conn	Nov. 5, "
Curing tobacco stems—see class XXII, "Tobacco"			
Distilling oleaginous matter‡	Anthony M. Poisat and David C. Knabb	Paris, France	Feb. 26, "
Distilling spirits of turpentine	Chas. J. Meinicke	New York, N. Y	July 30, "
Fats and oils, hardening	Carl W. Schindler	New York, N. Y	Nov. 5, "
Gas, coal, purifying	Joseph A. Sabbaton	Albany, N. Y	July 30, "
Gases, preparing illuminating‖	Stephen White	Manchester, Eng	Jan. 22, "
Gas generating apparatus	Christopher F. Brown	Baltimore, Md	Feb. 26, "
Gas, manufacture of illuminating from bitumen	Abraham Gesmer	Halifax, N. S	Jan. 29, "
Gas metres	James Long	Chicago, Ill	Mar. 5, "
Gas metres	Thomas W. Lane	Woburn, Mass	Oct. 8, "
Glucose, process in the manufacture of	George Riley	New York, N. Y	Mar. 5, "
Gold, process for amalgamating	Calvin C. Knowles	Lowell, Mass	Aug. 6, "
Gutta Percha, process of working	Samuel F. Armstrong and Chas. J. Gibbert	New York, N. Y	Sept. 17, "
India rubber cloth, process of rolling	Francis D. Hayward and John C. Bickford	Colchester, Conn	Mar. 19, "
India rubber springs for cars, &c., manufacture of	Fowler N. Ray	New York, N. Y	April 2, "
Indian rubber, use of oxide of tin in the manufacture of	John Pridham, ass'or to Horace H. Day	N. Brunswick, N. J; New York, N. Y	Mar. 19, "
Indian rubber, vulcanising	Jonathan T. Trotter	New York, N. Y	Dec. 3, "
Oils, filter for	Thomas Antisell	New York, N. Y	Nov. 12, "
Oxide of zinc, manufacture of the§	Edme Jean Leclaire and Jean Joseph Ernest Barnrel	Paris, France	May 17, "
Paint, process of making from bituminous coal	Charles Mortimer	Philadelphia, Pa	April 9, "
Paints, drying	Aquilla Jones	New York, N. Y	Nov. 12, "
Particoloring yarn, apparatus for	Alexander Smith	West Farms, N. Y	June 18, "
Pill boxes, machinery for making—see class XIV			
Preparing wheat for grinding	Joseph W. Carpenter	Pontiac, Mich	Sept. 17, "
Preserving wood, process for ¶	Chas. Payne	Sth. Lambeth, Eng	May 28, "
Stannates of potash and soda, process for making**	James Young	Manchester, Eng	Aug. 20, "
Starch from maize, manufacture of	Thomas Bragg	West Milton, O	Dec. 24, "
Sugar, defecating	Robert de Massy	Bocourt, near Saint Quentin, France	May 7, "
Sugar, manufacture of ††	Louis Henry F. Nelsens, ass'or to Louis de Saulles	Lorain, Belgium; New Orleans, La	Jan. 29, "
Sugars, draining‡‡	Conrad W. Finsel	Bristol, England	Sept. 3, "

CLASS V.—CALORIFIC, *comprising Lamps, Fire-places, Stoves, Grates, Furnaces for heating Buildings, Cooking Apparatus, Preparation of Fuel, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bagasse, machine for drying	James H. Dakin	Baton Rouge, La.	May 21, 1850
Blast pipes, for conveying heated air and gases to furnaces—see class II			
Burning fluid	Ephraim Howe	Brooklyn, N. Y.	Sep. 24, "
Chimney caps	Edward Whitley	Boston, Mass.	Mar. 5, "
Chimney caps	Michael H. Collins	Boston, Mass.	
Chimney caps	Augustus M. Rice, ass'or to H. Lombard and A. M. Rice	Boston, Mass.	Apr. 9, "
Dampers for cleaning stove pipes and regulating the draft in the same	Frederick Bleier	Pittsburg, Pa.	Jan. 15, "
Dryers, grain	Martin C. Dudley	New Orleans, La.	Apr. 30, "
Dryers, grain	John R. Hoopes	W. Philadelphia, Pa.	Aug. 27, "
Dryers, grain	Charles S. Snead	Louisville, Ky.	Oct. 1, "
Fire, apparatus for extinguishing*	William H. Phillips	Langton Place, Eng.	April 9, "
Fire places and throats of chimnies—construction of	Charles W. Russell	Washington, D. C.	Mar. 5, "
Firing kilns for pottery ware, black lead crucibles	Joseph Dixon	Jersey city, N. J.	Mar. 5, "
Furnaces, air heating	Henry Adolph Engles	Cincinnati, O.	Feb. 12, "
Furnaces, air heating	James McGregor	Wilton, N. Y.	Mar. 5, "
Furnaces, air heating	Gardner Chilson	Boston, Mass.	Nov. 19, "
Furnaces for calcinizing gypsum	Benj. Fowler	Lubec, Me.	June 18, "
Furnaces for heating sad irons	John T. Davy	Troy, N. Y.	Mar. 12, "
Furnaces, hot air	George E. Waring	Stanford, Conn.	Dec. 24, "
Furnaces, portable	John P. Hayes	Boston, Mass.	Nov. 5, "
Furnaces, portable	Merritt F. Potter	Charlemont, Mass.	Jan. 22, "
Furnaces, steam boiler	Benj. Crawford, ass'or to Wm. B. English, J. J. Bennett, A. D. Frisbee and B. Crawford	Alleghany, Pa.	Jan. 29, "
Grate, apparatus for raising the, in cooking stoves	Benj. K. Maltby, ass'nor to Ira M. Mead	Cleveland, O. / Mogadore, O.	June 18, " / June 18, "
Grates, coal	Chauncey D. Greene	West Troy, N. Y.	Jan. 1, "
Grates, coal, agitating	Abel Keeney	Carlisle, Pa.	April 2, "
Grates, coal, agitating	John B. Chollar	West Troy, N. Y.	Aug. 27, "
Grates, fire place	Gardner Chilson	Boston, Mass.	June 4, "
Grates for cooking stoves	John T. Davy	Troy, N. Y.	April 16, "
Grates, furnaces, coal stirrers for	William R. Nichols and Barritt C. Boyes	Philadelphia, Pa.	April 23, "
Heating air by hot water, apparatus for	Adrian Janes	New York, N. Y.	Jan. 29, "
Lamps for lighting gas burners	Robert Thompson	Lowell, Mass.	Dec. 17, "
Lamps, gas, self-generating	Sharpless Clayton and Yarnall Bailey	West Chester, Pa.	Aug. 27, "
Lamps, metallic, making the reservoirs of	P. J. Clark	Meriden, Conn.	May 28, "
Lamps, safety	John W. Hoffman	Southwark, Pa.	April 23, "
Lamps, safety, tubes for	Franklin Stewart	Philadelphia, Pa.	July 2, "
Lamp tubes	Isaiah Jennings	New York, N. Y.	July 9, "
Lids for boiler holes of cooking stoves	Tho's G. Clinton & Geo. H. & Edw'd H. Knight	Cincinnati, O.	Feb. 19, "
Oil cans—see class XIII			
Ovens, bake	Hosea Ball	Philadelphia, Pa.	Nov. 19, "
Ovens, heating, elevated	P. A. Palmer	Le Roy, N. Y.	Sep. 24, "
Ranges, cooking	Frederick H. Stimpson	Boston, Mass.	Mar. 5, "
Ranges, cooking and air heating, furnaces connected therewith	James MacGregor, jr.	New York, N. Y.	Mar. 5, "
Ranges, cooking, and heating air	Elias T. Beers	Honesdale, Pa.	Apr. 2, "
Ranges, cooking, water backs for	Herbert H. and Frederick H. Stimpson	Boston, Mass.	May 28, "

* In England, December 4, 1844.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Registers, hot air	George Pollock	Roxbury, Mass.	Aug. 20, 1850
Registers, warm air	Peter G. Woodside	Philadelphia, Pa.	Oct. 8, "
Stove pipes, joints of	James N. Warner	Buffalo, N. Y.	May 14, "
Stoves	Peter Sweeney	Buffalo, N. Y.	Feb. 26, "
Stoves	Anson Atwood	Troy, N. Y.	May 14, "
Stoves	Sherman S. Jewett and F. H. Root	Buffalo, N. Y.	Sep. 3, "
Stoves, air heating	Perry Goodhue	Cincinnati, O.	Mar. 12, "
Stoves, air heating	James L. Cathcart	Washington, D. C.	May 17, "
Stoves, coal, for roasting, baking and boiling	Tho's G. Clinton, Geo. H. and Edward H. Knight	Cincinnati, O.	Aug. 27, "
Stoves, cooking	Charles M. Nelson	Cincinnati, O.	Mar. 5, "
Stoves, cooking	Hosea H. Hartley	Cincinnati, O.	Mar. 19, "
Stoves, cooking	William Abendroth	Port Chester, N. Y.	April 23, "
Stoves, cooking	Jordan L. Mott	New York, N. Y.	May 7, "
Stoves, cooking	James R. Hyde	Troy, N. Y.	May 7, "
Stoves, cooking	Jordan L. Mott	New York, N. Y.	May 14, "
Stoves, cooking	Abraham Keagy	Mid. Woodbury, Pa.	June 25, "
Stoves, cooking	James White	Milton, Pa.	Aug. 6, "
Stoves, cooking	Samuel Pierce	Troy, N. Y.	Nov. 12, "
Stoves, cooking	Loftes Wood	New York, N. Y.	Nov. 26, "
Stoves, cooking, arrangement of dampers in	Henry L. Sheperd	Dayton, O.	Aug. 6, "
Stoves, cooking, construction of	S. H. Ransom	Albany, N. Y.	July 2, "
Stoves, double, cooking	Henry Jackson	Evansville, Ind.	Apr. 23, "
Stoves, double oven, cooking	James MacGregor, jr.	Wilton, N. Y.	Mar. 19, "
Stoves, Franklin, blowers of	David Steuart, ass'nor to Wm. P. Cresson	Philadelphia, Pa.	Aug. 27, "
Stoves, parlor	Gardner Chilson	Boston, Mass.	June 18, "
Stoves, parlor, air heating	Lemuel W. Gosnell	Baltimore, Md.	April 2, "
Stoves, with circular shaking grate	Edward B. Finch	Peekskill, N. Y.	Aug. 27, "
Ventilating railroad cars	James Cunningham	Reading, Pa.	Mar. 12, "
Ventilating railroad cars	Hezekiah Bradford and Ephraim Morris	New York, N. Y.	June 4, "
Ventilators, ship	Warren Robinson	Lebanon, Conn.	Aug. 13, "
Ventilators, ship	Ralph Bulkley	New York, N. Y.	Nov 26, "

CLASS VI.—STEAM AND GAS ENGINES, *including Boilers and Furnaces therefor, and parts thereof.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Air engines, method of distributing the air over the heating and cooling surfaces of	Ernst Buckup	New York, N. Y.	July 2, 1850
Boiler, cupola and grate combined	Loftes Wood	New York, N. Y.	Nov. 26, "
Boiler feeder, balanced	William D. Allen	Durhamville, N. Y.	Dec. 10, "
Boiler, steam*	Richard E. Dibble	New York, N. Y.	Aug. 21, "
Boilers, corrugated	Richard Montgomery	New York, N. Y.	Oct. 29, "
Boilers, method of applying fusible metal to	Edward H. Ashcroft	Boston, Mass.	Mar. 17, "
Boilers, steam	Frederick P. Dimpfel	Philadelphia, Pa.	July 16, "
Boilers, steam, galvanic regulators for—see class VIII, "Galvanic regulators, &c."			
Boilers, steam, registers for	James D. Rice	Philadelphia, Pa.	Aug. 20, "

* Antedated July 20, 1850.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Boilers, steam, the alarm and indicator for	Joseph Dilks	Philadelphia, Pa	Dec. 3, 1850
Condensers of steam engines	Ethan Baldwin	Philadelphia, Pa	July 9, "
Condensers, surface for steam engines	Joseph P. Poisson	New York, N. Y	Apr. 2, "
Cut off motion for puppet valves	Samuel H. Gilman	Cincinnati, O	Dec. 10, "
Cylinder, steam, exhaust passages for	George Shield	Cincinnati, O	Sep. 10, "
Engines, horizontal, expansion gear for	Samuel H. Gilman	Cincinnati, O	Dec. 17, "
Engine, steam, arrangement of	Richard F. Loper & John W. Nystrom	Philadelphia, Pa	Dec. 17, "
Furnaces—see class V.			
Furnaces for steam boilers	F. P. Dimpfel	Philadelphia, Pa	Nov. 5, "
Locomotive engines, apparatus for reversing or stopping	James Cunningham	Reading, Pa	Oct. 22, "
Locomotive engines for working heavy grades, boilers and gearing of	George Escol Sellers	Cincinnati, O	July 9, "
Packing metal, compound, hard and soft	Andrew Fulton	Pittsburg, Pa	Mar. 25, "
Safety apparatus for steam boilers	John C. Sement and John Workman	Philadelphia, Pa	Aug. 13, "
Spark arresters	James Radley and John W. Hunter	New York, N. Y	Jan. 22, "
Spark arresters	Samuel Swett	New York, N. Y	Nov. 19, "
Steam boilers, interior arrangement of	Sylvanus Knight	Winchester, Ind	Mar. 12, "
Steam, method of employing the exhaust	Geo. H. Hoagland	Piermont, N. Y	Mar. 19, "
Valve gear for steam engines	Geo B. Milner	Houston, Texas	July 30, "
Valve gridiron slide	William W. Hubbard	Boston, Mass	Jan. 22, "
Valves for governors	Junius and Alfred Judson ass'rs to Junius Judson	Rochester, N. Y	Nov. 5, "
Valves, oscillating of steam engines	Thomas C. Thenker	Mansfield, O	May 7, "
Valves, puppet, expansion gear for	Thomas McLaughlin	New York, N. Y	Jan. 29, "
Valves, slide, arrangement of several in the same steam chest	Cyrus Richardson	Woburn, Mass	May 7, "

CLASS VII.—NAVIGATION *and Maritime Implements, comprising all Vessels for conveyance on water, their construction, rigging and propulsion, Diving Dresses, Life Preservers, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Cordage, &c.—see class III.			
Grummet strap	Eli F. Southward	Wellfleet, Mass	Oct. 8, 1850
Paddle wheels, opening and closing bucket for	George Tingle	New York, N. Y	Aug. 20, "
Propeller, centripetal	John W. Nystrom	Philadelphia, Pa	Mar. 19, "
Propeller, shell	James Trees	Salem, Pa	May 14, "
Propellers and chimneys for canal boats, arrangement of	Benjamin M. Smith	Ridgeway, N. Y	April 23, "
Propellers, screw arrangement and connection of	Patrick L. Derlan	Reading, Pa	May 21, "
Propelling boats in shallow water, method of	John Dougherty	Mount Union, Pa	Aug. 20, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Sewing mallets	Thomas Batty	New York, N. Y	Aug. 20, 1850
Ship's timbers, instruments for laying down curves of	Charles Scales	Bath, Me	Dec. 17, "
Steering apparatus	Phineas P. Quimby	Belfast, Me	Mar. 19, "
Steering apparatus	Charles F. Brown	Warren, R. I	July 22, "
Steering apparatus, parallelogram	Jesse Reed	Marshfield, Mass	Feb. 26, "
Stoppers, cat head and shank painter	Charles Perley	New York, N. Y	April 2, "
Trusses, method of attaching yards to	Tilgath Odeon	Portsmouth, Va	Aug. 27, "
Vessels, apparatus attached to for indicating the depth of water	Henry B. Sommers	Ithaca, N. Y	Dec. 10, "
Vessels, apparatus for trimming	Evan L. Evans	Mount Holly, N. J	Mar. 19, "
Vessels' holds, apparatus for measuring the depth of water in	Nelson Edwards	Chittenden Co., Vt	Mar. 5, "
Vessels, method of carrying over shoals	J. A. Winslow	Roxbury, Mass	Aug. 20, "
Vessels, method of fitting the bows of	Benjamin Barstow	New York, N. Y	July 2, "
Vessels, model for	Solomon Andrews	Perth Amboy, N. J	June 25, "
Vessels, submarine	Lambert Alexander	France	Sep. 3, "
Windlass jigger—see class XII.			

CLASS VIII.—MATHEMATICAL, *Philosophical and Optical Instruments, including Clocks Chronometers, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Calculating machines	Du Bois D. Parmelee	New Paltz, N. Y	Feb. 5, 1850
Callipers	Wm. W. Smith	Boston, Mass	
Compasses for measuring, joints for	Theodor Altenedor	Philadelphia, Pa	July 16, "
Compasses, surveyors'	John Locke	Cincinnati, O	July 16, "
Dividers, or compasses	Dexter H. Chamberlain, ass'or to Charles W. Homer, S. J. M. Horner, and W. G. Ladd	Boston, Mass. Cambridge, Mass. Boston, Mass	Apr. 9, "
Electro magnetic engines	John H. Lillie	Joliet, Ill	Apr. 16, "
Electro magnetic machines, for shocks	Samuel B. Smith	New York, N. Y	June 4, "
Enunciators, electro magnetic, for signals in hotels, &c	Charles S. Bulkley	Macon, Ga	Oct. 29, "
Galvanic regulators for steam boilers *	Arthur Dunn	Dalston, Eng	May 28, "
Gauge for water casks—see class XI, "Water casks, &c."			
Level, fluid	William G. Ladd, jr	Cambridge, Mass	Apr. 9, "
Levels, collimating	John Locke	Cincinnati, O	July 2, "
Lightning conductors, attachments for	James Spratt	Cincinnati, O	Feb. 5, "
Magnetic needles, correcting	Calvin Guiteau	Syracuse, N. Y	Mar. 26, "
Rules, board and log	Charles B. Hutchinson	Waterloo, N. Y	June 4, "
Rules, board and log	Benj. M. Van Der Neer	Clyde, N. Y	Apr. 30, "
Telegraph, electric, manipulator	Austin F. Park	Troy, N. Y	Aug. 27, "
Telegraphs, electric	Wm. S. Thomas	Norwich, N. Y	Feb. 12, "
Telegraphs, electric	Geo. H. Horn	Boston, Mass	June 25, "
Telegraphs, electro chemical	G. Westbrook. Henry J. Rogers	Washington, D. C. Baltimore, Md	May 28, "
Telegraphs, repeaters for electro magnetic †	Charles S. Bulkley	Macon, Ga	Nov. 12, "
Telescopes, submarine	Willard Day	Brooklyn, N. Y	Apr. 16, "

* In England, October 12, 1848.

† Antedated Sep. 10, 1850.

CLASS IX.—CIVIL ENGINEERING *and Architecture, comprising works on Rail and Common Roads, Bridges, Canals, Wharves, Docks, Rivers, Wiers, Dams, and other Internal Improvements, Buildings, Roofs, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Balloons and their appendages—see class XI.			
Blinds, Venitian, suspending	Joseph Bohrer	Philadelphia, Pa	June 4, 1850
Bridges, arch, truss for	Henry Lanergan	Boston, Mass	Apr. 23, "
Buildings, iron, construction of the frame, roof and floor of	James Bogardus	New York, N. Y	May 7, "
Canals, feed regulators for	Charles Ross	West Buddick, O	May 21, "
Chairs, machines for making wrought iron railroad	Wm. Van Andear	Poughkeepsie, N. Y.	Apr. 30, "
Chair, wrought iron railroad	Edward S. Renwick	Washington, D. C.	Oct. 22, "
Cornices and mouldings, plaster tool for forming	Sylvester Groesbuck	New York, N. Y	Sep. 17, "
Drilling stone, machines for	Geo. Fletcher, sr	Greensburg, Ind	Apr. 23, "
Eaves trough and gutter, machine; see class II.			
Embankments, levees, and method of forming	Duff Green	Dalton, Ga	June 11, "
Excavating and conveying earth	John A. Sprague	Dayton, O	Oct. 5, "
Excavating auger	James Buck	Buckaport, Me.	Feb. 5, "
Excavating, machines	Martin Newman, 2d	Lanesboro, Pa.	Nov. 19, "
Excavator, the screw	Richard Montgomery	New York, N. Y	May 7, "
Fences	Isaiah Subers	Philadelphia co., Pa.	Feb. 19, "
Fences, portable	Peter M. Purdy	Haysville, O	Feb. 19, "
Gates for fences	Jesse Bailey	Leatherwood, O	Jan. 15, "
Gates, hanging and operating	Thomas Parkinson	Naples, N. Y	Aug. 6, "
Lewis, lever—see class XIII.			
Lock, bolts, method of operating	Thomas Slaight, ass'or to Henry C. Jones	Newark, N. J	Mar. 12, "
Mantel piece	Hiram Tucker	Cambridge, Mass	April 2, "
Piles, &c., method of sinking hollow by exhausting the air from the interior of the same*	Lawrence H. Potts	London, Eng	Jan. 29, "
Rail, compound tubular	Alfred B. Seymour	New York, N. Y	April 16, "
Railings, iron	Wm. Hamilton		Feb. 26, "
Railings, iron	John Krauser, Sommers Crowell, and Cyrus Krauser	Reading, Pa	Nov. 12, "
Railroad frog, oscillating, self adjusting	John W. Hoffman	Philadelphia, Pa	April 2, "
Rails of railroads, method of securing	H. H. May	Galesburg, Ill	Nov. 26, "
Road scrapers, adjustable mouth piece to	Shadrach Davis	Dartmouth, Mass	May 7, "
Roads, machine for repairing	Nathan Potter	East Hamburg, N. Y	June 25, "
Roadway for rail cars and ordinary vehicles	Jordan L. Mott	Mott Haven, N. Y	Sep. 17, "
Scraper, combination of a guide tooth with an inclined	John P. Wood	Hounie, La	June 18, "
Scrapers, removable teeth for	Joseph Sweet	Hughesville, Pa	Apr. 2, "
Stump extractor, wheel and axle	John Rogers	Orleans co., Vt	Jan. 1, "
Wickets, for lock gates	John Jack, ass'r to Alfred Bell	Nunda, N. Y	May 21, "

*In England, Dec. 5, 1848.

CLASS X.—LAND CONVEYANCE, *comprising Carriages, Cars, and other Vehicles used on Roads, and parts thereof.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Axles and shafts, bearings for	Wm. H. Hovey	Hartford, Conn	Dec. 10, 1850
Axles, mail	Wm. H. Saunders	Hastings, N. Y	Mar. 5, "
Balloons and their appendages—see class XI.			
Brakes, connection of with cars	John Kimbell and Harvey Rice	Concord, N. H	Jan. 1, "
Brakes for carriages	Wm. J. Welch, jr	Churchville, Md	Mar. 12, "
Boxes and axles, packing	Wm. H. Hovey	Hartford, Conn	Aug 13, "
Boxes, compound wagon	Inla Drake	Mansfield, N. J	Aug. 20, "
Car couplings	Hiram Baldwin	Nashville, N. H	April 16, "
Car couplings	David S. Neale	Lynn, Mass	Sept. 3, "
Car couplings	Nathan Haskins	Manchester, N. H	Oct. 29, "
Carriage bodies, hanging	M. G. Hubbard	Hume, N. Y	Feb. 12, "
Carriage bodies, hanging	M. G. Hubbard	Geneva, N. Y	Nov. 26, "
Carriage jacks	Thomas G. Clinton, G. H. & E. H. Knight	Cincinnati, O	Mar. 5, "
Carriages	James Patterson	Franklinville, N. Y.	April 16, "
Carriages	Miles S. Watkins	Sommerville, Tenn.	June 25, "
Carriages	Edward and Charles Everett, jr.	Washington, D. C.	Dec. 17, "
Carriages, apparatus for releasing horses from	Tapley B. Pyron	Salina, Tenn	Oct. 22, "
Carriages, dash board for	Lewis Lupton	Winchester, Va	Oct. 1, "
Carriages, detaching horses from	John W. Harrison	Logansport, Ind	Aug. 27, "
Carriage tops, elevating and lowering	John L. Allen	Syracuse, N. Y	Feb. 19, "
Carriage tops, raising and lowering	Solomon Goddard & Henry Warfield	Truxton, N. Y	Feb. 19, "
Cars, apparatus for retaining on the rails	William Payne	New York, N. Y	Mar. 5, "
Car seat backs	Thomas E. Warren	Troy, N. Y	July 30, "
Cars for plank roads, wooden rail, &c.	Gideon Morgan	Calhoun, Tenn.	June 11, "
Cars, railroad	Geo. S. Hacker	Charleston, S. C	Mar. 5, "
Cars, ventilating railroad—see class V, "Ventilating."			
Felloes, machine for cutting	Joseph and Levi Adams	Hadley, Mass	July 9, "
Friction rollers	Joseph M. Totten	Peoria Ill	
Hubs and axles, connecting and disconnecting	A. M. Billings and Thomas A. Ambrose	Claremont, N. H	June 25, "
Hubs, connecting with axles	Junius Foster	Bridgeport, Conn	Feb. 26, "
Hubs with axles, connecting	Eliphalet S. Scripture	Green Point, N. Y	July 30, "
Neck yokes, attaching to poles of carriages	James M. Brown	Bloomfield, O	June 18, "
Omnibuses, turning up the steps of	Stephen Burdett	New York, N. Y	Aug 27, "
Packing for oil boxes of axles, &c. adjusting	Warner Groat	Troy, N. Y	June 11, "
Skeins, connecting with axles	Abel Combs	Farmington, O	May 14, "
Springs for cars, &c., manufacture of India rubber—see class IV. "India rubber, &c."			
Spring, vulcanized India rubber	Fowler M. Ray	New York, N. Y	Oct. 18, "
Trucks, connection with car bodies	George Vanderhoof	Patterson, N. J	Feb. 12, "
Trucks, railroad	James Ingersoll	Grafton, O	Feb. 2, "
Wagon tops, apparatus for regulating the setting of bows in	A. McKinney	Montgomery, N. Y.	Aug. 13, "
Wheels, car	Geo. W. Eddy	Waterford, N. Y	Jan. 8, "
Wheels, car machines for making wrought iron	Nathan Starks	Albany, N. Y	Oct. 29, "
Wheels, cast iron car	Lyman Kinsley	Norfolk co., Mass.	Mar. 12, "
Wheels, cast iron car	Lyman Kinsley	Norfolk co., Mass.	Mar. 12, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	
Wheels, cast iron car	Asa Whitney	Philadelphia, Pa	Mar. 19,	"
Wheels, cast iron car	James Boon	Lancaster, Pa	Apr. 16,	"
Wheels, cast iron car	Albert Fuller	Boston, Mass	Aug. 27,	"
Wheels, cast iron car	Nathan Washburn	Worcester, Mass	Oct. 8,	"
Wheels, cast iron R. R. car	Benj. Severson	Schenectady, N. Y	Sept. 17,	"
Wheels, wrought iron car	Herrick Aiken	Franklin, N. H	Oct. 1,	"
Wheels, wrought iron car, clamp to be used in the manufacture of	Herrick Aiken	Franklin, N. H	Apr. 2,	"
Whiffletrees, connecting with carriages	James Barnes	Franklin, N. Y	June 11,	"

CLASS XI.—HYDRAULICS AND PNEUMATICS, *including Water-wheels, Windmills, and other implements operated on by air or water, or employed in raising and delivering fluids.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	
Balloons and their appendages*	Hugh Bell	London, England	Mar. 26,	1850
Engines operated by steam air and water	James Black	Philadelphia, Pa	Jan. 8,	"
Filtering and drinking tube, pocket	Abijah Fess[illegible]	Boston, Mass	April 2,	"
Filtering cocks	Daniel Bart[illegible], Jr	Boston, Mass	Oct. 15,	"
Filters	Chas. D. Birdseye, ass'or to Warring Latting	New York, N. Y	Mar. 26,	"
Hose, India rubber	Horace H. Day & Rich'd McMullin	New York, N. Y G. Barrington, Mass.	Sept. 17,	"
Hydraulic apparatus for producing blast	Ransom Cook	Sarat'a Springs, N.Y.	June 11,	"
Hydraulic blowers	Jeremiah Darling	Cincinnati, O	Dec. 24,	"
Hydraulic blowers for furnaces, &c.	Ransom Cook	Sarat'a Springs, N.Y.	Apr. 16,	"
Hydrolator	Zariel Swope	Lancaster, Pa	Feb. 26,	"
Molasses gates	Erastus Stebbins	Chicopee, Mass	Oct. 15,	"
Pipe coupling	Chapman W[illegible]ner	Louisville, Ky	Apr. 30,	"
Pipe, lead, manufacture of	William P. Latham	Philadelphia, Pa	Sept. 3,	"
Pipes and hose, couplings for	A. H. Brown	Albany, N. Y	Apr. 30,	"
Pumps, attachments to, for agitating the surface of the water in the well	Wm. D. Mayfield	Elkton, Ky	Dec. 24,	"
Pumps for deep wells	Nehemiah Dodge	New York, N. Y	Mar. 12,	"
Pumps for ships, &c	Franklin Ransom	New York, N. Y	Mar. 19,	"
Pumps, rotary	William H. Davis	Maysville, Ky	Nov. 5,	"
Regulators, feed for canal—see class IX., "Canals."				
Sprinkling streets, &c., apparatus for	Joseph D. Price	Smithsburgh, Md	April 9,	"
Valves of hydraulic engines, arrangement of the	William Kentish, ass'or to Cornelius Van Wagoner	Paterson, N. J	Jan. 15,	"
Waste gates	Hiram Yaw, and Thos. P. How	Boston, Mass Buffalo, N. Y	June 25,	"
Water, apparatus for drawing	Cam Broyles	Green Co., Tenn	Apr. 30,	"
Water casks, gauge for	John Mc[illegible], Jr., ass'or to Henry Schreiner	Reading, Pa	Mar. 12,	"
Water metres	William S[illegible]ell, Jr	Williamsburg, N.Y.	Feb. 5,	"
Water metres	Timothy Rose	Cortlandsville, N.Y.	Sept. 24,	"
Water wheels, directing water upon	Marcius B. Ashley	Watertown, N. Y	July 30,	"

* In England, Nov. 2[illegible], 184[illegible].

CLASS XII.—LEVER, SCREW, AND OTHER MECHANICAL POWER, *as applied to Pressing, Weighing, Raising and Moving Weights.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	
Hoisting machines	Sandy Harris	Philadelphia, Pa	Mar. 19,	1850
Hoisting, machines for	William C. Allison	Philadelphia, Pa	April 2,	"
Lever jacks	James Leffel	Springfield, O	Dec. 10,	"
Lewis, lever	Thos. Lidgerwood	Brooklyn, N. Y	Mar. 12,	"
Press boxes or vats for cheese	Augustus N. Severance	Cherry Valley, O	April 30,	"
Press, cotton	A. D. Brown	Clinton, Ga	Jan. 22,	"
Presses, cheese	Augustus N. Severance	Cherry Valley, O	Mar. 26,	"
Presses, cheese	Joseph Card	Fairport, O	Oct. 22,	"
Presses, cheese, self-acting	John Underwood	Montpelier, Vt	June 25,	"
Presses, cotton	J. T. Elliot	Carrolton, Miss	Oct. 22,	"
Presses for copying letters	George Burnham	Philadelphia, Pa	Oct. 8,	"
Presses, oil	Edwin Hills	Cincinnati, O	Mar. 12,	"
Pressing cotton and other substances into bales	S. A. Clements	Granby, Conn	Sept. 3,	"
Scale beams	Samuel T. McDougal	New York, N. Y	Feb. 26,	"
Scale beams	Wm. P. Pierce, ass'or to E. & T. Fairbanks & Co	St. Johnsbury, Vt	April 9,	"
Weighing frames	Chas. Downer	Philadelphia, Pa	Mar. 19,	"
Weighing grain, machines for	Sam'l R. Wilmot	Lafayette, Ind	Dec. 24,	"
Weighing machines	George Houston	Washington, N. C	Aug. 13,	"
Weighing machines, self, for grain, etc.	W. W. W. H. T. Bramble	Lafayette, Ind	July 16,	"
Windlass, jigger	Charles Perley	New York, N. Y	July 30,	"

CLASS XIII.—GRINDING MILLS, *and Mill-gearing, including Grain Mills, Mechanical Movements and Horse-Powers.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	
Attachments to mills for preparing corn in the cob for grinding	John M. Seely and Wm. E. Tomlinson	Lockport, O	May 21,	1850
Bran dusters	Ezra R. Benton	Milwaukie, Wis	May 7,	"
Cider Mills	Sam'l Jackson	Hamilton, O	Jan. 15,	"
Clutches, friction	Nelson Barlow	St. Louis, Mo	Aug. 13,	"
Connecting rods of steam engines and other machinery	Levi Bissell	New York, N. Y	May 14,	"
Corn shellers	Sam'l Graves	Springfield, Ill	Sept. 17,	"
Corn shellers	David Eldridge	Philadelphia, Pa	Nov. 19,	"
Corn shellers, concave of	Daniel Hoats	Milton, Pa	Jan. 22,	"
Cutters, machinery for forming rotary—see class II.				
Feed apparatus for mills	John Sherlock and Wm. Brackbill	Portugal, Pa	June 18,	"
Flour bolts	John M. Reed and Wm. B. Willis	Charlestown, Va	Jan. 29,	"
Flour, elevating, cooling and conveying	Jesse White and Jon'n Bundy	Barnesville, O	Dec. 16,	"
Flouring mills	Alexander F. Menefree	Woodville, Va	Mar. 12,	"
Gearing for regulating speed	[illegible]	Manches[illegible], N. H	Apr. 20,	"

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Gearing for sugar cane mills	Edward Phelps	Pittsburgh, Pa	Jan. 29, 1850
Grinding and bolting machines combined	James M. Clark	Lancaster, Pa	Jan. 1, "
Grinding, steaming grain preparatory to	Benj. F. Broomell, ass'or to Israel Jackson	London Grove, Pa	May 14, "
Gudgeons, wing	Mark Wilder	Princeton, Mass	April 9, "
Horse powers	James L. Carthcart	Washington, D. C.	July 16, "
Mills for grinding	Chas. W. Brown	Boston, Mass	Jan. 15, "
Mills for grinding	Joseph W. Webb, ass'or to Benj. Gould	Auburn, N. Y.	Jan. 29, "
Mills for grinding	J. R. Stafford	Cleveland, O	June 18, "
Mills for grinding	Willis P. Coleman	New Orleans, La	Oct. 1, "
Mills for grinding	John Rogers, Jr	Jackson, Mich	Dec. 17, "
Mills for grinding	Joseph N. Walker	Cincinnati, O	Dec. 24, "
Mills for grinding and crushing	William Frost	New York, N. Y	
Motion, &c.—see "Reciprocating" &c.			
Oil cans	David G. Starkey	New York, N. Y	April 9, "
Paint mills	Wm. W. Draper	Greenfield, Mass	
Riciprocating motions, changing into a rotary motion	Peter Yates	Milwaukie, Wis	Apr. 23, "
Reciprocating motion, changing rotary motion into	Isaac D. Garlick	Lyons, N. Y	Aug. 20, "
Registers for machinery, hydraulic*	Leman B. Pitcher	Syracuse, N. Y	April 9, "
Rubbing surfaces for regulating abrasion, form of†	Christian Schiele	Frankfort, Germany	May 21, "
Smut machines	Joseph G. Goshon	Sherleysburg, Pa	Jan. 8, "
Smut machines	Leonard Smith	Troy, N. Y	Feb. 12, "
Smut machines	David Ulam	Mt. Pleasant, Pa	Apr. 23, "
Smut machines	Cyrus D. Gordon and Samuel S. Goldthrite	W Martinsburg, NY. Lowville, N. Y	May 28, "
Smut machines, the rubbers of	Franklin Wright	Indianapolis, Ind	Apr. 30, "
Sugar, machines for pulverizing	Oliver R. Chase, ass'or to Silas E. Chase and O. R. Chase	Boston, Mass	Oct. 15, "

* Antedated Mar. 13, 1850.

† In England, Nov. 23, 1848.

CLASS XIV.—LUMBER, *including Machines and Tools for Preparing and Manufacturing; such as Sawing, Planing, Mortising, Shingle and Stave, Carpenters and Coopers' Implements.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Augers attaching to their handles	John E. Larkin	Ballston Spa, N. Y	Nov. 19, 1850
Augur handle	Augustus Thayer	Malden Bridge, N.Y.	Dec. 3, "
Barrel machinery	Solomon Andrews	Perth Amboy, N. J	Feb. 12, "
Bench hooks	W. B. Kean	Worcester, Mass	Aug. 13, "
Bitts, expansible	Clinton L. Adancourt	Troy, N. Y	Aug. 27, "
Boards, apparatus for jointing	David Foster	Whitestown, N. Y	May 28, "
Boring instruments, connecting cutters to shafts of	Lewis W. Miller	Mesopotamia, O	Jan. 8, "
Boring machines	Andrew Weikart	Greenford, O	Jan. 15, "
Boring machines, augers for	George Flautt	Cave Town, Md	Feb. 12, "
Branding tool	Lewis Stark	Chicopee, Mass	Jan. 1, "
Chucks for boring and mortising machines	Eli K. Wisell	Warren, O	Jan. 22, "
Clothes pins, machines for slitting—see class XVII.			

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Dividers or compasses—see class XIV.			
Irregular forms, machines for dressing	Alanson Cary	Worcester, Mass	Nov. 5, 1850
Irregular forms, mackines for turning	Smith Beers	Naugatuck, Conn	Dec. 3, "
Irregular forms, mills for sawing	Oliver Wright	Rochester, N. Y	Jan. 8, "
Lath cutting machines	Wm. Bullock, ass'or to Chas. Graff	Philadelphia, Pa	July 9, "
Lathes, for turning	J. D. White	Hartford, Conn	May 21, "
Mortises, machines for boring dove tailed	Henry T. Betjeman	Cincinnati, O	Dec. 3, "
Mortising machines	Smith Spencer	Angelica, N. Y	Sept. 10, "
Pill boxes, machinery for making	Asa Fessenden	Templeton, Mass	Mar. 12, "
Pill boxes, machinery for making	Nelson D. White	Winchenton, Mass	Dec. 10, "
Planes for tonguing and grooving boards, &c	James A. Woodbury	Boston, Mass	June 11, "
Planing machines	Nicholas G. Norcross	Lowell, Mass	Feb. 12, "
Planing machines	J. F. Ostrander	New York, N. Y	Sept. 3, "
Planing machines	Dan'l H. Southworth	New York, N. Y	Dec. 10, "
Planing machines, arrangement of pressure and feed rollers in	Chas. A. Spring and Peter Boon	Kensington, Pa	July 30, "
Planing machines, cutters for	Enos G. Allen & Charles H. Briggs	Boston, Mass. New Bedford, Mass.	Nov. 26, "
Planing machines, means for preventing back lash in the feed motion of	Thos. H. Burridge	Jersey City, N. J	Dec. 24, "
Planing ornamental mouldings, machines for—see class XVIII., "Mouldings," &c.			
Planing slats for blinds, machinery for	Geo. Boormill	Frederick, Del	Mar. 5, "
Saw gate	Oliver B. Judd	Rockton, N. Y	Oct. 1, "
Sawing with circular, saw mills for	Orlando Child	Granville, Ill	Dec. 17, "
Saw mills	Wartman Davis	Near Granville, Va	April 2, "
Saw mills, apparatus for setting logs in	Thos. C. Theaker	Mansfield, O	May 21, "
Saw mills, circular	Nicholas G. Norcross	Lowell, Mass	Jan. 15, "
Saw mills, noddle irons for	Gideon Hotchkiss	Windsor, N. Y	Mar. 12, "
Saws	Hazard Knowles	Washington, D. C.	Aug. 27, "
Saws, hanging in saw mills	E. H. & S. E. Parsons	Wilkesbarre, Pa	Apr. 30, "
Scrapers used by cabinet makers	Hiram Carver	Edinburgh, Va	Aug. 6, "
Scribing lumber, machines for	John Shellenberger	Indianapolis, Ind	Sept. 10, "
Shingles, machines for cutting	Wm. Wood	Westport, Conn	Jan. 8, "
Shingles, machinery for dressing	Augustus Welch & Robt. Walker	Bennington, Ind	Jan. 8, "
Slats, boards, &c., apparatus for jointing	Alanson Blanchard	W.Cambridge, Mass.	May 28, "
Splint machines	Horace Patterson	Baldwinsville, Mass.	May 14, "
Spokes, machines for dressing	Orville Mather	Cincinnati, O	Dec. 3, "
Staves, machinery for sawing	Edwin Jenney	New Bedford, Mass.	May 21, "
Staves, machinery for cutting	Chas. B. Hutchinson	Waterloo, N. Y	Feb. 5, "
Staves, machines for dressing	Lewis S. Chicester	Troy, N. Y	Sept. 3, "
Tenon bitts	Eli K. Wisell	Warren, O	Aug. 6, "
Tenoning machines	E. M. Shaw	Baltimore, Md	Aug. 6, "
Tonguing and grooving, machinery for	Robert Kittle	Dansville, N. Y	Jan. 15, "
Tools for preparing hubs for boxes	Sam'l Fahrney, ass'or to A. & J. Fahrney	Near Boonsboro, Md.	Mar. 19, "
Umbrella sticks, &c., machines for turning	Solomon West and Hiram Plumb	Honesdale, Pa	Feb. 12, "
Veneers, &c., machines for cutting	Conrad Poppenhusen	New York, N. Y	July 16, "
Wooden bowls, machinery for turning out	Addison Everett	Middlefield, Mass	July 30, "
Wood, machines for sawing	Spencer Lewis	Tiffin, Ohio	May 21, "

CLASS XV.—STONE AND CLAY MANUFACTURES, *including Machines for Pottery, Glass making, Brick making, Dressing and Preparing Stone, Cements, and other Building Materials.*

INVENTIONS OR DICOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Brick machines, preparing clay for	Charles M. Ferris and Nathan Swan	New Milford, Conn. Patterson, N. Y.	April 16, 1850
Brick presses	Charles Carnell	Kensington, Pa.	Jan. 15, "
Brick presses	John Butler	Buffalo, N. Y.	Jan. 29, "
Brick presses	Collins B. Baker	Troy, N. Y.	Mar. 26, "
Brick presses	Nathan Sawyer	Baltimore, Md.	Apr. 23, "
Brick presses	Shepherd Whitman	New Albany, Ind.	Apr. 23, "
Brick presses	John W. Hope	New York, N. Y.	June 4, "
Brick presses	Thomas Culbertson and Geo. Scott	Philadelphia, Pa.	June 25, "
Kilns, lime	Wm. McCoy	Farnettsburg, Pa.	Nov. 5, "
Marble, machines for sawing	A. H. Tingley, ass'or to E. W. H. F. and A. H. Tingley	Providence, R. I.	Mar. 19, "
Slates, machines for holding and dressing	Samuel E. Crocker	Boston, Mass.	Apr. 30, "
Stone, machines for dressing	Robert Eastman	Concord, N. H.	June 18, "
Stone, machines for polishing	Ames Walter	Middletown, Ind.	May 7, "
Stone, rubbing and polishing	Adrian Olcott	Milistone, N. J.	July 30, "

CLASS XVI.—LEATHER, *including Tanning and Dressing, Manufacture of Boots, Shoes, Saddlery and Harness.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Boot trees	Wm. Upfield	Lancaster, Pa.	June 25, 1850
Buckles	Geo. R. Kelsey	Middletown, Conn.	Jan. 15, "
Buckles for harness	Solon Bingham, jr.	Poestenkill, N. Y.	Dec. 10, "
Buckles, harness	Jacob S. Embich	Green village, Pa.	May 21, "
Buckles, machinery for making four-sided	Alvin & Oliver B. North, and Stephen Frink	New Britain, Conn.	May 28, "
Harness, &c., rings for	Andrew Dietz	New York, N. Y.	Apr. 9, "
Harness, breast plate for	Orrin Ramsdell, ass'or to Joseph B. Sawyer and Sylvanus Sawyer	Westfield, Vt. Mouson, Mass. Templeton, Mass.	Feb. 19, "
Harness, hames	Andrew Dietz	New York, N. Y.	Apr. 2, "
Harness, hames	John Low	New Britain, Conn.	Apr. 9, "
Harness, hames, fastenings for	Timothy Taylor, ass'or to Mortimer Taylor	Purcell's store, Va. Govanstown, Md.	Jan. 15, "
Hide handling cylinders, beaters in	James R. Janis	Easton, Pa.	Mar. 19, "
Hides, machines for breaking	Charles Buchanan	North Whitehall, Pa.	Apr. 16, "
Leather, apparatus for splitting and stretching	Bradford Rowe	Albany, N. Y.	Apr. 30, "
Leather, machine for cutting in hollow-ware forms	Francis Durant and Onesiphore Pecqueur, ass'r to Richard E. Rubeau	Paris, France. Philadelphia, Pa.	June 18, "
Morocco, machines for finishing	Edward Bookhout and Henry Cochen, jr.	Williamsburg, N. Y.	June 11, "
Pegging jacks	Jacob Jenkins	Andover, Mass.	Oct. 15, "
Saddles, harness	Robert Spencer	Brooklyn, N. Y.	Aug. 6, "
Saddles, spring	Geo. Fisher	Raleigh, N. C.	July 16, "
Shoes, over	Peter Dorn	Philadelphia, Pa.	May 7, "
Stirrups, safety	Nathan Post	East Cleveland, O.	June 18, "
Tanning apparatus	Wm. H. Rosensteel	New Oxford, Pa.	Feb. 12, "
Terrets, fastening in saddle harness	Peter B. Cool	Columbus, O.	Mar. 12, "
Vats for tanning hides	Lewis C. England	Williamsburgh, N. Y.	Dec. 24, "

CLASS XVII.—HOUSEHOLD FURNITURE, *Machines and Implements for Domestic Purposes, including Washing Machines, Bread and Cracker Machines, Feather Dressing, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Annunciator, or bell telegraph	John Garvey	New York, N. Y.	Nov. 19, 1850
Bedstead fastenings	Matthew Elder	Mansfield, O.	Jan. 22, "
Bedstead fastenings	Robert R[illegible]sey	W[illegible]ington, Pa.	Feb. 19, "
Bedstead fastenings	Ch[illegible] Coolidge, ass'r to F[illegible] Harrington and C. C. Coolidge	Boston, Mass.	May 7, "
Bedstead fastenings	Charles H. Parker	New Geneva, Pa.	June 11, "
Bedstead fastenings	John Morrison	McArthurstown, O.	Oct. 29, "
Bedsteads	Will[illegible] Zaizer	Cincinnati, O.	Nov. 19, "
Bedsteads and sacking bottoms, portable	Samuel Whitmarsh	Northampton, Mass.	Oct. 8, "
Bedsteads, camp	Wm. C. Shaw James Stakeup	Philadelphia, Pa. Wilmington, Del.	Sept. 10, "
Bedsteads, folding	John Binder	Chelsea, Mass.	Jan. 15, "
Bedsteads, invalid	Alexander W. Bartrer	Suffolk co., Mass.	Mar. 5, "
Bedsteads, machinery for cutting screws on the rails of	Spencer Lewis	Tiffon, O.	Apr. 9, "
Bedclothes clasps	Francis A. Rockwell	Ridgefield, Conn.	Feb. 12, "
Beef, dried, apparatus for cutting	Daniel W. Goble, ass'or to G. S. Ward and G. F. Musselman	Newark, N. J.	July 9, "
Beefsteaks, preparing for cooking	Thomas G. Stagg	New York, N. Y.	Oct. 22, "
Bread, portable soup, preparation of	Gail Borden, jr.	Elizabethport, N. J.	July 30, "
Bureau drawers, fastenings for	Geo. W[illegible]	Galveston, Texas	Feb. 5, "
Casters for furniture	Solomon [illegible] Sillman	New York, N. Y.	Feb. 12, "
Chairs, exercising—see class XX, "Exercising chairs."			
Chairs, nursery	Samuel S. May	Sterling, Mass.	June 4, "
Clothes frames	Humphrey Kempton	Fairhaven, Mass.	Feb. 26, "
Clothes pins, machine for slitting	Oratia P. Allen	Rindge, N. H.	May 14, "
Coffee, apparatus for making	Nathaniel Waterman	Suffolk co. Mass.	Feb. 19, "
Coffee roasting	W. H. Trissler and Elias Brecht	Fairhaven, Mass.	Feb. 26, "
Comfits, kettle for manufacturing	Wm. Holt	Hartford, Conn.	Oct. 8, "
Crackers, machines for cutting	Wm. R. Nevins	New York, N. Y.	Aug. 20, "
Cream, process of preparing—see class I.			
Curtains, window, adjustable rollers for	Edward S. Clark	Suffolk co., Mass.	Feb. 19, "
Dough, method of kneading	Henry N. Rider	Adams, Mass.	Feb. 19, "
Fly-brushes	Samuel R. Wilmott	Lafayette, Ind.	Nov. 5, "
Fulling mills—see class III.			
Knives, spiral, machines for grinding—see class II.			
Mattresses, spring	John V. McElwee	Philadelphia, Pa.	April 2, "
Mattresses, spring	Wm. F. Ressegine	Cincinnati, O.	June 11, "
Meat cutting apparatus	John G. Perry	South Kingston, R.I.	Feb. 26, "
Meat, process for curing—see class IV.			
Quilting frames	Wm. T. Barnes	Buffalo, N. Y.	May 28, "
Quilting frames	Charles H. Cook	Coeyman's hollow, N. Y.	July 9, "
Refrigerators	Ephraim Larrabee	Baltimore, Md.	Feb. 26, "
Rule and socket joint	Charles Chinnock	New York, N. Y.	Feb. 12, "
Sad irons, furnaces for heating—see class V. "Furnaces."			
Sausage stuffers	Simon McNair	Hatborough, Pa.	Nov. 26, "
Sofa bedsteads	Edwin B. Bowditch	New Haven, Conn.	Feb. 26, "
Sofa bedsteads	A. G. Warren	Norwich, Conn.	May 21, "
Sofa bedsteads	Russell Scarrett	St. Louis, Mo.	Oct. 8, "
Stands, the construction of bases for	Ezra Ripley	Troy, N. Y.	Apr. 16, "

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Table furniture, machines for washing	Joel Houghton	Ogden, N. Y.	May 14, 1850
Tables, self-waiting	Josiah Lamb	New London, Ind.	Jan. 29, "
Tables, extension	Edwin F. Shoenberger	Pittsburg, Pa.	Nov. 19, "
Washing machines	Ransom Mareau	Lawrenceville, Pa.	Jan. 1, "
Washing machines	Joel Haines	West Middleburg, O	Feb. 5, "
Washing machines	Richard A. Fisher	Sunbury, Pa.	Nov. 5, "
Wash mixtures*	Stephen Crane	Charleston, S. C.	Jan. 29, "

* Antedated, Jan. 19, 1850.

CLASS XVIII.—ARTS, POLITE, FINE, AND ORNAMENTAL, *including Music, Painting, Sculpture, Engraving, Books, Printing, Binding, Jewelry, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Burning ornamental figures upon wood	Hamilton Wood	New York, N. Y.	Feb. 19, 1850
Copying presses, damping paper for	Geo. Burnham	Philadelphia, Pa.	Dec. 24, "
Daguerreotype pictures, cases for	Am F. Stiles	Southbury, Conn.	Jan. 22, "
Daguerreotype plate holders	Geo. Mallory	New York, N. Y.	Sep. 17, "
Daguerreotype plates, holding	Samuel Peck	New Haven, Conn.	April 30, "
Electrotyping	Geo. Mathiot	Washington, D. C.	Dec. 10, "
Figures, cutting in relief on wood	John T. Bruen	New York, N. Y.	Mar. 12, "
Files for keeping papers	Edwin D. Dodd	Cincinnati, O.	Jan. 15, "
Guitar heads and caps d'astra	James Ashborn	Walcottville, Conn.	April 16, "
Lozenges, machines for cutting	John W. Pepper	Salem, Mass.	July 2, "
Melodeon	Amos L. Swan	Cherry valley, N. Y.	May 7, "
Mouldings, machines for planing ornamental	John B. H. Chatain	New York, N. Y.	Mar. 19, "
Musical instruments, reed	Charles Austen	Concord, N. H.	April 30, "
Musical instruments, reed	James P. Sleeper	Worcester, Mass.	Oct. 29, "
Musical scales, mode of representing	W. B. Billings	Eastport, Me.	Sep. 10, "
Ornamenting textile fabrics*	Robert Milligan	Harden, Eng.	Aug. 13, "
Paper filers	William A. Collard	Cincinnati, O.	Sept. 17, "
Paper, machines for folding	Geo. R. Snow	Boston, Mass.	Oct. 15, "
Pen and pencil cases	Albert G. Bagley	New York, N. Y.	Jan. 1, "
Pens, fountain	Charles W. Krebs	Baltimore, Md.	Nov. 26, "
Pens, fountain	Ellsworth H. Hyde and Rollin L. Dawson	Haydenville, Mass.	Nov. 26, "
Pentagraphs	Allen Judd	Chicopee	Aug. 13, "
Photographic pictures, coloring	Aaron O. Dayton	Washington, D. C.	Mar. 12, "
Photographic pictures, producing upon transparent media	William B. Jones	Boston, Mass.	June 25, "
Photographic pictures on glass, &c	Frederick Langenheim	Philadelphia, Pa.	Nov. 19, "
Piano forte action	John Buck	New York, N. Y.	April 16, "
Piano fortes	James Poisson	New York, N. Y.	Aug. 13, "
Piano fortes	John Buck	New York, N. Y.	April 23, "
Piano fortes, upright	Lemuel Gilbert	Boston, Mass.	June 18, "
Pianos, sounding boards for	Conrad Meyer	Philadelphia, Pa.	July 9, "
Portfolios	James Shaw	Providence, R. I.	Dec. 24, "
Printing†	Bartholomew Beniowski, (Polish refugee)	London, Eng.	Oct. 29, "
Printing calico, mode of cleansing and drying gum elastic bands in	James Hunter, ass'or to Jeremiah Knight	Blockley, Pa. / Providence, R. I.	Aug. 27, "

* In England, March 8, 1850. † In England, Nov. 17, 1846.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Printing floor oil cloths*	Nathaniel B. Powers	Lansingburg, N. Y.	Mar. 26, 1850
Printing floor oil cloth	Leveret Moore	Balston, Spa, N. Y.	Mar. 26, "
Printing machines	Oliver T. Eddy	Baltimore Md.	Nov. 12, "
Printing presses	Charles W. Hawkes	Boston, Mass.	Dec. 24, "
Printing presses	Geo. P. Gordon	New York, N. Y.	Mar. 26, "
Printing presses	Frederick J. Austin	New York, N. Y.	May 7, "
Printing presses	Charles W. Hawkes	Boston, Mass.	June 4, "
Printing presses and paper machines, apparatus for receiving and transferring to the pile sheets of paper from	Isaac Adams	Boston, Mass.	Mar. 26, "
Printing presses, copper and steel plate	Elijah C. Middleton, Ed. Nevers, & Rob't Neale	Cincinnati, O. / Mount Carmell, O.	Nov. 19, "
Printing presses, cylinder†	Bartholomew Beniowski	London, Eng.	Aug. 13, "
Rule and socket joint—see class XVII.			
Seraphines	Rufus H. Green	Poultney, Vt.	Feb. 19, "
Stereotype plates, casting	Jason M. Mahan	Philadelphia, Pa.	Sept. 24, "
Studs for shirt bosoms	James P. Heiss	Philadelphia, Pa.	Feb. 12, "
Type cases, printers'	John Bell	Harlem, N. Y.	Jan. 8, "
Types, metallic, engraved plate &c., preparing the face of	Luke Vander Veer Newton	New York, N. Y.	Aug. 20, "
Writing and drawing, clamps for holding paper in	Eliakim B. Forbush	Buffalo, N. Y.	Sept. 3, "

* Antedated Sept. 26, 1849. † In England, Oct. 14, 1847.

CLASS XIX.—FIRE-ARMS *and Implements of War, and parts thereof, including the Manufacture of Shot and Gunpowder.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Barrels for fire arms, method of making	Jesse Pannabecker	Elizabeth towns'p Pa	Aug. 6, 1850
Breech pin, piston, devices for moving and holding	Wm. W. Marston	New York, N. Y.	June 18, "
Cartridges, winged metallic	Alonzo D. Perry	New York, N. Y.	Mar. 5, "
Caps, percussion, machine for forming and charging	Geo. Wright	Washington, D. C.	Sept. 24, "
Chargers attached to fire arms	Orville B. Percival, and Asa Smith	East Haddam, Conn / New York, N. Y.	July 9, "
Fire arms, repeating	Samuel Colt	Hartford, Conn.	Sept. 3, "
Fire arms, revolving hammer	Geo. Leonard, jr.	Shrewsbury, Mass.	July 9, "
Gun, percussion, method of preventing accidental discharge in the	John Warflein	Philadelphia, Pa.	April 30, "
Lock for fire arms	Nathan B. Cook	Chicago, Ill.	Aug. 27, "
Lock for fire arms, toothed segment	Dexter H. Chamberlain	Boston, Mass.	May 14, "
Locking, apparatus, the repeating fire arms	Joshua Stevens	Chicopee, Mass.	Nov. 26, "
Revolving breech fire arms	Hans Iverson	New York, N. Y.	Mar. 26, "
Revolving chambered fire arms	Samuel Colt	Hartford, Conn.	Sept. 10, "
Revolving fire arms, method of attaching cylinder in	Dexter H. Chamberlain, ass'nor to Thomas J. Whittemore	Boston, Mass. / Cambridge, Mass.	April 23, "
Rifles, machinery for giving increased twist in cutting	Edwin Williams and Jas. Culbertson	Kenton co., Ky.	Mar. 12, "

CLASS XX.—SURGICAL AND MEDICAL INSTRUMENTS, *including Trusses, Dental Instruments, Bathing Apparatus, &c.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Chairs and supporters, obstetric	Asa Blood	Jarnesville, Wis	Aug. 27, 1850
Dental and surgical chairs	Flavius Searle	Springfield, Mass	Mar. 25, "
Dentists' chairs	Abraham M. Asay	Philadelphia, Pa	April 23, "
Exercising chairs	Solomon Chapin	Ashland, O	Mar. 26, "
Horses, flying	Eliphalet S. Scripture	Greenspoint, N. Y	June 4, "
Leeches, mechanical	Marcellin Dellac	New York, N. Y	May 7, "
Legs, artificial	George W. Yerger	Philadelphia, Pa	Mar. 19, "
Legs, artificial	W. C. Stone	Boston, Mass	Dec. 17, "
Paring horses' hoofs, instruments for—see class XXII., "Horses' hoofs, &c."			
Pessaries	Jonathan M. Robinson	Charlestown, Mass	Nov. 19, "
Plasters, gauges for spreading	James M. Keep	Bath, Me	April 30, "
Respiring apparatus	Benj. J. Lane	Cambridge, Mass	July 2, "
Splints for fractures	Adam Hays	Madison, Ind	Aug. 13, "
Splints for surgeons	Benj. Welch	Larksville, Conn	Sept. 3, "
Supporters, abdominal	Samuel S. Fitch	New York, N. Y	Mar. 19, "
Supporters, obstetrical	Wm. W. Finch, Jacob Blaisdell and Leander Babbit	Essex co., N. Y	June 15, "
Supporters, obstetrical	Mary W. O'Meara	New York, N. Y	Mar. 12, "
Supporters, obstetrical	F. H. Chase	Clintonville, N. Y	Aug. 20, "
Supporters, utero vaginal	Russel Caulkens	Sandusky city, O	June 29, "
Teeth, setting artificial by atmospheric pressure	John A. Cleveland	Charleston, S. C	June 25, "
Truss pads	Frederick M. Butler	New York, N. Y	July 22, "
Trusses for hernia	Wm. R. Battle	Powelton, Ga	Jan. 22, "
Vaccinating, instruments for	Junius F. Tozer	Rochester, N. Y	Aug. 13, "
Vaccinating, instruments for	Henry Mellish	Walpole, N. H	Dec. 24, "

CLASS XXI.—WEARING APPAREL, *Articles for the Toilet, &c., including Instruments for Manufacturing.*

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Buckles, suspender	Wm. Scarlett	Newark, N. J	May 14, 1850
Buckles, suspender	Chas. Benedict, ass'or to Hotchkiss & Merriman Manufacturing Co	Waterbury, Conn	Oct. 22, "
Buckles, suspender	Elisha Steele	Waterbury, Conn	Dec. 3, "
Buttons, process of varnishing	Elisha M. Pomeroy	Wallingford, Conn	Feb. 19, "
Cap fronts, machines for cutting	Geo. Burgess	New York, N. Y	Feb. 26, "
Hat bodies, machines for making	Edw'd F. Condit, and Alfred Taylor, ass'or to W. Eaglesford	Springfield, N. J	Mar. 19, "
Hats, machinery for pressing	Bennett Potter, Jr	Templeton, Mass	Oct. 29, "
Hooks and eyes, attaching to paper cards	Peter Kirkham	Waterbury, Conn	July 30, "
Hooks and eyes, fastening upon cards, mode of	Ezra J. Warner	Waterbury, Conn	Nov. 5, "
Shirt studs and buttons	Benton P. Coston	Philadelphia, Pa	Aug. 27, "
Stays, ladies'	Louisa Baylis	Orriskany, N. Y	Sep. 10, "
Tailors' measures	Amos Stocker	Ogdensburg, N. Y	May 28, "
Tailors' measures	William W. Allen	Bordentown, N. J	Sep. 16, "

CLASS XXII.—MISCELLANEOUS.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Axes and hoes, application of electro chemical printing in colors to taking	Albert N. Henderson	Buffalo, N. Y	[illegible], 1850
Ballot boxes	Joseph A. [illegible], [illegible] to John P. [illegible] and Abner Hold[illegible]	Bloomington, Ind.; Helonsville, Ind.; Greensburg, Ind	Aug. [illegible], "
Branding tools—see class XIV.			
Embroidery [illegible] clamps for grinding	Henry S. Vrooman	Springfield, Mass	Nov. 5, "
Fire, apparatus for extinguishing—see class [illegible]			
Grapple, spring	Orra Warner and Chas. S. Gaylord	Gaylord's Bridge, Ct	Oct. 5, "
Harpoon, gun	Robt. Brown	New London, Conn	Aug. 20, "
Harpoon, gun	William Allerson	New London, Conn	Nov. 19, "
Harpoon and lances, gun	Robt. Brown	New London, Conn	Aug. 20, "
Harpoons, method of attaching lines to	Chas. F. Brown	Warren, R. I	Sep. 3, "
Horses, apparatus for breaking	Seymour Tomlinson	Washingt'n Hollow, N. Y	Sep. [illegible], "
Horses' hoofs, instruments for paring	Ashley Crafts and Ebenezer Weeks	Auburn, O	Jan. [illegible], "
Ice, scraper for removing snow from	Nathaniel J. Wyeth	Cambridge, Mass	[illegible], "
Locking portable safes to the floor	Henry Hotchsasser	Philadelphia, Pa	Feb. [illegible], "
Privies, apparatus for emptying	Florimond Da[illegible]by	New York, N. Y	Dec. 17, "
Stanchions for cattle	Geo. W. Hatch	Parkman, O	July 20, "
Store counters	Evan O. Thomas	Philadelphia, Pa	July 9, "
Tobacco, method of dressing cut	Gideon Wales	Liberty, N. Y	Mar. 26, "
Tobacco stems, curing	Thos. Hoyt	New York, N. Y	Jan. 8, "
Trap for catching flies	Joel B. Fuller and Geo. W. Pierce	Worcester, Mass	April 16, "
Trunks, arrangement of mirrors in	James Stevens	Middletown, Md	June 11, "
Wedges, &c., bevelling the surface of	William Field	Providence, R. I	Sep. 3, "
Whip lashes	David N. and Edward B. Day	Westfield, Mass	Feb. 5, "
Whips, raw hide, machines for polishing	Chas. Baeder	New York, N. Y	May 21, "
Whips, raw hide, manufacture of	Thos. J. Ba[illegible]	Lowell, Mass	Aug. 16, "

PATENTS RE-ISSUED DURING THE YEAR 1850.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	RE-ISSUED.
Ball, loaded	Walter Hunt, ass'or to Geo. A. Arrowsmith	New York, N. Y.	Aug. 10, 1848	Feb. 26, 1850
Brick presses	Isaac Gregg	Philadelphia, Pa.	June 6, 1848	Sept. 17, "
Bridges and other structures, constructing, the truss frames of	William Howl	Springfield, Mass	Aug. 3, 1840	Sept. 3, "
Carding and spinning machines	Moses Chase, of whose patent George Law, deceased, is assignee, of whom R. S. S. Stewart is executor	Baltimore, Md.	Mar. 23, 1842	Jan. 1, "
Cartridge, method of attaching	Walter Hunt, ass'or to W. R. Palmer	New York, N. Y.	Aug. 10, 1848	Feb. 26, "
Carriages, railroad, manner of constructing so as to ease the lateral motion of the bodies thereof	Chas. Davenport and Albert Bridges	Cambridgeport, Mass.	May 4, 1841	Dec. 3, "
Churns	Z. C. Robbins	St. Louis, Mo.	June 1, 1849	Jan. 1, "
Curry combs	William Beach	Philadelphia, Pa.	Mar. 13, 1849	Feb. 12, "
Distilling apparatus	Chas. A. Krechler	Stockholm, Sweden	July 10, 1849	Feb. 26, "
Door knobs, shanks for	L. R. Livingston, J. J. Roggen and C. Adams	Pittsburg, Pa.	July 7, 1846	Oct. 1, "
Fire arms, concealed trigger for	Jacob Pecare and Josiah M. Smith	New York, N. Y.	Dec. 4, 1849	Aug. 13, "
Furnaces, portable	Merritt F. Potter	Charlemont, Mass.	Jan. 22, 1850	Oct. 22, "
Harvesters of clover heads and other grain	John Hinton	Packs Ferry, Va.	May 22, 1849	Aug. 13, "
Irregular forms, machinery for turning	Timothy Clark	New Haven, Conn.	Jan. 19, 1847	Nov. 12, "
Lard and tallow, machines for rendering	Ebenezer Wilson	Cincinnati, O.	Oct. 9, 1844	May 7, "
Leather, cutting and stretching	Bradford Rowe	Albany, N. Y.	Apr. 30, 1850	
Mills for grinding	Sidney A. Bantz and Wm. Andrews	Frederick, Md.	Dec. 4, 1849	Oct. 15, "
Paper, machines for boiling and washing rags for manufacturing	Geo. Spafford, ass'or to John Campbell	New York, N. Y.	Sept. 2, 1840	June 11, "
Planing machines	Calvin Emmons, Wm. Emmons administrator of	New York, N. Y.	June 27, 1848	May 21, "
Printing presses	Stephen P. Ruggles	Boston, Mass.	Nov. 10, 1840	Sept. 17, "
Pumps	Birdsill Holly	Seneca Falls, N. Y.	June 5, 1849	May 7, "
Screw machines, feeders for	Solyman Merrick	Springfield, Mass.	Mar. 7, 1846	May 7, "
Screws, wood, machine for cutting the threads of	Cullen Whipple, ass'or to A. Hodges, agent of the New England Screw Company	Providence, R. I.	Aug. 18, 1842	Mar. 5, "
Stoves, coal	Anson Atwood	Troy, N. Y.	May 14, 1850	Sep. 7, "
Stoves, cooking	James Root	Cincinnati, O.	July 18, 1848	Jan. 22, "
Stoves, cooking	Jordan L. Mott	New York, N. Y.	Aug. 22, 1848	April 30, "
Stoves, cooking	Darius Buck, deceased, Desire Buck, administrator of	Albany, N. Y.	May 20, 1839	Aug. 30, "

CLASSIFIED LIST OF PATENTS—CONTINUED.

DESIGNS.

DESIGNS.	PATENTEES.	RESIDENCE.	DATE OF PATENT.
Bas relief of Henry Clay	C. Y. Haynes	Philadelphia, Pa.	Nov. 12, 1850
Blower stand	Walter Bryent	Boston, Mass.	Sep. 24, "
Bracket, cast iron	Walter Bryent	Boston, Mass.	Aug. 13, "

PATENTS EXTENDED DURING THE YEAR 1850.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF ORIGINAL PATENT.	EXPIRATION.	TERM OF EXTENSION.
Caoutchouc, application to cloths	Edwin N. Chaffee	New Brunswick, N. J.	Aug. 31, 1836	Aug. 31, 1850	Seven years from Aug. 31. 1850
Dye woods and dye stuffs, machine for cutting and shaving	Bereah Swift	Washington, N. Y.	Aug. 10, 1836	Aug. 10, "	Seven years from Aug. 10,
Friction matches	Eulia T. Swift, adm'r of A. D. Phillips	Charlestown, Mass.	Oct. 24, 1836	Oct. 24, "	Seven years from Oct. 24, "
Printing presses	Isaac Adams	Boston, Mass.	Mar. 2, 1836	Mar. 2, "	Seven years from Mar. 2, "
Turn-about for railroads	Jeremiah Myers	Meredith, N. H.	May 7, 1837	May 8, 1851	Seven years from May 8, 1851
Water wheels, steam engines, &c., the art of regulating the motion of	Nathan Scholfield	Norwich, Conn.	May 17, 1836	May 17, 1850	Seven years from May 7, 1850
Wool, hair, &c., forming web without spinning	John Arnold, Peter U. Morgan, adm'r of, and Geo. G. Bishop	Norwalk, Conn.	Oct. 1836	Oct. 20, "	Seven years from Oct. 20. 1850

ADDITIONAL IMPROVEMENTS GRANTED DURING THE YEAR 1850.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	IMPROVEMENT ADDED.
Freezers, ice cream	H. P. Masser	Sunbury, Pa.	Dec. 12, 1848	Jan. 1, 1850
Stearine from oleine, process of preparing	John H. Smith	Brooklyn, N. Y.	Apr. 1, 1842	April 9, "
Tailors' measures	Amos. Stocker	Ogdensburg, N. Y.	May 28, 1850	Sept. 3, "

DISCLAIMERS ENTERED DURING THE YEAR 1850.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	DISCLAIMER ENTERED.
Frog for railroads	John W. Hoffman, ass'or to Henry A. Landry.	Philadelphia, Pa. Camden, N. J.	Dec. 4, 1849	June 6. 1850
Turn-about for railroads	Jeremiah Myers	Meredith, N. H.	May 8, 1837	April 18. "
Turning wooden bowls, machinery for	Parley Hutchins, Jr., ass'or to A. Everett	Middlefield, Mass.	Sep. 25, 1847	Aug. 21. "

RENEWAL.

INVENTIONS OR DISCOVERIES.	PATENTEES.	RESIDENCE.	DATE OF PATENT.	RENEWED.
Capstans	Andrew Morse, Jr.	Boston, Mass.	Mar. 12, 1836	Jan. 8. 1850

[J.]

ALPHABETICAL LIST OF PATENTEES FOR THE YEAR 1850.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
	Abbott, J. G.—see C. W. Warnick, et al.		
7297	Abendroth, William	Stoves, cooking	V.
	Adams, Isaac	Printing Presses	Extension.
7205	Adams, Isaac	Printing presses and paper machines, apparatus for receiving and transferring to the pile sheets of paper from	XVIII.
7421	Adams, Stephen H. and John A. Wood	Carding and mixing wool and cotton	III.
7485	Adams, Joseph and Levi	Felloes, machines for cutting	XIV.
	Adams, Calvin—see J. R. Livingston, et al.		
7589	Adancourt, Clinton L.	Bits, expansible	XIV.
7012	Adkins, Homer	Mowing machines	I.
7229	Aiken, Herrick	Wheels, wrought iron car, clamp to be used in the manufacture of	X.
7676	Aiken, Herrick	Wheels, wrought iron car	X.
7777	Albertson, William	Harpoons, gun	XXII.
7609	Alexandre, Lambert	Vessels, submarine	VII.
7793	Allen, Enos G. and Charles Briggs	Planing machines, cutters for	XIV.
7097	Allen, John L.	Carriage tops, elevating and lowering	X.
7715	Allen, John L.	Carriage tops, braces for	X.
7355	Allen, Oratio P.	Clothes pins, machines for slitting	XVII.
7641	Allen, William W.	Tailors' measures	XXI.
7817	Allen, William D.	Boiler feeder, balanced	VI.
7502	Aller, Zachariah	Cloth, wide, machinery for double folding	III.
7230	Allison, William C.	Hoisting, machines for	XII.
7501	Altender, Theodore	Compasses for measuring, joints for	VIII.
	Ambrose, Thomas A.—see Billings and Ambrose.		
	Ames, Winslow—see W. B. Gleason.		
7298	Andrews, John	Churns	I.
	Andrews, William—see Sidney A. Bantz and W. Andrews		
7077	Andrews, Solomon	Barrel machinery	XIV.
7449	Andrews, Solomon	Vessels, model for	VII.
7694	Anthony, David, sr.	Forks, hay, shanks of	I.
7767	Antisell, Thomas	Oils, filter for	IV.

	Arnold, John, Peter W. Morgan, adm'r of and Geo. G. Bishop	Wool, hair, &c. forming web without spinning	Extension.
273	Archer, E. S. and R. F. Warner	Chandeliers	Design.
299	Archer, E. S. and R. F. Warner	Lamps	Design.
7643	Armstrong, Samuel T. and Charles J. Gilbert	Gutta percha, process of working	IV.
	Arrowsmith, George A—see Walter Hunt.		
7299	Asay, Abraham M.	Dentists' chairs	XX.
7279	Ashburn, James	Guitar heads and caps d'astra	XVIII.
7179	Ashcroft, Edward H.	Boilers, method of applying fusible metal to	VI.
7522	Ashley, Marcius B.	Water wheels, directing water upon	XI.
	Ashmead, James H—see Vine & Ashmead.		
7356	Atwood, Anson	Stoves	V.
176	Atwood, Anson	Stoves, coal	Re-issue.
7768	Atwood, Charles and George Kellog	Jack chains, machine for making	II.
7317	Austin, Charles	Musical instruments, reed	XVIII.
7335	Austin, Frederick J.	Printing presses	XVIII.
7792	Ayers, Frederick J.	Nail plate, machine for feeding	II.
7064	Babbett, Avery	Spooling, machinery for	III.
7714	Babbett, Avery	Looms for weaving figured goods	III.
	Babbit, Leander—see Finch, Blaisdell & Babbit.		
	Babbit, Leander—see Chase, Weston & Babbit.		
7659	Bachelder, John	Sewing machine	III.
268	Bacon, Lathrop S.	Stoves	Design.
7373	Baeder, Charles	Whips, rawhide, machines for polishing	XXII.
6981	Bagley, Albert G.	Pen and pencil cases	XVIII.
	Bagley Daniel C.—see Carey & Bagley.		
	Bailey James S.—see Charles T. Tuttle.		
7013	Bailey Jesse	Gates for fences	IX.
286	Bailey, Joel C. and Russell Wheeler	Stoves	Design.
	Bailey, Yarnall—see Clayton & Bailey.		
7206	Baker, Collins B.	Brick presses	XV.
7486	Baldwin, Ethan	Condensers of steam engines	VI.
7280	Baldwin, Hiram	Car-couplings	X.
	Baldwin, Hiram—see Morrill & Baldwin.		
7778	Ball, Hosea	Ovens, bake	V.
330	Ballard, William	Railings, iron	Design.
7627	Balis, Louisa	Stays, ladies'	XXI.
180	Bantz, Sidney A. & Wm. Andrews	Mills, for grinding	Re-issue, XIII.
7131	Barker, Alex. W.	Bedsteads, invalid	XVII.
7557	Barlow, Nelson	Clutches, friction	XIII.
7132	Barnard, Wm. B.	Door springs, adjustable cord hook for	II.
7155	Barnard, Wm. B.	Sash stopper, spiral spring	II.
7255	Barnard, Wm. B.	Door springs and levers, arrangement of	II.
7422	Barnes, James	Whiffletrees, connecting with carriages	X.

ALPHABETICAL LIST—Continued.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7342	Barnes, Thomas J.	Whips, raw hide, manufacture of	XXII.
	Barnes, Turner—see Fleicher & Barnes.		
7391	Barnes, William T.	Quilting frames	XVII.
	Barnell, Jean, Joseph, Ernest—see Leclaire & Barnell.		
7469	Barstow, Benjamin	Vessels, method of fitting the bows of	VII.
	Barstow, A. C. & Co.—see Apollos Richmond.		
7716	Bartlett, Daniel, Jr.	Filtering cocks	XI.
278	Bartlett, David L.	Stoves	Design.
7032	Battle, William R.	Trusses for hernia	XX.
7571	Batty, Thomas	Sewing mallets	VII.
7281	Bauchman, Charles	Hides, machines for breaking	XVI.
161	Beach, William	Curry combs	Re-issue.
7695	Beaumont, William D.	Compound for imparting a gloss to cloths	IV.
7231	Beers, Elias T.	Ranges, cooking and heating air	V.
7806	Beers, Smith	Irregular forms, machines for turning	XIV.
	Bell, Alfred—see John Jack.		
7207	Bell, Hugh	Balloons and their appendages	XI.
6994	Bell, John	Type cases, printers'	XVIII.
7726	Benedict, Charles, assignor to Hotchkiss & Merriman, Manufacturing Company	Buckles, suspender	XXI.
7558	Beniowski, Bartholomew	Printing presses, cylinder	XVIII.
7738	Beniowski, Bartholomew	Printing	XVIII.
	Bennett, J. I.—see Benj. Crawford.		
7336	Benton, Ezra R.	Bran dusters	XIII.
7727	Bertholf, Henry W.	Straw cutters, feeding apparatus for	I.
7807	Betjeman, Henry I.	Mortises, machines for boring dove-tailed	XIV.
7374	Bevan, John	Girder, arched	IX.
	Bevington, Henry C.—see Knowles & Bevington.		
	Bickford, John C.—see Hayward & Bickford.		
7660	Bigelow, Erastus B.	Loom for weaving tapestry and Brussels carpets	III.
7450	Billings, A. M. & Thomas A. Ambrose	Hubs and axles, connecting and disconnecting	X.
7256	Billings, Hosea	Composition for covering hams	IV.
7628	Billings, W. B.	Musical scales, mode of representing	XVIII.
7014	Binder, John	Bedsteads, folding	XVII.
7818	Bingham, Solon, Jr.	Buckles for harness	XVI.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7208	Birdseye, Charles D., assignor to Waring Latting	Filters	XI.
7644	Birdseye, Charles D.	Cream, process of preparing	I.
	Bishop, George G.—see Arnold & Bishop.		
7357	Bissell, Levi	Connecting rods of steam engines and other machinery	XIII.
6995	Black, James	Engines, operated by steam, air and water	XI.
7065	Blackman, Samuel G.	Carding machines for preparing bats for felting	III.
	Blaisdell, Jacob—see Finch, Blaisdell & Babbit.		
7645	Blake, William	Spike machines	II.
7392	Blanchard, Alanson	Slats, boards, &c., apparatus for jointing	XIV.
307	Blanchard, Reuben J., ass'or to Billings P. Learned and George H. Thatcher	Stoves	Design.
321	Blanchard, Reuben J., ass'or to B. P. Learned and George H. Thatcher	Stoves	Design.
232	Blanchard, Reuben J., ass'or to B. P. Learned and George H. Thatcher	Stoves	Design.
7015	Bleier, Frederick	Dampers for cleaning stove pipes and regulating the draft in the same	V.
7849	Bless, Eleazer	Fanning mills	I.
7590	Blood, Asa	Chairs and supporters, obstetric	XX.
7337	Bogardus, James	Buildings, iron, construction of the frame, roof and floor of	IX.
7408	Bohrer, Joseph	Blinds, Venetian, suspending	IX.
7133	Bonwill, George	Planing slats for blinds, machinery for	XIV.
7433	Bookhout, Edward & Henry Cochen, Jr.	Morocco, machines for finishing	XVI.
7882	Boon, James	Wheels, cast iron car	X.
	Boon, Peter—see Spring & Boon.		
7661	Booth, James C.	Gold, process of refining	II.
7066	Borden, Gail	Bread, portable soup, preparation of	XVII.
7116	Bowditch, Edwin B.	Sofa bedsteads	XVII.
7677	Bowerman, Stephen	Harvester, cotton stalk	I.
7662	Bowers, Geo. W.	Grain cleaning machine	I.
7717	Boyd, Amos H.	Looms	III.
	Boyes, Burritt C.—see Nichols & Boyes.		
	Brackbill, Wm.—see Sherlock & Brackbill.		
7409	Bradford, Hezekiah and Ephraim Morris	Ventilating railroad cars	V.
7078	Bradshaw, Fields	Cotton stalks, cutting in the field	I.
7850	Bragg, Thomas	Starch from maize, manufacture of	IV.
7503	Bramble, W. W. W. H. T.	Weighing machines, self, for grain, &c.	XII.
	Brecht, Elias—see Trissler & Brecht.		
7404	Breed, Zephaniah	Rakes, hay, spring teeth of	I.
	Bridges, Albert—see Davenport & Bridges.		
	Briggs, Chas.—see Allen & Briggs.		
7358	Broomell, Benj. F.—ass'or to Israel Jackson	Grinding, steaming grain preparatory to	XIII.
7047	Brown, A. D.	Press, cotton	XII.

ALPHABETICAL LIST—CONTINUED.

7318	Brown, A. H.	Pipes and hose, couplings for	XI.
7516	Brown, Charles F.	Steering apparatus	VII.
7610	Brown, Charles F.	Harpoons, method of attaching lines to	XXII.
7115	Brown, Christopher F.	Gas generating apparatus	IV.
7016	Brown, Charles W.	Mills for grinding	XIII.
7663	Brown, David S.	Plants, machines for fumigating	I.
	Brown, Edward R.—see Anthony W. Jones.		
7359	Brown, Hiram C.	Sash, balancing	II.
7435	Brown, James M.	Neck yokes, attaching to poles of carriages	X.
7410	Brown, Robert	Harpoon, gun	XXII.
7572	Brown, Robert	Harpoons and lances, gun	XXII.
285	Brownell, Asa C.	Stoves	Design.
7319	Broyles, Cain	Water, apparatus for drawing	XI.
7156	Bruen, John T.	Figures, cutting in relief on wood	XVIII.
7180	Bryant, Mertoun C.	Looms for weaving piled fabrics	III.
7452	Bryant, Mertoun C.	Looms for weaving cut piled fabrics	III.
287	Bryent, Walter	Umbrella stands	Design.
305	Bryent, Walter	Bracket, cast iron	Design.
314	Bryent, Walter	Blower stand	Design.
174	Buck, Darius, Desire Buck, administratrix of	Stoves, cooking	Re-issue.
7067	Buck, James	Excavating auger	IX.
7470	Buckup, Ernst	Air engines, method of distributing the air over the heating and cooling surfaces of	VI.
7678	Buffum, Arnold and Philip Thorpe	Washing gold, double acting rocker for	II.
7739	Bulkley, Charles S.	Enunciators, electro magnetic, for signals in hotels, &c.	XVII.
7769	Bulkley, Charles S.	Telegraphs, repeaters for electro-magnetic	VIII.
7794	Bulkley, Ralph	Ventilators, ship	V.
	Bullock, Thomas—see Hamilton & Bullock.		
6996	Bullock, William	Drills, grain	I.
7487	Bullock, William, assignor to Charles Graff	Lath cutting machines	XIV.
	Bundy, Jonathan—see White & Bundy.		
7591	Burdett, Stephen	Omnibuses, turning up the steps of	X.
7114	Burgess, George	Cap fronts, machines for cutting	XXI.
7696	Burnham, George	Presses for copying letters	XII.
7851	Burnham, George	Copying presses, damping paper for	XVIII.

7852	Burridge, Thomas H.	Planing machines, means for preventing backlash in the feed motion of	XIV.
	Burt, Enoch	Loom, power	III.
7209	Burton, Russell	Gold washers, method of connecting the sections of	II.
7764	Butcher, John	Cloth, apparatus for stretching and smoothing	III.
7517	Butler, Frederick M.	Truss pads	XX.
7048	Butler, John	Brick presses	XV.
7646	Calvert, Francis A.	Cotton, machinery for ginning or picking	III.
7471	Cameron, Charles C.	Sash stopper	I.
7592	Camp, Harry	Straw, machines for cutting	I.
7033	Camp, Herman	Candle mould apparatus	IV.
	Campbell, John—see George Spafford.		
	Cannon, John R.—see Joseph A. Hill.		
7770	Cannon, Samuel	Planters, seed	I.
7728	Card, Joseph	Presses, cheese	XII.
7079	Carey, Augustus C. and Daniel C. Bagley	Cloth, machinery for folding	III.
7017	Carnell, Charles	Brick presses	XV.
	Carpenter, Jesse—see Cullen Whipple.		
7647	Carpenter, Joseph W.	Preparing wheat for grinding, process for	IV.
7543	Carver, Hiram	Scrapers used by cabinet makers	XIV.
7750	Cary, Alanson	Irregular forms, machines for dressing	XIV.
7779	Case, Jarvis	Bee hives, working the doors of	I.
7338	Cathcart, James L.	Stoves, air-heating	V.
7504	Cathcart, James L.	Horse powers	XIII.
7050	Caulkins, Russell	Supporters, utero vaginal	XX.
	Chadbourne, Thomas—see David M. Smith.		
	Chaffee, Edwin M.	Caoutchouc, application to cloth	Extension.
7257	Chamberlain, Dexter H., assignor to C. W. and S. J. M Horner and W. G. Ladd	Dividers or compasses	VIII.
7300	Chamberlain, Dexter H. assignor to Thomas J. Whittemore	Revolving fire arms, method of attaching cylinder in	XIX.
7360	Chamberlain, Dexter H.	Lock for fire arms, toothed segment	XIX.
7210	Chapin, Solomon	Exercising chairs	XX.
7573	Chase, F. H., Adan Weston and Leander Babbit	Supporters, obstetrical	XX.
7505	Chase, Mark L. assignor to William L. Chase	Ploughs, hill-side	I.
158	Chase, Moses, of whom George Law is assignee, of whom Richard S. Stewart is executor	Carding and spinning machine	Re-issue.
7718	Chase, Silas E. and O. R. Chase, assignees of O. R. Chase	Sugar, machines for pulverizing	XIII.
7518	Chase, William L.	Ploughs, fastening the shoes of hill-side	I.
	Chase, William M.—see Halvor Halvorson.		
7181	Chatain, John B. H.	Mouldings, machines for planing ornamental	XVIII.
7611	Chichester, Lewis S.	Staves, machines for dressing	XIV.
7411	Chilson, Gardner	Grates, fireplace	V.
7436	Chilson, Gardner	Stoves, parlor	V.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7780	Chilson, Gardner	Furnaces, air-heating	V.
7832	Child, Orlando	Sawing with circular saws, mills for	XIV.
7090	Chinnock, Charles	Rule and socket joints	XIV.
7593	Chollar, John B.	Grates, coal, revolving	V.
	Churchill, William A.—see L. E. Hicks.		
7134	Clark, Alinzor	Forks, hay and manure, fastening for	I.
7697	Clark, Alinzor	Forks, hay	I.
7098	Clark, Edward S.	Curtains, window, adjustable rollers for	XVII.
6982	Clark, James M.	Grinding and bolting machines, combined	XIII.
7393	Clark, P. J.	Lamps, metallic, making the reservoirs of	V.
182	Clark, Timothy	Irregular forms, machinery for turning	Re-issue.
7594	Clayton, Sharpless and Yarnall Bailey	Lamps, gas, self-generating	V.
7612	Clemens, S. A.	Pressing cotton and other substances into bales	XII.
7451	Cleveland, John A.	Teeth, setting artificial by atmospheric pressure	XX.
7099	Clinton, Thomas G. George H. and Edward H. Knight	Lids for boiler holes of cooking stoves	V.
7135	Clinton, Thomas G. George H. and Edward H. Knight	Carriage jacks	X.
7595	Clinton, Thomas G. George H. and Edward H. Knight	Stoves, coal, for roasting, baking and broiling	V.
	Clute and Brothers—see William L. Sanderson.		
7719	Coates, William B.	Harvesters, hemp	I.
	Cochen, Henry, jr.—see Bookhout and Cochen.		
	Cole and Mosher—see William L. Sanderson.		
7679	Coleman, Willis P.	Mills for grinding	XIII.
7437	Collier, Elisha H.	Nails, method of making by rolling	II.
7232	Collins, Michael H.	Chimney caps	V.
7361	Collins, Thomas M.	Gold washer, cylinder and trough	II.
7648	Collard, William A.	Paper filers	XVIII.
7629	Colt, Samuel	Revolving chambered fire-arms	XIX.
7613	Colt, Samuel	Fire-arms, repeating	XIX.
7362	Colver, Nathaniel, ass'or to Nath'l Colver and W. S. Damrell	Wrench, revolving jaw	II.
7680	Colvin, Robert J.	Seed planters, slides for	I.
7363	Combs, Abel	Skeins, connecting with axles	X.
7833	Conant, Joseph and Lucius Dimock	Silk, &c., machinery for doubling and twisting	III.
7182	Condit, Edward F. and Alfred Taylor, ass'ors to W. Eaglesfield	Hat bodies, machines for making	XXI.
272	Conklin, James H.	Stoves	Design.
266	Conklin, James H., ass'or to S. B. Sexton & Co.	Stoves	Design.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
302	Conklin, James H. and A. W. Jones, ass'ors to James MacGregor	Stoves	Design.
7488	Cook, Charles H.	Quilting frames	XVII.
7596	Cook, Nathan B.	Lock for fire arms	XIX.
7283	Cook, Ransom	Hydraulic blowers for furnaces, &c.	XI.
7211	Cook, Ransom	Blast pipes for conveying heated air and gases to furnaces	II.
7423	Cook, Ransom	Hydraulic apparatus for producing blast	XI.
7157	Cool, Peter B.	Terrets, fastening of, in harness saddles	XVI.
7339	Coolidge, Chas. C., ass'or to Francis Harrington and Chas. C. Coolidge	Beadstead fastenings	XVII.
7597	Coston, Benton P.	Shirt studs and buttons	XXI.
	Cotter, Thos.—see Chas. A. Read.		
7795	Cowing, Henry	Ploughs, gang	I.
	Cox, A. & Co.—see Joshua Crandall.		
	Cox, D. B.—see J. Crandall.		
6983	Crafts, Ashley and Ebenezer Weeks	Horses' hoofs, instruments for paring	XXII.
6997	Crafts, Ashley and Ebenezer Weeks	Cultivators	I.
279	Crandall, Joshua, ass'or to A. Cox & Co.	Stoves	Design.
297	Crandall, Joshua, ass'or to E. Johnson and D. B. Cox	Stoves	Design.
6984	Crane, Jonathan and F. H. Hamilton	Hemp brakes	III.
7049	Crane, Stephen	Wash mixtures	XVII.
7051	Crawford, Benj., ass'or to Wm. B. English, J. J. Bennett, A. D. Frisbee and B. Crawford	Furnaces, steam boiler	V.
270	Cresson, W. P., David Stuart and P. Seibert, ass'ors to W. P. Cresson	Stoves	Design.
271	Cresson, W. P., David Stuart and P. Seibert, ass'ors to W. P. Cresson	Stoves	Design.
261	Cresson, Wm. P., David Stuart and P. Seibert, ass'ors to W. P. Cresson	Stoves	Design.
262	Cresson, Wm. P., David Stuart and P. Seibert, ass'ors to W. P. Cresson	Stoves	Design.
	Cresson, Wm. P.—see D. Stuart.		
7729	Crocker, Luther H.	Cores for casting, machines for making and holding	II.
7320	Crocker, Samuel E.	Slates, machines for holding and dressing	XV.
	Crossley, John, Joseph and Francis—see James Taylor.		
	Crowell, Sommers—see Krauser, Crowell & Krauser.		
	Culbertson, James—see Williams & Culbertson.		
7453	Culbertson, Thomas and George Scott	Brick presses	XV.
7158	Cunningham, James	Ventilating railroad cars	V.
7730	Cunningham, James	Locomotive engines, apparatus for reversing or stopping	VI.
7614	Current, David	Spinners, hand	III.
7375	Dakin, James H.	Bagasse, machines for drying	V.
7258	Dalton, John E. and Thomas Stevens	Bee hives, entrance to	I.

ALPHABETICAL LIST—Continued.

Number.	Patentees.	Inventions or discoveries.	Class.
	Damrell, W. S.—see Nath'l Colver.		
7649	Danford, Ebenezer	Harvesters, grain	I.
7472	Daniels, Reuben	Straw cutters	I.
7681	Daniels, Reuben	Vegetable cutter	I.
7853	Darling, Jeremiah	Hydraulic blowers	XI.
7834	Datichy, Florimond	Privies, apparatus for emptying	XXII.
183	Davenport, Charles and Albert Bridges	Carriages, railroad, manner of constructing so as to ease the lateral motion of the bodies thereof	Re-issue.
7559	Davis, James G. assignor to A. B. Warner and James G. Davis	Candles, manufacture of	IV.
7233	Davis, Robert W	Churns	I.
7340	Davis, Shadrach	Road scrapers, adjustable mouth piece to	IX.
7234	Davis, Waitman	Saw mills	XIV.
	Davis, William C.—see Lamb & Harris.		
7751	Davis, William H	Pumps, rotary	XI.
7159	Davy, John T	Furnaces for heating sad irons	V.
7284	Davy, John T	Grates for cooking stoves	V.
288	Davy, John T	Stoves, coal	Design.
7068	Day, David N. and Edward B	Whip lashes	XXII.
	Day, Horace H.—see John Pridham.		
7650	Day, Horace H. and Richard McMullin	Hose, India rubber	XI.
7285	Day, Willard	Telescopes, submarine	VIII.

	De Massey, Robert—see Massey, Robert de		
7081	Dermond, John	Fliers and spindles, arrangement of	III.
7376	Devlan, Patrick S	Propellers, screw, arrangement and connexion of	VII.
7576	Dibble, Richard E	Boiler, steam	VI.
7519	Dickerson, Alexander	Iron, wrought, method of making directly from the ore	II.
7235	Dietz, Andrew	Harness, hames	XVI.
7259	Dietz, Andrew	Harness, &c., rings for	XVI.
7808	Dilks, Joseph	Boilers, steam, the alarm and indicator for	VI.
	Dimock, Lucius—see Conant & Dimock.		
7506	Dimpfel, Frederick P	Boilers, steam	VI.
7752	Dimpfel, Frederick P	Furnaces for steam boilers	VI.

Number.	Patentees.	Inventions or discoveries.	Class.
7136	Dixon, Joseph	Firing kilns for pottery ware, blacklead crucibles, &c	V.
7260	Dixon, Joseph	Steel, cast, process for making	II.
398	Doane, Calvin	Stoves	Design.
7018	Dodd, Edwin D	Files for keeping papers	XVIII.
7364	Dodge, John C	Spinning machines, preventing fibres from winding on drawing rollers in	III
7161	Dodge, Nehemiah	Pumps for deep wells	XI
309	Donavan, Robert	Stoves	Design.
7343	Dorn, Peter	Shoes, over	XVI.
7574	Dougherty, John	Propelling boats in shallow water, method of	VII.
7183	Downer, Charles	Weighing frames	XII.
7575	Drake, Imla	Boxes, compound wagon	X.
7630	Draper, William W	Paint mills	XIII.
6998	Du Bois, John	Gins, cotton	III.
7321	Dudley, Martin R	Driers, grain	V.
7394	Dunn, Arthur	Galvanic regulators for steam boilers	VIII.
7424	Durand, Francois, and Onesiphore Pecqueur, assignors to Richard E. Rabeau	Leather, machine for cutting into hollow ware forms	XVI.
	Dyer, E. G.—see J. E. Owens, et al.		
	Eaglesfield, W.—see Condit & Taylor.		
7438	Eastman, Robert	Stone, machines for dressing	XV.
7034	Eberly, David	Seeding apparatus, gearing and ungearing	I.
7698	Eberly, David	Seed planters	I.
	Ebert, J.—see J. E. Owens, et al.		
7137	Eccles, Samuel	Looms for figured fabrics	III.
6999	Eddy, George W	Wheels, car	X.
	Eddy, George W.—see Ezra Ripley.		
329	Eddy, Laben	Stoves	Design.
7771	Eddy, Oliver T	Printing machines	XVIII.
7302	Edes, Oliver	Rocker, submerged, for separating ores	II.
7138	Edwards, Nelson	Vessels' holds, apparatus for registering the depth of water in	VII.
7035	Elder, Matthew	Bedstead fastenings	XVII.
7781	Eldridge, David	Corn shellers	XIII.
7454	Ellicott, Peter F	Churns, atmospheric	I.
7322	Elliott, Hosea	Gearing for regulating speed	XIII.
7731	Elliott, J. T	Presses, cotton	XII.
7377	Embich, Jacob S	Buckles, harness	XVI.
7236	Emerson, Simeon F	Churns, atmospheric	I.
170	Emmons, Calvin, Wm. Emmons, adm'r of	Planing machine	Re-issue.
7082	Engles, Henry Adolph	Furnaces, air heating	V.
7854	England, Lewis C	Vats for tanning hides	XVI.
	English, W. B.—see Benj. Crawford.		
7473	Erb, John E	Straw cutter, feeders of a	I.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7425	Green, Duff	Embankments, levees, etc., method of forming	IX.
267	Green, Jeremiah D. and George Warren	Stoves	Design.
280	Green, Jeremiah D. and George Warren	Stoves, cooking	Design.
7113	Green, Rufus H.	Seraphines	XVIII.
6985	Greene, Chauncey O.	Grates, coal	V.
7772	Greene, Samuel S.	Horse-shoe machinery	II.
177	Gregg, Isaac	Brick presses	Re-issue.
7426	Groat, Warner	Packing for oil boxes of axles, &c., adjusting	X.
7654	Groesbeeck, Sylvester	Cornices and mouldings, plaster, tool for forming	IX.
7187	Groshon, John P.	Planters, seed	I.
	Grove, George A.—see Flory & Grove.		
7216	Guiteau, Calvin	Magnetic needles, correcting	VIII.
7140	Hacker, George S.	Cars, railroad	X.
7070	Haines, Joel	Washing machines	XVII.
7665	Hall, Elijah	Looms, stop motion of	III.
	Hallman, W. G.—see Chas. Gilbert.		
7682	Halvorson, Halvor, assignor to William M. Chase	Loom	III.
7397	Hamilton, Edward	Tubes, copper, machinery for making	II.
	Hamilton, F. H.—see Crane & Hamilton.		
6987	Hamilton, Farwell H. and Thomas Bullock	Hemp scutchers	III.
7119	Hamilton, William	Railings, iron	IX.
7508	Hardaway, Moore	Spike machines	II.
7578	Hardeman, J. Locke	Hemp, machines for cutting	III.
7053	Hare, Robert	Manure, preparation of animal and other	I.
	Harrington Francis—see Charles C. Coolidge.		
	Harris, Conrad—see Lamb & Harris.		
7666	Harris, Darius W.	Thrashing machine	I.
7188	Harris, Sandy	Hoisting machines	XII.
7600	Harrison, John W.	Carriages, detaching horses from	X.
7544	Hart, Edson	Planters, seed	I.
7700	Hart, George	Mowing machine, mounting cutters of a	I.
7289	Harvey, Thomas	Fastener, combined shutter and sash	II.
7741	Haskins, Nathan	Car couplings	X.
	Hartshorn, Jas.—see W. B. Gleason.		
7524	Hatch, George W.	Stanchions for cattle	XXII.
7241	Haverstick, Levi	Planters, seed, construction of drill teeth in	I.
7413	Hawkes, Charles W.	Printing presses	XVIII.
7855	Hawkes, Charles W.	Printing presses	XVIII.
7165	Hayden, Whiting	Drawing rollers, regulators for	III.
7765	Hayes, John P.	Furnaces, portable	V.
331	Haynes, C. Y.	Bas relief of Henry Clay	Design.
7561	Hays, Adam	Splints for fractures	XX.
7189	Hayward, Francis D. and John C. Bickford	India rubber cloth, process of rolling	IV.
7020	Heath, John E.	Harvesting machines	I.
7520	Heath, John E.	Grain, machines for raking and binding	I.
7096	Heiss, James P.	Studs for shirt bosoms	XVIII.
7521	Henderson, Albert N.	Ayes and noes, application of electro-chemical printing in colors for taking	XXII.
7683	Herndon, John J.	Harvester, rice	I.
7701	Hey, Moses	Yarn, machinery for doubling and twisting	III.
7474	Hibbs, Jonathan	Thrasher, clover, setting the teeth on the concave of a	I.
7242	Hicks, Daniel	Hammer, forge, attachment of the, to its helve	II.
7839	Hicks, Lucien E., assignor to William A. Churchill and James Stanley	Eyelets, machine for making	II.
7490	Hight, Cornelius R. and John	Churn dashers, spiral	I.
7545	Hill, Joseph A., assignor to John R. Cannon and Abner Hobbs	Ballot boxes	XXII.
7166	Hills, Edwin	Presses, oil	XII.
173	Hinton, John	Harvesters of clover heads and other grain	Re-issue.
	Hirst, Benjamin—see Goodyer & Hirst.		
7190	Hoagland, George H.	Steam, method of employing the exhaust	VI.
7036	Hoats, Daniel	Corn shellers, concave of	XIII.
	Hobbs, Abner—see Joseph A. Hill.		
	Hodges, Alexander—see Cullen Whipple.		
7243	Hoffman, John W.	Railroad frog, oscillating, self-adjusting	IX.
7303	Hoffman, John W.	Lamps, safety	V.
	Hoffman, John W., assignor to Henry W. Landry	Frog for railroads	Disclaimer.
7618	Hogle, Orange W.	Rakes, hay, fastenings of	I.
7491	Holland, Joel K.	Manure, carts, for spreading	I.
7509	Hollen, Joseph	Knitting machines	III.
168	Holly, Birdsill	Pumps	Re-issue.
7702	Holt, William H.	Comfits, kettle for manufacturing	XVII.
	Homer, C. W. & S. J. M.—see Dexter H. Chamberlain.		
7601	Hoopes, John R.	Dryers, grain	V.
7414	Hope, John W.	Brick presses	XV.
7415	Hope, Joseph D.	Ploughs, gang	I.
7455	Horn, George H.	Telegraphs, electric	VIII.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7809	Horton, William H.	Tin cutting and bending machines, arrangement of the bending rollers in	II.
	Hotchkiss & Merriman, Manufacturing Co.—see Charles Benedict.		
7167	Hotchkiss, Gideon	Saw mills, noddle irons for	XIV.
7101	Hotchstraser, Henry	Locking portable safes to the floor	XXII.
7365	Houghton, Joel	Table furniture, machines for washing	XVII.
7840	Houghton, Joel	Grain cradle fingers	I.
274	House, Samuel A.	Stoves	Design.
7562	Houston, George	Weighing machines	XII.
7084	Hovey, Alvan	Rakes, horse	I.
7563	Hovey, William H.	Boxes and axles, packing	X.
7819	Hovey, William H.	Axles and shafts, bearings for	X.
	How, Thos. P.—see Yaw & How.		
7456	Howard, Jason G.	Tacks, carpet, machine for forming washers and attaching them to	II.
7667	Howe, Ephraim	Burning fluid	V.
175	Howe, William	Bridges and other structures, constructing the truss frames of	Re-issue.
7021	Howell, John and Wm. D., and Joseph Sipe	Clevis, substitute for the	I.
7001	Hoyt, Thomas	Tobacco stems, curing	XXII.
7085	Hubbard, M. G.	Carriage bodies, hanging	X.
7796	Hubbard, M. G.	Carriage bodies, hanging	X.
7037	Hubbard, William U.	Valve, grid iron slide	VI.
7002	Hughes, William M.	Ore washers	II.
163	Hunt, Walter, assignor to William R. Palmer	Cartridge, method of attaching a ball to	Re-issue.
164	Hunt, Walter, assignor to George A. Arrowsmith	Ball, loaded	Re-issue.
7602	Hunter, James, assignor to Jeremiah Knight	Printing calico, mode of cleansing and drying gum elastic bands in	XVIII.
	Hunter John W.—see Radley & Hunter.		
7191	Huntley, Hosea H.	Stoves, cooking	V.
	Hutchins, Parley, Jr., assignor to Addison Everett	Turning wooden bowls, machinery for	Disclaimer.
7069	Hutchinson, Charles B.	Staves, machines for cutting	XIV.
7416	Hutchinson, Charles B.	Rule, board and log	VIII.
282	Hutchinson, James, ass'or to D. A. E and N. B. Powers	Floor cloth, painted	Design.
7217	Hyde, Ellsworth H. and Rollin L. Dawson	Pens, fountain	XVIII.

7345	Hyde, James R.	Stoves, cooking	V
7086	Ingersoll, James	Trucks, Railroad	X.
7192	Innis, James R.	Hide handling cylinders, beaters in	XVI.
7218	Iverson, Hans	Revolving breech fire arms	XIX.
7379	Jack, John, ass'or to Alfred Bell	Wickets for lock gates	IX.
7072	Jackson, Charles and James Moir	Carding and drawing wool, engines for	III.
7304	Jackson, Henry	Stoves, double cooking	V.
	Jackson, Israel—see Benj. F. Broomell.		
326	Jackson, James L.	Grate frame and fender	Design.
7022	Jackson, Samuel	Cider mills	XIII.
7054	Janes, Adrian	Heating air by hot water, apparatus for	V.
7721	Jenkins, Jacob	Pegging jack	XVI.
	Jenks, Alfred—see Goodyer & Hirst.		
7380	Jenny, Edwin	Staves, machinery for sawing	XIV.
7219	Jennings, Andrew	Cutters, machines for forming rotary	II
7492	Jennings, Isaiah	Lamp tubes	V.
7244	Jennings, Lewis	Lock, revolving plate and tumbler	II.
300	Jewett, S. S. & F. H. Root	Stoves	Design.
308	Jewett, S. S. & F. H. Root	Stoves	Design.
7619	Jewett, S. S. & F. H. Root	Stoves	V.
7457	Johnson, A. Livingston	Shutters, the hinge of rolling iron	II.
	Johnson, Cox & Fuller—see Samuel Pierce.		
	Johnson, Cox & Fuller—see George W. Ring.		
	Johnson, E.—see J. Crandall.		
7262	Johnson, Jasper	Vises, parallel, method of working the pawl in	II.
7168	Johnson, John, ass'or to Elias Johnson	Looms for weaving piled fabrics	III.
7797	Johnson, M. Y., adm'r of James H. Johnson	Cordage, processes for rendering uninflammable	III.
	Jones, A. W.—see Conklin & Jones.		
325	Jones, Anthony W., ass'or to Edward R. Brown	Stove	Design.
7773	Jones, Aquilla	Paints, drying	IV.
	Jones, Henry C.—see Thomas Slaight.		
7856	Jones, John	Window blinds and their slats, apparatus for operating	II.
	Jones, Wm. B.—see Whipple & Jones.		
7564	Judd, Allen	Pentographs	XVIII.
7684	Judd, Oliver B.	Saw gate	XIV.
7755	Judson, Junius & Alfred, ass'ors to Junius Judson	Valves for governors	V.
7459	Keagy, Abraham	Stoves, cooking	V.
7565	Kean, W. B.	Bench hooks	XIV.
7245	Keeny, Abel	Grates, coal, agitating	V.
7323	Keep, James M.	Plasters, gauges for spreading	XX.
	Kellogg, George—see Atwood & Kellogg.		
7417	Kelly, Oliver A.	Looms, shuttle motion of	III.
7810	Kelly, William	Casting large kettles, metallic flask for	II.

ALPHABETICAL LIST—Continued.

Number.	Patentees.	Inventions or discoveries.	Class.
7025	Kelsey, George R.	Buckles	XVI.
7120	Kempton, Humphrey	Clothes frames	XVII.
7023	Kennish, William, ass'or to Cornelius S. Van Wagoner	Valves of hydraulic engines, arrangement of the	XI.
7525	Kershaw, Edward	Locks, prism, attachment of	II.
313	King, John C.	Bust of Daniel Webster	Design.
7141	King, Robert J.	Ploughs, corn	I.
7169	Kinsley, Lyman	Wheels, cast iron car	X.
7170	Kinsley, Lyman	Wheels, cast iron car	X.
6988	Kimball, John and Harvey Rice	Brakes, connexions of with cars	X.
7526	Kirkham, Peter	Hooks and eyes, attaching to paper cards	XXI.
7024	Kittle, Robert	Tonguing and grooving, machinery for	XIV.
	Knab, David C.—see Poisat & Knab.		
	Knight, Geo. H. and Edward H.—see Clinton & Knights.		
	Knight, Jeremiah—see James Hunter.		
7171	Knight, Sylvanus	Steam boilers, interior arrangement of	VI.
7546	Knowles, Calvin C.	Gold, process for amalgamating	IV.
7475	Knowles, Hazard and Henry C. Bevington	Harvester, cutters and rakers of a grain and grass	I.
7603	Knowles, Hazard	Saws	XIV.
7324	Knowles, Jonathan	Looms, let off motion of	III.
7774	Krauser, John, Sommers Crowell and Cyrus Krauser	Railings, iron	IX.
7798	Krebs, Charles W.	Pens, fountain	XVIII.
162	Krechler, Charles A.	Distilling apparatus	Re-issue.
	Ladd, W. G.—see Dexter H. Chamberlain.		
7263	Ladd, W. G., Jr.	Level, fluid	VIII.
260	Lamb, Joseph G. and Conrad Harris, ass'or to W. C. Davis	Stoves	Design.
322	Lamb, Joseph G.	Stove	Design.
323	Lamb, Joseph G.	Stove	Design.
7055	Lamb, Josiah	Tables, self-waiting	XVII.
340	Lambard, Charles A.	Stoves	Design.
7220	Lamborn, Lewis	Cultivator teeth	I.
	Landry, Henry A.—see John W. Hoffman.		
7476	Lane, Benjamin J.	Respiring apparatus	XX.
7703	Lane, Thomas W.	Gas metres	IV.
7305	Lanergan, Henry	Bridges, arch truss for	IX.
7784	Langenheim, Frederick	Photographic pictures on glass, &c.	XVIII.

Number.	Patentees.	Inventions or discoveries.	Class.
7785	Larkin, John E.	Augers, attaching to their handles	XIV.
7121	Larrabee, Ephraim	Refrigerators	XVII.
	Latting, Warring—see Charles D. Birdseye.		
	Law, George—see Moses Chase.		
	Lawrence, A.—see C. W. Warnick, et al.		
7246	Lawrence, Jabez F. and Luke A. Farnsworth	Blind and shutter opener and fastener	II.
7841	Lazelle, William H.	Fasteners, sash	II.
	Learned, Billings P.—see Reuben J. Blanchard.		
	Learned, B. P. and George H. Thatcher—see Reuben J. Blanchard.		
7668	Leavitt, O. S.	Hemp, drawing and parting fibres of	III.
7351	Leclaire, Edme Jean and Jean Joseph, Ernest Barnel	Oxide of zinc, manufacture of the	IV.
7704	Lee, John	Eaves trough and gutter machine	II.
7820	Leffel, James	Lever jacks	XII.
	Leibrandt, F.—see C. W. Warnick, et. al.		
7493	Leonard, George, Jr.	Fire-arms, revolving hammer	XIX.
7381	Lewis, Spencer	Wood, machines for sawing	XIV.
7264	Lewis, Spencer	Bedsteads, machinery for cutting screws on the rails of	XVII.
7172	Lidgerwood, Thomas	Lewis, lever	XII.
7287	Lillie, John H.	Electro-magnetic engines	VIII.
179	Livingston, Lawreston R., John J. Roggen and Calvin Adams	Door knobs, shanks of	II.
7477	Locke, John	Levels, collimating	VIII.
7510	Locke, John	Compasses, surveyors'	VIII.
	Lombard, Sanford H.—see A. M. Rice.		
7154	Long, James	Gas metres	IV.
7247	Loomis, Osbert B.	Churns, rotary	I.
7842	Loper, Richard F. and John W. Nystrom	Engine, steam, arrangement of	VI.
7265	Low, John	Harness hames	XVI.
7685	Lupton, Lewis	Carriages, dash board for	X.
7142	MacGregor, James, Jr.	Ranges, cooking and air heating furnaces connected therewith	V.
7143	MacGregor, James, Jr.	Furnaces, air heating	V.
7193	MacGregor, James, Jr.	Stoves, double oven cooking	V.
	MacGregor, James, Jr.—see Conklin and Jones.		
7756	Macomber, A. S.	Straw cutters	I.
6990	Maguire, William	Fastener and mover, blind and shutter	II.
7003	Maguire, William	Sash, counterbalancing by means of a heavy weight	II.
7026	Maguire, William	Lock, door	II.
7669	Mahan, Jason M.	Stereotype plates, casting	XVIII.
7511	Mallerd, William	Compounds, sizing for warps or yarns	IV.
7655	Mallory, George	Daguerreotype plate holders	XVIII.
7412	Maltby, Benj. K., ass'or to Ira M. Mead	Grate, apparatus for raising the, in cooking stoves	V.
6989	Mareau, Ransom	Washing machines	XVII.
7173	Marquart, John, Jr., ass'or to Henry Schreiner	Water casks, gauge for	XI.

ALPHABETICAL LIST—Continued.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7527	Marsh, Joseph	Churn dashers	I.
7443	Marston, William W.	Breech pin piston, devices for holding and moving	XIX.
93	Masser, H. B.	Freezers, ice cream	Additional imp'mt.
7342	Massy, Robert de	Sugar, defecating	IV.
7811	Mather, Orville	Spokes, machines for dressing	XIV.
7636	Mathews, Moses M.	Ink, printers', use of rosin oil in	IV.
7821	Mathiot, George	Electrotyping	XVIII.
7799	May, H. H.	Rails of railroads, method of securing	IX.
	May, Philip—see Bathelemy Thimmonier, Sr.		
7418	May, Samuel S.	Chairs, nursery	XVII.
7857	Mayfield, William D.	Pumps, attachments to, for agitating the surface of the water in the well	XI.
7382	Maynard, James A.	Tuyers, devices for discharging ashes from	II.
7757	McCoy, William	Kilns, lime	XV.
7670	McCulloh, Richard S.	Gold bullion, process of reducing	II.
7122	McDougal, Samuel T.	Scale beams	XII.
7248	McElwee, John V.	Mattresses, spring	XVII.
	McGriff, Allen R.—see Joseph Pollock.		
7566	McKinney, A.	Wagon tops, apparatus for regulating the setting of bows in	X.
7056	McLaughlin, Thomas	Valves, puppet, expansion gear for	VI.
	McMullin, Richard—see Day & McMullin.		
7800	McNair, Simon	Sausage stuffers	XVII.
	Mead, Ira M.—see Benj. K. Maltby.		
7528	Meinicke, Charles J.	Distilling spirits of turpentine	IV.
7858	Mellish, Henry	Vaccinating instruments	XX.
7057	Melsens, Louis Henri F., ass'or to Louis de Saulles	Sugar, manufacture of	IV.
7174	Menefee, Alexander F.	Flouring mills	XIII.
169	Merrick, Solyman	Screw machines, feeders for	Re-issue.
	Merrick, S. V.—see John H. Towne.		
7671	Metcalf, Joseph	Electricity, removing from wool in the process of manufacture	III.
7494	Meyer, Conrad	Pianos, sounding boards for	XVIII.
7786	Middleton, Elijah C., Edward Nevers and Rob. Neale	Printing presses, copper and steel plate	XVIII.
7579	Millar, John C.	Fulling mills	III.
7478	Miller, Joseph R.	Amalgamator, re-immersing	II.
7004	Miller, Lewis W.	Boring instruments, connecting cutters to shafts of	XIV.

7567	Milligan, Robert		
7529	Milner, George B.	Ornamenting textile fabrics	
	Moir, James—see Jackson & Moir.	Valve gear for steam engines	XVII.
7073	Montgomery, Richard		VI.
7346	Montgomery, Richard	Punching between rollers, method of	
7742	Montgomery, Richard	Excavator, the screw	II.
7221	Moore, Leverett	Boilers, corrugated	IX.
7479	Moore, Lewis	Printing floor oil cloth	VI.
7427	Morgan, Gideon	Planters, seed, seeding apparatus of	XVIII.
	Morgan, Peter U.—see Arnold & Bishop.	Cars for plank roads, wooden rails, &c	I.
7604	Morrill, Alden R. and Hiram Baldwin		X.
	Morris, Ephraim—see Bradford & Morris.	Drilling machines, self-acting, adjustable feed gear for	
7743	Morrison, John		II.
7656	Morrison, William	Bedstead fastenings	
	Morse, Andrew, Jr.	Ploughs, spring beams to	XVII.
7266	Mortimer, Charles	Capstans	I.
166	Mott, Jordan L.	Paint, process of making from bituminous coal	Renewal.
7347	Mott, Jordan L.	Stoves, cooking	IV.
7366	Mott, Jordan L.	Stoves, cooking	V.
7657	Mott, Jordan L.	Stoves, cooking	V.
7687	Murkland, Willian and Joseph Milner	Roadway for railroad cars and ordinary vehicles	V.
	Musselman, Geo. F.—see Daniel W. Goble.	Weavers' shuttle	IX.
	Myers, Jeremiah		III.
		Turn about for railroads	
7460	Myers, Nathaniel and Frederick C. Smith		Disclaimer and extension.
7271	Nash, Adkins	Sash stopper, arrangement of	
7348	Nash, William R.	Thrashers, endless aprons for	II.
7620	Neal, David S.	Churn dasher, working a rotary and vertical	I.
	Neale, Robt.—see Middleton, Nevers & Neale.	Car couplings	I.
7144	Nelson, Charles M.		X.
7461	Nelson, John R.	Stoves cooking	
	Nevers, Ed.—see Middleton, Nevers & Neale.	Straw cutters, mounting the knife of	V.
7580	Nevins, William R.		I.
	New England Screw Co.—see Cullen Whipple.	Crackers, machines for cutting	
7787	Newman, Martin, 2d		XVII.
7581	Newton, Luke Vanderveer	Excavating machines	
7306	Nichols, William R. and Burritt C. Boyes	Types, metallic, engraved plates, &c., preparing the face of	IX.
7480	Nock, Joseph	Grates, furnace, coal stirrers for	XVIII.
7027	Norcross, Nicholas G.	Lock bolt for shutters	V.
7087	Norcross, Nicholas G.	Saw mills, circular	II.
7398	North, Alvin and Oliver B., and Stephen Frink	Planing machines	XIV.
7194	Nystrom, John W.	Buckles, machinery for making four sided	XIV.
	Nystrom, John W.—see Loper & Nystrom.	Propeller, centripetal	XVI.
			VII.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7605	Odeon, Tilgath	Trusses, method of attaching yards to	VII.
7530	Olcott, Adrian	Stone, rubbing and polishing	XV.
7175	O'Meara, Mary W.	Supporters, abdominal	XX.
7531	O'Neil, John	Churns, atmospheric	I.
7195	Ostrander, Wm. and Wm. Webster	Tubes, method of forming sheet metal	II.
7621	Ostrander, J. F.	Planing machines	XIV.
7812	Otis, Melville	Nail plate feeder and turner	II.
294	Owens, J. E., J. Ebert and E. G. Dyer	Stoves	Design.
303	Owens, J. E., J. Ebert and E. G. Dyer	Stoves	Design.
7732	Pagett, Wm. C.	Ploughs, subsoil	I.
7642	Palmer, Aaron	Planters, seed, seeding rollers of a	I.
281	Palmer, P. A.	Stoves	Design.
7612	Palmer, P. A.	Ovens, heating elevated	V.
	Palmer, Wm. R.—see Walter Hunt.		
7547	Pannabecker, Jesse	Barrels for fire-arms, method of making	XIX.
7145	Paris, Charles E. and Charles H.	Composition for enameling hollow ware	IV.
7608	Park, Austin F.	Telegraph, electric, manipulator	VIII.
7428	Parker, Charles H.	Bedstead fastenings	XVII.
7307	Parkhurst, Stephen R.	Gins, cotton	III.
7548	Parkinson, Thomas	Gates, hanging and operating	IX.
7071	Parmelee, Dubois D.	Calculating machines	VIII.
7125	Parry, John C.	Casting chilled rolls, method of giving a rotary motion to metal in	II.
7383	Parry, John C.	Casting rolls, method of giving rotary motion to fluid iron in	II.
7859	Parry, John C.	Castings, hollow, method of loosening metallic cores from	II.
7325	Parsons, E. H. and S. E.	Saws, hanging in saw mills	XIV.
7367	Patterson, Horace	Splint machines	XIV.
7290	Patterson, James	Carriages	X.
289	Paul, Amos	Stoves	Design.
304	Paul, Amos	Grate, portable	Design.
7038	Pawling, John	Tuyere	II.
7399	Payne, Charles	Preserving wood, processes for	IV.
7146	Payne, William	Cars, apparatus for retaining on the rails	X.
7058	Pearl, Oliver	Bobbins upon spindles, driving	III.
7744	Pease, Dan., Jr	Grain screens, rotary	I.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7267	Pease, Julius A.	Sash-bearer, elastic roller	II.
172	Pecare, Jacob and Josiah M. Smith	Fire arms, concealed trigger for	Re-issue.
7326	Peck, Samuel	Daguerreotype plates, holding	XVIII.
	Pecqueur, Onesiphore—see Durand & Pecqueur.		
7268	Pierson, Jacob	Planters, seed, gearing for	II.
7481	Pierson, Jacob	Harvester, arrangement of cutters in a grass and grain	I.
7368	Pelton, A. S.	Thrashing machines	I.
290	Penniman, Elijah P.	Stoves	Design.
7495	Pennock, Samuel and Morton	Planters, seed, seeding apparatus of	I.
7822	Pennock, Samuel and Morton	Planters, seed	I.
7482	Pepper, John W.	Lozenges, machines for cutting	XVIII.
7496	Percival, Orville B. and Asa Smith	Chargers attached to fire arms	XIX.
7249	Perley, Charles	Stoppers, cat head and shank painter	VII.
7532	Perley, Charles	Windlass, jigger	XII.
7147	Perry, Alonzo D.	Cartridges, winged metallic	XIX.
	Perry, David—see Slaughter & Perry.		
7123	Perry, John G.	Meat cutting apparatus	XVII.
275	Peterson, Richard, David Stuart and Peter Seibert, assignors to Richard Peterson	Stoves	Design.
7059	Phelps, Edward	Gearing for sugar cane mills	XIII.
	Phillips, Alonzo D.—see E. T. Swift.		
7269	Phillips, William H.	Fire, apparatus for extinguishing	V.
	Pierce, Geo. W.—see Fuller & Pierce.		
7775	Pierce, Samuel	Stoves, cooking	V.
338	Pierce, Samuel, ass'or to Johnson, Cox & Fuller	Stoves	Design.
7270	Pierce, William P. ass'or to E. and T. Fairbanks & Co.	Scale beams	XII.
7349	Pierpont, William	Straw carriers	I.
7758	Pine, Joseph, ass'or to Benjamin Pine	Carriages, running gear of	X.
7568	Pirsson, James	Piano fortes	XVIII.
7250	Pirsson, Joseph P.	Condenser, surface for steam engines	VI.
7272	Pitcher, Leman B.	Regulators for machinery, hydraulic	XIII.
	Plumb, Hiram—see West & Plumb.		
7497	Pohl, Henry	Paper, machinery for measuring pulp in the manufacture of	III.
7124	Poisat, Anthony M. and David C. Knab	Distilling oleaginous matter	IV.
7582	Pollock, George	Registers, hot air	V.
7104	Pollock, Joseph, Allen R. McGriff, administrator of the estate of	Hulling clover seed	I.
7005	Pomeroy, Ebenezer G.	Iron, coating with copper, or its alloy	II.
7102	Pomeroy, Elisha M.	Buttons, process of varnishing	XXI.
7512	Poppenhusen, Conrad	Veneers, &c. machines for cutting	XIV.
7444	Post, Nathan	Stirrups, safety	XVI.
7745	Porter, Bennett, Jr	Hats, machinery for pressing	XXI.
7059	Potter, Merritt F.	Furnaces, portable	V.. Re-issued.

ALPHABETICAL LIST—Continued.

Number.	Patentees.	Inventions or discoveries.	Class.
181	Potter, Merritt F.	Furnaces, portable	Re-issue.
7462	Potter, Nathaniel	Roads, machine for repairing	IX.
7060	Potts, Lawrence H.	Piles, etc., method of sinking hollow, by exhausting the air from the interior of the same	IX.
	Powers, D., A. E., & N. B.—see James Hutchinson.		
7228	Powers, Nathaniel B.	Printing floor oil cloths	XVIII.
	Pratt, David—see Wager, Pratt & Richmond.		
	Prescott, Jedediah—see Rembert & Prescott.		
7273	Price, Joseph D.	Sprinkling streets, &c., apparatus for	XI.
7196	Pridham, John, assignor to Horace H. Day	India rubber, use of oxide of tin in the manufacture of	IV.
7103	Purdy, Peter M.	Fences, portable	IX.
7733	Pyron, Tapley B.	Carriages, apparatus for releasing horses from	X.
7197	Quimby, Phineas P.	Steering apparatus	VII.
7705	Quincey, Edmund	Harvester, grain and maize	I.
	Rabeau, Richard E.—see Durand & Pecqueur.		
293	Race, Washburn	Stoves	Design.
295	Race, Washburn	Stoves	Design.
7040	Radley, James and John W. Hunter	Spark arresters	VI.
7106	Ramsdell, Orrin, assignor to Jos. B. & Sylvanus Sawyer	Harness, breast plate for	XVI.
7107	Ramsey, Robert	Bedstead fastenings	XVII.
7198	Ransom, Franklin	Pumps for ships, &c.	XI.
7483	Ransom, S. H.	Stoves, cooking, construction of	V.
291	Rathbone, John F.	Stoves	Design.
292	Rathbone, John F.	Stoves	Design.
306	Rathbone, John F.	Stoves, coal	Design.
7251	Ray, Fowler M.	India rubber springs for cars, etc., manufacture of	IV.
7706	Ray, Fowler M.	Spring, vulcanized India rubber	X.
	Read, Charles A. and Thomas Cotter, assignors to Charles A. Read	Fulling cloth, machinery for	III.
7274	Reasin, James F.	Plough cleaners	I.
7126	Reed, Jesse	Steering apparatus, parallelogram	VII.
7063	Reed, John M. and William B. Willis	Flour bolts	XIII.
7028	Reed, Josiah G.	Spindles, bobbins for spinning	III.
7843	Rees, Edward	Cores for castings, composition for making	II.
7222	Rembert, Samuel S.	Thrashing harvesters	I.

7631	Rembert, Samuel S. and Jedediah Prescott	Cotton, picking from the bolls in the field	I.
7734	Renwick, Edward S.	Chair, wrought iron railroad	IX.
7429	Ressigine, William F.	Mattresses, spring	XVII.
7223	Reynolds, Ira	Ploughs, clevis	I.
7369	Reynolds, O. L.	Sewing machines	III.
7823	Rhodes, Dexter B.	Planters, seed	I.
7275	Rice, Augustus M., assignor to Sandford H. Lombard and A. M. Rice	Chimney caps	V.
	Rice, Harvey—see Kimball & Rice.		
7583	Rice, James D.	Boilers, steam, registers for	VI.
7350	Richardson, Cyrus	Valves, slide, arrangement of several in the same steam chest	VI.
301	Richmond, Apollos, assignor to A. C. Barstow & Co.	Stoves	Design.
333	Richmond, Apollos, assignor to A. C. Barstow & Co.	Stoves	Design.
	Richmond, Volney—see Wager, Pratt & Richmond.		
7533	Rider, Elias P.	Cotton batting, apparatus for sizing and drying	III.
7105	Rider, Henry N.	Dough, method of kneading	XVII.
7148	Riley, George	Glucose, process in the manufacture of	IV.
310	Ring, George W., assignor to Johnson, Cox & Fuller	Stoves, parlor	Design.
7291	Ripley, Ezra	Stands, the construction of bases for	XVII.
327	Ripley, Ezra, assignor to Geo. W. Eddy	Stoves	Design.
328	Ripley, Ezra, assignor to Geo. W. Eddy	Stoves	Design.
159	Robbins, Zenas C.	Churns	Re-issue.
7006	Robbins, Zenas C.	Churns	I.
7400	Roberts, Jesse	Fanning mills	I.
	Robertson, John W.—see John G. Webster.		
7824	Robinson, Frederick R.	Sewing machines	III.
7788	Robinson, Jonathan H.	Pessaries	XX.
7569	Robinson, Warren	Ventilators, ship	V.
7088	Rockwell, Francis A.	Bedclothes, clasps	XVII.
7463	Rodger, Charles	Cultivator, weed cutters of a	I.
6991	Rogers, John	Stump extractor, wheel and axle	IX.
7844	Rogers, John, Jr.	Mills for grinding	XIII.
	Roggen, John J.—see L. R. Livingston & Co.		
7513	Rohr, George	Planters, seed, seeding apparatus of	I.
	Rohr, George—see Gervis S. Gardner.		
7845	Rohr, David E.	Seeding cylinders, oscillating	I.
284	Root, D.	Stoves	Design.
334	Root, D.	Stoves	Design.
	Root, F. H.—see Jewett & Root.		
	Root, F. H.—see Jewett & Root.		
160	Root, James	Stoves, cooking	Re-issue.
7674	Rose, Timothy	Water wheels	XI.
7029	Rosensteel, William H.	Tanning apparatus	XVI.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7384	Ross, Charles	Canals, feed, regulators for	IX.
7759	Rouse, Wanton	Spinners, cop, operating the copping rail of	III.
7199	Routzahn, Nathaniel	Churn dashers	I.
7327	Rowe, Bradford	Leather, apparatus for splitting and stretching	XVI.
	Rowe, Bradford	Leather, cutting and stretching	Re-issue.
335	Royce, John S.	Carriage plates	Design.
7292	Ruck, John	Piano forte, action	XVIII.
7308	Ruck, John	Piano fortes	XVIII.
7584	Ruggles, Stephen P.	Metal, sheet, &c., machine for cutting	II.
178	Ruggles, Stephen P.	Printing presses	Re-issue.
7149	Russell, Charles W.	Fire places and throats of chimneys, construction of	V.
7534	Sabbaton, Joseph A.	Gas, coal, purifying	IV.
7813	Sabin, Harvey W.	Rakes, horse	I.
7293	Sage, Marcus & Silas S.	Planter, seed, attachment of harrow to	I.
269	Sanderson, William L., ass'or to Clute & Brothers	Stoves	Design.
269	Sanderson, Wm. L.	Stoves, cooking	Design.
311	Sanderson, Wm. L., ass'or to S. Cole & G. C. Mosher	Stove	Design.
7294	Sandoe, Anthony	Planters, seed, gearing of	I.
7688	Sanford, Gelston	Auger handle	II.
	Saulles, Louis de—see Louis H. F. Melsens.		
7150	Saunders, William H.	Axles, mail	X.
324	Savery, William	Stoves	Design.
7200	Sawyer, Edmund	Spike machines, movement of the pointing dies in	II.
	Sawyer, Jos. B. and Sylvanus—see Orrin Ramsdell.		
7309	Sawyer, Nathan	Brick presses	XV.
7846	Scales, Charles	Ships' timbers, instruments for laying down curves of	VII.
7370	Scarlett, William	Buckles, suspender	XXI.
7707	Scarritt, Russell	Sofa bedsteads	XVII.
7385	Schiele, Christian	Rubbing surfaces for regulating abrasion, form of	XIII.
7760	Schindler, Carl W.	Fats and oils, hardening	IV.
	Scholfield, Nathan	Water wheels, steam engines, &c., the art of regulating the motion of	Extension.

	Schreiner, Henry—see John Marquart, Jr.		
	Scott, George—see Culbertson & Scott.		
7630	Scott, Melchi	Smiths' strikers	II.
7419	Scripture, Eliphalet S.	Horses, flying	XX.
7535	Scripture, Eliphalet S.	Hubs with axles, connecting	X.
7224	Searle, Flavius	Dental and surgical chairs	XX.
7386	Seely, John M. and Wm. E. Tomlinson	Attachments to mills for preparing corn in the cob for grinding	XIII.
	Seibert, Peter—see Cresson, Stuart & Seibert.		
	Seibert, Peter—see Peterson, Stuart & Seibert.		
7498	Sellers, George Escol	Locomotive engines for working heavy grades, boilers and gearing of	VI.
7225	Severance, Augustus N.	Presses, cheese	XII.
7328	Severance, Augustus N.	Press boxes or vats for cheese	XII.
7658	Seversson, Benjamin	Wheels, cast iron railroad car	X.
7075	Sewell, William, Jr.	Water metres	XI.
	Sexton, S. B. & Co.—see James H. Conklin.		
7295	Seymour, Alfred B.	Rail, compound tubular	IX.
7549	Shaw, E. M.	Turning machines	XIV.
7860	Shaw, James	Portfolios	XVIII.
7633	Shaw, William C. and James Stalcup	Bedsteads, camp	XVII.
7636	Shellenberger, John	Scribing lumber, machines for	XIV.
7607	Sheperd, Henry L.	Stoves, cooking, arrangement of dampers in	V.
258	Sheperd, Henry L.	Stoves	Design.
7445	Sherlock, John and Wm. Brackbill	Feed apparatus for mills	XIII.
7550	Sherman, Robert S.	Churn dashers	I.
7634	Shield, George	Cylinders, steam, exhaust passages for	VI.
	Shipton, Thomas N.—see Signer & Shipton.		
7789	Shoenberger, Edwin F.	Tables, extension	XVII.
7387	Shuttleworth, John	Looms, power	III.
7831	Signer, John and Thomas N. Shipton	Planters, seed	I.
259	Simmons, Peter J.	Stoves	Design.
	Sipe, Joseph—see Howells & Sipe.		
7176	Slaight, Thomas, ass'or to Henry C. Jones	Lock bolts, method of operating	IX.
6992	Slaughter, Franklin and David Perry	Cordage, cotton, machinery for making	III.
7007	Slaughter, Franklin and David Perry	Cordage, cotton, machinery for making	III.
7747	Sleeper, James P.	Musical instruments, reed	XVIII.
7499	Sloan, Thomas J.	Screws, machines for cutting	II.
7748	Sloan, Thomas J.	Screws, wood, machines for nicking the heads of	II.
7801	Sloan, Thomas J.	Screw threading machine	II.
7446	Smith, Alexander	Parti-coloring yarn, apparatus for	IV.
7825	Smith, Alexander	Carpets, manufacture of two and three ply	III.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
	Smith, Asa—see Percival & Smith.		
7310	Smith, Benjamin M.	Propellers and chimneys for canal boats, arrangement of	XIII.
7296	Smith, David M., ass'or to Thomas Chadbourne.	Sewing machines	III.
94	Smith, John H.	Stearine from elaine, process of preparing	Additional Imprv't
	Smith, Josiah M.—see Pecare & Smith.		
7090	Smith, Leonard	Smut machines	XIII.
339	Smith, Morris & Benona S. Gleason	Stoves	Design.
7420	Smith, Samuel B.	Electro magnetic machines for shocks	VIII.
7689	Smith, William W.	Callipers	VIII.
7690	Snead, Charles S.	Dryers, grain	V.
7091	Snedaker, Samuel B.	Fasteners and window shutter openers, method of bolting in	II.
7722	Snow, George K.	Paper, machines for folding	XVIII.
7430	Snyder, Elisha S.	Thrashing machines	I.
7826	Sommers, Henry B.	Vessels, apparatus attached to for indicating the depth of water	VII.
7708	Southward, Eli F.	Grummet strap	VII.
7827	Southworth, Daniel H.	Planing machines	XIV.
171	Spafford, George, ass'or to John Campbell	Paper, machine for boiling and washing rags for manufacturing	Re-issue.
7551	Spencer, Robert	Saddles, harness	XVI.
7635	Spencer, Smith	Mortising machines	XIV.
7723	Sprague, John A.	Excavating and conveying earth	IX.
7008	Spratt, James	Alloys for points of lightning rods	IV.
7076	Spratt, James	Lightning conductors, attachments for	VIII.
7536	Spring, Charles A. and Peter Boon	Planing machines, arrangement of pressure and feed rollers in	XIV.
7637	Stadden, Robert	Hullers, clover	I.
7447	Stafford, J. R.	Mills for grinding	XIII.
7735	Stagg, Thomas G.	Beefsteak, preparing for cooking	XVII.
	Stalcup, James—see Shaw & Stalcup.		
	Stanley, James—see L. E. Hicks.		
6993	Stack, Lewis	Branding tools	XIV.
7276	Starkey, David G.	Oil cans	XIII.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7746	Starks, Nathan	Wheels, car, machines for making wrought iron	X.
7766	Starkweather, George	Curing meat, process for	IV.
7724	Stebbins, Erastus	Molasses gates	XI.
7814	Steele, Elisha	Buckles, suspender	XXI.
7431	Stevens, James	Traps, arrangement of mirrors in	XXII.
7802	Stevens, Joshua	Locking apparatus, the of repeating fire arms	XIX.
7388	Stevens, Silas, assignor to George Forbes	Knives, spiral, machine for grinding	II
	Stevens, Thomas—see Dalton & Stevens.		
7484	Stewart, Franklin	Lamps, safety tubes for	V.
	Stewart, Richard S.—see Moses Chase.		
7041	Stiles, Ann F.	Daguerreotype pictures, cases for	XVIII.
7514	Stiles, David, Jr.	Straw cutters, feeding apparatus of	I.
7151	Stimpson, Frederick H.	Ranges, cooking	V.
7161	Stimpson, Herbert H. and Frederick H.	Ranges, cooking, water backs for	V.
7402	Stocker, Amos	Tailors' measures	XXI.
95	Stocker, Amos	Tailors' measures	Additional imp'mt.
7847	Stone, W. C.	Legs, artificial	XX.
7338	Stoner, John B.	Clevises, plough	I.
7537	Stout, Joseph and James T. Stanton	Tubes of sheet metal, machines for forming	II.
7698	Stuart, David, assignor to William P. Cresson	Stoves, Franklin, blowers of	V.
	Stuart, David—see Cresson, Stuart and Seibert.		
	Stuart, David—see Peterson, Stuart and Seibert.		
7108	Subers, Isaiah	Fences	IX.
7352	Swan, Amos L.	Melodeon	XVIII.
	Swan, Nathan—see Ferris & Swan.		
7127	Sweeney, Peter	Stoves	V
7252	Sweet, Joseph	Scrapers, removable teeth for	IX.
7790	Swett, Samuel	Spark arresters	VI.
	Swift, Beriah	Dye woods and dye stuffs, machine for cutting and shaving	Extension.
	Swift, Erdix T., administrator of Alonzo D. Phillips	Friction matches	Extension.
7749	Swift, Horatio N.	Spike machines	II.
7128	Swope, Zuriel	Hydrolator	XI.
7624	Tatham, William P.	Pipe, lead, manufacture of	XI.
	Taylor Alfred—see Condit & Taylor.		
7403	Taylor, James, assignor to John, Joseph and Francis Crossley	Pile for rugs, &c., preparation of	III.
7030	Taylor, Timothy, assignor to Mortimer Taylor	Harness hames, fastenings for	XVI.
7570	Tennent, John C. and John Workman	Safety apparatus for steam boilers	VI.
	Thatcher, George H.—see Reuben J. Blanchard.		
7815	Thayer, Augustus	Auger handle	XIV.
7353	Theaker, Thomas C.	Valves, oscillating, of steam engines	VI.
7389	Theaker, Thomas C.	Saw mills, apparatus for setting logs in	XIV.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7623	Thimmonier, Barthelemy, Sr., assignor to Philip May	Sewing machines	III.
7500	Thomas, Evan O.	Store counters	XXII.
7861	Thomas, Samuel T. and Edward Everett	Looms for weaving figured fabrics	III.
7092	Thomas, William S.	Telegraphs, electric	VIII.
7311	Thompson, Henry G.	Lathe for turning a peculiar species of curve	II.
7848	Thompson, Robert	Lamps for lighting gas burners	V.
	Thorpe, Phillip—see Buffum A.		
7464	Timby, T. R.	Water wheels for increasing or diminishing their diameters	XI.
7585	Tingle, George	Paddle wheels, opening and closing bucket for	VII.
7201	Tingley, Albert H., assignor to E. W., H. F. and A. H. Tingley	Marble, machines for sawing	XV.
7625	Tomlinson, Seymour	Horses, apparatus for breaking	XXII.
	Tomlinson, W. E.—see Seely & Tomlinson.		
7623	Towne, John H., assignor to S. V. Merrick	Hammer, direct action steam	II.
7691	Townsend, Ashley	Thrashing machines and grain cleaners, endless aprons for	I.
7277	Townsend, Benjamin M.	Hay, machines for raking and loading	I.
	Totten, Joseph M	Friction rollers	X.
7560	Tozer, Junius F.	Vaccinating, instruments for	XX.
7371	Trees, James	Propeller, shell	VII.
7329	Trissler, W. H. and Elias Brecht	Coffee roasting	XVII.
7816	Trotter, Jonathan T.	India rubber, vulcanizing	IV.
7515	Truscott, Samuel	Car wheels, apparatus for regulating the contraction of	II.
7253	Tucker, Hiram	Mantel piece	IX.
7061	Turnbull, James, Jr., and Jno.	Looms, for piled fabrics	III.
315	Tuttle, Charles T. and James S. Bailey	Register and ventilator, plates for	Design.
316	Tuttle, Charles T. and James S. Bailey	Register and ventilator, plates for	Design.
317	Tuttle, Charles T. and James S. Bailey	Register and ventilator, plates for	Design.
318	Tuttle, Charles T. and James S. Bailey	Register and ventilator, plates for	Design.
319	Tuttle, Charles T. and James S. Bailey	Register and ventilator, plates for	Design.
320	Tuttle, Charles T. and James S. Bailey	Register and ventilator, plates for	Design.
7312	Ulam, David	Smut machines	XIII.
7093	Ulmann, Solomon B.	Castors for furniture	XVII.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7465	Underwood, John	Presses, cheese, self-acting	XII.
7466	Upfield, William	Boot-trees	XVI.
7330	Van Anden, William	Chairs, machine for making wrought iron railroad	IX.
7586	Van Brocklin, John	Bolts, rivets, etc., machine for heading	II.
7094	Vanderhoof, George	Trucks, connecting with car bodies	X.
7331	Van Der Veer, Benj. M.	Rules, board and log	VIII.
	Van Wagoner, Cornelius S.—see William Kennish		
	Viall, Daniel H.—see Grant & Viall.		
7552	Vine, William and James H. Ashmead	Gold, machines for beating	II.
7553	Vogel, Kasimir	Harness, weavers', machinery for dressing	III.
263	Vose, Samuel D.	Stoves	Design.
264	Vose, Samuel D.	Stoves	Design.
265	Vose, Samuel D.	Stoves	Design.
7761	Vrooman, Henry S.	Emery wheels, clamps for girding	XXII.
277	Wager, James	Stoves	Design.
293	Wager, James, David Pratt and Volney Richmond	Stoves	Design.
7226	Wales, Gideon	Tobacco, method of dressing cut	XXII.
7109	Wakefield, Charles A.	Planting barrows, seed	I.
7110	Wakefield, Charles A.	Planters, seed	I.
7862	Walker, Joseph N.	Mills for grinding	XIII.
	Walker, Robert—see Welch & Walker.		
7554	Walker, William and Matthew C.	Churn dashers	I.
7354	Walter, Amos	Stone, machine for polishing	XV.
	Ward, Gilbert S.—see Daniel W. Goble.		
7538	Ward, William E.	Bolt and rivet machine	II.
	Warfield, Henry—see Goddard & Warfield.		
7863	Waring George E.	Furnaces, hot air	V.
	Warner, A. B.—see Jas. G. Davis.		
7332	Warner, Chapman	Pipe coupling	XI.
7372	Warner, James N.	Stove pipes, joints of	V.
7762	Warner, Ezra J.	Hooks and eyes, fastening upon cards	XXI.
7709	Warner, Orra and Charles J. Gaylord	Grapple spring	XXII.
	Warner, R. F.—see Archer & Warner.		
276	Warnick, Charles W., F. Leibrandt, J. G. Abbott and A. Lawrence	Furnace, portable	Design.
312	Warnick, Charles W	Stoves	Design.
7404	Warren, A. G.	Sofa bedsteads	XVII.
7640	Warren, David	Plough cleaner	I.
	Warren, George—see Green & Warren.		
	Warren, George—see Green & Warren.		
7539	Warren, Thos. E.	Car seat backs	X.
7710	Washburn, Nathan	Wheels, cast iron car	X.

ALPHABETICAL LIST—CONTINUED.

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7129	Waterman, Nathaniel	Coffee, apparatus for making	XVII.
7467	Watkins, Miles S.	Carriages	X.
7725	Watson William	Harvester, maize	I.
7062	Webb, Joseph W., assignor to Benjamin Gould	Mills for grinding	XIII.
7711	Webb, Joseph W., assignor to Benjamin Gould	Straw cutters, adjustment of knives in	I.
7112	Webster, John G., assignor to John W. Robertson and John G. Webster	Cloth, measuring on looms	III.
	Webster, William—see Ostrander & Webster.		
	Weeks, Ebenezer—see Crafts & Weeks.		
7405	Weidman, John	Fanning mills	I.
7031	Weikart, Andrew	Boring machines	XIV.
7009	Welch, Augustus and Robert Walker	Shingles, machinery for dressing	XIV.
7626	Welch, Benjamin	Splints, surgeons'	XX.
7177	Welch, William T., Jr.	Brakes for carriages	X.
7042	Welsh, George	Shutters, window, chain and flange apparatus for opening and closing	II.
7692	Wescott, Amos	Door spring	II.
7095	West, Solomon and Hiram Plumb	Umbrella sticks, &c., machinery for turning	XIV.
7406	Westbrook, C. and Henry J. Rogers	Telegraphs, electro-chemical	VIII.
	Weston, Adan—see Chase, Weston & Babbit.		
	Wheeler, Russel—see Bailey & Wheeler.		
7130	Whipple, Cullen, ass'or to Jesse Carpenter	Yarn, machinery for spinning and making rope	III.
165	Whipple, Cullen, ass'or to Alexander Hodges, agent of the New England Screw Company	Screws, wood, machine for cutting the threads of	Re-issue.
7458	Whipple, John A. and William B. Jones	Photographic pictures, producing upon transparent media	XVIII.
7390	White, J. D.	Lathes for turning	XIV.
7555	White, James	Stoves, cooking	V.
7828	White, Jesse and Jonathan Bundy	Flour, elevating, cooling and conveying	XIII.
7829	White, Nelson D.	Pill boxes, machines for making	XIV.
7043	White, Stephen	Gases, preparing illuminating	IV.
7540	Whitehead, Jesse	Speeder, counter twist	III.
7152	Whiteley, Edward	Chimney caps	V

NUMBER.	PATENTEES.	INVENTIONS OR DISCOVERIES.	CLASS.
7202	Whitney, Asa	Wheels, cast iron car	X.
7313	Whitman, Shepherd	Brick presses	XV.
7712	Whitmarsh, Samuel	Bedsteads and sacking bottom, portable	XVII.
7314	Whiton, E. F.	Cloth, instruments for measuring	III.
	Whittemore, Thomas J.—see Dexter H. Chamberlain.		
7736	Whittlesey, Austin and Austin K.	Coulters to ploughs, fastenings of	I.
7227	Wicks, Edward	Planter, seed, the seed roller of a	I.
7278	Wilder, Mark	Gudgeons, wing	XIII.
7803	Willcox, Thomas T.	Looms, shuttle motions in	III.
7203	Williams, David R.	Blind slat operator	II.
7178	Williams, Edwin and James Culbertson	Rifles, machine for giving increased twist in cutting	XIX.
7044	Willis, William B.	Planters, seed	I.

II.

INVENTIONS AND CLAIMS

FOR THE YEAR 1850.

No. 6981.—*Improvement in Pen and Pencil Cases.*

Having thus described my invention, I claim the auxiliary interior tube C, in combination with the two outside tubes A and B, in the manner substantially as herein described, and for the purpose set forth.

ALBERT G. BAGLEY.

No. 6982.—*Improvement in combining Grinding and Bolting Machines.*

What I claim as my invention, and desire to secure by letters patent, is the combination of an adjustable grinding mill, with an adjustable bolting machine, both worked on one shaft, and adapted to each other, so that both or either can be adjusted independent of the other, substantially in the manner and for the purposes above made known.

JAMES M. CLARK.

No. 6983.—*Improvement in Instruments for Paring Horses' Hoofs.*

Having thus described the mannner of constructing and using our combined gripe and lever knife for paring the feet of horses for shoeing, what we claim as our invention and desire to secure by letters patent, is the combination of the gripe (A,) arm (E,) and knife (D,) whether made with or without the adjustive plates (G,) and joint pin (B,) or in any way, substantially the same and of any suitable size and material.

ASHLEY CRAFTS.
EBENEZER WEEKS.

No. 6984.—*Improvement in Hemp Brakes.*

What we claim as our invention and desire to secure by letters patent, is the combination of the revolving rollers, with the swords or beaters arranged and operating substantially in the manner herein described.

JONATHAN CRANE.
F. H. HAMILTON.

No. 6985.—*Improvement in Coal Grates.*

What I claim as my invention, and desire to secure by letters patent, is the formation of a revolving cylinder grate, by placing circular grate bars or flanges around a hollow cylinder, a draft of cold air being passed through the said hollow cylinder for the purpose of cooling the same, at the same time making it answer the purpose of a hot air chamber substantially as above described.

CHAUNCY O. GREENE.

No. 6986.—*Improvements in operating Shuttle Boxes in Looms.*

Having thus described our improvements in looms, what we claim therein as new and desire to secure by letters patent is, shifting a series of shuttle boxes substantially as herein set forth by means of a corresponding series of cams, acting through levers, cords or other means, severally brought into action at the required intervals by the pattern wheel face, cam and spring, or other equivalent devices, the whole arranged and operated substantially as described.

ROBERT BURNS GOODYEAR.
BENJAMIN HURST.

No. 6987.—*Improvements in Hemp Scutchers.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the circular back or head, with the inclined knives or scrapers, and the hub and rest, substantially as is herein mentioned.

F. H. HAMILTON.
THOMAS BULLOCK.

No. 6988.—*Improvement in Connections of Brakes with Cars.*

What we claim as our invention is the enclosure of said link or pin in a tube, coating or lining of India Rubber or other elastic substance, and securing said rubber in a box or casing so as to confine the same permanently in such way as to allow the action of the brake or other machinery, without wear or friction, rattling or noise.

JOHN KIMBALL.
HARVEY RICE.

No. 6989.—*Improvement in Washing Machines.*

What I claim as my invention and desire to secure by letters patent, is the combination of a bed of rollers moving at different velocities with a compressor for the purpose of washing, rinsing, and wringing clothes; substantially as herein set forth.

RANSOM MAREAN.

No. 6990.—*Improved Blind and Shutter mover and fastener.*

Having thus fully, clearly, and exactly described the nature and operation of my invention in window blind fasteners; what I claim therein as new and desire to secure by letters patent is, the combination of the finger (e,) and wheels (h) and (l,) with the gravitating catch (j,) its recess (p,) and spring (p',) and hook (n,) for moving, fastening, and unfastening the blind.

WILLIAM MAGUIRE.

No. 6991.—*Improvements in the Wheel and Axle Stump Extractor.*

What I claim as my invention, is the arrangement and combination of the axle or journals of the wheels and the axle or journals of the windlass barrel of a stump extracting machine, substantially in the manner, and with respect to the bed frame and other parts of the machine, as herein before specified and exhibited in the accompanying drawings, the same being for the purpose essentially as above set forth.

JOHN ROGERS.

No. 6992.—*Improvement in Machinery for making Cotton Cordage.*

Having thus fully described our improved machine for making cords or ropes, directly from cotton or other slivers, what we claim therein as our invention, and desire to secure by letters patent, is first, the improved form of the nipper heads E, (shown in figs. 4 and 7,) when the nippers (e,) are combined therewith, by means of the steadying pins q q. projecting from the inner edge of the nippers into guiding holes v, in the nipper heads, and by suitable actuating springs b, b, or their equivalents, substantially as represented and described; by means of which the nippers are prevented from becoming clogged and obstructed in their movements, and from pressing against the slivers, by the accumulation of trashy matter about them.

2nd. In combination with the planetary motion of the series of flyers that receive and twist the cotton slivers, and lay the threads formed thereby into a cord or rope as described, we claim the independently moving and self adjusting compressing forming block c, for giving a round and perfect form to the cord, or rope, (after its component threads have been laid together,) substantially in the manner herein set forth.

FRANKLIN SLAUGHTER.
DAVID PERRY.

No. 6993.—*Improvement in Branding Tools.*

I claim as my invention and desire to secure by letters patent, the combination of the inner with the outer shell, substantially in the manner described, as applied to the branding tool.

LEWIS STARK.

No. 6994.—*Improvement in Printers' Type Cases.*

I confine my claim to grooving the bottoms of type cases for the reception of the lower edges of the partitions and to securing these in them by glue, in the manner herein set forth, or of modes substantially the same.

JOHN BELL.

No. 6995.—*Improvements in Engines operated by Steam and Water.*

What I claim as my invention and desire to secure by letters patent, is the manner of combining steam, and air for the purpose of giving motive power to the wheel B, consisting in a jet of the former being thrown from the nozzle E, of the pipe C, into the pipe F, simultaneously introducing therein a quantity of the latter, which together are discharged through the lower orifice of said pipe F, into the buckets of the wheel, and displacing the water therein, causing said wheel to revolve, *in combination with* the pipe G, through which the hot air is drawn from the top of the box, or reservoir into the pipe F, and reintroduced with the steam into the box at its bottom, thus using it repeatedly over again. The apparatus, by means of which the above is accomplished, is constructed and arranged substantially in the manner described in the foregoing specification.

JAMES BLACK.

No. 6996.—*Improvement in Grain Drills.*

What I claim as new and of my invention, and desire to secure by letters patent is:

First. The rollers *a*, which rollers serve to clear the teeth from rubbish and govern the depth of the teeth.

Second. The spring z, in combination with the sheaves and teeth, by which arrangement the whole or a part of the teeth can be held by a spring of the same power, and range of movement that it would require for a single tooth.

Third. The moveable bar u', to which the team is attached, in combination with the mode of hanging the teeth by means of sheaves or other similar device, by which arrangement the teeth will pass over obstructions in which the action of the team in hauling the drill or cultivator will bring the teeth forward to their proper places as soon as they pass over the obstructions.

And Fourth. The feeding band, substantially in the manner and for the purpose set forth

WILLIAM BULLOCK.

No. 6997.—*Improvement in Cultivators.*

We do not claim to be the original inventors of any of the individual parts of this wheeled, rotary cylindrical cultivator, but what we do claim is the combination of the levers D, rollers A, and driving wheel G, in the manner and for the purpose set forth.

ASHLEY CRAFTS.
EBENEZER WEEKS.

No. 6998.—*Improvement in Cotton Gins.*

I claim the back ribs F, in combination with the front ribs E, they (THE BACK RIBS) being constructed with a horn or projection h, each, behind which they curve downwards, to allow the saws to pass twice between the ribs, to remove the motes, and other impurities, in the manner substantially as described.

JOHN DU BOIS.

No. 6999.—*Improvement in Car Wheels.*

What I claim as my invention and desire to secure by letters patent, in rail-road car wheels, is the combination of the rods which connect the hub and rim with the plate or plates, which also unite the hub and rim, substantially as herein described, whereby the plate or plates, are protected against fracture from any sudden jar, and the hub prevented from being separated from the rim should the plate or plates break, as herein described.

GEORGE W. EDDY.

No. 7000.—*Improvement in Smut Machines.*

What I claim as my invention and desire to secure by letters patent, is constructing the shoe, (having the perforated plate for separating large extraneous matter from the grain) with a screen D^2 for separating the cockle and cheat from the grain, and an imperforated plate D^3 and spout for conducting the same to the outside of the machine as described.

JOS. G. GOSHEN.

No. 7001.—*Improvement in Curing Tobacco Stems.*

What I claim as my invention and desire to secure by letters patent, is the process of curing stem or other parts of tobacco with charcoal, by combining or mixing the two together, substantially in the manner and for the purpose herein set forth.

THOMAS HOYT.

No. 7002.—*Improved Ore Washer.*

What I claim as my invention, and desire to secure by letters patent, is separating substances differing in specific gravity, or washing metallic ores, by means of oblique currents of water, and a horrizontal one passing over the same in a reverse direction, substantially in the manner herein described. The oblique currents being produced by inclined surfaces or their equivalents.

WM. M. HUGHES.

No. 7003.—*Method of counterbalancing Sash by means of a heavy weight.*

What I claim therein as new and desire to secure by letters patent, is counterbalancing the sash, (and consequently enabling it to be suspended at any desired point) by means of metallic racks within the window frame, these racks being operated by pinions rotating on fixed shafts within the window frame, and these pinions being driven by other racks attached to the sides of the sashes throughout their entire length, the whole being constructed and arranged in the manner, and for the purpose set forth.

WILLIAM MAGUIRE.

No. 7004.—*Improvement in connecting cutters to shafts of boring instruments.*

What I do claim as new and for which I desire to secure letters patent, is the fastening, by which the knives *(k & m)* are affixed to the mandrel, being a keyed ring, to sustain the shank of the knives firmly, in adjusting slots in the mandrel, substantially as above described.

LEWIS W. MILLER.

No. 7005.—*Improvement in Coating Iron with Copper or its alloy.*

What I claim as my invention or discovery, and desire to secure by letters patent, is—

First. The before described process of coating and impregnating iron in all useful shapes and forms, with copper or any alloy of which copper forms a part, the said process consisting of cleansing with sulphuric acid, defending the cleansed surface with a coating of clay or other aluminous earth—drying the same, and then plunging the article thus coated into melted copper, or some alloy of that metal.

Second. I also claim the use of the clay paste to protect the metal from oxidating during the process of alloying or coating the metal plates, or pieces of iron, as set forth herein.

E. G. POMEROY.

No. 7006.—*Improvement in Churns.*

What I claim therein as my invention, and desire to secure by letters patent, is the placing the inner surfaces of the series of outer blades a, a, in positions tangential, or nearly so, to their circle of rotation, when they are combined with the inclined inner series of blades b b, substantially in the manner and for the purpose as herein set forth. Not intending, however, to limit myself to the exact number, proportions, positions, and arrangement of the dasher blades, as herein described and represented, but shall vary them to suit the different sizes of churns required for operating upon milk, and for operating upon cream, whilst I attain the same results by means substantially the same as those herein particularly set forth.

Z. C. ROBBINS.

No. 7007.—*Improvements in Machinery for making Cotton Cordage.*

What we claim as our invention, and desire to secure by letters patent, is the constructing the nipper springs of parallel bars *n n*, (one or both of which may be made elastic,) having series of holes (or slots) formed in them for the reception of the connecting, and adjusting screw bolts *s s'*, for the purpose of enabling us to cause the several nippers to press with the same amount of power and elasticity, upon the slivers during their passage through the nipper heads; and also to vary the elasticity of the springs as circumstances may require, substantially as herein set forth.

F. SLAUGHTER.
DAVID PERRY.

No. 7008.—*Improvement in Alloys for Points of Lightning Rods.*

What I claim and desire to secure by letters patent as my invention, is the formation of an alloy, composed of English block tin, oxide of tin, antimony, bismuth, refined silver, platinum, and silex, in proportions as shown in the above specification, and for the purposes of being manufactured into lightning rod points.

JAMES SPRATT.

No. 7009.—*Improvement in Machinery for Dressing Shingles.*

What we claim therein as new, and desire to secure by letters patent, is the combination of two planes, (*c c*,) guided and moving to and fro in the straight converging grooves (*b*) with the spring-plates (*j j*,) in front of the plane-irons for holding the slab, and those (*k k*,) behind the plane-irons for discharging the finished shingle from the machine, the whole being arranged and operating as herein set forth.

AUGUSTUS WELCH.
ROBERT WALKER.

No. 7010.—*Improvement in Machines for Cutting Shingles.*

What I claim as my invention, and desire to secure by letters patent, is the mode of moving the carriage *G*, sideways, and forcing the same toward the knife, alternately, by means of the cams (*k k'*) moving over the grooved shaft *B*, by means of the bar *I*, and groove (*l*) operating on the curved bars *H*, cams (*m m'*) inclined bars (*k*,) bolts *J*, arranged in the tubes (*s*,) and pressed against the notches (*t*) of the slotted bars (*o*) by the spiral springs (*u*,) spring *L*, the whole arranged and operated, substantially in the manner and for the purpose herein set forth.

WILLIAM WOOD.

No. 7011.—*Improvements in Mills for sawing Irregular Forms.*

I claim the mode of raising, and lowering the table or platform G, on the segmental plates or bars H, for adapting the same to any thickness of timber to be cut, and keeping the middle of the timber between its top and bottom, always in a line with the centre, of which the segmental plates or bars H, form arcs of circles, through which (the centre) the saw passes, to prevent it from bending in the timber when sawing a curvilinear surface, by means of the ribs (*h*) having slots (*i*) near their ends, through which the screws (10) which enter the segmental plates or bars H pass, in the manner herein described.

OLIVER WRIGHT.

No. 7012.—*Improvement in Mowing Machines.*

Having thus explained my invention, I claim the master wheel *A*, constructed with cogs on its face, in combination with the rocking shaft *R*, constructed with two knobs or projections N^1, N^2, on it, to give a rocking motion to the said shaft, in the manner substantially as described.

HOMER ADKINS.

No. 7013.—*Improvements in Gates for Fences.*

What I claim as my invention, and desire to secure by letters patent, is the method of balancing and adjusting gates by the panel of fence secured to the gate posts, substantially as herein set forth.

JESSE BAILEY.

No. 7014.—*Improvement in folding Bedsteads.*

What I claim as my invention, and desire to have secured to me by letters patent, is arranging said centre joint with the centre rivet below the other two, in combination with the curving of the adjacent edges of the parts of the side bars, so as to rest upon said centre rivet as described; and also the forming of the inner connecting bar with lateral projections, or shoulders, which when the bedstead is open, shall rest on the top of the two cross bars of the bedstead adjacent to the joint in the side bars of the same, all as herein above set forth.

JOHN BENDER.

No. 7015.—*Improvement in Dampers for cleaning Stove Pipes and regulating the draft in the same.*

What I claim as my invention, and desire to secure by letters patent, is the scraper (F,) with the rods attached in such manner that it may be used for the purpose of cleaning the stove pipe, and also to act as a damper, as set forth in the above specification.

FREDERICK BLEIER.

No. 7016.—*Improvement in Mills for Grinding.*

I claim the employment of a sliding adjustable tube, within, and in combination with the brush of the stationary stone, and the spindle, for the purpose and in the manner, substantially as described.

CHARLES W. BROWN.

No. 7017.—*Improvement in Brick Presses.*

Having thus fully shown the construction and operation of my improvement, what I claim as new and desire to secure by letters patent, is—

First. The arrangement of levers B and C, by which arrangement the bearing of C, is near the fulcrum of B, thereby giving the operator power to start the brick out of the mould, and by which arrangement the motion of the piston is increased by the bearing of C on B.

CHARLES CARNELL.

No. 7018.—*Improvement in Files for keeping Papers.*

Having thus fully described as my invention, what I claim therein as new, and desire to secure by letters patent, is the top (*a*, *b*,) consisting of a stationary part for about half its length, and a lid hinged thereto for the remainder, in conjunction with the end lid (*g*,) and one or more side openings (*f*,) substantially after the manner, and for the purposes described—namely, that of combining with sufficient facility of reference, the greatest attainable dispatch, in the abstraction, and insertion of papers, and moreover constituting when closed, a secure and portable paper holder.

EDWIN D. DODD.

No. 7019.—*Improvement in Obstetrical Supporters.*

Having described the construction and use of our improved spine abdominal obstetrical supporter, what we claim therein as new and for which we solicit letters patent, is—

First. The combination of the back supporter A, feet straps E, E, and adjustive shoulder braces C, constructed as described, with the back pad B, by which the female is enabled to apply the necessary pressure to the back, by the simultaneous or alternate action of the shoulders and feet on the straps connected with the back pad, for relieving the labor and irritation of parturition, without the assistance of any other person, as herein fully set forth.

WM. W. FINCH.
JACOB BLAISDELL.
LEANDER BABBITT.

No. 7020.—*Improvement in Harvesting Machines.*

What I claim in the foregoing as my invention, and desire to secure by letters patent, is the method of cleansing the cutters by giving them at suitable intervals a larger vibration than ordinary, substantially in the manner herein set forth—thus detaching the dirt and gum which accumulates upon them.

J. E. HEATH.

No. 7021.—*Substitute for the Clevis.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the crownhead A, and bolt D, with the upright, by which the plough is made to cut any width and depth desired, made substantially as herein described.

JOHN HOWELL.
WILLIAM D. HOWELL.
JOSEPH SIPE.

No. 7022.—*Improvement in Cider Mills.*

What I claim as my invention, and desire to secure by letters patent, is the particular combination of machinery used for the purpose of grinding and pressing fruits, and juicy substances, viz:

First. The cutter drum A, with its teeth *a*, fig. 2, running into teeth *b*, in bed mould B, used to grind the fruit or juicy substance.

Second. The strap C, fig. 1, made of felting, hair cloth, or other porous fabric, used to carry the pomice, or ground substance between the pressing drums D and E, where it is pressed, and to strain the juice thus expressed.

Third. The press drums D and E, used to press the juice from the pomice, or ground substance.

Fourth. The brush L, used to remove the pomice or ground substance, from the strap C, figs. 1 and 2, all of the above being performed by one application of power and continued rotary motion.

SAMUEL JACKSON.

No. 7023.—*Improved arrangement of the Valves of Hydraulic Engines.*

What I claim as my invention, and desire to secure by letters patent, is arranging four register valves upon one spindle, in such a manner with reference to each other, and their seats, so that the pressure upon any one of them shall be counterbalanced by the pressure upon some other of them, substantially in the manner herein described, for the purpose of regulating the induction and eduction to and from hydraulic engines.

WILLIAM KENNITH.

No. 7024.—*Improvement in Machinery for Tonguing and Grooving.*

What I claim as my invention, and desire to secure by letters patent, is the placing the finishing, grooving, and tonguing cutters *c*, *d*, in the same heads A, B, with the primary grooving, and tonguing cutters *a*, *a*, *a*, and *b*, *b*, *b*, and in reversed positions thereto, when the said cutter heads are connected to operating cranks at one end, and are jointed to working levers *e*, *e'*, at points between the primary grooving, and tonguing cutters, and the finishers, substantially as above described, for the purpose of giving to the said cutters the movements and action herein set forth.

ROBERT KITTLE.

No. 7025.—*Improvement in Buckles.*

What I claim as my improvement, and desire to secure by letters patent, is the mode of making buckles entire from a single piece of sheet metal as above described; the buckle opening and shutting by means of the spring given to it in the construction thereof, as aforesaid.

GEORGE R. KELSEY.

No. 7026.—*Improved Door Lock.*

Having thus fully, clearly, and exactly described the nature and construction of my combination lock, what I claim therein as new, is—

First. The combination of parts forming the key, constructed substantially as described, and represented, viz: the shaft with its slot (*a*,) the slide (*b*,) with its slots (*c*, *c'*,) pins (*d*,) rack (*f*,) jaws (*e*,) pinion (*g*,) and bit (*h*,) with its teeth (*i*).

Second. Constructing the knob with a central opening in its face, closed by a spring disc, for the purpose of introducing these through the semicylindrical spindle (*k*,) with its annular shoulder, and a key such as aforeclaimed, the shank of the knob being hollow, for the purpose of receiving the same.

Third. Arranging the bent lever (*h'*,) that lifts the spring tumbler (*e''*,) so that the key must operate this lever before it can be inserted into the notch (*o'*,) of the compound lever and tumbler (*b'*,) for lifting the same, substantially in the manner as described.

Fourth. Constructing the compound lever and tumbler (*b'*,) with the following characteristics, viz: so that its projection (*n''*,) in combination with the spring lever (*e''*,) prevents the bolt (*f*,) being forced back by pressure on its face, when the bolt has been thrown forward; so that its projection (*o''*,) in combination with the projection (*p'*,) on the latch (*p''*,) prevents the retraction of the same when the bolt (*f*,) is thrown forward; and so that its cam (*a''*,) prevents the spring (*z*,) in the spindle from throwing the catch (*y*,) on the other end of the lever (*x*,) into the cavity (*w*,) on the face of the shank of the knob, so long as the bolt (*f*,) is thrown forward; the knob being thereby permitted to rotate on the spindle when the bolt is thrown forward, and to rotate with the spindle when by the elevation of the compound lever and tumbler, the cam (a'',) is carried below the lever (x); the compound lever and tumbler (b',) being thus combined with the spring tumbler (e'',) the bolt (f',) the latch (p'',) the spindle (k,) through its lever (x,) and the knob (n,) substantially in the manner and for the purposes described.

WILLIAM MAGUIRE.

No. 7027.—*Improvement in Circular Saw Mills.*

What I claim as my invention, and desire to secure by letters patent, is the application to circular saw frames of rocker boxes, and a swing frame as herein set forth, and suspending said frame in position, by means of the driving belt as above described, for the free and successful operation of the saw, by the motion before mentioned.

N. G. NORCROSS.

No. 7028.—*Improvements in Spindles and Bobbins for Spinning.*

What I claim as my invention, and desire to secure by letters patent, is making the life spindle or bobbin tube, with two conical shoulders, substantially as described, in combination with the conical supports in which they run, one or both ends being adjustable, substantially as described.

And finally, I claim the method substantially as described of driving the life spindle by means of a warve tube running on a dead spindle, or a step, and embracing the lower end of the spindle, substantially as described.

JOSIAH G. REED.

No. 7029.—*Improvement in Winnowing Machines.*

Having thus described my improved winnowing machine, what I claim therein as new, and desire to secure by letters patent, is the combination of a series of wind passages (e,) with a separating chamber (D,) or other device for presenting the foul grain to the action of the blast, and a fan (C,) for producing the blast, substantially as herein set forth.

ABRAHAM STRAUB.

No. 7030.—*Improvement in Fastenings for Harness Hames.*

What I claim as my invention, and desire to have secured to me by letters patent, is the combination of the hook lever C, and metallic plate A, secured to the lower end of one of the hames H, for tightening or slacking the connecting strap D, attached to the lower end of the fellow hame H, and for the purpose herein fully set forth, by which the hames may be connected and disconnected instantaneously, by simply moving the hook lever (C,) in the arc of a circle—thus doing away with the troublesome and insecure fastening usually employed to connect the lower ends of hames.

TIMOTHY TAYLOR.

No. 7031.—*Improvement in Boring Machines*

I do not in this application claim to be the original inventor of an adjustive boring machine, to be affixed to the stationary timber to be bored, as I have heretofore patented such a machine, and as various combinations of mechanical devices to produce such a machine have been made and used, but what I do claim as my original invention and desire to secure by letters patent, is the combination of the jointed hook lever N P, pawl X, notched plate M,

perforated flanched plate T, crane C, adjustive clamping block E, with the adjustive stock A, for adjusting and confining the bearings of the boring tool to the timber to be bored in any desired position, for boring holes in the timber at any required angle without moving the timber, as described.

A. WEIKHART.

No. 7032.—*Improvement in Trusses for Hernia.*

What I claim as my invention, and desire to secure by letters patent, is the peculiar bend of the elliptical springs, as described in the foregoing specification, so as to cross them in front and make the spring on one side support the opposite side, thereby giving a better pressure with more ease and comfort to the wearer.

WILLIAM R. BATTLE.

No. 7033.—*Candle Mould Apparatus.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The before described mode of making candles by using the candles previously drawn from the moulds, to hold the wicks for the succeeding candles in the centres of the moulds, until the latter become sufficiently hard to sustain their own wicks as described.

Second. I claim the combination of the frames F, K, recessed candle holders H, I, J,—H′, I′, J′, frames M, M, and spools O[b] containing the continuous wicks N, with the candle moulds D, as described.

Third. I claim the employment of the revolving platform in combination with the hinged moulds, constructed as aforesaid, arranged and operated in the manner and for the purpose herein fully set forth.

Fourth. I also claim the manner of raising the outer end of the spout (Y,) of the vat Q, simultaneously with lowering the gate T, for the purpose of stopping the dripping of the tallow whilst turning the frame of moulds, by combining the spout with the gate by the stirrup roller and lever, as described. I do not however, intend to confine my claim to the precise construction described in the foregoing specification, but to use such a form of construction as may be the best adapted to accomplish the desired object, by means substantially the same. Neither do I claim any portion of the machine above described that has been practised successfully by others, prior to its being invented by myself.

H. CAMP.

No. 7034.—*For an Improvement in Gearing and Ungearing Seeding Apparatus.*

I do not claim the four double lever cog wheels J, or the horizontal level cog wheels F, as my invention, as they have been heretofore used in machinery and are old devices, but what I do claim as my invention and desire to secure by letters patent, are the devices used herein for gearing and ungearing the seeding apparatus, as described.

DAVID EBERLY.

No. 7035.—*Improvement in Bedstead Fastenings.*

My invention consists in giving such forms to the respective portions of the fasteners A, D, that they can be secured to the posts and rails of a bedstead, without making a mortise in either the one or the other, thereby producing a saving of labor in the manufacture of bedsteads; and also producing economy in the use of materials by enabling the posts to be made of smaller size than they are required to be when other forms of fasteners are made use of. Having thus fully described my improved bedstead fastener, what I claim therein as my invention, and desire to secure by letters patent, is the giving the portion D, of the fastener that is secured to the ends of a rail a tubular shape, and such a size that the portion thereof that projects from the end of a rail will embrace the fastening plate A, that is secured to the side of a post, when this arrangement is combined with the lugs *c*, *c*, projecting inwards from the extremity of D, and the notches *e*, *e*, and inclined planes *b*, *b*, on the plate A, substantially as herein set forth, by means of which the respective parts A, D, of the bedstead fastener can be secured to the posts and rails of a bedstead without forming a mortise in either the one or the other.

MATTHEW ELDER.

No. 7036.—*Improvement in the Concave of Cornshellers.*

What I claim as my invention, and desire to secure by letters patent, is—

First. I claim, connecting the opposite sides of the concave, substantially as herein described, whereby they may be moved simultaneously towards or from the cylinder, without changing their relative distances from the same.

Second. I claim the combination of the screen or grate with the punches for freeing its meshes from obstructions, substantially as described.

D. HOATS.

No. 7037.—*Improvement in the Gridiron Slide Valve.*

What I claim as my invention, and desire to have secured to me by letters patent, is the peculiar arrangement of the exhaust mortises or spaces *o*, *o*, *o*, &c., *p*, *p*, *p*, &c., in the sliding valve, *between* and *around* the inducting and educting passages *h*, *h*, &c., *b*, *b*, &c., through said valve, in combination with the elongated side slots or passages *g*, *g*, &c., through the valve seat leading to the exhaust chamber *q*, *q*, the whole arrangement and operation being substantially as herein above set forth.

WILLIAM W. HUBBARD.

No. 7038.—*Improved Tuyere.*

What I claim as new, and of my invention, and desire to secure by letters patent, is placing within a chamber, having numerous apertures at the top, and a discharge valve at the bottom, an upright pipe open at both ends, in the manner described, whereby a blast of the greatest intensity is delivered at the centre of the fire and the vertical pipe may be readily freed from ashes, cinders, &c.

JOHN PAWLEY.

No. 7039.—*Improvement in Portable Furnaces.*

I claim the mode herein described of constructing my portable furnace, viz: with a diving flue, open at the bottom, so as to adapt it readily for use to the boiler holes of cooking stoves, in the manner above specified.

MERRITT F. POTTER.

No. 7040.—*Improvements in Spark Arresters.*

What we claim as our invention, and desire to secure by letters patent, is—

First. The arranging of a series of chambers and channels between two conically shaped plates, the channels being so formed as to cause the products of combustion to impinge against that side of each of the dirt chambers, which has the openings and caps, and thereby force the sparks, dirt, &c. &c., into them, in the manner described herein.

We also claim the combination of the double conical cap or cover for the formation of the second series of dirt chambers, with the pipe (*p*,) the whole being combined and operating substantially as described herein.

JAMES RADLEY.
JOHN W. HUNTER.

No. 7041.—*Improvement in Cases for Daguerreotype Pictures.*

What I claim as my invention, and desire to secure by letters patent, is the new manufacture of daguerreotype cases, to wit: securing the picture in a glass tube or case provided with a magnifying lens, said tube being blackened on part of its inner surface, and admitting the light through another part, to the plate in the manner herein described.

ANN F. STYLES.

No. 7042.—*Chain and Flange Apparatus for opening and closing Window Shutters.*

What I claim as my invention, and desire to secure by letters patent, is the combination of links, and a centre nut with a stationary curved flange, exterior to the chain to guide the links in such a manner, that they may be operated to turn the centre pulley or nut, either by pushing or pulling, as herein described.

I also claim, in combination with the sliding bar and links herein described, the arm *e*, on the centre nut, and the notch *b*, on the *bar* for locking the shutter and taking the pressure off of the links when the bar is pushed in and the shutter fastened, as described.

G. WELSH.

No. 7043.—*Improvement in Preparing Illuminating Gases.*

I claim the method which I have described of producing hydrogen gas, oxide of carbon gas, and light carburetted hydrogen gas combined, freed, or nearly freed, from the presence of carbonic acid gas, by passing the gas evolved by the decomposition of water, through a mass of materials consisting of charcoal, coke, or anthracite coal, in combination with thin iron plates, or iron wires, or iron turnings heated to a high temperature; such compound gas, produced as aforesaid, being combined with heavy carburetted hydrogen gas, produced by the decomposition of resin, oil, fat, or pit-coal, or such other substances as herein before designated, as described. But I do not claim the modes herein described of decomposing the water.

I claim the use of small chains or other similarly connected pieces of metal, as a means of presenting a large amount of iron surface, for decomposing the resin, tar, oil, or fats, or other such substances herein before designated, such chains or other similarly united pieces of metal being so arranged as to expose the vapors disengaged from the above mentioned substances to a multitude of small divided and heated surfaces.

STEPHEN WHITE.

No. 7044.—*Improvement in Seed Planters*

I do not claim the frame, hopper, stirrer, slide, drills, nor any of the parts heretofore used in seeding machines. I only claim as my invention the employment of the flanged, supporting, conveying, cleaning and covering wheels A, made as described in combination with the rest of the machine, when made in the manner as above set forth, for planting cotton and other seeds, and for other purposes.

WM. B. WILLIS.

No. 7045.—*Improvement in Chucks for Boring and Mortising Machines.*

What I claim in the before described machine for mortising and turning, as my invention and desire to secure by letters patent, is the self-centering chuck, constructed substantially as herein set forth.

ELI K. WISELL.

No. 7046.—*Improvement in Atmospheric Churns.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the inverted vessel (H,) and the disc (*i*,) on the stem of the dasher to prevent the splashing out of the cream at the churn lid.

JOHN YOUNG.

No. 7047.—*Improvement in the Cotton Press.*

I claim the pully F, with its axis S, eccentric to its centre, in combination with the stock or follower of the pressure block D, to compress cotton, &c., in the bale box, in the manner substantially as herein represented and described.

A. D. BROWN

No. 7048.—*Improvement in Brick Presses.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the crank K, chain *n*, and oscillating frame or carriage J, with the stationary bed of rollers *c*, *c*. the whole being arranged and operated as herein described, for the purpose of supporting the moulds while being filled and pressed, striking the bricks and then pushing the moulds out of the machine.

JOHN BUTLER.

No. 7049.—*Improvement in Wash Mixtures.*

Having thus fully set forth my improved compound and its operation, I wish it to be understood, that I do not claim any of the ingredients contained therein, when employed separately, as they have long been known, but what I do claim as my invention and for which I desire to secure letters patent, is the above described compound consisting of soap and ley, pearlash, or soda with ammonia, and spirits of turpentine in the proportions, substantially as herein set forth.

S. CRANE.

No. 7050.—*Improvement in Utero-Vaginal Supporters.*

Having described my invention, I will now state what I claim as new and desire to secure by letters patent.

First. I claim the combination of the elevating levers *E*, *E*, with the tube *A*, made of any material, and the mode of raising and spreading the said elevating levers by the screw F, with its conical groove as herein described, or in any way, substantially the same.

Second. I further claim the capsule *H*, distended by the sponge *G*, introduced through the tube A, for the purpose of supporting the uterus and vagina, in the manner herein set forth.

RUSSELL CAULKINS.

No. 7051.—*Improvement in Steam Boiler Furnaces.*

Having thus described the several improvements I have made in the construction, and arrangement of my steam boiler furnace, and the steam blower therefor, for the purpose of economizing fuel by rendering its combustion more perfect, and by reclaiming a portion of the waste heat of the flues and exhaust steam, what I claim therein as new and desire to secure by letters patent, is the injection of whirling jets of highly heated steam among the gases evolved by the fuel on the grate, simultaneously with the forcing by the steam blower of a stream of mingled steam and heated air through the ash-pit into the fire; the air being heated, substantially in the manner described by the exhaust steam and waste heat of the flues, and the draught of the flues being maintained by whirling jets of steam injected by the steam blower.

BENJ. CRAWFORD.

No. 7052.—*Manufacture of Illuminating Gas from Bitumen.*

What I claim as my invention, and desire to secure by letters patent, is the use of compact and fluid bitumen, asphaltum, chapapote, or mineral pitch for the production of illuminating gas, to be substituted for other materials now in use. I also claim the retort B, B, in combination with its movable case C, in the manner and for the purposes set forth.

ABRAHAM GESNER.

No. 7053.—*Preparation of Animal and other Manure.*

I am aware that sulphuric acid has been employed as a manure alone, and also to decompose bones for the purpose of procuring super phosphate of lime to be used as a manure; these applications of it I therefore do not claim.

What I do claim as my invention, and desire to secure by letters patent, is the use of the mineral acids to act upon the soft parts of animals, or upon azotous vegetable matter, at temperatures varying according to circumstances, as herein set forth for producing a concentrated manure.

Second. I also claim the combination of the mineral acids with the different salts as described, for modifying the antiseptic action of the acids on azotous materials, and for rendering them pulverulent, whether said azotous materials be animal or vegetable.

Third. I also claim the combination of the mineral acids with wood tar, coal tar, or their equivalents, in the manner and for the purposes herein set forth.

ROBT. HARE.

No. 7054.—*Improvement in Apparatus for Heating Air by Hot Water.*

Having thus fully described my improved apparatus, what I claim therein as new, and for which I desire to secure letters patent, is the peculiar construction and arrangement of the heating apparatus by uniting the series of straight horizontal pipes into gangs by vertical end pieces C, through which the circulating water is conveyed to all the pipes in the gang, in combination with the union boxes D, D', the series of gangs forming the cluster being united at one end at the top of the end pieces by the union box D, and at the opposite end, at the bottom by a similar box D', through which the water circulates to all the pipes, by means of a flow and return pipe, connected with the boiler or heater at the furnace, as herein clearly specified.

ADRIAN JANES.

No. 7055.—*Improvement in Self-waiting Tables.*

Having thus fully described the nature of my invention, what I claim therein as new and desire to secure by letters patent, is arranging and operating a dumb-waiter and fan, so as to cause them to be self-acting, substantially in the manner and for the purpose described.

JOSIAH LAMB.

No. 7056.—*Expansion Gear for Puppet Valves.*

Having now described my invention, I will state what I claim and desire to secure by letters patent. What I claim therefore, is the use and employment of the connecting rod I, acted upon by two eccentrics in combination with the reciprocating plate H, and arm K, having an angular opening in it, and quadrant shaped plate J', or its mechanical equivalent attached thereto, for the purpose of working puppet-valves in form and manner, substantially as herein set forth.

THOMAS McLAUGHLIN.

No. 7057.—*Composition for the Manufacture of Sugar.*

That which I claim as my invention, and that which I desire to have secured to me by letters patent, is the *mutisme*, or process of treating saccharine solutions by means of a solution of acid sulphite of lime, baryta or stronitia as herein before described, applied to products containing sugar from the cane or other vegetables, that the crystallizable sugar may undergo no chemical change either by the formation of secondary products which destroy it, or by the generation of ferments which modify or transform it.

MELSENS.

No. 7058.—*Improvement in Driving Bobbins upon Spindles.*

What therefore I claim as my invention, is the counter-sunk friction button, made substantially as specified, or in other words the combination of the friction annulus with the enclosed space for the reception of dirt and extraneous matter, when used in connection with the spindle and bobbin, substantially as specified.

OLIVER PEARL.

No. 7059.—*Improvement in Gearing for Sugar Cane Mills.*

I do not lay claim to the general arrangement, by which a heavy horizontal wheel is made to traverse on friction rollers. This I am aware, has often been done, when such wheel was fixed to its vertical axis, by permanent arms, especially for the purpose of enabling the wheel to support heavy weights, as in the common turn tables of railroad stations.

But in such cases there is no strain or vibration primarily given to the vertical shaft, as is the case of the cane mill, having one of its rolls on the vertical shaft which is to be driven by the heavy face wheel.

But what I do claim as my invention, and desire to secure by letters patent, is the wheel A, revolving horizontally in combination with the jointed or loose braces *b*, *b*, *b*, *b*, connecting, but not fastening it to the shaft S, and with the fixed arm D, the vertical grooves *g*, *g*, and the friction rollers *i*, *i*, acting together, substantially in the manner and for the purposes herein set forth, not limiting myself in these claims to the exact number and arrangement of the several parts herein described, but varying the same at pleasure, while I attain the same ends by means substantially the same.

EDWARD PHELPS

No. 7060.—*Method of Sinking Hollow Piles, &c., by exhausting the Air from the Interior of the same.*

Having described what I consider as generally the most attainable means for producing the required effects, I do not intend to limit myself thereto, but to use any known mechanical means that may be best adapted to any particular circumstances, as I hereby disclaim any invention of the parts employed, irrespective of the manner in which they are to be used for any of these purposes.

What I claim as new, and of my own invention of improvements in the mode of sinking piles, tubes, caissons, shafts and other structures, and which I desire to secure by letters patent of the United States, consists in the attenuation of the air approaching to, or forming a vacuum in the interior of a hollow pile, tube, caisson, shaft, or other structure, by any of the known means of producing what is termed "suction," by which the hollow pile, tube, shaft, or other structure, is made to descend as before described.

L. H. POTTS.

No. 7061.—*Improvement in Looms for Piled Fabrics.*

We do not wish to confine ourselves to the precise mechanical arrangements herein specified for operating or shifting the picker tappets, although we have essayed it with success, and deem it the best; but other arrangements may be devised for carrying this part of our invention into effect.

As to the third part of our invention, any desired known means of regulating the friction of the fly-wheel on the shaft may be substituted for the temper screws herein above described, as the means of regulating the friction is not of the substance of our invention; nor is it essential to our invention, that the friction be adjustable, although we deem it advisable to have it so. In the adjustable mode of throwing back the shuttle staffs, we do not wish to confine ourselves to the use of a nut, to regulate the tension of the helical spring, as other mechanical equivalents may be substituted therefor—such as a wedge in a slot; but we have described and represented the nut as the most advantageous in our estimation.

In relation to the fifth part of our invention, we do not wish to limit ourselves to the number of rollers, nor to the mode of making friction on the rollers, over which the warps pass, as our invention is irrespective of these.

We do not wish to limit ourselves to the precise arrangement above described, for connecting the ratchet wheel of the take up motion with the roller, as this may be varied at pleasure, without affecting the mode of operation of this part of our invention.

And finally, with regard to the last part of our invention, we do not wish to be limited to the precise direction, in which the thread is carried from the eye near the end of the shuttle, to the delivering eye, near the middle of the length thereof, as this may be slightly varied, and still retain the character of this part of our invention.

What we claim as our invention, and desire to secure by letters patent, is—

First. Dividing the heddles into two or more divisions to be worked in succession, substantially as herein described, that the entire opening of the shed may be effected in succession, and thus avoid the evil effects consequent on the opening of the shed, at one operation, as heretofore described.

Second. Operating the two picker levers or treddles, by means of a shifting tappet operated or shifted alternately for each pick by means of an eccentric or its equivalent, that the shaft which carries the tappet or tappets, may make one entire rotation for each throw of the shuttle, substantially as herein described, and thus operating the shuttle by a tappet rotating with greater velocity than by any means heretofore known, as described.

JAMES TURNBULL, Jr.
JOHN TURNBULL.

No. 7062.—*Improvement in Mills for Grinding.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the cone screws as above described, with the beaters or rubbers on the cylinder, substantially as described.

JOSEPH W. WEBB.

No. 7063.—*Improvements in Flour Bolts.*

We do not claim to be the original and first inventors of bolts for bolting the flour, or of any of the several parts of the bolting apparatus that have heretofore been used for that purpose in the ordinary modes, but what we do claim as our invention, and desire to secure by letters patent, is—

The combination of the revolving wire screens with the ordinary bolts, whether stationary or revolving, for bolting flour, by which the larger particles of bran and extraneous substances that may chance to pass into the bolts with the meal are separated therefrom by the said wire screens, and are thus prevented from coming in contact with the bolting cloth, whilst the wings drive the flour through the screens and bolting cloth, by the combined action of centrifugal force and currents of air produced by the rotary motion of said wings, by which the advantages stated in the foregoing specification are obtained.

JOHN M. REED.
WM. B. WILLIS.

No. 7064.—*Improvement in Machinery for Spooling.*

Having thus described fully the material parts of the machine in which my improvements are introduced, and also those improvements, what I claim as my invention, and desire to secure by letters patent, is not the abstract production of friction between the thread or yarn, and any other substance, as the thread or yarn passes from the runners to the bobbin or spool, so as to secure the winding of the thread or yarn, tightly on the bobbin or spool; but I do claim as my invention, and desire to secure by letters patent, the combination of machinery herein before described, whereby in machines for winding yarns or threads on bobbins or spools, the thread or yarn on its passage from the runners to the bobbin or spool, has applied to it friction produced between the thread or yarn, and any other substance, which friction diminishes with uniformity as the pull upon the thread or yarn from the runners increases, and increases with uniformity, as the pull upon the thread or yarn from the runners diminishes—such combination consisting, as shown in the accompanying drawing, of the vibrating lever M, M, the stand L, L', the joint L', the three pins N, O, P, the four pins H, I, J, K, the box G, G, the spiral spring Q, any one of the three hooks S, T, U, the staple at R, and the guide W, substantially as herein set forth.

AVERY BABBETT.

No. 7065.—*Improvement in Carding Machines for preparing Bats for Felting.*

Having thus fully described my invention, I would state that I do not claim the producing an interlocking of the fibres of wool, by means of a reciprocating longitudinal movement of either the carding cylinders of a carding machine working against the doffer.

But what I do claim as my invention, and desire to secure by letters patent, is the production of the requisite interlocking combination of the fibres of wool, preparatory to converting the same into felt cloth, by subjecting the said fibres to a rubbing or combing action, while they are upon the doffer of a carding machine, by means of auxiliary cards, or other suitable friction surfaces, substantially as herein set forth; not intending by this claim, however, to limit myself to the special and particular manner of producing the said interlocking of the fibres of wool, while they are upon the carding machine doffer, as herein set forth.

SAMUEL G. BLACKMAN.

No. 7066.—*Preparation of Portable Soup Bread.*

Having thus explained my invention, I do not claim the extract of flesh made into what is known as portable soup; but I claim the new and useful manufacture of desicated soup bread, formed of the concentrated extract of alimentary animal substances, combined with vegetable flour or meal, made into cakes and baked into bread, in the manner, substantially as herein described, for the purpose set forth.

G. BORDEN, Jr.

No. 7067.—*Improved Excavating Auger.*

What I claim as my invention, and desire to secure by letters patent, is the formation of a machine or instrument, for boring the earth under water, or otherwise, and retaining the substance bored until it can be brought to the surface, which I construct in the manner following: I first make two sections of a cylinder, or pods, the one of which is enough smaller than the other to admit its turning into the larger one, and I connect them together by pivots through the ends of each, the larger section of a cylinder or pod having a lip similar to a pod auger, and I attach a shaft or handle firmly to the upper pivot, which pivot passes through the centre of the outer section of a cylinder or pod, and is attached firmly to the smaller section of a cylinder or pod, so that by turning the shaft one way, I put it into a pod auger shape ready for boring. By reversing the motion of the handle or shaft it turns the inner section of a cylinder out of the other, making it into a cylindrical or bucket shape, and thereby secure the substance bored.

JAMES BUCK.

No. 7068.—*Improvement in Whip Lashes.*

What we claim as our invention, and desire to secure by letters patent, is a new manufacture for whip lashes, by making plaited whip lashes of spun and twisted threads or cords, as described, instead of leather thongs, the same being plaited over a central cord or core, extending the whole length as described, and a swell made of cotton, or other soft and pliable cloth attached to the central core, without rolling, substantially as described.

DAVID N. DAY.
EDWARD B. DAY.

No. 7069.—*Improvement in Machines for Cutting Staves.*

What I claim as my invention, and desire to secure by letters patent, is the mode of cutting staves to the required curvature, with a spiral drawing stroke, by means of the segmental plate *D*, having bar or ribs (*e*,) at its ends, to which the knife *f*, is attached, segmental rims *C*, moving in the segmental slots *B*, formed in the side plates *A*, and containing slots through which the segmental plates *D*, move spiral slots *E*, in the plates *D*, and bars (*g*,) passing through the same, substantially as herein set forth.

CHARLES B. HUTCHINSON.

No. 7070.—*Improvement in Washing Machines.*

I do not claim the tub, nor do I claim fluted rubbers for cleaning clothes, or any of the parts heretofore used for washing clothes; but what I do claim, is making the disc, with a hinged segment, to admit the clothes beneath the same, being so arranged as to rise and fall vertically, as it is turned horizontally over the clothes, by turning the vertical rock shaft to the right and left, as described.

JOEL HAINES.

No. 7071.—*Improved Friction Roller Sash Supporters.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the loose roller, spring and friction wheel, applied to the window sash, as herein set forth, whereby the sash is held in any position to which it may be raised.

JOSEPH MAYNARD.

No. 7072.—*Improvement in Engines for Carding and Drawing Wool.*

First. Having thus explained our invention, we claim the combination of what is termed the main or condensing cylinder, with the reciprocating rod F, to give the carding cylinder a reciprocating side-to-side motion, in combination with its rotary motion, in the manner substantially as herein described, or in any other manner, substantially the same, to produce the same effects.

Second. We claim the combination of a twisting band and drawing rolls, with rub rolls of the common construction, for the purpose of reducing roping, by drawing it with twist upon the carding machine in the manner substantially as herein described, or in any other analogous manner.

CHARLES JACKSON.
JAMES MOIR.

No. 7073.—*Improved method of Punching between Rollers.*

Having thus fully described my improvements, in the preparation of iron

plates for boilers, what I claim therein as new, and for which I desire to secure letters patent, is the apparatus for the purpose of punching, consisting of a series of punches thrown out at proper intervals, substantially as above described, either with or without the combined operation of corrugating said plates as above described.

R. MONTGOMERY.

No. 7074.—*Improvement in Calculating Machines*

What I claim, therefore, as of my own invention, and for which I desire letters patent of the United States, is the making additions of figures, by means of a finger board of keys, each communicating a proper and known motion to an indicator, substantially in the manner and for the purposes herein described.

DUBOIS D. PARMALEE.

No. 7075.—*Improvement in Water Metres.*

Having thus fully described my improved machine for measuring water in its passage through pipes; what I claim therein as new, and for which I desire to secure letters patent, is the employment of a flat spring (*e*,) with both sides of which the water as it enters communicates, substantially in the manner and for the purposes set forth, in combination with the wings, with an adjusting spring in the centre, by means of which improvements I relieve the apparatus from danger arising from obstruction in its movement, and the strain caused by the transmission of a non-elastic fluid, and cause it to move with less friction than any other form with which I am acquainted.

WILLIAM SEWELL, Jr.

No. 7076.—*Improvement in Attachments for Lightning Conductors.*

What I claim herein as new, and of my invention, and desire to secure by letters patent, is forming the eye of the metallic attachment with an opening (*c, c*,) to allow the passage of a lug (*a*,) on the neck of the isolator, and so that the rod also can be inserted, after the attachment is secured to its place, when this is combined with a lug on the shank of the attachment, corresponding to that on the isolator, substantially after the manner and for the purposes herein set forth, that is to say, enabling the rod at any time to be inserted or withdrawn, without disturbing the attachment in the building.

JAMES SPRATT.

No. 7077.—*Improvement in Barrel Machinery.*

I claim as my invention in the stave cutter, and desire to secure by letters patent, the eccentric groove and cap, extending over or around the shaft to the side opposite the knife, the said cap constituting a part of the eccentric cam ring passing around the shaft, and having an opening through the said cam ring at the posterior termination of the cap, where the staves make their exit. And I also claim the whirl or secondary shaft, as described in combination therewith. I claim as my invention, the right and left stave holders, in the jointer, having flanges or thumb pieces to support the edge of the stave during the operation of jointing, and to ensure an equal width at each end.

I also claim as my invention, the horizontal jointer, in combination with an inside and an outside frame, to which the right and left stave holders are attached by hinges, and by which arrangement four or more boys may work

120 Ex. Doc. No. 32

Ex. Doc. No. 32 121

around one horizontal wheel or jointer, and operate simultaneously, being also thereby enabled to joint the staves with the grain of the wood, without loss of time.

I claim as my invention, the moveable centre in the head machine, in connection with the opposite face plate on an universal joint, between which the head block is held before it is brought in contact with the rubber of the face of the chuck, and the slide which holds the chissels, constructed substantially in the manner set forth.

I claim as my invention, the combination of the cutter (*c*,) with the jointed spring cutter (*g*,) and levers (*b*, *b*,) in fig. 6, for cutting the locks in wooden hoops, substantially as herein before described.

SOLOMON ANDREWS.

No. 7078.—*Machine for Cutting Cotton Stalks in the Field.*

What I claim as my invention, and desire to secure by letters patent, is the adaptation of iron and steel knives or cutters, to the cutting down, and cutting to pieces of cotton stalks, either in a green or dry state, in the manner and for the purpose above described.

FIELDS BRADSHAW.

No. 7079.—*Improvements in Machinery for Folding Cloth.*

What we claim as our invention, and desire to secure by letters patent, is the mode of folding and laying the cloth on the table or platform B, kept in a state of equilibrium by the weight (*h*,) wheel (*e*,) chain (*d*,) and rod (*g*,) by means of the notched bars (*l*, *l'*,) attached to the radial rods (*k*, *k'*,) secured to the shafts E, E, combs (*j*, *j'*,) attached to the shafts D, D', segmental plates G, G, bent bars (*p*, *p*;) and H, H', arms J, J', horizontal and inclined connecting rods or bars (*r*, *s*,) slotted arm or crank (*t*,) constructed, combined, arranged and operated, as herein set forth.

AUGUSTUS C. CAREY.
DANIEL C. BAGLEY.

No. 7080.—*Improvement in Rule and Socket Joints.*

What I claim as my invention, and desire to secure by letters patent, is the application to the rule joint, and to the ball and socket joint of the rod D, which is hinged into the ball or rule joint, to hold the joint as firm as desired, by means of the spiral spring G, on the India rubber spring P, as described.

CHARLES CHINNOCK.

No. 7081.—*Improvements in Arrangements of Fliers and Spindles.*

What I claim as my invention, and desire to secure by letters patent, is the manner of suspending the flier, separate from the spindle, by the flier being connected to, and forming a part of the tube (E,) the lower end of which revolves in a socket bearing, allowing the spindle of the bobbin to pass and move through it without touching it, so that however great the speed of the flier may be, it will be prevented from vibrating the spindle.

JOHN DERMOND.

No. 7082.—*Improvement in Air-Heating Furnaces.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of my improvements in air-heating and steam infusing apparatus, for warming and keeping moist the atmosphere in apartments, what I claim therein as new, and desire to secure by letters patent, is constructing a furnace for heating air, with a spiral flue passing up between concentric cylinders, when this is combined with a conical roof to the furnace within the inner concentric cylinders, thus obtaining the most extensive radiating surface within the least space, and in the most compact and simple form.

HENRY ADOLPH ENGLES.

No. 7083.—*Improvement in Augers for Boring Machines.*

What I claim as my invention, and desire to secure by letters patent, is making the pod of an auger separate from the stem on which it is revolved, with a considerably greater velocity than the cutting bit, substantially as herein set forth.

GEORGE FLAUTT.

No. 7084.—*Improvement in Horse Rakes.*

What I claim as my invention, and desire to secure by letters patent, is the method of working the rake head, by means of the treadle (*g*,) in combination with the hand bars (*t*, *t*,) and the back piece A, *a*, as described.

I also claim the attachment of the stilts to the thills—(1,) in the manner and for the purpose described; all of which gearing being so arranged that a person on his seat, may change and discharge, or suspend the rake head at pleasure, as herein set forth.

ALVAN HOVEY.

No. 7085.—*Improvement in Hanging Carriage Bodies.*

Having thus fully described my improvement, what I claim therein as new, and for which I desire to secure letters patent, is the combination of cross reaches and springs, substantially in the manner and for the purpose set forth.

M. G. HUBBARD.

No. 7086.—*Improvement in Railroad Trucks.*

Having thus described my improvements in railroad cars, and other carriages, what I claim therein as new, and desire to secure by letters patent, is the combination of an endless track on the frame of the carriage, with an endless series of rollers running thereon, and guided by flanges, the endless track being supported on the peripheries of the rollers which intervene in endless succession between it and the surface of the ground or rail, and which are broad enough to keep themselves erect and steady without the use of axles or rods, extending across the carriage.

JAMES INGERSOLL.

No. 7087.—*Improvements in Planing Machines.*

What I claim as my invention, is the combination of the rotary planing cylinder E, and the rest *f*, with mechanism, by which the two can be freely moved up or down simultaneously, and independently of the bed or platform B, B', or any analogous device, substantially in the manner and for the purpose of reducing a board to equal thickness throughout its length, all as herein before specified.

I also claim the above described improvement of making the under side of the rest concave, in combination with so extending the part B, under the rest *f*, and applying it to the concave part thereof, as to cause the board, as it passes across the rest to be bent, and presented with a concave surface to the operation of the rotary cutter planing cylinder, substantially as specified, the same being for the purpose herein before mentioned.

NICHOLAS G. NORCROSS.

No. 7088.—*Improvement in Bedclothes Clasps.*

What I claim as my invention, and desire to secure by letters patent, is the use of the cam and lever *e*, *e*, acting on the spring *b*, to constitute a clasp, in the manner and for the purpose set forth.

FRANCIS A. ROCKWELL.

No. 7089.—*Improvement in Tanning Apparatus.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Revolving the tanning cylinders alternately in opposite directions, substantially as herein set forth.

Second. Handling the hides in the spent liquor from the tan vats E, substantially in the manner herein set forth.

Third. Liming hides or skins in a close revolving cylinder, substantially as herein set forth.

W. H. ROSENSTEEL.

No. 7090.—*Improvement in Smut Machines.*

Having thus described, and represented the construction, and operation of my new and improved smut machine, for cleaning grain, what I claim therein as new, and desire to secure by letters patent, is—

First. The grates (B, B,) in the top of the machine, in combination with the scrolls or spiral chambers A, A, and spouts C, C, for discharging smut and other light materials carried up by the blast, as set forth.

Second. I claim the chamber I, at the bottom of the cylinder which concentrates and gives free discharge to all foreign matter, to be separated from the grain by the blast in the last stage of operation of the machine, in the manner described and represented.

Third. I claim in combination with the concave bottom which gathers the grain for its discharge from the machine, the distributors *j*, *j*, fig. 6, which gives direction in the discharge of the grain separated from the foreign matter by the blast.

Fourth. I claim the draft floats *h*, *h*, *h*, *h*, fig. 5, in combination with the scouring surfaces *f*, *f*, for cleaning buckwheat, as set forth.

The whole being constructed, arranged, and operating, substantially in the manner and for the purpose set forth as made known.

LEONARD SMITH.

No. 7091.—*Improved Method of Bolting in Window Shutter Openers and Fasteners.*

Having thus fully described the nature, construction, and operation of my invention, what I claim therein as new, and desire to secure by letters patent, is fastening the window blind at any suitable point by means of bolts projecting on opposite sides of the pintle of the hinge by a driver, the bolts and driver being suitably guided, and the bolts passing into suitable notches on a plate attached to the blind or to the upper leaf of the hinge, thus not only retaining the blind in any desired position, but also at the same time relieving the pintle of the hinge from any strain athwart its axis, the whole being arranged substantially in the manner and for the purposes described.

S. B. SNEDEKER.

No. 7092.—*Improvement in Electric Telegraph.*

Having thus described my invention, and exemplified the manner in which it may be carried into effect, what I claim therein as new, and desire to secure by letters patent, is the making of signals or marks for telegraphic purposes, by the agency of the heat generated, induced, or controlled, by a current of electricity passed along attenuated conductors, wires or points, substantially as herein set forth. The signals being the flashes of light emitted by the heated conductor or points are manifest to the eye of the operator.

The marks being produced on the paper by the heated points or conductor are the record of the message.

WM. S. THOMAS.

No. 7093.—*Improvement in Castors for Furniture.*

What I claim and desire to secure by letters patent, is neither the ball, the socket, the vertical pivot, or either of the pivots of the ball, but the combination of the whole as above, substantially specified, whereby the ball of the castor is enabled to revolve across the two centres of the two axes of the ball, as set forth.

SOLOMON BERNHARD ULMANN.

No. 7094.—*Improvement in Connecting Trucks with Car Bodies.*

What I claim as my invention, and desire to secure by letters patent, is the mode of attaching car bodies to trucks by means of the trough A, (with the sloat *c*, and king bolt F,) and the rail B, constituting the segment traverse, as above described.

GEORGE VANDERHOOF.

No. 7095.—*Improvements in Machinery for Turning Umbrella Sticks, &c.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the hollow shaft or cylinder F, graduating cutters or knives L, made and ground exactly alike, and arranged on opposite sides of said shaft or cylinder, and cutting inward and in exact unison with each other, the feeding rollers O, arranged in front, and the receiver or carriage K, arranged in the rear of the shaft F, together with the case U, surrounding the cutters and wings (*d*,) for enabling them to act as a fan or blower to discharge the shavings; the whole being arranged and operated, substantially as herein set forth.

SOLOMON WEST.
HIRAM PLUMB.

No. 7096.—*Improvement in Studs for Shirt Bosoms.*

Having thus described the construction and operation of my improved fastening for shirt-studs, what I claim therein as new, and desire to secure by letters patent, is constructing the shank in two sections, the first being fixed to, and projecting from the back of the stud, and the other being hinged to the first in such a manner that it can be brought in line with it or be turned across it, as herein set forth, but I make no claim to the mere fastening of a stud, by means of a cross bar attached to a chain or other similar arrangement.

JAMES P. HEISS.

No. 7097.—*Improvement in Elevating and Lowering Carriage Tops.*

What I claim as my invention, and desire to secure by letters patent, is connecting a handle, lever, or any analogous device upon the inside of carriage tops, with joints or jointed braces upon the outside of the same, substantially in the manner and for the purpose set forth above.

JOHN L. ALLEN.

No. 7098.—*Adjustable Rollers for Window Curtains.*

I do not claim the confining the end of a curtain or piece of cloth, to a roller by means of a groove, and a strip of wood or other substance, placed and fastened therein, as I am well aware that such is not new; but what I do claim, is my improvement in the construction of the curtain roller, whereby I do not only attain all the advantages of securing cloth to it by the groove and strip, but am enabled to regulate or adapt the roller to any window of any ordinary width; my said improvement consisting in making the curtain roller and its guide heads in two parts, in such manner that the grooved section of the roller, and one head shall be united together and form a separate part, while the other section or tongue and the other head, shall also be united and constitute another part, the two parts being so applied, that when put together the tongue may be slid or fitted endwise into the groove in manner described, such a combination of the heads and groove, and tongue sections, enabling me to cut each section to the length required, and to readily adapt the roller to a window.

EDWARD S. CLARK.

No. 7099.—*Improvement in Lids for Boiler-holes of Cooking Stoves.*

Having thus fully described the nature, construction, and operation of our invention, what we claim therein as new, and desire to secure by letters patent, is—

Firstly. So arranging the lid (or centre plate,) in connection with the top plate of the stove, as that the lid, (or centre plate) when withdrawn from the opening, may be made to add its area to, and at the same time lie flush with or below the level of the top of the stove; this being effected by a neck proceeding from the lid (or centre plate,) in the direction of its plane, said neck, (whether the lid or centre plate be closed or folded back,) fitting and filling a notch in the stove top, and having lugs projecting from its sides, which lugs, bearing upwards against the top plate, or against shoulders projecting therefrom, sustain the lid when folded back.

Secondly. The arrangement, substantially as described, of journals on the neck, at or about midway of its length, forming a fulcrum upon which the lid can be folded back, either with its top face, or with its flue face uppermost, the lugs in this case being behind the journals, and midway of the thickness of the neck.

Thirdly. Constructing the lid (or centre plate,) with a handle projecting therefrom in the direction of its plane, and at its coldest point, so as to afford a means of operating the lid by hand, with comparative impunity and facility, and so as to avoid on the one hand any impediment to the shifting of the

cooking utensils, and on the other hand, the usual cavity difficult to mould, liable to collect dirt, and placed unavoidably at the hottest part of the lid.

THOS. G. CLINTON.
GEO. H. KNIGHT.
EDWARD H. KNIGHT

No. 7100.—*Improvements in Raising and Lowering Carriage Tops.*

We do not claim the use of levers or handles upon the inside of carriage tops, connected with the jointed braces upon the outside, for the purpose of working the braces, but all that we claim as of our own invention, and which we desire to have secured to us by letters patent, is connecting the jointed braces upon opposite sides of carriage tops, by means of a shaft (A,) or rod passing back of the seat, in such a manner that the braces may be worked simultaneously upon both sides, substantially as herein described.

SOLOMON GODDARD.
HENRY WARFIELD.

No. 7101.—*Improvement in Locking Portable Safes to the floor.*

What I claim as my invention, and desire to secure by letters patent, is the device for locking down a portable safe or box to the floor, and at the same time locking the box, as described and shown herein.

HENRY HOCHSTRASSER.

No. 7102.—*Improved Process of Varnishing Buttons.*

What I claim as my invention and discovery, and desire to secure by letters patent, is the process of japanning and baking the buttons in bulk, substantially as is herein before described, after they have been prepared for the reception of a smooth coat of japan or other varnish, in the manner specified in my former letters patent, respectively, or in any other method, substantially the same.

ELISHA M. POMEROY.

No. 7103.—*Improvement in Portable Fences.*

What I claim as my invention, and desire to secure by letters patent, is fastening together the panels of portable fences, substantially as herein set forth, by means of binding irons and wedges.

PETER M. PURDY.

No. 7104.—*Improvement in Hulling Clover Seed.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement, and combination of the cylindrical cups R, R, and D, D, with each other, for the purpose of discharging the grain at C, and the lighter materials at O, as herein described.

JOSEPH POLLOCK,
Administrator of Allen K. M'Griff.

No. 7105.—*Improved method of Kneading Dough.*

What I claim therein as my invention, and desire to secure by letters patent, is the combination of a reciprocating kneading table, with a reciprocating breaker, substantially as herein set forth, but irrespective of the devices by which they are severally put in motion.

HENRY NORMAN RIDER.

No. 7106.—*Breast Plate for Harness.*

What I claim as my invention, and desire to secure by letters patent, is the centre draft and expansion breast plate for the horse harness, in combination with the use of the double fulcrum self-adjusting pad, applied either to the double or single harness, as set forth.

ORIN RAMSDELL.

No. 7107.—*Improvement in Bedstead Fastenings.*

What I claim as my invention, and desire to secure by letters patent, is the employment of bush pieces C, C, locked by the key piece E, in the manner and for the purpose set forth herein.

ROBERT RAMSEY.

No. 7108.—*Improvement in Fences.*

What I claim as my invention, and desire to secure by letters patent, is the method of constructing a self-adjusting and self-fastening fence of any material whatsoever, substantially such as herein described, the parts of which, when put together fasten themselves firmly, by means of a combination of locks and chairs, substantially as described, without the use of lead rivets, screw bolts, wedges, or any other of the modes heretofore adopted and used for the purpose.

ISAIAH SUBERS.

No. 7109.—*Improvement in Seed Planting Barrows.*

What I claim as my invention, is the employment of the gauge plate G, of variable thickness, in combination with the moveable tube L, and face plate K, and its springs, the same being applied to the hopper and conducting tube leading in to the furrow opener, and the whole being made to operate, substantially as specified.

CHAS. A. WAKEFIELD.

No. 7110.—*Improved Seed Planter.*

What I claim as my invention, is as follows:—I claim the combination of the curtain or apron, with the cylindrical or broadcast regulator.

I also claim the manner of constructing the regulator, or in other words, the combination of the prism with the side plates or boards, and their adjusting and confining mechanism, as set forth.

CHAS. A. WAKEFIELD.

No. 7111.—*Improvement in Burning Ornamental Figures upon Wood.*

What I claim as my invention and discovery, and desire to secure by letters patent, is—

First. The method I have described for constructing the mould or dies, so as to allow for the excessive depth they will charr the wood in certain parts of figures, in order that the whole figure when finished, shall be an exact resemblance of the original.

Secondly. I claim the channels or other like devices, cut in the face of the dies, for escape passages for the gases, smoke, &c.

Thirdly. I claim the use of an alkaline and acid solution, or baths to aid the removal of the charred surface.

I do not claim branding, or the production of uneven surfaces or fingers, by hot metal mould pressed upon wood, but the several improvements, as above claimed on the art within described.

HAMILTON WOOD.

No. 7112.—*Improvement in Measuring Cloth on Looms.*

I am aware that a roller or cylinder and clock work have been combined and used for indicating the length of any surface, against which the periphery of the said roller might be placed and rolled, such a contrivance being generally known by the name of "way metre," "carriage metre," or "pedemetre." I am also aware that a roller or cylinder, and a pencil marking apparatus have been applied to the cloth beam of a loom, in order to mark into equal lengths or parts, the cloth woven upon the said cloth loom.

I therefore, neither claim such contrivances, nor the methods by which they have been applied and used. But what I do claim as my invention, is the arrangement of the roller and clock work directly upon the breast beam of the loom, and with respect to the cloth or selvage thereof, as specified.

JOHN G. WEBSTER.

No. 7113.—*Improvement in Seraphines.*

I do not claim the use of wooden sounding reeds abstractly, nor the adjustable blocks, nor the combination of duplicate blowers with a keyed reed instrument. But what I do claim as new, and desire to secure by letters patent, are—

First. The combination of wooden sounding reeds with wooden reed-plates, constructed in the manner herein described.

Second. The combination of the adjustable blocks T, with the duplicate blowers A, and the lifting rods X, arranged as herein described, and

Third. The combination of the two sounding boards *a*, *a*, and the piano board *b'*, *b'*, with the sounding reeds and keys, arranged in the manner and for the purpose herein set forth.

RUFUS H. GREEN.

No. 7114.—*Improvement in Machines for Cutting Cap Fronts.*

I do not claim any one part used herein separately, as all are well known. But what I do claim as new, and of my own invention, and desire to secure by letters patent, is the construction and application of the frame *f*, with the blades 6, and 7, and guide pins 4, 4, taking holes in the bed *e*, to work in either direction from the centre, all these parts being constructed and operating, substantially as described and shown; and I claim in combination with the foregoing, the bed *k*, fitted with supporting guide rollers 11 and 12, and adjusting bar 14, with rollers 15, moving over the bar *l*, and taking the indentations to adjust the position of the material, over the cutter blades 6 and 7, the whole constructed and operating, substantially as described and shown.

GEORGE BURGESS.

No. 7115.—*Improvement in Gas Generating Apparatus.*

Having thus fully described my improved apparatus, and mode of manufacturing gas, what I claim therein as new, and for which I desire to secure letters patent, is the supply tube, combined with the vaporizing cup, as herein set forth, for the double purpose of supplying liquid for making gas, and for vaporizing the same before it comes in contact with the decomposing surfaces in the retorts, for the purposes set forth. I also claim the compound retort, constructed and arranged as above specified.

CHRISTOPHER T. BROWN.

No. 7116.—*Improvement in Sofa Bedsteads.*

First. What I claim as my invention, and desire to secure by letters patent, is the ordinary seat of a sofa, (or other suitable article of furniture,) so arranged as to revolve on a centre at each end, in a frame so constructed, as to turn over and bring the top or stuffed side of the seat, (by revolving the same,) on a level with another seat or bed, placed under the ordinary seat.

Second. I also claim the use of the stuffed ends forming the support for the top seat when turned over and used as a bed.

No. 7117.—*Improvement in Connecting Hubs with Axles.*

What I claim as my invention, and desire to secure by letters patent, is enclosing the spring collars that fit and run in the groove of the axle, within a box at the inner end of the hub, substantially as herein described, when this is combined with the ring fitting to and turning on the outer periphery of the box, and acting on the ends of the spring collars for the purpose of drawing them out of the groove when it is desired to take off the hub, substantially as described.

JUNIUS FOSTER.

No. 7118.—*Improvement in Churn Dashers.*

What I claim as my invention, and desire to secure by letters patent, is the hinging the series of beaters *b*, *b*, to the dasher rod, in such a manner that their faces will be thrown into inclined positions by the upward movement of the dasher, and into horizontal positions by the downward movement thereof; when the said vibrating beaters (*b*, *b*,) are combined and act in concert with the series of vertical faced beaters or wings *d*, *d*, (upon the same dasher rod,) substantially as herein set forth.

ISAAC D. GARLICK.

No. 7119.—*Improvement in Iron Railings.*

I wish it to be understood, that I do not claim forming joints, or connecting irons by lead packing, as that has before been done, but what I do claim, and for which I desire to secure letters patent, is constructing the pailings or upright rails, as herein described with holes in them, by means of which they slide freely in the horizontal bars, and with a cavity for containing lead or other proper metal surrounding said bar, for the purposes of allowing the pailings to be placed and fastened at any desired distance from each other, substantially in the manner and for the purpose set forth, by means of which I form a cheap and perfect railing of different lengths with the same number of palings, and firmly secure the rails in place.

WM. HAMILTON

No. 7120.—*Improvement in Clothes Frames.*

Having thus fully described the construction and operation of my improved portable clothes frame, what I claim therein as new, and desire to secure by letters patent, is the combination of the jointed arm G, G, bars H, H, and rods I, I, with the collars B, C, D, E, F, and the mast A, by means of the stay cords *n*, *n*, and the cords *l*, *l*, and *m*, *m*, substantially in the manner and for the purpose herein set forth.

HUMPHREY KEMPTON.

No. 7121.—*Improvement in Refrigerators.*

Having thus fully described the construction, and operation of my improved refrigerator, what I claim therein as my invention, and desire to secure by letters patent, is the inclosing water space A, for cooling the preserving chamber B, in combination with the pipe *d*, for discharging the waste water, substantially in the manner herein represented and described.

EPHM. LARRABEE

No. 7122.—*Improvement in Scale Beams.*

What I claim as of my own invention, and desire to secure by letters patent, is the combination of two or more scale beams, (having fixed and independent points of suspension,) with each other at the points (*e*,) and (*f*,) where the weight is usually attached, substantially in the manner, and for the purpose herein set forth.

S. T. McDOUGALL.

No. 7123.—*Improvement in Meat Cutting Apparatus.*

Having thus explained my invention, I claim the studs placed on the bar, in combination with the openings L, L, to direct the minced meat &c., into the said openings, that is, directing the said minced matters into either one of the openings, every revolution of the block, to prevent the minced meat, &c. from undergoing unmincing as set forth.

JOHN G. PERRY.

No. 7124.—*Improvement in Distilling Oleaginous Matter.*

What we claim as our invention, and desire to secure by letters patent, is facilitating and improving the distillation of fatty and oleaginous substances by the introduction of steam, at or near the bottom of the boiler, containing such substance, substantially as herein described, in combination with the application of external heat as described.

And we also claim the process, substantially as described, of distilling fatty and oleaginous substances by means of a bath of melted lead, or any alloy which will melt at the same temperature, substantially as and for the purpose described—whereby we are enabled to effect the distillation of the lowest possible temperature, and have a practical indication of such temperature as described.

A. M. POISAT.
D. C. KNAB.

No. 7125.—*Method of giving a Rotary Motion to Metal in Casting Chilled Rolls.*

Having thus described my invention, while I disclaim any exclusive right to the use of the circular motion in casting chilled rolls, inasmuch as that ha been for many years known and used, what I do claim as my invention, a desire to secure by letters patent, is the use of the dam *d*, attached to the r, placed inside the mould in chilled rollers, and similar castings, as he before described, for the purpose of producing a circular motion in the m metal.

JOHN C. PAR

128 Ex. Doc. No. 32.

Ex. Doc. No. 32. 129

in the retorts, for the purposes set forth. I also claim the compound retort, constructed and arranged as above specified.

CHRISTOPHER T. BROWN.

No. 7116.—*Improvement in Sofa Bedsteads.*

First. What I claim as my invention, and desire to secure by letters patent, is the ordinary seat of a sofa, (or other suitable article of furniture,) so arranged as to revolve on a centre at each end, in a frame so constructed, as to turn over and bring the top or stuffed side of the seat, (by revolving the same,) on a level with another seat or bed, placed under the ordinary seat.

Second. I also claim the use of the stuffed ends forming the support for the top seat when turned over and used as a bed.

No. 7117.—*Improvement in Connecting Hubs with Axles.*

What I claim as my invention, and desire to secure by letters patent, is enclosing the spring collars that fit and run in the groove of the axle, within a box at the inner end of the hub, substantially as herein described, when this is combined with the ring fitting to and turning on the outer periphery of the box, and acting on the ends of the spring collars for the purpose of drawing them out of the groove when it is desired to take off the hub, substantially as described.

JUNIUS FOSTER.

No. 7118.—*Improvement in Churn Dashers.*

What I claim as my invention, and desire to secure by letters patent, is the hinging the series of beaters *b*, *b*, to the dasher rod, in such a manner that their faces will be thrown into inclined positions by the upward movement of the dasher, and into horizontal positions by the downward movement thereof; when the said vibrating beaters (*b*, *b*,) are combined and act in concert with the series of vertical faced beaters or wings *d*, *d*, (upon the same dasher rod,) substantially as herein set forth.

ISAAC D. GARLICK.

No. 7119.—*Improvement in Iron Railings.*

I wish it to be understood, that I do not claim forming joints, or connecting irons by lead packing, as that has before been done, but what I do claim, and for which I desire to secure letters patent, is constructing the pailings or upright rails, as herein described with holes in them, by means of which they slide freely in the horizontal bars, and with a cavity for containing lead or other proper metal surrounding said bar, for the purposes of allowing the pailings to be placed and fastened at any desired distance from each other, substantially in the manner and for the purpose set forth, by means of which I form a cheap and perfect railing of different lengths with the same number of palings, and firmly secure the rails in place.

WM. HAMILTON

No. 7120.—*Improvement in Clothes Frames.*

Having thus fully described the construction and operation of my improved portable clothes frame, what I claim therein as new, and desire to secure by letters patent, is the combination of the jointed arm G, G, bars H, H, and rods I, I, with the collars B, C, D, E, F, and the mast A, by means of the stay cords *n*, *n*, and the cords *l*, *l*, and *m*, *m*, substantially in the manner and for the purpose herein set forth.

HUMPHREY KEMPTON.

No. 7121.—*Improvement in Refrigerators.*

Having thus fully described the construction, and operation of my improved refrigerator, what I claim therein as my invention, and desire to secure by letters patent, is the inclosing water space A, for cooling the preserving chamber B, in combination with the pipe *d*, for discharging the waste water, substantially in the manner herein represented and described.

EPHM. LARRABEE

No. 7122.—*Improvement in Scale Beams.*

What I claim as of my own invention, and desire to secure by letters patent, is the combination of two or more scale beams, (having fixed and independent points of suspension,) with each other at the points (*e*,) and (*f*,) where the weight is usually attached, substantially in the manner, and for the purpose herein set forth.

S. T. McDOUGALL.

No. 7123.—*Improvement in Meat Cutting Apparatus.*

Having thus explained my invention, I claim the studs placed on the bar, in combination with the openings L, L, to direct the minced meat &c., into the said openings, that is, directing the said minced matters into either one of the openings, every revolution of the block, to prevent the minced meat, &c. from undergoing unmincing as set forth.

JOHN G. PERRY.

No. 7124.—*Improvement in Distilling Oleaginous Matter.*

What we claim as our invention, and desire to secure by letters patent, is facilitating and improving the distillation of fatty and oleaginous substances by the introduction of steam, at or near the bottom of the boiler, containing such substance, substantially as herein described, in combination with the application of external heat as described.

And we also claim the process, substantially as described, of distilling fatty and oleaginous substances by means of a bath of melted lead, or any alloy which will melt at the same temperature, substantially as and for the purpose described—whereby we are enabled to effect the distillation of the lowest possible temperature, and have a practical indication of such temperature as described.

A. M. POISAT.
D. C. KNAB.

No. 7125.—*Method of giving a Rotary Motion to Metal in Casting Chilled Rolls.*

Having thus described my invention, while I disclaim any exclusive right to the use of the circular motion in casting chilled rolls, inasmuch as that has been for many years known and used, what I do claim as my invention, and desire to secure by letters patent, is the use of the dam *d*, attached to the rod *r*, placed inside the mould in chilled rollers, and similar castings, as herein before described, for the purpose of producing a circular motion in the melted metal.

JOHN C. PARRY.

No. 7126.—*Parallelogram Steering Apparatus.*

Having thus described my improvements, I shall state my claims as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is a steering apparatus in which the operating screw, and nut are connected to, and turn the rudder post by means of a series of parallel arms and cross bars, arranged and combined together in the form of a parallelogram, and jointed together so as to turn freely, substantially as herein described.

JESSE REED.

No. 7127.—*Improvement in Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the flues W, C, and *a*, in the accompanying drawing, in combination with the funnel shaped air pipe E, in fig. 2, of the accompanying drawings, in such manner that a union will be formed between the oxygen of the atmosphere, and the hydrogen of the smoke at the lower extremity of the flue W, W, in the accompanying drawings, where the heat caused by the action of the fire on the partition between the flue W, W, and the flue C, in the drawings, and radiating from it will produce combustion of those gases as they ascend through the flue W, W, in the drawings accompanying this specification

PETER SWEENY.

No. 7128.—*Improved Hydrolator.*

I am aware that an elevating rope has been passed through an opening in a windlass drum, and confined to the shaft within the same, for the purpose of enabling the length of the rope to be regulated as circumstances might require, and therefore I do not claim this as my invention, but what I do claim as new and desire to secure by letters patent, is the combining with a hydrolator (for first elevating water or other substance, and then conveying the same to a distance,) a double acting drum, constructed substantially as herein described, in such a manner that the vertical raising and lowering movement of the bucket or its equivalent, may be at a slow movement, and an accelerated leverage and the horizontal or inclined conveying movement may be at an accelerated speed and a diminished leverage.

ZURIEL SWOPE.

No. 7129.—*Improvement in Apparatus for Making Coffee.*

The strainer *a*, and its spring contrivance in their application to the coffee receptacle or box, constitute what I have termed the spring expander, and in the employment of the same, I do not intend to confine my invention, to the precise form or arrangement of parts as exhibited in the drawings, as I am aware that the same may be varied in various ways, while the principle of the invention is still maintained. For instance, the spring may be placed between the tops of the two boxes F, and H, instead of on the outside of the top of the box H, as seen in the drawings. The spring expander may be disposed within the box F, but I do not consider such change as presenting the advantages of construction, operation, and repair, as are presented by the mode of making the improved cafetiene, as exhibited in the drawings.

What therefore, I claim as my invention, and as new, is the spring expander, in combination with the coffee box or receptacle, the same being for the object or purpose, substantially as herein before specified.

NATH'L WATERMAN.

No. 7130.—*Improvement in Machinery for Spinning Yarn and making Rope.*

What I claim as of my own invention, and desire to secure by letters patent, is—

First. Giving to the strand during the operation of spinning, a double twist to each revolution of the rings or flyers, in the manner described herein, the same being applied to, and claimed in the spinning of yarns from any fibrous material, and also in laying the strand into rope, in the manner set forth.

Second. I claim the combination of the weight (*l*,) and (*e*,) with the bobbin stands for the purpose of preventing those from being carried around with the rings or flyers; the whole being arranged and operated, substantially in the manner and for the purpose herein described.

CULLEN WHIPPLE.

No. 7131.—*Improvement in Invalid Bedsteads.*

What I claim therefore, as my invention, is the combination of the inclining frame B, with the back seat, foot frames and main bedstead, substantially in manner, as herein before specified.

A. W. BARKER.

No. 7132.—*Adjustable Cord Hook for Door Springs.*

Having thus described my invention, what I claim as new, and desire to secure by letters patent, is the use of the adjustable cord hook or attachment (H,) for the cord, whereby the tendency of the spring to close the door is made to vary at pleasure, as herein set forth. I also claim in combination with a spring and fuse, having the diminution of the diameter of the coils on the fuse more rapid than the decrease of elasticity in the spring, by uncoiling the moveable cord attachment (H,) whereby the tendency of the spring to close the door is varied more rapidly than would be due to the simple change of position of the hook alone, in the manner and for the purpose herein set forth.

WM. B. BARNARD.

No. 7133.—*Improvement in Machinery for Planing Slats for Blinds.*

Now, what I claim as my invention, and desire to be secured by letters patent, is the engaging and disengaging the propelling slide block and carriage, by the continued action and connection of the dart holder T, springs D, D, and expander S.

GEO. BONWILL.

No. 7134.—*Fastening for Hay and Manure Forks.*

What I claim as my invention, and desire to secure by letters patent, is forming the tines or prongs *B*, of the hay fork, and the additional tines or prong *C*, which connect the same into a manure fork, out of single bars of steel, bent to the desired form, and securing the same to the handle *A*, by inserting them through the slot or mortise in the same, and driving keys or pins (*b*, *c*,) behind the same, substantially as herein set forth

ALINZOR CLARK.

No. 7135.—*Improvement in Carriage Jacks.*

Having thus fully, clearly and exactly described, and represented the [illegible], construction, and operation of our improvement, in carriage [illegible]; what we claim therein as new, and desire to secure by letters patent, is [illegible]structing the lever (*c*,) or its equivalent, with teeth ([illegible]) [illegible]

(d,) or their equivalents, in such juxtaposition, the one with regard to the other, that when it is necessary to release the rack from its load, these parts of the lever appropriately unite in action with the teeth (c,) and the ways (b,) of the rack (a,) or their equivalents, and with the pendents (r,) and the tooth (n,) of the latch (j,) or their equivalents, to take the load off and release the catch, retreat and make the frame of the catch a fixed point of resistance for the prongs of the lever, force out the lever tooth from the rack tooth, (the cam the while putting pressure upon the ways of the rack,) and oppose by the cams the requisite friction, and consequently resistance to the descent of the rack, the whole being arranged, substantially in the manner and for the purpose set forth.

THOS. G. CLINTON.
GEO. H. KNIGHT.
EDWARD H. KNIGHT.

No. 7136.—*Improvement in Firing Kilns for Pottery Ware, Black Lead, Crucibles, &c.*

I am aware that rosin as fuel has been incidently substituted for wood and coal in various kinds of furnaces, for melting glass, &c., but I am not aware that it has ever been substituted for other kinds of fuel in baking pottery, bricks, or other kinds of earthenware, with the view to equalize the baking, and to prevent the action of oxygen on the surface of such articles to be baked as are injuriously affected by it, and therefore, I do not claim generally as my invention, the use of rosin as a substitute for other kinds of fuel; but what I do claim as my invention, and desire to secure by letters patent, is the use of rosin or the distillation thereof, as a combustible, for baking pottery and all other kinds of earthenware, substantially as described, as a means of preventing such articles from being "over fired," or "slack burned," and whereby also, the injurious action of atmospheric air on the surface of black lead crucibles, pottery ware, bricks, &c., is avoided as described.

JOS. DIXON.

No. 7137.—*Improvements in Looms for Figured Fabrics.*

Having now described the nature of my improvements and their mode of operation, I claim as my invention, and desire to secure by letters patent, the following, viz.:

Firstly. Obtaining the picking motion, or (otherwise expressed) giving action to the picking shaft, by means of the shaft D, carrying the picking fingers D', oscillating with the lay, in combination with the mode of raising and depressing the fingers D', by the combination of the cam a^c and lever e^4, the said cam being detached from the other parts of the loom, thereby enabling it to be easily changed, in the manner and for the purpose above specified.

Secondly. I claim the pattern plates p^3, made and worked in the manner and for the purpose herein fully made known, in combination with the pattern levers o, with the pins o' fixed in them, the lever T, and cam T^2, for the purpose of lifting said pattern levers o, the star driver p'', and the star plate p^9, the mitre wheel p^7, and p^8, shaft p^6, and bevel wheel p^4, and p^5, in connection with cylinder p. The respective motions herein referred to, being carried on or effected, substantially in the manner and for the purpose herein fully made known.

Thirdly. I claim the combination formed by the mechanism, for moving the shuttle boxes, that is to say, the cam s^3, lever s, and pulling catcher o^2, together with the bevel wheels K^2, ^{3}, ^{4}, ^{5}, and intermediate bevels K', and K^6, together with the star driver L, and star plate L', and pinion I, and the shaft K^7, bevels L^2, and L^3, and shaft L^4, together with the star driver M', and star plate M^2, said bevels, shafts, star drivers, and stars oscillating, with the lay, and acting from the same centre, so that the connection between the shuttle boxes and bevels, is never broken or detached. The whole being constructed and arranged in the manner and for the purpose herein fully described. I do not limit my claim to the precise arrangement herein set forth, nor to the moving of any particular description of shuttle boxes, but I do claim my combination of motions used for the purpose of moving shuttle boxes of any description, when such arrangements and combinations are, substantially the same with that herein described.

Fourthly. I claim the apparatus for holding the pins in star driver L, or the pins in the bevels K^2, ^{3}, ^{4}, ^{5}, and consequently the shuttle boxes connected therewith, in a proper position, or more particularly the lever D^2, and rod c^o, connected to the bracket or carrier a^o, and the action to said lever being given by the oscillation of the lay, in the manner and for the purpose herein specified.

SAMUEL ECCLES.

No. 7138.—*Improved Apparatus for Registering the Depth of Water in Vessels' Holds.*

What I claim as my invention, is the combination of the secondary index hand apparatus, with the primary index hand apparatus, or that which denotes the depth or rise of water, the secondary index hand apparatus being for the purpose of registering the extreme depth, as above stated.

NELSON EDWARDS.

No. 7139.—*Improvements in Machinery for Dressing Hemp and Flax.*

Having thus described my invention, what I claim is the combination of the toothed cylinder B, the wind passage P^2, the trunk O^2, the endless apron I, the set of feed rollers F, F, G, the concave K, and the waste apron N; the whole arranged and made to operate together, substantially in manner and for the purpose as above set forth.

And in combination with the feed apron, its roller F, and toothed cylinder B, I claim the projecting shield N^2, the same being for the purpose of protecting the apron from injury and wear as specified, also to protect the journals of the rollers from winding up with waste or lint.

WM. W. GRANT.

No. 7140.—*Improvements in Railroad Cars.*

Having thus pointed out the nature or principle of my invention, the manner of constructing and using the same, and the advantages thereof, what I claim as my invention, and desire to secure by letters patent, is supporting and connecting both ends of the main platform of a railroad car, each with the centres of secondary platforms, which secondary platforms are connected at each end with, and supported each on four wheeled trucks, all substantially in the manner and for the purpose specified

GEO. S. HACKER.

No. 7141.—*Improvement in Corn Ploughs.*

Having thus fully described my improved corn and potato plough, what I claim therein as new, and for which I desire to secure letters patent, is the moveable expanding wings, combined and moved, substantially in the manner and for the purpose herein described, by means of right and left screws on a cranked shaft, that can be turned while the plough is in motion.

ROBT. J. KING.

No. 7142.—*Improvement in Cooking Ranges and Air-Heating Furnaces connected therewith.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Equalizing the heat in the oven, by allowing the air to circulate and ascend through the chamber, between the fire box and front oven plate, for the purpose, substantially as set forth.

Secondly. I also claim so constructing the contractors, as that two of the boiler holes may be changed into one of the same size as either of the other two, by which means a boiler hole may be had directly over the centre of the fire, or four boiler holes reduced to two, all being of the same size as described.

Thirdly. I claim in combination with the air-heating apparatus, the disposition or arrangement of the valves d', and t, t, with either of the valves s, s, on the door c', for the purpose of ventilation as described. The position of the valves are not material, so that their combined operation shall be as set forth.

JAMES McGREGOR.

No. 7143.—*Improvement in Air-Heating Furnaces.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Making the heating cylinder in sections, in combination with the segments of tubes or vertical cavities, cast on the plates at the laps containing sand, substantially as described, whereby they are rendered air-tight, as described.

Second. I claim the mode of fastening the handle to the grate, and keeping the grate true with the handle, by means of the bolt (t,) by which they are connected with the two studs (v, v',) as substantially set forth.

Third. I claim the separate chamber for the fire pot, which is suspended below the chamber of combustion, to prevent the air heated by the fire pot from entering into the air chamber (b',) surrounding the heating cylinder for the purpose, and in the manner as substantially set forth.

Fourth. I claim admitting air and flame through the pipe (w,) and its aperture or apertures (z, z, z,) into the chamber of combustion and radiation, in the manner and for the purpose, substantially as set forth.

Fifth. I also claim this mode of introducing the heated air and flame, in combination with the descending draught as described.

JAMES McGREGOR.

No. 7144.—*Improvement in Cooking Stoves.*

Having thus fully described my improved coal cooking stove, what I claim as my invention, and desire to secure by letters patent, is the arrangement of the valve or damper A, above the back plate of the fire chamber in combination with the register F, for regulating the draft, as herein fully set forth.

CHARLES MURRAY NELSON

No. 7145.—*Improvement in the Composition for Enameling Hollow Ware.*

Having thus described the nature of our said invention, and the manner of performing the same, we would have it understood, that we do not confine ourselves to the details herein given, but what we claim is the new and useful glazing composition for coating articles of iron to prevent oxidation, substantially as specified.

CHARLES EMILE PARIS.
CHARLES HENRIE PARIS.

No. 7146.—*Improvement in Apparatus for Retaining Cars on the Rails.*

What I claim as my invention, and desire to secure by letters patent, is combining the trucks or other suitable parts of locomotives, freight, and passenger cars with the rails, by means of two bars, one vertical and one horizontal, connected in such way that oscillations and other vibratory movements of said cars, will be permitted without disengaging the hooks or rollers attached to the lower ends of the vertical bars, from the flange of the rails, the whole being arranged, substantially in the manner described herein.

W. PAYNE,
Late Capt. R. L. Engineers.

No. 7147.—*Improved Winged Metallic Cartridges.*

What I claim as my invention, and desire to secure by letters patent, is the method of enclosing the charge of powder in the hollow part of the ball, by slitting its rear end and bending in the parts so slitted, substantially as herein described, that when the ball is discharged the parts so slitted may be forced out, to become feathers or wings to guide the ball, substantially as described.

A. D. PERRY.

No. 7148.—*Improved process in the Manufacture of Glucose.*

What I claim as my invention, and desire to secure by letters patent, is the conversion of corn meal into a solution of grape, sugar, or glucose, by boiling the same under a pressure greater than that of the atmosphere in water, acidulated with sulphuric acid, substantially in the manner described.

GEORGE RILEY.

No. 7149.—*Improvement in the construction of Fire Places and Throats of Chimnies.*

What I claim as my invention, and desire to secure by letters patent, consists in constructing chimnies with an additional flue A, in the back of the fire place, made in the manner and for purpose herein fully set forth, in combination with the bringing down of the main flue D, of the chimney stack, as above described, with the horizontal offset c, at the top of the back of the fire place, and the spaces E, at the sides, all as herein fully set forth.

CHAS. W. RUSSELL.

No. 7150.—*Improvements in Mail Axles.*

What I claim as my invention, is the making open grooves of whatever form, cast, or cut in, or upon the large end of axle boxes upon carriage axles, technically known as mail axles, and upon axles for cars with short bolts, with whatever form of head, fitted into the grooves for securing the wheels and boxes upon such carriage axles, and upon cars in the place of, and to supercede long bolts, which are now in use for securing such wheels and boxes.

W. H. SAUNDERS.

No. 7151.—*Improvement in Cooking Ranges.*

What I claim as my invention, and desire to secure by letters patent, is extending back the front boiler chamber or chambers, to form the back boiler chamber or chambers, at the side or sides of the elevated oven, substantially as described, in combination with the partition or partitions at the side of the front boiler chamber or chambers, and extending back of the back boiler chamber or chambers, when the said partition or (partitions) is provided with flue holes at the side of the side boiler or boilers, and back of the back boiler or boilers, and leading to the flue around the elevated oven, substantially in the manner and for the purpose specified.

FRED. H. STIMPSON.

No. 7152.—*Improvement in Chimney Caps.*

What I claim as my invention, is the improved ventilator, constructed of a combination of a series of external plates, a series of internal plates and openings, or smoke passages, arranged, covered, and applied to a flue, and made to operate together, substantially in the manner as above specified.

EDWARD WHITELEY.

No. 7153.—*Improved Scraper for Removing Snow from Ice.*

Having thus described my improvements, I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is an ice scraper, constructed substantially as above described, that is, in the form of a triangle, (so that in moving in either direction, the snow will be thrown by the diagonal sides at right angles to the course of the scraper,) and the base having guides which move in grooves forward in the ice, and control the motions of the implement, as herein above set forth.

NATH'L J. WYETH.

No. 7154.—*Improvement in Gas Metres.*

What I claim as my invention, and desire to secure by letters patent, is—the use of the four mercurial valve cups, as described, for filling and discharging alternately, the two measuring gasometers, as set forth.

I also claim the shaft *c*, in combination with the levers B, *e*, and pall *f*, for giving simultaneous movement to the hands of the dials, the valves, and the gasometers, as set forth.

JAS. LONG.

No. 7155.—*Improvement in the Spiral Spring Sash Stopper.*

What I claim as my invention, and desire to secure by letters patent, is—the combination with the ratchet and click, or any well known equivalent therefor, to arrest the action of the sash elevator, of the spring bolt (B), for fastening the sash, thereby giving double security against any disturbance of the position of the sash, substantially in the manner and for the purposes herein set forth.

WM. B. BARNARD.

No. 7156.—*Improvement in cutting Figures in Relief on Wood.*

Having thus described my invention, and exemplified the manner in which it may be carried into effect, I wish it to be distinctly understood, that I do not confine myself to the precise mechanical devices herein described for holding the material, for moving the carriages to and fro, for setting the cutters, or for holding the rack, teeth and blocks, but intend to vary them as circumstances may render expedient.

But what I claim as my invention, and desire to secure by letters patent, is the combination of an adjustable guide rack with an adjustable guide block, to produce the transverse, in combination with the longitudinal motion, for the purpose of producing on wood or other material, forms of a curvilinear, zigzag, or mixed outline, substantially as herein set forth.

I likewise claim the device for effecting the reversal of the shifting lever, constructed and arranged substantially as herein set forth, and composed essentially of the adjustable stops (*g*), springs (*i*), dotents (*k*), vibrating frame (F), and wheels (*d' d''*).

J. H. BRUEN.

No. 7157.—*Fastening of Terrets in Harness Saddles.*

What I claim as my invention, and desire to secure by letters patent, is—the combination of an adjustable pad (B,) and a terret (C,) with each other, and with one of the legs (A,) of a harness saddle-tree, by means of a single point, so constructed that neither the pad or the terret can be turned on their axis from their proper positions, substantially as herein set forth, to wit: by means of a rectangular opening in each leg A, of the saddle-tree, with lugs *d*, *d*, descending from its sides for the reception of the shank *f*, of a terret C, and by the ears *e*, *e*, rising from the upper side of the pad (B,) that receive between them the end of the shank (*f*,) of the terret, through holes, in which ears and terret shank the rivet (*i*,) passes, and holds the three parts A, B, C, securely together.

PETER B. COOL.

No. 7158.—*Improvement in ventilating Railroad Cars.*

What I claim as my invention, and desire to secure by letters patent, is—the employment of jets of air produced, substantially in the manner herein set forth, for preventing the entrance of dust into railroad cars or carriages of any description.

JAMES CUNNINGHAM.

No. 7159.—*Improvement in Furnaces for heating Sad Irons.*

What I claim as my invention, and desire to secure by letters patent, is—combining with a portable furnace of the usual construction, a surrounding heating chamber, provided with apertures or slots to admit of the insertion or removal of the flaps combined with the door or flap at top, substantially as described.

I also claim providing the said air heating chamber with a revolving top, provided with a single small door or flap, which, by the rotation, may be brought directly over the slots in succession, and the flats inserted or removed, substantially as described.

JOHN T. DAVY.

No. 7160.—*Improvement in coloring Photographic Pictures.*

What I claim as my invention, and desire to secure by letters patent, is—the application to photographic pictures taken upon paper or upon any transparent or translucent medium, of the mode of coloring I have described, or any other substantially the same, and which will produce a similar effect.

A. C. DAYTON.

No. 7161.—*Improvements in Pumps for deep Wells.*

Having fully described my improvements in pumps, what I claim therein as new, and desire to secure by letters patent, is the combination of the pump barrel, having a valve as described, with the water chamber at the bottom, and the lever at the top, substantially as described, so as to raise the water by elevating and depressing the barrel, thereby dispensing with the ordinary piston and piston rod, and avoiding the inconveniences incident thereto.

NEHEMIAH DODGE.

No. 7162.—*Improvement in Machinery for making Pill Boxes.*

Having invented an automatic or self-directing machine of great value in the manufacture of boxes, and having herein before described the same, what therefore I claim as my invention, is as follows:

I lay no claim to the particular tools or reducing cutters used in cutting the wood of a stick, but what I do claim is the above described peculiar arrangement of two or more sets of reducing cutters applied to one carriage V, as above set forth, two or more sets of reducing cutters, applied to another carriage W, in a similar manner, feeding apparatus applied as above set forth, to each cutting apparatus, and two circular saws playing between and acting in concert with the adjacent opposite cutting apparatus of both carriages V, W, the whole operating together, substantially as above specified.

I also claim the combination of machinery by which each of the circular saws, or their puppet heads or carriages, are alternately moved, first in one direction, and next in the opposite direction, and on their supporting ways; the said machinery consisting of the arm o', or p', affixed to the upright shaft K, the slide t', and its projecting pin applied to, and of the said arm, the grooved cam plate w^2, the lever or arm r', connecting rod s', the pin c^2 projecting from the under side of the carriage, and the springs a^2, b^2, the whole being constructed and made to operate, substantially in the manner and for the purpose as therein before specified.

ASA FESSENDEN.

No. 7163.—*Cultivating Seed Planter.*

What we claim as our invention, and desire to secure by letters patent, is: The combination of the roller and the harrow for crushing and pulverizing the soil, with the cultivator teeth for forming the furrows and depositing the seed; the roller preceding the harrow, and both preceding the cultivator teeth, as herein set forth.

WM. FLORY.
GEO. A. GROOVE.

No. 7164.—*Improvement in Air Heating Stoves.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of my invention in heating stoves, what I claim therein as new, and desire to secure by letters patent, is inserting the vessel *(f,)* as described for throwing down jets of air directly upon the flames, and other results of combustion; the cylindrical vessel *(f,)* being of lesser diameter than the drum *(c,)* half way up, and within which it is placed, so that the flame and results of combustion are commingled with the jets of air, and more thoroughly consumed, and are also forced to lick the sides of the drum and thus cause the greatest possible radiation of heat. And in combination with the foregoing, I claim the pipe *(d,)* with the enlargement *(e,)* and the reservoir *(h,)* as described, for carrying a column of air through a pipe led through the heart of the fire, this pipe being enlarged about the level of the top of the fire bowl, so as to throw jets of air athwart the direction of the downward jets before described, and this pipe being also continued up to a reservoir on the top of the drum, through perforations in the top of which air reservoir, jets of heated air, are continually thrown into the domestic or other apartment; by which general construction of this pipe, I effect a complete, commingling, consuming, and outward forcing of the results of combustion against the sides of the drum, and at the same time, furnish to the apartment an agent for heating and keeping up an active circulation of the atmosphere in the room to which heat is to be imparted.

P. GOODHUE.

No. 7165.—*Improvement in Regulators for Drawing Rollers.*

What I claim as my invention, and am desirous of securing by letters patent, is the combination of the tube B, lever D, D, weight C, jointed bar E, E, oscillating shaft F, and pinion G, gears H, I, M, screw shaft N, nut O, arms P, P, with their belt guides Q, Q, belt V, cones R, R, shaft K, and level gears 1, 2, 3, 4, 5, 6, for changing and regulating the speed of the rolls, for equalizing the drawing or making the sliver the required size, substantially in the manner described in the foregoing specification.

WHITING HAYDEN.

No. 7166.—*Improvement in Oil Presses.*

Having thus described the construction and operation of my improved press, what I claim therein as new, and desire to secure by letters patent, is:

First. The construction and arrangement of a series of press cases, substantially as herein set forth, each box forming or carrying the follower of the one next above it, and all being supported when not in action, at suitable distances apart by the offsets on the guides.

Second. The combination of the perforated lining plates, with the grooves or channels on the interior of the press cases, substantially as herein set forth.

EDWIN HILLS.

No. 7167.—*Improvement in Noddle Irons for Saw Mills.*

What I claim as my improvement in noddle irons for saw mills, and desire to secure by letters patent, is the combination of the four pointed knuckle, with indented straps and screw tie bolts, the whole constructed and arranged substantially in the manner, and for the purposes set forth.

GIDEON HOTCHKISS.

No. 7168.—*Improvements in Looms for Weaving Piled Fabrics.*

What I claim, therefore, as my invention, and desire to secure by letters patent, is the method of inserting the figuring wire (or wires) into the open shed, and withdrawing the same from under the woven file or loops by means of a carrier (or carriers) to which one end of the figuring wire (or wires) is (or are) attached, when the said carrier (or carriers) is so operated, substantially as herein described, as to receive a motion from and towards the selvage of the fabric, to withdraw and insert the wire,—and towards and from the lay to carry the wire to the open shed, and when inserted back against the woven part of the fabric, all substantially as herein described.

I also claim combining with each carrier and figuring wire, a guide or support through which the wire passes, substantially as described, when the said guide receives a motion towards and from the lay in unison with the carrier, substantially as described. I also claim forming each range of figuring loops on two wires introduced from opposite sides, and over-lapping in the middle with the lapping ends champered or bevelled, substantially as described.

JOHN JOHNSON.

No. 7169.—*Improvement in Cast Iron Car Wheels.*

What I claim as my improvement, is the wheel, or combination of the arched support plate E, E, the curved spokes or arms F, F, and the curved plate C, C, with the solid or undivided hub and the chilled rim, all cast together, and in one piece, substantially as above specified.

LYMAN KINSLEY.

No. 7170.—*Improvement in Cast Iron Car Wheels.*

I am aware that a cast iron wheel with a hollow felloe, or made with two concentric rings connected at their sides, and having a space between them, was invented and patented, on about the 15th day of February, A. D, 1838, by one Henry R. Dunham. This wheel, however, had a series of straight spokes, and a split or divided hub, the hub being connected to the felloe by such spokes only. I do not claim as my invention, such wheel or any part thereof, although it was able to resist vertical blows or shocks, better than a wheel having a solid or single rim felloe, as usually made, it has not the requisite power or strength to resist the lateral strains against the flanch of its tread. Nor could it be cast in one piece, and with a solid or undivided hub and chilled rim.

What I do claim as my invention, is the wheel made with the chilled rim a hollow felloe, or a support plate E, extending around and within the chilled rim, a curved plate C, uniting the rim and hub, a series of curved arms F, F, F, &c., and an undivided or unsplit hub, all cast, or founded, and combined together in one piece, substantially in manner as above specified.

LYMAN KINSLEY.

No. 7171.—*Improvement in the Interior Arrangement of Steam Boilers.*

What I claim herein as new and of my invention, and desire to secure by letters patent, of the United States, is the troughs (*i*,) surmounting diaphragms (which separate the water space vertically, into as many isolated chambers,) and having sides which rise higher toward the outside, in order to collect such water as overflows, and to distribute it among the several parts when the boiler recoils.

SYLVANUS KNIGHT.

No. 7172.—*Improved Lever Lewis.*

And what I therefore claim as my invention, and desire to secure by letters patent, is attaching a bent lever having its foot resting against or hooking under one of the vertical sides of a stone, to that same vertical side of the stone, by any of the well known forms of lewis, substantially in the manner and for the purpose herein described.

THOMAS LIDGERWOOD.

No. 7173.—*Improvement in the Gauge for Water Casks.*

What I claim as my original invention, and desire to secure by letters patent, is the combination of the joints or rods E, E, with the piece A, C, D, scale F, and piece B, C, D, in the manner set forth.

JOHN MARQUART, Jr.

No. 7174.—*Improvement in Flouring Mills.*

Having thus described the manner in which I construct my improved flour bolting machine, and the operations thereof, what I claim therein as new, and desire to secure by letters patent, is the manner herein stated, in which I have arranged and combined the spouts *i*, *j*, *k*, *l*, and tubes *b*1, *b*2, *b*3, *b*4, &c., and their slides *c*, *c*, *c*, *c*, &c., with each other, and with the bottom of chest B, and with the boxed conveyers F, and L, by which complete control is obtained over the quality of the flour passed into the packing chest, and also to give a similar control over the quality and quantity of the flour carried from B, into L, to be returned through *f*, to the flour elevators, substantially as before described.

I claim the manner in which I have arranged and combined spouts *k*, *l*, pipes *b*, *b*, &c., and their slides *c*, *c*, *c*, &c., with each other, and with B, F, L, and M, and O, with F, and F, with G, and H, by which the flour and bran are mingled in any desired proportions, and passed together into H, so as to give complete control over the action and products of H, and to prevent the choking or filling up of the meshes of the bolting cloth, substantially as before described. I claim also the manner in which I have combined spout *d*, with the bottom of I, and top of L, and *g*, with the bottom of L, and the burrs, so as to pass to the burrs such portion of middlings as require regrinding, substantially as before described.

And while I do not claim as my invention, the separate parts of my bolting machinery, taken individually, I do claim as new, and of my invention, the manner of combining and arranging those parts, substantially as before described, so that entire control is given over the process of bolting, and it is made one entire and continuous action, and by machinery, by which any desired portion of the flour in the first bolting chest B, is passed through *i*, or through *i*, and *j*, into the packing chest; and any portion thereof passed through *k*, or *l*, into L, and thence through *f*, with the flour from I, through *e*, to the elevators, and any portion at the miller's discretion, passed through *b*, *b*, &c., into F.

And the flour unbolted from M, the flour from *b*, *b*, &c., and the bran from O, mingled and passed together in any proportions through G, into I, and H, and then thoroughly bolted and separated without any choking of the meshes of the bolt, the bran passed off through J, and the offal through *h*, in any required condition, the middling forced through *d*, into L, and from thence through *g*, to the burrs to be reground, while the flour is forced through *e*, into L, and meeting with the flour passed into L, from *l*, with it carried through *f*, to the flour elevators.

A. F. MENEFEE.

No. 7175.—*Improvement in Abdominal Supporters.*

Having thus explained my invention, I claim this abdominal supporter, constructed with the bodice A, as described, in combination with the trunk hose D, in the manner described, or in any other manner, substantially the same for the purpose set forth

MARY W. O'MEARA.

No. 7176.—*Improved Method of Operating Lock Bolts.*

What I claim as my invention, and desire to secure by letters patent, is operating by means of reciprocating slides, a vibrating lever provided with a bolt at one end, and projecting from the back face of the lock, substantially as described.

THOS. SLAIGHT.

No. 7177.—*Improvement in Brakes for Carriages.*

Having described my improvements, all that I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the suspended toothed or notched bar K, staple N, spring-hook rod Q, connecting rod H, and plate O, for actuating and locking the rubbers against the peripheries of the wheels, and unlocking the same in passing over plains, by the action of the horses, as described and represented.

WILLIAM T. WELCH, Jr.

No. 7178.—*Machines for giving Increased Twist in Cutting Rifles.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of our invention, what we claim therein as new, and desire to secure by letters patent, is the jointing the guide (*i*, *i*, *i*, *i*,) in combination with the chord piece (*w*,) for sustaining it in position (or their equivalents) for the purpose of giving the guide as bent, when operated upon by the aforesaid lugs, or screws, or their equivalents, a rocking motion; making the point of attachment to the traversing bar, or other similar contrivance, describe a curve with reference to the bed which traverses beneath, thereby compelling the point of attachment to the traversing bar, or its equivalent, to recede in a gradually increasing ratio, (accompanied by an equivalent increased velocity of the rotary head,) from the axis of the mandrel, for the purpose of producing an increasing or decreasing twist to the groove in the bore, after the manner, substantially as herein described.

EDWIN WILLIAMS.
JAMES CULBERTSON.

No. 7179.—*Improved Method of Applying Fusible Metal to Boilers.*

Having thus described my protected safety fusible plug, what I claim therein as new, and desire to secure by letters patent, is inserting the fusible metal in a perforated cap which is protruded through, and screwed into any sheet of the fire or flue surface of the boiler, substantially as herein set forth; in such manner that the bottom of the cap is exposed directly to the action of the heat, the fusible metal within the cap closing the end of the tube through which the steam rushes, to give warning when the metal melts.

EDWARD H. ASHCROFT.

No. 7180.—*Improvement in Looms for weaving piled Fabrics.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Cutting the loops in the grooved wires as the cloth is woven, by means of a reciprocating knife, combined with the weaving parts of the power loom, and operated substantially as herein described.

Second. Combining with the reciprocating knife for cutting the loops, a take-up roller provided with cogs, which enter between the looping wires, substantially as herein described, for the purpose of presenting the ranges of loops in succession, and in a proper position to the action of the knife, as herein described.

Third. Combining with the reciprocating knife for cutting the loops, beveled or wedge formed guides placed near the selvage of the cloth, substantially as herein described, for guiding the knife at the commencement of the cut, as described.

Fourth. Combining with the reciprocating knife for cutting the loops, a trough into which the wires fall from the cut pile, and a second trough, into which they are successively transferred, substantially as herein described.

Fifth. Combining with the second trough, into which the wires are transferred, chains with projecting wings or spurs, substantially as herein described, for taking the wires in succession from the said trough, and transferring them to a wire box attached to the lay, substantially as herein described.

And lastly. Guiding and supporting the looping wires as they are introduced under the warps by means of slots or notches in the dents, substantially as herein described.

MERTOUN C. BRYANT.

No. 7181.—*Improvement in Machines for planing Ornamental Mouldings.*

I do not claim to have invented or improved upon any plan of a planing machine whatever, neither do I claim to be the inventor of any plan of a machine for forming ornamental mouldings by a scraping process in which only one gauge and one scraper are used in combination with a tool frame or carriage, which has only a vertical motion.

But what I do claim, and desire to secure by letters patent, is the method of using two scrapers, one in advance of the other, in combination with a single gauge.

I also claim the method of using the universal joint, in combination with the swivel carriage and two gauges, the same being constructed, arranged and operated essentially as above set forth and described.

JOHN B. H. CHATAIN.

No. 7182.—*Improvement in Machines for making Hat Bodies.*

What we claim as our improvement, and desire to secure by letters patent, is the combination of the rotating brush for throwing the fibres, with the cards which take the fibres from the feed rollers, and separate and prepare them, and with the trunk which guides, and the exhausted former on which the fibres are deposited, substantially as herein described.

EDWARD F. CONDIT.
ALFRED TAYLOR.

No. 7183.—*Improvement in Weighing Frames.*

What I claim as my invention, and desire to secure by letters patent, is—the manner of constructing the portable frame for the scale beam, as set forth, said frame consisting essentially of the hinged beam *c*, moveable standard *e*, and platform *a*, these parts being arranged and combined, substantially as set forth.

CHARLES DOWNER.

No. 7184.—*Improved Apparatus for Trimming Vessels.*

What I claim as my invention, and desire to secure by letters patent, is—the herein described method of trimming vessels by means of a shifting weight operated by an adjustable cradle, substantially as herein set forth.

E. L. EVANS.

No. 7185.—*Improvement in Tools for preparing Hubs for Boxes.*

Having thus described the construction and operation of my improved hub excavator, what I claim as my invention, and desire to secure by letters patent, is the construction of the implement or tool above described and represented by the accompanying drawings, for excavating or cutting out the ends of hubs of carriage and other wheels by hand, for the reception of the ordinary wheel boxes and linch pins, the cutter P P′, being made to recede from the centre of the hub simultaneously with the operation of cutting the excavation in concentric circles, by the combined and simultaneous action of the screw G, and nut H, in connection with the recessed bar A, and handles B, B, transverse bar J, and box N, arranged and operating in the manner and for the purpose set forth. SAMUEL FAHRNEY.

No. 7186.—*Improvement in Abdominal Supporters.*

What I claim as my invention, and desire to secure by letters patent, is—two short elastic arms S shaped, connected with other parts of a supporter, with a pad upon each end, one pad to rest upon the short ribs behind the curve and free from the spine, while the other rests upon the flat plate of the os illium, each S plate being united at the middle to a long elastic arm, by a mortise allowing no motion but that of sliding in and out; the long arm and short arm always crossing at right angles through the mortise.

Secondly. I claim the invention of two long elastic arms, in connection with other parts of a supporter, and with the S shaped arms, by a mortise and screw bolts: these arms so cut as when laid upon a flat surface, that the edge will be convex, then concave, and then straight, and formed so as to set flat upon the person, rising above the hips with a point of rest about one-third of its length from the back, and falling down in front to a pad, and by so adjusting the shape of the arms and point of rest, as to press directly upon the hernial rings, and lift up the abdominal contents toward the top of the hips.

Thirdly. A supporter pad so formed as to be thicker on the inside, near its lower and outer edge at the point of termination or lower fastening to it, of the long elastic arms, so as to press directly on the hernial rings, the lower outer edges being cut so as to follow the course of the grain, and the lower edge yoked or cut convex, to go above the os pubes, thus acting upon all those parts occupied by the abdominal rings. S. S. FITCH.

No. 7187.—*Improvement in Seed Planters.*

I claim the levers constructed with their ends k, in the manner substantially as described, to prevent the slides from being actuated when the motion of the wheel is reversed. JOHN P. GROSHEN.

No. 7188.—*Improvement in Hoisting Machines.*

What I claim as my invention, and desire to secure by letters patent, is—the twist break, whether constructed as set forth, or in any other way, substantially the same, and whatever the nature or purpose of the machine to which it may be attached. SANDY HARRIS.

No. 7189.—*Process of rolling India Rubber Cloth.*

What we do claim is the new or improved process of applying and fixing rubber to cloth by means of rollers; the said improved process being a combination of the method of spreading the rubber by the pressure of rollers, and the method of grinding and fixing it at the same time, against and into the substance of the cloth, all as specified. FRANCIS D. HAYWARD.
JOHN C. BICKFORD.

No. 7190.—*Improved method of employing the Exhaust Steam.*

What I claim as my invention, and desire to secure by letters patent, is—the running the exhaust pipe into the main steam pipe, curving it, and providing it with an aperture and valve, substantially as herein described, by which the current of steam from the boiler has a tendency to open the valve at intervals, and draw into the steam pipe a portion of the exhaust steam. GEO. H. HOAGLAND.

No. 7191.—*Improvement in Cooking Stoves.*

What I claim therein as new, and desire to secure by letters patent, is—making the front part of what is usually an open flue under the oven, to consist of a hot air chamber *(d,)* as described, and the rear part of the same; and also the space at the back of the oven to consist of reverting flues, by compelling the draft to pass over the top of the oven down back corner diving flues, reaching from top to bottom of the stove, and then lick under the oven and around the division plate, between these diving flues and the discharge flue; thus prolonging the contact of the heat with the back vertical and horizontal positions of the oven, and equalizing the distribution of the heat and flame, so as to make the oven look well from all directions. HOSEA H. HUNTLEY.

No. 7192.—*Improved Beaters in Hide Handling Cylinders.*

What I claim as new and of my invention, and desire to secure by letters patent, is:—

First. The wheel having buckets diagonally across the surface, alternately from right to left, and left to right.

Second. The rollers or slats in combination with the chamber, substantially in the manner and for the purpose set forth. JAMES R. INNIS.

No. 7193.—*Improvement in Double Oven Cooking Stoves.*

1. What I claim as my invention, and desire to secure by letters patent, is the moveable flue $(i,)$ for dividing the oven into two parts, as above specified.

2. I also claim, forming an aperture in the division plate $(a,)$ between the front boilers, to protect it from the intense heat of the fire, and to supply air for combustion as described. JAMES M'GREGOR, JR.

No. 7194.—*Improved Centrifugal Propeller.*

What I claim, therefore, as my invention, and desire to secure by letters patent, is—the peculiar curve given to the propeller blades as herein set forth, to counteract the tendency of the centrifugal force to deflect the issuing water, obliquely to the axis of the propeller. JOHN WILLIAM NYSTROM.

No. 7195.—*Improved method of forming Sheet Metal Tubes.*

What we claim as our invention, and desire to secure by letters pater the method of forming sheet metal tubes, &c. upon a mandrel, supported by and obtaining its revolution from these rollers, one (or more) of which are adjustable, substantially in the manner herein described.

WM. OSTRANDER.
WM. WEBSTER.

No. 7196.—*Use of the Oxide of Tin in the Manufacture of India Rubber.*

Having described the nature of my invention, together with the best mode of manufacturing the same, I hereby declare, that I do not claim the combining of ochres, or pipe clay with India rubber, nor submitting rubber to high heat, nor mixing sulphur with rubber.

What I do claim as my invention, and desire to secure by letters patent, is the combining rubber with tin as set forth, and the combination of these with sulphur and heat; whereby, I produce a fabric having a black surface, and which is capable of withstanding all the elements which distinguish vulcanized from other preparations of rubber.

JOHN PRIDHAM.

No. 7197.—*Improvement in Steering Apparatus.*

I am aware, that a screw placed athwart ships, and acting upon a turning and travelling nut, attached directly to the tiller or its equivalent on the rudder head, has been employed for the purpose of steering vessels; I therefore, do not claim the invention of that arrangement.

In my apparatus, I introduce the lever, fig. 4, for the purpose of moving the rudder with the same length of tiller through a given space, with less turns of the wheel, than can be done in any other way with the same pitch of screw, by which I obviate a great objection in former apparatus for steering. To wit: the want of command over the rudder, by reason of the great numbers of turns of the wheel, or the great friction produced by increasing the pitch of the screw. These being the only two modes used by former inventors for obtaining this velocity in the improvement of the rudder, to wit: shortening the tiller, or increasing the pitch of the screw. In my apparatus any required velocity in the movement of the rudder may be obtained with the same length of the tiller, by diminishing or increasing the length of my lever, without increasing the pitch of the screw, as increasing the pitch of the screw, or shortening the tiller, makes it operate stiffly and unnaturally. And in fact, I am enabled by the introduction of the lever, to obtain that particular combination of power and velocity which the exigency of all occasions may demand in an apparatus for steering vessels.

Therefore, what I claim as my invention, and desire to secure by letters patent, is attaching the nut acted upon by the screw to an interposing lever arranged substantially as herein described, by which arrangement I am enabled with the same pitch of screw, and the same number of revolutions of the wheel, to move the rudder through a larger arc than in the old apparatus.

P. P. QUIMBY.

No. 7198.—*Improvement in Pumps for Ships, &c.*

What I claim as my invention, and desire to secure by letters patent, is—combining the pump barrel of suction pumps, in which are placed the check or stop valve and the piston, with the supply pipe or pipes, by means of an exhaust chamber into which the water flows by atmospheric pressure, and

from which it runs by gravity into the pump barrel, substantially as and for the purpose specified.

I also claim, in the combination next above specified, making a lateral hole through the pump barrel, and communicating with the exhaust chamber, substantially in the manner and for the purpose specified.

I also claim combining with the exhaust chamber, which unites the pump barrel and the supply pipes, and interposed between these, a strainer, sieve or filter, substantially as described, and for the purpose specified.

FRANKLIN RANSOM.

No. 7199.—*Improvement in Churn Dashers.*

What I claim in the foregoing as my invention, and desire to secure by letters patent, is the combination of the whirls with the revolving frame dasher; the several members being arranged and constructed substantially in the manner herein set forth. NATHANIEL ROUTZAHN.

No. 7200.—*Improved movement of the Pointing Dies in Spike Machines.*

Having thus described my improvements, I shall state my claims as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is operating the curved dies for pointing a spike, by setting them in the adjacent ends of two sets of toggles arranged with the cam projections o', p', and guiding blocks q', r', and the whole operating, substantially as herein above described. EDMUND SAWYER.

No. 7201.—*Improvement in Machines for Sawing Marble.*

What I claim as my invention, is as follows, that is to say: I claim the combination of mechanism applied to the sprocket wheels, endless chain, windlasses and suspension chains of the saw frame: the said combination being for the purpose of gradually lowering the gang of saws in the proportion required, as the sawing process progresses. This combination consists of the train of mechanism which is applied to the lower sprocket wheel shaft, or axle b, and the driving shaft, and intervenes between the two, and is actuated by the revolutions of the driving shaft; said train of mechanism consisting of the tooth gear a, pinion c, gear wheel e, endless screw f, beveled wheel h, pinion i, and ratchet wheel l, together with the pawl x', arm m, connecting rod n, slotted plate o, rocker shaft p, crank q, screw t, screw nut u, washers v, w, cranks x, and z, and connecting rod y, as above specified; not meaning to claim as any part of the same, the crank l', click k', and ratchet wheel i', except in their combination therewith, and for the purpose of enabling a person to raise or lower the gang of saws, by applying his hand to the crank, it being understood, that, when these last contrivances are not used, the wheel e, must be firmly fixed to its axis and not placed loosely thereon, as it is when such contrivances are employed.

I also claim the employment of the two arms f', g', extended in opposite directions, above and below their rocker shaft p, and used in the manner and for the purpose as specified.

I also claim the vibratory tubular watering apparatus m', n', o', p', and mechanism combined with it, said mechanism consisting of connecting rod p 2, pulley q, endless band r', and pulley s', for giving to it, a reciprocating movement over the gang of saws and stone as specified.

ALBERT H. TINGLEY.

No. 7202.—*Improvement in Cast Iron Car Wheels.*

I do not claim, that the invention above described, is an improvement in the form of any part of railroad wheels, than that contained between the hub and the rim. But what I do claim as my invention, and desire to secure by letters patent, is the projecting ribs, in combination with the corrugated disk, in the manner and for the purposes herein set forth.

ASA WHITNEY.

No. 7203.—*Blind Slat Operator.*

I do not claim the construction of the bevel wheels, or the moveable joint as my invention, as they have been heretofore used and are old devices, nor do I wish to confine myself to the precise mechanical arrangement herein specified, as slight alterations may be made therein, without varying the principle of my invention.

What I claim, is the combination of the bevel wheels, and the moveable joint, essentially in the manner and for the purposes herein described.

DAVID R. WILLIAMS.

No. 7204.—*Improvement in Artificial Legs.*

Having described the nature, character, and action of my artificial leg, what I claim as my invention, and desire to have secured to me in this application, is the exclusive privilege of making artificial skeleton legs of thin metallic ribs or plates, and rings or hoops united together by rivets, or other suitable fastenings, substantially in the manner herein set forth, irrespective of any particular combination with other parts connected therewith.

GEO. W. YERGER.

No. 7205.—*Improvement in Apparatus for receiving and transferring to the pile sheets of paper from Printing Presses and Paper Machines.*

I claim and desire to secure by letters patent, the above described device, viz: the cylinder *c'c'*, *cc*, in combination with the rollers *a*, *a*, and the bands marked *o*, or any device, substantially the same, (the above named "fly" not being included) for receiving the printed sheets from printing machines or printing presses, upon a curved or cylindrical surface, and by means of said curved or cylindrical surface, transferring them with their printed sides upwards, to the pile, or the table provided to receive them.

I also claim the device embodied in the combination, consisting of the screws *l*, *l*, the pawl *m*, *m*, the lever *n*, the part *h'*, the click *p*, the wheels *r*, *r*, *r'*, and the tables *d*, *d*, or any device, substantially the same, for lowering the pile of sheets, the accumulation of sheets upon said pile governing the operation as aforesaid.

ISAAC ADAMS.

No. 7206.—*Improvement in Brick Presses.*

What I claim therein as new, and for which I desire to secure letters patent, is:

First. The employment of the mounted roller (*a*,) turning independent of the wheels on which it is borne, and forming a guiding carriage for the moulds, substantially in the manner, and for the purpose set forth.

I also claim the stop or weighted catch-lever, for guiding the moulds in entering under the grating.

COLLINS B. BAKER.

No. 7207.—*Improvement in Balloons and their Appendages.*

I would have it understood, that I do not confine myself to the precise details herein set forth; but what I claim as my invention, and desire to be protected under letters patent, is the application of one or more flexible partitions which I have termed the "septum membrane," to balloons for the purpose herein before described.

Secondly. I claim the application of a rotary motion, in conjunction with a hinge motion, for the purpose of producing motion in the fan or blade forming the tail, which motion is more or less assimilated to that of a bird's tail, in order to effect the steerage, substantially in the manner herein described.

Thirdly. I claim the use of the water grapnel for the purpose of arresting the motion of aerial machines, and also the application of elastic ropes to grapnels, either for land or water, and which elastic ropes may be formed entirely of elastic material, or by introducing some elastic material, or metal spring in its length.

And lastly. I claim the construction of the valve shown in figs. 3, 4, 5, sheet 2, as applied to balloons, in which the valve or plate during its motion, retains a position parallel to its seat.

HUGH BELL.

No. 7208.—*Improvement in Filters.*

What I claim therein as new, and for which I desire to secure letters patent, is the construction and arrangement of the filter with a woollen woven fabric wound on to a spool, substantially as herein set forth, and, admitting the water so as to pass down through the cloth presented edgeways, as above fully described.

CHAS. D. BIRDSEYE.

No. 7209.—*Method of connecting the Sections of Gold Washers.*

I do not claim the constructing of gold washers in sections, neither the connecting of said sections together by hinges; but what I claim as my invention, and desire to secure by letters patent, is the mode of connecting and holding firmly together said sections, by means of the strip of iron (J,) the rods (K, K,) the socket (L,) and the chain (T,) substantially in the manner and for the purpose above set forth.

RUSSEL BARTON.

No. 7210.—*Improvement in Exercising Chairs.*

What I claim therein as new, and desire to secure by letters patent, is connecting the moveable apron and back by means of adjustable arms, substantially as herein set forth, whereby the back and legs of the sitter can be so equally balanced that he can rock himself to and fro with the slightest exertion.

I also claim the adjustable self-adjusting foot-board, in combination with the moveable apron, substantially in the manner and for the purpose set forth.

SOLOMON CHAPIN.

No. 7211.—*Improvement in Blast Pipes for conveying Heated air and Gases to Furnaces.*

What I claim as my invention, applicable to heating and smelting operations, and which I desire to secure by letters patent, is the application of this method of creating such draught or partial vacuum, to the return of the smoke and other escaping products of combustion to the fire, in order that such of them as are combustible may be there consumed, the method or means consisting, substantially in the manner of employing the blast pipe F, enclosing the hot air pipe E, as herein set forth.

RANSOM COOK.

No. 7212.—*Improvement in Bee Moth Traps.*

What I claim therein as new, and desire to secure by letters patent, is the combination of the fluted roller, operated as described, with the moth entrance of the bee hive to act as a moth catcher and killer, substantially in the manner and for the purpose described.

GEORGE FLETCHER, Sen.

No. 7213.—*Improvement in Seed Planters.*

What we claim as new, and desire to secure by letters patent, is—

First. The introduction of a cleaning rod, operated as described, into the hollow share of a seed planter, for the purpose of removing extraneous matters that may have entered the orifice, tending to impair or prevent the action of the machine.

GEORGE FLETCHER, Sen.
TURNER BARNES.

No. 7214.—*Compound Hard and Soft Metal Packing.*

What I claim as my invention, and desire to secure by letters patent, is the compound metallic packing ring constructed of hard and soft metals, substantially as herein set forth, the hard rings being for the purpose of preventing the substance of the softer from squeezing out around the follower and flange of the piston.

A. FULTON.

No. 7215.—*Improvement in Printing Presses.*

What I claim as new and useful in the above described improvements, and desire to secure by letters patent, is first, the peculiar manner of constructing the nippers, so that their upper surface shall be even with the surface of the paper, and their inclined or curved surface shall incline away from the surface of said paper.

I also claim an adjustable table, to be adjusted to the nippers, the nippers being first adjusted to the type or form, substantially as above set forth and described.

I further claim a frisket operated on by the motion of the carriage, so that when the carriage goes in with the sheet its forward end shall raise under and support the paper, and (from the upward pressure of the nippers against the platen in giving the impression) grip it firmly and relieve it from the type after the impression is given, and on the receding of the carriage with the printed sheet, its forward end shall lower and allow the said sheet, which rests upon it, to slide or fall off into a box or drawer placed to receive it, operating substantially as above described.

I further claim the application of the vibratory power to the handle of a distributing roller, (see figs. 1 and 2) (said handle projecting from the frame of said roller midway from its respective ends) and not to the end of the roller frame, as in general use.

I further claim the combination and arrangement for opening the nippers when the carriage moves out with the printed sheet, and closing them just previous to its going in, which combination consists of the horizontal bars or polls y, (see figs. 3 and 4) the curved pieces a', the lever c', attached to the shaft b', (see fig. 9) the hub d', with its projection e', on the main shaft J, and the spiral spring y, one end of which is attached to the press frame; the whole being arranged and operating together, substantially in the manner herein above set forth and described.

GEO. P. GORDON.

No. 7216.—*Improvement in Correcting Magnetic Needles.*

What I claim as my invention, and desire to secure by letters patent, is the method herein described of producing perfect harmony and coincidence between the axis of a magnetic needle and the magnetic axis; and also of producing perfect harmony between any number of magnetic needles, to wit:—removing portions from the needle, whether by the formation of channels upon the upper or lower surface of the needles, of the form and in the position, substantially as herein set forth, or merely by grinding, or filing, or cutting away.

CALVIN GUITEAU.

No. 7217.—*Improvement in Fountain Pens.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the moveable spring tongue, with the pen, (for the purpose of forming a fountain pen) when the whole is constructed, arranged, and combined, substantially as herein described.

ELLSWORTH H. HYDE.
ROLLIN L. DAWSON.

No. 7218.—*Improvements in Revolving Breech Fire-arms.*

I therefore claim as new and of my own invention, and desire to secure by letters patent of the United States, first, the arrangement of the arm k, slides l and m, or their equivalents, whereby the motion of half-cocking and cocking the hammer is communicated to the barrel, to open the joint formed by the grooves v, around the breech w, and also to close said joint on the discharge of the piece by the operation of the hammer, slides l and m, and spring 13, alone or in conjunction with the main spring g, substantially as described and shown.

Second. I claim the arrangement of the slide q, and circular ratchet s, or their equivalents, whereby the motion of the barrel sliding forward, is made to revolve the chambers the required amount, to bring the next chamber in line for the next discharge of the piece, substantially as described and shown.

H. IVERSON.

No. 7219.—*Machines for Forming Rotary Cutters.*

What I claim as of my own invention, and for which I desire letters patent of the United States, is the arrangement upon puppet heads having a sliding motion upon a bed plate, of adjustable slides, supporting disks, to which are attached the boxes in which the cutter shafts revolve, the disks being capable by means of vibratory motion on their axis, of adjusting the cutter shafts to any required angle with the horizon, and the whole machine being for the purpose of shaping at the same time, both faces of a revolving cutter, substantially as herein described.

ANDREW JENNINGS.

No. 7220.—*Improvement in Cultivator Teeth.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The manner of constructing the cultivator tooth, substantially as above described, by which a separate steel cutter is embraced between the two halves of the tooth, removable at pleasure, and by which wedges can be applied against the shoulders of the tooth and the under side of the beam, for the purpose of changing the angle of inclination of the share, in order to increase or diminish the depth of culture, the tooth turning on the bolt passing through the head of the same, and the beam, whilst inserting the wedges, the wings of the tooth being secured to the four-sided changeable share, by means of screws and nuts or other equivalent means.

LEWIS LAMBORN.

No. 7221.—*Improvement in Printing Floor Oil Cloth.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the stops G, H, I, J, K, with the block E, by which the printing of the floor oil cloth is performed, without moving the stops until the first printing is finished, and dispensing with a second block to cover the parts of the cloth not printed at the first operation, by simply changing the position of the hinged gauges on the block without moving the stops on the bar as above described, thus dispensing with the second block usually employed.

LEVERETT MOORE.

No. 7222.—*Improvement in Thrashing Harvesters.*

What I claim as my invention, and desire to secure by letters patent, is the mode of cutting and thrashing the grain by forcing the same against the knife (k,) and after being cut, between the teeth of the concave D, and the teeth of the gathering or thrashing wheel or shaft, of bars or beaters (i,) during the progress of the machine, as herein set forth.

SAMUEL S. REMBERT.

No. 7223.—*Improvement in Plough and Clevis.*

What I claim and desire to secure by letters patent, is—

First. Making the reversible point F, with the triangular shoulders F′, F″, in combination with the screws f', and nut N, for binding firmly together the landside E, mould board C, cutter G, and share H, as well as securing itself, in the manner herein fully described.

Second. I claim the device of fastening the reversible share to the flange on the lower part of the mould board, substantially as set forth.

Third. I also claim the manner of employing the inclined brace rod I, in combination with the box plate P, cast on the inside of the mould board, for adjusting the beam, to take more or less land, to act as a substitute for the clevis, and at the same time to brace or stiffen the wood work of the plough by attaching it to the cast iron mould board and land side, as described.

IRA REYNOLDS.

No. 7224.—*Improvement in Dental and Surgical Chairs.*

What I claim as my invention, and desire to secure by letters patent, is the application to chairs of the middle section B, B, substantially as herein described, whether operated by rack and gear, or by lever, or windlass, or screw, at two corners of the chair or at four, or at any intermediate point, provided the same results are obtained, by means substantially herein set forth.

FLAVIUS SEARLE.

No. 7225.—*Improvement in Cheese Presses.*

What I claim as my invention, and desire to secure by letters patent, is combining with cheese presses, two beds upon which the cheese is alternately pressed, which revolves together on a horizontal axis, substantially in the manner and for the purpose herein set forth.

AUGUSTUS N. SEVERANCE.

No. 7226.—*Improved Method of Dressing Cut Tobacco.*

What I claim as of my invention, and desire to secure by letters patent, is the method of dressing cut tobacco, by passing it through a revolving cylinder, having holes through it, to sift the short from the long pieces, and with hooks or pegs projecting from its inner surface towards the centre, for lifting the threads of tobacco, as described above.

GIDEON WALES.

No. 7227.—*Improvement in the Seed Roller of a Seed Planter.*

What I claim as my invention, and desire to secure by letters patent, is the before described mode of constructing the planting cylinder D, by which the cavities or cells M, in the periphery are enlarged or diminished, simultaneously by simply turning the plate (o,) or other similar device, having its section P, of male screws on its inner face, and causing said sections to act on all of the radial slides Q, forming the bottoms of the cavities at the same time, and holding them firmly in the required positions by the thumb screw i, or other equivalent mechanical device, substantially as aforesaid, by which like results are produced.

EDWARD WICKS.

No. 7228.—*Improvement in Printing Floor Oil Cloth.*

But what I do claim as my invention, and desire to secure by letters patent, is the employment of the before described combination of the gauge A, and stops C, constructed, arranged, and operated in the manner and for the purpose above set forth, for guiding the printing block without the use of pitch pine, during the operation of stamping the colors on the cloth, by which the work is rendered much more accurate, and is executed with greater despatch, and is not so liable to become blurred during the operation of handling the blocks, nor of having the colors to overlap, by a misplacement of the blocks.

N. B. POWERS.

No. 7229.—*Clamp to be used in the Manufacture of Wrought Iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is the construction and application of the above described combined cylindrical clamp, consisting of the following parts—namely, the ring A, A², of an L shaped section with handles (a, a,) attached, and ring D, and screw bolts E, applied for the purpose of confining and holding the wrought iron arms B, or spokes, in a true circle, together with the pieces c, d, e, in the centre to form the hub during the operation of welding the several parts together, as above described.

HERRICK AIKEN.

No. 7230.—*Improvement in Machines for Hoisting.*

What I claim as my invention in the above described machine, and desire to secure by letters patent, is the separate and independent action, each upon its own axis, of the two upper pulleys whereby the buckets or weights are suffered to pass freely between them, without let or hindrance, and in combination therewith, I claim also the swinging of the buckets or weights, between the chains, so that they shall always hang downward, in whatever position the parts of the chains to which they are attached may be.

WILLIAM C. ALLISON.

No. 7231.—*Improvement in Cooking Ranges and Heating Air.*

But what I do claim, is the employment and use of the combination of the furnace and oven, in the hot air chamber, with the radiating pipes E, flues and dampers D, and I, and H, J, K, and F, for the purpose, substantially as herein above set forth.

ELIAS T. BEERS.

No. 7232.—*Improvement in Chimney Caps.*

What I claim as new, is the injector G, in its combination with the cap plate C, tube A, and frustum B, and made stationary against the cap plate, all substantially as herein before specified; and in combination with the cap plate C, the frustum B, and tube A, I claim one or more flat plates or rain fenders E, as applied and used, substantially in the manner as herein before explained.

MICHAEL HENNY COLLINS.

No. 7233.—*Improvement in Churns.*

What I claim as new therein, and for which I desire to secure letters patent, is first, the self-adjustable float or slat (C,) which opens when churning the cream, and closes of itself when the dasher is turned in the opposite direction, to gather the butter, as before described.

R. W. DAVIS.

No. 7234.—*Improvements in Saw Mills.*

What I claim as my invention, and for which I solicit letters patent, is—

First. The combination and arrangement of levers T, U, V, X, (*n*,) with the catch bar W, and cam (*m*,) and sliding bar (*p*,) by which the depression of the foot lever V, is made to actuate the several levers T, U, X, (*n*,) and the cam (*m*,) made to lift the lever (*n*,) and thus operate the turning bar (*q*,) and with the gauge bars (*s*, *s*,) and thus set the log, and at the same operation elevate the foot lever V, and engage the reaching arm R, with the rag wheel Q; to feed the carriage forward, as described and represented.

Second. I also claim the combination of the upright gauge, turning bars (*s*, *s*,) with the horizontal weighted turning bar (*q*,) holding bars (*v*, *v*,) and eccentrics (*w*, *w*,) thereon, by which the log is set simultaneously at both ends, and the slides K', and L', prevented from moving, during the operation of sawing, by the holding bars (*v*, *v*,) as described and set forth.

Third. I also claim the arrangement of the shaft V, and pinion Z, for engaging with the rack of the carriage, simultaneously with the descent of the foot lever, for winding up a cord and weight, for relieving the tightening lever from the band G, and unwinding the same with the ascent of the foot

lever V, after the setting of the log, and gigging back of the carriage, to give motion to the crank shaft C, as described and set forth.

WEIGHTMAN DAVIS.

No. 7235.—*Improvement in Harness Hames.*

I will now claim, firstly, curving or inclining forward the upper and lower parts of the back or drawing surface, and the inner projecting edge of the hame, substantially in the manner and for the purpose herein described.

Secondly. The stock *k*, of the draught iron for securing the same to the hame, by means of the shank *f*, of the breast ring, passing through the said stock *k*, of the draught iron, and rivetted to the hame, as described.

Thirdly. The hook studs B, B, B, for receiving the straps which secure the upper ends of the hames together, when on the horse, so as to allow the straps to be easily shifted, constructed in the manner described, or in any other way, substantially the same.

ANDREW DEITZ.

No. 7236.—*Improved Atmospheric Churn.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the dasher with the stationary inclined air channels, on the churn tub, the two being made, arranged, and operating, substantially as herein set forth.

SIMEON F. EMERSON.

No. 7237.—*Improvement in Temples used in Weaving Double Cloth.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the jointed rods with the wheels or pulleys at the ends of the rods.

I also claim the wires fastened at one end to the bars or rods, and having the other end bent at such an angle as to enter a slot in or upon the breast beam, for the purpose of retaining the temple in a proper position.

I also claim the slot in or upon the breast beam, when the same is used in connection with the temple, as herein described.

STEPHEN EVERETT.

No. 7238.—*Improved Pocket Filtering and Drinking Tube.*

What I claim as my invention, and desire to secure by letters patent, is the fitting a filter to a tube of greater or less length, substantially in the manner herein before set forth, so that water may be strained by the very act of drinking.

ABIJAH FESSENDEN.

No. 7239.—*Improvement in Parlor Air heating Stoves.*

What I do claim as my invention, and desire to have secured to me by letters patent, is the combination of the cold air chamber L, and valve M, with the hot air annular chamber H, and the reservoir or chamber B, below the horizontal plate E, in the chimney flue, and behind the recessed fire-board A, as described, said chamber L, being provided with an opening R, to let the cold air into the annular hot air chamber H, and small openings N, to let a portion of the cold air into the reservoir B, and the valve M.

I likewise claim the combination of the hinged water holders J, with the recessed fire-board, said holders serving the double purpose of evaporator, stands and valves, as described, for moistening the air and admitting warm air from the reservoir or space B, behind the fire-board, or directly into the parlors.

I also claim the arrangement of the valves P, in the segmental top of the fire-board, as described, for letting the warm air from the recess of the fire-board into the reservoir B, to be conveyed thence wherever described.

L. W. GOSNELL.

No. 7240.—*Improved Sash Stopper.*

What I claim therein as my invention, and for which I desire letters patent, is the arrangement, substantially as herein described and represented, in one compact and connected mechanism of a pair of oppositely acting eccentric tumblers, held in contact with the jamb, by a single spring, or its equivalent, and both operated by the same key or other usual substitute, and so disposed and constructed as to oppose any attempt (except by one who has control of the catch) to either raise or lower the sash from the position in which it may be placed.

GEORGE H. GRAY, SEN.

No. 7241.—*Construction of Drill Teeth in Seed Planters.*

What I claim therein as new, and desire to secure by letters patent, is the spring coupling, constructed and arranged, substantially as set forth.

LEVI HAVERSTICKE.

No. 7242.—*Improved attachment of the Forge Hammer to its Helve.*

What I claim as my invention, and desire to secure by letters patent, is—limiting the depth of that portion of the hole in the helve, which receives the shank of the hammer, and at the same time, making the crown A', solid, excepting a hole of sufficient size through the same, to admit of a punch, substantially in the manner and for the purposes herein described.

DANIEL HICKS.

No. 7243.—*Improved Oscillating Self-adjusting Railroad Frog.*

What I do claim as new, and my invention, desiring to secure the same by letters patent, is a railroad frog, constructed, applied, and operating essentially in the manner, and only for the purpose herein set forth.

J. W. HOFFMAN.

No. 7244.—*Improved Revolving Plate and Tumbler Lock.*

What I claim as my invention, and desire to secure by lettters patent, is the arrangement of a series of permutation plates in a line, and on the same axis of motion, each having a central hole for the reception of the entire key, and a projecting tongue for the key to act upon, and a recess or recesses on the periphery, for the reception of the tumbler; but this I only claim in combination with a tumbler attached to and rotating with the cylinder, substantially as herein described.

I also claim making the recesses of the key plates (or the equivalent thereof,) of different lengths, but all starting from the same line, substantially as herein described, to facilitate the insertion and removal of the key as described.

I also claim the cylinder which contains the permutation plates, and which carries the tumbler as above described, in combination with the permanent flanch enclosing the same, and having a recess to receive and hold the tumbler when thrown out, substantially as described. And finally, I claim the arrangement of the eccentric for throwing the bolt with the rotating cylinder, carrying the tumbler, and containing the permutation plates, as described.

L. JENNINGS.

No. 7245.—*Improvement in Agitating Coal Grates.*

What I claim in the above described stove as new, and desire to secure by letters patent, is giving the compound vertical and horizontal oscillating motion to the grate bars, as herein set forth.

ABEL KEENEY.

No. 7246.—*Improved Blind and Shutter Opener and Fastener.*

What we claim as our invention, and desire to secure by letters patent, is the opening and closing of window blinds, and retaining them when open or closed, by means of the rotary opener B, (which is circular at its centre, and gradually enlarges into scroll-shaped extremities, having a groove *f*, in its surface, extending spirally from one of its scroll-shaped terminations to the other,) combined with the arm C, secured to the window casing, and the lever D, made fast to the blind, substantially in the manner herein set forth.

JABEZ F. LAWRENCE.
LUKE A. FARNSWORTH.

No. 7247.—*Improvement in Rotary Churns:*

What I claim as my invention, and desire to secure by letters patent, is—the devices of gearing as described, by which I change the motions of the churn box and dasher, with regard to each other, so that while one is stationary, the other shall rotate, and vice versa.

OSBERT B. LOOMIS.

No. 7248.—*Improvement in Spring Mattresses.*

What I claim as my invention or improvement, and desire to secure by letters patent, is so constructing a spring mattress, that the springs of the same shall project outwards beyond the light frame work, which supports them in their places, so that the whole upper and under surface, as well as the edges of the mattress shall present a yielding surface to the touch, by means of the projecting springs.

I also claim the manner of constructing the hair quilted upper or under coverings of the springs as set forth: that is to say, the hair covering which rests on or against the springs, is first made separately like a quilted bed-spread, and when drawn over the springs, by which the mattress, though long used, presents a uniform and elastic surface.

V. M'ELWEE.

No. 7249.—*Improvements in Cat Head and Shank Painter Stoppers.*

But I do claim as new, the application of the lock piece *g*, with the wedge or lug[1], to act in the mortise[3], to hold the link *d*, on the lug *e*, when put down for that purpose, or let the anchor "go" by raising it, without the intervention of any other moving part, such lock piece *g*, and lug or wedge[1], being connected or combined, and operating with the other parts, substantially in the manner and with the effects described and shown.

CHARLES PERLEY.

No. 7250.—*Improved Surface Condenser for Steam Engines.*

What I claim as my invention, and desire to secure by letters patent, is the combination of a surface or radiating condenser with a box or case in such a way, that the condensation of the steam shall be effected therein, without subjecting the said radiating condenser to atmospheric pressure, in the manner described.

Secondly. I claim the aperture (w,) or its equivalent, for maintaining the equilibrium, and as a passage for any steam which may remain uncondensed in the radiating condenser, in the manner set forth.

Thirdly. I claim connecting the evaporator with the chamber (h,) substantially in the manner described, whereby I am enabled to draw off the saturated water from the bottom of the evaporator.

JOSEPH P. PIRSSON.

No. 7251.—*Improvement in the Manufacture of India Rubber Springs for Cars.*

What I claim as my invention, and desire to secure by letters patent, is the method of making cylinders, or rolls, of prepared India rubber, by rolling up a thin sheet of prepared India rubber on a mandrel, whilst the said sheet is in a green state; and as it comes from the heated calendering cylinders, substantially as described. And I also claim as my invention, in combination with the calendering cylinders, such as are usually employed in the manufacture of prepared India rubber, a mandrel or cylindrical rod pressed against the periphery, or a cylinder, or roller, so that the thin sheet of prepared rubber, in the green state, and taken as it comes from the calendering cylinders, may be wound upon the mandrel, and the several windings made to adhere by pressure, substantially as described.

FOWLER M. RAY.

No. 7252.—*Improved Removable Teeth for Scrapers.*

What I claim as my invention, and desire to secure by letters patent, is securing the removable teeth to any common scraper, in the manner herein set forth, so that they can be attached and detached at pleasure, whereby the same scraper is adapted to ordinary earth excavation, or to the excavation of gravel or cobble stones, as described.

JOSEPH SWEET.

No. 7253.—*Improved Mantel Piece.*

What I claim therein as my invention, and desire to secure by letters patent, is the manufacture of mantel pieces, by the combination of cast iron frames of ornamental open work, with a back or ground work of plate glass, or other vitrified substance, colored in imitation of marble, or after any other style of decoration, the said ground work being secured to the frames by means of plaster of Paris, or any other means, that gives strength and support to the whole, substantially as described.

HIRAM TUCKER.

No. 7254.—*Spring Inclined Plane and Roller Sash Stopper.*

What I claim as my invention, and desire to secure by letters patent, is the depressed form of the spring or inclined plane, as I have called it, and the roller so adjusted to this depression by the slide, that in raising the window sash, it operates as a friction roller, but in lowering the window sash, it operates as a dog to keep it from falling, substantially as described above.

SETH E. WINSLOW.

No. 7255.—*Improved arrangement of Door Springs and Levers.*

What I claim as new, and of my own invention, and desire to secure by letters patent of the United States, is attaching the spring d, and rod f, to the jamb of the door or standing part of the hinge, when combined with a swinging rod attached to the door, or swinging part of the hinge, all the parts being arranged, substantially as described, whereby the spring tends to close the door until opened to its fullest extent, and then acts to hold the door open.

W. B. BARNARD.

No. 7256.—*Composition for Covering Hams.*

What I do claim as my invention, and desire to secure by letters patent, is the formation of a preserving composition for coating meats, fruits, vegetables, &c., by the union of resin, shellac, and linseed oil, substantially in the manner and in nearly the proportions as herein set forth.

HORACE BILLINGS.

No. 7257.—*Improvement in Dividers and Compasses.*

What I claim as my invention, and desire to have secured to me by letters patent, is making dividers or compasses, with the micrometer adjustment, herein above described, the combination of devices for the same, consisting of a circular rack bar, arranged in slots, in the legs of the divider, with a spring in the slots of the moveable leg b, b, and the micrometer screw, all working together, as herein above specified.

D. H. CHAMBERLAIN.

No. 7258.—*Improved Entrance to Bee Hives.*

What we claim as our invention, and desire to secure by letters patent, is the devices for opening and closing the entrance of the bee house, in the manner set forth.

JOHN E. DALTON.
THOMAS STEVENS.

No. 7259.—*Improvement in Rings for Harness, &c.*

What I claim as new in my invention, and desire to secure by letters patent, is the combination of a sliding bar or sliding bars, (either with or without guides or guard bars,) with a ring, in the manner, substantially as described, for the purpose of being applied to straps for harness, or for any other purpose to which it may be applicable.

ANDREW DEITZ.

No. 7260.—*Process for making Cast Steel.*

What I claim as my invention, and desire to secure by letters patent, in the above process of making cast steel, is partly decarbonizing pig or cast iron in an oven, stratified with pulverized oxide of iron, substantially as described, and then melting such decarbonized pig or cast iron in crucibles, substantially as described.

JOS. DIXON.

No. 7261.—*Improvement in Machinery for making Wire Heddles.*

I do not claim the old machine herein described, as being one heretofore used and by which an incomplete heddle is produced; but what I do claim as my invention, and desire to secure by letters patent, is the before described arrangement, combination and adjustment, with the said old machine, of the additional wheel (H,) on the main transverse shaft (Y,) fig. 1. The pinion (U,) and the shaft (S,) moved by it, wheel (*a*,) on the other end of the shaft, the short shaft (*d*,) and the two wheels (*c*,) and (*h*,) (*o*,) upon it, wheel P, and its attachments, and the cutter *a*, attached to the pincers as shown in fig. 5, for trimming off the burr at the end of the heddle, and also the levers (D,) (*f*,) (W,) (I,) (3,) (4,) (O,) (*e*,) and (*r*,) whereby the heddle is made complete in one machine, at one and the same operation, or any other combination, which is substantially the same thing, and by which analogous results are produced. I also claim what is herein termed wheel P, as herein described, and as shown in fig. 2, 3, and 4.

MILTON FINKLE.

No. 7262.—*Improved Method of Working the Pawl in Parallel Vises.*

But what I do claim as my invention, and desire to secure by letters patent, is the within described combination of the spring pawl *c*, and the metallic plate (or lever) *b*, with the foot of one of the crossed levers *a*, by which the spring pawl is made to act upon, and retain the rack bar *e*, when any article is grasped between the jaws of the vise, substantially as herein set forth.

JASPER JOHNSON.

No. 7263.—*Improvement in the Fluid Level.*

What I claim as my invention, and desire to have secured to me by letters patent, is a lever for determining a horizontal and perpendicular line, and the inclination of any slope with the same, constructed substantially as herein above set forth, that is, with a shallow cylindrical vessel or a tube, in the shape of an entire ring, half filled with quicksilver, or other liquid, in combination with a graduated annular dial, whether a floating needle or indicator be used or not, the whole arrangement being substantially as herein above set forth.

WM. G. LADD, Jr.

No. 7264.—*Improvement in Machinery for Cutting Screws on the Rails of Bedsteads.*

What I claim as my invention, and desire to have secured to me by letters patent, is—

First. The combination of the adjustive clasp I, screw H, and holder C, for suspending and confining the nut C^3, to the end of the rail, and centering the same, so that the axis of the nut shall always be coincident with the centre of the rail, whether the latter be of large or small diameter, substantially as herein set forth. I likewise claim the peculiar form and manner of securing the V cutter to the cylindrical head E, as described, that is to say, making the cutter as represented (in figure 7,) and letting the tapered end of the shank into the recess, at e^2, bringing the angular shoulder against the cylinder e', and sustaining the bevelled points against the interior bevelled surface of the cylinder head at e^3, by which arrangement the instrument, during the operation of cutting, is forced firmly against the head E, at e', e^2, e^3, the strain upon the confining screw T, being thereby greatly reduced, and the cutting tool itself strengthened.

SPENCER LEWIS.

No. 7265.—*Improvement in Harness Hames.*

What I claim as my invention, and desire to secure by letters patent, is

making the hame of a single piece of wrought iron, inclosing a piece of wood in such a manner as to present an entire iron surface, so that it may be readily finished in any convenient or ornamental way, and in a durable manner, when the hame is constructed, substantially as herein described.

JOHN LOW.

No. 7266.—*Process of making Paint from Bituminous Coal.*

What I claim as new, and desire to secure by letters patent, is the process of making black paint from bituminous coal, by the cleansing in water, grinding, mixing with acid, re-grinding in acid, and washing, substantially as herein fully set forth.

CHARLES MORTIMER.

No. 7267.—*Elastic Roller Sash Bearer.*

But what I do claim as my invention, and desire to secure by letters patent, is the combination of an elastic roller, with a shaft and box, the whole constructed and arranged as before described, for the purpose of supporting a sash in any desired position.

JULIUS A. PEASE.

No. 7268.—*Improvement in Gearing for Seed Planters.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the latch plate M, in combination with the connecting plate O, carrier P, and intermediate cog wheel R, for alternately gearing and ungearing the cog wheel S, on the axle of the plating cylinder with the cog wheel T, on the hub of the driving wheel F, in the manner and for the purpose described.

JACOB PEIRSON.

No. 7269.—*Improvement in Apparatus for extinguishing Fires.*

What I claim, is the means of subduing and extinguishing fire by generating carbonic acid gas and other gases, resulting from combustion, in apparatus, substantially as herein described, and applying them by the pressure of their generation to the purposes above described.

W. H. PHILLIPS.

No. 7270.—*Improvement in Scale Beams.*

I claim in combination with the beam, and the knife edge bearings of the loop, the two vertical or nearly vertical projections, salients or knife edges *b*, *c*, as arranged with respect to the loop and beam, substantially in the manner and for the purpose herein before specified.

WILLIAM P. PIERCE.

No. 7271.—*Improvement in Endless Aprons for Thrashers.*

What I claim therein as my invention, and desire to secure by letters patent, is the endless grating composed of bars secured to the hide or leather straps, by twisting the latter in the manner and for the purposes herein set forth.

ADKINS NASH.

No. 7272.—*Improvement in Hydraulic Regulators for Machinery.*

In this invention, I do not claim the size, form, or shape of any piece or part as new, or the general combination of pumps, pistons or floats, or other parts connected to the machinery to be regulated, or to the motive power to be regulated, which are in use in the general combination of hydraulic motion regulators; but claim to have overcome two several difficulties, which have heretofore existed in this kind of regulators, as follows:

First. The want of sensitiveness to take early notice of any variation of motion, or quickness in motion to open or close the steam valve, of power energetically applied to overcome friction of steam valve.

Secondly. The difficulty which has always existed in obtaining and maintaining a uniform discharge of water or liquids, from under pistons, rising and falling as motion varied, connected to steam valve, and acted upon by water moved by pumps; but I do claim and desire to secure by letters patent of the United States, the combination of pump A, moved with a reciprocal motion, with the machinery sought to be regulated, and with the water or fluid acting on piston C, and parts connecting it to steam valve, which controls the steam moving said machinery in such a manner as to cause the piston C, to rise and fall at each action of pump A, without moving the valve, while the machinery has the proper speed, and moving, or opening, or closing said steam valve with a quick striking motion, or overcoming friction about said valve, as with the blow of a hammer, when the motion of said machinery is too fast or too slow, or any analogous arrangement which will produce the same result, substantially in the manner and for the purposes and objects herein before shown and set forth.

LEMAN B. PITCHER.

No. 7273.—*Improvement in Apparatus for Sprinkling Streets, &c.*

What I claim therein as new, and desire to secure by letters patent, is the combination of the sprinkling pipe and force pumps with the revolving water vessel, the several parts being arranged and operating, substantially as herein set forth.

JOSEPH D. PRICE.

No. 7274.—*Improvement in Plough Cleaners.*

What I claim therein as new, and desire to secure by letters patent, is the plough cleaner constructed of two shave blades, substantially as herein set forth, for the purpose of cutting in two the weeds and other obstructions, which accumulate upon the coulter, and thus detaching them therefrom.

JAS. F. REASIN.

No. 7275.—*Improvement in Chimney Caps.*

I lay no claim to the invention of a ventilator, made with a series of conic or pyramidal guards, fenders, or frusta as represented in figures 4 and 5; but what I do claim as my improvement, is one made with the helical continuous fender or guard, applied to the chimney or flue, and having its coils arranged or inclined with respect to one another, substantially as herein before specified.

AUGUSTUS M. RICE.

No. 7276.—*Improvement in Oil Cans.*

I claim the combination of the socket (C,) carrying the male screw (*d*, *d*,) and the taper tubes or spouts (D, D,) screwing into the socket (B,) with the collapsable gutta percha reservoir (A,) in the manner and for the purpose described, or in any way, substantially the same.

DAVID G. STARKEY.

No. 7277.—*Improvement in Machines for Raking and Loading Hay.*

What I claim as my invention, and desire to secure by letters patent, is the simultaneous raking and loading of hay from the ground by machinery, substantially as herein set forth; whereby, the labor of making windrows and cocking as in the usual process of hay making is saved, at the same time that the operation is both expedited and cheapened.

B. M. TOWNSEND.

No. 7278.—*Improvement in Wing Gudgeons.*

What I claim is the improvement of making the wing gudgeon (when cast or founded,) with a clear space G, between each of the wings, and the flanch or face plate B, the same being for the purpose herein above set forth.

MARK WILDER.

No. 7279.—*Improvement in Guitar Heads and Capio d'astra.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of tuning guitars by winding the strings each on a spindle, having a part below the guitar head of enlarged diameter, connected and combined with a peg of the usual construction by means of a cord, in the manner and for the purpose, substantially as described.

I also claim, combining an eccentric roller with a capio d'astra for moving and holding it down on to any desired part of a guitar handle, by means of a metal strap made to embrace the handle and capio d'astra plate, and attached thereto, substantially in the manner and for the purpose specified.

JAMES ASHBORN.

No. 7280.—*Improvement in Car Couplings.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the draw iron *a*, with the bearing *b*, the bolt *c*, the bed piece *d*, and the wedge or key *e*, in such manner that the draw iron *a*, makes a vertical joint with the bearing *b*, and through the bearing *b*, makes a horizontal joint with the bolt *c*, and the bed piece, *d*, and through the wedge or key *c*, all these joints are brought to any desirable rigidity of bearing.

I claim this particular combination of the parts described, whereby a free, but close horizontal and vertical joint, is at all times maintained between the bodies to which it is attached, and especially the applications of couplings upon this construction, to the connection of locomotive engines and tenders.

HIRAM BALDWIN.

No. 7281.—*Improvement in Machines for Breaking Hides.*

What I claim as my invention, and desire to secure by letters patent, is the breaking of hides, the working out of the lime and the bate, and the scouring of the tanned hides by means of revolving cylinders and beaters, substantially as herein set forth.

CHARLES BAUCHMAN.

No. 7282.—*Improvement in Cast Iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is the casting a "chilled railroad cast iron car wheel," giving a uniform chill to the wheel, by separating the arms B, from the rim of the wheel, by the inverted flanges D, forming a hollow rim, together with the combination of the

arches or ovals C, as herein described; thus using the solid hub to the chilled arches or ovals C, as herein described; thus using the solid hub to the chilled wheel, adding strength to the whole, and securing regularity in the wear.

JAMES BOON.

No. 7283.—*Improvement in Hydraulic Blowers for Furnaces, &c.*

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the cavities or air cells, formed in part by the partitions D, D, D, on the periphery of the drum of the wheel or receiver of compressed air B, B, with said drum or receiver B, B, the exterior floating valves E, E, E, the interior valves H, H, H, and the hollow shaft O, all forming parts of, or connected with a wheel, to be turned when partially immersed in water, for the purpose of producing a blast of air through the hollow shaft O, to be used in heating, smelting, and other manufacturing and mechanical operations.

RANSOM COOK.

No. 7284.—*Improvement in Grates for Cooking Stoves.*

What I claim therein as new, and desire to secure by letters patent, is the manner herein described of arranging and combining the fire grate of cook stoves with the front fire plate A, and curve plate C, so that it shall retain its proper position for retaining the fuel in the chamber by its own weight, and shall be raised for removing coals and ashes, substantially in the manner and for the purpose herein described and represented.

JOHN T. DAVY.

No. 7285.—*Improvement in Submarine Telescopes.*

I claim, first, the main tube A, constructed with the side opening C, in it, to allow a spy glass B, to be used in combination with the telescope, as herein set forth.

Second. The mirror chamber constructed to allow the mirror to move through a space of about ninety degrees, and with a glass K, in the bottom of it, in the manner substantially as herein described, and for the purpose herein set forth.

Third. I claim the arrangement of the lamps or artificial lights on each side of the mirror, and leading the feeding draft from the main tube to the lamps under the mirror and lamps, and carrying the smoke away through the separate passage J, in the manner substantially as herein described, or in any other manner substantially the same.

WILLARD DAY.

No. 7286.—*Improvement in Preparing Clay for Brick Machines.*

What we claim as our invention, and wish to secure by letters patent, is the method of constructing the grinding apparatus or mill, in such a way that the knives on the shaft shall be set so as to describe a spiral line at their junction with the shaft, in order that no two of them shall be able to pass between any two pairs in the curb at the same instant, and under the same circumstances. It being understood that we do not claim, in general, this mode of setting the knives on the shaft, but only the use of the same, in connection with the fixed knives in the curb, for the purpose specified.

CHARLES M. FERRIS.
NATHAN SWAN.

No. 7287.—*Improvement in Electro Magnetic Engines.*

What I claim therein as new, and for which I desire to secure letters patent, is first, the employment of induced electricity, as above stated, in producing magnetism, in the secondary electro magnets, to be used as a motive power, in connection with the prime mover, and to neutralize the secondary currents of the principal magnets formed by the direct current from the battery.

I claim the combination of the magnet changer (h, h',) and pole changer (k, k',) substantially in the manner and for the purpose set forth.

JOHN H. LILLIE.

No. 7288.—*Trap for catching Flies.*

What we claim as our invention, and for which we wish to secure letters patent, is the application of the devices for conveying flies into a box or vessel by wheels or belts between floats or projections, moving either by a circular or straight forward motion, in the manner and for the purpose herein specified.

JOSEPH B. FULLER.
GEORGE W. PIERCE.

No. 7289.—*Combined Shutter and Sash Fastener.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The lever f, secured by a fulcrum pivot to the sill of a window frame, when it is so arranged that the hook at its outer end can be made to interlock with the holder g, made fast to the blind, and when in that position the inner end of the lever be so connected with the apparatus for fastening down the sash, that the lever cannot be operated without previously unfastening the sash, substantially as herein set forth.

Second. I also claim the arrangement of the lever f, placed upon the window sill, the holder g, secured to the blind, and the latch l, secured to the lower bar of the sash, by which, when the blind is closed, and the window sash is raised, the descent of the sash will operate the lever, and thereby securely fasten the blind, substantially as herein set forth.

Third. I also claim the arrangement of the lever f, the holder g, the latch l, and the spring catch m, (respectively secured to the sill of the window frame, and to the blind and sash,) in such a manner that the closing of the sash will securely fasten it down, and at the same time operate and firmly retain the lever f, in such a position that it cannot be detached from its hold upon the blind, without previously unfastening and raising the sash, substantially as herein set forth.

THOMAS HARVEY.

No. 7290.—*Improvement in Carriages.*

What I claim as my invention, and desire to secure by letters patent, is—making the king bolt, the fixed ring of the fifth wheel, and perch in one piece, whereby the liability to accident is diminished, and the durability of the parts is increased, as herein described.

I likewise claim connecting the perch and its braces with the hind axle tree, and the thills with the fore axle tree, by screwing them into pipe clips, as herein described, whereby the great number of screw-bolts and nuts generally employed, are dispensed with, and a cheap and durable connection is obtained which at the same time admits of the ready disconnection of the parts.

JAMES PATTERSON.

No. 7291.—*Improvement in the Construction of Bases for Stands.*

What I claim therein as new, and desire to secure by letters patent, is the mode herein described of employing a base piece, that the legs or feet may hook into, and be held firmly in place by the cap plate, and rod running through the centre, the same being constructed and operating, substantially in the manner and for the purpose described and represented.

EZRA RIPLEY.

No. 7292.—*Improvement in Piano-Forte Action.*

First. I claim the spring tongue, in combination with the under angular lever M, for the purpose set forth, not limiting myself to the exact construction of it, as herein described, while the same effects by a like combination may be produced.

Second. I claim the regulating screw Q, for the purpose set forth, viz: to regulate the strike key separately, as set forth.

JOHN RUCK.

No. 7293.—*Improvement in Attachment of Harrow to Seed Planter.*

What we claim as our invention, and wish to secure by letters patent, is connecting with the machine a harrow, constructed with spring teeth, so arranged by means of a slide hinge *g*, *g*, that the wheel track towards the land to be sewed, can always be left undisturbed as an accurate guide in returning across the field.

MARCUS SAGE.
SILAS S. SAGE.

No. 7294.—*Improvement in Gearing of Seed Planters.*

What I claim as new, and for which I desire to secure letters patent, is—

First. The sliding frame R, in combination with the rod D, for the purpose of raising and depressing the drills A, A, and also for stopping the feeding, simultaneously, as above set forth.

Second. I do not claim the simultaneous throwing out of, and into action, the feed roller and its respective drills, nor do I claim the slide or shut-off J, as I am aware these both have been done. But what I do claim, is operating the shut-off J, and lever I, by means of the arm D, as set forth, for the purpose of causing the same to be self-acting, either when coming in contact with any obstruction, or when desired for sowing pointed or irregular lands.

ANTHONY SANDOC.

No. 7295.—*Compound Tubular Rail.*

What I claim as my invention, and desire to secure by letters patent, is the making of a two part break joint hollow rail, substantially as herein described, and in combination with the two part rail made hollow, as specified, I claim the blocks, inserted in such hollow, at the junctions of the sections, substantially as described.

ALFRED B. SEYMOUR.

No. 7296.—*Improvement in Sewing Machines.*

What therefore, I claim as my invention, is the herein before described disposition of the thread eye of the needle, (that is to say, the said eye, being placed near the point of the needle,) in combination with the afore described manner of supporting the needle, and applying it to the machinery which produces the corrugations or foldings of the cloth, not meaning to lay claim to

the combination of a needle and gears or other analogous contrivances for producing sewing, as the same have heretofore been applied and used, but meaning only to claim my improvement as constructed and made to operate, substantially as above specified.

DAVID M. SMITH.

No. 7297.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is causing the heat and products of combustion to enter the flue over the oven, on one side, and carrying the same across the top of the oven, down the other side thereof, in a broad sheet, thence under the oven, and thence up in a broad flue to the smoke pipe, substantially as described.

WM. ABENDROTH.

No. 7298.—*Improvement in Churns.*

What I claim as my invention, is the combination of the external chambers, their plungers and discharging passages, with the middle or air chamber, the whole being constructed, applied, and used, substantially as specified, and in combination with the above, I claim the air entering passages *d*, *d*, &c., applied and used, substantially in manner and for the purpose above specified.

JOHN ANDREWS.

No. 7299.—*Improvement in Dentists' Chairs.*

What I claim, and desire to have secured to me by letters patent, is the manner in which I arrange the operating parts within the frame work, and under the seat, in combination with the seat, so made as to move up and down within the frame work, and appear like an entire seat, as herein set forth.

A. MERRITT ASAY.

No. 7300.—*Improved Method of Attaching the Cylinder in Revolving Fire Arms.*

What I claim, is the improved mode of attaching the cylinder of barrels to the stock, viz: by means of the cylindrical tube B, in combination with the flanch and stud, or their equivalents, whereby I dispense with the usual spindle and hole for its reception in the centre of the cylinder of barrels, being thus enabled to enlarge the bore of the barrels in a cylinder of equal size.

D. H. CHAMBERLAIN.

No. 7301.—*Improvement in Machines for Drilling Stone.*

What I claim therein as new, and desire to secure by letters patent, is the combination of the lever (*z*,) with the cranks and pitman, which operate it, for the purpose of rotating the drill periodically, by impingement against the cogs of the pinion (*a'*,) at its greatest elevation, returning to position when the pinion is removed from its range, the whole arranged and operated, substantially in the manner and for the purpose set forth.

GEORGE FLETCHER, Sr.

No. 7302.—*Submerged Rocker for Separating Ores.*

What I claim as new in my invention, and desire to secure by letters patent, is the combination of the rocking frame C, the pans F, F, F, the levers B, B, and the bars E, E, attached, secured, and adjusted to the box A, or to a platform or boat, in the manner and for the purpose, substantially as herein described.

OLIVER EDES.

No. 7303.—*Improvement in Safety Lamps.*

What I do claim as my invention, and desire to secure by letters patent, is the sliding tubes I, I, in combination with the screw C, the said screw C, being furnished with the opening E, through which to fill the lamp, substantially in the manner and for the purpose described.

J. W. HOFFMAN.

No. 7304.—*Improvement in Double Cooking Stoves.*

What I claim and desire to secure by letters patent, is the construction of a double cooking stove, having two compartments I, I, and a smoke flue K, passing round one compartment first, and then around the other, in such manner that one shall be heated in a much higher degree than the other, arranged and constructed, substantially as herein described, and for the purposes set forth.

HENRY JACKSON.

No. 7305.—*Improved Arch Truss for Bridges.*

What I do claim, is the so combining or arranging them with respect to each other, and with the radial suspension rods, and on the cord or beam to which they are applied, that they and their suspension rods may overlap one another, and have the feet or parts of each which rest on the cord, upheld by the crown and suspension rods of the central part of an adjacent arch, all substantially as above specified.

HENRY LANERGAN.

No. 7306.—*Improvement in Coal Stirrers for Furnace Grates.*

What we claim as new, and desire to secure by letters patent, is—

First. The rake frame having numerous vertically moving fingers, constructed and operating to stir and clean the fire only by a vertical movement, said fingers being distributed beneath the grate, substantially in the manner, and for the purposes described.

Second. We also claim, in combination with the passages round the rim of the grate, admitting warm air above the fire, the vertically moving rake teeth, which open passages for the free escape of combustible gases, to be burned by said warm air, thereby maintaining a copious volume of flame all around the interior of the fire box, as herein set forth.

WILLIAM R. NICHOLS.
BURNITT C. BOYES.

No. 7307.—*Improvement in Cotton Gins.*

What I claim as new, and of my own invention, and desire to secure by letters patent of the United States, is—First. The making card cylinders with gutta percha, or other similar substance, filled in among the teeth, to form a regular surface, and stiffen the teeth, whether such cylinders, so fitted, are used for this or any other purpose for which they are available.

Second. I claim the application of one or more card cylinders with gutta percha, or other similar substance between the teeth, in connection with an equal number of smooth cylinders, to card cotton from the seed, substantially as described and shown.

Third. I claim the application of the wire gauze drum G, and roller h, beneath; first, for the purpose of allowing the blast to drive the dust and chaff from the cotton; and second, for the purpose of leading the cleaned cotton

duces the contig-

out in a sheet, or bat, whether this roller and drum be applied to act with card or with the common saw gin.

STEPHEN R. PARKHURST.

No. 7308.—*Improvement in Piano Fortes.*

I claim the manner of constructing the tuning block, substantially as herein described, of the arched slab A, and the back piece B, with the wedge or piece a, and the diagonal bolts or keys b, b, b, whereby it is made capable of withstanding the great strain of the strings.

I also claim the metal plate D, carrying the ribs d, d, d, projecting from and forming part of it, the plate being attached to the upper surface of the tuning block, each of the strings of the instrument passing over and resting on a rib, and passing through a hole in the rib immediately behind, whereby the strings obtain a solid bearing on the tuning block, which will make them produce a full, round, clear tone.

JOHN RUCK.

No. 7309.—*Improvement in Brick Presses.*

What I claim therein as new, and for which I desire to secure letters patent, is first, the combination of the grated disk and hopper, constructed and arranged, substantially in the manner and for the purpose set forth, and in combination with the revolving moulds.

Secondly. I do not claim the mould as herein described, or the manner of holding the brick firmly while being cut off, these claims having already been granted to me in my patent of September 27th, 1844, but

What I do claim is the arrangement of the moulds (whether conical or otherwise, as before patented) in a revolving cylinder, with pistons revolving with them, and working under a stationary cam, as herein described, in combination with stationary cutters, or cutters revolving on their own axes, working in a groove, near the lower ends of the moulds, and also below the moulds, in the manner and for the purposes herein set forth.

Thirdly. I claim the apparatus for trimming the bricks, consisting of a stationary cutter and a piece in front thereof, to press up against the brick as the clay is cut.

Lastly. I claim the combination of adjustable headed pistons, with stationary cam, as herein fully specified.

NATHAN SAWYER.

No. 7310.—*Improved Arrangement of Propellers and Chimneys for Canal Boats.*

What I claim as my invention, and desire to secure by letters patent, is the employment, in combination, of two propellers, arranged in a recess at the stern of a boat, each being on a separate shaft, one above the other, and one of the propellers being placed back of the other, substantially as herein described, whereby a greater amount of paddle surface can be obtained within a case, and with a given width of stern, than by any other known plan.

And I also claim, in combination with the propellers arranged with a part of one of them above the water line, and enclosed in the recess at the stern of the boat, substantially as herein specified, the employment of a fan for exhausting the chimney of the steam boiler furnace, and for discharging the products of the combustion into the recess in which the propellers work, substantially in the manner and for the purpose specified.

BENJAMIN M. SMITH.

No. 7311.—*Lathe for turning a Peculiar Species of Curve.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of turning the periphery of steam wheels, or other articles, with regularly curved projections and depressions from a true circle, by combining with the mandrel of a lathe, or (what is equivalent thereto,) the shaft of the steam wheel, a cutter, which, in addition to the usual longitudinal motion parallel with the axis, receives a reciprocating motion towards and from the axis, by means of a cog wheel, and pinion and crank, or their equivalents, as herein described.

H. G. THOMPSON.

No. 7312.—*Improvement in Smut Machines.*

What I claim therein as new, and now desire to secure by letters patent, is as follows: the peculiar construction of the rubber pieces *o*, substantially as described and represented, whereby all parts of their surfaces may be successively appropriated to the rubbing action, each plate being susceptible of four changes before it becomes necessary to replace it by a fresh rubber.

DAVID ULAM.

No. 7313.—*Improvement in Brick Presses.*

What I claim as my invention, and desire to secure by letters patent, is the clearer *s*, *s*, as used in connection with the two plungers O, and P, for the purpose of delivering the brick and preventing the plunger O, and P, from becoming foul at their passing ends, and the clearer itself being kept clean, and polished by the action of the plunger P, upon its lower surface.

SHEPHERD WHITMAN.

No. 7314.—*Improvement in Instruments for Measuring Cloth.*

What I claim, is the manner herein described, of measuring cloth or other fabrics, by causing the material to pass over and give rotary motion to the roller B, carrying on its axis the endless screw gear E, gearing into the teeth of, and giving motion to the traveller wheel H, carrying an indicator *f*, pointing out the distance travelled by the periphery of the roller B, in the graduated adjustable index plate I, or by any other mechanical combination, substantially the same.

E. F. WHITON.

No. 7315.—*Improvement in Adjustable Shares of Corn Ploughs.*

What I do claim as my invention, and desire to secure by letters patent, is increasing or diminishing the angle of the ploughs with the central line of draft, by shifting the screws K′, K′, to the holes (*c*,) in the ploughs, and the screws L′, L′, to other holes in the beams C, C, without changing the position of the shanks J, J, and braces, M, M, by which more or less earth may be thrown toward the row of plants under culture, as described.

DAVID WOLF.

No. 7316.—*Improvements in changing a Reciprocating Motion into a rotar Motion.*

What I claim as new and of my own invention, and desire to secure b letters patent of the United States, is the application of the levers *h*, *h*, 1, catc blocks 8, 8, with the bevels 9 and 10, and springs *i*, *i*, or their equivalents, t interlock and unlock with the crank arms *g*, and *g*, 1.

And I claim, also, making the governing bar adjustable in combination with the levers *h*, *h*, 1, in such a manner as to give either a direct or reversed motion to the pulleys, *F*, *F*, 1, and I claim the above applications severally, and in combination in the whole and in the parts; the apparatus being constructed and operated, substantially in the manner, and for the purposes described and shown.

PETER YATES.

No. 7317.—*Improvement in Reed Musical Instruments.*

What I claim as my invention, or improvement in reed instruments made with a sounding board, is to make the reed opening *c*, directly through the wooden sounding board, in combination with the applying of the reed directly to the same, and fastening it to the sounding board, instead of using any metallic frame, for the opening and reed, as has been the customary method of making and constructing such instruments.

CHARLES AUSTIN.

No. 7318.—*Coupling for Pipes and Hose.*

I claim the construction of couplings for hose and tubing, by forming one part thereof into a hollow cylindrical cup or box, having wedge shaped flanges of metal inside and next to the edge thereof, and by forming the other part of the coupling of a flange equal in diameter to the first described coupling, having its face edge ground with the edge of the first coupling to make a tight joint with a cylindrical ring, (whose bore is equal to that of the tubes to be coupled) projecting from said flange concentric with it, and in diameter just large enough to pass between the flanges of the cup or box, and to reach just to the bottom of the cup, whose bottom face with the outer face of said ring are ground together to form a tight joint. Also said ring having on its periphery at the outer edge, wedge shaped flanges similar in form and angle to the flanges of the cup or box, and so arranged as to pass between the intervals of the same, so that by being turned round underneath them, they compress the ground surfaces of the couplings together firmly.

A. HEYER BROWN.

No. 7319.—*Improvement in Apparatus for Drawing Water.*

What I claim as my invention, and wish to secure by letters patent, is the plan herein described, of bringing water upon a level, over a hill, or in any situation where the fountain is not higher than where the water is wanted for use, viz: I claim the combination of the weight and its cord, pulley and ring, with the cord by which the bucket is drawn, and the hook or catch upon the carriage, the whole being arranged, substantially as described, for the purpose of drawing the empty bucket from the place of discharge over the highest point of the way to the spring.

CAIN BROYLES.

No. 7320.—*Improvement in Machines for Holding and Dressing Slates.*

What I claim therein as new, and desire to secure by letters patent, is the endless series of clamp carriages operating, substantially as herein set forth, to hold and carry the slates beneath the cutters.

SAMUEL E. CROCKER.

No. 7321.—*Improvement in Grain Driers.*

What I claim as new and useful in the foregoing, and desire to secure by letters patent, is the construction and arrangement of the apparatus as herein described, by which a stratum of air is forced into a case enclosing the grain cylinder where it protects the grain from the direct action of the heat from the fire, and is there heated and conveyed through the grain so as to carry off the moisture therefrom, substantially in the manner and for the purpose set forth.

M. R. DUDLEY.

No. 7322.—*Improvement in Gearing for Regulating Speed.*

I claim, therefore, as my invention, and for which I wish to obtain letters patent, the employment of the wheel or pulley F, in combination with the cone and governing shaft O, substantially in the manner and for the purpose set forth

HOSEA ELLIOTT.

No. 7323.—*Improvement in Gauges for Spreading Plasters.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the adjustable, expanding and contracting frame with the adjustable, expanding, and contracting bed, the several portions of the combination being arranged and constructed, substantially as herein set forth.

JAMES M. KEEP.

No. 7324.—*Improvement in Let-off Motion of Looms.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the yielding, weighted, and the stationary whip rolls, in connection with the let-off motion, as herein set forth, whereby the texture of the cloth is rendered more uniform than has been heretofore done, while it can be varied at will.

JONATHAN KNOWLES.

No. 7325.—*Improvement in Hanging Saws in Saw Mills.*

What we claim as our invention, and desire to secure by letters patent, is the method of hanging a mill saw, from guides in advance of its front edge, which sustains the whole pressure caused by the advancement of the wood on the carriage against the saw teeth, the plate of the saw swinging on the advanced guides as pivots, so that when cutting, it is kept running in a plane passing through the guides, in the direction in which the carriage moves, as a vane is kept by the wind in the direction in which it blows.

E. HERVEY PARSONS.
SANFORD E. PARSONS.

No. 7326.—*Improvement in Holding Daguerreotype Plates.*

What I claim as my invention, and wish to secure by letters patent, is the construction of a moveable holder for securing daguerreotype plates, by pressure from within, outwards, while the plates are being polished, burnished, buffed, or cleaned.

I also claim as new, the construction or arrangement of a holder composed of two parts with springs between the parts, pressing them from within outwards, against the bent edges or corners of the daguerreotype plate, and secured from contraction by a button or wedge, substantially as in the drawings. And in combination with such a holder, I claim the bending of the edges or corners of the plate so as to secure the same to this holder.

I also claim the adaptation of a daguerreotype plate, with its edges or corners bent, as shown in the drawings, to a moveable holder, constructed substantially as above described.

SAMUEL PECK.

No. 7327.—*Improvements in Apparatus for Splitting and Stretching Leather.*

I claim the construction of a machine performing the business of rolling, splitting, and stretching leather, at one operation, as set forth in the above specification and drawings, viz: the following combination of machinery, one roller (G,) driven by the motive power, having another roller N, moving above it, between which two rollers, the leather is to be compressed, the upper roller running free upon its own axis, which is fixed in a vibratory frame, in order that said upper roller may be adjusted thereby, to any variable or determinate pressure upon the leather, by proper power applied to said frame. A second roller placed a short distance in front of, and parallel with the first named one, running free on its own axis. A smaller roller (placed in a second vibrating frame, similar to, and adjustable like the first mentioned frame,) running above the last mentioned roller, to perform the functions of compressing the leather and holding it firmly, to receive the cut of the knife. A knife supported by strong springs and placed just in front of the last mentioned pair of rollers, with its cutting edge a short distance from the point of compression of these rollers, so as to act upon the leather directly, as it leaves the rollers.

A moveable frame to carry the leather to be operated on, moved by a gearing connecting it with the first roller (G,) and giving it a certain proportional rate of movement, compared with that of the roller, by which the quantity of stretch to be imparted to the leather can be regulated. An apparatus for gauging the knife to cut the leather to a given thickness, consisting of a pair of eccentrics *g*, and *g*, on the ends of a shaft, running parallel with the knife, and operating upon each end of it equally, as the said shaft is turned round, with an index plate *z*, and set lever *y*, to regulate and fix the same, during the operation of the machine.

BRADFORD ROWE.

No. 7328.—*Improvement in Vats or Press Boxes for Cheese.*

What I claim as my invention, and desire to secure by letters patent, is providing cheese vats with a moveable joint which is operated by a crank or lever, to enlarge and diminish the size of the vat, substantially in the manner and for the purposes herein set forth.

AUGUSTUS N. SEVERANCE.

No. 7329.—*Improvement in Roasting Coffee.*

What we claim as our invention, and desire to secure by letters patent, is the application of steam or vapor to the grains of coffee, just previous to subjecting them to the action of a dry roasting heat, within an apparatus constructed and operated, substantially in the manner herein set forth.

W. H. TRIPLER.
ELIAS BRECHT.

No. 7330.—*Machine for Making Wrought Iron Railroad Chairs.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The double or parting die F, *f*, substantially as described, parting by means of a joint at the top or otherwise, for the purpose above set forth.

Second. The vertical shears and benders V, V, working in connection with the double die F, *f*, in such manner as to cut and form the lips of a chair at one operation, substantially as described.

Third. I also claim the combination of dies, shears, punches, benders, and

clearers, arranged and operated in the manner and for the purpose above set forth, or any similar arrangement, wherein the combination is essentially the same.
WILLIAM VAN ANDEN.

No. 7331.—*Improvement in Board and Log Rules.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the log table and board rule, in the way and manner and in the form described and illustrated herein.
BENJ. M. VAN DER VEER.

No. 7332.—*Pipe Coupling.*

What I claim as my invention, and desire to secure by letters patent, is fastening together the abutting ends of two pipes, by forcing a sleeve of some hard substance over a belt of a softer substance, which envelopes the seam and is thus compressed between the sleeve and the pipes.
CHAPMAN WARNER.

No. 7333.—*Improvement in the Rubbers of Smut Machines.*

What I claim therein as new, and desire to secure by letters patent, is the vibrating rubber (e,) in combination with the feeding and rubbing cylinder (d,) constructed and operated, substantially in the manner and for the purpose described.
FRANKLIN WRIGHT.

No. 7334.—*Method of preventing Accidental Discharge in the Prussian Gun.*

What I claim therein as new, and for which I desire to secure letters patent, is the guard (n',) to prevent the discharge of the arm when all the parts are not in proper position, constructed, combined, and arranged with the arm, and operated substantially in the manner and for the purpose set forth.
JOHN WURFFLEIN

No. 7335.—*Improvement in Printing Presses.*

I claim the mode of governing the vertical motion of the type bed N, by the conjoint application of the crank L, and two part pressing bar M, made as a hollow cylinder and slide, with stop shoulder, to give the upward motion and pressure, and arranged to lengthen by sliding out at the back motion of the crank L, and the combination therewith of the grooved cam $b5$, and backing bar b, b, to regulate the descending motion of the type bed, substantially as described and shown.

I claim the application of the rotating cams $c3$, to act through the fork $c4$, and connect or disconnect the clutches 26, to give the shaft $c6$, a rotary motion during half of the rotation of the shaft b, and suspend the motion of the shaft $c6$, by the disk $c8$, and pins t, on the fork $c4$, during the other half rotation, so that the shaft b, goes two continuous revolutions to one intermitted revolution of the shaft $c6$, such intermitted revolution being applied to give an intermitted alternate motion to the double paper carriage in a printing press, or to give any similar intermitted alternate motion by any competent means, substantially as described and shown.

I claim the application crank $c9$, male wheel d, fixed female wheel $d1$, and connecting bar $d2$, for the purpose of communicating the intermitted alternate motion to the double paper carriage $d3$, substantially as described and shown.
F. G. AUSTIN.

No. 7336.—*Improvement in Bran Dusters.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the exterior stationary shell or cylinder E, the intermediate revolving cylinder D, covered in sections with wire cloth of different qualities, and the central revolving cylinder A, with the ventilator y, for the admission of air, and the openings between the staves in the cylinder, for the emission of air to drive the flour and other stuff separated from the bran, through the wire cloth; the several parts, with their driving gear and apparatus, being constructed and arranged, substantially as herein described, and intended for the purposes set forth.
E. R. BENTON.

No. 7337—*Improvements in the construction of the Frame, Roof, and Floor of Iron Buildings.*

What I claim as my invention, and desire to secure by letters patent, is the method substantially as herein described, of making the frame work of iron houses of more than one story, by means of beams cast in sections, with end flanches, which receive bolts for uniting and drawing them together, and with top and bottom parallel flanches, when this is combined with columns, pilasters, or posts cast with horizontal flanches at top and bottom, the top flanche of one column, and the bottom flanche of another, being secured by bolts to the horizontal flanges of two beams, one column above and the other below, the point at which the beams are joined, for the purpose and in the manner substantially as described.

I also claim the method, substantially as herein described, of making the floors by means of thin plates of metal, formed with a groove on one edge, and tongue on the other, by riveting narrow strips of metal to their under surface, and near the edges, the plates so formed being put together breaking joints, substantially in the manner and for the purpose specified.

I also claim the method, substantially as described, of covering the roofs of houses by means of series of thin metal plates, formed each with a groove on one edge, by riveting narrow plates or strips to the under surface thereof, that the edge of one plate may fit into the groove on the lower edge of the next above, and so on throughout the series, substantially as described, when these plates are also provided with the lapping pieces or plates, riveted or otherwise secured to the upper surface of one end of each plate in each series, to lap over the end of the contiguous plates of the next series, the said lapping pieces of each series being also made to lap one over the other, substantially as and for the purpose specified.
JAMES BOGARDUS.

No. 7338.—*Improvement in Air Heating Stoves.*

What I claim as my invention, and desire to secure by letters patent, is—

First. A grate combined with and around the hollow cylinder through which the air passes and becomes heated.

Second. A conical hood placed above the air cylinder and the grate, and connected with a smoke pipe for the purpose of creating a draft, concentrating the heat, and conducting of the smoke or gas from the burning wood or coal.

Third. The placing the grate on friction rollers, as described, in connection with the cylinder, for the purpose of clearing the grate of ashes, or bringing any part of it under the operation of a stronger draft or current of air.

Fourth. The combination of the air pipes, or air passages with the hood, as described, by which the air that has become heated in the cylinder, is conveyed to the room, or place to be warmed.

Fifth. The circular fender, which is also made to answer the purpose of a blower, by being raised and connected with the hood, as described.

Sixth. The method of introducing air into a hollow cylinder or air chamber, connected with and inside of the grate, and taking the air from beneath the hearth.

JAS. L. CATHCART.

No. 7339.—*Improvement in Bedstead Fastenings.*

What therefore I claim, is the lip N, in combination with the pawl and ratchet arc, substantially in the manner and for the purpose as described, and when the bedstead bottom is made of the said flexible strips, having such a flexibility as to enable them to be readily wound upon the windlass, and unwound therefrom, as stated.

CHAS. C. COOLIDGE.

No. 7340.—*Adjustable Mouth Piece for Road Scrapers.*

What I claim as my invention, and desire to secure by letters patent, is combining with the body of a scraper, a mouth piece which can be adjusted to form various angles with the bottom of the scraper, substantially in the manner and for the purpose herein described.

SHADRACH DAVIS.

No. 7341.—*Improvement in Mechanical Leeches.*

What I claim as my invention, and desire to secure by letters patent, is:

First. The arrangement of the wire G, L, of the button H, and of the covering of the instrument I, connected with the piston rod by the India rubber tube K, which allows the cylinder D, placed in the vacuum produced by the piston to work without admitting the air.

Second. The blades of the lancet, shaped like a V.

M. DELLUC.

No. 7342.—*Improvement in Defecating Sugar.*

I claim the process as described, for the immediate separation of the sugar from all foreign matter, which injures the purification by the manner above set forth, by forming a solid saccharate of baryta, pressing, decomposing, and separating the solid cakes and finishing the process as set forth, to the almost total suppression of heat necessary to evaporation.

ROBERT DE MASSY.

No. 7343.—*Improvement in Over Shoes.*

What I claim therein as new, and for which I desire to secure letters patent, is an over shoe covering the front of the boot at the sole, substantially in the manner and for the purpose set forth.

PETER DORN.

No. 7344.—*Improvement in Plough Cleaners.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the lever, notched arm, and vertical wheel B, with a conical roller placed under the beam and upon the cutter of the plough as above de-

scribed, for the purpose of operating the conical roller and cleaning the plough in the operation of ploughing, as set forth.

DANIEL D. GITT.

No. 7345.—*Improvement in Cooking Stoves.*

What I claim therein as new, and desire to secure by letters patent, is:

First. The mode herein described of constructing fire boxes for stoves, furnaces, &c. in two pieces, so that they are not confined as they are when made whole, or four pieces as described, but are free to move on their bed plate.

Secondly. I claim the manner herein described, of dividing the sliding hearth of cook-stoves in such a manner as to admit of its sliding under the stationary part, and be entirely out of the way; the whole being constructed in the manner and for the purpose, substantially as herein described and represented.

JAMES R. HYDE.

No. 7346.—*Improvement in Screw Excavator.*

What I claim as my invention, and which I desire to secure by letters patent, is:

First. The employment of a screw excavator combined with an adjustable tube as above described, for the purpose of excavating and conveying off earth, said tube being placed at any angle, or vertically, or horizontally as the case may require.

I also claim the apparatus for sustaining, moving, and guiding the excavator as above described, by which it is combined with the prime mover, so as to be readily pointed in any direction, said apparatus consisting of a ring with shifting bearings and a moveable bearing for the shaft to rest in which is connected with the prime mover by universal joints.

R. MONTGOMERY.

No. 7347.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the method of protecting boiler covers against the injurious action of varying temperatures, by combining therewith a lining made of metal, so formed that in its cross section, it shall present a curved line, that is, a line longer than a straight line as described.

And I also claim the method of supporting the doors of stoves, by means of a lever or levers so connected with the doors, substantially as described, that the said lever shall be moved in and out by the closing and opening of the door as described.

JORDAN L. MOTT.

No. 7348.—*Improvement in Working a Rotary and Vertical Churn Dasher.*

I claim the application of the shaft B, to communicate a vertical reciprocatory movement to the dasher F, and a rotary one, and the dashers M, and G, so that either can be used as desired, as herein set forth.

WILLIAM R. NASH.

No. 7349.—*Improvement in Straw Carriers.*

What I claim therein, and for which I desire to secure letters patent, is an elongated apron, or pierced platform, hung upon and worked by cranks connected with and forming a part of the thrashing and separating machine, substantially in the manner and for the purposes herein described.

WILLIAM PIERPONT.

No. 7350.—*Arrangement of several Slide Valves in the same Steam Chest.*

What I claim as my own invention, and desire to secure by letters patent, is the arranging of two or more valves in the same steam chest, to open and close the several steam ports or passages, leading to and from the cylinder of a steam engine, arranged and operated to graduate the admission of steam into the cylinders of steam engines in the manner and for the purpose, substantially as above set forth, in the foregoing specification.

CYRUS RICHARDSON.

No. 7351.—*Improvement in the Manufacture of the Oxide of Zinc.*

What we claim as our invention, and desire to secure by letters patent, is:

First. The use of a draft of air, through the suction tubes Q, Q, described above for oxidizing the metal, and carrying forward the products and the arrangement of tubs or basins for the reception of the heavier portion of the products as described herein.

Second. The arrangement of the oxidizing chamber, in combination with the receiving chambers, so as to allow the products which they contain, to be gathered without entering the chambers.

E. LECLAIRE.
E. BARNELL.

No. 7352.—*Improvement in the Melodeon.*

What I claim as my invention, and desire to secure by letters patent, is:

First. The employment of the arms P, in combination with the top O, of the bellows in the manner and for the purpose set forth in the foregoing specification.

A. L. SWAN.

No. 7353.—*Improvement in Oscillating Valves of Steam Engines.*

What I claim as new, and desire to secure by letters patent, is the recess j^2, sunk in the oscillating valve, and communicating with the steam passage *f*, in combination with the recess *k*, formed in the valve chamber, the same acting in the manner and for the purposes herein specified.

T. C. THEAKER.

No. 7354.—*Improvement in Machines for Polishing Stone.*

What I claim as my invention, is the manner or mode of giving a compound or double motion to the rubbers by means of two carriages, or a double carriage, each carriage moved by its respective cranks, substantially in the manner and for the purpose herein described, so that one motion of said rubbers will not interfere with the other motion; said machine can be propelled by any power now in use.

AMOS WALTER.

No. 7355.—*Improvement in Machines for Slitting Clothes Pins.*

What I claim as my invention, and desire to have secured to me by letters patent, is cutting the two sides of the outer end of the slot or fork of a clothes pin, on a regular sweep, by means of knives formed alternately on each side of the circular saw, which cuts the straight part of said slot, and in the direction above explained, whether said knives be made of portions of the plate of said saw, and bent outwards, as described, or in separate pieces, and attached to said sides of said saw.

HORATIO P. ALLEN,

No. 7356.—*Improvement in Stoves.*

What I claim as new therein, and which I desire to secure by letters patent, is first, the air chamber in which the air is heated, previously to its admission to the fuel, in combination with the spiral apertures, by which the heated air is caused to impinge on the upper surface of fuel, substantially in the manner and for the purposes as described.

ANSON ATWOOD.

No. 7357.—*Improvement in Connecting Rods of Steam Engines and other Machinery.*

What I claim as new and of my own invention, and desire to secure by letters patent of the United States, is the application of prepared India rubber, or of any similarly effective elastic substance, in the parts forming the joints of connecting rods of steam engines and other machinery, for the purposes of preventing jars, and breakage of the parts, when a reciprocating motion is changed to a rotary, substantially in the manner described and shown.

LEVI BISSELL.

No. 7358.—*Improvement in Steaming Grain preparatory to Grinding.*

I claim, in combination with a steam pipe (I,) and grain passage (B,) the deflecting partition (C,) for directing the steam upward, and the grain downward, whereby the current of grain is steamed by direct contact with the current of steam at the moment before entering the mill, substantially as herein set forth.

BENJAMIN F. BROOMELL.

No. 7359.—*Improvement in Balancing Sash.*

What I claim as my invention, and desire to secure by letters patent, is—

First. In connection with the grooves in the sash, the distribution of the several pulleys and friction wheels, and the cord attached to the bottoms of the sashes, instead of their tops, whereby the cord and pulleys are kept entirely out of view.

Second. The combination of the barrel axle, ratchet wheel and pin, with its case or bearings, or their equivalents, with the cord and pulleys, the whole arranged and operating, substantially as herein set forth.

HIRAM C. BROWN.

No. 7360.—*Tooth Segment Lock for Fire Arms.*

What I claim as my invention, is the moveable toothed segment G, and escapement or spring pawl I, or any mechanical equivalent therefor, (the said segment and escapement being arranged within the trigger,) and the toothed segment or arc C, (of the hammer,) in combination together, and with the trigger, hammer, and stock, and made to operate, substantially in the manner as herein before specified.

D. H. CHAMBERLAIN.

No. 7361.—*Cylinder and Trough Gold Washer.*

What I claim as my invention, and desire to secure by letters patent, is the separating gold or other heavy substances from others of less specific gravity, and water with which it may be mingled, by the use of a wheel or cylinder, and trough, the periphery of the former, and the bottom of the latter being covered and constructed, substantially in the manner herein set forth.

THOS. M COLLINS

No. 7362.—*Revolving Jaw Wrench.*

I claim the revolving jaw block N, and feather E, as combined together, and with the screw shank A, and made to operate, substantially as herein before specified.
NATH'L COLVER.

No. 7363.—*Improvement in Connecting Skeins with Axles.*

What I claim as my invention, is the combination with the skein of the screws g, g', for the purpose of tightening the skein on the axle tree, as set forth in the foregoing specification.
ABEL COMBS.

No. 7364.—*Improvement in preventing Fibres from Winding on Drawing Rollers in Spinning Machines.*

What I claim, is the improved manner of applying and using the roller, the same consisting in placing it not exactly in contact with the lower front drawing roller, but at a distance therefrom, and by means of separate or additional machinery, giving to it a rotary motion, at the same velocity, and in the same direction with those of the said lower front drawing roller, the whole being, substantially in the manner and for the purpose, as herein before specified.
JOHN C. DODGE.

No. 7365.—*Improvement in Machines for Washing Table Furniture.*

What I claim as my invention, and desire to secure by letters patent, is the construction of a cylinder with a cylindrical rack, supported by an upright shaft resting upon and being within, and supported by the cylinder, the rack having within it a conical rack and hoop, to receive and hold table furniture, in combination with a curb, containing a horizontal wheel with buckets to throw water upon the cylindrical rack; the whole supported by a frame, and by these mechanical means cleansing the surface of table furniture, without the use of hands, the entire machine being arranged, combined, and operated, substantially as is herein fully set forth.
JOEL HOUGHTON.

No. 7366.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is—

First. I claim making the cover of the feeder, projecting in front with curved sliding doors, substantially as described.

Second. I claim forming the bottom grate by casting projections, from the edge of the fire back, or the equivalent thereof, substantially as described.

Third. I claim giving the required strength to the fire brick lining of stoves, to prevent them from breaking or separating when cracked by the heat by the insertion into them of metal rods, wires, or wire cloth, substantially, as described.

Fourth. I claim the combination of the two series of flue tubes, arranged one above the other, and with a space between them, all for the circulation and radiation of heat; for the purpose of giving a greater heat at the bottom of the oven, substantially as described; and this I also claim in combination with the above arrangement of flues, as described.

And lastly, I claim the method of supporting and bracing the door or doors, by means of the bracing rod hinged to the door, and passing through a hole below, (or the equivalent thereof,) and bearing against the bottom of the stove or a stop, or the equivalent thereof, substantially as described.
JORDON L. MOTT.

No. 7367.—*Improvement in Splint Machines.*

What I claim as my invention, is the combination of the circular or tubular cutters e, e, their lateral wing knives or cutters, their rib knives or cutters h, h, and the waste escape passages for the waste strips f', f', f', substantially in the manner and for the purpose above specified.

I also claim the improvement by which I am enabled not only to make round or cylindrical splints, but to introduce them to the dipping frames; that is, I do not claim the combination of cutters, dipping frames and passages leading from the cutters to the dipping frames, as these have been before invented and used for making square splints, and setting them in the frames, but I claim, in combination with cutters for forming the round splints and passages m, m, for receiving them and conducting them to the dipping frames, the passages i, i, or F, for the escape of the waste wood or strips f', f', f', the same being applied together and made to operate in connection with the reducing plane iron e, and the plates C, D, substantially as above specified.
HORACE PATTERSON.

No. 7368.—*Improvement in Thrashing Machines.*

What I claim as my invention, and desire to secure by letters patent, is First. The peculiar serrated and duplex conformation of the beaters B, substantially after the manner and for the objects herein described; that is to say, consisting of a pair of plates B, and c, c, c, diverging rectangularly from each other, and the latter consisting of teeth chamfered off from their inner side at their points, as represented in fig. 4.
A. S. PELTON.

No. 7369.—*Improvements in Sewing Machines.*

What I claim as new in my invention, and desire to secure by letters patent, is Firstly. The adaptation of the bearded needle (a,) such as is used in knitting or stocking frames, in combination with the manner of closing the beard or hook thereof previous to drawing it back with the thread, to prevent the point tearing the cloth, by passing it through the hole (v,) in the plate (t,) in the manner substantially as herein described.

Secondly. The combination of the spring thread leader or guide V, the arched spring (k,) and the friction roller (j,) for the purpose of leading the thread under the point of the beard of the needle.
O. L. REYNOLDS.

No. 7370.—*Improvement in Suspender Buckles.*

What I claim as my invention, and desire to secure by letters patent, is the constructing a buckle, by combining a curved plate (c,) with an angular lever (d',) substantially in the manner herein set forth.
WM. SCARLETT.

No. 7371.—*Shell Propeller.*

What I claim therein as new, and desire to secure by letters patent, is giving the shell of a submerged propeller the form of a section cut from the open extremity of sea shells, of the class of which that represented in the drawing may be considered a type, the mouth of the helical tube at which the water enters, being of greater area than its hinder extremity, at which the water is discharged.
JAMES TREES.

No. 7372.—*Improvement in the Joints of Stove Pi...*

No. 7372.—*Improvement in the Joints of Stove Pipes.*

What I claim as my invention, and desire to secure by letters patent, is the stove pipe herein described, as a new article of manufacture.

JAMES N. WARNER.

No. 7373.—*Improvement in Machines for Polishing Raw Hide Whips.*

What I claim as my invention, and desire to secure by letters patent, is the before described method of grinding, smoothing and polishing raw hide whips, in the manner and for the purpose herein fully set forth; that is to say, by the combination of the endless revolving belts D, D, between which the rough raw hide whip is placed, the suspended frame containing the upper endless belt, being arranged and operated in the manner and for the purpose set forth.

CHARLES BAEDER.

No. 7374.—*Improved Arch Girder.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as above described, of strengthening arches by means of metal straps, chains, or ropes, which constitute the cords, and pass around the ends and over the arched surfaces thereof, without being attached thereto, substantially in the manner and for the purpose specified.

I also claim providing the arch or beam with rollers at the ends around which the strap, chain, or rope passes, substantially as described, when this is combined with a coupling and tightening screw for varying the length of the said strap, chain, or rope, substantially in the manner and for the purpose specified.

JOHN BEVAN.

No. 7375.—*Improvement in Machines for Drying Bagasse.*

What I claim as my invention, and desire to secure by letters patent, is the employment of a revolving or rotary inclined flue, as applied and used for drying the bagasse or compressed sugar cane, or any other green or wet substance intended for fuel, with the heat and the flame coming from the furnace under the sugar kettles, or from any furnace whatever, all passing into and through this said inclined or rotary flue, at one and the same time, causing thereby the said bagasse or compressed sugar cane, or other said substance, intended for fuel, to become dry and combustible, and prepared for fuel, the moment that it has passed through said flue, using such machinery or mechanical means as I have herein described, or any other suitable mechanical agency or means that will enable me to carry out and put into practical execution or use, the principle or principles herein set forth, described and claimed, and to obtain the intended objects and results in combination as a whole.

JAMES HARRISON DAKIN.

No. 7376.—*Arrangement and connexion of Screw Propellers.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the principal and auxiliary propellers, connected by cog-gearing, or its equivalent, with that of the water pipes, in the manner and for the purposes, substantially as herein set forth.

PATRICK T. DEVLAN.

No. 7377.—*Improvement in Harness Buckles.*

What I claim as my invention, and desire to secure by letters patent, is a buckle constructed, substantially as herein set forth, of a fixed plate, and of a moveable plate, between which the strap is retained, by pins secured to the one, and engaging in the other.

JACOB S. EMBICH.

No. 7378.—*Improvement in Hand Looms.*

What I claim as my invention, and desire to secure by letters patent, is the shedding the web by the direct action of the lathe on the treddles, by means of the moveable finger Y, fig. 6, and the finger staff W, fig. 6, or any similar fixtures for the purpose, bearing down the treddle, and thereby producing a shed in the web at the backward vibration of the lathe.

I also claim as my invention, the combined action of the hand, fig. 10, cam wheel, fig. 4, finger staff W, fig. 6, and the finger Y, fig. 6, upon the treddles K, fig. 9, as above described, for the purpose of shedding the web by the backward vibration of the lathe.

I also claim the combined action of the hand, fig. 10, cam wheel, fig. 4, by the zigzag groove *n*, fig. 4, lifting slide, fig. 8, and drivers fig. 7, upon the picker staff P, fig. 3, as above described, for the purpose of throwing the shuttle back and forth alternately at each backward vibration of the lathe, immediately after the shed is produced, the loom to be propelled by hand or other suitable power. All of the above parts being substantially as herein described.

JOHN G. GARRETSON.

No 7379.—*Improved Wickets for Lock Gates.*

What I claim in the foregoing as my invention, and desire to secure by letters patent, is making and arranging a sliding wicket gate, in such manner that when shut, it shall rest upon its seat, and make a tight joint; but when moving to or from its closed position, shall be raised from its seat and supported on wheels to diminish the friction, and consequently the expenditure of power required to open or close it; the power for operating it, being applied through a lever, (or its equivalent,) so as to move the gate very slowly but with great force, until it is started from its seat, and the weight thrown upon the friction wheels, and then to act upon it with diminished force, but move it faster until it is fully open, thus counterbalancing as near as may be the force and the resistance.

I do not claim the mere counterbalancing of the weight of the gate, and the pressure of the water on its upper edge, by means of the pressure of the water acting upon a flange at its lower edge. But what I do claim, is placing a flange for this purpose in an inclined position, substantially as described, so that the rena contracta shall not prevent the issuing water from pressing against it.

JOHN JACK.

No. 7380.—*Improvement in Machinery for Sawing Staves.*

What I claim as my improvement, is the mode of steadying a long cylinder saw, viz.: by means of a shaft and proper connections at one end of the saw, in combination with a series of friction rollers and their supporting frame applied outside of the saw, and made to bear against the curved surface of the same, and at or near its other or serrated end, substantially as herein before explained.

EDWIN JENNEY.

No. 7381.—*Improvements in Machines for Sawing Wood.*

What I claim as my invention, and desire to secure by letters patent, is—

1st. The combination and arrangement of the suspended vibrating feeding lever S, and rotating forked arm X, jointed reaching arm (N,) rack M, and slide bar H, with the self-champing, self-adjustive hinged jaws *k*, *k'*, for holding the wood firmly during the operation of sawing, the feeding of the log being effected by means of the rotating forked arm X, actuating the feeding lever S, in the manner described and represented.

2nd. I also claim the combination and arrangement of the suspended lifting lever O, and rotating lifting arm W, on the shaft E, with the swinging sash F, as described, by which the descent of the swinging sash will cause the lever O, to advance towards the rotating lifting arm W, when the wood is cut, and thus elevate the swinging sash F, in the manner and for the purpose herein set forth.

3d. I likewise claim the combination of the transverse bent lifting arm T, and suspended lifting lever O, with the suspended feeding lever S, bent rod V, for unlocking the spring dog U, and vertical spring catch R, as described, by which the feeding lever S, is engaged with the jointed reaching arm N, simultaneously with the ascent of the swinging sash, in the manner and for the purpose set forth.

SPENCER LEWIS.

No. 7382.—*Devices for Discharging Ashes from Tuyers.*

What I claim, and desire to secure by letters patent, is combining with the valve E, on the end of the discharge pipe, a scraper, substantially as herein described, so that the opening of the valve by the stopping of the blast, shall cause the scraper to act in the manner and for the purpose herein specified.

JAMES A. MAYNARD.

No. 7383.—*Method of giving Rotary Motion to Fluid Iron in Casting Rolls.*

What I claim as my invention, is the combination of the paddle or fan *h*, with the rod *i*, and rod *r*, and the frame work and gearing for giving motion to the face, for the purpose of producing the rotary motion of the iron in casting chilled rolls and similar castings.

JOHN C. PARRY.

No. 7384.—*Improvement in Feed Regulators for Canals.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the box G, the float L, sliding valve T, segment gate B, C, and float Z, arranged and connected with the mechanism, whereby they have an united action in the manner and for the purpose herein described.

CHARLES ROSS.

No. 7385.—*Improvement in the Form of Rubbing surfaces for Regulating Abrasion.*

What I claim as my invention, and desire to secure by letters patent, is the application of the curved form above described, to the rubbing surfaces of cocks or valves, pivots of upright shafts, mill-stones, or other parts of machinery in general, where the rubbing surfaces have to bear a pressure in the direction of their axis.

CHRISTIAN SCHIELE.

No. 7386.—*Improvement in Attachments for Mills for preparing Corn in the Cob for Grinding.*

What we claim as new, and desire to secure by letters patent, is the block (*e*,) with its arrangement of inclined planes, knives, throats, and other devices

which adapt it, to operate on corn cobs or ears of corn received from a suitable feeder, and also to be inserted in the eye, and be driven by the irons of the runner stone of grinding mills, substantially in the manner and for the purpose described.

We also claim the block (*e*,) arranged as described, in combination with the tubular feeder arranged, substantially in the manner represented in fig. 1, and for the purpose described.

JOHN M. SEELY.
WM. E. TOMLINSON.

No. 7387.—*Improvement in Power Looms.*

What I claim therein as new, and desire to secure by letters patent, are

Firstly. The imparting to the heddle bearer (*r*,) a motion simultaneous with, and in opposite direction to the vertical one of the cylindrical jacquard (*i*, *j*, *k*,) by an arrangement of supplementary levers (*x*,) and their appendages as herein described, or by mechanism, substantially equivalent, the scroll cam or split pulley *v*, *w*, being so arranged as to act alternately as a lock and guide, and as a cam.

Secondly. The arrangement and combination, substantially as described and represented, of a segmental shell (*k*,) and stoppers (*t*,) for the ready adjustment of the jacquard to the pattern.

JOHN SHUTTLEWORTH.

No. 7388.—*Machine for Grinding Spiral Knives.*

What I claim as my invention, is the employment and use of the radial arm M, and its pivots or contrivances for supporting the knife, substantially in the manner and connected with the other parts of the mechanism, as herein before specified.

SILAS STEVENS.

No. 7389.—*Improvement in Apparatus for Setting Logs in Saw Mills.*

What I claim and desire to have secured to me by letters patent, is the combination of the alternating cylinder I, eccentric sliding dog P, cog K, notch L, and spiral spring O, with the common vibrating hand lever G, and concentric circles of teeth E, inclining in opposite directions for turning the ratchet wheel B, on the end of the pinion axle C, to the right or to the left, for moving the log on the head or tail block, either to the right or left, toward or from the saw, as before described.

T. C. THEAKER.

No. 7390.—*Improvement in Lathes for Turning.*

I claim the central stock heads G, and the chuck H, and the large spur wheel I, with the slots in them, to allow the axle to be placed in and taken out of the chuck sideways; the spur wheel I, being driven by spur wheels G, S, S, and T, T, the one T, acting as a compensation gearing to the other, while the slot of the large spur wheel is passing the other spur wheel T, in the manner, substantially as set forth.

J. D. WHITE.

No. 7391.—*Improvement in Quilting Frames.*

I claim the the folding and rolling the layers of any fabric, (which it may be desirable to quilt,) verily by the use of check rods attached to rollers as herein described, the rollers when operating, made to revolve alternately till the fabrics are folded and strained to the desired tension and position.

WILLIAM T. BARNES.

No. 7392.—*Improvement in Apparatus for Jointing Slats, Boards, &c.*

What I claim as my invention, is the combination of the frame A, with supporting rails a, a, the adjustable support or bed bar C, its supporting a elevating screws and contrivances, and the moveable clamping bars L, l with their clamp screw mechanism, the whole being applied and made to op rate together, and in connection with the plane, substantially as above specifie

ALANSON BLANCHARD.

No. 7393.—*Improvement in Making the Reservoirs of Metallic Lamps.*

What I claim as new in my invention, and desire to secure by letters paten is making the shell A, of the lamp reservoir, with the feeder a, standing o from one side of one single plate of metal, so as to require only one seam o solder joint, in the manner substantially as herein described.

P. J. CLARK.

No. 7394.—*Improvement in Galvanic Registers for Steam Boilers.*

What I claim is a galvanic battery or generator of electricity, and its cur rent wires or conductors, an alarm or bell apparatus, and a mercurial colum tube, combined with a steam boiler, and made to operate, substantially i manner and for the purpose of indicating the temperature or pressure of stea in the boiler, as specified.

ARTHUR DUNN.

No. 7395.—*Improvement in Apparatus for Jointing Boards.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the grooved plane, with the guides A, the sliding posts I, and adjusting screws G, and H, arranged in the manner and for the purpose herein described.

DAVID FOSTER.

No. 7396.—*Improvement in Smut Machines.*

What we claim as new in our invention, and desire to secure by letters patent, is—

First. The combination of the cup Q, with the shaft H, for the purpose of receiving the grain, and conducting it all around between the plates C, and F, as herein described.

Second. The adjustable bearing or guide, for setting the shaft H, vertical, consisting of the box M, blocks N, N, N, N, and the screws n, n, n, n, constructed and arranged as herein set forth.

Third. The circular revolving winged and slotted drum E, in combination with the scouring plates C, and F, in the manner, substantially as described, producing a current of air for carrying off the smut, dirt, and other foreign matter.

SAMUEL S. GOULDTHRITE.
CYRUS D. GORDON.

No. 7397.—*Improvement in Machinery for making Copper Tubes.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the horizontal heat retaining conducting tubes h, in combination with the grooved rollers r, arranged and operating in the manner and for the purpose herein set forth.

EDWARD HAMILTON.

No. 7398.—*Improvement in Machinery for making Four Sided Buckles.*

What we claim as our invention, and desire to secure by letters patent, are—

First. The combination of the vibrating carriage F, (in which is placed the die c,) the toggle levers or benders K, K, the gauge bars L, L, detacher, e, holders M, and N, and cutting lever O, the whole constructed and operating, substantially as herein described, by means of which a four sided buckle is formed.

Second. The combination of the sliding frame J, and the vibrating hook i, (fig. 10,) with the grooved die H, and the fly punch C′, the whole constructed and arranged, substantially as described.

Third. The combination of the vibrating jaws U, the cam P′, and levers V′, with the forming block and rod Q′, k', and sliding bar O′, the whole constructed, arranged, and acting, substantially as herein described.

ALAM NORTH.
OLIVER B. NORTH.
STEPHEN FRINK.

No. 7399.—*Improvement in Processes for Preserving Wood.*

Therefore, what I claim as my invention or improvement, is the combination of the processes of immersion, absorption, exhaustion, pressure and decomposition, substantially in the manner and for the purpose herein before explained.

CHAS. PAYNE.

No. 7400.—*Improvement in Fanning Mills.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the racks A, perforated gauge plates H; hooks (i,) and confining rodes I, in combination with the shoe (s,) for confining and adjusting the riddles D, D, and screen G, in the shoe, in the manner described. I also claim the arrangement of the vibrating longitudinal inclined conducting trough T, in combination with the transverse inclined conducting trough Q, attached to the vibrating shoe, for receiving the cleansed grain from the screen and conducting it directly into the measure or bag, as described.

JESSE ROBERTS.

No. 7401.—*Improvement in Water Backs for Cooking Ranges.*

What we claim as our invention, and desire to secure by letters patent, is casting the induction and eduction pipes of the hollow back of cooking ranges, each with a convergence towards the other, when the lines of the inside of the top and bottom of the hollow back converge with the same angle, and coincide respectively with the lines of the induction and eduction pipes, for the purpose and in the manner described.

We also claim constructing the hollow back itself, with the lines of the inside of the top and bottom converging towards each other, for the purpose of preventing the accumulation of air, and securing a ready flow of water, as described.

H. H. STIMPSON.
FRED. H. STIMPSON.

No. 7402.—*Improvement in Tailors' Measures.*

What I claim as my invention, is the instrument as above represented at fig. 3, for ascertaining the slope of the shoulder, also the instrument represented at fig. 2, for ascertaining the measure from the socket bone to a line perpendicular to the most prominent parts of the back, substantially as scribed, and for the purposes set forth in the specification.

AMOS STOCKER.

No. 7403.—*Improvements in the Preparation of Pile for Rugs, &c.*

What I claim, is the herein before described mode or process of combini or arranging together, and in the pile, the threads or yarns composing the fi ure or figures, the same consisting in winding the said threads on a beam roller, by the aid of a collar, pattern and index, and other contrivances, e sentially as specified, and cutting the said threads and transferring them, and by means of the roller, to the pile in the machine, in which they are con pressed, cemented and cut, all as herein before explained.

JAS. TAYLOR.

No. 7404.—*Improvement in Sofa Bedsteads.*

What I claim as new therein, and desire to secure by letters patent, is—

First. The drawer with castors, made so as to serve the double purpose o a receptacle for the bed clothes, and a support for the back, as described.

Second. I claim the sliding head and foot boards, so connected with th back that they slide in or out as the back is raised or lowered by the contri vances as above described, or other equivalent devices.

A. G. WARREN.

No. 7405.—*Improvement in Fanning Mills.*

What I claim as my invention, and desire to secure by letters patent, is— my improved construction and arrangement for shaking and operating the sieves in a winnowing mill, in the manner herein described.

JOHN WIEDMAN.

No. 7406.—*Improvement in Electro Chemical Telegraphs.*

What we claim, and desire to have secured to us by letters patent, is recording telegraphic signs on the surface of a revolving metallic cylinder, plate, or other equivalent surface, by means of an acidulated liquid, or saline solution, or water, held between the point of the wire conductor, and the metallic recording surface, by means of a non-conducting porous substance contained in a glass, or other non-conducting reservoir, in which the recording fluid is contained, to which the electric current from a battery is applied, by means of any of the known forms of manipulators and anvils used for making and breaking the circuit, the recording fluid being applied to the metallic recording surface, substantially in the manner herein fully set forth, by which the use of every description of paper is dispensed with, thereby saving great expense in telegraphing.

C. WESTBROOK.
HENRY J. ROGERS.

No. 7407.—*Improvements in Machines for Shearing Cloth.*

What I claim as my invention, and desire to have secured to me by letters patent, is—First. A flexible rest constructed substantially as herein above described.

Second. Making the rest susceptible of extension on each or either end, by combining with the ordinary stationary rest, and on each side thereof, a flexible and moveable rest, as herein above specified.

Lastly. I claim making an extension or flexible and moveable rest, self-ope ing, or so as to be changed by the cloth itself, in its passage through the achine, all as herein above set forth.

AMASA WOOLSON.

No. 7408.—*Improvement in Suspending Venetian Blinds.*

What I claim as my invention, and desire to secure by letters patent, is— e combination of pulleys *e*, *f*, and *g*, with cords *i*, *i*, for the independent ovement of the supporting slat *d*, *d*, in the manner and for the purpose de ribed.

JOSEPH BOHRER.

No. 7409.—*Improvement in Ventilating Railroad Cars.*

What we claim as our invention, and desire to secure by letters patent, is e method of ventilating the cars of a railroad train, and keeping out dust, noke and sparks, by combining therewith a tube made in sections, and uni d by flexible joints at the junctions of the cars, which tube receives a cur nt or currents of air forward, of the chimney of the locomotive, and dis harges it into the cars, through apertures, all substantially as herein described.

HEZEKIAH BRADFORD.
EPH'M MORRIS.

No. 7410.—*Improved Gun Harpoon.*

What I claim therein as new, and desire to secure by letters patent, is— ttaching the line to both the shank and the head of the harpoon, in such nanner that the extremity of the line is loaded with the harpoon into the gun, nd lays in recesses made in the shank, and when the gun is fired, the line vill trail from the butt of the shank, and will not tend to depress the head luring its flight.

ROBERT BROWN.

No. 7411.—*Improvement in Fire Place Grates.*

What I claim therein as new, and for which I desire to secure letters patent, s—First. The combination with the open fire place or grate, having the side draughts as described, of the air heating chambers, consisting of an air chamber surrounding the fire, and a projecting chamber above, surrounded by heat, ubstantially as above set forth.

Secondly. I claim dividing the draught of an open fire, and causing the products of combustion to be drawn off at each end of the fire, as herein de cribed. I also claim the sliding collar, at the exit pipe, in the manner and for the purposes specified.

GARDNER CHILSON.

No. 7412.—*Improved Method of making Shafts, &c., of Sheet Iron.*

What I claim as new therein, and which I desire to secure by letters patent, is the constructing of hollow plate iron shafts, of short cylinders, combine and connected together, in the manner and for the purposes above described.

CHARLES F. FISHER.

No. 7413.—*Improvement in Printing Presses.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The application of the toggle lever *x*, working on the stationary cam *y*, to raise the platen, in the manner and for the purpose herein describe

Secondly. I claim the combination of the toggle lever x, and toggle w, and v, with the stationary cam y, substantially in the manner and for the purpose herein set forth.

Thirdly. I claim the combination of the toggle lever x, and toggle w, and v, with the swing platen, as herein set forth.

Fourthly. I claim the combination of the spiral springs J, and the trip G, when used in combination with the swing platen, substantially in the manner and for the purpose herein described.

CHARLES W. HAWKS.

No. 7414.—*Improvement in Brick Presses.*

What I claim therein as new, and desire to secure by letters patent, is operating the roll (N,) for holding the mould box, the gate (P,) for regulating the discharge of clay, and the piston (E,) for compressing the clay into the moulds, by means of a wheel (J,) furnished with series of teeth (H, H′, H″,) secured to it, and acting through trundles, shafts, cranks, and connecting rods, connected with the roll (N,) the gate (P,) and the piston (E,) respectively, substantially as herein set forth.

JOHN W. HOPE.

No. 7415.—*Improvement in Gang Ploughs.*

What I claim as new, and desire to secure by letters patent, is the spur wheel (3,) so constructed and arranged within the periphery of the driving wheel, that it may be made at pleasure to pass its rowels through the holes or notches in the tire, into the surface of the ground when under compression, and thereby grapple and gain adhesion to the ground, substantially in the manner herein set forth.

Second. I also claim the combination of parallel bars (P, P′,) to regulate the breadth of each separate furrow, with the adjusting curve (a',) for determining the horizontal direction of the draught, so as to adapt the amount of work done by a single traverse of the engine, to the adhesive power of the wheels when applied to the particular kind of land under cultivation, substantially as herein set forth.

Third. I also claim preventing the choking of the plough, by means of the recurved point (E,) of the mould board, acting to turn aside and guide backwards the choking material, as herein set forth.

Fourth. I also claim the manner of connecting the harrow to the locomotive, so that the conductor may at pleasure, by turning a crank, reverse its advancing side for the purpose of freeing the harrow teeth from choking materials, in the manner, substantially as herein set forth.

J. D. HOPE.

No. 7416.—*Improvement in Board and Log Rules.*

What I claim as my invention, and desire to secure by letters patent, is the combination with the inner revolving plate of the rotary tape measure, of the several tables thereon, substantially as described.

CHARLES B. HUTCHINSON.

No. 7417.—*Improvement in Shuttle Motion of Looms.*

What I claim as my invention, and desire to secure by letters patent, is attaching the bat wing, by an adjustable connection to one extremity of a lever

ose outer extremity is connected by a short strap with the picker stick, the er turning on a single adjustable vertical pivot, and being interposed between wiper, operating as described, and the picker stick motion from the wiper ng transmitted through this lever, strap, and picker stick, to the driver, so to cause it to throw the shuttle with the proper degree of suddenness and ocity, when the loom is working at a high speed; this arrangement adting of the easy and quick graduation of the suddenness and velocity with ich the shuttle is thrown, as herein set forth.

OLIVER A. KELLY.

No. 7418.—*Improvement in Nursery Chairs.*

claim the improvement of the moveable back piece L, and its sustaining ures, in their application to the back and seat, substantially as specified, for the purpose of using the chair either as a cradle or as a lolling chair, stantially as specified, the said improvement consisting in so combining one he arms with the seat, by means of a slide adapted to such seat, that both arm and slide may be moved in a direction away from the other, or staary arm, so as not only to lengthen the seat so as to enable it to support a ttress or bed, disposed on it, but to render the arm a foot guard, for an int or child, placed on the said mattress or bed.

SAMUEL S. MAY.

No. 7419.—*Improvement in Flying Horses.*

What I claim as my invention, and desire to secure by letters patent of the ited States, is the combination and arrangement of the undulated cams with levers, and these with the flexible connections to the front part of the horses, the purpose of, and by which I produce the rising and falling motion, which erm the galloping motion, as herein before described and represented.

ELIPHALET S. SCRIPTURE.

No. 7420.—*Improvement in Electro Magnetic Machines for Shocks.*

What I claim therefore, as my invention, and desire to secure by letters ent, is separating the shock derived from the initial secondary current of double coil magneto electric machine, for that of the terminal secondary, causing the latter to pass through a closed circuit, substantially in the nner and for the purposes set forth. I also claim the manner of adapting the ne machine to transmit both the initial and terminal secondary currents at asure, by bearing off the spring (G,) by the arm L, substantially as deibed.

SAM'L B. SMITH.

No. 7421.—*Improvements in Carding and Mixing Wool and Cotton.*

What we claim as our invention, and desire to secure by letters patent, is picking and carding of the wool and the cotton, separate from each other, the drawing them off together from the second carding machine, and n mixing their fibres with each other, by means of the finishing or condeng card.

STEPHEN H. ADAMS.
JOHN A. WOOD.

No. 7422.—*Improvement in connecting Whiffletrees with Carriages.*

What I claim as of my own invention, and which I desire to secure by lets patent of the United States, is the stops or blocks (e, e,) cast upon or otherwise affixed to the box (*a*,) and the stops or blocks (*n*, *n*,) cast upon or affixed to the follower (*h*,) in such manner that when the two are joined by a central bolt passing through, they will interlock and form a stop coupling, secure from derangement from external causes, the whole being constructed, substantially as herein described.

JAMES BARNES.

No. 7423.—*Improvements in Hydraulic Apparatus for producing Blast.*

What I claim as my invention, and which I desire to secure by letters patent, is—

First. The use and application of boxes, tubs, or cavities, attached to wheels, disks, or arms, by moveable joints or journals, and then carried in a rotary direction alternately, through air and water; said boxes or cavities, moving at the same time on their own journals, in such a manner that they shall enter the water with their open sides downwards, and when beneath the same shall empty or discharge the air which has been compressed within them by the water, into a receiver which is separate from such wheels and air boxes; all for the purpose of producing a blast of air to be used in heating, smelting, and other mechanical operations.

Second. I also claim, for this purpose, the disk, recess or concavity of the wheel, so as to allow the receiver to project over the mouths of the air boxes, to receive their compressed air.

Third. I also claim for the same purpose, the cam D, the cranks J, J, J, and the cranks K, K, K, attached to the air boxes, together with the piece U, U, in the open side of the boxes, the mouth T, for discharging their compressed air and the block G, for throwing forward the cranks J, J, J.

RANSOM COOK.

No. 7424.—*Machine for Cutting Leather into Hollow Ware Forms.*

What we claim therein as new, and desire to secure by letters patent, is the combination of the vibrating knife with the fluted rollers, constructed and operating, substantially in the manner and for the purpose above fully set forth, one of which rollers being fluted longitudinally and the other circumferentially, serve firmly to hold the leather in any position.

DURAND & PECQUEUR.

No. 7425.—*Improved method of Forming Embankments, Levees, &c.*

What I claim as my invention, and desire to secure by letters patent, is the method herein described of depositing earth, to form embankments, levees, etc. and to fill up low situations by means of filtering dams or their equivalents, and a trough or conduit conveying earth and water from a higher level, substantially as herein specified.

DUFF GREEN.

No. 7426.—*Improvement in Adjusting Packing for Oil Boxes of Axles, &c.*

What I claim as new, and desire to secure by letters patent, is the employment of an adjustable band surrounding the oil packing of rail road cars or other journals, so as to admit of adjustment from the outside of the box, in adjusting the packing around the journal, and render the box oil tight in the manner and for the purpose, substantially the same as herein described and represented.

WARNER GROAT.

No. 7427.—*Improvements in Cars for Plank Roads, Wooden Rails, &c.*

What I claim as my improvement, is the combination of a chain of rollers with broad bearing surfaces running around a stationary rail or track, on the carriage with an independent chain, which forms a track for said rollers to travel over when resting on the ground, and which passes around outside of said chain of rollers.

I also claim the mode of constructing said track chain (*k*,) by lapping the links thereof, so that the rollers shall have a constant bearing on the three plates, which form two succeeding links, and break joint with each other, as clearly represented in fig. 2.

GIDEON MORGAN.

No. 7428.—*Improvement in Bedstead Fastenings.*

What I claim in the above described bedstead as new, and desire to secure by letters patent, is the device for securing the ends of the side rails to the posts, consisting of a headed tenon on the rail and two wedge-shaped and dovetailed boxes in the post, the latter held in place by the pendant arms and tie rods, by which the mattress is stretched, substantially as herein set forth.

CHAS. H. PARKER.

No. 7429.—*Improvement in Spring Mattresses.*

What I claim as my invention, and desire to secure by letters patent, is the construction of the jointed spring mattress, substantially as set forth in the specification.

WM. F. RESSEGINE.

No. 7430.—*Improvement in Thrashing Machines*

What I claim as my invention, and desire to secure by letters patent, is surrounding the twisted wings with an unperforated case, and placing the same inside the thrashing cylinder—the whole revolving together in the manner and for the purpose set forth.

Second. Constructing the concave of adjustive star or other shaped teeth attached to rods fastened to the frame, substantially as described and set forth in the specification.

I am aware that such teeth have been used in the throat of the feeding apparatus of a corn sheller to aid in feeding, and therefore, I only claim them when used for the rubbing surface of the concave.

Third. Placing the curved spring rack between the concave of adjustive teeth, and the vibrating separator, in the manner and for the purpose described.

ELISHA S. SNYDER.

No. 7431.—*Arrangement of Mirrors in Traps.*

What I claim therein as new, and desire to secure by letters patent, is the arrangement of the mirrors, substantially in the manner and for the purpose set forth.

JAMES STEVENS.

No. 7432.—*Improvement in Planes for Tonguing and Grooving, &c.*

What I claim as my invention, and desire to have secured to me by letters patent, in said apparatus, is the combination of a gouge or gouges (for removing the bulk or greater portion of a shaving in forming tongues or grooves, in boards or planks) with smoothing tools having a chisel edge, a cutting and side lip on either, or both sides thereof, (for smoothing the sides and bottom of the grooves, and the edges about the tongues as set forth,) said gouges being set in front of said smoothing tools, and the whole being arranged and operating, substantially as herein above set forth.

JAMES A. WOODBURY.

No. 7433.—*Improvement in Machines for Finishing Morocco.*

What we claim as our invention, and desire to secure by letters patent, is—

First. A sliding head with finishing tools (one or more) attached, said tools to be held down by weight or springs; said sliding head to do its work while in a backward or forward motion, and running on straight ways, as herein set forth.

Secondly. We claim as our invention, the application of one or more clasps (G, G,) for the purposes described in the specification, in combination with one or more finishing tools, whose motions are parallel with said clasps.

We also claim the application of one or more finishing tools which are held stationary while rubbing the skin or paper, and allowed to revolve a little when required to equalize the wear on the peripheries of the same.

EDWARD BOOKHOUT.
HENRY COCHEN, Jr.

No. 7434.—*Improvement in Spring Teeth of Hay Rakes.*

What I claim as my invention, and desire to secure by letters patent, is the construction of the spring teeth of the hay rake of a double wire, in place of the single one generally used, as described in the specification.

ZEPHANIAH BREED.

No. 7435.—*Improvement in Attaching Neck Yokes to Poles of Carriages.*

What I claim as my invention, and desire to secure by letters patent, is the mode herein described of constructing the neck yoke, (either solid or divided,) and fitting the tongue or pole of the carriage, and these so constructed and fitted, in combination with the moveable band on which are projections, as in fig. 3, or knobs, by which means the whole are securely connected, and thus form a universal joint for the purpose stated, and not otherwise.

JAMES M. BROWN.

No. 7436.—*Improvement in Parlor Stoves.*

What I claim therein as new, and for which I desire to secure letters patent, is the arrangement of the flues in combination with the fire chamber, substantially in the manner and for the purposes set forth.

GARDNER CHILSON.

No. 7437.—*Improved method of making Nails by Rolling.*

What I claim as new therein, and which I desire to secure by letters patent, is the auxiliary furnace, in combination with the machinery for rolling nails, &c., as above described, for retaining the heat of the plates or rods of iron, while they are separately passed into the machine.

E. H. COLLIER.

No. 7438.—*Improvement in Machines for Dressing Stone.*

What I claim as my invention, and desire to secure by letters patent, is dressing stone by means of chilled cast-iron burrs, substantially as herein set forth.

ROBERT EASTMAN.

No. 7439.—*Improvement in Furnaces for Calcining Gypsum.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the pan or boiler with the three chambers, when they are combined with the beams, slides and dampers, when the whole is constructed, arranged and combined, so as to operate, substantially according to the method and to effect the purpose, substantially as herein described.

BENJ. FOWLER.

No. 7440.—*Improved Spike Machine.*

What I claim therein as new, and desire to secure by letters patent, is:

First. The rising and filling guide and cutter frame, in combination with a moving series of dies, whereby the spike rod is guided into the moving dies and a slip of proper length cut off to form the spike, the knives being operated by levers which force them towards each other whenever the movement of the frame brings the levers in contact with stationary arms projected from the main frame.

Secondly. The forked and hinged clamp (J,) constructed substantially as herein set forth, in such manner that when open its inner fork performs the office of a gauge, to regulate the length of the spike, and when closed, its outer fork gripes the shoulder of the spike during the heading, and its inner fork is withdrawn to allow the formation of the point.

Thirdly. The combination of the arm L, with the clamp J, and its tongue *m*, by means of which the heading, griping, and pointing of the spike are effected, substantially as herein described, at one operation.

AMMI M. GEORGE.

No. 7441.—*Improvement in Upright Piano Fortes.*

What I claim as my invention, and desire to have secured to me by letters patent, is—First. Combining with each of the standards *a*, *a*, *a*, *a*, of the frame, a sustaining and strengthening rod, arranged in a curved groove in the back of said standards, and operating substantially as herein described.

Second. I claim connecting the stem *s*, *s*, to the rocker bar, fastened to the key lever, as described, and also to the horizontal arm *t*, *t*, on which the jack, &c. is supported, by which the whole action becomes attached to the key lever, and the hammer is made to return when the end of the key lever descends, all as herein above set forth.

I also claim combining the back catch with the fly of the jack, as above set forth, and in combination with a jack and back catch, so arranged, the curved arm *l'*, *l'*, projecting from the hammer stem, and having a regulating button *m*,' connected to said arm, as above set forth.

Lastly. I claim regulating the throwing off the hammer from the strings by the projection O', from the centre block of the hammer, and below its centre of action, in combination with a regulating button passing through the fly of the jack.

LEMUEL GILBERT.

No. 7442.—*Improvement in Apparatus for Raising the Grate in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the apparatus for lowering and raising the grate, so constructed as to act without liability to obstruction from the baking of ashes between the parts of machinery, having sliding pieces or racks, furnished with perforations instead of cogs, in combination with pinions acting upon them by cogs, said pinions having the spaces between the cogs beveled, bringing them to a kind of edge, thus admitting no flat spaces to intervene where ashes may accumulate to prevent the working of the machinery.

BENJ. K. MALTBY.

No. 7443.—*Devices for Moving and Holding a Piston Breech Pin.*

I claim as new, and of my own invention, and desire to secure by letters patent of the United States, the arrangement of the parts described and shown, in which arrangement the radius bar *a*, is connected to the rear end of the sliding breech pin *c*, by a tenon 10, and slot 9, taking a pin 8, on the jaws 6, at the rear end of the breech pin, for the purposes of holding the breech pin in place while the charge is exploded, removing the breech pin to receive successive charges, and forcing the charge into the barrel by replacing the breech pin for the next successive discharges; the whole constructed, arranged, and acting substantially as described and shown.

WM. W. MARSTON.

No. 7444.—*Improvement in Safety Stirrups.*

What I claim as my invention, and desire to secure by letters patent, is the safety bar A, and the spring H, arranged in the form set forth, or in any other form, substantially the same in principle.

Second. The arrangement of the loop cap, by which I place the stirrup bars S, S, at right angles with the stirrup strap.

Third. The flat bar U, rising from the top of the loop V, to prevent the rolling of the stirrup in the strap.

NATHAN POST.

No. 7445.—*Improvement in Feed Apparatus for Mills.*

What we claim as new therein, and desire to secure by letters patent, is the feeding apparatus, as above described, for keeping a regular supply constantly fed to the grinding surfaces.

JOHN SHERLOCK.
WM. BRACKBILL.

No. 7446.—*Improvement in Apparatus for Parti-coloring Yarn.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of parti-coloring yarns by winding them on reels arranged in frames, so constructed as to admit of immersing in dying liquor, such portions of the yarns as are desired to be dyed, and shifting the same for dying other parts in like manner, substantially as described.

And I also claim connecting one or both of the reels in each frame, by means of slides, to admit of removing the reel from contact with the yarns, whilst in the process of dying, substantially as specified.

ALEXANDER SMITH.

No. 7447.—*Improvement in Mills for Grinding.*

What I claim as my invention, and desire to secure by letters patent, is the combination of crushing rollers with a disintegrating apparatus, arranged and operating substantially in the manner and for the purpose, as herein set forth.

J. R. STAFFORD.

No. 7448.—*Combination of a Guide Tooth with an Inclined Scraper.*

What I claim therein as new, and for which I desire to secure letters patent, is the guiding tooth or revolving cutter, combined with the inclined scraper, substantially as above stated, for regulating the course of the machine.

JOHN F. WOOD.

No. 7449.—*Model for Vessels.*

What I claim as of my invention, and desire to secure by letters patent, is the forming a vessel with a scow shaped bow, having on its sides two wide keels running the whole, or a part of its entire length, and so constructed that a portion of the inclined surface of the bottom shall always be above the water at the bow, and this with or without the supplementary keels forming small channels, by which construction air enters at the bow, in the manner set forth, and is retained under the bottom of the vessel, for certain purposes described herein.

SOLOMON ANDREWS.

No. 7450.—*Improvement in Connecting and Disconnecting Hubs and Axles.*

What we claim as our invention, and desire to secure by letters patent, is the method herein described, of securely fastening the hub of a wheel to its axle, or easily detaching the same therefrom, to wit: by means of the two sliding plates B, B, combined with the double scroll shaped cam A, in such a manner that by turning the said cam, in one direction the sliding plates (B, B,) will fasten the axle journal within the hub so securely, that it cannot be unfastened by any jar or shock upon the wheel; and by turning the said cam in an opposite direction, the sliding plates (B, B,) will be detached from their hold upon the axle journal, and permit the wheel to be detached therefrom.

A. M. BILLINGS.
T. A. AMBROSE.

No. 7451.—*Improvement in Setting Artificial Teeth by Atmospheric Pressure.*

What I claim therein as new, and which I desire to secure by letters patent, is the air chamber (*e*,) constructed and arranged, substantially as herein above set forth, and for the purposes described.

JOHN A. CLEVELAND.

No. 7452.—*Improvement in Looms for Weaving Cut Pile Fabrics.*

What I claim as new and of my invention, is—

First. The use in power looms for weaving cut pile fabrics, of intersecting plates, entering between the two pieces of cloth, and allowing the pile warps to cross and recross, from one to the other, which extend through the reed, thereby forming on the upper surface a plane upon which one of the shuttles is supported, in passing through the web, substantially as described.

Second. The continuing of the intersecting plates to the outside of the warps, by adding the within described false reed, or otherwise, for the purpose of supporting the ends of the intersecting plates, and for guiding the warps by them, substantially as described.

MERTOUN C. BRYANT.

No. 7453.—*Improvement in Brick Presses.*

What we claim as our invention, and desire to secure by letters patent, is the method of preventing clay from adhering to the surfaces, which make pressure on it, or in which it is pressed or moulded, by the application of artificial heat to such surfaces, substantially as herein described.

And we also claim the method of elevating the followers of the moulds for discharging the bricks, by combining with the carriage of moulds, a platform or carriage, which slides on inclined ways, and which receives motion from a carriage of moulds, substantially in the manner and for the purpose specified.

THOMAS CULBERTSON.
GEORGE SCOTT.

No. 7454.—*Improvement in Atmospheric Churns.*

What I claim as my invention, and desire to secure by letters patent, is a hollow staff, connected with a square or round hollow plunger, with a valve placed at the top, or at any point inside of said staff, said valve to be so arranged, that when the said staff and plunger are raised, the valve will open; and when said staff and plunger are forced down, the valve will close, and the atmospheric air in the plunger will be forced through the body of the milk or cream, by which operation butter will be formed; said staff, dasher, and valve, to be used in any vessel containing milk or cream.

PETER F. ELLICOTT.

No. 7455.—*Improvement in Electric Telegraphs.*

What I claim as my invention, is the above described new, or improved electro-caustic telegraph, or application to telegraphic purposes, and substantially as specified, of heat generated by electric apparatus, or a current or currents of electricity, passed through a fine platinum wire or other proper conductors or equivalents therefor, as explained; the marks produced in or through the paper or other material, used in connection with the heated wire, being regulated in their length and number, so as to be characters or expressions of letters, figures, or words, indicative of any message which it may be desirable to transmit, from the battery end of the telegraph, to the other end of the line, all essentially as set forth, or in the manner generally understood by telegraphic operators.

G. H. HORN.

No. 7456.—*Machine for forming Washers and attaching them to Carpet Tacks.*

What I claim as my invention, and desire to have secured to me by letters patent, is the spring nippers *s, s, s, s*, arranged on a vibratory arm, and having a tapering bore, formed one half in each of said nippers, for guiding the point of the tack to the centre of the washer. Also the combination of said nippers with the circular die, and vertical moving punch, arranged and operating, as above set forth.

I also claim a machine for preparing carpet tacks, consisting of the parts above stated, in connection with an adjustable feeding motion, composed of the double endless bands, ratchet, and pawl, and parts which connect the same with the driving lever, as herein above set forth.

JASON G. HOWARD.

No. 7457.—*Improvement in the Hinge of Rolling Iron Shutters.*

What I claim therein as new, and desire to secure by letters patent, in constructing the hinges or joints of rolling iron shutters of thin slats of iron, is having a bar or wire inserted within the coiled edges of the joint or hinge, to give strength and stiffness to the joint, said bar having its ends bent, to prevent the several strips of iron composing the shutter, from sliding laterally on each other, and the projecting bent ends of the wire being curved by eaves projecting from the ends of the strips, and turned down, thus forming an even edge to the shutter, which will slide easily in the groove of the frame in which it is placed, the whole being constructed, substantially as herein described.

A. LIVINGSTON JOHNSON.

No. 7458.—*Improvement in producing Photographic Pictures upon Transparent Media.*

What we claim as our invention, and desire to secure by letters patent, is—

First. The taking of photographic pictures upon transparent media, by coating them with some suitable vehicle for the sensitive material, substantially as set forth.

Second. We claim the process of preparing and using the sensitive coating or film upon surfaces, whether of transparent, translucent, or opaque bodies, substantially in the manner and for the purposes set forth.

JOHN A. WHIPPLE.
WM. B. JONES.

No. 7459.—*Improvement in Cooking Stoves.*

What I claim, and desire to secure by letters patent, is the combination of the flues with a single damper (*e*,) so that by a single movement, I cause the hot air to traverse once or twice entirely round the oven at pleasure, substantially as described.

ABRAHAM KEAGY.

No. 7460.—*Improved Arrangement of Sash Stopper.*

What we claim as our invention, and desire to secure by letters patent, is placing the eccentric J, within the bar or stile of the window sash E, in such manner as to act upon a weather strip S, instead of against the frame or casing of the window; the former being thereby firmly pressed against the latter, and all defacement of the window frame by the eccentric avoided, as described.

NATHANIEL MYERS.
FRED. C. SMITH.

No. 7461.—*Improvement in Mounting the Knife of Straw Cutters.*

I claim of the above arrangement, the placing of the pivot N, of the knife upon a spring, for the purpose of enabling the operator to give the knife a draw or sliding cut.

JOHN R. NELSON.

No. 7462.—*Machine for Repairing Roads.*

What I claim as new in my invention, and desire to secure by letters patent, is hanging the cutters E, E, for cutting off the ridges at the sides of the ruts, the scrapers F, F, for scraping the dirt into the ruts, and the roller D, for pressing and smoothing the road, upon the same frame; all the said parts operating together, in the manner and for the purposes, substantially as herein set forth.

NATHANIEL POTTER.

No. 7463.—*Improvement in the Weed Cutters of a Cultivator.*

I claim the combination of the bar *a*, with the weed cutter *b*, in the manner and for the purpose set forth and represented.

CHARLES RODGER.

No. 7464.—*Improvement in Water Wheels for Increasing or Diminishing their Diameters.*

What I claim therein as new, and desire to secure by letters patent, is the double adjustable arm, constructed as above described, for expanding or contracting the size of the wheel, for the above specified purpose, so that the absolute diameter of the wheel and arms shall be reduced or expanded, to go within a suitable curve.

T. R. TIMBY.

No. 7465.—*Improvement in Self-acting Cheese Presses.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the rollers H, H, and K, K, and wedges I, I, in combination, with the inclined planes D, D, acting in the manner and for the purpose herein set forth in the foregoing specification, to produce a sufficient pressure upon the cheese, or other article to be pressed.

JOHN UNDERWOOD.

No. 7466.—*Improvement in Boot Trees.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the sliding wedges A, A, and the right and left screws B, B, with the inclined planes or grooves C, C, substantially in the manner and for the purpose above set forth, the screws B, B, being made to play within the groove D, and being confined to its place longitudinally, by the bar E, working in the groove H.

WILLIAM UPFIELD.

No. 7467.—*Improvement in Carriages.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the open elliptical axletree (*i, j*,) with the sliding slotted frame (*n*,) attached to the body of the vehicle, and passing through the upper half of the axletree, and attached to the upper leaf of the elliptical spring, placed inside of the axletree, the lower leaf of said spring being secured to the inner side of the lower half of the axletree, the several parts being arranged, and operating in the manner and for the purpose herein fully set forth.

MILES T. WATKINS.

No. 7468.—*Improvement in Waste Gates.*

What we claim as our invention, and desire to secure by letters patent, is a waste gate which is hung upon a vertical axis, the lower part of which is made wider one side of the axis than it is the other, the side which is narrowest towards the bottom of the gate, being sufficiently wider than the other towards the top, that the balance of the pressure of the water will change from one side of the axis to the other, and open and close the gate as the water rises and falls.

HIRAM TAN.
THOMAS P. HOW.

No. 7469.—*Improved Method of fitting the Bows of Vessels.*

What I claim as my invention, and desire to secure by letters patent, is making the rear edge of the cut water to project on each side of the stern, to form a recess on each side, substantially as described, in combination with the sheathing pieces which fill up such recesses, and which cover and protect the ends of the plankings, and which also admit of giving better lines for the passage of the bow of the ship or other vessel through the water, substantially as described.

BENJAMIN BARSTON

No. 7470.—*Improved Method of Distributing the air over the Heating and Cooling Surfaces of Air Engines.*

What I claim as of my own invention, and desire to secure by letters patent, is causing the air entering and leaving the cylinder, to pass over the heating and cooling surfaces in a thin stratum, by means of the plates (*i, i'*,) or their equivalents, substantially in the manner and for the purpose set forth.

ERNST BUCKUP.

No. 7471.—*Improved Sash Stopper.*

What I claim as my invention, and desire to secure by letters patent, is the triangular shaped double acting wedges or fasteners *f, f*, placed within recesses of corresponding shape, formed in the front or rear sides of the sash side bars (or in the side slats of a window frame,) acted upon by any kind of handles or levers, in such a manner that they will press the sashes inwards or outwards, in contradistinction to side ways, and thus retain them in any desired position, and render them air tight within the window frame.

CHARLES C. CAMERON.

No. 7472.—*Improvement in Straw Cutters.*

What I claim as my invention, and desire to secure by letters patent, is the method of feeding straw, fodder, and other substances, to a series of rotating cutters, by means of a continuous motion by a roller armed with pointed teeth, and hung in a swinging frame, substantially as described.

I also claim the method of cutting straw, fodder, and other like substances, by means of the cutting cylinder, provided with cutters, the outer faces of which, from the cutting edge, are curved or inclined in towards the axis, so as to admit of continuous feed, the blades of the cutters acting as gauge plates for the length of the cut, in combination with the feeding the straw, fodder, or other substance to be cut, by a continuous motion, substantially as set forth.

REUBEN DANIELS.

No. 7473.—*Improvement in the Feeders of a Straw Cutter.*

What I claim as my invention, is the guard piece S, in combination with the feed rollers, to carry the straw or other material to the cutters, as described.

JOHN E. ERB.

No. 7474.—*Improvements in Setting the Teeth on the Concave of a Clover Thrasher.*

What I claim and desire to secure by letters patent, is the right to use and manufacture machines for the purpose of thrashing and hulling clover and other seeds of a similar nature, having the teeth of the concave, or the stationary set of teeth so inserted in leather on a bed of cork, as to give them an elasticity sufficient to cause them to resume their original position when misplaced by the passage of any foreign substances which may be introduced by accident or otherwise into the machine.

JONATHAN HIBBS.

No. 7475.—*Improvement in the Cutters and Rakers of a Grain and Grass Harvester.*

What we claim as new, and desire to have secured to us by letters patent, is—

First. Making the pointed cutters N, concave on the faces towards each other, in the manner and for the purpose set forth, by which the cutters are rendered self-sharpening, and bending the upper plate over the back of the lower, or sliding cutter plate, and bringing the notched or turned edge against the lower plate, in the manner and for the purpose described.

Second. The arrangement of the stationary cyma reversa fingers P, in combination with the vibrating hook teeth or claws (*o*,) bands *c*, and the appendages for operating the same, by which the grain is collected into sheaves or gavels, before being discharged upon the ground.

Third. The combination of the hook teeth or claws *o*, rock shaft *m*, bent arm (*n*,) lever (*s*,) spring (*j*,) and revolving arm *l*, for arresting the grain whilst removing the gavel or sheaf from the cyma reversa fingers P, on to the ground, as described.

We likewise claim the combination of the pinion H, perch *p*, and axle F, the former working into the segment on the front axletree, for steering the forward part of the frame and cutters.

HENRY C. BEVINGTON.
HAZARD KNOWLES.

No. 7476.—*Improvement in Respiring Apparatus.*

What I claim as my invention, and desire to secure by letters patent, is the valve represented by figs. 2, 3, 4 made of any metallic substance, and a nose piece represented by fig. 5 and 6, having an air tight tube surrounding that part which is designed to fit about the nose to accommodate the features of any person, and the use of these together with a cylinder vessel, air chamber, or bag, for the purpose of enabling a person to breathe with perfect ease, air which has been condensed more or less in any such cylinder vessel, air chamber or bag, which is to be confined to the person of the wearer while the surrounding air is impure from any cause.

BENJ'N J. LANE.

No. 7477.—*Improvement in Collimating Levels.*

What I claim, and wish to secure by letters patent, is the mode, substantially as herein described, of forming a levelling instrument, by combining the spirit level with the collimator having a partial lens, viz: by means of a partial reflector so placed as to reflect both the cross wire and the spirit level bubble in such manner, that the image of the latter may be seen bisected by the image of the former when the instrument is horizontal, the image of the cross wire being at the same time seen in optical contact with the distant point, which marks the level with the observer's eye.

JOHN LOCKE.

No. 7478.—*Improved Re-immersing Amalgamator.*

What I claim as new, and desire to secure by letters patent, is the combination of the revolving basin, and its attached tubes, or spouts with the trough containing mercury, the tubes having sufficient length to force the issuing currents to the bottom of the mercury, or nearly so, and their discharging

orifices being above the surface of the mercury, which latter peculiarity causes the streams, as they pass and enter in succession, to force below the surface any particles of metal which may not have been amalgamated by the first immersion.

J. R. MILLER.

No. 7479.—*Improvement in the Seeding Apparatus of Seeding Planters.*

What I claim as my invention, and desire to secure by letters patent, is:

First. The employment of a reciprocating sliding gauge plate, when said plate is provided with oblique feed openings, in combination with openings in the grating plates of different obliquity and bottom of the hopper, for increasing or diminishing the quantity of seed to be sown while the machine is in motion, by adjusting the end of the connecting rod *m*, nearer to or farther from the fulcrum of the vibrating bar (*p*,) and thus increasing or diminishing the traverse or sliding movement of the gauge plate *j*.

Second. I also claim the combination of the hooked connecting rod (*m*,) arm (*l*,) vibrating plate (*p*,) provided with a series of holes (arranged in the arc of a circle scribed from the pivoted end of the rod *m*,) and undulatory cam *s*, with the reciprocatory sliding gauge plate (*j*,) by which the reciprocatory movement of the sliding gauge plate is regulated for the purpose of increasing or diminishing the feed or sowing of the seed.

LEWIS MOORE.

No. 7480.—*Improved Lock Bolt for Shutters.*

What I claim therein as new and of my invention, and desire to secure by letters patent, is the bolt, having a slot through which the key passes, which will admit the bolt to be moved back sufficiently far to prevent the spring catches from catching in the notches in the bolt, in combination with a key hole in the guard, which renders it necessary to remove the key before the shutters can be opened, substantially in the manner and for the purpose set forth.

JOSEPH NOCK.

No. 7481.—*Improved arrangement of Cutters in a Grain and Grass Harvester.*

Having thus fully described the nature of my improvements in mowing and reaping machines, what I claim therein as new and original, and desire to secure by letters patent, is the arrangement, substantially as herein described and represented, of cutters bolted to an endless belt *s*, revolving in a vertical orbit, and moving on a rail *m*, guarded and disposed after the manner described.

JACOB PIERSON.

No. 7482.—*Improvement in Machines for cutting Lozenges.*

What I claim, and desire to have secured to me by letters patent, is the adjustive spring fingers *g*, connected to the two wheeled car *i*, *j*, *k*, *l*, said car being appended to the axle *b*, of the revolving cutters, the wheels and the screws that fasten the finger plate to the transverse bar, preventing the finger plate from touching the sheet of paste during the operation of cutting the lozenges therefrom, as herein fully set forth.

JOHN W. PEPPER.

No. 7483.—*Improvement in the construction of Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is making the fire bottom, and front hearth, or summer arrangement, of the class of stoves herein specified, in one piece, connecting the two with inclined plates placed within the front plate of the stove, substantially as described, whereby I am enabled to have the hearth below the level of the fire bottom, whilst the inclination given to the connecting parts are not visible, thereby effecting the purposes herein specified.

I also claim the above method of making the hearth and fire bottom, in combination with the method of connecting them with the oven bottom and stove bottom, by means of tongues and grooves, whilst the fire bottom extends under the fire back, substantially in the manner and for the purpose specified.

And I also claim, in combination with the above described method of making the hearth and fire bottom, the extension of the front stove plate, down in front of the parts which unite the hearth and fire bottom, the said front stove plate, being provided with projecting pieces to rest against the inclined joints to aid in securing in place, the said united hearth and fire bottom, substantially as described.

S. H. RANSOM.

No. 7484.—*Improvement in Safety Tubes for Lamps.*

What I claim as my invention, and desire to secure by letters patent, is the application or addition of inner pipe or pipes, (one or more, as the case may be,) inserted into a piece of metal or other material, as before described, being either stationary or revolving, thereby preventing the top of the lamp from being removed, without drawing it over the inner pipe or pipes, and thus extinguishing the flame.

FRANKLIN STEWART, M. D.

No. 7485.—*Improvement in Machines for Cutting Felloes.*

What we claim as our invention, and desire to secure by letters patent, is the causing the shaft E, of the cutter head, to automatically descend during its forward motion, until the felloe has been formed by the cutters in the cutter head, and then be thrown upwards to its starting position, substantially in the manner herein set forth, to wit: by resting the said shaft E, upon the moveable bar L, which bar is forced upwards by a spring or weight, and has a rack *k*, and a pin *l*, connected to its moveable end; the said rack *k*, being connected with, and caused to descend, by the forward movement of the cutter head shaft, through the medium of the band *v*, the shaft *f*, and the pinions *h*, and *i*, on the shaft *g*, which movements are thrown out of gear with the rack *k*, at the proper time, by the pin *l*, and the spring *s*, which act upon the levers N, and M, and the shaft *g*, substantially as herein represented and described.

JOSEPH ADAMS.
LEVI ADAMS.

No. 7486.—*Improvement in Condensers of Steam Engines.*

What I claim, and desire to secure by letters patent, is combining with a tubular condenser, the receiving and heating reservoir, which is connected at or near its top, with the exhaust passage, and with one end of the series of condensing tubes, and at or near its bottom with the other end of the series of tubes, and with exhausting and feeding pump, the whole constructed, substantially in the manner and serving the purposes herein specified.

ETHAN BALDWIN.

No. 7487.—*Improvement in Lath Cutting Machines.*

What I claim therein as new, and of my invention, and desire to secure by

letters patent, is the arrangement of the lever N1, in combination with the quadrant Y, rack X, pinion Z, ratchet G1, screw T, and wheel P, thereby moving the periphery of the log being cut, an equal distance at each stroke of the knives, (the log being moved by the chuck Q, instead of applying the power to the periphery of the log,) by which arrangement I can cut laths from square logs, substantially in the manner and for the purposes set forth.

WM. BULLOCK.

No. 7488.—*Improvement in Quilting Frames.*

What I claim as my invention, and desire to secure by letters patent, is the adjustable quilting frame, constructed in the manner herein described, whereby the strained surface of the quilt can be placed in an inclined position, and at any convenient height, thus enabling the quilter to preserve an erect position of the head and chest while at work.

C. H. COOK.

No. 7489.—*Improvement in Apparatus for Cutting Dried Beef.*

First. What I claim as my invention, and desire to secure by letters patent, is the combination of the knives E, and F, F, forming an angle to each other, as described.

Second. I claim the combination of the bed B, with the other parts, to graduate the thickness of the shavings, as described.

DANIEL W. GOBLE.

No. 7490.—*Improvement in Spiral Churn Dashers.*

What we claim as our invention, and desire to secure by letters patent, is the application of a re-acting spiral revolving dash, (the wings of which may be constructed of wood or tin, or any other suitable material,) to a box churn, as described and set forth in the above specification and accompanying drawings, or to any of the usual forms of churns, to which it may be attached, to good advantage.

CORNELIUS R. HIGHT.
JOHN HIGHT.

No. 7491.—*Improvement in Carts for spreading Manure.*

What I claim and desire to secure by letters patent, is the combination of the box B, bottom D, rollers C, cylinder E, cog wheels F, and A, lever G, arranged and operated, substantially in the manner herein described.

J. K. HOLLAND.

No. 7492.—*Improvement in Lamp Tubes.*

What I claim as of my own invention, and desire to secure by letters patent, is the combination of the two conical tubes, as shown, for forming a regulator for the flame of a lamp, substantially as described.

ISAIAH JENNINGS.

No. 7493.—*Improvement in Revolving Hammer Fire Arms.*

What I claim as my invention, and desire to secure by letters patent, are as follows:—First. A central hammer, to be shifted from some convenient position, so as to bear on the central cone, and to be driven by the usual operations of the lock.

Second. A revolving carriage, to carry and turn the hammer.

Third. A trigger turning on a pivot in the cocking lever, and which is thrown forward into a position convenient to be drawn, by pulling said cocking lever, the whole to be substantially as herein described.

GEORGE LEONARD, Jr.

No. 7494.—*Improvement in Sounding Boards for Pianos.*

What I claim therein as my invention, and desire to secure by letters patent, is the supporting the bridge (C,) upon a thin base piece (B,) secured over an opening formed in the ordinary sounding board (A″) substantially in the manner and for the purposes herein set forth.

CONRAD MEYER.

No. 7495.—*Improvement in Seeding Apparatus of Seed Planters.*

What we claim as new, and desire to have secured to us by letters patent, is constructing the tubular drill tooth with a hook shaped arm, in the manner and for the purpose herein set forth, by which the drill tooth is braced laterally whilst in operation, and hooked to the axle when not in operation, and by which the angle of the drill tooth may be changed at pleasure, by changing the position of the wooden pin in said arms, and by which the drill tooth may be folded towards the drag bar in backing the machine, or turning short round, whilst the drill tooth is in the ground, without breaking the wooden pin, said wooden pin resting upon the top of the drag bar, instead of passing through it, as herein fully set forth.

We also claim the spiral or any other form of spring, in such combination with the hopper, grate and seeding cylinder, or the distributing apparatus, as will make the said cylinder and grate, and hopper, self-adjustant, each to each, and to the others in case there should be a want of evenness or uniformity upon the surface of the seeding cylinder or distributing apparatus, for the purpose and in the manner above set forth.

SAMUEL PENNOCK.
MORTON PENNOCK.

No. 7496.—*Improvements in Chargers attached to Fire Arms.*

What we claim, is the revolving ball magazine, in connection with the revolving cylinder.

ORVILLE B. PERCIVAL.
ASA SMITH.

No. 7497.—*Improvement in Machinery for Measuring Pulp in the Manufacture of Paper.*

I claim, in combination with the measuring vessel herein described, the adjustable lid D, constructed with an opening in it, communicating with the pulp chamber in the cylinder, and with the atmosphere, through the small cylindrical chamber E, and the pipe F, the communication being closed and opened by the ball, in the manner substantially as described, for the purposes set forth.

HENRY POHL.

No. 7498.—*Improvement in the Boilers and Gearing of Locomotive Engines, for working Heavy Grades.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of operating the two horizontal

auxiliary driving wheels of locomotive steam engines, by connection with the auxiliary engine, when this is combined with the connection of the piston rods of the two auxiliary engines, with a crank shaft, having the cranks thereon at right angles, substantially as described, whereby the engines are made to alternate in their action, as specified.

I also claim the method, substantially as described, of establishing a connection between the dome and the forward end of the boiler, when this is combined with the extending of the flue tubes to the top of the boiler, as described, whereby the boiler is adapted to heavy grades, as described.

I also claim, in combination with the water ways surrounding the fire chamber, the water channel at the bottom of the boiler, as described, whereby a circulation of the water is established between the two ends of the boiler.

GEO. ESCOL SELLERS.

No. 7499.—*Improvement in Machines for Cutting Screws.*

What I claim, therefore, as my invention, and desire to secure by letters patent, is, substantially as herein described, of determining the pitch of the threads of wood screws by means of a leader, the threads of which are alternately engaged and disengaged from the teeth of a comb on a sliding bar, when this is combined with a relief and return cam, which, at the end of each threading motion, pushes the comb forward to relieve the leader before it is disengaged from the teeth of the comb, and then eases off the return motion of the comb bar, substantially as described.

THOS. J. SLOAN.

No. 7500.—*Improvement in Store Counters.*

I claim the construction of a store counter made in two parts, in the manner described; for the purpose of varying the capacity within, and at the same time to give better security in case of burglary, and aid transportation in case of fires, as herein set forth.

EVAN C. THOMAS.

No. 7501.—*Improvements in Joints for Compasses for Measuring.*

What I claim as new therein, and which I desire to secure by letters patent, is a compass joint, formed of two surfaces held together by centre screws, passing through a cap piece, substantially as herein described.

THEODORE ALTENEDER.

No. 7502.—*Improved Machinery for Double Folding Wide Cloth.*

What I claim as my invention, and desire to secure by letters patent, is the use and application of the rigid prong or extension piece A, to act upon the middle of the piece of the cloth in the process of folding it, in connection with the winding rollers C, D, to secure the exact double folding of the cloth, as above described.

ZACHARIAH ALLEN.

No. 7503.—*Improvement in Self-Weighing Machines for Grain, &c.*

What I claim therein as new, and which I desire to secure by letters patent, is the combination of a steel yard with a weighing box, having several compartments which receive the grain alternately, and when a certain quantity has been received the full compartment is discharged, being disengaged by the depressed position of the steel yard; at the same time, another compartment is presented for filling; the apparatus being operated by the weight of the grain itself, so as to form an automatic weighing machine, by which, with the aid of a register or index the amount weighed is ascertained, substantially as above set forth.

W. W. W. H. T. BRAMBLE.

No. 7504.—*Improvement in Horse Powers.*

What I claim, and desire to secure by letters patent, is the eccentric pivot, which by being turned round allows the entire wheel to be withdrawn from the pinion, and when raised by the lever (t,) the wheel can be tilted up for the purpose of taking the horses in or out, substantially as set forth.

JAS. L. CATHCART.

No. 7505.—*Improvement in Hill Side Ploughs*

What I claim, is the combination of the adjustments of the hooked bar r, with those of the main brace K, whereby the pitch of the mould board may not only be increased or diminished; but the proper support of the upper part of the plough share, be maintained under any angle of pitch, all as specified. The same also admits of a change of the mould board, viz: the substitution of one larger or smaller.

I also claim the above described peculiar construction of the sword cutter with its groove, to receive the sharp edge of the land side, in combination with the notch in the land side of the share for receiving its lower end, and the notch or shoulder in the upper part of the sheath for receiving its upper end, substantially as specified.

MARK S. CHASE.

No. 7506.—*Improvement in Steam Boilers.*

What I claim as my invention, and desire to secure by letters patent, is:

First. Arranging a series of bent water tubes within the flue space of a boiler, and connected at each end with the body of water in the boiler, substantially as herein described, by means of which the circulation of water is greatly increased, and the injurious effects due to expansion and contraction avoided, substantially as described.

Second. I also claim surrounding the crown sheet to which the ends of circulating tubes or their equivalents are attached with a rim, substantially as and for the purpose specified.

Third. I also claim extending the ends of the tubes, or the equivalent thereof, above the crown plate or roof of the fire-box, or any other plate or plates, one side of which is fire surface, to which they are attached when the other or lower end communicates with a water space or spaces below or beyond the plate to which the upper ends are attached, substantially as, and for the purpose specified.

I am aware that a patent was granted to Richard Prosser, in England, February, 1839. See Newton Journal, vol. 15, conjoined series, page 271, in which are represented circulating tubes with one end projecting above a plate. I do not claim such an arrangement, believing that described by me to be substantially different, and producing an entirely different effect.

Fourth and lastly. I claim giving a forced circulation to the water through the boiler or generator by mechanical means, substantially as, and for the purpose specified.

F. F. DIMPFEL.

No. 7507.—*Improvement in Spring Saddles.*

I claim the springs g, g, or springs of any other form producing the same effect, placed between the moveable seat B, and the body of the saddle A, in such a manner as to be easily taken out and changed, as herein described.

GEORGE FISHER.

No. 7508.—*Improvement in Spike Machines.*

What I claim as my invention and improvement, and desire to secure by letters patent, is the method of imparting to the header D, a compound motion for first bending the end of the spike downward, and then moving it forward against the die, to form the hook end simultaneously with the operation of rolling the opposite end to the form of a wedge, with a roller of the same width of periphery, as the thickness of the spike, the said header being fixed to the end of a turning shaft E, passed through the lever H, and inserted into a segmental cogged or toothed plate F, made to match into a fixed segment rack G, by which the angle of the header is changed to correspond with the required form of the head of the spike, as the lever H, is vibrated by the motion of the cam shaft M, and the roller U, being moved in the arc of a circle as it rotates on its own axis, by being attached to the short arm of the bent lever T, whose long arm is attached to a wrist of the wheel or plate W^2, on the cam shaft M, as herein fully set forth.

MOORE HARDAWAY.

No. 7509.—*Improvements in Knitting Machines.*

What I claim as my invention, and desire to secure by letters patent, is:

First. The projecting and withdrawing the needles separately and singly, with their arrangement as described, by which I am enabled to knit closer work with stouter needles, substantially as described.

And secondly. In combination therewith, I claim the combination of the jack, the sinkers and depressers, substantially as described.

Thirdly. I claim the thread bearer (V,) having an extended sideway motion to and fro at each stitch, by which it lays the thread across the needle at each stitch, and returns with it to be ready for the next stitch.

Fourthly. I claim the spring vice for regulating the supply of thread to the needle opened by the rod (w,) substantially as described.

Fifthly. I claim the particular arrangement and combination of the several parts of the machine, by which their various motions are derived from a single crank and screw thread, substantially as described.

JOSEPH HOLLEN.

No. 7510.—*Improvement in Surveyors' Compasses.*

What I claim as my invention, and wish to secure by letters patent, is the application of the partial lens, or lens of reduced size, by means of which to view a cross-wire or a sight mark in optical contact with the object aimed at, either in the compass in gunnery, or for any other purpose requiring and using a sight, in the manner herein described, or any other, substantially the same, and which will produce the intended effect; especially do I claim also, the arrangement by which my compass sight is made susceptible of having either end used as the eye piece, and by which back and forward sights can be taken without disturbing the instrument.

I claim also, the convenient model of the compass to be used with the sight here described, viz: with a super imposed plate, and with the sight planted and supported upon it, and with the opposite readings at such places as are required, in order to obtain indirectly the reading of the occasionally concealed end of the needle, as in fig. 6 and 7.

JOHN LOCKE.

No. 7511.—*Improvement in Sizing Compounds for Warps or Yarns.*

What I claim, consists first, in the combination of the same, and the composition of animal tallow, oil, and caoutchouc, in or about, in the proportions specified, and for the purpose described. I also claim the combination of alcohol, with the composition of resinous alkaline, and other matters as specified, and for the purposes as above stated. WILLIAM MALLERD.

No. 7512.—*Improvement in Machines for cutting Veneers, &c.*

What I claim as my invention, and desire to secure by letters patent, is the application to machines for cutting veneers and thin boards, of a sliding carriage, (or gate,) with knife and spring, substantially in manner and for the purpose herein described.

C. POPPENHUSEN.

No. 7513.—*Improvement in the Seeding Apparatus of Seed Planters.*

What I claim as my invention, and desire to have secured to me by letters patent, is—

First. The combination and arrangement of the segmental plates h, or valves secured together by circular rings and heads i, i, and arranged over the circumference of the cylinder c, adjacent to the opening therein, with the rotating cylinder, constructed as described, for the purpose of partially or entirely closing the openings in the cylinder, through which the seed passes to the depositing tubes, and thus regulate or check the discharge of the seed, as described and shown in the drawings.

Second. The arrangement and combination of the elliptical spring (p,) rising and falling beam (n,) pivoted beam (m,) and hand lever (f,) with the depositing tubes and drill teeth, by which all the depositing tubes and drill teeth may be raised and lowered simultaneously as described, without stopping the planting.

Third. The arrangement of segmental shields or covers (w,) on either side of the upper portion of the rotating cylinder (c,) in combination with the intermediate semicircular spouts or gutters x, beneath the cylinder, by which any waste of the seed is prevented, during the rotation of the cylinder or its discharge from the openings before passing the segmental shields or covers, as described. GEORGE ROHR.

No. 7514.—*Improvement in feeding Apparatus for Straw Cutters.*

What I claim as new, and of my invention, and desire to secure by letters patent, is attaching the feed hand to the reciprocating knife gate, below the bottom of the feed trough, when said bottom is made with an opening next the knife, in which the feed hand operates, and through which all extraneous and hard substances descend before reaching the knife, so that whilst the said feed hand acts on the hay or straw, or whatever is to be cut, at its most compact part, it at the same time offers no obstruction to the insertion of the straw, as it stands entirely out of the way, and leaves the top open and free, the opening in the bottom of the trough serving to rid the hay or straw, or corn stalks, or sticks, stones and other objectionable substances which would tend to injure the knives.

DAVID STILES, Jr.

No. 7515.—*Improved Apparatus for regulating the contraction of Car Wheels.*

What I claim as my invention and improvement, and desire to secure by letters patent, is the combination of the apparatus for discharging the cooling fluid, centripetally against the outside surface of the hub, when constructed in the manner herein set forth, with the apparatus for letting the sand descend from around the hub and retaining it over and about the arms and rim, as described.

I likewise claim the combination of the bed plate, made with the curved conductor and slide, to confine and discharge the sand with the circular iron ring which forms and chills the tread of the wheel.

SAMUEL PRESCOTT.

No. 7516.—*Improved Steering Apparatus.*

What I claim as new in my invention, and desire to secure by letters patent, is operating or turning the rudder, by means of the socket C, so guided that it can be moved only in the direction of its length, and having helical threads or grooves fitting to corresponding grooves or threads on the head of the rudder post, and being moved in either direction, in the line of the axis of the rudder post, by means of a screw D, attached to and operated by the steering wheel, substantially in the manner herein described.

C. F. BROWN.

No. 7517.—*Improvement in Truss-Pads.*

What I claim as my invention, and desire to secure by letters patent, is the formation of the pads for trusses, braces, supporters, &c., as above described, to wit: made of shape in the boundary seen at figs. 5 and 6, (a rounded obtuse angle,) and the padding made somewhat hollow and fullest on the sides A, A, A, as seen in figs. 1, 3, and 4, adapted to bear under and outwards of the fulness of the abdomen, making a plano-concave pad, whether single or double, (the latter seen in figs. 7, 8, 9, 10.)

FRED'K M. BUTLER.

No. 7518.—*Improvement in fastening the Shoes of Hill-side Ploughs.*

What I claim therein as new, and desire to secure by letters patent, is the device for attaching and detaching the removable shoe, having the mould board hinged to it, and being fastened to the landside, substantially as herein set forth.

W. L. CHASE.

No. 7519.—*Improvements in the method of making Wrought Iron directly from the Ore.*

What I claim as my own invention, in the above process of making wrought iron direct from the ore, and desire to secure by letters patent, is deoxidising the ore, in a chamber which is so constructed and arranged, as to be heated by the waste heat, and at the same time prevent the product of combustion from coming directly in contact with the ore, (except during the time of charging,) and likewise permits the charge of deoxidised ore to descend upon the puddling floor or working bottom, without exposure to the atmospheric air, the whole substantially in the manner and by the use of apparatus, substantially such as herein described.

ALEXANDER DICKERSON.

No. 7520.—*Improvement in Machines for raking and binding Grain.*

What I claim therein as new, and desire to secure by lettters patent, is—

First. Gathering the grain and compressing it into a sheaf, substantially as herein set forth, by means of the rake and standards.

Second. Carrying the cord round the sheaf and holding the latter until the band is tied, by means of the curved lever h, and toothed arms g', substantially as herein described.

Third. The employment of the split thimble and sliding hook, to aid in tying the band.

Fourth. Alternating the rake to gather the grain and compress the sheaf, by means of the spring, strap, and drum, substantially as herein set forth.

Fifth. Bridging the space through which the bound sheaf drops, to support the grain while it is being gathered, substantially as herein set forth.

J. E. HEATH.

No. 7521.—*Improvement in the application of Electro-chemical Printing in colors for taking Ayes and Noes.*

What I claim as new therein, and for which I desire to secure letters patent, is—

First. The mode, substantially as herein described, of imprinting words, letters, figures, &c., upon paper or other fibrous substances, by placing the paper or other substance, either chemically prepared or not, as above set forth, between two surfaces of a metal which is not acted on by the substances employed, on one of which the letters or figures are raised by passing a current of galvanic electricity through the prepared material, substantially as above described.

Second. I claim passing the electric current between metallic surfaces, as above described, through damp paper, otherwise unprepared, and afterwards applying a chemical solution, by which the effect of the electricity becomes visible wherever it has passed through the paper, for the purposes above described, telegraphing, &c.

ALBERT N. HENDERSON.

No. 7522.—*Improvement in directing Water upon Water Wheels.*

I claim the adjustable vertical water mouths or openings, arranged in combination with the outer or longest edge of the buckets, as described, whereby the greatest effect is obtained.

MARCUS B. ASHLEY.

No. 7523.—*Improvement in Machinery for turning out Wooden Bowls.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the moveable frames B and C, with the reciprocating frame D, carrying the curved cutter arm M, connected, and operating as described; also the combination of the curved cutter arm M, with the reciprocating frame D, for the purpose described, and also the cutters N, the spurs O, and the guards P, constructed as described, and connected and fastened to the curved cutter arms M, in the manner and for the purpose, substantially as herein described.

ADDISON EVERETT.

No. 7524.—*Improvement in Stanchions for Cattle.*

What I claim as my improvement, and desire to secure by letters patent, is the arranging of the stanchions in a vibrating frame, to accommodate the position of the animal when lying down.

I also claim the stanchion, or fall piece g, in connection with the stay cords k, by which means it is brought to an upright position when closing the stanchion h, thereby preventing an animal taking the place which is occupied by the stanchion h, when open.

I further claim the catch and spring m, n, fig. 4, to hold the stanchions in an upright position, in combination with the rope o, for releasing the cattle from confinement, as herein specified.

G. W. HATCH.

No. 7525.—*Improvement in the Attachment of Prison Locks*

What I claim as my invention, is the combination of the shed e, and its recess or hole f, or their equivalents, with the side of the cell door opening, and the double hinged arm G, and lock, substantially in manner and for the purpose of preventing strain on the lock by pressure against the cell door by a prisoner or person within the cell, as above specified.

EDWARD KERSHAW.

No. 7526.—*Improvement in attaching Hooks and Eyes to Paper Cards.*

What I claim as my invention, is the indenting or impressing the cards or sheets of paper in such a manner as to retain the hooks and eyes in their proper places upon the card, until they can be fastened; in whatever manner they may be finally secured.

I claim nothing in regard to machinery for forming the indentations, nor for the spring, or whatever may be used in fastening, nor for the manner of applying it by gum or paste.

PETER KIRKHAM.

No. 7527.—*Improvement in Churn Dashers.*

What I claim as my invention, and desire to secure by letters patent, is the double concave, perforated, discoid churn dasher, as herein described and represented, and for the purposes set forth.

JOSEPH MARSH.

No. 7528.—*Improvement in Distilling Spirits of Turpentine.*

What I claim as my invention, and desire to secure by letters patent, is the process as described, for distilling turpentine, so that the spirits of turpentine are distilled, and the rosin saponified, ready for soap making at one operation.

CHARLES J. MEINICKE.

No. 7529.—*Improved Valve Gear for Steam Engines.*

What I claim as new, and desire to secure by letters patent, is the combination of the fixed cam E, with its frame and rods, and the adjustable cam I, with its frame and rods, to which latter are attached the traversing and oscillating bar n, having secured to one end of it the rod g, and at or near its centre, the rod H, which actuate respectively, the eduction and induction valves, substantially in the manner herein described, forming together a simple valve motion, and one which enables the engineer to regulate the degree of cut-off at will.

GEORGE B. MILNER.

No. 7530.—*Improvement in Rubbing and Polishing Stone.*

What I claim as my invention, and desire to secure by letters patent, is attaching the stone D, to be faced, to a chain *a*, one end of which is attached to a windlass *c*, by which it may be lengthened or shortened; the stone being left free, so as to be continually changing its position on the bed, during the operation of rubbing, by which an uniform and even wear is produced on the bed, and a true face given to the stone, in the manner substantially as described.

ADRIAN OLCOTT.

No. 7531.—*Improvement in Atmospheric Churns.*

What I claim as my invention, and desire to secure by letters patent, is the construction of the air tube *b, c, d, d*, in combination with the plungers and partition, as set forth, whereby the cream is thoroughly agitated, and intimately mixed with atmospheric air, by forcing it alternately to the opposite sides of the partition, through branches of the air tube, as herein set forth.

JOHN O. NEIL.

No. 7532.—*Jigger Windlass.*

I therefore claim as new, and desire to secure by letters patent of the United States—First. The application of the double acting pawls 3, 3, ratchet 4, disk *e*, socket *f*, and handspike *g*, with or without the winch-head D, whereby the power is applied to the horns *d, d*, to rotate them in either direction, as required, said application and arrangement being a combination of the double acting winch, as described in my patent of 29th May, 1849, and the cable lifting horns described in my patent of 21st March, 1848, heretofore referred to, whereby this combination of these two previously patented inventions effect new and useful purposes, not contemplated and not attainable by either of the inventions separately, substantially as described and shown.

CHARLES PERLEY.

No. 7533.—*Improvements in Apparatus for sizing and drying Cotton Batting.*

What I claim as my invention and improvement on all other modes of glazing cotton wadding, and desire to secure by letters patent, is—First. Doubling or turning the ragged and uneven edges of the bat of cotton, as it comes from the carding engine, and pressing them down to form a smooth selvage, as set forth, by means of the curved plates *a*, in combination with the cylinders *b, c*, as described, or other equivalent means.

Second. I claim heating and ironing the surface of the bat of cotton, previous to being glazed, for the purpose herein set forth, whether performed by the means herein described, or other equivalent means.

I likewise claim making the floating cylinder with check rings, or their equivalents, in the manner and for the purpose described.

I claim passing the bat through a space between the floating cylinder and compressive cylinder, and imparting the sizing to the bat of cotton without pressure, as described.

I claim making the drying chamber a double inclined plane, in combination with the chimney, constructed as aforesaid, for the purpose of increasing the circulation. I also claim the peculiar combination of the heating, selvaging, ironing, and glazing, and drying apparatus, by which the bat of cotton, as it comes from the carding engine, is selvaged, ironed, glazed, and steam dried by a continuous process, as herein fully set forth, the sizing vat being placed directly beneath the compressive cylinder, so that the sizing can be introduced fresh from the vat to the bat, as it comes from the ironing cylinder, as described.

E. P. RIDER.

No. 7534.—*Improvement in Purifying Coal Gas.*

What I claim as my invention, and desire to secure by letters patent, is the mixture with lime of coke dust or breeze, charcoal dust, or other carbonaceous substance, for the purpose of acting mechanically in the separation of the particles of lime, and at the same time acting chemically in removing various impurities from the gas, (which cannot be separated by the ordinary methods of purifying gas,) substantially as above set forth.

JOS. SABBATON.

No. 7535.—*Improvements in connecting Hubs with Axles.*

What I claim as new, and of my own invention, and desire to secure by letters patent of the United States, is the application of the half boxes *d*, and *d*, with the semicircular lip 5, and rib *e*, constructed to enter the grooves 4 and 8, near the end of the axle box *c*, said boxes being secured together and connected to the axle bar by any competent means, and said ribs, grooves, and boxes operating as a substitute for a collar on the axle, and to hold the axle box and wheel on the axle, and also to keep dust out of the parts, substantially as described and shown.

ELIPHALET S. SCRIPTURE.

No. 7536.—*Improvement in the Arrangement of Pressure and Feed Rollers in Planing Machines.*

What we claim as new therein, and desire to secure by letters patent, is connecting the moveable weighted pressure rollers with the stationary ones by oblique links, in combination with the additional rollers (f',) the whole arranged substantially in the manner and for the purposes set forth.

CHARLES A. SPRING.
PETER BOON.

No. 7537.—*Improvements in Machines for forming Tubes of Sheet Metal.*

What we claim as our invention, and desire to secure by letters patent, is supporting the forming roller (3,) upon the short ends of the bent levers (G, G,) in combination with the upper roller (2,) supported by springs, substantially in the manner and for the purposes herein described.

JOSEPH STOUT.
JAMES T. STANTON.

No. 7538.—*Improved Bolt and Rivet Machine.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Gauging the length of the shank, after a head has been formed on the end, by pushing the head against a gauge beyond the header, which has a lateral motion to allow it to pass by, substantially as described, in combination with the operation of cutting off the shank at such distance from the griping dies, as by the same operation to determine or gauge the length of rod or wire, which shall be left projecting beyond the griping dies for forming the next head, substantially as described.

And lastly, cutting off the rod or wire, after the head has been formed, by the return lateral motion of the header, in combination with the rest, substantially as described, the edges of the rest and heading die, being formed to answer the purpose of shears, as herein described.

WM. E. WARD.

No. 7539.—*Improvement in Car Seat Backs.*

What I claim as my invention, and desire to secure by letters patent, is the forming of the backs of car seats, of double curved plates of metal attached by the ends to the arms of the seat, made to embrace both sides of the end pieces to which they are pivoted, and on which the car seats are reversed, formed, stayed, and braced, substantially in the manner and for the purpose herein specified.

THOS. E. WARREN.

No. 7540.—*Improvement in the Counter-twist Speeder.*

What I claim as new, and desire to have secured to me by letters patent, is making the shaft with a serrated groove *d*, in combination with the reduced portions *c*, *c*, of the shaft adjacent to said groove, wherein the roving runs from the twisting band to the bobbin in the manner and for the purpose herein fully set forth.

I also claim the combination of the spring *g*, and pendent tapered arm *f*, with the vibrating bobbin arm *i*, arranged and operated in the manner and for the purpose herein set forth, or in any other way which may be considered substantially the same, and by which analogous results shall be produced, that is to say, any arrangement wherein a rubbing pressure is imparted to the arms or their equivalents, containing the journals of the bobbin for producing the effect herein stated, said arrangement preventing the sudden rebounding of the bobbin on the shaft, when it becomes uneven from any cause, which the mere spring and weight applied to the bobbin axle or its arms, will not prevent, as I have fully tested by experiment; the spring when used alone being too elastic, and the weight too dead, whereas, the combination of the two, causes the bobbin to rise and fall gradually, as herein fully set forth.

JESSE WHITEHEAD.

No. 7541.—*Improvement in Fastenings for Bureau Draws.*

What I claim as of my own invention, and desire to secure by letters patent of the United States, is—

First. The metallic strip or its equivalent, constructed with the notch for receiving the fastening bolt, as set forth.

Second. The locking bolt operated by the opening or closing of any one of the drawers, for the purposes herein named, the whole being constructed, substantially in the manner herein set forth.

GEORGE WODE.

No. 7542.—*Improvement in the Manufacture of Raw-hide Whips.*

What I claim as my invention, is the above described improvement, in the manufacture of whips, or a whip having its external covering as well as its turk's heads or buttons, made in whole or in part of corrugated strips or bands of raw hide, laid or woven together, and on the handle or stock, substantially as herein before specified.

THOMAS J. BARNES.

No. 7543.—*Improvement in Scrapers used by Cabinet Makers.*

What I claim as my invention, and desire to secure by letters patent, is the scraper stock set in a frame for holding and guiding the scraper, so that the forward end only of the frame shall rest on the surface to be scraped, and thereby enabling the workman to manage the tool with the whole hand, apply a steady force instead of using the fingers only, as heretofore, for that purpose.

Second. I also claim reversing the position of the scraper stock and plate in the stock frame, whereby I am enabled to use both feather edges or corners of the plate successively, without taking the plate from the stock, as herein set forth.

HIRAM CARVER.

No. 7544.—*Improvement in Seed Planters.*

What I claim therein as new, and desire to secure by letters patent, is the combined operation of filling and discharging the revolving cups or cavities, in the planting rollers Z, Z, by a single blow of the arms F, F, on the said rollers, substantially as herein set forth.

EDSON HART.

No. 7545.—*Improvement in Ballot Boxes.*

What I claim therein as new, and desire to secure by letters patent, is the arrangement, substantially as herein described, of a moving band or tape, imprinted with numerals, and actuated by pedals, ratchet movement, and rollers or other equivalent device, in connection with spring detention latches, and a liberating brake or their equivalents, so that while the number polled for each respective candidate is exhibited by appropriate tape, each pedal as it is brought into play by the voter, is detained by its respective latch, until again liberated by the attending officer, thus effectually preventing the duplication of votes.

JOSEPH ADDISON HILL.

No. 7546.—*Improvement in Processes for Amalgamating Gold.*

What I claim as my discovery, and desire to have secured to me by letters patent, is saturating or dampening the sand or quartz, with which gold is found, with a solution in soft water of chloride of sodium and tartaric acid, mixed in about equal proportions, and applied to the sand, &c., prior to the introduction of quicksilver, to effect amalgamation with the gold.

CALVIN C. KNOWLES.

No. 7547.—*Improved method of making Barrels for Fire Arms.*

What I claim as my invention, and desire to secure by letters patent, is making barrels for fire arms, with a double seam or weld, from two bars of metal previously rolled into a semi-cylindrical form, the whole operation being conducted as herein described.

JESSE PANNABECKER.

No. 7548.—*Improvement in Hanging and Operating Gates.*

What I claim as my invention, and desire to secure by letters patent, is the manner of hanging and operating the gates, substantially as described.

THOMAS PARKINSON.

No. 7549.—*Improvement in Tenoning Machines.*

What I claim therein as new, and desire to secure by letters patent, are the planes for cutting the tenon, whose irons are made to turn alternately from and towards the faces of their respective stocks, so as alternately to cut and clear the lumber on which they are acting.

E. M. SHAW.

No. 7550.—*Improvement in Churn Dashers.*

All that I claim, and desire to secure by letters patent, is the combination of the funnel shaped tubes B, radial wings or plates D, inclining upward and outward, directly over the ends of the tubes B, with the circular cap plate or disk F, for the purpose as described.

R. S. SHERMAN.

No. 7551.—*Improvement in Harness Saddles.*

What I claim therein as my invention, and desire to secure by letters patent, is the combination of the separated elastic plates C, C, with the skirt portions B, B, of the casting A, B, B, and the pads F, F, substantially in the manner herein set forth, for the purpose of causing the pads to have a springy and equable bearing upon a horse, and to adapt themselves to horses of different sizes and conditions.

ROBERT SPENCER.

No. 7552.—*Improvement in Machines for Beating Gold.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the adjustable differential cams (H,) with the pendulums, by means of which the packet is shifted under the hammer, so as to regulate the distribution of the blows upon it, as herein set forth.

WM. VINE.
JAS. H. ASHMEAD.

No. 7553.—*Improvements in Machinery for dressing Weavers' Harness.*

What I claim therein as my invention, and desire to secure by letters patent, is the within described combination of the size or glue receptacle K, *k*, and the rotating brushes *y*, *y'*, with each other, and with the shafts B, B', the screw shafts C, C', the sliding rod E, the lever *v*, the clutch X, the pulleys W, Y, and the drawing pulley Z, by which the brushes *y*, *y'*, are made, simultaneously to rotate on their axes, and to alternately traverse from one end of the harness A, to the other, (or any portion of it,) and deposite the size or glue evenly and smoothly upon the threads of the harness, substantially as herein set forth.

In combination with the size or glue receptacle K, *k*, and the rotating and reciprocating brushes *y*, *y'*, above set forth, I also claim the imparting a reciprocating movement to the frame G, G, in which the harnesses A, A, are placed simultaneously with the combined movements of the said brushes *y*, *y'*, substantially in the manner herein set forth.

I also claim the making the sliding frame G, G, of such shape and capacity as to receive two sets of harness A, A, when it is combined with the shaft D, the pulley Q, the crank or lever *q*, the elastic lever R, the pitman S, and the crank wrist *t'*, substantially as herein set forth; by which without stopping the machine, a dressed harness can be removed from the frame, and an undressed harness secured in its place, whilst another harness is being dressed with size or glue in the opposite receptacle of the said frame, substantially in the manner herein set forth.

KASIMIR VOGEL.

No. 7554.—*Improvement in Churn Dashers.*

What we claim as our invention, and desire to secure by letters patent, is the double curved, shaped dasher H, with the groove pieces J, J, and N, N, in combination as herein described, for the purposes herein set forth.

WILLIAM WALKER.
MATTHEW C. WALKER.

No. 7555.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is:

1st. The manner of forming the front *d*, wing flues (*a*, *a*,) on either side of the stove, by recessing the centre of the front plate above and beneath the plate forming the hearth, and bottom of the fire chamber, and inserting plates (*e*, *e*,) to form the insides of the flues (*a*, *a*,) in the fire chamber, so that they can be re-placed when burnt out without disturbing the sections of said plates below the hearth, as described.

JAMES WHITE.

No. 7556.—*Improvements in Tenon Bits.*

What I claim as my invention, and desire to secure by letters patent, is the combination of converging slides with a pair of planes, the latter being combined with the former in such manner, that by pressure and turning, they are caused to approach each other and reduce the extremity of the spoke to which they are applied, substantially as herein set forth, the slides and planes being turned by a hand-brace or by machinery.

ELI K. WISELL.

No. 7557.—*Improvement in Friction Clutches.*

What I claim as new, and desire to secure by letters patent, is the sliding collar *k*, connected to and in combination with the nut *g*, substantially in the manner and for the purposes herein specified.

NELSON BARLOW.

No. 7558.—*Improvement in Cylinder Printing Presses.*

That which I claim, is constructing a printing machine, in which the form or forms of types, or blocks are placed on, or secured to the inner or concave surface of a cylinder or drum, which is made to revolve or carry the form or forms secured thereto, from the inking roller to the printing or impression cylinders, all of which parts are mounted inside the cylinder or drum.

Second. I claim the methods above shown, and described of the making the inking rollers or balls of printing presses or machines.

BARTHOLOMEW BENIOWSKI.

No. 7559.—*Improvement in the Manufacture of Candles.*

What I claim therein as new, and desire to secure by letters patent, is the arrangement and manner of operating the knives, by which the cylinder of fat, with its central wick, is cut into suitable lengths for candles, and the fat removed from the end of the wick.

I also claim the device for regulating the length, and delivering the candles, substantially as herein described.

JAS. G. DAVIS.

No. 7560.—*Improvement in Instruments for Vaccinating.*

What I claim as my invention, and desire to secure by letters patent, is the sliding cylinder D, in combination with the thumb key F, spring M, and piston O, for the purposes herein described and set forth.

JUNIUS F. FOZER.

No. 7561.—*Improvement in Splints for Fractures.*

What I claim as my invention, and desire to secure by letters patent, is the cutting out a portion of the splint, to afford an opportunity for dressing as often as may be necessary, the upper and lower portions of the splint being kept firmly united by means of the brace B, so as by extensions and counter extensions, to keep throughout the treatment, the proper relative position of the parts concerned, the slide being re-placed after each dressing, or any other device, substantially the same.

ADAM HAYS.

No. 7562.—*Improvement in Weighing Machines.*

What I claim as my invention, and seek to secure by letters patent, is the iron frame, together with the skids and regulating screw, used in connection with a weighing beam, as described in the foregoing specification, and represented in drawings accompanying this.

GEO. HOUSTON.

No. 7563.—*Improvement in Packing Boxes and Axles.*

What I claim as new, and desire to secure by letters patent, is the combination of the metallic packing ring E, having is outer periphery of conical form, the arched springs F, F, having their ends inclined to fit the said ring E, and the regulating screws *h*, *h*, with the journal box C, and axle A, in the manner and for the purposes, substantially as herein described.

WM. H. HOVEY.

No. 7564.—*Improvements in Pentagraphs.*

What I claim as new, and for which I desire to secure letters patent, is the instrument, constructed and arranged as above set forth, consisting of a pencil moving parallel with the eye tube, with which it is connected as herein described, and marking on a vertical plane, or a plane, parallel with their axes of horizontal motion, such objects as the sight through the eye tube passes over.

ALLEN JUDD.

No. 7565.—*Improvement in Bench Hooks.*

What I claim as new in my invention, and desire to secure by letters patent, is forming the head *c*, with any suitable number of edges of any required form, to suit various kinds of work, and having the spindle, of which the head forms part, grooved and fitted in a socket, set at an inclination to the bench, so that any edge of the head can be set to the work and secured by a spring catch, and whatever edge is turned to the work, will be higher than the back or opposite edge as herein set forth.

W. B. KEAN.

No. 7566.—*Improvement in Apparatus for Regulating the Setting of Boxes in Wagon Tops.*

I claim the combination and arrangement of the rules G, G, K, K, the rods

H, H, the pins *h*, *h*, the adjusting screws I, I, and the holdfast bolts J, J, arranged and adjusted upon a frame, in the manner and for the purposes, substantially as herein described.

And I also claim the adjustable rule M, sliding in the swinging bar L, and attached to the same frame with the before described combination, in the manner, and for the purpose herein set forth

A. McKINNEY.

No. 7567.—*Improvement in Ornamenting Textile Fabrics.*

What I claim as my improvement, is the new or improved ornamental fabric or manufacture, made substantially as specified, viz: having any ground suitable or unsuitable for receiving and exhibiting bright color or colors when imprinted thereon, and having figures, stripes, or other portions of surface floated over the said ground, in material and color, suitable for representing such bright color or colors, and having such bright color or colors printed on the said boated surfaces.

ROB'T MILLIGAN.

No. 7568.—*Improvement in Piano Fortes.*

What I claim as of my own invention, and desire to secure by letters patent of the United States, is combining two sets of strings operated by separate actions with one and the same sounding board, whereby I am enabled to produce greater effects, both in quality of tone and in power than heretofore, and also to maintain the unison of the notes, and the tune to a degree not possible before, the whole being constructed and operated, substantially in the manner described herein.

JAS. PIRSSON.

No. 7569.—*Improvement in Ship Ventilators.*

Firstly. I claim the ventilating chamber, constructed in the manner substantially as above described, having a tube or air passage, communicating with the cabin, or between decks of a ship or other vessel, entering it at *a*, *b*, figs. 2, 3 and 4, and provided with a register, represented by *a*, *b*, in fig. 1, either for the purpose of admitting pure air, by long tubes, to the lower parts of the cabins, or between decks, or for carrying off the ventilated air by short tubes from their upper parts.

Secondly. I do not claim the use of a float valve in the ventilating tube, irrespective of the manner of applying them, but I claim having the two float valves A and B, attached together, in the manner substantially as described, and each acting independently of the other, upon a separate seat in the ventilating chamber; so that any water passing one valve, may be shut off by the other.

WARREN ROBINSON.

No. 7570.—*Safety Apparatus for Steam Boilers.*

What we claim as our invention, and desire to secure by letters patent, is the application of a rope, made of any combustible material (using for this purpose, wool as prepared in the manner before noticed, or any other material which will answer the intended effect,) to the upper surfaces of one or more tubes or flues of a boiler, which, when said tubes or flues are uncovered of water, will burn off, or part in the manner as before described, for the action of the excessively heated metal and surcharged steam, which rope is connected with, and by its parting actuates the apparatus herein described, or any part thereof, for the purpose either of giving alarm, or putting in action means of safety, or both, substantially as herein described.

JOHN C. TENNENT.
JNO. WORKMAN.

No. 7571.—*Improved Serving Mallets.*

What I claim as new in my invention, and desire to secure by letters patent, is—First. Attaching friction rollers to the periphery of a serving mallet, substantially in the manner and for the purposes herein described.

Second. Making the groove or face (*c*,) deeper or larger at the part (*h*,) which fits the served part of the rope, in the manner and for the purposes substantially as herein described.

THOMAS BATTY.

No. 7572.—*Improvements in Gun Harpoons and Lances.*

What I claim as my invention, and desire to secure by letters patent, is attaching a tail of cords, (or their equivalent,) to gun lances, substantially in the manner and for the purpose herein set forth.

I also claim attaching the button to the shank of gun harpoons or lances, in such manner that when the lance or harpoon is discharged from the gun, the button will drop off, being thereby prevented from retarding the flight, and from deflecting the lance or harpoon from the line in which it is projected from the gun, substantially as described.

ROBERT BROWN.

No. 7573.—*Improvement in Obstetrical Supporters.*

What we claim as new and useful in our invention, and desire to secure by letters patent, is the combination, in the manner described, of the sliding plate C, with the back pad B, which is connected to the seat, for the purpose of enabling the bearing of the instrument to be moved higher up or lower down the back, without disturbing the patient.

F. H. CHASE.
ADAM WESTON.
LEANDER BABBIT.

No. 7574.—*Method of Propelling Boats in Shallow Water.*

What I claim therein as new, and desire to secure by letters patent, is—First. The combination and arrangement of the setting pole E′, sliding in the sheath E″, with the spring bolt *y*, and cords 3, 3, 3, and 6, for the purpose of shortening or lengthening the setting pole, substantially as herein fully described and shown.

Second. The manner herein described, of checking or snubbing the boat by means of a chain or cord attached to the foot of the setting pole, and passing over pulleys to a windlass placed in the stern of the boat near to the helm, as herein described.

JOHN DOUGHERTY.

No. 7575.—*Improvement in Compound Wagon Boxes.*

What I claim as my invention, and desire to secure by letters patent, is making the fastenings of a compound wagon body by combining with screw bolts, so jointed to the axles, frame or body of the carriage, as to be laid down or set up at pleasure, two cross pieces to each pair of bolts, with pres-

sure nuts above the upper, and sustaining nuts beneath the lower cross bar, whereby the whole load may readily and easily be secured, or the lower part may be released and withdrawn, without disturbing that which is above it, substantially as herein set forth.

IRNLA DRAKE.

No. 7576.—*Improved Steam Boiler.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of pendent water vessels (D,) in the fire box, in connection with water tubes (*e*,) which pass along the flue, and are connected at one extremity with a water space near the back of the boiler, and at the other with the water vessels at the fire box, substantially as herein set forth.

RICHARD E. DIBBLE.

No. 7577.—*Improvement in changing Rotary Motion into Reciprocating Motion.*

What I claim as my invention, and desire to secure by letters patent, is the mechanical arrangement and combination of parts, by which I convert the rotary motion of the wheel A, into a reciprocating movement of the churn dasher rod W, to wit: by means of the action of the lugs *a*, *a*, that project from the face of the said wheel A, upon the forked rocker K, *l*, *m*, and the vibrating beam G, when aided by the inclined planes *t* and *r*, substantially in the manner herein set forth.

ISAAC D. GARLICK.

No. 7578.—*Improvement in Machines for Cutting Hemp.*

What I claim as my invention, and desire to secure by letters patent, is the attaching a series of blades upon an arm, back to back, in a V form, their edges elevated in order to give a smooth glancing stroke upward, through the stalk of hemp, after manner of the cutting performed by the common scythe in hemp and grain.

I claim the introduction and use of a cleaning shear over the crotchet or junction of the blades (to remove such hemp as may be imperfectly cut or pulled up,) substantially in the manner as herein set forth.

I claim the method of separating and bunching the hemp after it has been cut, by means of a wedge or inclined plane, and a revolving cone.

I claim the invention and use of the revolving rack as a substitute for the over-head reel in supporting the hemp while being cut.

J. LOCKE HARDEMAN.

No. 7579.—*Improvement in Fulling Mills.*

What I claim as my invention, is so arranging a vertical fluted or ribbed cylinder, and fluted or ribbed concave, that the rotation of the former on its axis, shall cause the goods to be fulled to assume a cylindrical form, and to rotate on its own axis, by means of the friction of the two fluted or ribbed surfaces acting upon and sustaining in its position, the cloth or goods, as set forth.

JOHN C. MILLAR.

No. 7580.—*Improvement in Machines for Cutting Crackers.*

I claim the combination of the three following elements: First. The constant velocity of the breaking rollers.

Second. The number of strokes of the cutters adjustable thereto, by means substantially as described, so that within certain limits they may be varied in relation to the number of revolutions of the feed rollers.

Third. An adjustable feed to the apron, derived from the shaft carrying the cutters, so that it always makes the same number of strokes, but each stroke may be varied in length, by which, in the same machine, I am enabled to cut crackers of any given size.

WILLIAM R. NEVINS.

No. 7581.—*Improvement in preparing the face of Metallic Types, Engraved Plates, &c.*

What I claim as my invention and discovery, and desire to secure by letters patent, is the plating or coating of the surfaces of metallic printing types, stereotype plates or other printing plates, whether cast or engraved, with an additional coat of metal, by means of galvanic electricity, in the manner and for the purposes described.

L. VANDER VEER NEWTON.

No. 7582.—*Improvement in Hot Air Registers.*

What I claim as new therein, and which I desire to secure by letters patent, is the method of moving the dampers in registers or ventilators, by means of the slider (*d*,) and the oblique bars (*g*.) with their several forms and parts, substantially as described, in combination with the oblong dampers hung in the middle of their width, in the manner and for the purpose set forth.

G. POLLOCK.

No. 7583.—*Register for Steam Boilers.*

What I claim as of my invention, and desire to secure by letters patent, is connecting the gauge rods with the gauge cocks, in such manner as herein described, that the pressure of steam and height of water shall be registered each time the gauge cocks are tried, the register indicating at the same time, the period of time of trying of the gauge cocks by opening and closing them.

JAS. D. RICE.

No. 7584.—*Machine for cutting Sheet Metal, &c.*

What I claim as my invention, is the toothed rack, or its equivalent, (applied to the bar B,) and a system of one or more gears, or the mechanical equivalents thereof, (applied to the cutter wheel, and made to engage with the said rack, or equivalents therefor,) in combination with the said bar B, the cutter wheel and its sliding carriage; the same being substantially in the manner as above described, and for the purpose of causing the cutting periphery of the rotary knife to travel around faster than the knife moves horizontally, and to thereby make said knife cut with a drawing stroke.

I also claim the combination of the swinging frame and gauge contrivance, or equivalents therefor, with a sliding carriage, its cutter wheel and the slide bar and straight cutting edge, as substantially specified, the same being for the purpose of enabling me to cut either circular or curved work, as described, and of any diameter or dimensions capable of being produced by the machine of whatever size it may be made.

STEPHEN P. RUGGLES.

No. 7585.—*Improved opening and closing Bucket for Paddle Wheels.*

What I claim as of my own invention, and desire to secure by letters patent, is—First. The formation of each of the blades composing the bucket, so that their inner or closing ends shall be heavier than the outer ends thereof, when combined with a stop or stops, substantially as herein described, thus effecting the closing together of the same by the action of gravity before entering the water, as set forth.

And secondly. I claim curving the inner edges so as to ensure the closing of said edges together, by the action of the water while backing, and thus complete a sufficient bucket for that purpose, substantially in the manner described herein.

GEO. TINGLE.

No. 7586.—*Improvements in Machines for heading Bolts, Rivets, &c.*

I am aware that spikes and bolts have been headed in a box, I therefore do not claim the box with the moveable header therein, but what I do claim as my invention, and desire to secure by letters patent, is attaching to or forming in the lower part of the box or holder, a flaring or bell mouthed cavity, such as R, which embraces the tapered ends of the dies, when the box is down or in a vertical position, and clamps them firmly together, while at the same time the cavity acts as a guide to cause the heading box to assume its proper position, and prevents the metal from being forced out between the ends of the dies and bottom of the cavity in the box, during the operation of heading.

JOHN VAN BROCKLIN.

No. 7587.—*Improved method of carrying Vessels over Shoals.*

What I claim as new therein, and which I desire to secure by letters patent, is the mode or method of transporting a vessel across shoals or bars, by means of a camel, having an unyielding platform for the vessel to rest on, and likewise provided with a bow, as herein described, the vessel being partly water borne, and partly supported by the camel.

J. A. WINSLOW.

No. 7588.—*Improvement in Processes for making Stannates of Potash or Soda.*

I claim as of my said invention, the mode of producing a stannate of soda, by heating a mixture of tin ore and sulphuret of sodium, and a stannate of potash by heating a mixture of tin ore and sulphuret of potassium, and afterward separating the sulphur from these mixtures respectively, by means of a metallic oxide, in manner herein before described.

JAMES YOUNG.

No. 7589.—*Improvement in Expansible Bitts.*

What I claim as new, and desire to secure by letters patent, is the herein described expansible bitt, in combination with the single or double collar or tube, constructed and operating in the manner, substantially as herein set forth.

C. L. ADANCOURT.

No. 7590.—*Improvement in Obstetric Chairs and Supporters.*

What I claim in the foregoing as my invention, and desire to secure by letters patent, is an obstetric chair with its seat composed of sections, hinged together, substantially in the manner and for the purpose herein set forth.

226 Ex. Doc. No. 32.

I also claim a chair back, hinged to the seat in such manner that it can turn both horizontally and vertically, substantially in the manner herein set forth.

I likewise claim the combination of the stirrups with the abdominal pad, substantially in the manner and for the purpose herein set forth.

ASA BLOOD.

No. 7591.—*Improvement in Turning up the Steps of Omnibuses.*

What I claim, is the turning up of the step, (it being properly prepared for the purpose,) by the action of the spiral or other spring, upon the stepping off of the passenger, and the withdrawing of the driver's foot, and its connection with the brake apparatus, thus preventing boys or others from riding on it, the whole being attached to the body of the carriage, and operating substantially as fully set forth in the accompanying drawings and model.

STEPHEN BURDETT.

No. 7592.—*Improvement in Machines for Cutting Straw.*

What I claim, and desire to secure by letters patent, is—First. The manner of hanging the knives to the wheel, as described.

Second. Forming the knives with a hook shaped end, in the manner and for the purpose set forth.

Third. The collar on the projecting end of the mouth-piece, forming a support for the detached end of the knife to rest against, as described.

HARRY CAMP.

No. 7593.—*Improvement in Revolving Coal Grates.*

What I claim as new, and desire to secure by letters patent, is the manner of arranging bars or flanges B, B, around the cylinder, at an angle of any desired degree from the axis of the cylinder, so as to move the coal alternately in opposite directions, the same forming a fire grate, in the manner and for the purpose, substantially the same as herein described and represented.

JOHN B. CHOLLAR.

No. 7594.—*Improvement in Self-generating Gas Lamps.*

What we claim as our invention, and desire to secure by letters patent, is the extension of the wick into a ball or cavity, where the gas may be generated by means of jets, as above set forth.

SHARPLESS CLAYTON
YARNALL BAILY.

No. 7595.—*Improvements in Coal Stoves for Roasting and Boiling.*

What we claim herein as new, and desire to secure by letters patent, is—

Firstly. The arrangement, after the manner and for the purposes herein described, of a grated or other more or less open fire back, whereby a roasting surface is presented to the interior of a stove.

Secondly. The provision, substantially as described, of dampers, whereby the roasting surface may be regulated or entirely closed up, or opened at pleasure.

Thirdly. The falling grate *g*, arranged and constructed, substantially as described, so as to enable extension horizontally, of the body of the fire, for a boiling surface.

Fourthly. The fire door having hopper sides, and forming, when extended, a canopy for the conduction of effluvia.

Fifthly. The hopper or funnel shaped door, as arranged and here applied for the insertion of fuel.

THOS. G. CLINTON.
GEORGE H. KNIGHT.
EDWARD H. KNIGHT.

No. 7596.—*Improved Lock for Fire Arms.*

What I claim as new, and desire to secure by letters patent, is the seer *j*, in combination with the pin and shoulder on the trigger, by which arrangement the hammer, after being brought back by the pressure of the finger upon the trigger, is held in its position by the seer, while the trigger passes forward, and the piece is discharged by a light touch of the finger upon the trigger, securing deliberation and certainty of aim, or may be discharged by one continuous pressure of the finger upon the trigger, at the pleasure of the person using the same. And in these claims I wish to be understood that I do not confine myself to the precise arrangement of the parts herein described, but shall vary the same at pleasure, while I attain the same ends, by means substantially the same.

NATHAN B. COOK.

No. 7597.—*Improvement in Shirt Studs and Buttons.*

What I claim in the foregoing as my invention, and desire to secure by letters patent, is constructing the shanks of shirt studs and buttons, in the manner and for the purpose herein set forth.

BENTON P. COSTON.

No. 7598.—*Improvement in Stoves with Circular Shaking Grates.*

What I claim as new, and desire to secure by letters patent, is casting the seat (G,) of the fire box separate from the top plate (C,) of the ash box, having the bar (D,) carrying the centre or pin (*d*,) for supporting the grate, cast with and forming part of the top plate (C,) of the ash box, substantially as described, and for the purposes set forth.

EDWARD B. FINCH.

No. 7599.—*Improvement in Cast Iron Car Wheels.*

What I claim as my invention, and desire to have secured to me by letters patent, is making the two plates which connect the hub and rim of a cast iron railroad wheel, in a series of lateral arching sectors connected by the curved partitions *c*, *c*, &c., in the manner and for the purpose herein above specified.

ALBERT FULLER.

No. 7600.—*Improvement in detaching Horses from Carriages.*

What I claim as my invention, and desire to secure by letters patent, is the application to buggies and other vehicles, drawn by horses and other draught animals, of a new and useful improvement on the swingle tree, which I entitle the safety swingle tree, together with its apparatus, consisting of a lever and ring bolt, a grooved headed screw bolt, a flat headed screw bolt, a force spring, and two stirrups combined, as above described, which, upon the ring bolts being raised as above described, will allow the horse to become unhitched and to pass off, freely from the same and every part thereof, without danger to the same, or to persons therein contained, using in the construction of the same, wrought iron or any other durable material that will ensure the desired object.

JOHN W. HARRISON.

No. 7601.—*Improvement in Grain Dryers.*

What I claim as my invention, and desire to secure by letters patent, is the arranging a series of drying plates, one above another, connected by passages as described, in connection with the vertical shaft and arms thereon, curving alternately in opposite directions, combined and arranged in the manner and for the purpose herein fully set forth.

JOHN R. HOOPES.

No. 7602.—*Improvement in the mode of Cleaning and Drying Gum Elastic or Cloth Bands in Calico Printing.*

I claim as my invention, the arrangement of the rollers and vat, above described, for washing the India rubber bands or other endless blankets, used in calico or other printing, said rollers being only partly immersed in water, and other parts arranged and operated, as set forth.

JAS. HUNTER.

No. 7603.—*Improvement in Saws.*

What I claim as my invention, and desire to secure by letters patent, is my improved saw teeth, constructed and operated, substantially as herein described and represented, viz: the cutting edges of the teeth inclining outwards from plane or curved surfaces *a*, *a*, a distance equal to the thickness of chip that each tooth is intended to remove from the wood, and being prevented from taking a deeper hold upon the wood, at the same time that they are strengthened by the said outer surfaces (*a*, *a*,) in consequence of these surfaces (*a*, *a*,) being in a line with each other, and parallel or nearly so, with an imaginary right line or circle, drawn over and touching the points of the saw teeth.

HAZARD KNOWLES.

No. 7604.—*Self-acting adjustable Feed-gear for Drilling Machines.*

What we claim as our invention, and desire to secure by letters patent, is the combination, substantially as described, of the splined screw *x*, the splined shaft *b*, the smooth wheel *r*, the toothed wheel *y*, carrying a nut, the arm *l*, the catch *n*, the small arm *o*, the spring *p*, and the segment *q*, so as to form a self-acting adjustable feed for boring or drilling machines.

ALDEN R. MORRILL.
HIRAM BALDWIN.

No. 7605.—*Method of Attaching Yards to Trusses.*

I claim suspending the yard to the truss, by means of linked and swivelled eye bolts, whereby the yard may either be allowed to hang freely below the eye which is swivelled, to the truss, or may be slung upward and inward toward the mast, so as to bring its centre above the bowed end of the truss, in the manner and for the purposes herein set forth.

TILGATH ODEON.

No. 7606.—*Improvement in Electric Telegraph Manipulators.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The two guides E, *h*, with their hook and detent spring, as described, in combination with the moveable connecting points, and D, D, the type forms for letters, substantially in the manner and for the purpose set forth, the guides being disconnected as soon as the moveable connecting point has passed them, thereby causing the finger key rods to resume their proper position to be again acted upon, and allowing the succeeding points to pass in their regular revolving course, without coming in contact with the type forms.

Secondly. I also claim the manner of disconnecting the two guides, viz: by the action of the moveable connecting point upon the detent spring, as above set forth.

Thirdly. I claim the employment of a clicking apparatus, to indicate the proper time of depressing the keys: the whole being constructed and arranged in the manner and for the purpose, substantially as herein set forth.

AUSTIN F. PARK.

No. 7607.—*Improved arrangement of Dampers in Cooking Stoves.*

What I claim therein as new, and which I desire to secure by letters patent, is the vertical dampers (*h*,) placed below the top of the oven in the division partitions (*g*,) substantially as herein before described.

HENRY L. SHEPERD.

No. 7608.—*Improvement in Blowers of Franklin Stoves.*

What I claim as new therein, and which I desire to secure by letters patent, is first, the inner doors or blowers (*f*,) made to slide in grooves within the front plates of the stove, serving when closed as a blower, and when not in use, being withdrawn out of the way and out of sight, substantially in the manner and for the purposes as above described.

DAVID STUART.

No. 7609.—*Improvements in Sub-marine Vessels.*

What I claim therein as my invention, and desire to secure by letters patent, is the method of effecting a circulation of the air, and of maintaining an atmosphere in the cabin of the requisite bulk, to prevent the encroachment of water during the descent of the vessel, and of preventing the waste of air by its expansion, and escape from the cabin during the ascent of the vessel, by pumping it either out of, or into the cabin, or air reservoir, as may be required, even when the density of the atmosphere in the compartment whence the air is drawn, is less than that of the atmosphere in the compartment into which it is forced, as herein set forth.

I also claim the device, consisting, substantially of the drop platforms, chains, and draw pin, for the purpose of carrying ballast on the exterior of a submarine vessel, and of discharging it at will, as herein set forth.

LAMBERT ALEXANDRE.

No. 7610.—*Improved method of Attaching lines to Harpoons.*

What I claim as new in my invention, and desire to secure by letters patent is the manner of attaching and securing the line to the harpoon, by means of the ring *H*, sliding on the shank, and the rounded end *d*, of the socket, or butt *C*, in the manner, substantially as herein described.

C. F. BROWN.

No. 7611.—*Improvement in Machines for dressing Staves.*

What I claim as my invention, and desire to secure by letters patent, in the before described machine, for shaving staves from rived bolts, is the employment of two concave knives for shaving the outer or convex surface of the staves, substantially as herein described, in combination with a single knife for shaving the inner or concave surface of the staves, when the said single knife is placed in a line midway between the other two, that is, opposite the space between the other two, substantially in the manner and for the purpose specified.

LEWIS S. CHICHESTER.

No. 7612.—*Improvement in Pressing Cotton and other Substances into Bales.*

What I claim as my invention, and desire to secure by letters patent, is the method of packing and compressing substances into bales or packages, in a series of successive layers or strata, by means of rolling pressure or its equivalent, substantially as herein specified.

I also claim, combining with the laying and compressing rollers or cylinders, or their equivalents, a bed which shall be gradually separated from the rollers or cylinders, as the layers or strata accumulate, and which shall also traverse from end to end, under the rollers, or cylinders, or vice versa, substantially as specified.

I also claim, in combination with the cylinders for packing and pressing substances in successive layers, a lapping apparatus for forming such substance or substances into a lap or laps, to be delivered to the rollers or cylinders, or their equivalents, to be laid and pressed into the bed, substantially as described.

I also claim, in combination with the laying and compressing cylinders, or their equivalents, the series of rollers or their equivalents, for retaining the layers or strata, as they are successively compressed, substantially as specified.

I also claim the bed, made without sides or ends, substantially as, and for the purpose specified, in combination with the carriage, provided with adjusting plates at the ends, for the purpose and in the manner, substantially as described.

And finally. I claim in combination with the adjusting plates at the ends of the carriage, the stationary plates at the ends of the frame, under which the adjusting plates pass, to remove any substance that may have accumulated on them, substantially as described.

S. A. CLEMENS.

No. 7613.—*Improvements in Repeating Fire-arms.*

What I claim as my invention, and desire to secure by letters patent, is making the central bore of the many chambered rotating breech, which fits and turns on a central pin or arbor, to extend from the rear part thereof, to within some distance from the front end, and thus leave the front end closed, substantially as described, to prevent the access of smoke, when this is combined with the connecting of the barrel with the shield piece and lock plate, substantially as described.

SAM'L COLT.

No. 7614.—*Improvement in Hand Spinners.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the clamp lever V, with the cords and drum, for the purpose and substantially as described.

DAVID CURRENT.

No. 7615.—*Machine for Beveling the Surfaces of Washers, &c.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of drawing out, and giving a bevel

form to metal clinch rings, washers, &c. by the action thereon of the surfaces of a series of travelling rollers turning on bearings, arranged about a common centre of rotation, and combined with a spindle or mandrel, adapted to the reception of the clinch rings or washers, to be formed and provided with the means, as substantially herein described, for turning it to present in succession, every part of the periphery to the action of the rollers, substantially as described.

I also claim, in combination with the spindle or mandrel, for presenting the clinch rings or washers, to the action of the travelling rollers, a gripe, substantially as described, for griping and holding the said rings or washers on to the spindle or mandrel, whilst passing under the action of the travelling rollers as described.

WILLIAM FIELD.

No. 7616.—*Improvement in Draining Sugars.*

I claim of my invention, the mode of applying steam or liquids, to machines used for separating syrups or fluids from sugar, by means of centrifugal force, for the purpose of clearing and keeping clear, the meshes or apertures in the periphery of the revolving cylinders of such machines, in manner herein described.

CONRAD WM. FINZEL.

No. 7617.—*Improvement in Clamps for Holding Paper in Writing and Drawing.*

What I claim as my invention, and desire to secure by letters patent, is the clamping slides A, made to slide freely on the parallel rods B, operated by the lever C, and the springs D, substantially in the manner, and for the purpose as herein set forth.

ELIAKIM B. FORBUSH.

No. 7618.—*Improvement in Fastenings of Hay Rakes.*

What I claim, and desire to secure by letters patent, is:

First. The manner of holding the teeth *d*, firmly in their required positions against the sliding bar *i*, during the operation of the machine, by means of the aforesaid combination of the ratchet wheel *f*, pawl (*g*,) sliding bar (*i*,) and stem (*e*,) helical spring *n*, fixed bar *m*, and slide *k*, attached thereto, with the parallel guiding arms *c*, and revolving finger shaft *a*, arranged and operating in the manner and for the purpose above set forth.

Second. I likewise claim, the combination of the slide *k*, helical spring *q*, strap (*o*,) and roller *p*, with the parallel arms *c*, and fixed bar *m*, for disengaging the sliding stop bar *i*, from the rake teeth *d*, without moving the hand from its usual position on the hand roller *h*, to allow the teeth to revolve to deposite the hay in windrows, as herein fully set forth.

ORANGE W. HOGLE.

No. 7619.—*Improvement in Stoves.*

What we claim as our invention, and desire to secure by letters patent, is the jambs of stove or grate fronts or ends, constructed with recesses closed by doors, within which, the doors of the fire-place are folded up and concealed from view; the fire-place doors being constructed and arranged to turn back into the recesses, substantially as herein described.

SHERMAN S. JEWETT.
FRANCIS H. ROOT.

No. 7620.—*Improvement in Car Couplings.*

What I claim therein as my invention, and desire to secure by letters patent, is the bearing roller (or rollers) *m*, placed within the body of the coupling, and the bearing roller *n*, located in one end of the connecting link *c*, for the purpose of enabling the connecting bolt A, to be easily detached from the link C, when the cars are in motion; when this arrangement of the said rollers and connecting bolt, is combined with the loop *h*, the catch head *f*, and cord, for uncoupling, in such a manner, that the loop will be disengaged when force is applied to withdraw the bolt; but will prevent the connecting bolt from being accidently thrown out of place, when the cars are in motion.

DAVID S. NEAL.

No. 7621.—*Improvement in Planing Machines.*

First. I claim the use and employment of the cutter I, made and fashioned in form and manner, or any analogous form and manner, whereby the peculiar cutting, bevelled scalloped edge is attained, for planing or dressing plank or other material, substantially as herein set forth.

Second. I also claim the use and employment of the cutter I, in combination with the compressing spring J, feed rollers and straight edge, or any one or more of them, in form and manner for the purposes, substantially as herein set forth.

J. F. OSTRANDER.

No. 7622.—*Improvements in Sewing Machines.*

What I claim, is the hook *z*, the surface *a*, the tube or holder *s*, and thread carrier *e*, working, substantially as above described.

BARTHELEMY THIMONNIER, Sr.

No. 7623.—*Improvements in the Direct Action Steam Hammer.*

What I claim as my invention, and desire to secure by letters patent, is attaching the hammer to the sliding steam cylinder, substantially as herein described, the steam being admitted and discharged to and from the sliding steam cylinder, substantially as herein described.

J. H. TOWNE

No. 7624.—*Improvements in Manufacture of Lead Pipe.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of setting or cooling the inside of the mass of metal within and throughout the length of the cylinder, and before or preparatory to pressing out the pipe, by passing a cooling fluid into or through a long core or core holder, extending through the length of the cylinder, as herein described, the said method having the effect at the same time to keep the said core or core holder cool and stiff, as described.

WM. P. TATHAM.

No. 7625.—*Improvement in Apparatus for Breaking Horses.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of breaking horses by means of the shafts, which are connected together by a bow passing around in front of the horses' breast, substantially as herein described, in combination with the two straps, one passing over the crest and the other under the breast, by which the horse is harnessed to the said shafts, substantially as described.

SEYMOUR TOMLINSON.

No. 7626.—*Improvement in Surgeons' Splints.*

What I claim as my invention, and desire to secure by letters patent, is my improved surgeons' splints, composed of thin strata of wood, combined with some elastic adhesive substance interposed between them, substantially as herein set forth.

BENJAMIN WELCH.

No. 7627.—*Improvement in Ladies' Stays.*

What I claim as my invention, and desire to secure by letters patent, is the peculiar arrangement (in the body of the stay) of the whale bones *a*, *a*, *a*, *a*, *b*, *b*, in combination with the gores *g*, *g*, and *f*, *f*, of the particular form, and in the particular position represented, whereby the usual irritating effects of ladies' garments upon the muscles, &c. about the loins are avoided, at the same time that effectual support is given to the whole waist, by means of the peculiar position and shape of the gores, and thence the easy curves given to the whale bones, as set forth.

LOUISA BALIS.

No. 7628.—*Improved mode of representing Musical Scales.*

I claim the manner herein described, of representing each and all of the scales used in music, by the combination of the board B, the side bars *c*, *c*, the centre piece D, and the bars *d*, *d*, *d*, and *d'*, *d'*, *d'*, having letters attached to them to indicate the name of the notes or sounds they represent, or any other combination of parts, substantially the same.

W. B. BILLINGS.

No. 7629.—*Improvement in Revolving Chambered Fire Arms.*

What I claim as my invention, and desire to secure by letters patent, is an improvement for fire arms, having a rotating breech with a series of parallel chambers, in combination with the locking holes of rotating chambered breech fire arms, substantially such as herein specified, making grooves leading to each locking hole, substantially in the manner and for the purpose specified, when this is combined with a bolt, independent of the mechanism which rotates the breech, and which bolt enters the lock by a spring, and is withdrawn by its connection with the lock, substantially as described.

And I also claim holding the rotating breech midway, or nearly so, between any two of the chambers, to prevent accidental discharges, by means of a recess or hole in the hammer or cock, fitting on to a projection of the rotating oreech between any two of the chambers, or vice versa, substantially as herein specified.

SAM'L COLT.

No. 7630.—*Improvement in Paint Mills.*

What I claim as my invention, and desire to secure by letters patent, is the broad depressions *b*, *b*, in the face of the muller *a*, when combined with the discharging grooves *c*, *c*, in the same, and with the plane surface of the bed *a'*, substantially in the manner and for the purpose as herein set forth.

W. W. DRAPER.

No. 7631.—*Improvement in picking Cotton from the Bolls in the Field.*

What we claim as our invention, and desire to secure by letters patent, is

First. The combination of the whipping cylinder M, with the picking disks A, A, and the strippers B, B, and also the combination of the whipping cylinder M, with the picking cylinders C, C, and the strippers D, D, substantially in the manner and for the purpose as herein set forth.

Second. We claim the combination of the picking disks A, A, and the strippers B, B, with the gathering planes L, L, and the cotton receptacle J, substantially in the manner and for the purpose as herein set forth.

Third. We claim the combination of the picking cylinders C, C, and the strippers D, D, with the gathering planes L, L, and the cotton receptacles K, K, substantially in the manner and for the purpose herein set forth.

SAM'L S. REMBERT.
JEDEDIAH PRESCOTT.

No. 7632.—*Improvement in Smiths' Strikers.*

What I claim as my invention, and desire to secure by letters patent, is attaching the raising and rebound springs, and the hammer, to the same adjustable frame, substantially as herein described, when this is combined with the adjustable attachment, between the hammer and the treadle, whereby the hammer can readily be adjusted to strike a flat blow on iron of different thicknesses.

MELCHI SCOTT.

No. 7633.—*Improvement in Camp Bedsteads.*

What we claim as new and of our own invention, and desire to secure by letters patent, is—First. So arranging the parts of a camp chest, that when it is unfolded in a direction parallel with its length, it will constitute a bedstead, which may be of the width of the inside of the chest, and when unfolded in a direction at right angles with its length, it will constitute a bedstead, which may be of the width of the inside of the length of the chest.

And Second. The arrangement by which a part of the front of the chest (B,) fig. 2, can be used as a table leaf, and the slides C, as seats at the table, substantially in the manner and for the purpose set forth.

WM. C. SHAW.
JAS. STALCUP.

No. 7634.—*Improved Exhaust Passages for Steam Cylinders.*

What I claim herein as new, and for which I desire to secure letters patent, is the two-fold outlet or steam passage from the cylinder into the exhaust valve chamber, which admits the steam above and below, and discharges it between the disks of the exhaust balance valve, and thus facilitates the insertion, withdrawal and adaptation to the exhaust side in the line of its stem or spindle of a balance valve, whose disks are cast in one piece, and are held down to their seats by the stress of steam.

GEORGE SHIELD.

No. 7635.—*Improvement in Mortising Machines.*

What I claim as new in the herein described mortising machine, and desire to secure by letters patent, is in combination with a device for giving the chisel a reciprocating motion, the device for giving it at the same time an oscillating motion, substantially as herein set forth.

SMITH SPENCER.

No. 7636.—*Improvement in Machines for Scribing Lumber.*

I claim the manner of operating the horizontal sliding carriage E, E, carrying the cutter blocks F, F, and cutters or scribers f, f, and the vertical sliding carriage I, I, carrying the cutter blocks F2, F2, and cutters or scribers $f2, f2$, in such a manner that they perform the duties in concert, without

interfering with each other, by means of the levers G, G, the rods h, h, the levers a, a, the straps e, e, the levers $i\,j, i\,j$, and weights k, k, in combination with the pulleys C, C, the straps J, J, the rods l, l, the levers K, K2, and the weights L, L1, the levers G, G, and the pulleys C, C, being hung upon the same shaft B, and operated by the same treadle D, substantially in the manner and for the purposes herein described.

JOHN SHELLENBERGER.

No. 7637.—*Improvement in Clover Hullers.*

What I claim as new and of my own invention, is the continuous wave form of the rubbers of the concave: and I further claim the continuous wave form of the rubbers, if it should be applied to the cylinder, instead of the concave.

ROBERT STADDEN.

No. 7638.—*Improvement in Plough Clevises.*

What I claim as new, and desire to secure by letters patent, is forming a plough clevis by means of two arcs of metal, of corresponding outward curvatures, having the point of attachment of the draught link to the martingale, for their common centre of curvature, in the manner and for the purposes herein set forth.

Second. I also claim, in combination with a fixed horizontal arc, having a slot between bearing edges, the vertical arc having notches on its inner curve, adapted to the bearing edges of the fixed arc, whereby the direction of draught may be varied horizontally or vertically, as required.

JOHN B. STONER.

No. 7639.—*Improvement in Friction Rollers.*

What I claim therein as my invention, and desire to secure by letters patent, is the friction rollers, each composed of a series of separate sections, held together by nuts, or otherwise, on a common spindle, in such manner that the spindle and roller sections usually turn together, but when any obstruction intervenes to stop the movement of any one section, and thus cause it to grind and flatten the adjacent sections with the spindle, continue to roll on, and by rubbing against the obstructed one, tend to move it past the obstruction, thereby preventing continued excessive wear on any one portion of its periphery: hence the irregular wear of any one of the sections will not affect the general roundness of the whole to such a degree as will materially impair the efficiency of this device as an anti-friction roller.

JOSEPH M. TOTTEN.

No. 7640.—*Improvement in Plough Cleaners.*

What I claim as my invention, and desire to have secured to me by letters patent, is the combination of the vibrating finger clearer, with the beam and sheath of the plough, said finger clearer being arranged in such a manner in relation to the sheath or throat of the plough, that by the use of the hand of the ploughman, to elevate and depress a lever, a series of curved or straight fingers will be made to vibrate back and forth, adjacent to the sheath, and clear away straw, stubble, and other obstructions therefrom, as described and set forth.

DAVID WARREN.

No. 7641.—*Improvement in Tailors' Measures.*

What I claim as my invention, and desire to secure by letters patent, is the use of the slides for laying off the division of the several measures for a coat, in combination with the fashion slides, for the purpose and in the manner herein set forth.

WILLIAM W. ALLEN.

No. 7642.—*Improvement in the Seeding Roller of a Seed Planter.*

What I claim as my invention, and desire to secure by letters patent, is the constructing a seeding wheel for a planting machine, by the combination of two parts *a* and *d*, of the form herein described, in such a manner that by turning one of the said parts within or upon the other, in one direction, the planting receptacles will be reduced in depth and size, and by turning the said part of the seeding wheel in an opposite direction, the planting receptacles will be enlarged in depth and size, substantially as herein set forth.

AARON PALMER.

No. 7643.—*Improvement in the Process of Working Gutta Percha.*

What we claim as our invention, and desire to secure by letters patent, under the first part of our invention, consists in the use of lime or other alkaline substance, with heat in the manner substantially as herein described, in the cleaning of gutta percha, to neutralize the acid or acids contained in that substance in its crude or native state, and thus preserve and render more permanent its useful properties, as specified.

And in the second part of our invention, we claim compounding lime with gutta percha, substantially as herein described, for the purpose of improving its qualities, preserving it wholly or partly from deterioration, and protecting it against the injurious effects of the atmosphere and heat, substantially as described.

S. T. ARMSTRONG.
CHAS. J. GILBERT.

No. 7404.—*Improvement in the Process of Preparing Cream.*

What I claim as my invention, and desire to secure by letters patent, is the process described herein of distilling milk, and condensing the same in sugar for the purpose of preserving the flavor, as set forth.

CHARLES DENNISON BIRDSEYE.

No. 7645.—*Improvement in Spike Machines.*

I claim the heading and carrying nippers *l*, *m*, in combination with the shears, the headed and the griping mechanism, the same being made to operate in connection therewith, substantially as above specified.

And in combination with the lower nipper, I claim the spring catches, latching and unlatching apparatus, applied to it for the purpose above specified.

WM. BLAKE.

No. 7646.—*Improvement in Machinery for Ginning or Picking Cotton.*

What I claim, is the combination of such parts as I have shown, forming a picking machine, and their mode of action, as hereinbefore described.

FRS. A. CALVERT.

No. 7647.—*Improvement in Processes for Preparing Wheat for Grinding.*

I claim the application of an acidulous composition to wheat or other grain, the said composition being principally vinegar; but I do not limit my claim to the exact composition of acids as herein described, while the same effects can be produced by the vinegar alone, or when combined with one or more of the other acids, especially with the sulphuric acid, for the purposes set forth.

JOSEPH W. CARPENTER.

No. 7648.—*Improvement in Paper Filers.*

What I claim therein as new, and desire to secure by letters patent, of the United States, are:—First. The arrangement and construction after the manner, substantially as described, of a box or receptacle for documents and papers, having a lid fitting loosely within it, which is made to press down upon the papers by a spiral or other suitable spring.

Second. The rod (*c*,) or its equivalent attached to the lid, and moving in the guide slits or apertures (*d*,) in the sides of the box, the said slits terminating in a notch or shoulder (*g*,) at their upper extremities, for the reception and retention of the rod during the manipulation and examination of the file.

W. A. COLLORD.

No. 7649.—*Improvement in Grain Harvesters.*

What I claim as my invention, and desire to secure by letters patent, is the application to a reaping and mowing machine, of two sickles working together in opposite directions, as set forth in the above specification and accompanying drawings, so as to throw the weight of the moving parts upon opposite sides of the centre of the crank or bit, for the purposes set forth.

EBENEZER DANFORD.

No. 7650.—*Improvement in India Rubber Hose.*

What we claim as our invention, and desire to secure by letters patent, is the making of flexible hose or pipe, by combining India rubber leather with a tube of rubber, substantially as herein described, the whole being united, forming one solid tube, making a strong, durable, and flexible hose, adapted as a substitute for leather, and other similar pipes for the conveying of fluids.

HORACE H. DAY.
RICHARD McMULLEN.

No. 7651.—*Improvement in the Plough Clevis.*

What I claim as new, and desire to secure by letters patent, is so making a clevis with teeth or prominences, and cavities on the front surface of a socket, matching with corresponding depressions or cavities, and elevations on the surface of a moveable bar, that the bar and socket when set together by a screw or other equivalent fastening in the required position, may have numerous bearings, and be wholly prevented from either sliding or revolving in any direction, without breaking the continuity of materials of which the parts are composed.

I also claim, in combination with a series of radial ridges, or a circle of cavities on the end of a clevis socket fixed at the extremity of the plough beam, a series of teeth, or of conical points on a moveable clevis bar, so adjusted to each other, that the guide hole of the clevis bar, may be held in any required position, and at any necessary distance from the axis of the beam, without relying on friction of the surfaces to prevent slipping, in the manner and for the purpose herein set forth.

GERRETT ERKSON.

No. 7652.—*Improvement in Printing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the mode of representing letters, and the sounds of letters, by means of characters made by changes wrought upon a less number of moveable type, than the number of letters or sounds of letters represented. The type being made upon, or attached to the bottom of wires or rods, which are worked by keys at or near the top, substantially as herein set forth.

JOHN B. FAIRBANK.

No. 7653.—*Improvement in Corn Shellers.*

What I claim as my invention, and desire to secure by letters patent, is the device herein described, for twisting and forcing the ears of corn, between spring shelling plates, substantially as herein set forth.

SAM'L L. GRAVES.

No. 7654.—*Improved Tool for Forming Plaster Cornices and Mouldings.*

What I claim as my invention, and desire to secure by letters patent, is arranging a former, for making mouldings upon the walls and ceilings of a room, upon the diagonal of a square frame, and making an angle of forty-five degrees with each side of said square, for the purpose and in the manner described.

SYLVESTER GROESBEECK.

No. 7655.—*Improvement in Daguerreotype Plate Holder.*

What I claim as my invention, and desire to secure by letters patent, is the daguerreotype plate holder, constructed substantially as herein described, of a block with a spring edge, by which the plate is secured to it.

GEORGE MALLORY.

No. 7656.—*Improvement in Spring Beams to Ploughs.*

What I claim as my invention, and desire to secure by letters patent, is the adjustable spring bar, interposed between the point of draft and the frame of the plough, in the manner and for the purpose herein set forth.

WILLIAM MORRISON

No. 7657.—*Improved Roadway for Rail Cars and ordinary Vehicles.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of making rails for the roadways of streets, &c., by combining with the rails on which flanched car wheels run, outer faces of sufficient breadth for the wheels of common carriages to run, made curved or inclined from the top of the rail, substantially as described.

And in combination therewith, I also claim, making wide faces on the inside of the rails, substantially as described, for the wheels of common carriages to run on, as described.

JORDON L. MOTT.

No. 7658.—*Improvement in Cast Iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is a cast iron wheel in one piece, having the rim connected to the hub by two plates joined together at intervals, at points as small as may be, and nearly equidistant from the rim and hub, said plates being of such form, that each section by the plane of the axes, passing through the points of union,

shall present two pointed arches, uniting at the apex, the one springing from the ends of the solid hub, and the other from the edges of the rim; and a similar section between the points of union, shall bestow flat curved lines bending towards each other, and joining the ends of the solid hub with the edges of the rim; and a circular section passing through the points of union of the two plates, shall produce a double series of flat arches united to each other at their ends. The whole being constructed, substantially in the manner and for the objects herein set forth.

BENJAMIN SEVERSON.

No. 7659.—*Improvement in Sewing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the machinery herein described, for making the stitch, viz: the combinations of the hook *v*, the plyer *w*, and needle *l*, as constructed and made to operate together, substantially as described.

JOHN BATCHELDER.

No. 7660.—*Improvement in Looms for Weaving Tapestry and Brussels Carpets.*

What I claim therefore, as my invention, and desire to secure by letters patent, is closing and opening the supports or guides, as they are raised, and depressed, to receive and support or guide the wires, and to liberate them in manner, substantially as herein described.

And I also claim, the employment of a stop motion in looms, for weaving looped or piled fabrics, in which the pile is formed on wires, for the purpose of stopping the loom whenever a wire fails to be introduced, substantially in the manner described.

E. B. BIGELOW.

No. 7661.—*Improvement in Processes for Refining Gold.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The process of dissolving alloyed gold, for refining it by developing nitric acid, or both nitric and muriatic acids gradually, from their salts, in the manner and for the purpose set forth in the specification.

Second. I claim the process of precipitating gold from its solution, and removing therefrom the insoluble chlorides, as set forth.

Third. I claim the process of refining alloyed gold, without the use of silver, so as to form a solution of gold and other metals, and a residue of chloride of silver and of other insoluble chlorides, and then precipitating metallic gold upon those insoluble chlorides in the same vessel without transfer, after the solution is effected; and afterwards dissolving out the insoluble chlorides from the gold, or reducing the insoluble chlorides to the metallic state in the wet way, and dissolving out the metals from the gold, all in the manner hereinbefore described. But I do not claim dispensing with the use of silver, except as a part of the main process herein described.

Fourth. I claim the process as described, of dissolving alloyed gold in wooden vessels, which may be made of any dimensions, corresponding to the extent of the operation.

Fifth. I claim the process as described, of dissolving alloyed gold, by blowing steam directly into the solvent liquids, all in the manner as herein before described.

JAS. C. BOOTH.

No. 7662.—*Improvement in Grain cleaning Machines.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the revolving slotted hollow barrel (B,) with the toothed wheels (F, F',) the same being arranged and operated, substantially in the manner and for the purpose herein set forth.

GEO. W. BOWERS.

No. 7663.—*Improvement in Machines for Fumigating Plants.*

I claim the combination in apparatus or instruments, for fumigating purposes, of a destroying magazine containing the fumigating or obnoxious substance, with a cylinder and exhausting fan or wheel, whereby the smoke is drawn in at one part of the cylinder, and driven out at another, and whereby, also the atmospheric air, necessary for the combustion of the substance, is drawn into it by the said fan or wheel, both as before described.

D. S. BROWN.

No. 7664.—*Improvement in Machines for making Ropes.*

What therefore I claim as my improvement, is to support the frame E, of the gears and strand spindles, on the main laying shaft alone, and combining with the said frame E, and the main frame of the machine, the lever U, or suitable machinery, whereby the said frame E, of the gears and strand spindles may be either clamped to the main frame, or so fastened, as to be prevented from revolving, while the main laying shaft and strand spindles are in revolution on their respective axes, or be unclamped, or unfastened therefrom, as occasion may require, and for the purpose of enabling the strands to be laid or twisted together, without previous removal from their spindles, as heretofore practised, and above described.

HENRY EVANS.

No. 7665.—*Improvement in Stop motion of Looms.*

What I claim as new, and desire to secure by letters patent, is the manner herein described, of securing the moveable reed bar and reed, while the filling is being put in, and releasing them after the filling is completed, by the combination of the levers G, G, having arms *d*, *f*, and snecks *e*, *e*, and the springs *h*, *h*, and H, the whole being arranged and operated in the manner, substantially as herein set forth.

ELIJAH HALL.

No. 7666.—*Improvement in the construction of Thrashing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the thrashing cylinders, constructed of fast and loose sections, the fast sections of one cylinder being opposite the loose sections of another, substantially as herein set forth.

D. W. HARRIS.

No. 7667.—*Improvement in Burning Fluids.*

What I claim as my invention, and desire to secure by letters patent, is the compounding rosin and the essential oil of vegetables or grain, (when the same is produced by distillation of whiskey or alcoholic liquors, and thereby become a refuse article,) for the purpose of making a material from which to make gas; also for a burning fluid, as set forth herein, whether compounded in the precise proportionate quantities set forth or other quantities, which will produce, substantially the same result, all of which is fully set forth herein.

EPHRAIM HOWE.

No. 7668.—*Improvement in Machinery for drawing Hemp and parting its Fibres.*

What I claim as my invention, and desire to secure by letters patent, is the employment of two sets of holding and drawing rollers, substantially as herein specified, in combination with a rotating cam, (or cams,) or the equivalent thereof, for each sliver, in the manner and for the purpose, substantially as described.

O. S. LEAVITT.

No. 7669.—*Improvement in Casting Stereotype Plates.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the dipper, constructed substantially as described, in the vertical casting of stereotype plates, in the manner herein set forth.

JASON M. MAHAN.

No. 7670.—*Process of reducing Gold Bullion.*

What I particularly claim as my invention and discovery, and desire to secure by letters patent, as a new and useful improvement in the art of refining gold bullion, is—

First. The reduction of argentiferous and other gold bullion, as a preparatory process in the art of refining thereof, into a pulverulent or spongy state, or a disintegrated molecular condition, by the means particularly of fusion therewith, and the subsequent removal by acids therefrom, of zinc or other metal, baser than silver, which will produce the desired effect, for the purpose of then separating by acids from such gold bullion, the silver and other impurities which it may contain, without quartation with silver, or any intermediate process, in order to fit the gold for coinage and other uses.

Secondly. I also claim, in addition to the above processes, the pulverizing by grinding, crushing, or percussion, of gold bullion, rendered brittle by union with lead, solder, or other like base metal, for the purpose set forth in the specification.

RICHARD S. McCULLOH.

No. 7671.—*Improvement in removing Electricity from Wool in the process of Manufacture.*

I claim as my improvement, in the manufacture of wool, the removal of electricity from its fibres, substantially in the manner and for the purpose herein set forth, but irrespective of the form, arrangement, or construction of the apparatus by which such removal of electricity is effected.

JOSEPH METCALF.

No. 7672.—*Improvement in Heating Elevated Ovens.*

What I claim as new, and desire to secure by letters patent, is the arrangement and combination of revertible flues in elevated ovens of cook stoves, in the manner and for the purpose herein described and represented.

P. A. PALMER.

No. 7673.—*Improvements in Machinery for Fulling Cloth.*

What we claim as our invention, and desire to have secured to the said Charles A. Read by letters patent, is the above described mode of fulling fabrics by means of toothed cylinders, by power machinery, the fabric being fed between the fulling toothed cylinders by means of feeding rollers, through guides with sufficient rapidity to prevent all strain upon the fabric, and at the same time to supply the fulling cylinders which receive the fabric, full it, and then pass it out between two cleaning rollers, which receive it from the fulling cylinders, prepared for other processes. The movements of the several parts of the machine being produced by a combination and adjustment of mechanism, similar to that herein described and represented, or any other which may be substantially the same, and by which analogous results may be produced.

CHARLES A. READ.
THOMAS COTTER.

No. 7674.—*Improvement in Water Wheels.*

What I claim therefore as my invention, and desire to secure by letters patent, is making the discharge aperture of the shutes moveable, relatively to the axis of the wheel, or the axis of the wheel moveable, relatively to the aperture of the shute, substantially as described, for the purpose of varying the effective diameter of the wheel, and thereby increasing or decreasing the velocity thereof, substantially as described.

TIMOTHY ROSE.

No. 7675.—*Improved Machine for Forming and Charging Percussion Caps.*

What I claim as new therein, and which I desire to secure by letters patent, is—

First. The combination of the several motions given to the sheet of metal, by which it is presented to the cutting punch by an intermittent motion from right to left, and vice versa, and when the edges are reached, reversing the direction, and at the same time advancing the sheet so that the blanks are punched in successive rows across the sheet, substantially as set forth.

Second. I claim the chisel (3,) moving with the punch stock (*c*,) by which the perforated sheet is cut into strips, for removing it piecemeal from the machine, substantially as described.

Third. I claim giving such a form to the slots of the carrying plate that the cups when lifted from the shaping die, are caught by them and taken on, substantially as described.

Fourth. I claim in combination with the slots of the carrying plate, the conducting groove, by which the caps are guided transversely in the slots, and made to present themselves accurately under the charger and polisher, and to drop out when completed, through the holes (16,) at the end of the slots, substantially as described.

Fifth. I claim operating the cap holder (33,) and the revolving polisher or pressing punch (31,) by a single cam in connection with the strong and weak springs (36 and 37,) substantially in the manner and for the purposes set forth.

Lastly. I claim the combination in one automatic machine of the several processes, by which the percussion caps are cut out of a sheet, shaped, charged, and the charge polished down, substantially in the manner described.

GEORGE WRIGHT.

No. 7676.—*Improvement in Wrought Iron Car Wheels.*

What I claim, is the combination of a rim E, with arms D, at the ends of the spokes C, by means of the inner flange F, and bevel E′, between the flange and opposite side of the rim.

HERRICK AIKEN.

No. 7677.—*Improvement in Cotton Stalk Harvesters.*

What I claim as my invention, and desire to secure by letters patent, is the combination of two saw-teeth wheels, with the frame, and supported thereby, and the triangular pieces of iron for disengaging the stalks, in the manner herein set forth.

STEPHEN BOWERMAN.

No. 7678.—*Improved Double Acting Rocker for washing Gold.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the moveable pan with the gold washing rocker, so arranged and operated, as to give to the pan inside of the rocker, a double rocking or vibrating motion, sidewise and endwise, substantially as described in this specification.

ARNOLD BUFFUM.
PHILIP THORP.

No. 7679.—*Improvement in Mills for Grinding.*

What I claim as my invention, and desire to secure by letters patent, is the elastic cushion, inserted in the bottom of the socket of the cock head, substantially in the manner and for the purpose herein set forth.

W. P. COLEMAN.

No. 7680.—*Improvement in Slides for Seed Planters.*

What I claim as new therein, and which I desire to secure by letters patent, is the combination of the reversing slides (*k* and *l*,) with each other, and the hopper, by which the machine can be readily adapted to different varieties of planting, in the manner and for the purposes set forth.

ROBERT J. COLVIN.

No. 7681.—*Improvement in Vegetable Cutters.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the double edged reciprocating blade, with the hopper and removable bars, for slicing vegetables, substantially as herein set forth.

REUBEN DANIELS.

No. 7682.—*Improvements in Looms.*

I claim the combination of the stationary circular plate *d*, the gears *f*, *g*, *h*, and *i*, the circular box *a*, with the tubular shaft H, and the main shaft, the same being for the purpose of effecting the rotations of the cam shaft H, without any such exposure of gears as is customary in most other looms, and which are not only often productive of accidents to attendants or workmen, but often destroy or injure the shuttles when thrown out of the lay, by the action of the pickers.

I also claim the combination of mechanism, for operating the harnesses, when they are constructed substantially as specified, the said combination consisting of the supporting or radial bars *r*, *s*, *y*, *z*, of the harness frames M, N, the rocker shaft *q*, and tubular shaft *t*, the arm *v*, and its pin or stud, which enters the groove of the cam *w*, and the endless chain a^s, and fixed pulleys *a′*, *b′*, the whole being applied together and made to operate, essentially as above described.

I also claim the mode of constructing each of the harness frames, viz: of a combination of a bar and thread carriers as applied together, and made to operate, in the manner as above described.

244 Ex. Doc. No. 32.

I also claim the combination of an endless belt c', or d', and its projection or picker f'', with each shuttle box and its picker staff, so as to constitute the floor or bottom of the shuttle box, and operate, and be operated in manner as described. This mode of constructing the shuttle box, in consequence of the belt moving with the shuttle, reduces the friction of the shuttle in its passage out of the box.

I also claim the combination of mechanism, for operating each picker staff, the same consisting of the cord and pulley attached to it, and the main frame, the spring of the foot of the picker staff, the spring latch on the lay, and the discharging cam or plane affixed to one of the harness frames, the whole being as above described.

I also claim the above described mode of making the race beam, viz: with elevations of plates x', x', x', to extend above it, and between and above the lower warp threads, and so as to constitute a support for the shuttle, in its passage over the race beam, the same enabling me to protect the yarns from injury from the shuttle, and to run the loom at a greater velocity than it would be safe to operate it with a race beam, constructed in the ordinary manner.

HALVOR HALVORSON.

No. 7683.—*Improvement in Rice Harvesters.*

What I claim as my invention, and for which I desire to secure letters patent, is the application of the vertical blade F, and wing attached to either, or both sides of a beam A, and their combination with each other, and the other parts of this machine running by hand or horse power. J. J. HERNDON.

No. 7684.—*Improvement in Saw Gates.*

What I claim as my invention, and desire to secure by letters patent, is raising and lowering the saw, for the purpose of using the whole cutting part of the same. OLIVER B. JUDD.

No. 7685.—*Improvement in Dash Boards for Carriages.*

I claim the arrangement of the winch shaped hand and foot lever (h, h,) in combination with, and the attaching the same to a jointed moving dash frame n, n, n, n, together also with the attaching of said jointed moving dash frame to the running gear part of the vehicle, instead of to the body part of the vehicle, as is usual. LEWIS LUPTON.

No. 7686.—*Use of Rosin Oil in Printers' Ink.*

What I claim as my invention, and desire to secure by letters patent, is the employment of rosin oil in the manufacture of printing ink, substantially as herein set forth. MOSES M. MATHEWS.

No. 7687.—*Improvements in Weavers' Shuttles.*

What we claim, and wish to secure by letters patent, is—

First. The combination and arrangement of friction levers in weavers' shuttles, in such a manner that the lever shall be allowed to vibrate towards, and from the bobbin, for the purpose of producing a more even tension, substantially as herein described.

Second. The combination and arrangement of a spring and cam surface, upon the friction lever, in order that as the friction lever is raised from its seat, the compression may be made more or less as desired, substantially as herein described.

JOSEPH MILNES.
WILLIAM MERKLAND.

No. 7688.—*Improved Auger Handle.*

What I claim herein as new, and of my invention, and desire to secure by letters patent, is securing augers and other tools, in their handles, by means of a tube attached to the inner half of one part, and an eccentric attached to the inner half of the other part of the handle, the eccentric part passing into the tube, and the eccentric fitting into the dovetailed grooved slot of the shank, substantially as herein described. GELSTON SANDFORD.

No. 7689.—*Improvement in Spring Callipers.*

What I claim as my improvement, and wish to secure by letters patent, is the circular spring enclosed within the hollow head, resting on the pivot on which the two parts turn, and acting on the two parts (or shanks,) throwing them outward against the nut on the cross bar.

WM. M. SMITH.

No. 7690.—*Improvement in Grain Driers.*

What I claim as new in my invention, and desire to secure by letters patent, is the revolving barrel, consisting of the wheels H, H, and the bars I, I, provided with arms h, h, carrying scrapers i, i, in combination with the troughs D, D, arranged one above another, in the manner substantially as herein set forth, for the purpose of drying meal, grain, &c.

CHAS. S. SNEAD.

No. 7691.—*Improvement in Construction of Endless Aprons in Thrashing Machines and Grain Cleaners.*

What I claim as my invention, and desire to secure by letters patent, is the method of constructing the closed metallic apron C, for separating grain, in the manner described. ASHLEY TOWNSEND.

No. 7692.—*Improved Door Spring.*

What I claim as my invention, and desire to secure by letters patent, is the door spring, consisting essentially of a spring, jointed lever, strap, and curved track, the latter being of the form herein described, to control the action of the spring, and the several parts, together with the door and the door frame, being arranged with respect to each other, substantially as herein described. AMOS WESCOTT.

No. 7693.—*Improvement in Straw Cutters.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the moving cleansing bar (j,) with the stationary blade (C,) substantially in the manner and for the purposes herein set forth.

I also claim the treadles (E, E,) constructed and arranged substantially as herein set forth, in combination with the cutter gate.

ISAAC WOODWARD.

No. 7694.—*Improvements in Shanks of Hay Forks.*

What I claim as my invention, and desire to secure by letters patent, is the constructing the hay, straw and manure forks with two or more tines, in a separate manner, and confined in a socket, as set forth in the above specification and drawings, or otherwise, substantially the same, in a way and manner so that either of the tines can be taken out of the socket, and another put in its place, if necessary.

DAVID ANTHONY, Sen.

No. 7695.—*Compound for Imparting a Gloss to Clothes.*

What I claim as my invention, and desire to secure by letters patent, is the within described compound of stearic acid, white wax, spermaceti, and quick lime, prepared as fully set forth.

WM. D. BEAUMONT.

No. 7696.—*Improvement in Presses for Copying Letters.*

What I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged and combined the two plates, or platens A and B, with the two levers E, E, and with the steel spring C, C, as set forth, the two plates being made to approach each other by the drawing apart of the levers E, E; the two bolts D, D, that are operated on by said levers, passing through the outer ends of the spring C, which is curved, and operates on the curved bottom of the plate B″, in the manner and for the purpose set forth.

GEO. BURNHAM.

No. 7697.—*Improvement in Hay Forks.*

What I claim as new in my invention, and desire to secure by letters patent, is the manner, substantially as herein described, of forming the tines *c*, *c*, and fitting them in the stock or handle, so that they can be secured in the stock or handle, either by the wedge shank *d*, of the centre tine D, or by a detached wedge *d*, of similar form, and the pin *b*, so as to make either a two tined or a three tined fork.

ALINZOR CLARK.

No. 7698.—*Improvement in Seed Planters.*

What I claim, and desire to secure by letters patent, is—First. The sliding link (*x*,) in combination with the lever (R,) the catch (S,) for working the seeding apparatus by the draught of the team, as set forth.

Second. I claim stopping the feeding, by slackening the bands, and the simultaneous elevation of the shovels, by the draught of the team, substantially as set forth.

DAVID EBERLY.

No. 7699.—*Improved Seeding Apparatus for a Seed Planter.*

What I claim as my invention, and desire to secure by letters patent, is the ratchet shaped vertically revolving feeding wheels, arranged and operated in the manner and for the purposes herein set forth.

G. S. GARDNER.

No. 7700.—*Improvement in Mounting the Cutters of a Mowing Machine.*

What I claim therein as new, and desire to secure by letters patent, is the method of constructing a revolving grass or grain cutter, so as to adapt itself to the varying surface of the ground, by means of hanging it by a universal joint on the end of a shaft, adjustable vertically, substantially as herein described.

GEORGE HART.

No. 7701.—*Improvement in Machinery for Doubling and Twisting Yarn.*

What I claim therein as new, and desire to secure by letters patent, is the stop wires, so constructed and connected with the head of the spindle, and with the strands of the yarn, that whenever any of the latter are broken or run out, the stop wires shall move and effect the disconnection of the machinery from the moving power, thereby stopping it, substantially as herein set forth.

MOSES HEY.

No. 7702.—*Improved Kettle for Manufacturing Comfits.*

What I claim as my invention, and desire to secure by letters patent, is the improvement in manufacture of comfits, by apparatus constructed upon the principle herein set forth, and consisting essentially of a pan moved by machinery, as herein described.

WM. H. HOLT.

No. 7703.—*Improvement in Gasometers.*

I claim the introduction of the secondary shaft, connecting by means of a wheel and pinion, with the drum shaft in the interior of the metre case.

Secondly. The arrangement, substantially as shown, by which the gas is passed at once into the interior of the drum, and removing the pressure from the chamber in which is the valve float, or by whatever means this effect is produced

T. W. LANE.

No. 7704.—*Improved Eaves Trough and Gutter Machine.*

What I claim as my invention, and which I desire to secure by letters patent, is the grooved moveable rib (*d*,) locking down to the mandrel, for the purpose of holding the beaded edges of the sheets while bending and soldering, and rising, to allow of inserting and removing the work, substantially as described.

I also claim, in combination with the revolving mandrel, the piece (*c*;) suspended on the journals of the mandrel, and resting when required, on the ledge (*a*″,) substantially in the manner and for the purposes described.

JOHN LEE.

No. 7705.—*Grain and Maize Harvester.*

What I claim as my invention, and desire to secure by letters patent, is the use of the revolving shaft D, in combination with a system of fingers, teeth, or knives, arranged on the shaft, as described, and for the purpose herein set forth, not confining myself to any particular size, shape, or curvature.

EDMUND QUINCY.

No. 7706.—*Improved Vulcanized India Rubber Spring.*

What I claim as my invention, and desire to secure by letters patent, is the employment of a ring or rings, or disks, made of any of the preparations of caoutchouc, known under the various appellations of metallic or vulcanized rubber, as a substitute for metal or other kinds of springs, heretofore known and used, when such ring or rings, or disk or disks, or the equivalents thereof, are applied, in manner substantially as herein described, in combination with a series of solid disks or plates, or their equivalents, substantially as herein described, whether made of metal or other solid or non-elastic substances.

I also claim making the surfaces of all or either of the plates above and below, and interposed between the elastic rings, or their equivalents, or the surfaces of the elastic rings, or either of them convex, substantially in the manner and for the purpose specified.

F. M. RAY.

No. 7707.—*Improvement in Sofa Bedsteads.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the frames D, D, which are of the same form as the sofa ends F, F, with the said sofa ends, substantially in the manner and for the purpose as herein set forth, to wit: when the back A, is elevated to convert the sofa bed into a sofa, the frames D, D, must be swung inwards against the sofa back, to retain it in an elevated position, and to throw the said frames out of the way and out of sight; and when it is desired to change the sofa bed from a sofa to a bed, the said frames D, D, can only be swung outwards, into a line with the sofa ends F, F, so that the ledges *l*, *l*, on the inner sides of the same will unerringly catch and retain the back A, when it reaches a horizontal position, as it is thrown rearwards, in which position the sofa ends F, F, and the swinging frames D, D, will form an ornamental and uniform head and foot to the bed form of my improved sofa bed.

RUSSELL SCARRITT.

No. 7708.—*Improved Grummet Strap.*

What I claim as new in this invention, is the mode of applying the above described strap, by encircling the rope therewith, and stitching or pegging the strap to the canvass, and so applying it as to insert the grummet through the strap and canvass, and this is what I desire to secure by letters patent.

ELI F. SOUTHWARD.

No. 7709.—*Improved Spring Grapple.*

What we claim, therefore, is not a set joint, but the arrangement of the tongs shaped spring talons and set joint, constructed and acting as herein described.

ORRA WARNER.
CHARLES S. GAYLORD.

No. 7710.—*Improvement in Cast Iron Car Wheels.*

What I claim therein as my invention, and for which I desire to secure letters patent, is the combination of the arch at the centre with the curved plate, and arms or brackets, connecting the hub and rim, in the manner and purpose set forth.

NATHAN WASHBURN.

No. 7711.—*Improvement in the Adjustment of Knives in Straw Cutters.*

What I claim as my invention, and desire to secure by letters patent, is the mode of attaching the knives to the permanent arms, by means of the pendulous or moveable arms rotating on the shaft, and secured to the permanent arms, by means of screw bolts passing through elongated holes in the moveable arms, thereby allowing the cutting edge of the knives to be placed at any required angle necessary for adjusting them to the bed cutter or shear, in combination with the moveable box, for regulating the mash of the cog of the pinion into those of the wheel, substantially as described.

JOSEPH W. WEBB.

No. 7712.—*Improvement in Portable Bedsteads and Sacking Bottoms.*

What I claim as my invention, and desire to secure by letters patent, in the making of a sacking bed of canvass, or other cloth, to be suspended from the edges, is the insertion of gores to fit the same to the swell of the body at the shoulders and hips, substantially as described.

And I also claim, making the frame of a portable bedstead, substantially as herein described, of a series of posts connected and combined together longitudinally and laterally by braces on the principle of the lazy tongs, the said braces being connected with the posts by means of joints and slides, substantially as herein described.

SAMUEL WHITEMARSH.

No. 7713.—*Improvement in Warm Air Registers.*

What I claim as my invention, and desire to secure by letters patent, is the manner in which I have combined the screw, racks, and segments of pinions, and the application of this combination to the purpose herein described, viz: that of opening and closing the valves of warm air registers.

PETER G. WOODSIDE.

No. 7714.—*Improvement in Looms for Weaving Figured Goods.*

What I claim to have invented, and desire to secure by letters patent, is as follows:

First. The arrangement of machinery for throwing the shuttles as herein described, in connection with the arrangement of the machinery for raising and lowering the shuttle boxes; the devices thus arranged, occupying the under part of the loom frame and being more simple, compact, and convenient than other arrangements heretofore in use, for the same purpose.

Second. The winding of the cloth round the beam with uniform tension by increasing the leverage of the weight M^3, in proportion as the diameter of the roll of cloth is increased, substantially as herein described.

Third. In combination with a positive let-off, I claim the use of a conditional let-off, constructed substantially as herein described, whereby, when there is an excess of strain on the warp threads an increased quantity of yarn is delivered from the yarn-beam; such conditional increased delivery of the yarn ceasing whenever the proper strain on the warp thread is restored.

Fourth. The preventing the opening and closing of the shed from producing an increased or diminished strain upon the warp threads, by means of the regular and positive advance of the let-off rolls toward the harness through an invariably equal distance at every opening of the shed, and by their return through the same distance at every closing of the shed, substantially as described.

Fifth. The causing the loom to throw itself out of gear, whenever a shuttle fails to go into its proper box at the proper time, and whenever the connection formed by any weft thread between its shuttle, and the cloth is not maintained during the whole of the passage of that shuttle through the warp thread, by the operation of the hooks combined with each other, and attached to the bed of the lay, substantially as described, the hooks being in the latter case combined with wires or prongs for the reception of the weft thread, substantially as described, and operated by the passage of the shuttle into the shuttle box, substantially as described.

Sixth. Forming and breaking in any required order, the connection between the draught boards respectively and the machinery that works them, by means substantially such as are herein described; this method of working the draught boards admitting of a more simple, compact, and convenient arrangement of the machinery than others before used to attain the same end.

Seventh. The combination of a rising and falling jacquard frame, with the draught boards, substantially as herein set forth; whereby the depression of the frame will be simultaneous with the elevation of a part of the draught boards, and the elevation of the frame with the depression of a part; the one in this manner aiding in working and equipoising the other.

Eighth. Elevating and depressing the harness and draught board, by the simultaneous elevation or depression of all the knot boards for the purpose of opening the sheds in looms for weaving figured fabrics when these knot boards are arranged above the draught boards, as herein described.

Ninth. In connection with the movement of the part of the jacquard, to which the harness is attached, substantially as described, I claim the arrangement of the harness and of the movement parts of the jacquard, and of their connections with the lower part of the loom, substantially as described, in such manner, that at the time when the loom is to be thrown out of gear, the weight of the harness and of those parts and connections, shall oppose the greatest possible resistance to the momentum of the loom.

Tenth. I claim the use as a part of the jacquard machine, of the combination of the machinery herein before described, as shown in fig. 4, of the accompanying drawings, such combination consisting of the two slides Y^{10}, the two springs Z^{10}, and the two needles Q^{10}, constructed substantially as described, and operating so as to permit the draught board to come down without crowding out the cylinder or prism, substantially as described.

AVERY BABBETT.

No. 7715.—*Improvement in Braces for Carriage Tops.*

What I claim as my invention, and wish to secure by letters patent, is the construction and arrangement of braces for carriage tops, so that when one limb or part of the brace is turned upon a prop, fulcrum or pivot, all the joints of such brace are simultaneously moved or operated, substantially as shown in the drawings. I also claim the adaptation of a graduating strap, loop or similar device, so as to secure the top at any desired elevation, as herein set forth.

JNO. L. ALLEN.

No. 7716.—*Improvement in Filtering Cocks.*

What I claim as my invention or improvement, is the combination of parts arranged, constructed, and made to operate together, substantially in the manner herein before set forth, the said combination consisting of the box or case A, the tubular passage way B, having three discharging orifices G, H, I, the turning or hollow plug C, made with a discharging orifice E, the central and two lateral chambers K, *i*, *k*, the passages connecting the openings G, H, with the chamber *k*, *i*, the self-operating valves, and their stem, and seats and valve openings; the passages leading out of the bottom of the two lateral chambers, the central discharge pipe leading out of the chamber K, the partitions *s*, *t*, and the filtering medium, having wire gauze chambers, as above specified, or being used without them, as occasion may require.

DANIEL BARTLETT, Jr.

No. 7717.—*Improvement in Looms.*

What I claim as my invention, is the combination of the vibrating posts and springs applied to them, as arranged and adapted to the loom frame, and the operative parts with which they are connected, substantially in the manner and for the purpose of easing the web, without varying its horizontal position, as herein before specified. A. H. BOYD.

No. 7718.—*Improvement in Machines for Pulverizing Sugar.*

I claim as my invention, the combination of a rotative series of cells, a rotative series of stampers, suitable machinery for actuating the stampers, and a cylindrical mortar, when arranged and made to operate together, and to receive, pulverize, and expel sugar or other material, substantially in the manner as herein before specified. O. R. CHASE.

No. 7719.—*Improvement in Hemp Harvesters.*

What I claim as my invention, and desire to secure by letters patent, is

First. The box on the right marked Q, which is a constant oil retainer.

Second. The combined sides X, X, and spring bottom R, R, for catching and laying the hemp, &c.

Third. I claim casting (or securing in any firm manner,) choppers on a rock shaft N, with the edges chisel shaped, and set so as to strike obliquely against the top and right edges of the teeth P, where the part N, moves by a lateral and semi-rotary motion in procuring this combined motion. I employ a male and female screw thread, as already fully described in the preceding part of these papers. I do not desire to be understood as confining myself to the screw in getting this motion in N, but will employ any other method most suitable to produce the desired result, and which shall be substantially the same. WILLIAM BAILY COATES.

No. 7720.—*Improvement in Grain Cradles.*

What we claim as our invention, and desire to secure by letters patent, is the particular construction and arrangement of the brace rods *c*, so as to fold down upon the fingers, as shown in fig. 2, each being bent in the proportionate angle, fitting their respective localities, the ends thus bent pass through the fingers perpendicularly at *d*, and are secured by rivetting the same upon the upper side of the fingers, which shape and form given to the wire braces, forms and constructs a hinge joint, and each may be turned or swayed in the direction desired, and when separated from the sneath, each wire brace is placed in the position as represented by fig. 2 aforesaid, permitting large numbers to be packed in a condensed form, in packages or boxes convenient and proper for removal, storage, or transportation, substantially the same as herein before set forth and described. ISAAC T. GRANT.
DAN'L H. VIALL.

No. 7721.—*Improvement in Pegging Jacks.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the two jaw blocks and the double spring connecting rod, as constructed and made to operate together, and in connection with the other parts of the apparatus, substantially as herein above specified.

JACOB JENKINS.

No. 7722.—*Improvement in Machines for Folding Paper.*

My improvement or combination, as invented and claimed by me, consists of the following elements:—First. A slotted plate B, table or contrivance for receiving and supporting the sheet.

Second. Two parallel planes or plates (L, M,) extending at right angles from such support, and so arranged that there shall be one of the said plates on each side of the slot *b*, of the first element or support of the sheet.

Third. A striking and folding frame or plate (D,) so arranged and operated as to press the paper against the middle or other proper part of it, force it downwards through the slot, and between the two parallel plates: the said parallel plates operating to complete the fold, and to hold the sheet of paper during the return or retrograde movement of the striking frame or plate: and in combination therewith, I claim a second striking and folding plate N, arranged at right angles to the said two parallel plates, and made so to pass or operate through them or their slots, and directly after the said retrograde movement of the first one, as to press against the sheet of paper, and force it through one of the said slots, and thereby once more, or a second time fold it.

And I claim, in combination with such second combination of mechanism, a third striking and folding plate (R,) and slotted parallel folding plate S, and friction rollers (*p, q*,) or equivalent contrivances, the same being for supporting the thrice folded sheet of paper, folding it a third time, and subsequently discharging it, such discharge taking place in consequence of the return or retrograde movement of the striking or doubling plate, as above described.

And I also claim the combination of mechanism which is applied to the striking plate, and its rollers or folding contrivances, and used for packing the sheets; the said mechanism consisting of the stationary plate T, and the spring plate U, or plate and its springs, or other proper equivalents, which permit the recession of the plate in proportion as the pack of sheets increases in size; the whole being arranged and made to operate together, substantially in the manner as herein before specified.

GEORGE K. SNOW.

No. 7723.—*Improved Machine for Excavating and Conveying Earth.*

What I claim, and for which I wish to obtain letters patent, is the combination of the series of elevators, with the scoop, and a rising and falling earth bed, furnished with an apparatus for emptying the same, the whole arranged and acting substantially as herein described.

I also claim a regulator to the scoop, attached in the manner and for the purposes herein specified.

JOHN A. SPRAGUE.

No. 7724.—*Improvement in Molasses Gates.*

What I claim, is the arrangement of the spring, the turning shaft, and their bearings at one end of the gate, and on the side of the screw or seat tube, substantially in the manner above specified, the same giving to my improved molasses faucet, several important advantages over that described in the said patent numbered 3002.

ERASTUS STEBBINS.

No. 7725.—*Maize Harvester.*

I wish it to be understood, that I do not limit myself merely to the various parts herein described, when combined together in a single machine, as some

of these parts may be used without the others; neither do I limit myself to the precise combination of parts described in this specification, as portions of one machine may be used in connection with portions of the others, thus constituting new machines, operating upon a common principle; but what I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of separating the ears of Indian corn from the standing stalks on which they grow.

I also claim, in combination with the gathering forks, apparatus for husking and shelling the corn, substantially as herein set forth, whereby the gathering, husking and shelling of corn, are performed at a single operation.

WILLIAM WATSON.

No. 7726.—*Improvement in Suspender Buckles.*

What I claim as my invention, and desire to secure by letters patent, is the connecting of the wire forming the tongue of the buckle, to the outside plate, by means of an eye or hinge formed by bending a portion of the plate, thus making the whole buckle of but two pieces of metal, also bending or forming the wire which forms the tongue of the buckle, in such a manner as to make a lateral spring for securing itself in its proper place, and also the method of securing the points of the tongue by the lateral hooks or guards, curved from the sides of the plate in such a manner as to receive and partially or entirely cover the points of the tongue, and the whole of these contrivances arranged, connected, and combined, substantially as herein described.

CHARLES BENEDICT.

No. 7727.—*Improvement in Feeding Apparatus for Straw Cutters.*

What I claim, therefore, is the use and employment of the adjustable and compressing lid C, in combination with the feed roller and a cutting-box, having an adjustable block piece to contract the mouth of it, and so arranged as to present the straw or stalk obliquely at different angles to the action of the knife, and compress it while under its edge, substantially in form and manner as herein set forth.

HENRY H. BERTHOLF.

No. 7728.—*Improvement in Cheese Presses.*

What I claim therein as new, and desire to secure by letters patent, is the elastic strap for raising the platen rod, arranged and operating substantially as herein set forth.

J. CARD.

No. 7729.—*Improvements in Machines for Making and Holding Cores for Casting.*

What I claim as new, and desire to secure by letters patent, is the combination of the two moving jaws O, O, with the stationary piece A, said moving jaws being shaped and actuated, substantially in the manner and the mechanical devices herein specified.

I also claim keeping the cores straight and stiff in the flasks, without the use of anchors, by means of contrivances substantially such as are herein described.

LUTHER H. CROCKER.

No. 7730.—*Apparatus for Reversing or Stopping Locomotive Engines.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement and connection of the system of devices, consisting substantially of a rock shaft (M,) with its hand lever (O,) and arms (H,) link rods (*c*, *q*,) helical segment (G,) drum (F,) sliding key (D,) and oscillating arms (*k*,) together with the eccentrics and valves, with their respective rods, by means of which the movement of the steam valves of a locomotive engine can be arrested or reversed, with proper lead, to reverse the motion of the locomotive by a single movement of the hand.

JAMES CUNNINGHAM.

No. 7731.—*Improvement in Cotton Presses.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the press herein described, so arranged that it may be conveniently charged in an upper story of the building in which it is placed, and actuated and uncharged in a lower story of the same, substantially as herein set forth.

J. T. ELLIOTT.

No. 7732.—*Improvement in Subsoil Ploughs.*

What I claim as my invention, and desire to secure by letters patent, is the scoop instrument A, A, with the combination of the cutters in the rear, as a subsoil plough.

WM. C. PAGETT.

No. 7733.—*Improvement in Apparatus for Releasing Horses from Carriages.*

What I claim as my invention and improvement, is combining two tapered trace bars F, F, with the flexible lever or disengaging strap I^2, attached to the upper end of the curved confining box plate J, projecting outward from the swingle tree A, in which the flexible lever I^2, and ends of the tapered trace bars F, F, fit, and are properly secured with the traces, by the curve of the box plate J, and a guard or holder L, attached to the flexible lever I^2, and fitting into the cavity of the box plate J, directly over the ends of the trace bars F, the disengagement being effected by drawing a cord K, attached to the flexible lever I^2, which will cause it to approximate to a straight line, and with it elevate the ends of the trace bars F, and liberate the same from the curved box plate J, as fully set forth.

TAPLEY B. PYRON.

No. 7734.—*Improved Wrought Iron Railroad Chair.*

What I claim as my invention, and desire to secure by letters patent, is a wrought iron railroad chair, with lips formed from that portion of the plate on which the rail is usually supported, substantially as herein set forth.

EDWARD S. RENWICK.

No. 7735.—*Improvement in Preparing Beefsteak for Cooking.*

What I claim as my invention, and desire to secure by letters patent, is preparing beef and other steaks for cooking, by running them through toothed rollers, substantially as set forth and described in the specification and drawings.

THOMAS G. STAGG.

No. 7736.—*Improvement in Fastenings of Coulters to Ploughs.*

What we claim as our invention, and desire to secure by letters patent, is the construction of the double plates, held in parallel position by the combined action of the coulter and the bolts K, K, substantially as described, and for purposes as above set forth.

AUSTIN WHITTLESY.
AUSTIN K. WHITTLESY.

No. 7737.—*Improvement in Processes for Manufacturing Alum.*

What I claim as my invention, and desire to secure by letters patent, is the obtaining of alum by the action of sulphuric acid, or its equivalent, upon the substance called green sand marl, or simply marl.

JACOB HENRY WURTZ.

No. 7738.—*Improvement in Printing.*

First. I claim marking on the shank and foot of types, by any convenient means, such as writing, engraving, casting, or electrotyping, the same letter or character, which is formed on its upper surface, and also the method herein shown and described, of casting the intaglio letters on the shank and foot of the types at the same time that the type itself is cast.

Second. Making types, having the combination with the usual letters in relief on the face of the type, intaglio letters on the foot thereof, for the purpose of serving as matrices, from which to obtain a polytype plate, while the types themselves will serve for printing.

Third. I claim casting spaces on the sides of the ordinary type for the purposes above mentioned, as above described.

Fourth. I claim the peculiar mode herein shown and described, of polycomposing, either from the ordinary cases, or from what I call the authoriton.

Fifth. I claim the process and apparatus herein shown and described, for facilitating the sorting and distributing of types and spaces, and making part of them of wood and iron, so that the wooden portion may be separated by means of water, the iron ones by a permanent or temporary magnet, and the others into their several receptacles by hand, the workman being considerably assisted in this operation by the type being marked on their sides.

Sixth. I claim the apparatus shown in figs. 8, 9, and 10, which I denominate the authoriton, and also of the use of copying sticks, shown in figs. 13, 14, and 15, for the purpose of facilitating composition, by which the above described types are brought into a convenient space for composing from, as herein before described.

BARTHOLOMEW BENIOWSKI.

No. 7739.—*Improvement in Electro Magnetic Enunciators for Signals in Hotels, &c.*

What I claim as my invention, and desire to secure by letters patent, in my improved electro magnetic enunciator for hotels, &c., is the manner in which the signal bell and any one of the signal plates can be simultaneously acted upon, at a distance from the enunciator, through the medium of the galvanic battery O, the series of electro-magnets A, and *g*, *g*, and the wires *k*, *l*, *n*, *n*, connected with each other, with the insulated point and the shank of the knob P, located within the walls of the different rooms, and with the bell S, and signal plates B, B, of the insulator, substantially in the manner herein set forth.

CHAS. S. BULKLEY.

No. 7740.—*Improvement in Winnowing Machines.*

What I claim therein as new, and desire to secure by letters patent, is the combination of the additional bottom board M, with the elevated fan O′, and fan case O, for the purpose of diminishing the space between the discharging board E, and screens, for concentrating the blast beneath, and in contact with the screens, for the purpose described.

J. G. GOSHON.

No. 7741.—*Improvement in Car Couplings.*

What therefore, I claim as my invention, is the improvement whereby the cars are connected or disengaged, under the above named circumstances, or in other words, I claim the combination of the suspended extension pin I, with its weighted pin or arm *h*, or any mechanical equivalent therefor, the hinge H, and the buffer socket to which they are applied, the same being constructed and made to operate, substantially as set forth.

NATHAN HASKINS.

No. 7742.—*Improvement in Corrugated Boilers.*

What I claim therein as new, and which I desire to secure by letters patent, is the employment of corrugated plates of metal, for forming the curved arches of fire chambers, and shells of steam boilers, the corrugations running in the direction of the curves, substantially as described.

RICHARD MONTGOMERY.

No. 7743.—*Improvement in Bedstead Fastenings.*

What I claim as my invention, and desire to secure by letters patent, is the construction and application of a triangular or forked plate of iron, made in such a manner, as that it can be secured to its place and draw the post and rail firmly together, by means of an eccentric or cam, substantially as above described.

JOHN MORRISON.

No. 7744.—*Improvement in Rotary Grain Screens.*

I claim the construction of a rolling screen consisting of a large and fine, and small, and coarse part, in combination with conductors D, to carry the grain from the large to the small part, for the above mentioned purpose, and substantially as above described

DAN. PEASE, Jr.

No. 7745.—*Improvement in Machinery for Pressing Hats.*

I do not claim merely so arranging the smoothing irons that they can all by a single movement be simultaneously brought over the block, I only claim this, when the irons are also at the same time and by the same movement brought into the requisite contact with the top and sides of the crown, and with the brim of the hat, to smooth and compress the same, substantially as herein specified.

I likewise claim the devices herein described, or their equivalent, for rendering the crown iron self-adjusting, with respect to the brim iron, so that the pressure of the crown iron, will be co-etaneous with that of the brim irons, without affecting the relative degree of pressure with which they respectively bear upon the surfaces, to be smoothed by them, substantially as herein set forth.

BENNETT POTTER, Jr.

No. 7746.—*Improvements in Machines for making Wrought Iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is the forging of solid wrought iron wheels, when made by drop and die, the use of a lower die or anvil, made to revolve during the process of forging, horizontally on a central vertical axis, either by hand, or by the machinery, which operates to drop the ram or hammer, substantially as set forth in the above specification.

NATHAN STARKS.

No. 7747.—*Improvement in Reed Musical Instruments.*

What I claim as my invention, is the improvement of the vibration string, or strings, wire or wires *e*, *e*, *e*, *e*, in their combination with the wind chest, the same being made to be vibrated by the air, in its passage into or through the wind chest, substantially as specified.

I also claim the above described extension or elongation of the passage *l*, in combination with the improved arrangement of the reed and valve opening, the said arrangement, consisting in placing the reed not directly over the valve opening, but at a distance therefrom, and in said passage, substantially as specified.

JAMES P. SLEEPER.

No. 7748.—*Improvements in Machines for Nicking the Heads of Wood Screws.*

What I claim as my invention, and desire to secure by letters patent, is interposing a spring between the griping jaw, and the lever or cam by which it is operated, in the manner substantially as herein described, and for the purpose specified.

I also claim making the spring, which is interposed between the griping jaw and the mechanism which operates it, so that its tension can be varied and regulated, in the manner and for the purpose specified.

And I also claim, causing the griping jaw to open slightly, after it has seized the blank, to permit the blank to assume its proper position, between the jaws, before it is finally griped, in the manner, substantially as herein specified.

THOS. J. SLOAN.

No. 7749.—*Improvement in Spike Machines.*

What I claim therein as new, and which I desire to secure by letters patent, is—

First. The adjustable cutter (5,) when in such position, with regard to the dies for holding the spike, that the rod forming the spike is both cut off, and the proper bend given to it, to form the head at one and the same operation, during which, the spike is held stationary, substantially in the manner described.

Second. I claim the jaw (3,) of the swage, kept open by a spring, in combination with the moving swage (2,) and the stationary swage (6,) the swage (2,) having an inclined face, which acting on a similar face on the back of the jaw (3,) closes it for forming the point for the spike, whether placed in front of the revolver, to point the rod, or behind it to point the spike, constructed substantially as described.

H. N. SWIFT.

No. 7750.—*Improvement in Machines for Dressing Irregular Forms.*

What I claim as new, and desire to secure by letters patent, is the toothed wheel *i*, upon the shaft S, arranged so that it is capable of being thrown in gear with either of the racks *d*, *d*, in combination with the dog S, on the slide D, and the notched projection on the table B, by which the slide is locked to, or unlocked from the table, for the purpose of enabling the wheel *i*, to give either a rectilinear motion to the said slide D, or a circular motion to the table B, as may be required, in the manner and for the purposes, substantially as herein set forth.

ALANSON CARY.

No. 7751.—*Improvement in Rotary Pumps.*

What I claim as new, and desire to secure by letters patent, is the two pistons, acting alternately with each other as rotary pistons, and as stationary partitions, in connection with the arms and apparatus, by which they are worked, substantially as above set forth.

WILLIAM H. DAVIS.

No. 7752.—*Improvement in Furnaces for Steam Boilers.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as described, of the making the box lining of furnaces, with a partition or division plate or plates, between the inner lining and outer shell, to direct the current or currents of air before entering the fire, substantially for the purpose and in the manner specified.

I also claim the manner of arranging the furnace door with its interior plate or lining, in combination with the tube or apertures for blowing or forcing in air, steam, or other cooling medium, between the door and said plate, all as herein described, irrespective of form, and also of the manner of producing the forced current of the cooling medium. F. P. DIMPFEL.

No. 7753.—*Improvement in Washing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of three vertical presses or washers, in combination with the fan, arranged and operated in the manner, and for the purpose above set forth.

R. A. FISHER.

No. 7754. [Sam'l W. Hawes,—cancelled.]

No. 7755.—*Improved Valves for Governors.*

What we claim as our invention, and desire to secure by letters patent, is making the valve openings of governor valves, to widen from the closed towards the fully open end, and also in such a manner, that when the governor acts upon the valve under low speed, it shall cause the opening or closing of that part of the steam passage, where the rate of widening or narrowing of the passage, is more rapid than at the parts at which the valve acts at high speeds.

Second. We also claim forming valve openings, substantially as described, in fig. 4, whatever may be the number of openings in to which the space or valve seat is divided, and whether the said openings are made in plane or curved surfaces.

Third. We also claim the spring set screw, re-acting against the pressure of steam in the valve, not only for relieving the valve from friction, but also for causing it to recede slightly from its seat when the valve approaches its open position, whereby an increased flow of steam is permitted, and the rate of flow augmented the more the valve opens, or the tension of steam diminishes, as herein set forth.

Fourth. We also claim, in combination with a valve lever, adjustable to the stem of the valve, an indicator not adjustable, for the purpose of setting the valve in any required position without opening the valve box.

JUNIUS JUDSON.
ALFRED JUDSON.

No. 7756.—*Improvement in Straw Cutter.*

What I claim as new in my invention, and desire to secure by letters patent, is the application and use of rotary spiral cutters D, D, which are self-

feeding, in combination with a stationary knife, or cutting edge, in the manner and for the purpose, substantially as described.

A. S. MACOMBER.

No. 7757.—*Improvement in Lime Kilns.*

What I claim therein as new, and desire to secure by letters patent, is:

First. The construction of an upper tier, or tiers of arches, in the manner and for the purpose herein fully set forth.

Second. I claim the recesses or openings F, F, in combination with an upper tier or tiers of arches, for the purpose of creating a draught through the structure, after the lower arches have become stopped up.

WILLIAM McCOY.

No. 7758.—*Improvement in the Running Gear of Carriages.*

What I claim, is the axles of the wheels having racks on their inner ends, meshing into central cog wheels, the front one of which meshes into a segmental rack on the inner end of the pole of the carriage, the whole being constructed, arranged, and operating in the manner, substantially as described.

JOSEPH PINE.

No. 7759.—*Improvements in Operating the Copping Rail of Cop-Spinners.*

What I claim as new in my invention, and desire to secure by letters patent, is changing the direction in which the ring rail is moved, and the speed at which it is operated, for the purpose of governing the winding of the thread on the cop, and forming a bind thread, by means of the combination of the shaft M, having a toothed wheel N, and smaller wheel O, fast upon its axis, with the shaft R, having on it a fast toothed wheel S, and a loose smaller wheel or pinion V, operated by shifting belts and pulleys, or other similar changing or reversing gear. WANTON ROUSE.

No. 7760.—*Improvement in Hardening Fats and Oils.*

What I claim as my invention, and desire to secure by letters patent, is the hardening of fatty or oily substances, without separating the stearine from the oleine to such a degree, that they can withstand a heat of at least 135 degrees Fah. without melting; using for that purpose, the ingredients of cera japonica and gum elemi, in the manner and proportions above described, which will produce the intended effect.

CARL WILHELM SCHINDLER.

No. 7761.—*Improvement in Clamps for Girding Emery Wheels.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the screws F, and G, and toggle joints C, C, with the jaws B, B, substantially as herein described and set forth, for the purpose of producing, first tension of the girding substance, and then the compound motion of the jaws in closing together, and settling down to the object on which the machine rests. HENRY S. VROOMAN.

No. 7762.—*Improved mode of Fastening Hooks and Eyes upon Cards.*

What I claim as my invention, is the putting on of the hooks and eyes, in such a manner upon paper perforated as herein described, that the points of the hooks are upon one side of the sheet, and the eyes upon the other side, thereby securing the eyes against dropping off from the hooks. I claim nothing in regard to the manner of perforating or folding the paper, nor for any other method of putting hooks and eyes upon perforated paper, than the method herein described.

E. J. WARNER.

No. 7763.—*Improvement in Fly Brushes.*

What I claim as new, is so constructing and adapting the revolving fan or brush, that it may be placed like a lamp upon a table, or may be fixed to the walls or ceiling of a room, or that it may be suspended by a cord over a bed, sofa, or cradle, by the means herein fully described.

SAMUEL R. WILMOT.

No. 7764.—*Improvements in Apparatus for Stretching and Smoothing Cloth.*

What I claim as my invention, is the combination of the revolving platform, or table W, and the guide roller or apparatus X, with the series of stretching rollers; the whole being substantially in the manner and for the purpose as herein before specified.

JOHN BUTCHER.

No. 7765.—*Improvement in Portable Furnaces.*

What I claim as my invention, and desire to have secured to me by letters patent, is a summer furnace in which the draft is derived to the fire chamber from the exterior of the furnace and at the bottom of the same, and passes first up through a flue chamber, (formed between the partition *i*, *i*, and the periphery of the furnace as above set forth,) and then down through the fuel, all as herein above set forth, and for the purpose specified.

JOHN P. HAYES.

No. 7766.—*Improvement in Processes for Curing Meat.*

What I claim as my invention, and desire to secure by letters patent, is the method of curing meat, by placing it with brine within a vessel, and then subjecting it to the combined action of agitation, and an alternate increase and diminution of atmospheric pressure, substantially as herein set forth.

GEORGE STARKWEATHER.

No. 7767.—*Improved Filter for Oils.*

What I claim as my invention, and desire to secure by letters patent, is the use of a filter formed as described, carried downwards by pressure, under the force of which the oleic acid is filtered upwards, and which, applied in connection with the arrangement described for applying cold, allows oils and fats to be purified in warm weather.

THOMAS ANTISELL.

No. 7768.—*Machine for making Jack Chains.*

What we claim as our invention, and desire to have secured to us by letters patent, is the combination of the parts, movements, and operations, in one machine, which are required to make jack chains by one process, from the straight wire, after it is cut off in suitable lengths, to finished chain, substantially as described.

We also claim, particularly, the stud pin with a recess in it, substantially as herein described—that is, the use of it as a mandrel, around which the bow of a link is bent, while the bow of another link is held in the recess, thereby forming a continuous chain, and irrespective of the mechanical devices by which it is moved or used.

We also further claim, the partly revolving mandrel with its stud and nipper, and other appendages, for bending the last bow of each link, substantially as combined and used in our machine, and constituting part of it.

CHARLES ATWOOD.
GEORGE KELLOGG.

No. 7769.—*Improvement in Repeaters for Electro Magnetic Telegraphs.*

What I claim therein as my invention, and desire to secure by letters patent, is the manner of connecting two galvanic circuits with the two electro-magnets (*a*, *a*, and *d*, *d*,) in the said repeater, substantially as herein represented and described, to wit: each of the said galvanic circuits, as it passes through my said telegraphic repeater, embracing in its course the armature of the opposite electro-magnet, in the said instrument, previous to its passing through the helices in the electro-magnet, embraced in its own respective circuit.

In combination with the above, I also claim the connecting the points *b*, *j*, with the galvanic battery O, (or batteries,) when the said points are placed in such positions, in relation to the armatures (*s*, *t*,) of the electro-magnets in my said telegraphic repeater, that when either one of the said electro-magnets is charged, it will, by attracting its armature against one of the points *b*, or *j*, close the poles of the galvanic circuit in which the opposite electro-magnet, (in the instrument,) is in connection, and thereby throw the battery O, into the said circuit, substantially as herein set forth.

CHARLES S. BULKLEY.

No. 7770.—*Improvement in Seed Planters.*

What I claim as my invention, and desire to secure by letters patent, is the attachment of my vertical cylinders J, J, to the rear of my ploughs or cultivator, (without regard to any particular plough,) in combination with its machinery, arranged substantially in the manner and for the purposes herein set forth.

SAMUEL CANNON.

No. 7771.—*Improvement in Printing Machines.*

What I claim as new, and desire to secure by letters patent, is—

First. I claim the type form, constructed substantially as described and represented, viz: with the types arranged in rows, longitudinally and laterally, in such manner as to permit each type to be brought to a given position, at the will of the operator, to be pushed upon the paper by the plunger C, No. 1, or its equivalent.

Second. I claim the combination of the two motions, which I have called lateral, and longitudinal, for the purpose of bringing the type or character required in position to make its impression.

Third. I claim the wedge shape movement, in combination with a type form, substantially as described and represented, for the purpose of giving motion to the latter.

Fourth. I claim the manner of adjusting with precision the required position of the type form, by the use of gauges, substantially as described and represented, in combination with the two motions already described, as giving motion to the type form, or in any combinations, substantially the same.

Fifth. I claim the inking of the types by the inker, interposed during the action of the machine between the face of the types and the paper.

Sixth. I claim the use of the bob (V,) substantially as described and represented, to furnish the power to cause the pressure on the types, or the inking of the same.

Seventh. I claim the combination of the bob, whose fall produces the pressure on the types, with a contrivance by which, after the blow is given, a second blow or vibration, is prevented.

Eighth. I claim the use of the slats, substantially as described and represented, or other analogous device, controlling the motions of the machine, combined with the rods answering to the letters or characters wanted, by means of the catches on which the slats may be moved separately or together, in any combinations of time, or extent of motion that may be required for the action necessary to produce the given characters.

Ninth. I claim the draft rod and lever, (see *r*, *i*, and *q*, *i*, No. 3,) in combination with the slat *p*, *i*, or its equivalent, to produce the various movements required to control the types.

OLIVER T. EDDY.

No. 7772.—*Improvement in Horse Shoe Machinery.*

What I claim, and want secured to me by letters patent, is the combination of the two flanged rotating dies, arranged with respect to each other, and operating substantially as herein described, said dies being so shaped as to give the requisite form to the metallic shoes of animals.

SAMUEL S. GREENE.

No. 7773.—*Improvement in Drying Paints.*

What I claim as my invention, is a method of giving a drying quality to oils, by the use of a mineral, commonly known by the name of the red oxyde of zinc, in a partially deoxydised state, and either in combination with those substances naturally associated with it, or by the use of any of its component parts, separated by mechanical means. AQUILLA JONES.

No. 7774.—*Improvements in Iron Railings.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the rods, tubes, and palings, with the manner of operating the same, as herein set forth and described.

JOHN KRAUSER.
SOMMERS CROWELL.
CYRUS KRAUSER.

No. 7775.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the method of heating the front end of the extended part of the oven, in combination with and receiving the heated air from the hot air chamber, behind the fire back, and causing it to pass through the oven, and out into the fire flues, in the manner substantially as described, and for the double purpose of heating the front end of the oven, and passing a current of heated air through the oven, substantially as specified. SAMUEL PIERCE.

No. 7776.—*Improvements in Sewing Machines.*

What I claim as my invention, and desire to secure by letters patent, is forming a stitch by each throw of the shuttle and corresponding motion of the needle; that is to say, making one stitch at each forward, and another at each backward motion of the shuttle, this being effected by the needle, in combination with the shuttle, both constructed, arranged, and operating as herein described, or in any other mode substantially the same.

Second. I claim the combination of the sliding bar Q, the plate *r*, the feeding plate V, the spring W, the screw *t*, the lever R, and the clamping plate T, for holding and feeding the cloth to the needle and regulating the length of the stitch, in the manner herein described, or in any way substantially the same. ALLEN B. WILSON.

No. 7777.—*Hinged Gun Harpoons.*

What I claim as new in my invention, and desire to secure by letters patent, is making the shank of harpoons, and other whale irons, to fold by a hinge or joint at any convenient point in their length, in the manner and for the purposes, substantially as herein described.

WILLIAM ALBERTSON.

No. 7778.—*Improvement in Bake Ovens.*

What I claim therein as new and of my invention, and desire to secure by letters patent, is the combination and arrangement of an endless chain platform N, with the oven, by which arrangement, the unbaked bread or other articles being put in at one end, are discharged at the opposite end completely baked; and in combination therewith, I claim the self-opening and closing door F′, arranged substantially as herein set forth.

HOSEA BALL.

No. 7779.—*Improvement in Working the Doors of a Bee-Hive.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the bee boxes and moth chambers, in combination with the sliding screen doors, pulleys and levers, as described, so that the doors may be worked by a sinlge movement of the lever, in the manner and for the purpose set forth. JARVIS CASE.

No. 7780.—*Improvement in Air-Heating Furnaces.*

What I claim therein as new, and desire to secure by letters patent, is:

First. The annular chamber, constructed and arranged, substantially in the manner and for the purposes set forth, with or without the cross pipe.

I also claim the mode of conducting off the products of combustion from the fire through ascending pipes *h*, into an annular chamber, and thence into a central descending pipe to their exit, and the surfaces being all so constructed of a curved figure, as to allow a diverging influence, and free circulation to the exterior air in the air chamber, to be warmed without over-heating it; while it is, by the arrangement of parts, forced to impinge directly against the heated surfaces.

I also claim the method of setting the furnace, consisting of a double walled chamber, the inner wall of which encloses a cold air trench, supplied from without that surrounds the ash pit, with openings at its top for the proper admission of air into the air chamber around the furnace, and with lateral openings into the space between the walls, to cause an upward current, which is connected with the warm air-pipes leading to the apartments, by means of which a constant and pure supply of air is insured, and the heat greatly economized.

GARDINER CHILSON.

No. 7781.—*Improvement in Corn Shellers.*

What I claim as new and my improvement, and desire to secure by letters patent, is the combination of the wheels C, D, E, for shelling corn, as herein described.

DAVID ELDRIDGE.

No. 7782.—*Improvement in Mills for Grinding and Crushing.*

What I claim as my inprovement, and desire to secure by letters patent, is the use of the cylinder D, grooved or notched, or smooth, being made to rotate, and having within it, any number of crushers formed as described, for the purpose of pounding, grinding, or mixing any substance, the crushers either running singly, or, for the purpose of working different substances simultaneously one within another, the jumping bar or pin at N, in combination with the arrangement shown, or any other arrangement substantially the same.

WILLIAM FROST.

No. 7783.—*Improved Annunciator or Bell Telegraph.*

What I claim as new and of my own invention, and desire to secure by letters patent, is the combination and arrangement of the spring levers I, suspender bar or striker F, with the pendulums K, and bells D, for simultaneously indicating the number of the room, and calling the attention thereto, by giving the alarm, there being a secondary or intermediate fulcrum bar L, against which the spring lever I, impinges on its descent, increased by the spring N, by which the rear end is made to descend, and with it the suspended striker F, upon the bells D, and at the same time suddenly elevating the front end of the lever I, and imparting a vibratory movement to its pendulum, said spring levers I, being provided with oblong openings or slots M, through which the fulcrum bar J, passes, for producing the aforesaid action of the spring levers, on its descent upon the intermediate fulcrum bar.

JOHN GARVEY.

No. 7784.—*Improvement in Photographic Pictures on Glass, &c.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the ground or frosted glass, or other semi-transparent substance interposed in connection with the picture, between the source of light and the spectator, substantially as described in the foregoing specification.

FREDERICK LANGENHEIM.

No. 7785.—*Method of Attaching Augers to their Handles.*

What I claim as new in my invention, and desire to secure by letters patent, is the handle made in two parts, one of which D, fits in a socket B, on the other A, and carries a bolt *b*, secured at its end, the said bolt passing through a hole in the auger shank, and screwing into a female screw or nut *a*, in the part A, for the purpose of clasping or firmly holding the auger shank between the ends of the parts A and D, of the handle or stock, in the manner herein described.

JOHN E. LARKIN

No. 7786.—*Improvement in Copper and Steel Plate Printing Presses.*

What we claim as of our invention, and which we desire to secure by letters patent, are—

Firstly. The arrangement of a tooth or catch, projecting from the roller, and operating upon a tooth or projection upon the platen, for the purpose of starting the platen, and causing the commencement of the convexity of the roller to impinge upon any required point of the length of the platen, for the purpose described.

Secondly. The combination of the racks (8 and 9,) with the cog wheel (*w*,) attached to the connecting rod of a gang of rollers, together with the beads (*p*,) and the grooves (*m'*,) in the rollers, for security, uniformity of action, and a proper relative position between the platen and the supporting rollers, upon which it traverses, thus preventing lateral and longitudinal aberation.

Thirdly. The method of heating and retaining at a suitable temperature, the plate from which the impressions are to be taken, by means of lamps or vessels containing inflammable material, placed under the upper plate of the platen, or traversing bed, within the recess formed between that and the plate resting immediately upon the gang of rollers.

Fourthly. The arrangement of a stationary and sliding clamp, adjustable longitudinally of the platen, for securing the plate in position, substantially in the manner described.

Fifthly. We claim, in combination with the D, roller, the method of retracing the platen by the weighted cord, assisted by making an inclined plane of the bed in which the rollers traverse.

E. C. MIDDLETON.
EDWARD NEVERS.
ROBERT NEAL.

No. 7787.—*Improvement in Excavating Machines.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Operating the bucket O, by giving motion to the band or chain Q, and to the drum I, in one direction, to fill the bucket, and then reversing its motion, so as to draw back the bucket, to be emptied, in the manner substantially as herein described.

Secondly. I claim the manner, substantially as herein described, of closing the bottom or trap P, of the bucket, by means of the spring or incline 17, over which it passes in its forward passage.

MARTIN NEWMAN, 2d.

No. 7788.—*Improvement in Pessaries.*

What I claim, is the solid connector *m*, with its connecting contrivance, (or its equivalent,) and joint, in combination with the supporting stem, the whole being substantially in the manner and for the purpose as herein before specified.

JONATHAN HOVEY ROBINSON.

No. 7789.—*Improvement in Extension Tables.*

What I claim as my invention, is the construction of extension tables in such a manner as that the sliding parts, when extended, shall constitute a table complete, without any replacing of panels to form the leaf, substantially in the manner herein before set forth.

EDWIN F. SHOENBERGER.

No. 7790.—*Improvement in Spark Arresters.*

What I claim as my invention, and desire to secure by letters patent, is combining, in manner substantially as described, with the chimney, the surrounding jacket and the cap, a valve for governing an aperture in the top plate of the cap, so balanced or weighted, that it shall open by gravity when the furnace is working under a draft due to the ramification of the column, and be closed by the force of the current when increased by the exhaust steam in the chimney, for the purpose and in the manner substantially as described.

I also claim, in combination with the valve and the wire gauze, or the equivalents thereof, and the deflector over the chimney, all arranged substantially as herein specified, the central tube of the deflector, and the conical ring within the wire gauze, substantially as herein specified, and for the purposes set forth.

SAMUEL SWETT

No. 7791.—*Improvement in Bedsteads.*

What I claim therein as new, and desire to secure by letters patent, is the combination of the slats $(c,)$ clasps $(d,)$ and hooks $(g,)$ athwart the length of the outside slats, in combination with the rails $(e,)$ and latches $(f,)$ on the posts $(a, b,)$ the whole combining to form a strong and portable bedstead.

WILHELM ZAISER.

No. 7792.—*Improvements in Machines for Feeding Nail Plate.*

What I claim, is the combination of such raising mechanism, with the machinery for imparting to the strip of metal, its progressive forward movements as specified, the mechanism so combined with the said machinery, being the valve a', the rod b', the lever or arm c', the crank f', shaft g', drum h', belts i', k', and the arms b', m', of the lever beam R, the whole being arranged and made to operate together, substantially as specified. And I further claim, in combination with the mechanism, which produces the progressive advancing movements of the strip of metal towards and between the cutters, the mechanism for producing the retrograde movement of the pincers, after the strip of metal has been entirely operated upon by the cutters; such mechanism being the pullies i^2, and t^1, the endless belt r^2, the moveable frame u^1, and clutch or their equivalent, the vertical rock shaft w^2, and its arms s^2, t^2, the cams g^3, h^3, the lifting bar y^2, and its spring catch, together with the slide d^3, and its projections, the whole being constructed and made to operate together, essentially as specified. And I claim the combination of the arms z^2, with the shaft w^2, and the mechanism for moving the clutch, the said arm being for the purpose of creating a retrograde movement of the clutch, so as to unclutch the pulley t^2, from the shaft e, and this when the entire retrogradation of the nippers has been effected, the same being accomplished as hereinbefore specified.

And in combination with the mechanism which produces the reciprocating rotary movements of the nippers, or strip of metal held thereby, I claim the combination of mechanism for arresting or stopping such rotary motions, immediately on the final retrogradation of the pincers taking place, such mechanism being the levers z^4, and n^3, connecting rod p^3, arm q^3, shaft v^3, arm fig. 3^3, spring catch y, as applied together, and to the lever beam R, and lifting bar y^2, as described.

And I claim the combination of mechanism, by which the progressive advancing and intermittent secondary retrograde movements of the strip of metal are produced, the same consisting of the long bar l^2, and its connecting frame

p^2, the feed and pressure rollers f^2, and m^2, the shaft g^2, and pulley f^2, the strap or belt e^2, and its rods c^2, d^2, the levers z', and v', connected together as described, and the cams r', s', on the shaft e.

And in combination therewith, and the lifting bar y^2, I claim the bent lever i^3, the same being applied to the same, and used for the purpose substantially as herein before specified.

FREDERICK J. AYERS.

No. 7793.—*Improvement in Cutters for Planing Machines.*

What we claim as our invention, and desire to secure by letters patent, is arranging a series of shaving knives, in continuous succession, upon the periphery of a conoidal wheel, whereby a continuous serrated shaving instrument is produced, whose uninterrupted action, by preventing jarring, produces a smoother surface.

ENOS G. ALLEN.
CHAS. BRIGGS.

No. 7794.—*Improvement in Ship Ventilators.*

What I claim as my invention, and desire to secure by letters patent, is the combination of floatable valves, with ventilators, for ventilating vessels and steamers, and the combination of floatable valve ventilators, with vessels and steamers. The valves to be acted upon by the raising and the falling of the water, when in contact with the ventilator, the rising water to cause the valve to close the air orifice, and prevent the entrance of water, and the falling water to permit the valve to recede by its own gravitation, and thereby open the air surface.

RALPH BULKLEY.

No. 7795.—*Improvement in Gang Ploughs.*

I claim the inclined coulters, so arranged as to throw out the ploughs without breaking, when they meet with an obstruction, in the manner and for the purpose set forth. I claim the apparatus shown at n, m, fig. 5, for setting the frames for hilling, in the manner above specified.

HENRY COWING.

No. 7796.—*Improvement in Hanging Carriage Bodies.*

What I claim as new therein, and which I desire to secure by letters patent, is the combination of elastic cross reaches, with a non elastic centre support, the reaches being so connected with the centre support, that they shall be free to bend throughout their length, substantially in the manner and for the purposes described.

M. G. HUBBARD.

No. 7797.—*Improvement in Processes for rendering Cordage Uninflammable.*

What I claim as my invention, and desire to secure by letters patent, is my improved process of rendering vegetable fibrous substances uninflammable, and preserving them in that condition, substantially as herein set forth.

JAMES H. JOHNSON.

No. 7798.—*Improvement in Fountain Pens.*

What I claim as my invention, and desire to secure by letters patent, is the pen nib, made to project through the conical termination of the fountain, substantially in the manner and for the purpose set forth, and in connection therewith, I claim making the pen nib adjustable, substantially as described.

CHARLES W. KREBS.

No. 7799.—*Improved method of securing Rails of Rail Roads.*

What I claim as new, and desire to secure by letters patent, is the diagonal position of the horses, by which, with the aid of the arms and clamps, the rails are secured in their proper position. H. H. MAY.

No. 7800.—*Improvement in Sausage Stuffers.*

What I claim as my invention, and desire to secure by letters patent, is the introduction of a tube or case D, into the case or cage B, of a press, and adapting it thereto, in such a manner as to form a sausage stuffer, in combination therewith, which is operated by the same power and under the same piston and rod, that acts upon the press, as herein substantially set forth.

SIMON McNAIR.

No. 7801.—*Improvement in Screw Threading Machines.*

What I claim as my invention, and desire to secure by letters patent, is the before described method of operating the jaws for griping and liberating the blank, by means of the toggle joint, and rod connected therewith, when this is combined with the method, substantially as described, of latching and unlatching the rod, by means of the sliding collar acting on the inclined or bevelled stem of the rod to draw it back, and force in the latch, and then holding it in place, by passing on to it, so as to avoid an endwise strain on the mandrel against its boxes, substantially as described, and for the purpose specified.

I also claim so connecting the mould, which governs the line of motion of the chaser, with the sliding frames, so that it shall be free to vibrate thereon, in manner substantially as described and for the purpose specified.

THOMAS J. SLOAN.

No. 7802.—*Improvement in the Locking Apparatus of Repeating Fire Arms.*

What I claim as my invention, consists in hinging the dog or catch, to the bolt, in combination with so making and applying the recess *i*, and the spring *g*, together, and to the dog or catch, as to cause said spring to perform two functions, or to not only operate the dog or catch, but to operate the bolt, substantially in the manner as above described.

JOSHUA STEVENS.

No. 7803.—*Improvement in Shuttle Motions in Looms.*

I claim the boxes P, P′, oscillating upon fixed points *p*, *p′*, and having the flat bar springs Q, Q′, attached to them, in combination with the chains *c*, *c′*, and the regulating screw *d*, and nut *e*, for giving a more free and easy motion to the picker staves, and for the more effectually controlling and graduating the amount of pick. THOMAS T. WILLCOX.

No. 7804.—*Combined Boiler, Cupola, and Grate.*

What I claim therein as new, and desire to secure by letters patent, is the boiler, descending from the top to the bottom of the cupola, in combination with the removable grate, the water contained in the boiler surrounding the heated iron, and coals, substantially as described. I do not claim the use of the subsidiary grate, but I do claim it, as making a part of the combination necessary to the proper and perfect action of my combined steam boiler and cupola smelting furnace. LOFTIS WOOD.

No. 7805.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is placing one or more ovens between one or more fires on each side in connection with a vertical flue or flues passing between the ovens, separating them, substantially as described. LOFTIS WOOD.

No. 7806.—*Improvement in Machines for Turning Irregular Forms.*

What I claim as original, and desire to secure by letters patent, is the mode herein described, of changing the position of the ratchet R, by means of the arrangement of the sliding rod, knee, lever, lifting plate and pawl.

SMITH BEERS.

No. 7807.—*Improvement in Machines for Boring Dovetailed Mortises.*

What I claim therein as new, and desire to secure by letters patent, is—

Firstly. The rotating cutters (*g*, *h*, *i*, *k*, *l*,) formed and arranged substantially as described, with conical heads and cylindrical necks, in combination with a rest or moveable table, for the reception and attachment of the bed-post, the said table while being advanced towards the cutters, being conducted by suitable guides (*p*, *p′*, *p″*,) as described, either upon the moving table or the stationary bench, in a course which is at first at right angles to the face of the post, and thence, as soon as the cylindrical cutter (*l*,) has begun to act in a longitudinal course, receding sufficiently from the face of the post to form a mortise which shall bind the dovetailed tenons of the rail, as they are pressed down in their sockets.

Secondly. I claim, in combination with the aforesaid guides, the stops (*r*,) substantially as here arranged and applied, or their equivalents, whereby the table is limited in its course, to the particular range of cutting action required for the time being. HENRY I. BETJEMANN.

No. 7808.—*Improvements in the Alarm and Indicator for Steam Boilers.*

What I claim as my invention, and wish to secure by letters patent, is the peculiar method of moving the indicator, by its attachment to the slide valve of the whistle, by which the connection is continued through the head of the boiler, as herein described, dispensing with the stuffing box and packing.

his
JOSEPH + DILKS.
mark.

No. 7809.—*Improved Arrangement of the Bending Roller in Tin Cutting and Bending Machines.*

I claim to so combine and arrange the roller Y, with respect to the jaws E, F, (as specified,) so as to enable the said roller to be operated in the manner substantially as set forth; that is to say, to be moved in a plane parallel to the common axes of the shafts C, D, the said roller being arranged in a turning frame Z, and supported by a moveable and adjusting frame A′: and the object of my improvement being to enable a person to move the roller against the tin, in manner and for the purpose of binding it down, substantially as herein before explained. WM. H. HORTON.

No. 7810.—*Improvements in the Metallic Flask for Casting Large Kettles.*

What I claim as new, and of my invention, is the elastic iron core supporter, or inner part of the flask, constructed of wings attached to the crown, and provided with covering strips, substantially as described.

WILLIAM KELLY.

No. 7811.—*Improvements in Machines for Dressing Spokes.*

What I claim therein as new, and desire to secure by letters patent, is—

First. Constructing a cylindrically rotating cutter head, with a separating joint athwart its middle, and in the plane of its rotation, so arranged as that by the mutual advance or recession (in the direction of their axes of rotation) of the respective sections of the cutter heads, as they traverse the length of the stuff, the cutting edges are adapted to impart the varying outline and form required for the work.

Second. The shafts (9,) and weighted levers (b', b',) in combination with the levers (v'', v'',) and the links (w, w,) or their equivalents, for sustaining in position the tongues (11,) upon the spoke, and the rollers (r, s,) upon the guides, and rendering them self-adjustable, under all the circumstances which can affect them.

ORVILLE MATHER.

No. 7812.—*Improved Nail Plate Feeder and Turner.*

What I claim as my invention, and for which I ask letters patent, is—

First. Giving the alternating motion to the nipper rod, by means of a pair of jaws actuated by the opposite ends of a vibrating beam, one of the jaws being provided with a spring and toggle, which causes it to grasp and release the nipper rod, the whole operating substantially as described.

Second. I claim giving to the said rod its progressive, advancing and slightly retrograde motions, by means of a pair of jaws actuated by a cam and an eccentric, and two springs, substantially as specified.

Third. I claim operating the follower, so that it is raised from the nail plate, and the nail plate from the lower cutting jaw of the machine, by means of a cam, a rock shaft, and a radius bar connected to one end of the follower, substantially as described.

Lastly. I claim transmitting the motion from the nail machine to the feeding machine, by means of a lever beam and connecting rods, when the lever beam is hung upon a cranked centre, and the actuating connecting rod is provided with knob acting upon a flat crank pin, substantially as described in the annexed specification and drawing, whereby I am enabled, with facility, to throw my feeding machinery in and out of gear.

But I do not intend, hereby to confine myself to the particular forms and proportions herein described, provided I construct a machine substantially the same.

MELVILLE OTIS.

No. 7813.—*Improvement in Horse Rakes.*

What I claim as my invention, and desire to secure by letters patent, in my improved horse rake, is the device for raising the teeth simultaneously, to clear them of the hay, and dropping them again, by means of the apparatus, substantially as described, being worked by the draught of the team, when thrown into gear, at the will of the operator.

HENRY W. SABIN.

No. 7814.—*Improvement in Suspender Buckles.*

What I claim as my invention, and desire to secure by letters patent, is

the construction of the buckle frame, and attaching the tongue or points thereto, so that the tongue or points slide out and into the buckle, instead of acting upon a hinge or roller, as above described.

ELISHA STEELE.

No. 7815.—*Improved Auger Handle.*

I claim the construction of auger handles, substantially as set forth in the above specification; that is, by making the principal part of the same, from end to end, of one piece of wood, or material, securing the central portion, through which the auger shank passes, with a metal band, and arranging a detent, for holding the shank, with machinery to operate it, as exhibited in the drawings forming part of this specification, the said handles being for use with augers or any other tools to which it may be adapted.

AUGUSTUS THAYER.

No. 7816.—*Improvement in Vulcanizing India Rubber.*

What I claim, therefore, is the use and employment of zinc, prepared by the process above described, whereby a hyposulphite, or similar preparation of zinc is obtained, in combination with India rubber, for the purpose of curing or vulcanizing it, substantially as herein before set forth, without the use of free sulphur in any way, in combination with the rubber.

JONATHAN T. TROTTER.

No. 7817.—*Improved Balance Boiler Feeder.*

What I claim therein as new, and desire to secure by letters patent, is having the piston B, with compartments and apertures, as described, passing completely through the boiler, and working in double packing boxes in short cylinders c, c, placed on opposite sides of the boiler, substantially as herein set forth.

W. D. ALLEN.

No. 7818.—*Improvement in Buckles for Harness.*

I claim the construction of a trace clasp, as a substitute for a buckle, for fastening together two straps of leather, by the use of a metal tongue fastened to one of the straps, having projecting from it pins or studs fitted to enter into holes to be made therefor in the other strap, the tongue and strap lying one against and upon, or near the other, the tongue and strap to be kept in this juxtaposition, by a slide or box enclosing them, the whole substantially as set forth in this specification.

SOLON BINGHAM, Jr.

No. 7819.—*Improvement in Bearings for Axles and Shafts.*

I claim the combination of the sliding plate E, having a conical seat a, and the conical packing ring F, applied and secured to the journal box of a car or other axle, or of a machine shaft, in the manner substantially as herein described, for the purposes set forth.

WM. H. HOVEY.

No. 7820.—*Improvement in Lever Jacks.*

I claim the hanging of the lever by links which permit the lever teeth to disengage themselves from those of the rack bar, with which they are engaged, by simply raising the lever, and allow them to re-engage with a new set of teeth, when the lever is depressed, substantially as herein set forth. I also claim the method of connecting the pawl with the lever, in such manner, that, by simply working the latter, the rack bar with the weight resting thereon, may be lowered tooth by tooth, substantially as herein set forth.

JAMES LEFFEL.

No. 7821.—*Improvement in Electrotyping.*

I claim to form a heterogeneous substance on the surface of the metallic plate, by exposing it to the action of iodine, bromine, chlorine, or other chemical, capable of forming an insoluble compound with the metal, for the purpose herein set forth.

I also claim to expose the metallic plate to the action of the light, after being acted on by a halogen element, substantially for the purpose of preventing the adhesion of the deposite as specified.

I claim the use of iodine in the electrotype process, in the manner herein substantially set forth, and for the purpose specified.

GEORGE MATHIOT.

No. 7822.—*Improvement in Seed Planters.*

What we claim as new, and desire to secure by letters patent, is the combination with the depositing tube, and the bar which connects said tube with the body of the machine, the joint *m*, *n*, as above described, said joint being of such peculiar construction as to be complete and effective in itself, without any moveable device whatever, and which admits of attaching or detaching said tube at pleasure, without the use of any kind of implement or tool, or separate connecting bolt or fastening, as before described.

SAMUEL PENNOCK.
MORTON PENNOCK.

No. 7823.—*Improvement in Seed Planters.*

What I claim therein as new, and desire to secure by letters patent, is the upper and lower sliding bottoms *n*, *n*, *l*, *l*, in combination with the adjustable side of the hoppers *r*, *r*, operating in the manner and for the purpose, substantially as herein described.

DEXTER B. RHODES.

No. 7824.—*Improvements in Sewing Machines.*

What I claim as my invention, is the combination of two needles, two thread guides and a cloth holder, made to operate together substantially, in the manner and for the purpose as herein before set forth.

And I also claim the improvement of making the needles with springs, and applying mouth pieces or pressers to them, and on each side of the flanch of the base plate, the whole being substantially as above described.

FREDERICK R. ROBINSON.

No. 7825.—*Improvement in the Manufacture of two and three Ply Carpets.*

What I claim therefore, as my invention, and desire to secure by letters patent, in the weaving of two or three ply ingrain carpets, is the employment of parti-colored warp and weft, operated by jacquard or other mechanical means, to form the figure when the same colors in the warp and in the weft, are caused to combine together, to form the same colored figure in the fabric, substantially as described.

ALEXANDER SMITH.

No. 7826.—*Apparatus attached to Vessels for Indicating the depth of Water.*

What I claim as my invention, and desire to secure by letters patent, is the combination of a sounding chain or jointed rod, with an indicator on the deck of a vessel, operated by means of a cord pulley, or other equivalents, so as to indicate the depth of water, whilst the boat is making headway, as herein described and represented.

H. B. SOMMERS.

No. 7827.—*Improvement in Planing Machines.*

I claim, first—the attachment, either whole or in segments, of a narrow circular saw blade to the front of the periphery of an iron or other metallic planing wheel, (properly counter sunk for the purpose,) in combination with the clearing and planing cutters, so that the saw shall be stiffened, and rendered free from trembling, shaking, or running in, and made to cut in advance of the planing cutters to cleanse and level the surface of the plank or timber, that the planing cutters may with facility, produce an extra smooth surface, and be cleared of timber or slab, by the clearing cutters as set forth, the attachment of the saw blade to the wheel being such, by screws or otherwise, that the saw blade may be easily removed or taken off, for the purpose of turning the reverse face to the plank or timber whenever the teeth on one side have become dulled, or out of set from long usage against the timber.

Second. The clearing cutters *n*, *n*, *n*, in combination with the saw and planing wheel, arranged in the manner and for the purposes herein set forth, the whole being arranged in the manner and for the purposes herein set forth and described.

DANIEL H. SOUTHWORTH.

No. 7828.—*Improvement in Elevating, Cooling and Conveying Flour.*

What we claim as our invention, and desire to secure by letters patent, is the method of elevating, conveying, and cooling flour or meal, by passing it by means of a blast through an air-trunk and head, constructed substantially as herein set forth.

JESSE WHITE.
JONATHAN BUNDY.

No. 7829.—*Improvement in Machines for making Pill Boxes.*

What I claim as my invention, is the contrivance for supporting the stick, and feeding each stick forwards towards the cutters, the same consisting of the saddle and orifice, (applied to the rotary block holder,) the endless screw D, the shaft E, the spring G, the bearing plate *g*, fixed to the shaft B, the pinion H, and the stationary gear wheel I, the whole being applied and made to operate together, substantially in the manner as above set forth.

What I claim also as my invention or improvement, is the combination of said saw, with the rotating series of sticks, or their rotating holding frame, substantially in the manner, and so that they shall be successively operated upon by it as specified.

NELSON D. WHITE.

No. 7830.—*Improved Cut-off Motion for Puppet Valves.*

What I claim therein as new, and desire to secure by letters patent, is:

Firstly. Raising and dropping at any desired point, the puppet valves that admit steam to the cylinder by means of a lifter, that vibrates with and upon the usual rock shaft, the said lifter being operated by a gravitating and counterbalancing toggle as described, so that the lifter in the manner described, or its equivalent, is fixed for raising the valve, and is depressed and allowed

18

gradually and easily, to drop the valve when the counterbalance of the toggle is operated by the adjustable stop, substantially as herein described.

SAMUEL H. GILMAN.

No. 7831.—*Improvement in Seed Planters.*

What we claim as new and of our invention, and desire to secure by letters patent, is dividing the drill teeth or depositing tubes into two separate sections G, H, and hinging or connecting the two sections at their upper ends, in such a manner as to permit the longest or rear section H, to recede, or turn on its connecting pin *a*, while the upper or short section retains its proper position in relation to the drag bar and flexible conducting tube, and providing the upper or short section G, with two arms J, J, having notches therein, which, when the two sections of the drill tooth are closed, become co-incident with a notch formed in an arm K, projecting from the rear or longest section H, into which is inserted a wooden pin, which it is intended shall break when the rear or longest section of the drill teeth, shall strike against a rock or other obstruction, and thus separate the sections, and permit the longest section H, to recede and clear itself from the obstruction, whilst the flexible conducting tube is held in its proper position by an oval loop on the inside of the section G, herein fully set forth and represented.

Second. We also claim, providing the clutch plate R, with an additional row of teeth (*l*,) adjacent to the side beam of the frame, for engaging with a tooth T, projecting therefrom, for arresting the motion of the seeding rollers simultaneously with unlocking the axle from the propelling wheel, and thus stop the operation of the machine, as fully set forth.

JOHN SIGNER.
T. N. SHEPTON.

No. 7832.—*Improvements in Mills for Sawing with Circular Saws.*

What I claim as new and of my invention, and desire to secure by letters patent, is—

First. The springs G, and G′, carrying the journal boxes *g*, and *g′*, attached and arranged in the manner substantially as herein described, for the purpose of guiding the saw, but at the same time allowing a sufficient degree of end play to the spindle, to admit of its accommodating itself to the lateral springing of the log.

Secondly. Arranging the saw N, and its spindle M, on the swinging frame H, H, which is adjustable, so as to bring the saw N, in any required position in a line forming part of a circle round the axis of the saw D, and adjusting the said saw N, either in a line with, or to the right or left of the saw D, by means of the slot in the spring G′, through which the bolt *b*, passes, in the manner herein described, or in any manner substantially the same.

ORLANDO CHILD.

No. 7833.—*Improvement in Machinery for Doubling and Twisting Silk, &c.*

What we claim as new, and desire to secure by letters patent, is so constructing the catch bar, that all the threads or silk, either before or after being twisted, may be secured by the catches simultaneously, by simply bringing the bar with its catches down upon the threads, and whilst in that position causing all the helical springs to act on the catches at the same time, by suddenly disengaging the slide lock plate from the end of the bar, the mortises in the said

plate, being so formed as to allow each catch to be opened separately, without the aid of the lock plate, or all to be opened simultaneously by moving said lock plate longitudinally, in the manner herein fully set forth.

JOSEPH CONANT.
LUCIUS DIMOCK.

No. 7834.—*Improvement in Apparatus for emptying Privies.*

What I claim as new therein, and which I desire to secure by letters patent, is the gasometer, connected with the receiver, as described, for the purpose of keeping the gases separated from the fecal matter, and preventing their mixture as set forth, and serving also as a reservoir for the compressed gases, from which the power for expelling the contents of the reservoir is obtained.

FLORIMOND DATICHIY.

No. 7835.—*Improvement in Carriages.*

What we claim as new therein, and desire to secure by letters patent, is the joint on which the fore carriage turns when placed in rear of the fore axle, in combination with the segment on which the end of the perch rests, substantially as described, for the purpose of allowing the carriage to be turned in a small space, without having the fore wheels to run under the body, or interfere with the hind wheels.

EDWARD EVERETT.
CHARLES EVERETT, Jr.

No. 7836.—*Improvements in Machinery for Cutting and Bending Sheet Metal.*

I claim the improvement in the bending mechanism, the same consisting in the combination of the conic or approximately conic roller or projection *n*, with the cylindric part or roller *m*, and with the circular discs or holders, in the manner as above described, and so as when pressed against the tin to gradually bend it over and down upon the disc or holder C, so as to enable the roller *m*, to pass over and upon the tin, and complete the bending of it down upon the periphery of the holder.

I also claim the improvement in the construction of the gauge B, whereby it is adapted to operate when the tin plate is rotated in a vertical plane, such improvement consisting in arranging its supporting journal at an inclination to the horizontal plane, and applying a weighted arm or its mechanical equivalent, to the gauge, as seen in the drawings, or so that the gravitating power of the weighted arm shall restore the gauge to its original and proper position under the holders, after it has been freed from the pressure of the surplus tin, or part removed by the cutters.

JOSEPH F. FLANDERS.

No. 7837.—*Improvement in Seed Planters.*

What I claim as my invention, and desire to secure by letters patent, is the peculiar construction of the adjustable shovels N, to clear the mouth of any obstructions. I also claim the mode and manner of sowing the grain through the slots, as herein described.

JOSEPH W. FAWKES

No. 7838.—*Improved Expansion Gear for Horizontal Engines.*

What I claim therein as new, and desire to secure by letters patent, is withdrawing the sliding tongue of the lifter of the supply valves of steam cylinders, so as to trip the valves at any desired point, by an adjustable prong, which is made to slide upon the arm holding the usual fixed prong, by the action of a tappet on the rock shaft, when this adjustment is effected by means of the shackle and links within the steam chest, the shackle and links being elevated or depressed by an index arm without side of the steam chest, and the whole being arranged and operating, substantially as herein described.

SAMUEL H. GILMAN.

No. 7839.—*Machine for making Eyelets.*

What I claim as my invention, and desire to secure by letters patent, is the sliding bolster, constructed with its two dies *c*, and *e*, and aperture *n*, in combination with the feeding tube, punches, and clearers, the whole being constructed, arranged and operated, substantially in the manner and for the purpose herein set forth.

L. E. HICKS.

No. 7840.—*Improvement in Grain Cradle Fingers.*

What I claim as my invention, and desire to secure by letters patent, is the insertion of a metallic plate into the edge of a cradle finger, by means of rivets and other fastenings, so as to keep the plate and finger permanently attached together, and in their place, and thereby effectually prevent the finger from straightening or springing back, when used in damp grain, prevent the grain from wearing it away, and prevent the grain from sliding endwise off the cradle, before the cradler gets it round into its own swath.

JOEL HOUGHTON.

No. 7841.—*Improved Sash Fastener.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the cam with the plate, when these are combined with the shaft C, and lips B, for turning back the cam when necessary, and locking it to fasten down the lower sash, when the whole is constructed, arranged, and combined, substantially as herein described.

WILLIAM H. LAZELLE.

No. 7842.—*Improved arrangement of Steam Engine.*

What we claim as our invention, and desire to secure by letters patent, is the arrangement herein set forth, of the beams, connecting rods, and cranks, of the two cylinders of a double cylinder engine.

RICHARD F. LOPER.
JOHN W. NYSTROM.

No. 7843.—*Improved Composition for making Cores for Casting.*

What I claim therein as new, and desire to secure by letters patent, is the use of white of egg, as a component in the preparation of loam, for cores and other similar things, intended for contact with molten metal, in the manner herein described, limiting myself to that use of white of egg, but not limiting myself to the precise proportions mentioned, while the same result is obtained by the said addition to the ingredients ordinarily used in loam for cores.

EDWARD REES.

No. 7844.—*Improvement in Mills for Grinding.*

What I claim, is hanging the bed stone, (when the shaft or spindle to which the runner is attached, passes through the same,) by means of the before described universal joint, in combination with the lever and screw, as aforesaid.

JOHN ROGERS, Jr.

No. 7845.—*Improvement in Oscillating Seeding Cylinders.*

What I claim as new, and of my invention, and desire to secure by letters patent, is oscillating the seeding cylinder H, upon its axis, for the supply and discharge of the seed as described, by means of the combination of the lever L, spring N, and pins M, with the propelling wheel B, as described.

DAVID E. ROHR.

No. 7846.—*Improved Instrument for laying down Curves of Ships' Timbers.*

What I claim as my invention, and desire to secure by letters patent, is the adjustable mould, constructed substantially as herein set forth, so that it can be set to the outside and inside curves of the timbers of a vessel, and can then be used to mark them upon the wood, of which they are to be formed.

CHARLES SCALES.

No. 7847.—*Improvement in Artificial Legs.*

What I claim as my invention, and desire to secure by letters patent, is the application of the whole action from the heel up to the knee joint in the artificial leg, which action prevents the knee joint from turning, slipping, or revolving out in the act of stepping, as herein described, using for that purpose the aforesaid springs, rod, lever, and pins, or any other substantially the same, and which will produce the intended effect.

W. C. STONE.

No. 7848.—*Improvement in Lamps for lighting Gas Burners.*

What I claim as my invention, is the protector, as made and applied to the lamp, and so as not only to be capable of exploding or inflaming the gas brought into contact with it, substantially as specified, but of protecting fibrous matters which may come in contact with the protector, from direct exposure to the flame.

ROBERT THOMPSON.

No. 7849.—*Improvement in Fanning Mills.*

What I claim therein as my invention, and desire to secure by letters patent, is the supporting and regulating the motion of the sieves *g*, *f*, by means of the rollers *c*, *c*, or their equivalents, and the spiral springs F, F, so arranged as to press the shoe, or sieve frame A, down upon the rollers, steadying its motion, and to a certain extent preventing any jar at the end of each vibration, substantially in the manner and for the purpose as herein set forth.

E. BLISS.

No. 7850.—*Improvement in the Manufacture of Starch from Maize.*

What I claim therein as new, and desire to secure by letters patent, is the method, substantially as described, of extracting from maize, and other grain or seeds subject to rapid putrescent decomposition, that portion of the starch which is inextricable, either by mechanical means, or by fermentation of the meal, by the subjection of the unbroken grain to an incipient germination, which is arrested at that stage of the vegetative action at which the starch that exists in the insoluble combination, being liberated, is capacitated for precipitation along with the free starch, by any of the usual processes of maceration and elutriation.

THOMAS BRAGG.

No. 7851.—*Improvement in Dampening Paper for Copying Presses.*

I do not confine myself to the employment of sheet metal as a material for my dampening tablets, as many other impermeable materials are well suited to the purpose, but what I claim as my invention, and desire to secure by letters patent, is a dampening tablet, constructed substantially as herein described, of some impermeable material.

GEO. BURNHAM.

No. 7852.—*Improved means for preventing back-lash in the Feed Motion of Planing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the combination in the travelling table motion of planing machines, of two racks L^1, L^2, sheets 1 and 2, operated on by two separate pinions M, N, one of which is made adjustable, shown by set screws *m*, *m*, *m*, *m*, with accompanying parts, and so arranged that the pinions M, N, may be set as to alternately operate, the one to drive the table forwards, and the other to drive it backwards, for the purposes herein set forth, and operating as shown and described, or in any manner substantially the same.

THOMAS H. BURRIDGE.

No. 7853.—*Improvements in Hydraulic Blowers.*

What I claim as new therein, and which I desire to secure by letters patent, is—First. The apparatus, substantially as above described, consisting of a revolving drum, partly filled with water, and provided with chambers, valves, &c., which cause the air to enter at one hollow journal, and escape in a compressed state at the other, for the purpose of producing blast, as set forth.

Second. I claim the manner of separating the water accidentally mixed with the blast, by means of the partitions and cells in the chambers (*l* and *n*.)

Third. I claim the pipe (*u*,) for conducting the water accumulated in the chamber (*n*,) to the hollow journal (*c*,) and returning it to the drum, substantially as described.

JEREMIAH DARLING.

No. 7854.—*Improvements in Vats for Tanning Hides.*

What I claim as of my own invention, and which I desire to secure by letters patent, is the slats, as described, in combination with the vat and the handler, substantially in the manner and for the purposes as herein set forth.

LEWIS C. ENGLAND.

No. 7855.—*Improvements in Printing Presses.*

What I claim as my invention, and desire to secure by letters patent, is—

Firstly. The combination of the rocker shaft C, and rocker arm D, and the fork lever A, with the swing platen, substantially in the manner and for the purpose herein set forth.

Secondly. I claim for feeding cards, the slide *k*, and rods *m*, in combination with the swing platen, substantially in the manner and for the purpose herein set forth.

Thirdly. I claim the combination and arrangement of the gauge *s*, the spring *u*, the lever *v*, the trip *w*, the catch *x*, and the wire *y*, with the swing platen, in the manner and for the purpose herein described.

Fourthly. I claim the knees *c*, to support the inking rollers, in combination with the spiral springs *h*, the rods *f*, the plate *l*, and the set screws *k*, substantially in the manner and for the purpose herein set forth.

CHARLES W. HAWKES.

No. 7856.—*Apparatus for Operating Window Blinds and their Slats.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the shaft P, having two levers J, G, thereto attached, with the connecting rod L, attached to the blind or shutter, the whole arranged substantially as herein described, and constituting a blind or shutter opener.

I also claim, in combination, the hollow shaft I, having a lever D, at one end of the same, and two arms B, H, at its other extremity, the bolt A, with its bracket N, and slot Q, and the two pins C, C, attached to the blind rod E, the whole forming an apparatus for working the slats and fastening the blind, when closed, substantially as herein described.

JOHN JONES.

No. 7857.—*Improvement in Attachments to Pumps for agitating the surface of the Water in the Well.*

What I claim therein as new, and desire to secure by letters patent, is the application of a series of floating blades to the rod that operates the plungers of pumps for cisterns or wells, for the purpose of agitating the surface of the water, and this I claim, whether the blades and rod are reciprocally prepared, in the manner described, or in any other equivalent way to effect the same purpose.

W. D. MAYFIELD.

No. 7858.—*Improvement in Instruments for Vaccinating.*

What I claim as my invention, is the sliding lancet B, when in combination with a cylinder A, charger E, piston H, and springs J, K, in the manner and for the purpose above set forth.

HENRY MELLISH.

No. 7859.—*Improved method of loosening Metallic Cores from Hollow Castings.*

What I claim as my invention in the above described mode of casting, is the application of cold water to the core or inner metallic flask of a hollow casting, when the metal begins to cool, so as to loosen the core (by the contraction caused by the action of the water,) sufficiently to remove it without injury to the casting.

JOHN C. PARRY.

No. 7860.—*Improvement in Portfolios.*

What I claim as my invention, and desire to secure by letters patent, is the roller back, in combination with the strings stretched thereon, the device, or its equivalent, at the ends, for securing and for tightening or loosening the strings, and the binders, to secure the sheets in their proper places.

JAMES SHAW.

No. 7861.—*Improvements in Looms for weaving Figured Fabrics.*

What we claim, and desire to secure by letters patent, is the improvement on the jacquard loom, as herein described, to wit: the horizontal harness, shafts or bars, of such length as may be desired, (according to the width of the cloth) upon which the several mail cords or heddles, which constitute the harness or entire mounting, are distributed, at any required distance from each other, together with their hooks, pins, loops or holes, upon or in which the several mail cords or heddles, which are caused to be raised or operated upon by one needle or distinct movement, are separately fastened or attached.

We also claim the improvement for producing the rotation of the pattern prism; the same consisting in combining with the machinery which advances the pattern prism, other mechanism, which at the same time, shall produce a movement of the draw pawl in an opposite direction, as described.

S. T. THOMAS.
EDWARD EVERETT.

No. 7862.—*Improvement in Mills for Grinding.*

What I claim therein as new, and desire to secure by letters patent, is the combination of the hollow spindle A, feeding tube E, and adjustable screw *a*, with the gimbal *i*, when said gimbal is placed above the openings through which the grain, or other material to be ground, passes to the surfaces of the stones, as herein fully set forth and represented, for the purpose of having an uninterrupted feed through and past the gimbal.

JOSEPH N. WALKER.

No. 7863.—*Improvement in Hot Air Furnaces.*

What I claim as my invention, and desire to secure by letters patent, is the annular flue between the cylinder of tubes, and the external casing of the furnace for the purpose of distributing the heat, equally over the external casing, substantially as described.

I also claim the distributor or annular distributing chamber, provided with arched passages, for the purposes of carrying the heat and products of combustion to the exit chamber, and which also admit of the free circulation of the external air in and around the fire-pot, substantially in the manner and for the purpose described.

GEO. E. WARING.

No. 7864.—*Improvement in Machines for Weighing Grain.*

What I claim as new, and desire to secure by letters patent, is the employment of the gate rod (*f*,) connecting to the sliding gate (*e*,) and weighing beam (*d*,) in combination with the said sliding gate and weighing beam, constructed and operating as aforesaid, for opening and closing the gate, to admit the grain to the dish or scale, or exclude it therefrom at the required periods, by the ascent and descent of the dish or scale, during the operation of weighing and discharging the grain, as herein fully set forth.

I also claim the manner of attaching the vibrating weighing scale *l*, to the weighing beam *d*, so that the said weighing scale, as soon as the required quantity of grain shall have entered it, shall descend and close the gate, and bring the hammer end *j*, of the gate rod against the lip of the dish or scale, and cause the scale to turn on its centre *m*, and discharge its load of grain, and immediately ascend and strike the gate rod and re-open the gate, and assume its former position for another weight of grain; every operation of the weighing apparatus being indicated by an index of the ordinary construction affixed to the end of the scales, the said scale being arranged below a hopper of the ordinary construction.

I likewise claim turning the short end of the weighing beam upwards, in the manner represented in figure 1, and placing the arms to which the bale of the scale are suspended, on a line drawn through the fulcrum of the weighing beam, forming an angle of about fifty degrees, with a horizontal line passing through said fulcrum, for the purpose of increasing the leverage of the short arm of the beam simultaneously with diminishing the leverage of the long arm as the scale or weighing dish descends, by which the gate is acted upon with increased speed and force, enclosing the same.

S. R. WILMOT.

PATENTS RE-ISSUED DURING THE YEAR 1850.

No. 158.—*Improvement on the Carding and Spinning Machines denominated the Card Spinner for Manufacturing Yarn from two or more different Materials at the same time.*

What I claim as new, and desire to secure by letters patent, is the combination by which the said composition, thread, or yarn is produced as above described, consisting of the delivering rollers *b*, and *c*, between which the covering material and the thread to be covered, come in contact as described, combined with the said doffer cylinder *a*, the spindle *d*, for twisting the thread while it is in contact with the covering material and the spool *g*, supplying the thread to be covered, all as described and represented in this specification, and the accompanying drawings or their mechanical equivalents in like combination, and for the purpose set forth.

R. S. STEUART,
Ex'r of Geo. Law.

No. 159.—*Improvement in Churns.*

What I claim as my invention, and desire to secure by letters patent, is the series of parallel floats or beaters (*a*, *a*,) formed and arranged within the agitator, substantially as above described, so that when their motion is reversed, their thick inclined rear edges, will gather the butter into a roll in the centre of the agitator, substantially as herein set forth.

Z. C. ROBBINS.

No. 160.—*Improvement in Cooking Stoves.*

Having thus fully described my improvements, what I claim as my invention, and desire to secure by letters patent, is the moveable back plate (*h*,) for contracting the fire, and protecting the oven plates, as herein set forth: and I wish it to be understood, that I do not claim the employment of double plates at the back of the fire, when such plates are stationary, but only when made moveable; so that the front and top plates of the oven are always protected back as far as the flanch on the moveable plate extends.

I also claim, in combination with the elevated fire chamber, and projecting oven under a part of said fire-chamber, the ash-pit, formed by projecting the bottom and sides of the stove under the sunk hearth, which is level with the bottom of said fire chamber.

JAMES ROOT.

No. 161.—*Improvement in Curry Combs.*

Having thus fully described my invention, what I claim as new, and desire to secure by letters patent, is combining the trough shaped bars (*a*,) which have the comb teeth on their edges, with the folded strips of metal (*b*,) and with the wires (*c*,) running through them, in the manner substantially as herein set forth, so as to form a curry comb with open or hollow back. I do not claim, separately, either trough shaped comb bars, or combs with open backs, but only in the combination herein set forth.

I also claim the shank, constructed with the fastening hole therein, made without drilling or welding, and combined with the comb as herein above described, so as to act as guards to the ends thereof.

WILLIAM BEACH.

No. 162.—*Improvement in Distilling Apparatus.*

I do not claim the use of charcoal as an absorbent of the essential oil, nor of the process of passing the vapors from the boiling liquid, through successive masses of a rectifying substance, neither do I claim the condensation of the aqueous vapor, by passing the ascending vapors through chambers cooled below the boiling point of water, nor the flavoring of a spirit by passing its vapor through any particular flavoring substance, as I am aware that all these things have been long since done.

But what I do claim as my invention, and desire to secure by letters patent, is the particular construction and arrangement of the rectifier, as herein set forth; that is to say, first—constructing the rectifying chambers and water cases with charging holes, substantially as herein set forth, by which means the various substances employed to rectify, or to flavor the spirit, can be easily charged into or discharged from any one chamber without dismounting the apparatus, or removing the substances in the other chambers.

Second. The particular form of the rectifying chambers, which are made of the frusta of two cones united at their bases, the upper forming the condensing surface of the aqueous vapor.

CHARLES A. KRECHLER.

No. 163.—*Method of Attaching a Ball to a Cartridge.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of attaching or joining to a ball, a cartridge, made of wood or other equivalent material, in manner substantially as herein described.

WALTER HUNT.

No. 164.—*Loaded Ball.*

What I claim as my invention, and desire to secure by letters patent, is making metallic balls for fire arms, with the rear part thereof cylindrical, and a cavity in the said cylindrical part of sufficient capacity to receive the entire charge of gunpowder, substantially as herein described, when the said charge is retained in the ball by a cap or the equivalent thereof, having a central hole through which the charge can be inflamed, substantially as described.

WALTER HUNT.

No. 165.—*Machine for cutting the Threads of Wood Screws.*

What is claimed as new, and desired to be secured by letters patent, is—

First. In combination with the shaft or mandrel, which gives the rotary motion to the screw blank, the employment of the rotating wedge formed cam, or the equivalent thereof, for determining the pitch of the thread, and for permitting the return motion to repeat the operation, substantially as described.

Second. Causing the chaser or cutter at each successive cut to approach nearer to the axis of the screw blank, by means of a revolving conical cam, which at each successive operation acts by a greater radius, substantially as described.

Third. Governing the motions of the chaser or cutter, to make the core or body of the screw, of a conical or tapered form along the whole or any part of its length, by combining therewith a cam of gradually enlarged diameter, substantially as described, the form of such cam depending on the form intended to be given to the core or body of the screw.

Fourth. Combining the cam which determines the form of the core or body of the screw, to make it tapering or conical in whole or in part, with the chaser or cutter, by means of a rock shaft and adjusting lever, substantially as herein described, the said adjusting lever being interposed between one of the arms of the rock shaft, and the face of the cam, so that by the use of a set screw or other analogous device, the cutter or chaser may be readily set, as described.

Fifth. Shifting the cam which determines each successive cut of the chaser or cutter, by combining therewith a ratchet movement, operated by an eccentric or cam, the wheel of the ratchet being provided with pins which operate a lever connected with the cam to shift, substantially as described.

Sixth. Disconnecting the shaft or mandrel from the driving power, at the end of each complete operation of the machine, by combining the clutch or the equivalent thereof, with the ratchet by means of an index wheel or perforated rim, which, at the required periods liberates or acts upon the connections of the clutch to disengage it, substantially as described.

Seventh. Making the chaser or cutter for chasing or cutting the threads of wood screws by machinery, with a groove of the form of the thread in its cutting face, and in the direction of its length, substantially as described, whereby the said chaser can be sharpened, by simply grinding off at the end, and without changing the form of the groove, and whereby also, the said chaser cuts on both sides of the thread, and finally on the edge thereof, as described.

CULLEN WHIPPLE.

No. 166.—*Improvement in Cooking Stoves*

What I claim as my invention, and desire to secure by letters patent, is—

First. Making the back of the oven, of a series of vertical flue tubes, in combination with the flue tubes in the bottom, substantially as herein described, to equalize the heat of the oven.

Second. I claim lining the inside surface of the bottom plate of the stove, with some refractory earthy cement or polished substance as described, in combination with the series of flue tubes constituting the back and bottom of the oven, for the purpose and in the manner substantially as described.

Third. I claim making the front part of the top plate separate from, and attached to the top plate by bolts or otherwise, substantially as described, when combined with the sunken connecting piece (*h*,) whereby the cracking consequent upon overheating and unequal expansion and contraction of that part which is exposed to a high temperature is prevented.

Fourth. I claim the combination of a fire box, made with a grate or openings for draught in the bottom thereof, substantially as described, with the coal feeder having an aperture or apertures for draught, between it and the upper edge of the fire pot, substantially in the manner and for the purpose above described. I am aware that a series of hook formed wipers playing between the grate bars, and arranged on a shaft, have been heretofore patented, for clearing the grates of an iron furnace, but these can only be turned in one direction, by reason of their hook form, and on this account, are not practically useful. I do not therefore, claim broadly the use of cam formed wipers, unless they are so formed that they can be operated in opposite directions, but

I do finally claim, in combination with a grate, a series of eccentric plates or cam formed plates, of equivalent form, arranged on a shaft, so located relatively to the grate bars, as by the vibration of the shaft in either direction, the said plates shall play between the grate bars, and separate and clear out cinder, slag, and other hard substances, substantially as herein described.

JORDAN L. MOTT.

No. 167.—*Improvement in the method of Rendering Lard.*

What I claim as my invention, and desire to secure by letters patent, in the above described apparatus for extracting or rendering lard, &c., by the action of high pressure steam, is combining with a steam tight tank, substantially such as herein described, and provided with one or more discharge holes, for the discharge of the residuum, and with a perforated steam pipe at bottom, for the introduction of high pressure steam, a perforated false bottom above the steam pipe, to sustain the charge under the weight and pressure, substantially as described, to admit of and insure the free passage of the steam thro' the charge, and also the free descent of the water of condensation, as described.

I also claim, in combination with the tank, substantially such as herein described, the employment of one or more try cocks near the top thereof, and a regulating discharge cock at or near the bottom, substantially as herein described, for the purpose of ascertaining when too much water of condensation has accumulated, and to discharge the same, to retain a sufficient space above for steam, to insure the passage of steam through the charge, as described.

And finally, I claim, in combination with a tank, substantially such as herein described, and for the purpose specified, the employment of a series of discharge cocks, arranged at different levels, substantially as described, for the purpose of drawing off the rendered lard, &c., as it floats on the water of condensation, and thus insure the separation of the pure lard, &c., from all foreign substances, when this is combined with the relief or discharge cock, substantially as described.

EBENEZER WILSON.

No. 168.—*Improvement in Pumps.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the nozzle with the pump barrel, in such a manner that the nozzle can be readily changed from side to side, and secured in any desired position, substantially as herein represented and described.

I also claim the manner of connecting the induction pipe J, the valve *n*, and its seat E, with the base D, of the pump, without the aid of rivets or solder,

and in such a manner that when the base of the pump has been securely fastened to a platform, the respective parts of the pump, as also the induction pipe, can be combined with the base, or detached therefrom, without disturbing its fastenings, to wit: by means of the cup rising from the centre of the base D, which has a screw cut in its inner periphery, and a hole in the centre of its bottom, through which hole the induction pipe J, is inserted, and enlarged by a mandrel; the metallic disk E, placed within the said cup, with the tube S, descending therefrom, inserted into the upper end of the induction pipe; the leather disk *t*, from the centre of which the valve *n*, is cut, placed on the disk E, and the whole securely combined with each other, by inserting the screw formed in the outer periphery of the lower end of the pump barrel, within the screw thread formed in the inner periphery of the base cup, and turning the pump barrel until the lower end thereof forces the above enumerated parts into the position represented in fig. 2.

BIRDSILL HOLLY.

No. 169.—*Improvement in Feeders for Screw Machines.*

What I claim as my invention, and desire to secure by letters patent, is

First. The method, substantially as described, of arranging screw blanks, &c., by the motion of oppositely inclined beveled or curved surfaces, with sufficient space between them to receive freely the shanks of the blanks, whilst they hang suspended by their heads, the said motion of such surfaces being in the direction of the space between them, substantially as described.

Second. Making one of the said inclined beveled or curved surfaces in two parts, one above the other, substantially in the manner and for the purpose specified.

Third. Combining with the said oppositely inclined beveled or curved surfaces, a fence or guard plate, placed across, from the one towards the other, and over the space in which the blanks are suspended, substantially in the manner and for the purpose specified.

Fourth. In combining with oppositely inclined beveled or curved surfaces, revolving arms, wings or beaters, substantially in the manner and for the purpose specified.

And lastly. In combining with the said oppositely inclined beveled or curved surfaces, a checking and delivering apparatus, substantially in the manner and for the purpose specified.

SOLYMAN MERRICK.

No. 170.—*Improvement in Planing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the lever frame B, B, B, B, cam wheel J, and plane stock G, substantially in the manner described, by means of which combination, and the configuration of the cam wheels, substantially as specified, and the plane stock, which is made to move in a different and lower line, during its forward stroke, than during its backward stroke, in the manner and for the purposes described.

Second. The combination and arrangement of the tonguing and grooving planes W and X, running with the slides *y*, *y'*, and the mode of adjusting the same, in combination with the surface plane G, the cam wheels J, and levers B, B, B, B, substantially in the manner specified, for planing, tonguing and grooving boards and plank, at one operation.

And finally. The mode of contracting and expanding the grated bed, in the manner specified, in combination with the tonguing and grooving planes.

CALVIN EMMONS.

No. 171.—*Improvement in the Machine for Boiling and Washing rags for Manufacturing Paper.*

What is claimed, is the herein before described process of preparing materials for making pulp in the manufacture of paper, by digesting them in a turning vessel with an alkaline solution or other liquid, the heat being applied to the outside of the vessel, or by steam introduced within it, substantially as herein set forth.

JOHN CAMPBELL,
Assignee of the whole right of the late George Spafford.

No. 172.—*Improved concealed Trigger for Fire-arms.*

What we claim as of our own invention, and which we desire to secure by letters patent, is the construction of a concealed trigger, capable of being disclosed and made ready to operate by simple pressure imparted by the hand to its rear end, as described herein.

JACOB PECARE.
JOSIAH M. SMITH.

No. 173.—*Improvement in Harvesters of Clover Heads and other Grain.*

What I claim as my improvement, and desire to secure by letters patent, is:

First. The combination and arrangement of the transverse pendant finger bar I, the mortised right angled plates F, the adjustive slide bars G, and knife or cutter K, with the revolving axle-tree of spring conveyer bars P, arranged and operating in the manner described, by which the heads of clover, wheat, and other description of grain, are severed from the stems or stalks, and delivered into a receiver.

Second. I also claim the combination of the right angled rods L, fingers J, and pendant bar I, with the transverse timber N, for adjusting the knife K, and fingers J, longitudinally and vertically in connection with the spring conveyer bars P, as described and represented.

JOHN HINTON.

No. 174.—*Improvement in Cooking Stoves.*

What I claim therefore, and desire to secure by letters patent, is:

First. The heating chamber in front of the oven, in combination with the arrangement of direct and return flues at the bottom and back of the oven, substantially as described, for the purpose of imparting an equal or nearly equal heat to the oven as described.

And secondly. I claim in combination with the heating chamber in front, and the arrangement of direct and return flues at the bottom and back, substantially as described, the extension of the oven under the open hearth or apron of the stove, substantially as described, whereby the capacity of the oven is increased, relatively to the other parts of the stove, and at the same time heated equally or nearly so, as described.

DARIUS BUCK.

No. 175.—*Improvement in the manner of constructing the Truss Frames of Bridges and other Structures.*

What I claim as my invention, and desire to secure by letters patent, in the construction of truss frames, is the method of uniting the upper and lower stringers without attaching them to the interposed timbers by the combination of the straining blocks, with the timbers interposed for keeping the stringers apart, and the tension rods for drawing them together, substantially as described, whereby the camber can be regulated with facility along the whole or any portion of truss, as described.

WM. HOWE.

No. 176.—*Improvement in Stoves.*

Having thus fully described my improvements in stove furnaces, &c., what I claim as new therein, and which I desire to secure by letters patent, is the air chamber, in which the air is heated previously to its admission to the fuel in combination with the apertures, by which the heated air is caused to impinge on the upper surface of the fuel, substantially in the manner, and for the purposes as described.

ANSON ATWOOD.

No. 177.—*Improvement in Brick Presses.*

What I claim as my invention, and desire to secure by letters patent, is the making the moulds C, C, of extra depth, in combination with the elevation of the bricks in the moulds, after they have been pressed a distance equal to the extra depth given to the same, and there moval of the surplus thickness of the bricks, raised above the tops of the moulds, by a knife or its equivalent, for the purpose of giving uniform solidity and perfection of form to the bricks, prior to their final removal from the moulds, substantially as herein set forth.

ISAAC GREGG.

No. 178.—*Improvement in Printing Presses.*

I claim a platen raised and lowered by machinery, substantially as above described, in combination with the moveable tympan plate on which the sheet of paper is placed, and the bed supporting the type with their faces downwards, the whole being arranged and operating together, substantially in the manner, and for the purpose herein explained and set forth.

I claim supplying the press with paper, and removing the same after it is printed into a box, in fig. 6, attached to the tympan carriage, by means of a vibrating table g', h', (operated by a cam a', fig. 4, on the shaft I, figs. 4 and 6, in combination with a frisket constructed as above described, connected to the frame g, g, of the tympan plate, and pressed down upon said plate by a spring j^2, k^2, and raised when the tympan carriage recedes with the printed sheet by means of a cam o', fig. 2, on the shaft I, through the intervention of a bar w', with a roller v', shaft y', and angular piece of metal a^2, the whole being arranged and operating together, substantially as herein above explained and set forth.

I claim grooving or channeling the fountain roller or plate under the same, in the manner and for the purpose above mentioned.

I claim the peculiar combination of machinery, for the lateral vibration of the distributing roller; said combination consisting of the pulleys v^2, on the shaft B, band w^2, pulleys x^2, rod y^2, z^2, lever a^3, b^3, c^3, rod e^3, f^3, shaft g^3, and distributing roller frame o^2, the whole being arranged and operating together, substantially in the manner and for the purpose above mentioned.

I claim the use of the side strips c^2, d^2, c^2, d^2, and cross strips e^2, f^2, or either of them, in combination with a tympan supported by the platen plate, the said combination forming a pair of nippers, as it were for rigidly holding the sheet, however small the margin may be, until it is effectually free, or disengaged from the form after an impression is produced.

STEPHEN P. RUGGLES.

No. 179.—*Improvement in Shanks of Door Knobs.*

What we claim as our invention, and desire to secure by letters patent, is the method of making the shank for door knobs in two pieces, coupled together near the middle by a notched connection, and held together by means of the escutcheon at one end, and the latch bolt B, (or by the tumbler B′, that operates a latch bolt) at the other, substantially as herein described.

We also claim the constructing the keeper H, and the lever fastener J, of such shape and proportions, that the keeper can be reversed in its position upon the latch plate A, and the lever fastener be reversed in its position in relation to the keeper, for the purpose of adapting our improved locks or latch to doors, opening either to the right or to the left, substantially as herein set forth.

We also claim the connecting the respective shanks of the knobs to each other, and to the lock or latch, by means of the tooth in the halved portion of one shank, fitting into an aperture in the halved portion of the other, and the two being confined to each other by the tumbler *i*, the tube F, projecting from the side of the lock or latch, and the escutcheon E, secured to the door, substantially in the manner herein set forth.

L. R. LIVINGSTON.
JOHN JAY ROGGEN.
CALVIN ADAMS.

No. 180.—*Improvement in Mills for Grinding.*

Having thus described the construction and operation of our bark mill, what we claim therein as our invention, and desire to secure by letters patent, is the vibratory motion given to the concave, substantially in the manner herein set forth.

SIDNEY A. BANTZ.
WILLIAM ANDREW.

No. 181.—*Improvement in Portable Furnaces.*

I claim as my invention, the construction of a portable furnace, by which it may be connected with a stove, in the manner described, that is, a furnace adapted to the boiler, or other hole of a stove, with a downward draft, or diving flue for the escape of the smoke, through the bottom into the stove, substantially in the manner and for the purposes set forth.

MERRITT F. POTTER.

No. 182.—*Improvements in Machinery for turning Irregular Forms.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the cutter wheel or saws, so as to cut in the direction of the grain of the wood or other substance to be formed, when this is combined with the rotation of the pattern, and substance to be formed during the operation of the cutters, substantially as described.

I also claim the rotating cutter wheel, constructed substantially as herein described, of a series of circular saws, secured in an inclined position to an arbor which carries them, as herein set forth.

TIMOTHY CLARK.

No. 183.—*Improvement in the manner of constructing Railroad Carriages, so as to ease the lateral motion of the bodies thereof.*

What we claim, is connecting the said turning bearing to the truck frame of the above described kind, resting on four wheels or more, by a mechanism, substantially such as described, that shall not only allow such turning bearing independently of the wheels and axles, a lateral play movement or movements, in directions transversely of the carriage, but bring or move it back to its central position after the lateral deflective force has ceased to act.

CHARLES DAVENPORT.
ALBERT BRIDGES.

ADDITIONAL IMPROVEMENTS.

No. 93.—*Improvement in Ice Cream Freezers.*

What I claim, and desire to secure by this additional improvement, is first, the spring blade or scraper, constructed and employed as above described.

H. B. MASSER.

No. 94.—*Improvement in separating Stearine from Elaine.*

What I claim as my additional improvement and desire to secure by letters patent, is the application of alcohol, as herein described, for the purpose of making candles.

JOHN H. SMITH.

No. 95.—*Improvement in Tailors' Measures.*

What I claim in these letters patent, additional, is the combinatiom of the socket and rule, figs. 6, 7, with the instrument represented, at fig. 2, also the socket in the arms 6, 7, as represented, also the manner of connecting two instruments together, by bar P, P, as represented on fig. 10, for the purpose of ascertaining the slope of both shoulders at one operation, also the additional width of the lower arm, and the combination of the groove and slide R, S, and rule X, with the lower arm as represented at 0, 8, as set forth.

AMOS STOCKER.

No. 96.—*Improvements in Apparatus for Splitting and Stretching Leather.*

I claim the improvement of the apparatus for splitting and stretching leather, secured to me by letters patent, in April 1850, by adding thereto an additional apparatus for stretching leather, especially belting, said apparatus consisting of the combination of two rods, placed one above the other, in juxtaposition, the upper rod maintaining two clamps to hold the leather to be operated on, the one clamp fixed to one end of the rod, the other clamp moveable along the rod. The said rod being separable from the machine with the leather, after the same has been stretched, for the purpose of allowing the repetition of the stretching operations, with another similar rod, and another piece of leather.

The under rod to be a permanent attachment to the machine, but moveable along its own length, by the wheel work of the machine, or otherwise, so that when the upper rod is temporarily secured to it by one end near the fixed clamp, and the other clamp is held in its position, the two clamps may be gradually separated, stretching the leather lying between them, substantially as set forth in the above specification.

BRADFORD ROWE.

DESIGNS.

No. 258.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of ornamental forms and figures, represented in the accompanying drawings, forming an ornamental design for a cooking stove.

H. L. SHEPERD.

No. 259.—*Design for Stoves.*

What I claim as my new design, and desire to secure by letters patent, is the design and configuration of a cook stove, substantially the same as described and represented in the annexed drawings.

P. J. SIMMONS.

No. 260.—*Design for Stoves.*

What we claim as new, and our invention, and desire to secure by letters patent, is the combination and arrangement of the above described and represented panelings, ornaments, mouldings, &c., into an ornamental design for cooking stoves, when constructed, combined, and arranged, substantially as herein specified and represented.

JOSEPH G. LAMB.
CONRAD HARRIS.

No. 261.—*Design for Stoves.*

We have thus described the ornamental design which we claim as our invention, or production, and desire to secure by letters patent, the design for a stove, called the cottage parlor air tight, herein fully described and represented in the accompanying drawings.

WM. P. CRESSON.
DAVID STUART.
PETER SEIBERT.

No. 262.—*Design for Stoves.*

We have thus described the ornamental design, which we claim as our invention, or production, and desire to secure by letters patent, the design for a stove, called a radiator screen, herein fully described and represented in the accompanying drawings.

WM. P. CRESSON.
DAVID STUART.
PETER SEIBERT.

No. 263.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of ornamental figures, forming respectively the front and side plates of my stove, as herein represented and described.

SAMUEL D. VOSE.

No. 264.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of ornamental figures forming respectively the outside plates of my parlor stove, as herein represented and described.

SAM'L D. VOSE.

No. 265.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of ornamental figures, forming respectively the front, top and side plates of my stove, as herein represented and described.

SAM'L D. VOSE.

No. 266.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the production of the new design for stoves, as described in this specification, and represented in the drawings hereto annexed at figures 1 and 2.

JAMES H. CONKLIN.

No. 267.—*Design for Stoves.*

What we claim as our invention, and desire to secure by letters patent, is the configuration and arrangement of the ornamental figures on the door panels and feet of the stove, constituting together, a design for a stove.

J. D. GREEN.
GEO. WARREN.

No. 268.—*Design for Stoves.*

I do not claim the figures in this plate fig. 1, as being new; but what I do claim as my invention, and desire to secure by letters patent, is the peculiar form, shape, or configuration of the said stove plate, fig. 1, to be used as the front oven plate to an elevated oven, such shape, form, or configuration being a design, independent of any particular ornaments.

LATHROP S. BACON.

No. 269.—*Design for Stoves.*

What I claim as new, and desire to secure by letters patent, is the design and configuration of ornaments constituting a parlor stove, substantially the same as herein described and represented.

WM. L. SANDERSON.

No. 270.—*Design for Stoves.*

We have thus described the ornamental design which we claim as our invention or production, and desire to secure by letters patent, the design for a stove called a cast iron parlor air tight, herein fully described and represented in the accompanying drawings.

WM. P. CRESSON.
DAVID STUART.
PETER SEIBERT.

No. 271.—*Design for Stoves.*

We have thus described the ornamental design which we claim as our invention or production, and desire to secure by letters patent, the design for a stove called air tight parlor, herein fully described and represented in the accompanying drawings.

WM. P. CRESSON.
DAVID STUART.
PETER SEIBERT.

No. 272.—*Design for Stoves.*

What I claim as original, and desire to secure by letters patent, is the arrangement and combination of the several original ornamental figures, letters and mouldings upon this particular stove, as herein described and represented by the annexed drawings. JAMES H. CONKLIN.

No. 273.—*Design for Chandeliers.*

We claim the ornamental design for a chandelier, set forth in the accompanying drawing, as our original design.

ELLIS S. ARCHER.
REDWOOD F. WARNER.

No. 274.—*Design for Stoves.*

What I claim as my new design, and desire to secure by letters patent, is the design and configuration of the ornaments, so disposed on the doors, feet, and other parts of the stove, constituting, in combination, a new design of cook stove, the same as herein described and represented.

SAMUEL A. HOUSE.

No. 275.—*Design for Stoves.*

We have thus described the ornamental design which we claim as our invention or production, and desire to secure by letters patent, the design for a stove, called a complete cook, herein fully described and represented in the accompanying drawings.

RICHARD PETERSON.
DAVID STUART.
PETER SEIBERT.

No. 276.—*Design for a Portable Furnace.*

What we claim, and desire to secure by letters patent, is the above described ornament and illuminated design for portable furnaces.

CHAS. W. WARNICK.
FRED'K LEIBRANDT.
JAS. G. ABBOTT.
ARCHILUS LAWRENCE.

No. 277.—*Design for Stoves.*

I claim as my invention or production, the above described combination of mouldings and illustrated ornamental figures for six plate stoves, and desire to secure the same by letters patent. JAMES WAGER.

No. 278.—*Design for Stoves.*

I claim the foregoing described and illustrated design for stoves.

DAVID L. BARTLETT.

No. 279.—*Design for Stoves.*

What I claim as my new design, and desire to secure by letters patent, is the design and configuration of the ornaments, so disposed on the doors, feet, and other parts of the stove, constituting, in combination, a new design of stove, substantially the same as herein described and represented.

JOSHUA CRANDALL.

No. 280.—*Design for Cooking Stoves.*

What we claim as our new design, and desire to secure by letters patent, is the design and configuration of ornaments in the panels of the doors, and on the feet, so as to constitute, in combination, a new design of cooking stove, as herein described and represented.

J. D. GREEN.
GEO. WARREN.

No. 281.—*Design for Stoves.*

Having thus described the nature of my new design, what I claim therein as new, and desire to secure by letters patent, is the design of ornament and configuration, constituting, in combination, a new design of stove, substantially the same as herein described and represented in the annexed drawings.

P. A. PALMER.

No. 282.—*Design for Painted Floor Cloth.*

And what is claimed as my invention, and desired to be secured by letters patent of the United States, is the arrangement of ornamental figures, forming a design for floor cloths, as shown in the aforesaid drawing.

JAMES HUTCHINSON.

No. 283.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the ornamental shape and configuration, of the respective pieces of castings for a stove, as represented in the accompanying drawings, and herein specified.

WASHBURN RACE.

No. 284.—*Design for Stoves.*

Having thus fully described and illustrated my design for cooking stoves, what I claim as new, and for which I desire to obtain letters patent, is the particular form and design, as herein described and illustrated.

D. ROOT.

No. 285.—*Design for Stoves.*

What I claim as my invention in the said design, and desire to have secured to me by letters patent, is the combination of the elongated horizontal panels *i*, *i*, *i*,—*k*, *k*, *k*, and vertical connecting panel *n*, *n*, *n*, all having mouldings in alto relievo, with the several doors and panels, having gothic arches with clustered raised ribs on their sides, and mouldings as above specified and shown in the drawings. A. C. BROWNELL.

No. 286.—*Design for Stoves.*

What we claim as our invention, and desire to secure by letters patent, is the design of the form of the plates consisting of the peculiar manner, the same are ornamented and constructed; we lay no claim to the general form of the stove.

JOEL C. BAILEY.
RUSSEL WHEELER.

No. 287.—*Design for Umbrella Stands.*

What I claim as my production, and desire to have secured to me by letters patent, is the new design for an umbrella stand, herein above described, consisting of branches of a grape or rustic vine, cast in a twisted form about the basin, and then rising vertically and crossing each other, to form the stem, from which other branches project horizontally, and are twined so as to form the loop holes g, g,—g, g, &c., all as above set forth and represented, in the accompanying plate of drawings. WALTER BRYANT.

No. 288.—*Design for Coal Stoves.*

Having thus described and represented my new design, what I claim as new and desire to secure by letters patent, is the ornamental design and configuration of stoves, substantially the same as herein described and represented.

JOHN T. DAVY.

No. 289.—*Design for Stoves.*

What I claim as my invention or production, and desire to have secured to me by letters patent, is the combination of the bull's eyes, in alto relievo, (having radial notches as described,) and of alternating concave and convex radial ribs, and surrounding mouldings, on the several doors and panels of the front and side plates, and the row of pointed leaves m, m, and of alternate notches and ridges n, o, &c., on the moulding of the hearth plate, all as herein above set forth and represented in the drawings.

AMOS PAUL.

No. 290.—*Design for Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination of the four ornamental figures, (as represented,) in the accompanying drawings. ELIJAH P. PENNIMAN.

No. 291.—*Design for Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms, represented in the accompanying drawings, forming together an ornamental design for a parlor stove. JOHN F. RATHBONE.

No. 292.—*Design for Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms, represented in the accompanying drawings, forming together an ornamental design for a cooking stove. JOHN F. RATHBONE.

No. 293.—*Design for Stoves.*

Having thus fully described our improvement, what we claim therein as new, and for which we desire to secure letters patent, is the above described ornamental design and configuration of the plates, as described and represented.

JAMES WAGER.
DAVID PRATT.
VOLNEY RICHMOND.

No. 294.—*Design for Stoves.*

Having thus fully and exactly described the ornaments of our stove, what we claim therein as new, and desire to secure by letters patent, is the com-

bined ornamental design, and configuration of plates, for a cooking stove, substantially as herein set forth and represented in the accompanying drawings.

J. E. OWENS.
JACOB EBERT.
E. G. DYER.

No. 295.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the design of the top and bottom stove plates, represented in the accompanying drawings, and herein set forth.

WASHBURN RACE.

No. 296.—*Design for Cooking Stoves.*

What I claim, and desire to secure by letters patent, is the design and configuration of cook stove, as herein described and represented in the annexed drawing. WM. L. SANDERSON.

No. 297.—*Design for Stoves.*

What I claim, and desire to secure by letters patent, is the design of cook stove, represented in the annexed drawings.

JOSHUA CRANDALL.

No. 298.—*Design for Stoves.*

What I claim as my production, and desire to have secured to me by letters patent, is the ornamental design, herein above described, for the front and back plates of a horizontal cylindroidal air tight stove, and the door of the former consisting of scollop shells, and razor shells, cast in alto relievo in the several positions on said plates, herein above specified, and represented in the drawings.

CALVIN DOANE.

No. 299.—*Design for Lamps.*

We claim the ornamental design of the column or pedestal, the oil cup and the border round the globe holder, set forth in the accompanying drawing as our original design.

REDWOOD F. WARNER.
ELLIS S. ARCHER.

No. 300.—*Design for Stoves.*

What we claim as our invention, and desire to secure by letters patent, is the shape and configuration of the ornamental plates for stoves herein described.

SHERMAN S. JEWETT.
FRANCIS H. ROOT.

No. 301.—*Design for Stoves.*

What I claim as my invention or production, and desire to have secured to me by letters patent, is ornamenting the several mouldings of the top and bottom of a pyramid stove, and the double doors resting on the latter with transverse, longitudinal, and clustered beak-heads cast in alto relievo, as herein above described and represented in the drawings.

APOLLOS RICHMOND.

No. 302.—*Design for Stoves.*

We claim as our invention, and desire to secure by letters patent, the above design which is fully set forth in the drawings accompanying this description.

JAMES H. CONKLIN.
A. W. JONES.

No. 303.—*Design for Stoves.*

Having thus fully and exactly described the ornaments of my stove, what I claim therein as new, and desire to secure by letters patent, is the combined ornamental, design and configuration of plates for a cooking stove, substantially as herein set forth and represented in the accompanying drawings.

J. E. OWENS.
JACOB EBERT.
E. G. DYER.

No. 304.—*Design for Portable Grate.*

What I claim as my invention or production, and desire to have secured to me by letters patent, is the new design herein above described, for the front plate of a portable grate, consisting of the five centred arch mouldings, supported by the triple column pilasters, in combination with the gothic panels on each side of said pilaster, and three sided panels on the horizontal part of the frame; said three sided panels, and the space beneath the arch moulding being filled with the wedge shaped radial ribs, all as herein above described.

AMOS PAUL.

No. 305.—*Design for Cast Iron Brackets.*

What I claim as my invention or production, and desire to have secured to me by letters patent, is the combination of the central Grecian scroll, with its pendent leaves, with the several smaller Grecian scrolls and fluted ties, herein above enumerated and represented in the drawings, the whole forming a connection between the vertical and horizontal plates of a cast iron bracket.

WALTER BRYANT

No. 306.—*Design for Coal Stoves.*

What I claim as my invention and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms, represented in the accompanying drawings, forming together an ornamental design for a coal cylinder stove.

JNO. F. RATHBONE.

No. 307.—*Design for Stoves.*

What I claim as my invention and desire to have secured by letters patent, is the combinations of leaves, vines, curves, and other ornaments, as represented in the annexed drawings, and herein described as a design for cast iron stove plates, making part of a cast iron stove.

R. J. BLANCHARD.

No. 308.—*Design for Stoves.*

What we claim as our invention, and desire to secure by letters patent, is the shape and configuration of the ornamental plates for stoves, herein described.

SHERMAN S. JEWETT.
F. H. ROOT.

No. 309.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the ornamental design for stove plates, as herein described, and which is fully set forth in the drawing accompanying this description.

ROBERT DONAVAN.

No. 310.—*Design for a Parlor Stove.*

What I claim as new, and desire to secure by letters patent, is the design and configuration of ornamental stove plates, substantially the same as described and represented in the annexed drawings.

GEORGE W. RING.

No. 311.—*Design for a Stove.*

Having thus described my design, what I claim as new, and desire to secure by letters patent, is the design and configuration of ornamental stove plates, substantially the same as herein described and represented.

WM. L. SANDERSON.

No. 312.—*Design for Stoves.*

Your petitioner claims to be the original inventor or producer of the design and ornamental part of said stove, as above described and represented in the drawings.

CHARL. W. WARNICK.

No. 313.—*Design for Bust of Daniel Webster.*

What I claim as my invention or production, is the design of a bust of Daniel Webster, as represented in the annexed drawings.

JOHN C. KING.

No. 314.—*Design for a Blower Stand.*

Having thus described my new design for a blower stand, I shall state my claim as follows:—What I claim as my invention or production, and desire to have secured to me by letters patent, is the new design herein above described for a blower stand, consisting in forming two halves of said stand in the form of an ancient lyre frame, ornamented with volute scrolls, as herein above set forth and as represented in the drawings.

WALTER BRYANT.

No. 315.—*Design for Plates for Registers, Ventilators, &c.*

What we claim and desire to secure by letters patent, is the particular configuration or design of open scroll or fret work, substantially as described by the annexed drawing, and alluded to in the foregoing specifications. The said design is used by us as a top or front plate of hot air registers and ventilators, and for other useful and ornamental purposes.

CHARLES F. TUTTLE.
JAMES S. BAILEY.

No. 316.—*Design for Plates for Registers, Ventilators, &c.*

What we claim and desire to secure by letters patent, is the particular configuration or design of open scroll or fret work, substantially as described by the annexed drawing, and alluded to in the foregoing specifications The said design is used by us as a top or front plate of hot air registers and ventilators, and for other useful and ornamental purposes.

CHARLES F. TUTTLE.
JAMES S. BAILEY.

No. 317.—*Design for Plates for Registers, Ventilators, &c.*

What we claim, and desire to secure by letters patent, is the particular configuration or design of open scroll or fret work, substantially as described by the annexed drawing, and alluded to in the foregoing specifications; the said design is used by us as a top or front plate of hot air registers and ventilators, and for other useful and ornamental purposes.

CHARLES F. TUTTLE.
JAMES S. BAILEY.

No. 318.—*Design for Plates for Registers, Ventilators, &c.*

What we claim, and desire to secure by letters patent, is the particular configuration or design of open scroll or fret work, substantially as described by the annexed drawings, and alluded to in the foregoing specification; the said design is used by us as a top or front plate of hot air registers and ventilators, and for other useful and ornamental purposes.

CHARLES F. TUTTLE.
JAMES S. BAILEY.

No. 319.—*Design for Plates for Registers, Ventilators, &c.*

What we claim, and desire to secure by letters patent, is the particular configuration or design of open scroll or fret work, substantially as described by the annexed drawing, and alluded to in the foregoing specifications; the said design is used by us as the top or front plate of hot air registers and ventilators, and for other useful and ornamental purposes.

CHARLES F. TUTTLE.
JAMES S. BAILEY.

No. 320.—*Design for Plates for Registers, Ventilators, &c.*

What we claim, and desire to secure by letters patent, is the particular configuration or design of open scroll or fret work, substantially as described by the annexed drawing, and alluded to in the foregoing specifications; the said design is used by us as the top or front plate of hot air registers and ventilators, and for other useful and ornamental purposes.

CHARLES F. TUTTLE.
JAMES S. BAILEY.

No. 321.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the design and ornaments, consisting of cornucopias, and fruits issuing from them, and of vines and leaves issuing from scrolls, as they are delineated in the accompanying drawings, and herein described: I do not claim the open spaces in figure 1; nor is it any part of my invention that there is some open work in figure 3; but I claim the ornaments seen in figure 3, whether the same are made in open work, or in relief. R. J. BLANCHARD.

No. 322.—*Design for Stoves.*

What I claim as new, and my invention, is the combination and arrangement of the above described and represented shapes, figures, ornaments, flutes and mouldings, into the above represented style and design for coal heating stoves, substantially as above shown.

JOSEPH G. LAMB.

No. 323.—*Design for Stoves.*

What I claim as new, and my invention, is the combination and arrangement of the above represented and described mouldings, shapes, figures and ornaments, into the above represented design for cooking stoves, substantially as above shown.

JOSEPH G. LAMB.

No. 324.—*Design for Stoves.*

Now what I desire to secure by letters patent of the United States, and what I claim as original, is the peculiar combination and arrangement of the several ornamental figures and mouldings forming the original design of this stove, as described in this specification, and as represented by the accompanying drawings.

WM. SAVERY.

No. 325.—*Design for Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms, represented in the accompanying drawings, forming together, an ornamental design for a parlor stove.

A. W. JONES.

No. 326.—*Design for Grate Frame and Fender.*

What I claim as my production herein, and desire to secure by letters patent, is the combination and general arrangement of the figures and ornaments, as set forth, and shown in the drawings herein described, for forming an ornamental grate frame, summer piece and fender, substantially as described.

JAMES L. JACKSON.

No. 327.—*Design for Stoves.*

Having thus described and represented my new design of stove plates and register door, what I claim as new, and desire to secure by letters patent, is the design of ornament, shape, and configuration of parlor stove plates, as described and represented in the annexed drawing.

EZRA RIPLEY.

No. 328.—*Design for Stoves.*

What I claim and desire to secure by letters patent, is the design and configuration of ornamental parlor stove plates, substantially the same as described and represented.

EZRA RIPLEY.

No. 329.—*Design for Stoves.*

What I claim as my invention, is the ornamental composition of each foot E or F.

I also claim the ornamental composition of either the base, the cornice, or the blockings, as well as a combination of the whole of the same.

I also claim the ornamental composition or design for the main oven door H, as well as that of either of the small doors I or K.

LABEN EDDY.

No. 330.—*Design for Iron Railings.*

What I claim, is the particular ornamental design or device for a railing and gate posts, as herein combined and specified; that is, the posts, panel, and marginal grape vine base, in form and design, substantially as herein set forth.

WILLIAM BALLARD.

No. 331.—*Design for Bas Relief of Henry Clay.*

What I claim as my design, and wish to secure by letters patent, is the combination of scroll work and vignette, which forms the ornamental tablet, the shield on which history is recording the extract of Mr. Clay's address, together with the side view attitude in which he is represented, and the ornamental tablet on which he stands, from which copies may be taken, for sale or use: either by casting, moulding, embossing, or in any manner, or with any material whatsoever, in bas-relievo, or by copies to be taken by painting, drawing, sketching, etching, engraving on wood or metal, or by any material spread upon it, or by the electrotype, talbotype, or daguerreotype process, or by ruling with machinery, or in any other manner whatsoever.

CHARLES YOUNGLOVE HAYNES.

No. 332.—*Design for Stoves.*

I do not claim the mouldings around the door, as seen in fig. 1, but what I do claim as my invention, and desire to secure by letters patent, is the bunch of leaves tied together, as seen in fig. 1, and the leaf ornament in fig. 2, as such a design as above mentioned.

R. J. BLANCHARD.

No. 333.—*Design for Stoves.*

What I claim as my invention or production, and desire to have secured to me by letters patent, is the combination of the several ornamented parts of the stove, viz: the base plate or hearth, having the diamonds and clustered beak heads cast thereon, as described, the side and back plates having a plinth with semi-pyramidal ribs, gothic arches, diamonds, beak heads, and band at top, with inverted semi-pyramidal beak heads, the cap, with its circular ornamented areas, n', n', and diamonds surrounding beak heads m', m', and the vase, with its exterior ornaments of diamonds, clustered beak heads, semi-pyramidal ribs and open work diamonds, all the mouldings, beak heads, and ribs being cast in alto-relievo, as herein above described and represented in the drawings, the whole combination forming an entirely new design for the exterior of a parlor air tight stove.

APOLLOS RICHMOND.

No. 334.—*Design for Stoves.*

What I claim as new, and which I desire to secure by letters patent, is the design formed and ornamented, substantially as above described and represented in the accompanying drawings.

D. ROOT.

No. 335.—*Design for Carriage Plates.*

What I claim as my invention, and desire to secure by letters patent, is my design for an ornamental carriage plate for the side of a wagon body, substantially in the manner herein set forth.

JOHN S. ROYCE.

No. 336.—*Design for Spool Handles.*

What we claim as our invention, is the new and useful ornamental design or configuration, substantially as represented in figure 1, and as herein before described.

CHARLES P. GORDEN.
GEORGE B. GORDEN.

No. 337.—*Design for Stoves.*

I claim the ornamental design or combination of the star *a*, the fillet *c*, the system of rays *b*, the six torus arcs *d*, *e*, *f*, *g*, *h*, *i*, and two straight connecting toruses *k*, *l*, disposed essentially as specified.

WILLIAM B. GLEASON.

No. 338.—*Design for Stoves.*

What I claim as new, and desire to secure by letters patent, is the design of ornament and configuration of cook stoves, substantially the same as herein described and represented.

SAMUEL PIERCE.

No. 339.—*Design for Stoves.*

Having thus described the nature of our new design, what we claim therein as new, and desire to secure by letters patent, is the design of ornament and configuration, constituting, in construction, a new design of stove, substantially the same as herein described and represented in the annexed drawings.

MORRIS SMITH.

No. 340.—*Design for Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms represented in the accompanying drawing, as making an ornamental design for an air tight cooking stove.

CHAS. A. LAMBARD.

No. 341.—*Design for a Cook Stove.*

What I claim herein as new and for which I desire letters patent, is the ornamental design for a stove, substantially as represented in the accompanying drawings.

W. C. DAVIS.

No. 342.—*Design for Stoves.*

What we claim as our invention or production, and desire to secure by letters patent, is the ornamental design, as above described and represented in the accompanying drawings.

CHAS. GILBERT.
W. G. HALLMAN.

No. 343.—*Design for Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms, representéd in the accompanying drawings, forming together, an ornamental design for a parlor stove.

ELIHU SMITH.

No. 344.—*Design for Stoves.*

What I claim as new, and my invention, is the arrangement and combination of the above described and represented shapes, figures, ornaments, flutes and mouldings, into the above specified design for coal heating stoves, substantially as above shown. JOSEPH G. LAMB.

No. 345.—*Design for Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the ornamental design for a stove, as herein described and represented in the annexed drawing. S. W. GIBBS.

No. 346.—*Design for Cooking Stoves.*

What I claim as my production, and desire to secure by letters patent, is the combination and arrangement of ornamental figures and forms represented in the annexed drawings, as making an ornamental design for a cooking stove.
S. W. GIBBS.

DISCLAIMERS ENTERED DURING THE YEAR 1850.

Turn-about for Railroads.

Your petitioner, therefore, hereby enters his disclaimer to that part of the claim in the aforenamed specification, which is in the following words, to wit: "a revolving circular platform, or turning table, is not claimed, but only the method of turning it, by the use or application of a circular rack and pinion, turned by a crank," which disclaimer is to operate to the extent of the whole interest in said letters patent, your petitioner being the sole proprietor thereof.
JEREMIAH MYERS.

Improved Frog for Railroads.

Your petitioner, therefore, hereby enters his disclaimer to that part of the claim in the aforesaid specification, which is in the following words, to wit: "What I claim as my invention, and desire to secure by letters patent, is a railroad frog, constructed with hinged leaves, acted upon by either weights or springs." I desire to limit and restrict this said claim, so that it will only cover and protect the attachment of the said "weights or springs" to that part of the said "hinged leaves" of a railroad frog, at or near the angles of the same, or the point of the V of the frog, and the hinged ends of the said leaves, which disclaimer is to operate to the extent of the interest in said letters patent, vested in your petitioner. HENRY A. LANDRY.

Turning Wooden Bowls, Machinery for.

Your petitioner, therefore, hereby enters his disclaimer to that part of the claim in the aforenamed specification, which is in the following words: "the combination of the semicircular arm E, with the knife frame F, holding one or more knives, and adjustable piece J, holding the gouge T, for the purpose of turning wood bowls or dishes," which disclaimer is to operate to the extent of the interest in said letters patent, vested in your petitioner.
ADDISON EVERETT.

RENEWAL.

No. 24.—*Improvement in Capstans.*

The invention here claimed, and desired to be secured by letters patent, is the improvement of the ships or vessels' capstans, so that increased power may be obtained at pleasure, as above described; with the arrangement, application, and adaptation of the several parts, as herein set forth.
ANDREW MORSE, Jr.

III.

EXAMINERS' AND MACHINIST'S REPORTS.

Honorable THOMAS EWBANK,
Commissioner of Patents.

SIR:—I have the honor to report from my desk, the following facts and observations for the year 1850. At the commencement of the year I had before me 9 applications unexamined. During the year, 559 new applications have been apportioned to me for examination, and I have now before me, 68 new applications untouched. Examination has therefore been had upon 500 new applications. Of these applications, adverse reports were made upon 175. Favorable reports have been made upon 314 applications, old and new, for which letters patent were ordered to issue. Of the 314 ordered to issue, 83 issues were for designs, and of the 175 adverse reports, 17 were upon designs; by which it will be seen that the proportion of adverse reports upon designs, is small. The whole number of adverse reports upon all cases, old and new, coming up for examination in 1850, was 267. It will be borne in mind that adverse reports are often repeated two, three, four or more times upon applications for reconsideration of the same case, and as often confirmed by your decision. The whole number of reports and actions upon applications, old and new, during the year 1850, is 1317. The whole number for 1849, was 1296. The number of cases of interfering applications, reported for 1850, is 17, of which number, 16 were declared and decided during the year.

It is my duty to state here, that the examining force of the office is insufficient, notwithstanding the increase in the number of examiners in 1848. That increase was barely sufficient at the time it was made, and the great increase since, in the number of applications, "calls loudly for help." Permit me here to call your special attention to the following consideration, viz: A numerical statement of the number of cases received or acted upon, cannot be taken as an accurate basis for estimating the amount of work required or performed; and further, that the labor required, increases in a greater ratio than the number of applications. It would be exceedingly difficult to establish the ratio of this increase, as the whole matter is very complicated. But certain facts as criterions, may be clearly stated, although no one but an examiner can fully appreciate the character or extent of his labors. One thing is certain; an examiner's work is never finished. If not a single new application should be presented to the office for the next year, each examiner would still have a full year's work to perform. This may appear a little paradoxical, but the position is fully borne out by the following facts. In addition to the number of applications remaining untouched upon the examiner's desks, there are 1895 applications still before the office, not yet finally decided, and liable

to be called up for action at any time. Upon 1196 of these, unfavorable reports and decisions have been made, but they still await the further intentions of the applicants. Upon 673, the action of the office has been only preliminary, the cases being, for the most part, postponed for the amendment of defects. The remaining 26 are cases of interference not yet decided. The number of applications received by me in 1849, was 481, and 559 in 1850. Applications for letters patent are distributed under the following classification,

LIST OF CLASSES.

Class 1.—Agriculture, including instruments and operations.

Class 2.—Metallurgy and maufacture of metals, and instruments therefor.

Class 3.—Manufacture of fibrous and textile substances, including machines for preparing fibres of wool, cotton, silk, fur, paper, &c.

Class 4.—Chemical processes, manufactures and compounds, including medicine, dying, color making, distilling, soap and candle making, mortars, cements, &c.

Class 5.—Calorific, comprising lamps, fire-places, stoves, grates, furnaces for heating buildings, cooking apparatus, preparation of fuel, &c.

Class 6.—Steam and gas engines, including boilers and furnaces therefor, and parts thereof.

Class 7.—Navigation and maritime implements, comprising all vessels for conveyance on water, their construction, rigging and propulsion, diving dresses, life-preservers, &c.

Class 8.—Mathematical, philosophical and optical instruments, including clocks, chronometers, &c.

Class 9.—Civil engineering and architecture, comprising works on rail and common roads, bridges, canals, wharves, docks, rivers, weirs, dams, and other internal improvements, buildings, roofs, &c.

Class 10.—Land conveyances, comprising carriages, cars and other vehicles, used on roads, and parts thereof.

Class 11.—Hydraulics and pneumatics, including water-wheels, wind-mills, and other implements operated on by air and water, or employed in raising and delivering fluids.

Class 12.—Lever, screw and other mechanical powers, as applied to pressing, weighing, raising, and moving weights.

Class 13.—Grinding-mills and mill gearing, containing grain mills, mechanical movements, and horse powers.

Class 14.—Lumber, including machines and tools for preparing and manufacturing; such as sawing, planing mortising, shingle and stave, carpenters and coopers' implements, &c.

Class 15.—Stone and clay manufactures, including machines for pottery, glass making, brick making, dressing and preparing stone, cements and other building materials.

Class 16.—Leather, including tanning and dressing, manufacture of boots, shoes, saddlery, harness, &c.

Class 17.—Household furniture, machines and implements for domestic purposes, including washing machines, bread and cracker machines, feather dressing, &c.

Class 18.—Arts—polite, fine and ornamental, including music, painting, sculpture, engravings, books, printing, binding, jewelry, &c.

Class 19.—Fire-arms and implements of war, and parts thereof, including the manufacture of shot and gunpowder.

Class 20.—Surgical and medical instruments, including trusses, dental instruments, bathing apparatus, &c.

Class 21.—Wearing apparel, articles for the toilet, &c., including instruments for manufacturing.

Class 22.—Miscellaneous.

Class 23.—Designs.

Of these 23 classes, 8 are assigned to my charge, viz:—Classes 5, 8, 12, 15, 16, 18, 20, 23. Under class 5, the applications have been very numerous, and principally for stoves, in which there has been the usual dearth of interest as regards any new principles or developments. An improvement in the candlestick has been patented, consisting of an eccentric ring around the candle holder, by turning which, pressure is made upon the candle, and holds it firmly in place, dispensing with the usual awkward mode of wrapping or packing the candle. Some improvements have been patented in the tubes for "*spirit gas*" lamps, for the purpose of preventing accidents, which not unfrequently arise from attempts to fill these lamps while they are burning. By one of these improvements, the lamp is necessarily extinguished before it can be filled. The unscrewing of the cap forces a slide up over the wick, and puts out the flame. There are few subjects of practical moment so interesting to the community at this time, as that of artificial light. The *camphine or pine oil*, and the *spirit gas* or *ethereal oil*, have to some extent superseded the common oils, but the great number of fatal accidents resulting from their use will prevent their general introduction. Another drawback is also and most justly operating to exclude them from use, and that is, the adulteration of the liquid. The pine oil or camphine, is or should be a pure oil of turpentine, but is now so frequently loaded with the spirits of turpentine or resinous matter, as to render it unfit for burning. The spirit gas or ethereal oil is not so easily adulterated, as it requires a very strong alcohol to mix well with the turpentine, but even this article is now so managed as frequently to burn but little better than alcohol itself. The fact is, it is difficult to get a pure article of anything at the present day. A pure sperm oil cannot be purchased; I say this not without authority. A large quantity of sperm and whale oil is now consumed to manufacture the celebrated cod liver oil, which as now sold, is about one-third part cod liver and other fish liver oils, and the remainder fish and whale oil. Lard oil is unfit for lamps, at least so far as we have had any experience in Washington. I have tried repeatedly that which has been the most highly recommended, and have never yet found any that appeared to be suitable, either for single draft or argand lamps. Seeing all the difficulties that beset us in this matter, we may reasonably account for the excitability of the public mind on the subject of artificial light, and the many vain projects that are from time to time put forth, promising a new and cheap light. The galvanic power has been taxed severely, but thus far to no practical account. Two ways of eliciting electrical light have been resorted to. First, by the arc of flame between two carbon points, and secondly by the incandescence of a platinum wire or foil between two electrodes. The arc of flame is subject to great fluctuations from very slight causes, and this is a serious difficulty to overcome. Several very ingenious contrivances have been made for regulating the light, by preserving a uniform distance between the electrodes, but notwithstanding these, the light is irregular. Of all modes of producing intense artificial light, the oxy-hydrogen light is thus far the most successful and economical, but it is not available, except for special purposes. It has lately been announced, that a new light has been invented in France, consisting in ren-

dering a platinum wire cage luminous by a jet of hydrogen. It would seem as if there must be something more than this simple fact to characterize it as a new invention, for the incandesence of platinum wire, foil, and sponge in a jet of hydrogen or spirit lamp has been known for many years.

Under class 8 there have been some very interesting improvements, especially in the matter of telegraphs. Letters patent have been granted for a thermal telegraph, the principal feature of which, is the use of a platinum wire, heated by the current for burning marks upon a fillet of paper. The platinum wire is bent to an acute angle, which touches with its apex, slightly upon the travelling fillet of paper. Each time the current passes in the wire, the heat generated makes a mark upon the paper. A new species of electro-chemical telegraph has been patented, in which marks are made upon a metallic plate, instead of paper. A small glass tube, holding some acidulated solution, rests upon a large metallic disk, and as the disk revolves, the point of the tube, which is slightly perforated, traverses a spiral line in which the marks or impressions conveying the intelligence are to be made. A platinum wire is inserted in the glass tube, and whenever the galvanic circuit is completed through the platinum wire, acid and plate, a black mark is made upon the plate, which is of brass. These marks are strong and well defined, and after the communication is read off, they are easily effaced from the brass disk. The perforation in the point of the tube is sufficiently small to prevent the acidulated water from running out, though sufficient escapes for electrolytic action.

Electro-magnetic Enunciator.—An invention with this title has been patented, as a substitute for the usual bell ringing apparatus in hotels and other places. It is, in fact, a species of electro-magnetic indicating telegraph, and ingenious in its construction and mode of operation.

Electro-magnetic Repeater.—This invention, but recently patented, is one of considerable novelty and beauty, and is designed for the purpose of repeating or recording a communication in several places at once, along a line of electro-magnetic telegraph, and at the same time allowing the galvanic circuit to remain open when the line is not in use, which is an important condition to be preserved. Another instrument for a similar purpose was patented about the same time, the operation of which requires the circuit to be kept closed.

Telegraph Manipulator.—A very ingenious, though complicated machine, for communicating signals in telegraphs where they are recorded in dots and lines. Ordinarily these are made by striking a lever or key with the finger, but by this instrument any combination of dots and lines representing a letter, is at once made and recorded, by simply depressing a key having the desired letter marked upon it. It requires but one motion of the finger, instead of the great number required for some of the letters in the ordinary way. If the machinery is made accurate, it will prevent many mistakes from being made by telegraphic operators.

Electro-magnetic Engines.—Two engines of this class have been patented, one of them having for its principal feature, the employment of the secondary current produced by one magnet, to charge an auxiliary magnet. The feature patented in the other engine, is a novelty in the *cut-off*. The cut-off is the contrivance by which the galvanic current is conveyed to, and intercepted from the electro-magnets, and is usually made to operate by the pressure of conducting metallic springs upon metallic disks, either the springs or disks being made to revolve according to circumstances. In the present case, revolving metallic points are brought successively into contact with the surface of a metallic roller, which is pressed against the points by means of a spring.

FINE ARTS.

Daguerreotype Plate Holder.—It has long been an object to obtain some means for holding daguerreotype plates in such a manner while cleaning and polishing them, that the plates should not be handled, and that they should present smooth edges to the buff stick or polishing wheel, and at the same time that the plates, when cleaned and polished, could be readily removed from the plate holder. Various kinds of clamps have been tried, and the plates have been cemented to blocks, &c., but no plan seems to have combined the advantages possessed by the one before us. The edges of the plate are turned down to a right angle or more, by means of a burnisher or other tool specially designed, and the block upon which the plate is secured, is an expansible block, the edges of which press against the turned edges of the plate, and thus hold it in place. The expansion of the block is to be produced by springs, wedges, screws, cams or other means.

Electrotyping.—An ingenious device in this art has been patented for preventing the electrotype cast from adhering to the original plate. Many ways have been tried, to obviate this difficulty, but the present is a decided improvement upon them. It consists in acting chemically upon the surface of the copper plate, to so slight an extent as not to injure the impression, nor interfere with the electric deposit. The inventor prefers, in his operations, to iodize slightly the surface of the plate, and then to submit it for some time to the direct rays of the sun.

Coating Types with Copper by the Electrotype Process.—A patented invention, and asserted to be one of great practical value. A very slight deposit of copper is put upon the types, which adds greatly to their durability.

Typographer is the name of a novel and ingenious machine for printing directly by hand. Several machines for writing and printing by hand, have been patented hitherto, but this seems to exceed them all in rapidity of execution. It is too complicated to describe here, but suffice it to say, that by pressing upon lettered keys, after the manner of playing the piano-forte, the printing is rapidly and neatly executed. A full size and very expensive working model is deposited in the office.

Respectfully submitted,

CHAS. G. PAGE,
Examiner.

SIR:—In compliance with your request, I have the honor to submit the following report of the condition of business at my desk, and of its progress during the past year.

The number of applications referred to me within the year is five hundred and twenty-two. You will recollect, however, that an unusually large number of cases were examined by me in 1849, and as actions on them were not all of a final character, many of them were at the date of my last report, in the hands of applicants or their agents, for amendment, or for their further consideration or action. As the whole number acted upon was very great, the number of those partially decided cases was also great—and as they have from time to time been returned during the past year, they of course increase

the number of cases upon which I have been called to act, much above the number referred to me during the year.

The number of applications passed at my desk for patents during the year 1850, is 227—and the number of rejections 406. This last number includes all rejections, and is not confined to the number of *cases* rejected, as it is well known that many applications under new forms are rejected more than once, the whole number of rejections, therefore, is always considerably larger than the number of applications finally rejected. And the number of applications patented and rejected, is much greater than the number referred to my desk during the year. Thus the business of each year runs into the next, and in consequence of inaction on the part of applicants, applications are sometimes left pending for several years; some have been finally decided, nearly ten years after the filing of the same. Thus each year a part of the business of many preceding years, may require the attention and labor of the examiner.

By comparing the number of patents and rejections for the year 1850, with those for the year 1849, it will be perceived that their ratio has not materially changed. It would naturally be supposed that the number of patents relatively to the rejections, would annually decrease, but there has been no such change at my desk during the year that has just closed.

Prior to the introduction of the present system of examinations, applications for patents were never numerous. Although patents were granted to all who applied for them, yet owing to a want of revision by men of artistic knowledge and experience, they were found to be so imperfect, and so large a proportion of them were granted for things that were old, that they afforded very little security. No one feared to infringe a patent, as he was almost sure to be able to defeat it, for insufficiency of description, a defective claim, or for covering what could be shown to be old. The maxim was, that any patentee could be defeated who dared to commence a suit, and the most valuable invention seldom afforded any remuneration to the inventor. Patents were not only defective, but their reputation was bad, and the government did little else for the inventor than keep its promise to the ear.

This system, so utterly defective and so little calculated to accomplish the object for which it was intended, which placed the fraudulent or ignorant pretender on a footing with the meritorious inventor, and gave no protection to either, was finally condemned and abandoned in 1836, and the present system, subjecting all applications to rigid examination, and basing all patents upon novelty and utility only, and refusing them for all spurious and pretended inventions, was adopted and immediately carried into effect. Under this system examinations immediately developed the fact, that nearly half the alleged inventions upon which patents were claimed, were mere repetitions of what was already known, and nearly all the papers filed, upon which patents were to be based, were partially defective, and required amendment before letters patent could be granted.

Thus was marked an important era in patent interests. The standard was by degrees elevated, and old defective patents began to be re-issued in a corrected form, and covering novelties only. When patents granted or re-issued under this system were brought before the courts, it was found that almost without exception they were affirmed, and it was found that the infringement of a patent which had previously been perpetrated, without fear and with impunity, had become a dangerous experiment. Patent property began to be viewed in a different light, and after a few years of experience of the practical effects of the new patent system, almost universal confidence was inspired, and those who had previously abstained from procuring patents because no confidence could be placed in them, now forwarded their applications to the patent office in great numbers. No considerable change was perceived, until the new plan had been long enough in force to be well tested—until the courts had by repeated decisions satisfied the public mind that patents granted under the new system could be relied upon, and that patents could not be infringed with impunity, and the new state of things was fully confirmed by "wailing and gnashing of teeth," among those who had been accustomed quietly and with unconcern, to reap where others had sowed, and to enrich themselves by the dear bought discoveries of starving inventors.

At this juncture, applications for patents began rapidly to increase. Prior to 1844, for several years, the number of applications had averaged about 800; but in 1844, they began steadily and rapidly to increase, until in the short space of seven years, they have almost trippled; the number filed in 1850, being about 2200, while for *fifty years* under the old system, and the incipiency of the new, they had only reached about 800. As time passes, this increase becomes more rapid; the increase of the last two years being much greater than during an equal space of time at any former period. It appears, therefore, that this system of examination, although it results in the rejection of half the applications filed in the office for want of novelty, gives such security for real inventions, as to foster and encourage the intelligent seeker after hidden truth in a vastly higher degree, than any system heretofore adopted in this or any other country.

A few remarks in relation to rejected applications cannot be amiss, as it is a subject much discussed before this office and elsewhere. When it is recollected, that about nineteen thousand patents have been granted in this country alone in less than sixty years—when to these are added the multitudes of thousands, which have been granted in the different States of Europe—when we recollect the thousands of volumes in our libraries of science and art devoted to inventions and discoveries; tens of thousands of which have never been made the subject of letters patent—when we recollect the vast extent and variety of machinery in shops, factories and laboratories, a description of which is nowhere published—we involuntarily exclaim, "who shall show us any new thing:" and when we consider how impossible it is, for inventors to be informed of all these things, or even to gain access to the archives, libraries, &c., where they are to be found, we cease to wonder, that so many inventions are found to be old, and our astonishment is awakened at the ingenuity and perseverance of a people, who can draw out so many new treasures which have been hidden from former votaries of science and art. We cease to wonder, that one-half of all that is presented to the Patent Office is old; but become surprised that nearly half who apply, have discovered something new. It is proper, further to remark, that the most respectable and best informed patent agents, decline to present *one half* the inventions presented to them, on the ground that they are unquestionably old. In all doubtful cases, they of course, make the application if requested. Other agents present a larger proportion, and nearly half who apply employ no agent. The proportion of the patented to the rejected, so far as can be judged by a general view of the subject, is quite as large as can be expected.

In relation to the inventions which are patented, it is proper to state, that it is believed there are very few, which would not be sustained by the courts with any amount of light which could be shed upon them; and this statement is fully sustained by past decisions. From remarks above, in relation to the

numberless improvements which have heretofore been made, and the multitude of books and records over which they are scattered, it could not reasonably be expected, that *every patent* should be sound. With the best opportunities, an old invention will sometimes be overlooked, and with the extraordinary amount of business constantly before examiners, the absolute avoidance of these oversights, would be positively miraculous. But their oversights are so few and trifling that little importance could be attached to them under any circumstances, and their importance is rendered still less considerable by the fact that the decisions of this office are not final, but can be revised by the courts, whenever there is ground to believe that an error has been committed; and it may probably be said, that less than one in a thousand of the patents granted since 1836, have been set aside. I do not recollect to have heard of one.

Indeed, since the re-organization of the office in 1836, patents have so uniformily been sustained by the courts, that many who desire to appropriate other men's inventions to themselves have changed their mode of attack, and strive to give battle under a parchment Ægis, similar to that which they have found so impenetrable in the hands of the inventor. The infringer accordingly takes the invention, which he desires to appropriate, and makes slight changes or additions, preserving the character of the invention, and then demands letters patent for his improvements. These changes are sometimes of a patentable character, though they are often of no importance whatever. If patentable, the patent is immediately used, and often with perfect success, to protect the infringer against the original patentee. Our patents on their face give to each patentee exclusive right to "make, use, &c." the thing invented, but this language does not convey the right idea; a large portion of our patents are granted, and rightfully, for new combinations which can neither be made nor used without infringing pre-existing patents. Thus the combination of A and B is patented, and subsequently some other person improves the machine, by adding another part D, to it. The improvement is obvious, and of course, a patent is granted for the combination of D, with A and B. It is seen at a glance, that this last combination cannot be used without involving the combination of A and B, and therefore, infringing the combination previously patented to another. Patents for combinations, necessarily involving previously patented parts or combinations, form a large proportion of the patents granted, and without them, there would be an end to improvements. But it is absurd to suppose that any patent is vacated by patenting an improvement upon it, however important, or that a patent for an improvement upon a machine gives a right to use the parts previously patented. *The patentee derives no right by his patent, to make or use anything which he would not have a right to make and use without his patent. But it simply gives him a right to prevent others from using his combination without his permission;* and if the wording of the patent could be so modified, as to "forbid all but the patentee to make, use or vend" the thing patented, it would conform to the true intent and meaning of the patent—would have the same force that the patent now has, and would save a vast amount of misapprehension, litigation, and loss to inventors, and prevent numerous impositions intentional and unintentional, upon purchasers, who now suppose from the wording of the patent, that they have a right to *use* anything patented, by permission of the inventor; but, who often learn shortly after the purchase, that there is another patent in the back ground, covering a part of what is embraced in the patent they have purchased.

These difficulties are incident to, and inseparable from the subject. The improvement is often vastly more important than the original machine, and a patent cannot be refused for it, without disregarding law and justice, and trampling upon the very objects for which patent laws are enacted; and as difficulties are great and unavoidable, they ought not to be aggravated by phraseology in the patent purporting to confer rights which are *not conferred, and are not intended to be conferred,* and which deceive a vast majority of those who are interested in patented improvements, and often enable a subsequent patentee of a trifling improvement to strip a prior meritorious inventor of his patent property.

When these improvements which are sought to be patented for purposes of fraud, as above indicated, prove to be unpatentable and are rejected, various kinds of influence are brought to bear upon officers charged with the case, and when finally rejected, the presses teem and the country echoes with charges of unspeakable frauds, and astounding disclosures, which are never made intelligible—and unspecified partisanship against the office and the officer who declines to be bullied or wheedled out of the path of his duty. It would be unjust to say that all who complain are of this character; some who are believed by this office to be honestly mistaken in regard to their rights, complain also—and although the office cannot agree with them in opinion, their feelings are entitled to respect. It is no trifle in the mind of any inventor to see the darling to which he has devoted the best part of his life, and to which perhaps his health and the comfort of his family have been sacrificed, in a moment, crushed before him, and his bright hopes scattered to the winds. It is no joke under such circumstances to return to his home to meet the despair of his family, and the mingled sympathy and jeers of his neighbors. Much may be pardoned to such a man, (and there are many of them,) and if his misfortune is without remedy, his complaints should meet with respect and commiseration. But the complaints of such men do not assume the fulminating character which generally belongs to those of the other class, and newspaper artillery and secret undermining intrigues, do not often emanate from such sources.

The law of patents is in many particulars difficult to understand. It is, as Mr. Justice Story justly remarked, the "metaphysics of law," and even if all who present their claims to the office were fair minded men, who desire nothing but what they thought themselves entitled to, and the law was perfectly administered, there would be many to think themselves aggrieved. But those who have business here are like other men, some are perfectly fair and others desire to carry their point, and are not particularly scrupulous; one class are opposed to the grant of patents, and another class desire that patents shall be granted much more freely than the law will justify; one class denounces nearly all patents as fraudulent, another is furious that so many should be rejected. When a patent of any importance is granted, the office receives the condemnation of one clique, and when refused, it receives the condemnation of the other. It is believed, however, that the great mass of those who are interested in the doings of this office belong to neither extreme, and that they are content with a strait forward discharge of duty, which does not bend to denunciations or commendations of either party of noisy extremists—the condemnation of both furnishing, perhaps, the strongest proof of undeviating faithfulness, as a just administration of the patent laws could not meet the approbation of either. Justice is not what they seek.

The classes under my charge are the following:—1st. Mills, comprehending all kinds of machinery for crushing and grinding, regulators, horse powers, and mechanical movements generally.

2nd. Land conveyance, comprehending all kinds of vehicles and implements of travel, and transportation.

3rd. Machinery for working in lumber, comprehending saw-mills, planing machines, stave machinery, shingle, clapboard, lath machines, boring and mortising machines, &c., with the various implements and tools used therein.

4th. Hydraulics and pneumatics, comprehending water-wheels, windmills, machines for raising water, fire engines, filters, hydraulic engines, &c., &c.

5th. Manufactures of fibrous and textile fabrics, and machinery therefor, comprehending machinery for preparing hemp and flax, cotton gins, wool pickers, carding machines, combing machines, spinning machines, looms, cloth dressing machines, &c., &c.

Some of the improvements in these classes which have been developed at my desk during the past year, I shall concisely notice. It is impossible to command sufficient time to enter thoroughly into the subject. The report of 1847, upon which the last increase of the examining force was based, presented 1531 applications filed during that year, and the number filed during the last year is about 2200, and at the close of the year there were 34 applications upon my desk unexamined. It may further be remarked, that the influx of business is at present much more rapid than usual, and nothing apparently but a considerable increase of force can prevent an accumulation of business as perplexing as that which occurred prior to the last increase of force.

MILLS.

About twenty-four patents have been granted within the past year for improvements belonging to this class, thirteen of which are for improvements in mills for grinding and crushing. So much has heretofore been done in this class, coming home as it does to the wants of man, even in a barbarous state, and having exercised the genius of the inventor from the earliest ages to the present time, that little of a radical character can be expected, and accordingly the improvements patented during the past year, consist of slight modifications of what was previously known. One of these patents is for a mode of steaming grain as it passes from the hopper to the stones, for the purpose of softening the outer coating of the grains to prevent its being ground so fine as to mingle with the flower in such a manner as not to be separated from it by the bolt. The idea of steaming preparatory to grinding, is not new, but the patent was granted for the inventor's convenient mode of applying the steam. Another of these mills consists of two or more hollow cylinders or rollers, the smaller being placed within the larger, and being free to revolve, so that when the outer cylinder revolves, the inner one will also revolve by its weight, and crush whatever substance may be placed in the outer cylinder. Up to this point the mill is old, but in addition it comprehends an arrangement by which the inner cylinder in addition to its weight in rolling, is caused to give a series of blows to the mass for the purpose of breaking the more refractory parts, and freeing others from their adhesion to the sides of the mill. Another pulverises sugar or other materials, in a series of mortars in which the beaters work in succession, while the range of mortars revolves in such a manner as to bring them to the feeding point, and to the discharge aperture, as the material in each becomes sufficiently pulverised. In another of the mills, a very firm elastic substance is placed in the spindle under the cock-head, to prevent abrasion, and to relieve concussions. In another of the mills, the crushing is effected by a series of rollers, between which the grain passes without being rubbed, and the crushed particles then fall upon a toothed roller working a concave, when they are opened and afterwards the flour is separated from the bran. Several other patents for improvements in grinding have been granted, but it is not deemed necessary to give further details. Several patents have also been granted for improvements in bolting and dusting bran, which will not be described, but will be understood by a peruser of the claims.

Horse Powers.—But one patent has been granted within the past year for improvements in horse powers. The subject seems to be nearly exhausted, and until some new track is discovered, very few patents can be expected in this plethoric branch of machinery. The patent above mentioned is for an improvement by which the master wheel is held in position, or allowed to cant over, for admitting the horse.

Letters patent have been granted for an improvement in the friction clutch adapted to various resistances. It is so arranged, that as the pulley revolves upon the shaft, the friction of the clutch will constantly increase, until it becomes sufficient to carry the shaft, at which point the pressure becomes constant; but if the shaft becomes loaded in such a manner that the friction is insufficient to carry it, the friction will immediately be increased to the requisite degree, by the action of the machinery. The device appears to possess much merit.

Letters patent have also been granted for an improved form of rubbing surfaces, for regulating abrasions; a full description of it cannot be given here, but will be found in the English journals. It was patented in England in November, 1848. All are aware that journals, after considerable use, become loose in their boxes, in consequence of friction, and it is well known that boxes and journals have been made in a conical form, or nearly so, in order that after being worn, the joint may be made tight by pushing the journal further into the box. But this plan is an imperfect one, as the different parts of the journal and box will not change their diameters equally. The invention above alluded to, is intended to obviate this inconvenience, with what success, the public have an opportunity of judging. As nothing further is deemed necessary on this division of the subject, I will proceed to the next.

LAND CONVEYANCE.

About fifty patents have been granted during the year, for improvements belonging to this class, and extending to nearly all its sub-divisions.

Railroad Cars.—Five patents have been granted for improvements in railroad cars within the past year. One is an apparatus for holding the wheels upon the rails, the parts of which are so connected as to yield, without injury or diminution of efficiency, to the lateral motions of the car. Another is for a kind of segment connection of the car body with the trucks, by which the trucks are carried as far as may be, to the outside of the curve, and thus afford more safety to the cars in turning curves at considerable speed. Very large car bodies have also been supported at a considerable distance from their ends, upon the centres of the frames of two eight wheeled trucks, the frame of each truck being connected with the wheels in such manner as to give to each truck the capabilities of ordinary eight wheeled cars. There has also been a re-issue of a patent for hanging car bodies, which was granted eight or ten years since, and which, at the proper time, was noticed in the examiner's report.

Car Couplings.—Four patents have been granted within the year, for improved modes of coupling railroad cars. Two of them are for self-coupling, with convenient arrangements for uncoupling in emergencies; one is self-disengaging when the car leaves the track, and a third is a firm coupling, which allows no play of the links, except laterally, and no disengaging or connecting, but by the withdrawal or insertion of the bolt by hand. They do not very strikingly differ from such as have heretofore been in use.

Cast Iron Car Wheels.—Seven or eight patents have been granted within the year, for modifications of cast iron car wheels. They do not greatly differ from those heretofore in use, and do not require a minute description in this place. The great difficulty in the construction of these wheels, consists in their liability to strain or fracture in cooling, and therefore, patents are granted with great liberality for such modifications as may obviate, in any degree, the inconvenience universally experienced in the construction of this kind of wheel.

A patent has been granted for improvements in cars for plank roads. It is a modification of those whose wheels carry around with them an endless chain, upon which the wheels always run. The links are so formed and arranged, as to prevent, in some degree, the injury which the road would sustain from the direct action of the wheels.

Carriages.—Two or three patents have been granted for brakes applicable to wheels of carriages and cars. One of them is so constructed, that after the brake is put upon the wheel, it will remain there, doing its duty, until removed by a device separate from that which brings it into use. In one of the patented carriages the dash board is connected indirectly with the fore wheels, so that as the horses turn, the board will constantly be kept directly behind the horses. Improvements have also been patented for improved couplings for swingle trees, and for improvements in detaching horses from the same by the driver, when the carriage is in motion.

A patent has also been granted for an arrangement of the parts of a carriage, in such a manner that the fore end of the carriage body shall always be supported at its centre, and the fore wheels under it shall be capable of swinging around, by virtue of a joint in the reach, in such a manner that very short turns may be made without bringing the fore wheel against the side of the carriage body. Several patents have been granted for improvements in connecting and disconnecting wheels and axles; for setting up carriage tops; in the construction of covered carriages; for improvements in neck yoking reaches, &c. In an omnibus patented, there is a device by which the driver, as the omnibus stops, may bring brakes upon the wheels, and by the same act put down the steps for the ingress or egress of passengers, and upon withdrawing his foot from the lever, the steps are again folded up and the brakes removed from the wheels.

Three or four patents have been granted for improvements in raising and lowering carriage tops by devices inside of the carriage. The joint rods in one of them, are so arranged on the outside of the cover, and so connected with a handle inside, that by placing the hand upon this handle, the whole carriage top may be raised or lowered at pleasure. In another, the whole or a part may be raised and lowered in a similar way. In another, a spiral spring is placed upon a rod in the inside of the carriage, and the rod so connected with the joint rods, that nearly the whole weight of the carriage top is sustained by the spring, and the slightest force from within is sufficient to raise or lower it.

Other patents have been granted belonging to this class; but those noticed, are a fair specimen of the whole. Very striking improvements are not to be expected in carriages, and it is unnecessary to pursue the subject further.

HYDRAULICS AND PNEUMATICS.

About 24 patents have been granted within the year, belonging to this class. They are quite diversified in their nature, and are scattered over ten sub-divisions.

Pumps.—Six patents have been granted for improvements in pumps, one of which is a re-issue. One of these is for use in very deep wells. It has no piston, but the pump tube, which has a valve at the bottom opening upwards, works up and down in a valve chamber at the bottom. It is said, that this pump may be worked by hand and with comparative ease will raise water eighty feet or more, when it would be impossible to raise water with a hand pump having a piston of any construction. A patent has also been granted for an improvement in that variety of rotary pump, in which there are two pistons, each of which serves alternately as a piston and a stop. The improvement has reference to the alternate releasing and carrying forward of the pistons. Another of these pumps consists of a tight chamber into which the induction tubes extend considerably *above* the bottom, and into which a pump is inserted, extending down very near to the bottom and below the tops of the induction tubes. The pump is separated from the induction pipes by a gauze partition to prevent grain or other matter from passing to the pump, and in the side of the pump, there is a small opening above the point where the water is intended to rise, through which the air which passes up through the induction pipes is pumped out. This apparatus is intended principally for vessels, which transport grain, &c. In another of these pumps, the piston rod has a fixture attached to it, for agitating the water in the well.

Filters.—Two patents have been granted for improvements in filters. One of these is composed of two concentric cylinders, the inner cylinder having flanches at its ends which entirely close the annular space between the two, so that the water enters the inner cylinder which has openings through it, to the annular space at both ends, and is divided into nearly equal parts, by a partition perpendicular to its axis, so that the water passes into the inner cylinder at one end, through into the annular space, and again from the annular space into the other end of the cylinder whence it escapes. Around the inner cylinder and between its flanches, is wound cloth or other filtering material filling the annular space, and if from any cause the filtering medium should cease to fill the space, the filter would be repaired by winding more on the cylinder. The other is called a pocket filter, and consists of a tube through which water is drawn by suction with a filtering material at its lower end. This filter is for use in drinking where the water requires filteration.

Three patents have been granted for improvements in hydraulic apparatus for producing blast. They consist of wheels with compartments in or connected with their peripheries, and revolving in reservoirs of water. The compartments of course, carry air down with them, which when they enter the water, is displaced by the water, and rises through tubes forming the blast. These machines are complex, and perhaps an equal or better result might be obtained in a more simple manner and at less expense.

Letters patent have been granted for a mode of drawing and bringing water from a distance. It much resembles those previously known.

A hydraulic regulator has been patented within the past year. The machinery to be regulated, works a pump which forces water into another cylinder with which the pump is connected at both ends. The cylinder into which the water is pumped, is in a vertical position, and has a piston in it with an adjustable opening through it, and a piston rod passing out at the end of the cylinder, and taking hold of an arm from the valve to be regulated by a slaut and pin; so that the piston and rod may move a certain distance without changing the valve at each operation of the pump. The apparatus is so adjusted, that the water pumped into the cylinder when the machinery works at proper speed, shall pass through the openings in the piston without giving it sufficient motion to disturb the valve; but when the operation is too fast or too slow, the vibrations of the piston will cause the end of the slaut to give a *blow* to the arm of the valve moving it in the direction desired.

Water Wheels.—Three patents have been granted for improvements in water wheels within the year. The modifications which they present, are very slight. Improvements upon water wheels at the present day, depend more upon correct calculations in adapting the wheel to circumstances and upon mechanical execution, than upon invention; and these are no more the subject of letters patent, than a change in the angle of an inclined plane or wedge, to adopt it to the particular duty it has to perform.

Two or three patents have been granted for improvements in waste gates. One of them is formed like a trapezoid, (but may be varied,) narrow at the bottom and broad at the top, with one side nearly vertical and hanging upon a vertical shaft, so that when the water is low, the surface of the gate upon which it presses, is mostly on the side which tends to close it, and as the water rises, the opposite side being wider at the top, finally causes the pressure to be greatest on that side; and the gate is opened and continues so, until the water descends to the point when the preponderance of pressure is changed, when the gate again closes.

Two patents have been granted for improvements in faucets; one of them is a molasses gate, and the other filters the water as it passes circuitously through.

Water Metres.—Two patents have been granted for improvements in water metres; both are intended to be operated on by the water. One of them presents a slight modification of a rotary engine and a rotary pump, of well known construction. The other is a modification of a double cylinder single acting engine, entirely enclosed in a case. In this the pistons remain stationary for a short time at the end of each stroke, in order that the discharge may be more perfect. There is nothing further in this class which need be particularly noticed.

LUMBER.

About sixty patents have been granted within the year for improvements in this class; and they extend to about ten of its sub-divisions, and to various improvements of a miscellaneous character. A considerable variety of machinery has long been known for performing almost every operation in lumber to which machinery is applicable, and in casting the eye over the improvements of the past year, little is seen which possesses commanding novelty. The inventor of the present day is in a very great degree limited to refinements of a practical character, upon principles long since in many ways reduced to practice. The object of improvements and inventions generally, is to produce a given result in a better or more convenient manner than heretofore, or to produce new or useful varieties of manufacture; but there are often other incentives to invention, equally powerful, and which are illustrated in the class under consideration. In several of the sub-divisions of this class, there are machines, the patents for which are still in force, which, according to the general current of decisions in the courts, lie at the foundation of, and monopolise the radical principles of all or nearly all machinery which can effect the objects which they are intended to accomplish. These varieties of machinery are greatly in demand, and are of the most extensive application, and consequently vast interest, and multitudes of our citizens are held under contribution to their more fortunate rivals, who first discovered and secured to themselves and their representatives, these invaluable elements. The condition of the enterprising and ingenious tributary is of course irksome, and he strives for freedom, while the patentee insists upon his "bond." This circumstance is the parent of multitudes of inventions and quasi inventions, and applies the most effective stimulants to ingenuity; each would be rejoiced, if possible, to produce better machinery than is now known for similar purposes; but if baffled in his attempts, he devotes himself even to those which are somewhat inferior, to avoid the claims of the prior patentee upon him. There is also, as I have remarked, an idea extensively entertained, that a patent will in some way give protection against the demands of the prior inventor, and consequently, patents are demanded far beyond what would be prompted by the force of different circumstances. These machines sometimes possess patentable novelty, but it is notwithstanding the province of the courts to determine whether, in addition to these novelties, they do not possess the essential elements of inventions previously patented. The *novelties* are secured by the new patent, *and not* the elements with which they may be united, or blended. It is not to be presumed that all these inventions are prompted in the manner above indicated, but the origin of many can be thus traced, and whatever cause may produce inventions, they ultimately result in the advancement of the arts, and in benefit to the world.

Saw Mills.—About ten patents have been granted within the year for improvements in sawing lumber. The saws in one of these mills are circular, and two are operated at the same time. The shaft of one of these saws is allowed end play, both by a spring and by adjustment, and is also capable of swinging upon the shaft of the other saw, as a centre. When the timber is large, the auxiliary saw can be placed in a proper position to co-operate with the main saw in cutting one kerf, and when the log is small, it may be so adjusted that the mill will saw off two boards at once. In another of these mills the saw is furnished with a kind of cross head at each end, which extends out some distance in front of the edge of the saw, extending around a way prepared for it, against the front of which it bears. Thus when the log presses against the edge of the saw, it has a direct tendency to preserve the width of the saw in the line in which the log moves. As the saw is generally hung, the tendency of the log is to turn the saw out of its proper position. One of these patents is for an improvement in the saw itself. The front of the tooth is slightly hooked, but the backs of the teeth are all parts of the same line, coinciding with the line of the edge of the saw, and the point of each tooth is bent out a little, to take hold of the work. The part of the tooth back of the point does not retire. Experiments made with this saw, seem to indicate that the improvement is of great value. Improvements have also been patented in noddle irons, in the mode of setting saw logs, and in cross cut sawing machines.

Five or six patents have been granted for machinery to cut veneers and clap-boards, and for cutting and dressing staves. In one of these, the knife is placed in an ordinary gate, and that part of the block which is to be separated, rests upon the edge of a spring attached to the table in a position nearly parallel to the knife.

Thus the edge of the veneer is supported until it is entirely separated, and when separated, the spring yields outwards to allow the knife to pass it without injury. In another a very perfect curved drawing cut is effected for cutting staves, which appears to answer a good purpose. The power is exerted lengthwise of the knife, and its descent in the proper curves is effected by slauts, pins and ways.

A patent has also been granted for a new mode of jointing staves, which evinces much ingenuity, but it could not be made intelligible in a short sketch, and must therefore be omitted with some others in this sub-division.

PLANING MACHINES.

Twelve or fourteen patents have been granted within the year for improvements in machinery for planing boards, shingles, &c. One of these machines is intended principally for planing timber. A disc cutter-head is used with smoothing irons in its face, and its edges armed with an annular saw and clearing cutters immediately back of the saw, for the purpose of removing such parts of the wood as are separated by the saw. The centre of the disc presses upon the smoothed surface of the timber, upon which the operation is performed.

Two or three devices for tonguing, grooving, jointing, rebating or otherwise dressing the edges of boards have also been patented, and promise considerable usefulness. In one of the patented planing machines a circular disc cutter-head is used, and the knives are placed around its edge in such a manner, that they move as nearly endwise as is consistent with continued cutting, and each commences cutting before the preceding knife has ceased. This machine has also for tonguing and grooving, a series of saws on shafts perpendicular to the face of the board, the saws varying in diameter according to the shape to be given to the edge, and the planes of all the saws making a slight angle with the axes on which they are placed. Another of these machines is adapted to dressing boards of varying widths,—the edge cutter on the edge of the board is by the action of the board, as it moves forward, caused to approach towards, or recede from the centre of the board, or it may be kept in the same position throughout the operation, for the purpose of producing a straight joint, or giving a certain angle to the edge of the board. This machine has also a device for adapting the feed rollers to any required thickness of stuff, without impairing the action of the gearing. In another of these machines, the board is made to bend slightly over a cylindrical cutter head, and the rest on the upper side of the board is connected to the cutter-head in such a manner as to render the smoothed face of the board parallel to the opposite face while the shavings pass downwards into a proper receptacle, the bend preventing the knots from being torn out by the cutters. The pressure rollers in these machines have also been so arranged, as to approach nearer to the cutter head as the stuff to be plained is thinner, and a cutter nearly in the form of a straight saw has also been used for planing the surfaces of boards. Some re-issues have also been granted.

Boring and Mortising.—Five or six patents have been granted within the year for improvements in machinery for boring, mortising, and tenoning. In one of these machines the central part of the auger is separated from the twist, passes through it, and revolves in boring at a different speed from it. Thus the clogging which often takes place, when the boring and clearing parts revolve together, may be avoided by adapting the motions of the different parts to each other, in such a manner, that each shall perform its duty unembarrassed by the other. In one of the tenoning machines patented, the cutters are jointed to the gates or sides, and are connected with such devices that when they descend they shall be thrown a little forward, to cut, and when they return, they are in like manner thrown back, so as to avoid rubbing against the surface upon which they have just operated. In one of the patented mortising machines, the parts are so arranged that the chisel turns as it descends, thus giving at each stroke a drawing cut. This will doubtless in some instances, be useful.

Some half-dozen patents have been granted within the year for improvements in fences and railings, and about twelve more for miscellaneous improvements in the class of lumber. They are of equal average importance with those which have been noticed, and enough has been said to give a fair idea of the character of improvement in this class, during the past year.

FIBROUS AND TEXTILE MANUFACTURES AND MACHINERY.

About seventy patents belonging to this interesting class, have been granted within the last year. As I have had occasion to remark in former reports, improvements in these branches of manufacture appear to be without limit, and notwithstanding all that has been done, the tide of useful and valuable inventions is still onward. Machinery for fibrous and textile operations requires a degree of perfection which is demanded in but few branches of the arts, and it consists of so many parts and combinations, and so much of it is of an extremely complicated character, as to afford the most ample room for improvement, and the time requisite to bring other branches of machinery to their full maturity, is scarcely sufficient to conduct this out of its infancy. Much as has been done in this class, and wonderful as its improvements have already been, every year makes numerous and important additions and gives promise of more astonishing developments in future. This class includes every variety of machinery which is necessary for reducing the various kinds of fibrous materials to perfect fabrics.

But three patents have been granted within the year for improvements in cotton gins. One of these machines has a plate with teeth at its end, passing between the saws and is placed in a horizontal position behind the grate, and is combined with a brush operating upon the fibres in the saws, to remove the dust and conduct it off upon the plate. The other has a series of small rollers grooved lengthwise, each having a portion removed from its side arranged around a toothed cylinder. These small rollers revolve slowly as the toothed cylinder revolves, and prevent the bolls which rest against them, from passing, while the toothed cylinder takes the cotton from the seeds. When the side of the small cylinder from which a part has been removed, comes opposite to the toothed rollers, if the boll is sufficiently reduced, it will be carried to the next roller, when the seeds will be still further stripped, and so on, to the completion of the operation. Brushes are prepared to take the fibre from the toothed cylinder. A third machine delivers the cotton in endless bats.

Hemp and Flax.—Four patents have been granted within the year, for improvements in machinery for preparing hemp and flax, which do not require particular description. In one of them, there is a device for separating and drawing out the fibres, so that it may be spun like cotton.

Carding.—About four patents have been granted for improvements in carding machines. In one of them, the main cylinder has, in addition to its usual motion, a reciprocating end motion, for the purpose of more perfectly spreading the staple over its surface. In another, a band armed with card teeth works constantly across the cylinder near the doffer, for the purpose of crossing the fibres to produce a bat proper for felting. In a third, wires are connected to good conductors, and with the teeth which operate upon the wool, for the purpose of preventing injurious electrical action. A process of mixing wool and cotton on the cards has also been patented. Each staple is prepared on separate machines until both are ready for the finisher, when they are carried together through the cards and mixed.

Letters patent have also been granted for improvements in apparatus for sizing and drying cotton batting, and for improved apparatus for making hat bodies. They do not greatly differ from such as have heretofore been known.

Spinning and Twisting.—About fifteen patents have been granted within the year for improvements in these sub-divisions; one for improvements in the counter twist speeder. Its object is to prevent the irregular and unsteady motion of the roller upon which the roving is wound. Another, is for an improvement in drawing regulators. It performs substantially the same duty as some already in use, but in a different way. The regulating apparatus is governed by the trumpet as in some other machines. A patent has been granted for improvements in cop spinning. It is a new arrangement of devices for regulating the winding of the yarn in the cop. A combination has also been patented to be used in doubling and twisting, and for stopping the machine when either of the threads break. An improvement has also been patented for use in doubling and twisting silk. It is for holding and releasing the threads, and consists of a bar with a series of spring catches closed by independent springs, but opened simultaneously by a sliding slotted bar—or each may be opened at pleasure, without the intervention of the bar. By this device, the operation is much facilitated. A hand spinner has also been patented, which is a slight modification of others in use. A device for regulating the tension of yarn in spooling, has also been patented; and also two or three machines for making cordage, which are said to answer a good purpose.

Patents have been granted for a knitting machine, for improvements in the manufacture of rugs, folding cloth, shearing cloth, pressing hats, and for other miscellaneous purposes.

Sewing Machines.—No less than seven patents have been granted within the last year for improvements in sewing machines; it is but a few years since these machines were introduced, but as they are found to be useful, inventive genius is already directed in no small degree towards them, and important improvements may be expected. In one of these machines, the needle lies in a groove made in the face of a straight rack, and is held in this position. A pinion works into this rack upon which the cloth is laid—the pinion being at the point of the needle. When the pinion is turned, it at once crimps and carries forward the cloth upon the needle and discharges the cloth by a reverse motion with the seam sewed. The eye of the needle is near its point. In another of these machines, the cloth is placed upon the plate of metal lying over an opening in the table, and perforated for the passage of the needle. The needle is forced through the cloth and the plate, by appropriate machinery. The thread is placed under the plate upon a bobbin, and when the needle is down, by an appropriate motion of parts in connection with the bobbin, the thread is thrown round the needle, which has a notch to hold it, and is drawn through as the needle is withdrawn, and forms a loop on the upper side. The cloth is then fed forward, and the needle is again forced through the cloth and plate, and through the last mentioned loop. The thread is again wound upon the hook of the needle, and drawn up through the cloth and the loop through which the needle previously passed, and by a continued repetition of these operations, the seam is perfected. Several of these machines make the seam with two threads, one of which passing through the eye of the needle, (which is at its point,) is at every stitch carried through the cloth, forming a loop on the opposite side. A shuttle having a thread passes through the loop, and as the needle returns its thread, is drawn down upon the shuttle thread which prevents it from being drawn through. I cannot go fully into the details of these machines; they are adapted to various circumstances, and make their seams by a variety of stitches.

Looms.—About twenty-five patents have been granted within the year for improvements in the different varieties of loom. An unusual degree of attention has been bestowed upon those which have reference to weaving piled fabrics. No less than six patents have been granted for improvements in the manufacture of this variety of fabric. In one of these looms two figuring wires are used, entering the fabric on opposite sides, operated by vibrating arms, and supported by guides at each side. In this manner, the wires may be made about half as long as would otherwise be necessary. Thus the binding of the wire in the act of insertion, is in a great measure prevented. Or these wires may be made of the full length, and inserted and withdrawn alternately, so that one will remain in the fabric, while the other is withdrawn and re-inserted. When such warps are used that two wires will be sufficient, the operation will be much facilitated by this modification. In another of these looms, when two fabrics are woven together, and connected by the threads which are to form the nap, a kind of grate is used to guide the fabrics as they are woven, and to keep them always at an equal distance apart. This device also enables the knife to separate the fabrics in such a manner, as to leave the nap or pile of uniform length. In another of these looms, the guides which support the wires, are composed of jaws which rise and close, leaving a series of small openings through which the wires pass for the purpose of being more perfectly guided, and which open and descend, leaving the wire after it has been properly inserted. In another of these looms, a knife is made to pass below the breast beam which cuts the pile, allowing at each cut one of the wires to be released and to fall into a trough below. An arm extends from the knife holder into this trough, and pushes the last wire, which was released to the left of the loom, and then leaving it in a trough, and two endless belts with hooks work into the trough, taking the wire and carrying it up above the lay at the left end of which there is a trough to receive it opposite the end of the lay. In this trough there is a follower moving lengthwise of it, which pushes the wire into the shed, there being a row of notches in the front sides of the dents of the reed to guide the wire. Thus the wires are inserted, and as the fabric is woven, the pile is cut and the wires returned for re-insertion.

Letters patent have also been granted for improvements in looms for weaving fabrics with small figures. It has not the compass jacquard loom, but it is less complicated, and much more easily adapted to different varieties of figures. The loom has sufficient compass to answer its appropriate purposes, and avoids some disadvantages in working the harness with the jacquard, without sacrificing any of its advantages which are important in weaving the kind of fabrics for which this loom is intended. Patents have been granted for improvements in throwing the shuttle; for making wire heddles; for sizing twine heddles, and for protecting the reed when the shuttle fails to enter the shuttle-box. A hand loom has also been patented, in which all the motions are derived *directly* from fixtures connected with the lay, and for a temple to be used in weaving seamless fabrics.

Other improvements in looms, apparently of great value, have been patented, but neither time nor the complicated nature of this variety of machinery, will justify a further analysis of this class.

It will be perceived by a perusal of the foregoing remarks upon the classes committed to my charge, that the past year, like most others, has developed but few inventions which open new paths, or are otherwise of commanding importance. They are all believed to be useful in the legal acceptation of the term, and many of them will be found beneficial in various degrees, in the branches of the arts to which they belong; some are, however, of very little importance, but their novelty, under the law, entitles them to security by patent, and it is not legally to the purpose, to say that they are no better than things previously known, if they are essentially different. Every one will admit that great and important inventions should be secured to the inventors, and that the benefits flowing from them to society, are so great that all the inconveniences of the system are as nothing. There are numerous inventions within the knowledge of all, which have produced results so important and beneficial, that any one of them would outweigh all the evils and expenses of all the patent systems of modern times; such inventions are of comparatively rare occurrence, but may be expected more frequently as a knowledge of the arts progresses. These, all admit, should be provided for; but the same law which provides for them, must provide also for minor inventions. It is impossible to separate them by legislation; we must loose *the one*, or receive it in connection with the other; and when we recollect that the greatest inventions are often based upon small beginnings, who would desire to frown down these apparently diminutive inventions, from which such splendid results may and often do arise?—a blow aimed at them would inflict a fatal wound upon the growth of the arts, and through them, upon the vital interests of mankind.

W. P. N. FITZGERALD,
Examiner of Patents.

To Hon. THOMAS EWBANK,
Commissioner of Patents.

SIR:—In accordance with your request, I have the honor to submit to you the usual report of the transactions, with reference to such applications for patents as are entrusted to my charge, accompanied as is also customary by brief notices of some of the inventions for which patents have been granted. The whole number of new cases submitted to me for examination during the past year, amounted to five hundred and twenty-nine; of these two hundred and four have been patented, and twenty-five remain unacted upon. The papers appertaining to others, are still in the possession of either the applicants or their attorneys, having been sent to them for amendment, and still others have been rejected and withdrawn. The number of actions upon these various cases has amounted to one thousand and ninety-five. And the number of formal rejections, sometimes two and three to a single case, included therein, reaches the number of three hundred and fifty-three.

As the nature of the various actions upon cases was explained with some care in the reports of myself and colleagues, for the year 1849, I do not deem it necessary again to call your attention to that subject, observing merely in reference to that portion of my own report, that the best efforts of myself and colleagues, have as I predicted, been unable to keep pace with the increased demand upon our labors, arising from the increased number of cases, and that the work before the office is now accumulating. It is my sincere hope either that the force may be increased, or that the cases presented during the year to come may be of such character and so limited in number, that we may be enabled to act upon them all. I know of no one cause which harasses the mind of the inventor to so great an extent as delay in the examination of his case, and I can well imagine how disappointment, arising from the discovery that his invention has been anticipated, is aggravated, when the communication of such unwelcome news is delayed from week to week, and month to month, during all which time he is, as men usually do, picturing to himself in no faint or undecided colors, the honors and the profits, which are to accrue to him, from the production of his brain. A communication to such an effect is to all men a disappointment; others it irritates, and there is a small, I am glad to say but a small number, who conceive that a decision against them, furnishes good ground for a quarrel with this office, and is based upon either ignorance or prejudice. These parties generally labor under misapprehension as to the duties of this office, and are unacquainted with the causes that led to the establishment of the present system. They do not seem to consider that the refusal of patents for devices which have been heretofore known, enhances the value of such patents as are based on novelty. They appear never to reflect that if all the patents asked for were granted, then would the community, unable to submit longer to the burden imposed upon it by patents granted for old things, and justly unwilling to pay for the right to use that which is common property, call upon the government not merely to establish such a system as is now in force, but perhaps to refuse protection even to original and useful inventions. It appears further, that it is a common misapprehension for these men to suppose that this office is established to protect and encourage invention, and to afford facilities to inventors, meaning by that term, not those who have contributed to the arts, but every person who may find it convenient to make application for a patent. When the term is employed in its true sense, then is their opinion a correct one, provided the duties that this office under the law owes to the public are also taken into consideration.

This office stands in fact between the public on the one side, and the inventor on the other; its duty to the former, however disagreeable it may be to those who perform it, is to see that no machine, art, or process, or improvement thereon, receives the protection of a patent, granting to the owner a monopoly of the same, unless there shall exist in it some new and useful thing heretofore undescribed. Its duty to the inventor, is to grant patents to him for such new and useful improvements, aiding and assisting him, as far as possible, to cover every inch of ground to which he has a clear title, and when the deed for that title is granted, seeing as far as the law will permit, that he is not harassed and ruined by the grant of other titles, for apparatus changed indeed in appearance, but not altered in reality, from that described by the original inventor.

There is another misapprehension, not productive of so much mischief, nor leading to so much ill feeling, which it will be well to notice. True inventors are often rejected, having their claims disallowed many times, merely on account of their not claiming that to which they are entitled, presenting to this office claims for old devices, covering ground which is either common property, or appertains to some previous invention.

By examination of references furnished by this office at each time it rejects, they at last perceive and are able to define the precise point in which the invention consists; their way to a patent is then a clear one, and the propriety of withholding the same up to that time, would appear to be obvious. Such however, is not the case, and there are some applicants, and even some patent attorneys, who ought to be better informed, who think that the office in this way, loads itself with useless labor and harasses the applicant with unnecessary delay. The absurdity involved in granting a deed for that to which there is no title, and not the shadow of a claim; when the applicant has, during the whole time good and sufficient warrant for something else which really belongs to him, and is afterwards, and as soon as he applies granted to him, seldom or never seems to strike their minds. When it does, they wonder that the office did not point out the new thing, light upon it by intuition, and explain it to the inventor, forgetting that he who made the machine is, or ought to be, best acquainted with its peculiarities; forgetting too, how excessively awkward it would be (to say the least,) for this office one day to state that it believes a thing new, and discover by examination, or be informed by the inventor himself the next day, that it is old.

I have discussed these points at some length, for one reason, and for one reason only, namely, that I believe an exposition of the true position of this office will lead to an increase of good feeling between it and the whole brotherhood of true inventors, and that they will continue to believe, that in performing our duties we are acting under a true sense of the responsibilities of our position, and striving with the best lights we possess to do those duties impartially and honestly; and that they will acknowledge when we happen to differ from them in opinions, and are perhaps in error, from which no human tribunal is free, that such errors in judgment arise merely from mistaken sense of duty, and not from want of sympathy with their feelings, or desire that they should be deprived of their rights.

During the past year, three appeals to his honor, the Chief Justice of the District of Columbia, have been taken from decisions made in the classes which are under my charge. In all of these, the question of novelty in the alleged invention was the point in dispute, and in all of them the decision of the office has been affirmed.

Of the patents granted in classes allotted to me, during the present year, but few are based on striking novelties in principle, but few point out entirely new pathways to old results; they are generally modifications in, and improvements on well known apparatus, detours from some points in the beaten track, passing around an obstacle and returning again to the old trodden road. A large majority of the inventions thus patented, promise to afford useful practical results, appearing to be made by those well acquainted with both the excellencies and the defects of existing contrivances, and not emanating from that class of minds which would reform before the evil is known; would bring forward systems new to them, but long since abandoned by those acquainted with the art. In noticing these inventions briefly, I will as far as possible follow in the order observed in my last report, not only as regards the classes, but the sub-divisions of the same.

METALLURGY.

In this large and important class, about ninety patents have been granted, which are divided among the various sub-divisions of this class, much in the same ratio that they were during the preceding year, with the exception of those which have for their object the separation of the precious metals from the impurities with which they are found mechanically mixed. These ore washers, or gold separators, are not so numerous in proportion, as during the year 1849. The field of invention has been, to a great extent, covered by the machines of the previous year, and there is more difficulty in discovering novelties, either in the application of principles, or in the adaptation of mechanical devices for bringing such principles into more successful action. Moreover, the market is filled with the machinery already manufactured, the demand and the profits are both more limited, and there is less inducement for the inventor to rack his brains, and concentrate his abilities for the improvement of this class of machines.

But five patents have been granted for such machines, and only two of these differ in any great degree, from those previously existing. In one of these the finely pulverized ore and water is introduced into a revolving basin, the cavity of which is deepest near the edges. From the bottom of the deepest part of the basin, and attached to it, descend tubes largest in their bore at their upper ends. As the basin revolves, the lower ends of these tubes, which are all on the same level, pass in succession over the surface of mercury contained in a ring shaped trough; their length being sufficient to give the stream of ore and water passing through them such an impetus as will drive it to the bottom of this trough. The water and the impurities rise by virtue of their greater levity, to the surface of the quicksilver, and run to waste over the sides of the trough. A portion of the gold is amalgamated and retained by the mercury; other portions of it rise to its surface, but as they rise are met, and again forced under by the stream of fluid proceeding from the next succeeding tube. The gold is thus immersed and reimmersed continually, until it is kept so long in contact with the mercury, as to be amalgamated and retained.

The machine is said to save nearly all the precious metal, and to be working to advantage on the Virginia ores, which yield but a small per centage of gold. In the other machine referred to, a species of oscillating and *shocking* motion in two directions, in planes at right angles to each other, is communicated to the same pan. It is not known that this machine has come into use, but its peculiarities appear to be such as would render its action successful upon ores, in which the gold is found in large particles.

A process *for making steel from cast iron* has been patented, the novelty in which consists in decarbonizing cast iron, in the shape of thin plates, and piled in layers, with strata of pulverized oxide of iron. The materials thus arranged, are exposed to the action of heat for several days, in an oven, such as is employed for making blistered steel, care being taken not to raise the heat sufficiently high to melt the mixed mass. Samples are from time to time withdrawn, to ascertain the degree to which decarbonization has proceeded. When the operator judges that the proper extent has been reached, the thin plates are withdrawn and treated in a crucible, much in the same manner as blistered steel is, when converting it into cast steel. Good steel is produced by this process, and works for carrying it on are now in successful operation.

A patent has been granted for improvements in well known processes for obtaining wrought iron directly from the ore; the novelty consisting in arranging the deoxydizing chamber, which is heated by the waste heat, in such a manner that its contents shall not be exposed directly to the flame; while at the same time they can be permitted, at pleasure, to descend upon the working bottom below, without being exposed to a current of unburnt atmospheric air.

Patents have been granted for several tuyers, and for an improved arrangement of a steam boiler, in connection with a cupola furnace.

A patent has been granted for an improvement in steam hammers, the novelty consisting in attaching the hammer to the cylinder, instead of to the piston rod. The piston stands at rest, while the cylinder rises and falls; the advantages of the arrangement are obvious, and the inventor proved that his discovery was prior to an English publication of the same apparatus.

A patent has been granted for certain very ingenious improvements in the blacksmith's striker, which is worked by the foot of the smith. An intelligent description of them, without a drawing, would be difficult.

Two patents have been granted for devices for giving a rotary motion to the fluid iron from which chilled rolls are cast, and one for a plan by which large kettles can be cast with facility in metallic flasks, which are in shape nearly similar to the kettle to be produced. The process consists in applying a stream of cold water to the inner half of the flask or lantern which supports the core, at a time when the melted metal enclosed, is arrived nearly at a solid state. The inner part of the flask is thus caused to contract rapidly, and when contracted in diameter, it can easily be withdrawn, both from the kettle and from the exterior half of the flask.

Another plan for accomplishing the same result, has been devised and patented; it consists in making the core supporter, or inner half of the flask, a flexible iron basket, which, it is obvious, cannot be either broken, or pinched fast by the contraction of the cooling kettle.

Patents have been granted for an apparatus for applying water to the outside of the hubs of cooling car wheels; for machinery for forming cores for small pipe; and for improvements in the composition from which small cores are formed.

A very ingenious machine has been patented for forming the wrought-iron railroad chairs, which are now by degrees taking the place of the cast ones hitherto employed. In this machine, the iron in bars of the width and thickness of the intended chair is fed by hand between a pair of moving jaws; which, as they approach each other, cut off the proper length for a chair, punch in it the spike holes and clamp it firmly between them. While the blank is thus held, a pair of punches rise up, make the necessary slits in the chair, and as they proceed, bend the lips at right angles to the bed. These same punches, then approach each other and bend the lips over towards a common centre, and into such a shape as shall embrace the lower fin of the rail. The upper jaw then rises and separates into two parts, and the finished chair is thrown from the machine by a discharger.

A machine for making chains into which a wire or rod is fed by self-acting mechanism, and from which a finished chain is discharged, presents, perhaps, the most curious triumph of persevering ingenuity over apparently insurmountable difficulties, that has been brought before my notice during the present year.

This machine is not complicated, when the various duties that it has to perform are taken into consideration; but its construction is such, and its parts are so numerous, that a clear description of it without drawings is almost impossible; suffice it to say, that the wire is first presented to nippers or shears, which cut off a length sufficient for a single link. One-half of this length is then bent into an annular figure, leaving the other half still unbent and projecting from the ring.

Other mechanism then approaches, seizes the unbent portion and forms it into another ring, a plane passing through which is perpendicular to a similar plane passing through the first named ring. A link, technically termed a jack-chain link, is thus completed. The last named mechanism then retires, leaving the link still held fast by the first set of bending machinery, which in its turn moves backwards, carrying and holding the finished link in such position, that the succeeding length of wire is fed through the last formed ring of the link. These operations are repeated in succession, and the finished chain drops in a stream from the bed plate of the machine.

Such chains are employed for chain pumps for household purposes, and are furnished so cheaply, that pumps constructed with them, and of sufficient size for ordinary wells are furnished complete for about 15 to 20cts. a foot.

Patents have likewise been granted for self-acting feed gear, for drilling and boring machines, for a method of punching sheet metal as it passes between rollers, for a machine for making eyelets, and for improvements in the machinery for making wrought-iron car wheels.

A machine or rather a series of machines for making four sided or harness buckles, and one for shaping the circular cutters or burrs, which are used to form the teeth of small gearing, have also served as the basis of patents.

Two couplings, one for hose, and the other for small metallic pipe, have been patented. In the latter device the pipes are cast without either flange or socket; a ring is attached to, and surrounds one of the pipes at a short distance from its extremity. Over the end of this pipe and projecting beyond it, with its larger end abutting against the before named ring, is slipped a sleeve of soft metal the exterior of which is the frustum of a cone; over this sleeve is adapted another of hard metal closely fitting the exterior of the former one. The end of the other joint of pipe is now inserted into the projecting end of the soft metal sleeve, until it abuts against the end of the first-named joint. The hard metal sleeve is then driven by a hammer over the soft one, and towards it, the larger end thus compressing it firmly against the periphery, and between the joints of the pipes.

This coupling is cheap, simple, secure, and easily attached and detached.

Two patents have been issued for improvements in lead pipe machines; the novelty in the one consisting in a method of cooling or setting the lead in

the cylinder before it is forced through the dies; and the other depending for its patentability upon a peculiar shape of both core and die. Certain minor improvements in the process for making copper pipe without a seam have also been patented.

In the subdivision of this class, under which are examined applications for patents in nail and screw machinery, many patents have been granted; among which are two for cutting the threads of wood screws, and one for nicking the blanks. The improvements in these machines would appear trivial, if not valueless, to those unacquainted with the fact that apparently slight differences produce important changes in the action of machines, which are required to perform such nice and accurate work as these execute. To those who have traced step by step the improvements in such machinery, which have resulted in the production of the deep threaded, highly finished American screw, which has taken the place of the rough imported article, but little if any superior to a nail, the improvements serving as the basis of these patents, will present themselves as important inventions.

The nail machines present no very important changes or improvements. One of the two patented machines, for feeding nail plates to the cut nail machine, deserves special notice. It has long been a desideratum to contrive some apparatus which should take the place of the nailor, as he is now termed, who feeds into the jaws of the machine, the heated iron plate, lifting it upwards, drawing it backwards, turning it half round, and advancing it again, each time that the machine makes a nail. These mechanics, by long practice, become so expert as to repeat this set of motions 300 times every minute. None of the many mechanical feeders that have been contrived, have answered in practice. The one here noticed, carries the nail plate through all the motions above cited, and is comparatively simple; as far as can be determined by examination, it appears to approach much nearer to the desideratum than those which have preceded it; whether or not this opinion be a correct one, practice alone can decide.

Several locks and bolts, sash fasteners, sash stoppers, door springs, and other apparatus appertaining to the closing, opening or securing of windows, doors, blinds and shutters, have been patented. Among the former is a very ingenious bank lock, numerous in its parts, but not complicated, and affording, as it would appear, sure protection against the skill of the pick-lock, or the destructive force of crow bars or gunpowder.

Several patents have been issued for machines for cutting and bending sheet metal, for making candle moulds, tin tubing, and cylindrical or conical boxes. These machines present many features of novelty, important when the great number of such articles that are annually manufactured, is considered, and two of them exhibit decidedly new devices for bending up the sides of cups, and such articles, from their bottoms.

A patent has been granted for a machine for beveling the surfaces of washers, clinch-rings, and circular metallic disks, in which a series of small rollers are located in, and project from the inner surface of a hub or drum, with their axes nearly parallel to the axes of the drum.

Revolution is communicated to the drum, and the small rollers act in succession upon the surface of such disks as may be presented to them, a revolving motion being also given to the disk. By this arrangement, the edges of the disk are drawn out and beveled, as they would be by drawing blows of a hammer, but in a more regular manner.

A machine which the inventor confidently asserts will supersede manual laber, as employed for beating gold into leaves, has also been patented. The gold in sheets, and protected by animal membrane, as is usual, is adjusted in layers within a frame which is supported by a marble slab. A trip-hammer, worked by machinery, beats upon the pile, which, in its enclosing frame, is moved hither and thither, and back and forth, under the hammer, by means of cams and levers.

The idea is not a new one; machines of a similar character having been long since employed in France, and I believe abandoned. The claims, therefore, rest upon the particular devices employed by the inventors, to give the requisite motions to the bundle of leaves.

Handles which are adjustable to many auger shanks, and can easily be attached to, or detached from them, have been patented; so also have been improvements in machinery for grinding twisted knives; devices for regulating the parallelism of vice jaws; modifications of the sliding wrench, and a machine for making horse shoes.

STEAM ENGINES.

Of the contrivances examined under this head, about thirty have been patented. Comparatively few applications have been presented, describing improvements in rotary engines, and none of them have been patented. An arrangement of two double acting cylinders, connected to the same shaft, through the intervention of rock shafts, arms, and connecting rods, located with respect to each other, in a peculiar manner, has some claims to notice. The result of the arrangement is such, that the main or driving shaft, makes two complete revolutions to each full stroke of the pistons, and this, without the intervention of cog wheels, drums and belts, or the other usual devices for changing the velocity of rotary motion. The engine is described, as applied to the driving of screw propellers, and is intended to put an end to the noise, and obviate the various other inconveniences resulting from the employment of gearing, or its equivalents, on ship board.

Boilers.—Five patents have been granted for improvements in boilers. Two of these describe modifications of that form of boiler, in which the water is contained inside of tubes, and the flame acts upon their outer surface. The outside shell of either of them may be made in any of the usual forms; so also may be constructed, the fire boxes and water legs, from the former of which, towards the chimney, extends a large rectangular flue, surrounded, or nearly so, by water spaces, the upper one of which is, as usual, in connection with the steam dome. In one of them a series of tubes is attached to the water space farthest from the fire. These tubes extend along the flue, rising slightly as they advance, until they reach the fire box; there they are bent gradually upwards, until they meet, and are attached to the crown sheet. In the other, the tubes are attached to the water space, and proceed from it in the same manner, but when they arrive at the fire box, are connected with a depending water space or spaces, which hang down from the crown sheet. The former depends for its novelty, upon combining in one boiler, the water spaces, the flue, and the bent tubes peculiarly located. The latter upon the peculiar manner in which the tubes in the flue are connected to the depending water space. The former has the advantage that the tubes are not liable to be broken by expansion or contraction, the curve acting as a spring: the latter possesses superior facilities for repair when any of the tubes have become injured. Both of them, it is believed, will cause the water to circulate more completely than it does in other boilers of the same species. The former

boiler has been actually employed on a locomotive fitted for burning anthracite coal, and is reported to have fully realized the expectations of its inventor; based not only upon the features above described, but upon other and minor improvements, upon which claims are granted.

Another of these boilers is specially adapted to the use of locomotives, working heavy grades, and in connection with it are patented certain improvements in the engines.

Several devices for indicating want of water, for registering the action of the firemen, etc., have been patented. One of these consists in attaching a rope of felt to either side of the shell, which is tightly stretched in such a manner, that it shall be in contact with the upper sides of the ordinary return flues. To this rope is attached a rod which communicates with bells, cocks, &c. When the water falls below the top of the flues, the felt rope parts from the action of the increased heat, the rod attached to it is free to be dragged upwards by a weight, and motion is thus communicated to the bells, cocks, and other appendages, which at the same time warn the engineer, and act of themselves to avert the impending danger.

Two spark arresters have been patented, and also an ingenious arrangement of mechanical devices, by which locomotive engines can be reversed, and the lead changed at the same time; only one set of eccentrics being employed, and the change being effected by the movement of a single hand lever.

Two improvements in the surface condenser are worthy of notice; in one of these a receiving vessel for the exhaust steam and the water resulting from the condensation of the same, is combined with the condenser proper in such manner, that a considerable quantity of the heat contained in any one portion of exhaust steam, is absorbed by the water which has resulted from the condensation of a previous portion of the same. Hotter water is thus supplied to the boilers, and a smaller quantity of fuel is required to evaporate an equal bulk of water.

The other condenser has for its object, to relieve the tubes in which the steam is condensed from pressure; thus obviating one of the great practical difficulties incident to the use of the condenser, familiarly known as Hall's. The tubes in this latter condenser contain exhaust steam and water, resulting from its condensation; their interior surface is in vacuo or nearly so: their exterior is surrounded by a constantly changing body of cold water, which presses upon the tubes, tending to colapse them, with a force due not only to the atmospheric pressure, but to the height of the column of fluid. These tubes are of small size, and their collective length in some steamers is more than a mile; there are consequently many joints, and these are liable to be broken by unequal expansion and contraction, or by the straining of the vessel. When a leak occurs, the cold water rushes with great force to the interior of the tubes, and a small leak is sufficient as it is technically termed, to drown the condenser, filling the tubes to such an extent with water, as to forbid access to the exhaust steam, and rendering the condenser useless. To obviate this difficulty, and to render practicable the employment of thin tubes, this patentee originated the idea of admitting the water to the outside of the tubes in such a manner, that in one of his arrangements they should be exposed on their exteriors to the pressure due to the height of the water only; that in the other arrangement, the pressure on both sides of the tubes should be exactly equal, and leakage in consequence, produce no evil whatever.

In this last arrangement, the case containing the tubes is air tight and sufficiently strong to resist atmospheric pressure; cold water is admitted to the top of it, and falls in a continuous shower through a perforated plate upon the cluster of tubes, cooling their surfaces, and condensing the steam within them; as it collects at the bottom it falls by gravity into the well of a pump, which latter lifts out the water. Openings are made through the tubes, connecting the space outside with that inside of them, and thus an absolute uniformity of vacuum in the two spaces is maintained. This condenser has been in actual use for several months; report speaks highly of its performance, and it is stated that it is as little liable to injury as the ordinary injection condenser, while it at the same time returns back to the boiler the steam condensed and unmixed with salt or impure water as is the case in Hall's condenser.

An improvement in packing for pistons, in which soft and hard alloys are employed, and an arrangement by which the inventor believes, that in high pressure engines a portion of the escaping steam may be returned to the working side of the piston, and this without increased pressure on the other side, have also been patented; so likewise have been several modifications of valves and valve gear, and of cut-offs, as applied to puppet-valves. In one of these latter, the toe which actuates the lifter is free to turn on the rock shaft during certain portions of the stroke, being clutched fast to it at the proper time for raising the valve, and disconnected when it is necessary to drop the same, by means of self-acting machinery, which can be so regulated, as to permit the valve to drop at any required time.

NAVIGATION AND MARITIME IMPLEMENTS.

In this class, some six and twenty patents have been granted, among which is one for a peculiar form of vessel, scow bottomed with keels at the sides projecting below the bottom, and below the water line at both bow and stern. By such a form, a wedge as it were of air with its edge toward the vessel is enclosed at the bow, by the keel, by that portion of the bottom which projects over the water, and by the surface of the water itself. As the vessel is forced onwards, and waves strike in this wedge shaped space, each one in its turn forces a quantity of air under the bottom, and below the surface of the water; this air is retained in contact with the same until it makes its way out astern, being prevented from issuing at the sides by the keels before cited. A patent was some years since granted, for applying air to the bottom of vessels: thus, in fact, supporting them on a thin layer of air, and alleviating the friction arising from the passage of water along the outside planking; which friction has of late years been discovered to form an important element among the resistances which oppose the progress of vessels. A vessel built on this better plan in which the air is discharged under the bottom by powerful pumps, is now in actual use in the harbor of New York, and with fair success. The patent granted the present year, has been presented as an improvement on this plan, and the inventor states that his peculiar model will enable him to dispense, not only with the pumps, but with the power necessary to work them.

An arrangement of two flexible bars connected to each other, and to a rigid bar between them by means of cross pieces, which are free to slide on the rigid bar, and can be clamped to it at any required point, has been patented. The whole apparatus constitutes a rule, the outer edges of which can be made to assume many different curves. Its object is to save the wood and labor employed in making the patterns or moulds, from which timbers for vessels are cut. The rule is set to the chalk lines on the laying down floor, and the position of the cross pieces with respect to the rigid bar is noted and marked: it is then set to the lines representing another timber, and so on for any convenient number. The rule is then carried to the yard, re-set by the marks in its previous positions, and the outline of its edges marked on various sticks of timber.

Patents have been granted for various improvements upon submerged propellers; for improvements in the method of propelling vessels in shallow water, by means of setting poles acted upon by machinery; for a method of arranging and operating swinging buckets for paddle wheels; and for an improved apparatus for indicating the depth of water in ships' holds. Several improvements in the gun harpoon have been patented, some of which promise to produce important practical results. A curious piece of machinery for regulating the trim of steamboats, consisting of an immense rocker running athwart ship, which supports a railway on which a chain box is free to move, has been patented. The machine appears to merit praise, rather from its ingenuity and originality, than from important advantages to be obtained by its employment.

An improvement in the truss for sustaining ships' yards; another in the method of attaching grummets to sails, and certain modifications in the deep sea diving vessel, have been protected by patents. A number of improvements in that class of steering apparatus, in which ropes and pulleys are dispensed with, cogs, screws, shanks, and cranks taking their place, have been patented; so also have been improvements in the pumping windlass, and an improved method of carrying ships over the bars which usually obstruct the mouths of the rivers and estuaries of our coast. The latter process consists in supporting the ship by an apparatus differing from the ordinary camels, chiefly in the fact that it is provided with a bow, connecting together the camels located on each side of the vessel, which not only renders easier the passage of the machine through the water, but prevents the sea from dashing between the sides of the vessel and the camel, causing them to change their relative location, and strike violently against each other to the imminent danger of both the vessel and its supporters.

CIVIL ENGINEERING AND ARCHITECTURE.

In the wide range of subjects examined under this head, about 28 patents have been granted.

Bridges.—Certain improvements in the arrangement of arches and tension rods, the feet of such arches resting on a long girder, and abutting against each other, while the feet of a second series of arches rest on the same girder, at points vertically beneath the crowns of the first set of arches, and the tension rods extending from the arches to the girder in lines radial to each arch, have been patented. A compound arched girder in which the arch or bow has, as is usual, a metallic string or tension rod, which rod—and here consists the novelty—is not attached to the feet of the arch, but is carried entirely over the exterior of the same, and resting upon, but not fastened to its periphery, has been patented. By this arrangement, it is said that the arch is prevented from rising at any one point, when pressed by a load unequally distributed upon it.

Several excavators have been patented, some of which are ingenious, but present no striking novelties; so also have been improvements in the method of fastening and forming the frame and filling of iron houses; improvements in window sash and shutters, in mantel pieces, canal gates, and stump extractors.

A process for forming embankments, and filling depressions in the earth's surface, through the agency of streams of water, has been patented, and likewise a method of sinking hollow piles, coffer dams, and other things of like character, by means of creating a vacuum therein, which causes the sand, mud, or shingle to rise within them, and the piles to descend. The process is the invention of a foreigner, was patented by him in England, some years since, and is reported to have been employed with great success in obtaining foundations in the hard sand banks found in the vicinity of the coast of that country.

An improvement in the form of railroad bars, rendering them applicable, not only to car wheels, but at the same time, to the use of those of ordinary carriages, has been patented. These rails are well fitted for being laid down in streets, and it is believed that they will obviate many, if not all the difficulties that have hitherto prevented the employment of rails in the great thoroughfares of our towns. A wrought iron railroad chair, the merits of which consist in the cheapness with which it can be manufactured, and in the iron being bent in such a manner as not to injure its strength, has been patented; and with certain improvements on the method of making cornices, and in the arrangement of inverted arches in bridge trusses, completes the list of such inventions as have been patented in the class under discussion.

FIRE ARMS, IMPLEMENTS OF WAR, &c.

Similar causes to those which led to a diminution of the numbers of the gold washers, presented to this office for examination, have acted upon the minds of those engaged in the manufacture or improvement of fire arms, and but fifteen patents have been granted during the past year in this class. Two of these are for improvements in the sliding piston breech gun, one of them being for a method of moving and holding the piston, and the other for certain apparatus for preventing accidental explosion of the charge, while the operation of loading is proceeding.

Several patents have been granted for modifications of those arms familiarly known as Cochrane's and Colt's.

Two of the latter have been issued to the original inventor, one of them being for certain improvements in the form of the locking notches of the revolving breech, which prevents any one chamber of the same form being thrown past the axial line of the barrel, and for arrangements rendering it impossible for the charge to explode when the pistol receives a violent fall or jar. The other consists in permitting the spindle on which the cylinder revolves to pass only partially through the hole in the latter, and in closing up that end of the same, which is nearest to the barrel. The improvements claimed under both patents, will remedy certain defects of the pistol, as at present manufactured, and the one last noticed is believed to be especially important, as it prevents all smoke, dirt, small pieces of lead, &c., from entering between the spindle and the cylinder, and obstructing, if not entirely preventing its revolution.

Patents have been granted for several improvements in that class of locks in which the hammer is raised and discharged by the same trigger. One of these is based upon such an arrangement of the parts, that one pull cocks the lock, and leaves all the parts held in position, as is an ordinary lock when cocked; a second pull of the same trigger, but requiring much less force, will then discharge the piece. Two advantages result from this arrangement, when applied to fire arms with revolving barrels; one being that the arm is not thrown out of the line of aim by the violent pull on the trigger in the act of discharging; the other that the barrel is at rest before it is discharged, and the ball has only the motion derived from the explosive force of the powder, and not the compound motion derived both from it and from the revolution of the barrel, as is usually the case.

Improvements in the method of revolving the travelling hammer noticed in last year's report; in the method of forging rifle barrels, and in the apparatus for giving increasing twist to the grooves in the same, have been patented.

An ingenious combination and arrangement of the two well known machines for forming and charging percussion caps, has been patented, and in connection therewith, certain improvements in the feeding and carrying apparatus appertaining to the same machines. By these improvements, caps finished and charged, are delivered from the machine, which is supplied merely with the copper in sheets, and with percussion powder. No previous slitting of the sheet is required, no sorting of the caps previous to charging them.

GENERAL MISCELLANEOUS.

In this class only five patents have been granted, and these are based upon improvements in traps, in apparatus for harvesting ice, and upon certain modifications of machines for removing the contents of sinks and privies. One of the former is based upon a curious arrangement of mirrors, by which is reflected to the entering rat, not only his own image, but those of the rats already caught, and all of them in such a position that they appear to be striving which shall first secure the bait. The question whether rats are animated by the passions of larger animals, and are urged by rivalry or emulation, must be determined by those more skilled in natural history than myself. If they decide in the affirmative, the trap here noticed will be as productive a source of danger to the rats, as it has been of amusement to those to whose attention has been brought the certainly very new and odd idea of the inventor.

This description closes my annual brief enumeration of machines, apparatus, processes, and articles patented during the year past; and in conclusion, I must remark, as heretofore, that a full and complete digest of inventions thus patented, would be of use, not only to the inventor, but to the office and the public, and express the hope that in future we may either have ourselves a sufficiency of time to make the same, or that the preparation of such a work may be confided to some competent officer.

All of which is respectfully submitted.

HENRY B. RENWICK,
Examiner.

Hon. THOMAS EWBANK,
Commissioner of Patents.

SIR:—In accordance with your instructions, I have the honor to submit a report of the history and present condition of the business of the office committed to my charge during the past year.

In my report for the year 1849, I gave as the number of cases received at my desk, during the year, 463. Besides these, there were upon my desk 180 cases, the arrears of 1848. All of these were acted on during the year 1849; so that at the commencement of 1850, I had no cases upon my desk that had not been examined. During the year 1850, there have been received at my desk 539 cases, only 497 of which, have been disposed of, leaving on hand 42 applications unexamined. It might seem singular without explanations, that 643 applications should have been examined by me in 1849, and only 497 in 1850; and I am the more anxious to give this explanation, because it illustrates an important principle. It will be remembered, that the honorable Commissioner of Patents, toward the close of the year 1849, expressed great anxiety that the arrears of cases on the desks of the examiners should be disposed of, if possible, at the close of the year. To meet this desire, an unusual amount of labor, both mental and physical, was accomplished by all the examiners on the work before them, and most of them brought up the business at the close of the year, so that there were but few cases in arrears. The business of my own desk was reported as finished up to 1850. But as it generally happens in work done hastily, so it was here. Much of the business had to be reviewed and re-examined, and the correspondence growing out of it, and the delays resulting from it, showed conclusively that hasty examinations of applications for patents, like hasty legislation, are productive of great evils and of little or no good. For these reasons I have examined fewer cases in 1850, than I did in 1849. But I have the gratification of feeling and of knowing that the work has been done on a more solid and broader foundation.

There will be fewer cases calling for re-examination in the coming year, than there have been in that which is past. This remark made of my own desk, it is believed, applies equally to the desks of the other examiners: showing as it is believed it does, that the business of examining patents was never done better than at the present time.

The classes exclusively under my charge at the present time, are the following:

1. Agriculture; 2. Chemistry; 3. Household Furniture; 4. Wearing Apparel; 5. Leather.

This last I also examined until April 1850, when that class was transferred to Dr. Page; consequently all of the cases in this class acted on previous to the transfer will be reported by me.

The class of *Agriculture*, embraces all the instruments used in cultivating the ground, and in collecting and preparing its products.

Chemistry, embraces chemical processes, apparatus for processes, and compositions of matter.

Household Furniture, includes machines and implements for domestic purposes.

Leather, embraces all operations in tanning and dressing leather, with the tools and machines used for such purposes; also the manufacture of leather into boots, shoes, saddles, and harness, and all other articles, usually made of leather.

Wearing Apparel, also embraces articles for the toilet, with the construction of the implements and machines used for their manufacture.

As before stated, 497 cases have been examined out of the cases referred to me during the past year, besides which, a large amount of pending applications from the preceding year have been disposed of, by being patented or withdrawn, or are still pending. It is, therefore, scarcely possible to give even a clue to the amount of work done on pending applications. The number of actions at my desk during the year, on new and old cases still pending, is more than a thousand. In exact number it is 1029. Now out of the 1029 actions recorded on my books, 240 were examinations where the cases were ordered to issue, 313 were first rejections, 90 were second or third rejections. The remaining actions, being 375, are on cases that have been withdrawn, or are still pending.

Of the applications which have been ordered to issue, 230 are patents, 7 re-issues, 2 extensions, and 1 additional improvement.

Character of the Inventions as compared with those of 1849.—It is a fact worthy of remark, that the progress of invention amongst mankind is by no means uniform. Sometimes a new field of invention is opened and a galaxy of inventors swarm about it to develop the hidden treasures. This principle is illustrated in the multitude of inventions that followed the cotton gin, the steam engine, and the electric telegraph. And the same principle is carried out in all the smaller details of the application of science to the useful arts.

The plough clevis is a very old and well known instrument, and is constructed with a vertical, and a right and left movement, so as to vary the width or the depth of the furrow, or both, as may be desired. After the different devices for doing this, had been exhausted, inventors began to look for substitutes for the clevis. One of the first of these was the plough beam, so constructed as to turn on the standard as a pivot, and the end attached to the handles by means of a horizontal graduated arc for varying the width of the furrow, and a vertical arc for varying its depth. When the various modifications of devices for accomplishing this result seemed to be exhausted, the rear end of the beam was made the pivot or centre of motion, and the beam caused to vibrate to the right or to the left, on the standard, by means of a slot in the beam of sufficient length to admit of the motion. A vertical motion of the beam through which the standard passes is accomplished in the same general way, &c.

During the year 1849, several patents among my classes opened new and important fields of invention, which were noticed in my report for last year. The present report, if it presents less of brilliant discovery or invention, embraces much that is useful, and performs an important part in the progress of general improvement.

In reviewing the several classes of my work for the year 1850, and comparing the inventions with those of 1849, I find a greater uniformity than was anticipated. Agriculture, which embraces nearly half of the cases presented at my desk, included in 1849, 117 issues, and the same number were issued in 1850.

The following tabular view will show a comparative representation of the cases patented in the last two years in my classes.

AGRICULTURE.—Cases patented in	1849.	1850.
Churn and Butterworkers	10	13
Ploughs	15	13
Cultivators	6	2
Seed Planters	20	27

	Cases patented in 1849,	1850
Rakes	4	6
Harvesting Machines	15	15
Thrashing and Grain Separators	9	5
Hullers and Smut Machines	8	8
Winnowing Machines	9	5
Corn Shellers	7	3
Straw Cutters	5	10
Bee Hives	5	3
Miscellaneous	4	7
	117	117
CHEMISTRY.		
Patents granted	44	53
LEATHER.*		
Boots and Shoes	7	0
Tanning and Finishing Leather	5	3
Saddles and Harness	9	6
Miscellaneous	0	5
	21	14
HOUSEHOLD FURNITURE.		
Washing Machines	6	3
Cutters of Meat and Vegetables	7	4
Bedsteads and Fastenings	19	13
Tables and Chairs	13	3
Miscellaneous, including Refrigerators	10	20
	55	43
WEARING APPAREL.		
Patents granted	9	11
Total No. of patents, re-issues, and additional improvements	246	238
Extensions		2
	246	240

CLASS 1.—AGRICULTURE.

Having stated the number of patents granted in the several classes referred to me, following the practice of the office for the last ten years, I should proceed to notice the most important inventions that have been examined at my desk during the past year. Commencing with the minor divisions of agriculture, I shall first notice

Churns.—Of the 13 patents granted, very little can be said of the merit of the inventions which they set forth. They are not entitled to any special notice, except to say, they are detailed variations in the modes of agitating fluids. I shall notice two of these. The first is what is called an *atmospheric churn*, consisting of an upright cylinder with a rotary dasher, which gives to the cream a rapid rotary current, causing a current of air to be drawn down through a series of vertical pipes bent at the bottom at right angles, and

* For the remaining patents in this class, see Page's Report.

in the direction of the current of liquid put in motion by the rotation of the dasher. Claims the combination of the dasher and the tubes, for discharging air beneath the surface of the cream.

Another patent was granted for an atmospheric churn, consisting of two vertical cylinders, and an intermediate air chamber communicating with the cylinders by a grated opening or passage—the two cylinders are supplied each with a plunger, and the plungers are moved from the ends of a working beam not unlike the pistons or plungers of a fire engine. The effect produced, is the agitation of the cream by forcing it alternately from one cylinder into the air chamber, and thence into the other cylinder and then back again, by reversing the motion of the working beam.

Ploughs.—Thirteen patents have been granted on this division of agriculture. Three of these for improvements in the plough clevis, three for devices for cleaning the various matters that are liable to adhere to ploughs as grass and stubble; two gang ploughs, two hill side ploughs, one subsoil, one coulter fastening, and one spring beam plough. None of these patents, except perhaps the last, requires any remarks—the subject having been so nearly exhausted, that there is little room for invention. The construction of a *plough beam*, so as to render it flexible, is believed to be a new device, and on the ground of obtaining the result of avoiding the breaking of the plough when striking a fast rock or stump by the spring of the beam, the patent was granted.

Cultivators.—Two patents have been granted under this division, neither of which seems to present any remarkable novelty worthy of notice.

Seed Planters.—Twenty-seven patents have been granted, most of which are for minor points of novelty, and require no notice from the examiner. The following may receive a passing notice.

A patent was granted for a *seed planting barrow*. In this the gist of the invention lies in the device for receiving and transmitting, or distributing the seed. It is so constructed, that the reciprocating, semi-rotating, horizontal seeding disk, takes the seed from the hopper above it into its seed measuring cups, in which cups the seed is carried around on the surface of the underlying plate, until it is brought over a hole in the said under plate through which it falls into the furrow. The patentee claims the devices for moving the seed disk in combination with the disk itself.

A patent was granted for the construction of a *drill tooth*, so that when it should meet with a fast rock or stump, or other fixed obstruction, it might disengage itself without the danger of being broken. Devices for accomplishing this result are rather common within the last year or two. The tooth in this case, is so made as to be hung by a pivot at its top, and to be grasped at its front and middle part by the lips of a pair of tongs, the jaws of which project horizontally backwards, and hold the tooth with sufficient force to resist the action of ordinary soils; but if the drill tooth meets with any fast obstruction, it pulls away from the grip of the tongs, and swings back on its pivot, and when it has past the obstruction, may be pressed between the jaws of the tongs by the attendant.

A patent was also granted for a *planting cylinder*, in which the invention consists in the device for varying the size of the seed cavities in its periphery. This is done by means of an arrangement of radial bars or rods like the spokes of wheels running towards the periphery, and extending into the bottoms of the seed cavities, and thus filling them up in whole or in part only. The radial arms or rods are moved in mortised grooves outward and inward, by means of cams working in screw thread depressions. The cylinder being composed of two short cylinders or disks on the same shaft, one having the cams and the other the screw thread depressions, so that by rotating the inner faces of the disks upon each other, the radial arms are advanced or retarded, so as to vary the size of the cavities in the seeding rollers.

A patent was granted for a *seed distributing apparatus*, in which the invention consists in the use of cogs of wheels having their peripheries pass through the hopper of a seed planter, and each cog takes up and carries over a small quantity of seed and deposits it in the seed drills; there being one drill tooth for each cog wheel.

Another patent was granted, the gist of which consists in the arrangement and in the working of the seed valves in the bottom of the hopper, in combination within one of the sides of the hopper, so made as to slide up and down, and thus vary the capacity of the seed measuring space, contained between the upper and lower slide valves, by causing the valves to recede from or approximate towards each other. In sowing seed, the two series of valves move alternately, the upper being opened first, lets down its charge upon the lower one, while the latter is yet shut, and as soon as the upper one is closed, the lower one is opened, and the seed falls into the furrow. The upper and lower valves, each is worked by a separate set of cams on the driving axle.

Cart for Spreading Manure.—A patent was granted for this apparatus, consisting of the sides and ends of a manure cart-body on a pair of wheels, on the axle of which the body is capable of being slided rearward, or run back on rollers for the purpose of the discharge of its contents. The bottom part of the said cart-body or box is made to consist of an endless apron on a series of rollers, the forward end of the apron is made fast to the forward end of the box, while the near end of the apron winds up on a roller situate underneath and near the rear end of the cart. It discharges the contents as the body of the cart moves or slides backward. The manure is spread by winding up the rear end of the apron on the under roller, which process brings the contents slowly backward, and distributes them broad cast or otherwise at the rear of the cart body.

Harvesters.—Under this division, fifteen patents have been granted. For the last two years much attention has been given to this class of agricultural machines. At first, they were confined to the cutting of grain chiefly, then to grain and grass, and now they have been extended to almost every herbaceous growth of the soil. Thus we have grain and grass harvesters, corn harvesters, cornstalk harvesters, cotton harvesters, cotton stalk harvesters, cloverhead harvesters, hemp harvesters, &c. I shall notice several of these, as they present something of interest to prairie farmers, especially.

The first machine which I shall mention in this class, is a *machine to harvest cotton stalks* in the field. It is a machine having two horizontal shafts, running from side to side. The upper and forward one has radial knives or beaters, which rotate rapidly, and beat down the stalks, while the rear shaft is supplied with radial longitudinal knife edges extending from side to side, and as the blades come down they chop the stalks in pieces.

The second machine noticed under this division, is a *grain and grass harvester*, presenting two principal points of invention. First; the cutters, which consist of two horizontal saw blades, lying flat upon each other, with the teeth looking forwards, and vibrating upon each other as the face of the saws is pushed forward against the standing grass. The peculiarity of these teeth consists in their being made concave on their inner faces, so that when

they slide past each other, they cut somewhat on the scissors' principle, and are, to some extent, self-sharpening. Second; there are what are called cyma-reversa fingers, working in combination with certain rake teeth, designed to hold the charge while the fingers take it and deposit it upon the ground.

The third machine of this division is a *corn stalk harvester*, the frame of which resembles a low three wheeled truck, and bearing upon its upper surface, near its middle part, two broad metallic disks, armed with teeth on their peripheries, which teeth slightly overlap each other, and are capable of seizing and holding within their grasp, any herbaceous matter, and as the machine moves forward, to tear it up by the roots. The meeting of these teeth is near the central part of the machine, anterior to which the space is perfectly clear, so that when the machine is driven over a row of the corn stalks, the latter are successively brought against the teeth of the metallic disks, and drawn out of, and deposited upon the ground.

The fourth machine is an ingenious contrivance for distributing the cut grain of a harvester into suitable parcels for bundles, by the weight of the grain. It is called a *grain binder*. It consists of a self-regulating rotary cylinder, mounted on the rear end or extreme right side of the machine and having its axle parallel with the rear end of the machine. This cylinder is supplied with catches and springs, and so arranged that when a certain weight of grain is received into one of its three compartments, it performs a third part of a revolution, and deposits the amount received for a bundle, while the next compartment of the cylinder is being charged for a second bundle, and so on.

One patent has been granted for a *machine to harvest hemp*, a prominent peculiarity of which consists in the method of severing the stalk, by means of an oblique chop stroke of the cutters falling obliquely across the spaces between the fingers, and upon the edge of the finger on the further extremity of the finger space; the oblique stroke being given by the shaft on which all the cutters are arranged, which shaft is semi-rotated in screw thread bearings, so that the shaft in so rotating and re-rotating as to raise and depress the cutters, should, in performing this operation, give the oblique motion which severs the stalk, as set forth.

Two machines adapted to harvest maize, have been patented. The first of these contains a thresher to husk and shell the grain. The harvester consists of a machine, in its general arrangement not unlike a clover head harvester. But it has a series of pairs of rollers, one pair between every pair of teeth, to seize the stalks and pull them downwards, until the ear is drawn against the tops of the fingers by which the ear is severed from the stalk. The ear then rolls down an inclined plane to the thresher. A *second machine for harvesting maize or grain* has also been patented. The gist of this invention consists in the construction of the grain reel, made with rows of fingers, projecting radially, and rotating over or through the standing grain. The stalks being received between the fingers, the ears are pulled off and deposited on an inclined endless apron.

A Grass Harvester of a novel construction has been patented, which it will be difficult to describe without the aid of drawings. Some idea of its general character, however, may be formed, by supposing a flat washer-like ring of metal to be cut out of a sheet of metal, and placing it in a horizontal position. Now place upon its surface, symmetrically, a series of sharp razor blades a few inches apart, having the shank confined to the ring by a screw or rivet, and the ends of the blades projecting beyond the periphery of the ring. If now the ring be rotated, so that the cutting faces of the blades be forward, and in this state be brought against the standing grass, it is contended by the inventor that the machine will be a successful instrument. The cutting blades are supported in their position by suitable contrivances, and the ring, with its cutters, has also suitable devices for supporting it, and rotating it as the carriage moves forward, which it is unnecessary to refer to here.

Horse Rakes.—Only one apparatus under this division is regarded worthy of special notice, although six patents have been granted.

This invention is denominated *a machine for binding grain.* The frame of it resembles the platform of an ordinary harvester, so constructed that curved rake teeth, projecting upward through the floor, and passing across the same from side to side, collect the grain at the opposite side, where it is brought against a curved arm, between which arm and teeth the grain is pressed, and at the same moment another curved finger rises through the floor from behind, to support that half of the bundle, while at the same time, the curved rake teeth, by means of the machinery, fall backward through the floor, and are carried back to the opposite side of the platform, or to the starting place, for a new charge.

The gearing could not be explained without a drawing. The only part required of the attendant with the machine, is to tie the band for each bundle or sheaf.

Thrashing Machines and Grain Separators.—Five patents have been granted; two thrashing machines, and three for separating the grain from the straw, or for carrying away the straw after thrashing. I shall notice only one of these, namely, a thrashing cylinder. This cylinder is constructed in short sections or rings, in such manner as to be slipped over a solid cylinder, and made moveable on it, so that when any one section receives a stone or other hard body between the teeth, instead of its breaking out the teeth, the ring will slip round the solid cylinder and thus allow the obstruction to pass through the machine without doing injury.

Winnowing or Fanning Mills.—Five patents have been granted; three of these for ordinary fanning mills, none of which present any general interest for their novelty in invention. The points claimed are minor ones.

Machines for Hulling Grain and Rice, and separating Smut and Dirt.—Eight patents have been granted; three of these for hulling clover, four for smut machines, and one for separating garlic from wheat. I shall notice three of these machines. The first is for the construction of the basis for setting the teeth on the cylinder of a clover huller, or on the concave of the same. The teeth are first set in a compact sheet of leather, and this fixed upon a basis of cork, for the purpose of rendering the teeth capable of a slight flexibility so as to prevent breaking from the accidental introduction of stones or other foreign bodies.

A Clover Huller has been patented; the novelty of which consists in the form and arrangement of the teeth on the concave and on the cylinder. The one (say the cylinder,) has teeth proper of an ellipsoidal form, running between serpentine ribs of alternate expanded and contracted dimensions on the sides, so that the grain between the roughened sides of the ribs and the roughened sides of the teeth, may receive a sufficient amount of friction to clear it of hulls.

A Garlic Machine has been patented, for the purpose of separating garlic from wheat or other grain. It consists mainly of a horizontal slatted or ribed cylinder, between whose ribs or slats the pinion teeth of another cylinder are allowed to mesh, and against which they are pressed by a spring with suffi-

cient force to crush the garlic without injuring the wheat. The garlic is thus mashed and made to work its way out of the machine, through the ends of the cylinder.

Corn Shellers.—Three patents have been granted; none of which present sufficient novelty to require special notice. One being to give the ear a screw motion as it is forced through the machine, another feeds the corn between the two contiguous faces of the concave rims of a pair of shelling wheels, another makes his shelling disk answer the double purpose of a sheller and a fly wheel.

Straw Cutters.—Ten patents have been granted. Three of these will be noticed—the first belongs to the class of straw machines in which the blade is worked by hand. The point of novelty is in the device of fastening the jointed end of the knife on a spring, so that in working the knife, the slight yield of the spring produces a draw cut in severing the straw.

In the *second* machine noticed in this division, the novelty of the invention consists in so arranging the spirally ribbed feeding rollers and horizontal knife with its edge towards the said rollers, and brought so close to the ribs, that those of the upper roller, cut against the upper edge of the knife, while those of the lower roller cut against the lower edge of the knife; and thus the straw that is fed through, is all cut either by the lower or upper edge of the knife.

Under this division of agriculture, there has been patented a *vegetable cutter,* presenting some novelty worthy of mention. The machine in the general consists of a short cylinder lying or supported on its side, and having its cutting apparatus on the upper part of the cylinder over which the hopper is placed. The two edged knives, which have a reciprocating motion in an arc corresponding with the periphery of the cylinder, are hung on arms attached to each end of the axle of the same, and vibrate across and just above the opening in the bottom of the hopper, and perform a cut with both the forward and back stroke.

Bee Hives.—Three patents have been granted; but none of them presents sufficient novelty to require special notice.

Miscellaneous of Agriculture.—Seven patents have been granted; one for a *curry comb,* three for *hay forks,* one for stanchions for cattle, one for a machine to fumigate plants, and one for the construction of an ox yoke. Of the last of these the novelty consists in having two staples instead of one, as is common, and placed in the middle. The design of the invention is to enable a weaker or a lighter ox, to draw his end of the yoke equally with a stronger animal. In the common ox yoke, the chain by which the animals draw the load, is attached to the staple in the middle of the yoke. In this improvement there are two staples, each one about three inches from the centre, one on each side of it. The chain leading, say from the plough, is divided twelve or eighteen inches from the yoke, into two branches, one leading each staple; one of the branches has an adjustable device for varying the relative lengths of the branches—by this adjustment, the advantage may be given to the one or other ox, as may be desired.

Class 4.—CHEMISTRY.

This class contains fifty-three patents, under the following heads:

Manufacturing candles and purifying the materials,	5
Preparing manure from animal compound,	1
Gas manufacture,	3
Manufacture of sugar,	3
Manufacture of soap,	1

	1
Manufacture of soup bread,	3
Distilling alcohol, oils, &c.,	1
Enameling hollow ware,	1
Manufacture of glucose, (grape sugar,)	2
Gas metres,	6
Manufacture of India rubber,	4
Paints, and covering cements,	1
Extinguishing fires, (by means of suffocating gases,)	2
Preserving vegetable fibre in wood or in cordage,	3
Refining and separating gold,	1
Grinding rags for paper making	1
Parti-coloring yarn,	1
Sizing compound,	1
Manufacture of stannate of potash and stannate of soda,	1
Manufacture of gutta percha,	1
Preparing wheat for grinding,	1
Preparing sugar cream, for the use of tea and coffee,	1
New burning fluid,	1
New material for printers' ink,	1
Manufacture of comfits, or sugar plums,	1
New glazing compound for the laundress,	1
Manufacture of alum from the green sand,	1
Apparatus for salting meat,	1
Machine for filtering oils,	1
Manufacture of starch from maize,	1
Manufacture of caviar, (an article of food from the roe of the sturgeon,)	1

Several of these inventions will be noticed more in detail.

Water Gas.—It will be remembered, that in my report for 1849, I noticed somewhat at length the subject then, and still regarded by the community as a prominent novelty of the day, namely, the *water gas.* I gave the outlines of the history of gas making from steam or water, and showed by the references, that the invention was at least twenty years old, and that four or more English patents had been granted for modifications in the manufacture. But as the public mind has been held in a state of feverish excitement by newspaper squibs, promulgating the most astonishing discoveries, from time to time, throughout the last year, on the subject of illuminating gas derived from water or its elements, I deem it proper to make some further remarks respecting it. Water gas is an old and well known invention, and it requires no small share of inventive power to make an improvement that would be valuable to the public. The pale combustible gases, as obtained from steam passed over red hot charcoal, have been more highly charged with carbon, to increase their illuminating power in two ways; the first, by forcing them through highly or finely pulverized charcoal or equivalent carbonaceous matter, and then through scraps of iron at a low red heat, to remove the excess of carbon. The second consists in mingling the pale combustible gas with the vapor of spirits of turpentine, naphtha, or other hydro-carbon, by which the gas is sufficiently carbonized to give the requisite illuminating power. It is stated in the American Year Book of Facts for 1850, that even atmospheric air may in this way be charged with the vapor of any hydro-carbon, so as to render it capable of being used as an illuminating gas. To this second mode of carbonizing combustible gases belongs the invention of Mr. Donovan, patented in England

in 1830, and of Molleras patented in 1834, and the celebrated Paine light of newspaper renown the world over.

A patent has been granted during the past year for a peculiar form of retort for the manufacture of the water gas. It consists of three cylinders cast in one piece of metal, designed to lie horizontally in the furnace, so that the three lie on nearly the same horizontal level; the largest in the middle, and a smaller one on each side. Suppose the spectator to be looking towards the end of the retort, as it lies in its position in the furnace, the small retort on his right is charged with finely pulverized charcoal, the one on his left with scrap iron, and the middle one is charged with anthracite coal or other matters, to increase the amount of decomposing surface. The water or steam is forced into the right hand compartment, and carried along the whole length of this retort through the red hot charcoal, where it takes up a certain amount and thence passes, by means of a small conducting tube, across to the left retort, through the length of which it passes, and deposits its excess of carbon, as alleged by the inventor, and then enters the large retort by means of a short tube at the end nearest the spectator, where it mingles with the rosin, or oil gas generated in the same vessel in the usual manner. The utility of the water gas has not been yet sufficiently tested to enable the public to judge of the cost of this gas, compared with that from coal, rosin, or other well known agents. The inference is pretty strong, that if the twenty years' experience in England, from the time of Michael Donovan's patent to the present, has not introduced the water gas there, it must be because it costs more than it is worth, or else they have not invented the right kind of apparatus for its successful use.

I have been led to make these remarks at greater length than might otherwise be deemed justifiable, from the frequent applications, public and private, made at this office for information respecting the so called Paine patent. No such patent has been granted in the United States. A patent has been granted for an apparatus for generating illuminating gas from asphaltum. The material is introduced into the retort in a semi-cylindrical iron tray, and the tray removed at the end of every charge of four or five hours heating.

Soup Bread.—This preparation is made by mixing up with flour, the liquid or soluble parts of meat, reduced by boiling and concentration to a jelly, and forming these materials into dough, which is then rolled out into cakes or loaves, and baked at a low oven heat.

Glucose, or Grape Sugar.—An article under this denomination has been patented; it is a process. The sugar found in raisins and in most acid fruits at maturity, belongs to one kind or species, and is distinguished from cane and maple sugar by being not more than half as sweet as the same weight of the former. It was found many years ago, that if starch were suspended in water, slightly acidulated with an acid, and boiled briskly for some ten hours, the starch would be converted into its own weight of a sugar identical with that found in raisins and other fruits, which fruits are acid in the green state; this product is called *glucose*. The patentee has learned by experiment, that if he boils his starch compound at a higher heat than 212°, he reduces the time required to finish the process, so that what was before done in ten or twelve hours, may now be done in six or seven. He mixes 25 bushels of corn meal with 150 gallons of water, at the temperature of 175°, and adds about 25 pounds of oil of vitriol, and after well stirring the same, adds 50 gallons more of water, and runs the whole into the boiler, lets in steam, and allows the contents to boil under pressure, by adding weight to the safety valve. He continues the boiling until the tincture of iodine no longer indicates the presence of starch in the material. Chalk is now added, to neutralize the sulphuric acid, and the solution concentrated to crystallize.

Zinc White, or White Oxide of Zinc, is now largely used as a subsitute for white lead, in painting. The great value of white lead as a vehicle for other paints, consists in the fact that the carbonate of lead is soluble, to a certain degree, in oils; it is now found that the same is true of the oxide of zinc, and hence its peculiar fitness for the uses set forth, as a vehicle for paints, and a substitute for white lead. The subject of the patent is the construction of a furnace for oxidizing the metal, arranged with air passages for oxidizing, and reception tubes for collecting the product.

Sugar.—A patent has been granted for a process of refining sugar from the beet or cane, which consists in adding to the cane juice, or beet juice, or to the solution of sugar in water, a quantity of baryta, to form the saccharate of baryta, which is removed from the liquor by mechanical means in the state of magma. The baryta is separated by means of carbonic acid gas forced through it; an insoluble carbonate of baryta is formed and precipitated by adding sufficient water, so that the solution of sugar will be of the strength of 30° Baumé, from which it may be concentrated to the state suitable for crystallization in the usual way.

Draining Sugars.—This is an improved apparatus on Hurd's machine for draining sugars by centrifugal force, and consists in surrounding the wire gauze cylinder by a steam case, to be supplied with steam, or a fine spray of water, the design of which is to prevent the gumming up of the meshes of the wire gauze, which is liable to occur when the surface of the cylinder is freely exposed to the atmosphere.

Refining of Gold.—Three processes have been patented for separating gold from other metals, or from gold sands, only two of which will be noticed here. As this subject is one of great importance, inasmuch as from present appearances, gold is likely to become the chief metallic currency of our land, I deem these processes of sufficient interest to the public, to give them somewhat in detail.

Most of the native gold brought to the mint for refining, contains silver, from which it must be separated before it can be supplied with the uniform proportion of alloy required by law in gold coin. For this purpose, the process now in use throughout the world, is to melt the gold to be refined previous to coining it, with two to three times its weight of silver. It is then granulated and exposed to the action of hot nitric or sulphuric acid, which dissolves out nearly all the silver, both that in the native metal, and that added by the refiner, and thus leaves the gold in nearly a pure state, and ready to receive the necessary portion of alloy required in the gold coin. It will be seen at a glance, that allowing a million of California gold to weigh (53,250) fifty-three thousand two hundred and fifty ounces, or nearly two tons, it would require nearly six tons, or (161,250) one hundred and sixty-one thousand two hundred and fifty ounces of silver, and worth about ($190,000) one hundred and ninety thousand dollars, to be kept constantly on hand to work it. The desideratum is, therefore, to find some process of working the gold, by which this great outlay of silver may be prevented, and by which greater celerity may be effected; both of these results, the inventors allege, they have obtained.

In the first, the argentiferous gold is converted into the chloride by the action of nascent nitro-muriatic acid generated by the re-action of sulphuric acid upon a mixture of nitrate of soda and common salt, or by other equivalent means. The silver contained in the native gold, is also coverted into the chloride by the same chemical re-action, and it is prevented from incrusting the gold by the more intense affinity, and the agitation produced by a jet of steam which is constantly being forced into it. The gold is next precipitated in the metallic state upon the chloride of silver, by means of pulverized copperas. After washing the precipitate of gold and chloride of silver, the latter is reduced to the metallic state, by the re-action of zinc and dilute sulphuric acid; and subsequently, the silver is dissolved out by means of nitric acid. From the nitrate of silver obtained above, the metal in the pure state is precipitated in the usual way by the re-action of zinc and dilute sulphuric acid.

In the second patent referred to, the design of the invention is to avoid the use of chlorine in the first part of the process. The argentiferous gold is first melted down with zinc or other metal baser than silver, from which alloy the baser metal may be dissolved out by dilute sulphuric or other cheap acid, and the bullion pulverized, or an alloy of great brittleness made, which may be easily crushed or broken down by mechanical means, so as to fit the gold bullion for the direct action of nitric or other acid. The inventor states, that he first mixes the argentiferous gold with twice or three times its weight of zinc, melts and stirs well the alloy, and then granulates the same by pouring it into water. The alloy thus obtained, is next treated in wooden vessels lined with lead, with dilute sulphuric acid, which removes the zinc, and leaves the argentiferous gold in a finely divided pulverulent or spongy state. In this second operation, heat is not required, and but little more sulphuric acid than will be necessary to form the sulphate of zinc.

Third. The argentiferous gold thus reduced to a spongy state, and still containing the silver untouched by the re-agents used, is treated with hot nitric or sulphuric acid, (the sulphate of zinc having been first entirely removed by washing,) by which the silver is entirely removed, and to be obtained in metallic state as in the former process or in usual way. Finally, the operation is finished by cupelling the gold or melting it with such fluxes as borax, nitre, &c., and casting it into bars.

Alum, process of Manufacturing, from the "green sand formation" of New Jersey. It consists in igniting the green sand free from lime and magnesia, stirring it in the mean time and exposing it freely to the air, the object of the exposure being to peroxidize the iron contained—care being taken to avoid carrying the heat so high as to fuse the mass and prevent the action of sulphuric acid upon it. It is next treated by sulphuric acid to dissolve out the potash, and the alumina is added in the requisite proportions to form alum.

Red Oxide of Zinc prepared as a Drier of Paint.—This ore is procured from Sussex County, N. J., is heated and partially converted into the white oxide, and by this means rendered friable, and the foreign matters are thus easily separated from it. It is then exposed to the action of the oil as other driers.

Manufacture of India Rubber.—Two patents for improvements in the manufacture of *India Rubber*, have been granted during the past year, which claim some notice in this place. The first of these, is for the use of the *hyposulphite of zinc.* This salt is prepared in the following manner: In a solution of caustic lime, pot-ash, or other caustic alkali, boil flowers of sulphur until the liquor be saturated, and into this liquid pass sulphurous acid gas by any of the known means for the purpose of obtaining a hyposulphite of the alkaline base. The liquid is allowed to stand and cool, and the clear liquor is then decanted into a vessel containing a suitable quantity of a saturated solution of the nitrate or other analogous salt of zinc. On mixing these solutions, the zinc is precipitated in a white powder which is regarded as the hyposulphite of zinc. It is then washed on a filter, dried and subsequently ground in a paint mill. Three pounds of this powder is mixed with ten pounds of India rubber, and heated from three to five hours at a temperature of 260°, 280°. The rubber, according to the inventor, will be found completely cured or vulcanized, and requires no free sulphur to be used in any part of the process, and no washing with alkali as do the ordinary materials used for vulcanizing. Hence, it is alleged, that this process is adapted to the covering of silks, and other delicate textures, and colored fabrics.

Another patent for a *compound for vulcanizing India rubber*, has been granted, in which the mode of treatment is much the same as the last, and produces the same result. The material is the artificial *bi-sulphuret of zinc.* The inventor claims the use of this composition without the use of sulphur in any part of the process of manufacture, and the washing with alkaline solutions is not required, and is not used in this mode of manufacture.

Manufacture of Caviar.—This is a process of preparing the roe of the sturgeon. The process consists in placing the roe in a pickle of salt and water for a time, by which a fermenting action takes place, and the roe rises to the surface of the liquor, while the various foreign matters settle to the bottom, and are in this way easily separated. The roe is then subjected to the process of being mixed, and incorporated with a portion of the oil of the male sturgeon, and is then packed in suitable tin canisters for the market.

Burning Fluid.—The ordinary burning fluids are mostly mixtures of spirits of turpentine and common alcohol, or spirits of turpentine alone, under the name of camphine, or chemical oil. To explain the nature of the invention patented, it must be premised that there are known to chemists several kinds of alcohol; 1st. *common alcohol* or spirits of wine; 2d. *amylic alcohol* obtained in the distillation of potatoes, Indian corn, or rye, or other cereal grain, and called *corn oil*, potato oil, essential oil of grain, &c; and 3d. *methylic alcohol*, pyroxylic alcohol, or wood spirits, obtained by the distillation of wood in close vessels. The compound burning fluid claimed herein, consists of a mixture of the amylic alcohol and common rosin, in such proportion that the carbon of the rosin shall neutralize the hydrogen in the alcohol—rules for which mixture are to be found in the specification.

Manufacture of Starch from Maize.—The process as stated by the patentee, consists in soaking the grain in water, until it germinates sprouts of a certain length, and then he extracts the starch in the usual way. It is stated by the inventor, that a bushel of corn weighing fifty-six pounds, will yield by this process twenty-eight pounds of starch.

Distilling Crude Turpentine, so as to accomplish two processes in one, namely, distilling the turpentine and boiling soap. This is done by mixing the raw turpentine with the requisite quantity of alkali to saponify the rosin at the same time that the spirits are evaporated and passed into a condenser for use; the rosin is thus saponified and prepared for the business of soap making.

Purifying Gas in the Retort where it is generated.—A patent has been granted for this device which consists in the mixture of coke and lime in the retort for generating coal gas. The inventor alleges that he increases the quantity as well as the quality of the gas, and saves a considerable amount of matter usually deposited in the purifiers and other parts of the condensing apparatus.

Preparing Wheat for Grinding.—The object being to so act on the hull of the grain by a chemical agent, as to render the process of separating it more easy and more perfect. This consists in sprinkling the grain before grinding with a dilute acid, which hardens and stiffens the hull, and thus loosens it, by which process it is readily separated, and as alleged by the inventor, grain so treated is fitted to make better flour.

Class 17.—HOUSEHOLD FURNITURE.—43 Patents.

Washing Machines.—Three patents have been granted; but none of them presents any novel features worthy of particular notice.

Cutters of Meat and Vegetables.—Four patents have been granted. One for a meat cutter with blades rotating in a circular box; two for sausage stuffers, and one for cutting dried beef. The last of these machines, consists of two blades fixed horizontally upon a small table with a suitable aperture for the cut beef to drop through, and a drawer beneath to receive it. The cutting blades are arranged on the table in front of the operator, in the form of an inverted V, and the beef is pushed by the hands against these blades so as to chip off a thin slice each time.

Bedsteads and Fastenings.—Thirteen patents have been granted. One for a bedstead, four for bedstead fastenings, three for sofa-bedsteads, one for an invalid couch, two for spring mattresses, one for a folding cot bedstead, and one for a camp bed. This last is a camp bed or chest, so arranged that when the chest or bureau lets down its top and sides, so as to be opened in the widest way, it constitutes a wide bed, that is, when the front and back are let down—but when the ends are let down it forms a narrow or single bed.

Chairs and Tables.—Three patents have been granted. One for a nursery chair, one for a car seat, and one for an extension table.

The first of these claims a passing notice. The principal feature of novelty consists in the removal of the back, and fitting it in front, and drawing out at the same time a slide in the side of the chair, and taking with it one of the arms, which together constitute the end piece and bottom support of the cradle, so that a rocking chair with a high back may be converted into a cradle by the removal and adjustment of the parts herein named.

The point of novelty in the extension table is chiefly confined to the leaf, or leaves, which are constructed of thin plates of metal, having the ends of the leaves bent down, so as to constitute a flange, each individual flange being received into that of its fellow, or vice versa, so that when the leaves are closed up to make a compact table, each leaf of the extensible parts is shut in under or over its fellow, and when drawn out the leaves, edge upon edge, lie over each other like the shingles of a roof, and yet the leaves are so thin that they appear when seen extended, as a plane surface.

Refrigerators.—Only one patent has been granted on this division of household furniture, and the novelty is of minor importance.

Miscellaneous of household furniture presents nineteen subjects of patent.

For kneading dough, ...	1
Furniture castor, ...	1
Frame for drying clothes, ...	1
Clasp for holding down bedclothes, for cradles, &c., ...	1
Rule joint, ...	1
Improved window curtain, (apparatus for,)	1

Venetian curtain blind,	1
Construction of a base, or support for a stand,	1
Fly trap,	1
Machine to wash dishes,	1
Quilting frames,	3
Store counter,	1
Bureau drawers,	1
Cracker machine,	1
Machine for pounding beef steaks to make them tender,	1
Fly brush,	1
Machine for cutting and assorting broom corn,	1

Some of these machines merit a more special notice. The machine for *kneading dough* is the combination of a reciprocating breaker or chopping knife, moving vertically, with a reciprocating kneading table, which moves horizontally, and with a motion separate from the other machinery. The table is moved forward and then backward, so as to bring every part of it under the breaker, which latter does not move out of its position.

A Fly Trap has been patented of the following construction. It consists of a horizontal cylinder, rotating within a box open above. The upper part of the cylinder with its ribs, projects a little above the body of the box, and has its surface smeared with molasses. On one side of the box, and that side towards which the cylinder rotates, a space is cut away and a glass plate let in, in its stead, which glass plate fits pretty closely to the projecting ribs on the cylinder. The cylinder rotates very slowly, by means of clock work. Flies alight on the upper surface of the cylinder and feed on the saccharine matter while the cylinder rolls slowly forward, and brings the fly behind the glass plate before he is aware, and from which there is no escape. He is gradually carried to the under and dark part of the box, where he is brushed off by machinery moved for this purpose.

Machine to wash dishes.—Designed as a substitute for the ordinary hand work. It consists of an oblong, somewhat irregular shaped vessel, generally made of tinned plate metal, and containing on one side a vertical rotating cylindrical frame, to contain the dishes to be washed, and on the other, a horizontal reel formed cylinder, with buckets or dashers on the arms of it, which are designed to dip into the water in the lower part of the vessel, and to dash the same against the dishes in the vertical revolving frame, so that every part of it shall be exposed to the hot water in the machine.

Beef Steak Machine.—The design of this patent, is a machine to be used as a substitute for the old method of pounding beef steaks to make them tender. It consists of a pair of rollers armed on their surfaces with cutting teeth, so as to sever the tough fibres of the beef, and render it more easy to masticate. When the steaks are ready to be cooked, they are run through these rollers one or more times, and transferred directly to the broiling apparatus.

A machine to cut and assort broom corn, has been patented, which it would be difficult to describe, without the aid of a drawing. The design of the machine, is to cut the broom corn into lengths according to the size of the stalk, and to assort them into parcels, according to their lengths, by the machine, so that they may be properly distributed for making different sized brooms. The machine consists of a long table with an endless apron running lengthwise, and beside it, and on the same level and a little obliquely to its direction, is arranged a pair of rollers running the whole length of the long

table. These rollers lie one upon the other, and are farthest from the endless apron at the entering end. This endless apron is a belt of slat work, put in motion by machinery, and gradually moving forward from the entering or feeding end of the table, where the broom corn is fed to it by hand, and laid directly across the apron with the butts all in one direction. When the broom corn has traversed about one-third the length of the table, it is brought under compressing rollers, while at the same time that the body of the stalk is held firm in its place, the butt is brought between two rotary disks with cutting edges arranged like two rotary or circular saws, having their cutting faces edge to edge, yet slightly lapping each other. The edges of these cutting disks are very thin, and the under one serrated. As the endless apron travels from the feeding to the discharging end, it brings successively the butts of all the corn stalks between the cutters by which they are severed, and as they still move forward, those stalks which are the longest, and consequently project farthest, are caught first between the rollers, and by this means carried from the endless table, while those which are shorter, are taken by that part of the rollers that is farther along. To avoid distributing the broom corn throughout the whole length of the assorting rollers, portions of the lower roller are turned out, leaving only enough to constitute the axle, and thus preventing any of the material from being drawn through in these sections, which divides the assorted material into several series or parcels, in number equal to that of the sections cut in the lower roller.

Class 21.—WEARING APPAREL.

Eleven patents have been granted under this class, as follows:

Instruments for drafting garments,	3
Mode of varnishing buttons,	1
Machine for cutting cap fronts,	1
Mode of fastening hooks and eyes upon paper cards,	2
Construction of shoulder stay and brace for ladies,	1
For improved suspender buckles,	2
For an improved stud and button for shirt bosoms,	1

None of these patents presents any novelty of general interest, and the class will be passed over without further remark.

Class 16.—LEATHER.

Fourteen patents have been examined at my desk and issued. This class having been transferred from my desk in the early part of the year, to equalize the work at the several examiners' rooms, with a single exception, I have only to report on the cases examined by me previous to the transference.

Improved fastening of terrets to saddle trees,	1
An improved breast plate for a carriage harness,	1
A mode of simultaneously locking a trunk and fastening it to the floor,	1
Improved harness buckle,	2
Machine for manufacture of leather into hollow ware, &c.,	1
Machines for breaking hides,	2
Harness hames,	2
Machines for splitting and stretching leather,	2
Spring wings to a harness saddle,	1
Improved process of tanning leather,	1

This last patent being the *re-issue* of a patent granted in 1849, and noticed in the report of that year as a new tanning process, demands further notice from your examiner as the experience of tanners brings it into use.

It appears from accounts, direct and indirect, that have reached this office, that the inventor so far as can be learned from statements that have been presented by the tanners from different sections of the country, who have made trial of the process, that the inventor has been enabled to penetrate the philosophy of tanning, and has developed the principle, or an important application of chemistry to this art, in the use of a *free acid* in combination with the *tannic acid;* the former to open the pores in what is called *plumping*, and the latter to enter through the openings when thus made and convert the gelatinous matter of the animal covering into leather. Quick tanning has been performed before. Such process, therefore, in itself, is not new, and has no claims to consideration. But the novelty consists in the combined use of the two acids named. This constitutes, what is denominated in the technical language of the office, a "*patentable combination*," in which neither of the elements by itself, is capable of performing that which is done by the combination.

Respectfully submitted.

L. D. GALE, *Examiner of Patents.*

Hon. Thomas Ewbank, *Commissioner of Patents.*

January 1st, 1851.

Hon. Thomas Ewbank,
Commissioner of Patents.

Sir:—In conformity with your requisition, I have the honor to submit to you the following report in relation to the condition of the model department, which you were pleased to place under my charge in November last, and also the number of models received each year, for the past fourteen years; the space occupied by them, and the room necessary for their proper exhibition.

It would be very inconvenient, if not impossible, to allow a free access to visitors, to see the drawings and records in the Patent Office, but not so with the "models;" they should be accessible to all, and particularly to inventors, who should be at liberty to see them without the aid of the machinist, or his assistant.

To carry out the requirements of the office, every model of rejected applications, as well as patented inventions, should be placed under glass, distinctly labelled, and classed according to the arrangement adopted in the published reports, and according to their dates. This was contemplated, and provided for in the 20th section of the act of July 4th, 1836—[Sec. 20. "And be it further enacted, that it shall be the duty of the Commissioner to cause to be classified and arranged, in such rooms or galleries as may be provided for that purpose, in suitable cases, when necessary for their preservation, and in such manner as shall be conducive to a beneficial and favorable display thereof, the models and specimens of compositions and of fabrics, and other manufactures and works of art, patented or unpatented, which have been, or shall hereafter be, deposited in said office. And said rooms or galleries shall be kept open during suitable hours, for public inspection "] but has never been fully carried

out, in consequence of the insufficiency of room. A printed catalogue, or index, should then be prepared, the cost of which would be trifling compared with its advantage to the office, as well as to inventors.

The average space required for the exhibition of the models, may be set down as about one square foot for each. The number now in the office is as follows:

Of patents granted,	8524
" applications rejected,	7890
" " pending,	170
" " suspended,	673
Total	17257

The models of patented inventions are now crowded into 22 cases, capable of holding for exhibition but 2720, (one model should never be placed before, or on top of another,) consequently they occupy less than one-third of the space required for their proper exhibition.

The models of rejected applications are now stored in the west basement of the building; and not being arranged in cases, they cannot be opened to the inspection of the public; this is contrary to the spirit of the law, which requires that they shall be open for public inspection.

As shown above, the cases now in use for the exhibition of models, measure but 2720 feet of available surface, while 16414 feet are required, not including room for models of pending and suspended applications.

The great hall on the upper floor, containing the collections of the late exploring expedition, also the collection of the National Institute, etc., in 62 cases constructed for the Patent Office, has not been used for the reception of models. These 62 cases are capable of holding 128 models each, or 7936 in all; which, added to those in the model room now in use, would give room for 12352 models; leaving 4062 without a place, unless they should be improperly crowded, as they are at present.

The number of models received during the past year was 2140, consequently, without calculating for any increase in the present year, over the last, we will have, in December, 1851, 6372 models unprovided for; they would nearly fill the hall of the east wing, which will be capable of accommodating about the same number estimated for the main hall, viz: 7936. The increase over former years, will certainly be sufficient to fill it, as soon as it is finished to receive them.

The following list of models received since the burning of the Patent Office in 1836, exhibits an increase annually, of about 225 in the last few years: the three first years being swelled by the models of restored patents, which had been destroyed by fire.

Year 1837, models received	1069
" 1838 " "	1263
" 1839 " "	1189
" 1840 " "	740
" 1841 " "	773
" 1842 " "	868
" 1843 " "	869
" 1844 " "	963
" 1845 " "	1149
" 1846 " "	1215

Year 1847	models received	1472
" 1848	" "	1698
" 1849	" "	1909
" 1850	" "	2140
Total now in the office,		17257

If this rate of increase should continue ten years, we may calculate on the reception of 33775 models; and by adding this to those already deposited, it will be seen that in the year 1860, inclusive, we shall have 51032; a number quite sufficient to fill, under proper classification, all the halls on the upper floor, including the north front and west wing of the building, supposing it to be finished for their reception, as originally designed; besides the hall designed for the same purpose, on the second floor of the west wing.

A room is indispensable for the models of pending applications, which require to be guarded from public view; it should be at least 20 × 40 feet square. These models are now kept in the machinist's room, where boxes are unpacked, and where applicants daily present their models in person. It is difficult, if not impossible, to prevent such applicants from seeing the models of other applicants, which have to remain sometimes thus exposed for months before the completion of their papers. A private room, of at least 20 feet square, with proper shelving, should also be provided for "caveated models," which have not, as yet, had a special place provided for them; a somewhat remarkable fact, as they are considered as belonging to the "secret archives" of the office.

A workshop is much wanted, where damaged models may be repaired: many of them being of delicate structure, are liable to injury in transporting them to the office, and afterwards subject to various accidents during their examination. A model maker should be employed, under the direction of the machinist, to perform this work, as well as to supply duplicates when required.

Here it may be well to remark, that models must be regarded as a part of the original records of a patent, and on no occasion should they be allowed to be removed from the office. Cases have occurred, when it was suggested that they were altered after they had been taken out of the office to be used in court as evidence, in cases of appeal; certified copies, in such cases, would answer the purpose better.

Workmen not belonging to the office, are engaged when duplicate models are wanted, who, from necessity, are admitted to the machinist's room, to take dimensions, while models of new applications are constantly being exposed to their view. This would be entirely prevented by having a suitable workshop, and a model maker under the control of the office, and in the same building. Two rooms of 20 feet square each, (one for working metals, and the other for woodwork,) now occupied by clerks in the basement, should be restored for this purpose. They could be better accommodated on the second floor of the east wing.

Other matter might be offered for your consideration, but for the present, the more important, above stated, it is believed, will be sufficient.

Respectfully submitted by

Your ob't servant,

SAM'L P. BELL,

Machinist.

IV.

HISTORICAL NOTICES OF INVENTORS AND PATENTEES.

JAMES RUMSEY.

THE preface to Mr. Fitch's "*Original Steamboat*," (see last year's Report,) is dated in May, 1788. The pamphlet purports to be a reply to one by James Rumsey, of which a second edition had just appeared, entitled, "A short Treatise on the application of Steam; whereby, is clearly shown from actual experiments, that steam may be applied to propel boats or vessels of any burthen against rapid currents with great velocity. The same principles are also introduced with effect, by a machine of a simple and cheap construction, for the purpose of raising water sufficient for the working of grist mills, saw mills, &c., and for watering meadows, and other purposes of agriculture. By James Rumsey, of Berkely County, Virginia. Philadelphia: Printed by Joseph James, Chestnut-st., 1788." [From a copy in the library of Colonel Force.]

This treatise on steam, constitutes House Doc., No. 189, 27th Congress, 2nd Session, and therefore, need not be re-printed here. Soon after the second edition appeared in 1788, Mr. Rumsey sailed for Europe, and his friend Mr. Joseph Barnes, "a very ingenious mechanic, employed by James Rumsey, in constructing his several machines," undertook to defend him from the charges contained in Fitch's "*reply.*" Mr. Barnes' pamphlet, now rare, is annexed.

REMARKS

ON

MR. JOHN FITCH'S REPLY

TO

MR. JAMES RUMSEY'S PAMPHLET,

BY

JOSEPH BARNES:

FORMERLY ASSISTANT, AND NOW ATTORNEY IN FACT,

TO

JAMES RUMSEY.

PHILADELPHIA:
PRINTED BY JOSEPH JAMES,
Chesnut Street.
MDCCLXXXVIII.

REMARKS, &c.

MR. RUMSEY, before his late departure for England, by an advertisement, begged the candid public to suspend their opinion, respecting the controversy between him and Mr. Fitch, until time should be afforded to state his claim, and answer such objections as should occur, from a pamphlet which Mr. Fitch then had in the press, but had not appeared before he left this city.

Since that time Mr. Fitch has been busily employed in traducing Mr. Rumsey's character, and endeavoring to establish, in the public mind, an opinion, that Mr. Fitch was the first person who actually attempted to apply the force of steam to the purposes of navigation. If this assumption was admitted, which, however, will be fully disproved, nothing would thence follow prejudicial to Mr. Rumsey's claims; for it will appear from a cloud of testimony, that although both of them entertained the idea of applying the force of steam to the purposes of navigation, their modes of effecting it were as different from each other as possible. Mr. Fitch proposed to apply the action of steam by a number of cranks to oars or paddles; Mr. Rumsey thought of the force of reaction on the fore part of the boat, by a column of water forced through a trunk in the body of it. That Mr. Fitch originally entertained no other idea, than applying the force of steam to the working of paddles, will abundantly appear from his repeated models and experiments; from the plan published in the magazine, taken from a draught sent to the proprietors of that publication by Mr. Voight; and from his public declarations, that Mr. Rumsey's scheme could not be made effectual. That Mr. Rumsey had a different mode of applying the force of steam to navigation, is sufficiently apparent, not only from his publications on the subject, but from his apparatus now in this city, which was fitted between two and three years ago, and was last year actually applied to the purpose on the river Potowmac, and produced the desired effect, by propelling a boat, with a burthen of three tons on board, at the rate of four miles an hour, against the stream of that river.

In order to destroy Mr. Rumsey's character and views, which Mr. Fitch has thought dangerous to his interests, (although fortified by an extraordinary act of assembly,) he has published a pamphlet, containing a variety of depositions and certificates, tending to shew that Mr. Rumsey has anticipated a whole year, and by an attempt at witticism, has acknowledged his powers of condensation in this respect. That Mr. Rumsey's narration of facts is true, will be proved (if further proof was necessary,) by the several certificates and depositions hereto annexed, to which the reader is referred: but this is not the immediate object of the present publication. Mr. Rumsey had in the year 1785, prepared a steam engine upon the plan used and improved in Europe, to propel his boat, but was prevented by the frost from exhibiting it that fall; being thus prevented, he employed himself during the ensuing winter, in projecting more easy methods of producing the like effects: and by experiment, he discovered a mode of generating steam, so effectual, as to promise very great advantages to the inventor. To bring this invention to act on his former machinery, required some time, which was employed in perfecting it; several experiments were accordingly made, and in the end Mr. Rumsey's principles were proved to be good. During this time, Mr. Arthur Donaldson, a very ingenious mechanic, (whether from the strength of his own genius, or from hearing something of Mr. Rumsey's scheme, is not material in this dispute with Mr. Fitch, to ascertain) took up the idea, and made several experiments, which fully proved that the re-action of a column of water, forced with rapidity from the stern of a boat, would propel her forward so as to answer the end required for navigation. Mr. Donaldson communicated his ideas and experiments to many gentlemen in Philadelphia, who were satisfied of his principles, but they doubted whether the size of a boiler, and the quantity of fewel necessary to keep it heated, would not occupy so large a part of a boat, as to render her freight of no value; to reduce this to a certainty, gentlemen acquainted with steam engines in Europe, were consulted, and their opinions confirmed the doubts entertained, so that Mr. Donaldson gave up the idea of prosecuting his scheme.

While Mr. Donaldson was employed in experiments, Mr. Fitch had applied to the assembly of Pennsylvania, for the exclusive privilege of navigating by the force of steam, and was opposed before a committee of the house by Mr. Donaldson, when Mr. Fitch claimed all possible modes whether *invented or to be invented by himself, or others*, of using steam for that purpose; and as Mr. Donaldson, before a report was made by the committee to the house, was convinced by his friends that no boiler *then known* would generate steam in a sufficient quantity, and at a cheap rate, to answer the end, he declined his opposition, and a grant was made to Mr. Fitch, of the exclusive use of steam for navigation, in very large and comprehensive words. Since this grant, Mr. Fitch, and a large company, who associated with him, have made many experiments to reduce their boat to practice; all of which were to apply the force of steam (generated in a large boiler, agreeably to the old practice, long used in Europe,) to the working a number of paddles, on the sides of the boat, the abortive events of which have been too public to need repetition.

But about the month of January last, Mr. William Askew, of Berkeley county, who had been long acquainted with Mr. Rumsey, and had seen his apparatus, came to this city, and stimulated by curiosity, went to see, Mr. Fitch's preparations, and there fell into conversation with Mr. Voight, Mr. Fitch's partner, and operator, and communicated to him such an idea of Mr. Rumsey's new invented boiler, as enabled him to form a plan of one upon the same principles. In the month of April last, Mr. Rumsey came to this city, and exhibited with little or no caution, a draft of his boiler, to a number of persons, and after some time laid it before the Philosophical Society, and was not a little surprised to find that Mr. Voight produced a draft of a boiler, upon the same principles, though a little differing in its form, before the society, the same evening. The several contrivances by which his cotemporaneous production of Mr. Rumsey's original invention, and a surreptitious copy from it was effected, are well known, and will be proved upon a proper occasion; it is sufficient for the present, to inform the public, that Mr. Rumsey's original boiler is now in this city, and may hereafter be exhibited to them; *that* a new one with great improvements, is making, with all possible dispatch; *that* its efficacy in producing steam with vastly less expense, and yet in greater quantities than any mode yet practised in Europe, will be proved; *that* Mr. Rumsey is *gone* to England, to prevent a surreptitious copy of his first invention (which there is reason to believe was sent thither with great secrecy) from being *there* palmed on the public as an original, *and to* claim to himself the rights of an inventor.

About three weeks ago I came to this city, and brought with me most of the following depositions and certificates, the publication of which will, I have no doubt, establish all the facts asserted by Mr. Rumsey in his pamphlet. The circumstance of my superintending the different mechanics who worked for Mr. Rumsey, gave me the advantage of being competent to the explanation of the subject, and I can assure the public that Mr. Fitch has not got a single affidavit or certificate from Frederick Town or Baltimore, that has any relation thereto, except Mr. Christopher Raborg's, the copper-smith, No. 21, in his pamphlet.

The certificates and affidavits Mr. Fitch obtained in Frederick Town, Nos. 14, 15, 16, 17, 18, 19 and 20, allude to an eight foot tube, which Mr. Rumsey had made in the year 1786, for a second machine, an improvement on the one prepared in the fall, and do not at all relate to the first machine fitted on the boat in the fall; which was actually ready for experiment, and prevented by the ice in December, 1785. And from those certificates and affidavits, Mr. Fitch endeavors to prove, that as this work was done for Mr. Rumsey in the year 1786, therefore it follows, that no other work could have been done for *him*, by any mechanic whatever, before that period; according to this kind of logic, it could be proved, that Mr. Fitch never can possibly invent a steamboat to answer any useful purpose; for instance, because after sundry fruitless experiments with his *crank boat* machinery, he has not yet been able to accomplish this business; therefore it follows, from the nature of things, that he never can invent a steamboat, *probatum est.*

I have introduced in the following pages, certificates and depositions, which I trust will be satisfactory to the public. No. 1, 3, 5 and 7, prove the priority of Mr. Rumsey to the pipe boiler.

The silver-smith, or watch maker, mentioned in Mr. Askew's deposition, No. 3, is Mr. Henry Voight, a partner in Mr. Fitch's *intended* steamboat, whose name Mr. Askew (being a stranger) did not recollect at the time his deposition was taken, but whose residence and occupation are therein sufficiently described; from which it appears *what* were Mr. Voight's sentiments of Mr. Rumsey's boiler for generating steam, at *that time;* his doubts concerning its efficacy, might either arise from the novelty of the idea, a want of a thorough knowledge of its principles, or from a desire to draw from Mr. Askew a more full explanation thereof; otherwise he would not have waited from that time until several weeks after Mr. Rumsey came to this city, and had more fully explained the principles of his boiler to many characters here, previous to his sending a plan thereof to the Philosophical Society, and (as it is said) to Europe, and that nearly in the same form, and exactly on the principles of the boiler made by Mr. Rumsey some years ago, and this before he had himself made such a boiler, with the necessary apparatus, or tried any experiment of its efficacy.

Certificate No. 2, and the depositions 4 and 6, are pointed to the proof of the time when the cocks were actually made. No. 8, is an additional proof of the time, that the steamboat with her machinery, was brought down to the Shanandoah Falls, in the month of December, 1785. No. 9, 15 and 16, prove that Mr. Rumsey's ideas and experiments of a steamboat, were prior to any theretofore, suggested by Mr. Fitch. No. 10, is Mrs. Zimmer's deposition, upon whose certificate of the particular workman, who turned some of the works, Mr. Fitch lays so much stress, which is explicit as to the time when the first machinery was made, agreeably to Mr. Rumsey's assertions.

No. 11 is Mr. Raborg's deposition, who has been more clear and explicit on this subject, than even Mr. Fitch would have wished; as in Mr. Fitch's pamphlet, No. 21, Mr. Raborg has given his belief of the time, which in this deposition is fully confirmed by circumstances since discovered by him.

No. 12 and 17, are also important, the first being Mr. Weir's deposition, proves that he was mistaken in the time he mentions (as to the making of the four brass cocks) in the certificate given to Mr. Fitch, and published in his pamphlet No. 22.

I consider myself happy, that Mr. Fitch, by a serious acknowledgment, has acceded to the merit of Mr. Weir, whose character as a man of honor and integrity, I am fully convinced of, and beg leave to mention, that the certificate he gave Mr. Fitch, No. 22, introduced in page 28, of Mr. Fitch's pamphlet, was from the best recollection he then had on the subject, and that this was from memory only; but upon his discovering a receipt, he candidly and ingeniously first informed Mr. Fitch of the mistake, and afterwards, gave an explicit deposition, which we pre-

sume will satisfy the public. The certificate No. 17, will explain how unhappy Mr. Fitch has been, in his mode of attempting to invalidate Mr. Rumsey's statement of facts, as it retorts the charge of encouraging *perjury, upon Mr. Fitch with the additional turpitude of soliciting the commission of so heinous a crime by the offer of a bribe.* How far this conduct will comport with the introductory declaration of Mr. Fitch, in his pamphlet, where he says: "*It is the duty of every man not only to avoid the commission of a crime; but so to conduct himself through life, as to bear the strictest scrutiny,*" I shall not at present comment on.

Certificates No. 18 and 19 corroborate the above fact, and introduce a further proof of Mr. Fitch's conduct in procuring certificates, by an actual commission of bribery being proved against him.

No. 13 proves the fact, which Mr. Weir's deposition No. 12, is adduced to authenticate, which is likewise stronger than from memory, from which alone, he gave Mr. Fitch the certificate No. 23, in his pamphlet.

Having now made a short reference to the depositions and certificates annexed, it may be proper to reply to Mr. Fitch's remarks on Governor Johnson's friendship towards him, when he disingenuously calls in question the Governor's *memory of candor*, though he seems *modestly* to acquit the latter. Whether Mr. Fitch's *gratitude* appears to advantage in this illiberal attack on so respectable a character, after such an instance of patronage and friendship, is easily decided. I shall take the liberty of stating, that, although previous to Mr. Fitch's application to Governor Johnson, Mr. Rumsey had in confidence, mentioned to him his idea of applying steam to the purposes of navigation, and bespoke some of the boat machinery at his iron works; yet Governor Johnson, not expecting, that either Mr. Rumsey or Mr. Fitch, had an exclusive right in the power of steam, as applied to navigation, or any other purpose; and taking it for granted, that their modes of application might be different, held himself at liberty to patronize both Mr. Rumsey and Mr. Fitch, not knowing which might produce the most approved plan, and succeed in so desirable an object. This line of conduct is consistent with the practice of the most enlightened characters in the philosophical world.

In pages 14 and 15 of Mr. Fitch's pamphlet, he says, "I have been greatly indebted to the assistance of my ingenious friend, Mr. Henry Voight, of this city; who has uniformly from my first undertaking to build a boat, afforded me valuable hints; and has united with me in perfecting my plans; to his inventive genius alone, I am indebted for the improvement in our mode of creating steam, a thought which struck him above two years ago; the drawing having been shewn to several persons, for we *never made a secret* of any part of our works; but a fear of departing from old established plans, made me fearful of adopting it, until I had found by his invention of *creating steam*, that a *condenser* might be constructed on the same principles, (viz: a spiral pipe or worm,) only by reversing the agent, for the best way of applying fire to evaporate *water into steam*, must also be the best way of applying *cold water* to condense steam, that is the bringing the greatest quantity of fire into action upon the greatest surface of water, or the contrary. And we had an additional inducement to study this subject, because the common way of fixing boilers required so great a load of brick work, that it overloaded our boat; therefore, the first thought that must occur to every man attempting to raise steam on board a boat, must be to acquire that method which would require the least weight." A few remarks on this extraordinary paragraph are subjoined; first, as it appears from his own words, "*we never made a secret of any part of our works.*" If such a boiler had actually been invented, the public would have heard of it long before Mr. Rumsey's arrival in Philadelphia, last April; and *a fear of departing from old established plans*, it is presumed would not have prevented his making use of it in some of his experiments, had he understood the principles, *because the common way of fixing boilers required so great a load of brick work, that it overloaded our boat*, more especially, *as the first thought which must occur to every man attempting to raise steam on board a boat, must be to acquire that method which would require the last weight.* How unhappy is it for Mr. Fitch, not to have attended to the first thought, which must have occurred to every man on the subject, until he actually was acquainted with the experiments made by Mr. Rumsey; however, we confess this is not much to be wondered at, when he says, he found that from what he calls Mr. Voight's invention of creating steam, a condenser might be constructed on the same principles, viz: *a spiral pipe or worm*, only by reversing the agent, which is a true definition of every worm of a common still, and which Mr. Fitch claims as an original invention, though we presume his claim of this invention, will scarcely be acceded to, by those who have even seen a distillery, and only shews how far he can carry his bold attempts to deprive others of their rights. This same wonderful *spiral pipe or worm*, Mr. Fitch has made use of to prove, that the thought of creating steam by reversing the agent, must be known to every man who did but consider the subject, and had seen a pipe used in condensation; if so, the common worm of a still must have suggested the idea to every man, who considered the subject from the earliest period. That this is not a truth, facts unquestionably declare.

It may not be improper to remark here, that when Mr. Rumsey applied to the different legislatures, it was in order to obtain an exclusive right to his boat exhibited at Bath, in 1784, although previous to that time, he had actually conceived the idea of applying steam to the purposes of navigation, but not having fully perfected the most advantageous mode of application, he did not think himself authorized to introduce to the committees of the assemblies an *immatured* subject, which it appears Mr. Fitch's *modesty* permitted him to do, for from his own pamphlet, it is evident he has not yet brought his plans to any maturity. This will reconcile what was said in General Washington's letter to Governor Johnson, of Mr. Rumsey's idea of steam, being in his opinion at that time an *immatured idea.* As to Mr. Rumsey's assertion in his letter to the General, 10th March, 1785, as mentioned in Mr. Fitch's pamphlet, page 13, "*that he was not less sanguine* in his boat projects, than when the General saw him at Richmond, and that he had made such further discoveries as would render them more extensively useful than was at first expected;" this can only apply to the machinery of the steamboat, as the use of the pole boat could not be extended so far as Mr. Rumsey in that letter has suggested his improvements would reach. See No. 19, in Mr. Rumsey's pamphlet in which are these words:

After mentioning that kind of machine for propelling boats which the General had seen a model of, I proceed to say—"I have taken the greatest pains to perfect another kind of boat, *upon the principles I mentioned to you at Richmond*, in November last, and have the pleasure to inform you that I have brought it to great perfection; it is true, it will cost something more than the other way, but, when in use, will be more manageable, and can be worked with as few hands; the power is immense—and I have quite convinced myself that boats of passage may be made to go against the current of the *Mississippi* or *Ohio rivers*, or in the *Gulf Stream* (from the *Leeward* to the *Windward Islands*) from sixty to one hundred miles per day. I know this will appear strange and improbable to many persons, yet I am very certain it may be performed, besides, it is simple (when understood) and is also strictly philosophical."

What can we think of Mr. Fitch's *candor* after this ungenerous violation of it, by alleging that these further discoveries could only allude to the pole boat, notwithstanding this letter is published unmutilated in Mr. Fitch's pamphlet, and Mr. Fitch must be sensible that Mr. Rumsey therein mentions another kind of boat; and that poles could not be used in the *Gulf Stream*, and from the *Leeward* to the *Windward Islands*.

Mr. Fitch goes on to say, that the *further discoveries* mentioned in General Washington's letter to Mr. Rumsey, will not apply to steam, because steam could be no *new* discovery; from this mode of reasoning, it will appear, that not only Mr. Fitch himself has made no *new* discoveries, nor even had a *new* idea on the subject of steam, (which will be readily granted by any candid man who is acquainted with him) but that no such *new* idea or discovery has ever been *suggested* to him by his friends, because as they related to steam, and that being no *new* idea or discovery, from Mr. Fitch's own relation of the subject, therefore as he has applied the conclusion to Mr. Rumsey, it is fair to hand it over to himself. Mr. Fitch, it seems, could not comprehend that the discoveries mentioned in the General's letter, could allude to the mode of applying steam to the purposes of navigation. This however is of a piece with the rest of the false reasoning which spreads very generally through Mr. Fitch's pamphlet, in order if possible, to evade the stubborn facts Mr. Rumsey has adduced. Mr. Fitch, when he finds himself hard pressed in the right of priority, says such a claim is entirely useless, as others "projected it before him, and if bare projections were sufficient to build a claim on, I have no doubt but there are people now in their graves, whose heirs may set up more early claims than either of us." On the contrary, when it is proved that Mr. Rumsey has succeeded earliest in this business, he then says it is shifting the ground, which sentiment will not be strenuously opposed, as it appears clearly to be the true ground on which the dispute will in all probability, eventually be determined; or lastly, he intrenches himself behind what he *with great propriety* calls "my laws," which were obtained, not because he was the first man who thought of steam in its application to natural purposes, nor because he first accomplished so desirable an object, but as being the first person who applied to different legislatures, in order to obtain an exclusive right to his own *immatured ideas*, or an exclusive right to exercise the faculties of the human mind, as far as they relate to *steamboats*, insomuch that Mr. Fitch has repeatedly in conversation alleged, that if any person in Pennsylvania should invent a steamboat, upon different principles, and far superior, either to his own or Mr. Rumsey's, the inventor dare not produce it to the public without being liable to the full penalties of *his* law; and it is alleged that should even a vessel owned and navigated by the citizens of any of the United States, or by the citizens of any foreign state, arrive at Philadelphia, propelled by the force of steam, however applied, such vessel would be liable to the penalties of *his* law. If this be really the case, the candid public will determine how far the principles of *this* law can be reconciled to the liberties of a free people, or to that encouragement which all enlightened states afford to every useful discovery in the arts and sciences.

In page 23 of Mr. Fitch's pamphlet, after some remarks on the principles on which exclusive privileges are founded in justice and policy, he proceeds in an uncandid manner to state the modes established in England, by which an inventor may claim the full benefit of what he had already invented; and endeavors to give so specious a turn to the period, as though a patent obtained in England, would give a person the exclusive privilege to things *invented*, or *to be invented*.

Should any one in England make application for an exclusive right in a steamboat, he must of necessity, first file or record a plan or model of the machinery by which she was to be propelled, in which alone he could have an exclusive right; and should he afterwards make further improvements therein, it would be necessary for him to apply for a patent for those second improvements, as has been the case in other instances; and should a person applying allege (agreeable to Mr. Fitch's ideas) that although he might not be the first person who thought of steamboats, neither had yet perfected any thing effectual, but that he was uncertain whether he should not try twenty different modes of obtaining some one useful model, and that he would therefore wish an exclusive right in any or all of them *when invented*; and that as a reward for his being the *first* person who had applied thus to register his thoughts on the subject, he considered that he ought in justice to be legally invested with the right of invention, to the exclusion of all others; the officer to whom such an application should be made (if persisted in) would require no other mark of the applicant's insanity. As a proof that Mr. Fitch's ideas on the subject were not so *matured* as to authorize him, in justice, to apply to the legislatures, it is sufficient only to add, that he repeatedly shifted the machinery of his steamboat, since he exhibited the model before the Phi-

losophical Society, in the year 1785, and that he at length made an experiment in the river Delaware, with a boat moved by paddles and cranks, which, notwithstanding his various accounts of her wonderful performance, he has since deserted, as totally incompetent to any useful purpose, and it is said he is now about making an experiment with another boat, wherein it has been suggested that he designs using a boiler nearly in the form, and exactly on the principles of the one invented by Mr. Rumsey, but still paddles and cranks are introduced. Should this plan not succeed, Mr. Fitch says in his pamphlet, page 22, "I am now trying an experiment, and the machine is nearly finished, to propel a boat, not by expelling *water*, but *air*, and I hope Mr. Rumsey will allow that this is a mode peculiar to myself." From this, one would suppose, that Mr. Fitch is not content with the exclusive privilege already obtained by a law, constituting him *prince* of the power of water or steam, but is desirous of being also created *prince of the power of the air*; and when this title is extinct in the present possessor, Mr. Fitch may step forward, it is presumed, upon clear and indisputable grounds, and his right of succession will not be disputed by Mr. Rumsey; but in the meantime, should this air boat fail, he may at length resort to Mr. Rumsey's plan of a trunk, &c., (in which he will meet with more difficulties than he may expect, although well described by Mr. Rumsey in his pamphlet) for which he appears to be paving the way, by introducing Mr. Clymer's certificate, No. 13, which he will say was originally Dr. Franklin's plan. Mr. Rumsey, to whom Mr. Fitch had read the whole or part of his pamphlet previous to its publication, conceived that it implied an accusation that he had taken his ideas from the Dr.'s communication of such a plan to the Philosophical Society, to which it is supposed Mr. Fitch must allude in page 22 of his pamphlet, where he also says the thought came originally from France, but by whom brought, or how communicated, he does not tell us; Mr. Rumsey, therefore, before his departure for Europe, (as I am informed) waited on Dr. Franklin, and mentioned that his plan of a *steamboat* was, as to *him*, an *original* invention, and assured him that before he came to this city, he had neither seen nor heard of his communication to the Philosophical Society; when the Dr., with his usual candor and politeness, presented him with one of his pamphlets written on this subject.

Mr. Fitch's assertion relative to the mode of drawing water in at the bottom, and *pushing* it out at the stern, and his contending the right of using it with Arthur Donaldson, before the assembly of Pennsylvania, in the beginning of 1786, is altogether false, as Mr. Donaldson was desirous that Mr. Fitch should only have an exclusive right to his own particular inventions, and not avail himself of the privilege of using any discovery or improvement *invented*, or *to be invented* by others; Mr. Fitch contended for the exclusive right of applying the agency of steam to the purposes of navigation, in every possible mode, and alleged that he did not know but he might try twenty methods of effecting this object. This vague manner of application, if it means any thing, certainly amounts to a desire to engross, not only the right of inventing, to the exclusion of all others, but to a claim of property in their inventions. Notwithstanding, at the time Mr. Donaldson and Mr. Fitch were before the committee of assembly, the latter appeared acquainted with the principles of a steamboat, as laid down by Mr. Donaldson, as Mr. Clymer expresses himself in No. 13, page 22, of Mr. Fitch's pamphlet; this only proves what otherwise might have been doubted, that Mr. Fitch is capable of understanding the principles of a thing, when communicated to him, which communication can be proved to have been made to him previous to this period—though this was long after Mr. Rumsey had bespoke some of his works for his steamboat, as will appear from the various certificates on this subject.

It may be necessary now to add that the heavy charges of perjury, falsehood, want of memory or candor, which are so illiberally brought by Mr. Fitch, against the fairest characters, were made by a *man*, who not only *attempted* to bribe a gentleman of character to swear to a falsehood, but who *actually committed* this heinous offence, in order either to avail himself of Mr. Rumsey's invention, or to prevent him from deriving the emoluments due to his ingenuity. How Mr. Fitch can, *after* this instance of flagitious conduct, expect the patronage of any *honest* man, I am at a loss to determine.

The depositions and certificates which follow, will, it is hoped, be sufficient to establish the principal facts stated by and in behalf of Mr. Rumsey, until a competent jurisdiction shall require a more full and pointed state of the case. Whether Mr. Rumsey's or Mr. Fitch's *patrons have committed themselves too unreservedly to strangers*, time alone will determine; but as Mr. Rumsey has been happy enough to cultivate and possess the friendship and esteem of some of the most eminent characters in the United States, so he has expressed the highest sense of gratitude for the honorable patronage afforded him, though a *stranger*, by a number of respectable characters in Philadelphia; and I am well assured, he will so conduct himself in the new and untried scenes of life, into which he is now about to enter, as not to cause a blush in the countenance of one of his friends, either in Europe or America; and he will expect the patronage of those friends, no longer than he shall himself support the character, not only of an *ingenious*, but of an Honest Man.

July 7th, 1788. JOSEPH BARNES.

PROOFS, &c.

Virginia, *Berkeley County*, ss.

[L. S.] I, Moses Hunter, Clerk of the said county, do certify, that the following certificates, to wit, No. 1, signed by John Ritchie, No. 2, signed by John Mark and Abraham Shepherd, and the following depositions, William Askew, No. 3, taken by John Kearsley

Charles Morrow, No. 4, taken by Cato Moore; Michael Entler, No. 5, taken by John Kearsley; Conrad Byers, No. 6, taken by Cato Moore; Jonathan Osborn, No. 7, taken by John Kearsley; Francis Hamilton, No. 8, taken by John Kearsley. I do certify, that the above named John Kearsley and Cato Moore, gentlemen, were at that time, and still are justices of the peace for the said county, and that all due faith and credit is, and ought to be given to all probates by them signed, as well in justice courts, as thereout.

In testimony whereof, I have hereunto set my hand, and affixed the seal of the said county, this 19th day of May, 1788.

MOSES HUNTER.

(No. 1.)

ANTEATUM IRON WORKS, Maryland, May 15th, 1787.

At the request of Capt. Charles Morrow, I have examined the books of Richard Henderson & Co., respecting the time when Capt. James Rumsey had some iron bars drawn here, in the shape, and about the size of gun-scalps. I find accordingly, that he had,

1786, January 26th,	2 scalps,	weigh	27½lb.
" February 1st,	do.	do.	84
" " 4th,	6 do.	do.	67

At the time Mr. Rumsey applied for the above, I understood he wanted it for some of the purposes of his machinery. Given under my hand, the date above.

JOHN RITCHIE.

BERKELEY COUNTY, May 17th, 1788.

We do certify that Mr. John Ritchie, manager of the Anteatum iron works, in a letter to us directed, set forth the very same facts, which are stated above on this paper, in his handwriting, and mentioned to us in his letter, that if necessity required, he would come into this county to acknowledge the same. Given under our hands, date above.

JOHN KEARSLEY.
CATO MOORE.

(No. 2.)

We, the subscribers, were at Capt. Charles Morrow's house at the time he received a letter from Mr. James Rumsey, dated at Philadelphia, 8th day of May, 1788, wherein he informed the said Morrow, that Mr. Fitch had obtained an affidavit from the founder that cast some large cocks for said Rumsey, setting forth that they were cast in March, 1786; said Morrow then produced his books, and turning to Mr. Rumsey's account, in which said Rumsey was charged with nine pounds, sixteen shillings, paid Mr. Raborg for cocks, the 29th of October, 1785

JOHN MARK.
ABRAHAM SHEPHERD.

I certify that the above signers are men of good fame; that they are personally known to me, and acknowledged their signatures before me, this 17th day of May, 1788.

CATO MOORE.

(No. 3.)

Berkeley County, ss.

This day, William Askew, of the county aforesaid, came before me, John Kearsley, one of the justices of the peace for said county, and made oath on the Holy Evangelists of Almighty God, that he was in the city of Philadelphia, in the month of September, 1787, when he had an opportunity of seeing the steamboat, (said to be constructed by Mr. Fitch,) which boat was shewn to this deponent by a gentleman, a silver smith, a German; who said, he was in connection with Mr. Fitch, in the undertaking of the boat aforesaid, and was so obliging as to invite this deponent to see the performance of said boat; the external incumbrance of the boat, the weight of the boiler, and the necessary quantity of wood, this deponent conceived, would render Mr. Fitch's boat of little utility, as he has endeavored to set forth in his depositiou, No. 6, in Mr. Rumsey's pamphlet. The gentleman alluded to as aforesaid, Mr. Fitch's partner, the silver smith or watch maker, in Second street, on the opposite side of the way from Messrs. Wager & Hawbacher, wine merchants, whom this deponent had a considerable discourse with, on the subject of Mr. Rumsey's steamboat; the said silver smith or watch maker, seemed to be of opinion, that Mr. Rumsey had borrowed his knowledge of the steamboat from said Mr. Fitch: this deponent then informed said silver smith or watch maker, partner to Mr. Fitch, that he personally knew Mr. Rumsey, had been about three years before that time at work at said steamboat, and that he had been endeavoring to perfect said boat since that period, under a variety of difficulties, for the want of mechanics, resources, &c. This deponent further saith, that he was again in the city of Philadelphia, in January and February last past, and that he then told the said silver smith or watch maker, that the boiler in said Fitch's boat was of such weight, and would require so much wood to boil the same, that of course, it would be of little or no use. This deponent drew the model of Mr. Rumsey's pipe boiler, and explained the manner of its working, and advised them to adopt a similar mode of making steam, and lay aside the mode of making steam in their way, which form said silver smith or watch maker seemed to be an entire stranger to. After a day or two spent, and after talking on the subject of steam, the silver smith aforesaid, endeavored to convince this deponent, that a pipe boiler could never be of any use,

and argued the impossibility of its answering the least good purpose; this deponent as strictly urged the practicability of the advantages of the pipe boiler, and said their boat in his opinion would be more perfect, if they would adopt Mr. Rumsey's new invented mode of making steam which mode the said silver smith or watch maker reprobated, and said it would not answer the purpose, and shewed this deponent several modes of making steam, as practised in Europe, and said they were preferable to the pipe boiler. And further, this deponent saith not.

This 15th day of May, 1788, William Askew, the above deponent, came before me, and made oath according to law, that the above deposition, is just and true, according to the best of his knowledge and belief.

JOHN KEARSLEY.

(No. 4.)

Berkeley County, ss.

This day, came Charles Morrow, before me, Cato Moore, one of the justices of the peace, for said county, and made oath, that to the best of his memory, Mr. Joseph Barnes, returned from Baltimore, early in the month of October, 1785, where he had been sent by Mr. Rumsey, to get some parts of the machinery cast for his steamboat, that the said Barnes on his return, told this deponent, that he had got four large cocks cast, that he had been disappointed in procuring money that he expected to receive in Baltimore, had therefore, left the cocks with Mr. Raborg, (the gentleman who had got the founder to cast them,) that they should be sent for the first opportunity, that he imagined they would cost somewhere about ten pounds: and this deponent further saith, that shortly after Mr. John Thornbury was going to Baltimore with his wagon, that this deponent wrote to Mr. Raborg, (Mr. Barnes being absent) either in his own or in Mr. Barnes name (he is not certain which) for the cocks, and sent the money by said Thornbury; and this deponent further saith, that upon examining his books, he finds Mr Rumsey charged the 29th October, 1785, with £9 16s. 0d. paid Mr. Raborg for cocks, which entry this deponent is persuaded, must have been after the said Thornbury returned with the cocks, as the sum they cost, could not have been ascertained until then; and further this deponent saith not.

Sworn to before me, this 16th of May, 1788.

CATO MOORE.

These are to certify, that the within named Capt. Charles Morrow, has lived in Shepherd's Town many years, great part of his time has been spent as a merchant, and has served in offices pertaining to the public. We believe, in every one of his employments, (and as a citizen,) he has distinguished himself as a gentleman of strict honor and veracity. Given under our hands, this 17th day of May, 1788.

THOMAS WHITE,	JOHN MARK,	CATO MOORE,
JOHN KEARSLEY,	SMITH SLAUGHTER,	HENRY BEDINGER,
DANIEL BEDINGER,	FRANCIS HAMILTON,	JOHN KEYES,
ABRAHAM SHEPHERD,	WILLIAM SPALDING,	CORNELIUS WYNKOOP,
WILLIAM MORGAN,	ADAM STEPHEN,	HORATIO GATES,
MOSES HUNTER.		

I certify, that the above signers are personally known to me, are men of good fame, and acknowledged their signatures before me, this 17th of May, 1788.

CATO MOORE.

(No. 5.)

Berkeley County, ss.

This day, came Michael Entler, before me, John Kearsley, one of the justices of the peace for said county, and made oath, that as well as he remembers, about the beginning of February, 1786, he and Jonathan Osborn, began to weld some pipes for Mr. James Rumsey; the pipes were about the size of gun barrels, and he well remembers, that at the time the last six scalps were brought to him from the forge, that he and said Osborn, were at work at the first brought scalps; that, after they were welded, he and said Osborn cut the male screw on one end, and a female screw on the other end of each barrel, in order that they might be all screwed together; that after they were so far finished, they lay in my shop six months, or perhaps longer; after which, Mr. Joseph Barnes came to me, and told me he wanted them put together; said Barnes then prepared a block, and assisted me to screw them together and bend them, they were bended nearly in the shape of a worm of a still, with this difference, that the rounds were placed so close, as nearly to touch each other; and this deponent further saith, that he understood that the above pipes were for the use of the steamboat, and further this deponent saith not.

Sworn before me, May 16th, 1788.

JOHN KEARSLEY.

We, the subscribers, have been long acquainted with the above named Michael Entler, and have found him a worthy, honest, sober man, and a man of truth.

THOMAS WHITE,	JOHN MARK,	HENRY BEDINGER,
CORNELIUS WYNKOOP,	WILLIAM SPALDING,	WILLIAM MORGAN,
ABRAHAM SHEPHERD,	THOMAS SHEPHERD,	JOHN KEYES,
JOHN MORROW,	CATO MOORE.	

I certify, that these signers acknowledged their signatures before me, this 17th of May, 1788.

CATO MOORE.

(No. 6.)

Berkeley County, ss.

This day came Conrad Byers, before me, Cato Moore, one of the justices of the peace for this county, and made oath, that about the latter end of October, or beginning of November, one thousand seven hundred and eighty-five, Mr. James Rumsey or Joseph Barnes, brought to my shop two large brass or copper cocks, and requested that handles might be made for them, which the said Byers, being assisted by Philip Strider, did make; they also made two springs, which the deponent understood was for the opening and shutting the same; and this deponent further saith, that toward the latter end of November aforesaid, he made (being assisted by said Philip Strider) two pistons of about thirteen inches diameter, to which he brazed flanches, about one and a half inch broad; and this deponent further saith, that he made sundry other things, which he understood were all of them parts of the machinery for Mr. Rumsey's steamboat.

Sworn before me this 16th of May, 1788. CATO MOORE.

We, the subscribers, have been long acquainted with the above mentioned Conrad Byers, and certify that he has supported the character of a worthy, honest man, and a man of truth.

THOMAS WHITE,	JOHN MARK,	HENRY BEDINGER,
CORNELIUS WYNKOOP,	WILLIAM MORGAN,	ABRAHAM SHEPHERD,
THOMAS SHEPHERD,	JOHN KEYES,	JOHN MORROW,

CATO MOORE.

(No. 7.)

Berkeley County, ss.

This day came Jonathan Osborn before me, John Kearsley, one of the justices of the peace for said county, and made oath, that as well as he remembers, about the first day of February, seventeen hundred and eighty-six, this deponent and Michael Entler, began to weld some pipes for Mr. James Rumsey, they were about the size of gun barrels, and this deponent well remembers that at the time the last six scalps were brought to them from Anteatum forge, they were at work at the scalps that were first brought to them; that after they were welded they cut a male screw on the one end, and a female screw on the other end of each pipe, as they were all to be screwed together; that after this was done, they were left in said Michael Entler's shop six months or upwards; that after this, Mr. Joseph Barnes and said Entler put them together and bended them round a block, in shape resembling the worm of a still; this deponent understood that these pipes were for some of the purposes of said Mr. Rumsey's boat machine, and further this deponent saith not. Sworn to before me, this 16th day of May, 1788.

JOHN KEARSLEY.

We, the subscribers, have been long acquainted with the above named Jonathan Osborn, and certify that he supports the character of an honest man.

JOHN MORROW,	THOMAS WHITE,	JOHN MARK,
HENRY BEDINGER,	CORNELIUS WYNKOOP,	WILLIAM SPALDING,
CATO MOORE,	WILLIAM MORGAN,	ABRAHAM SHEPHERD,
THOS. SHEPHERD,	JOHN KEYES.	

I certify that the above signing was acknowledged before me, this 17th day of May, 1788.
CATO MOORE.

(No. 8.)

Berkeley County, ss.

This day came Francis Hamilton before me, John Kearsley, one of the justices of the peace for said county, and made oath, that as by a review of his, the said Francis' day-book, it appears that in the month of December, in the year of our Lord one thousand seven hundred and eighty-five, Mr. Joseph Barnes and James McMechen brought down the river Potowmac, to the Shannandoah Falls, a boat of about six tons burthen, with a variety of machinery on board, amongst which were two cylinders of copper, about thirteen inches diameter, and near three feet long, a copper boiler, four large brass or copper cocks, pumps, &c., where the said Barnes and McMechen, under the direction of Mr. James Rumsey, continued adapting and suitably fixing said machine to said boat, until the seventh of January, 1786, when the ice driving in the river, obliged them to desist proceeding further for that season, and they accordingly, that same day, drew the boat in the mouth of the run, took off the machinery, and laid it in my cellar for and during the winter. Further, that on the fourteenth day of March, a trial was made of the same, with some alteration in the machinery; that she moved against the current some distance, though not to much satisfaction, owing to the imperfection of the machinery. Furthermore, that said Barnes and McMechen were on board, likewise Captain Charles Morrow, and I myself, steered—and further saith not. Sworn to before me, May seventeenth, 1788.

JOHN KEARSLEY.

We, the subscribers, have been long acquainted with the above named Francis Hamilton, and have ever found him a gentleman of strict honor and veracity.

THOMAS WHITE,	JOHN KEYES,	ABRAHAM SHEPHERD,
DANIEL BEDINGER,	HENRY BEDINGER,	CORNELIUS WYNKOOP,
CATO MOORE,	SMITH SLAUGHTER,	JOHN MARK,
JOHN MORROW,	WILLIAM MORGAN.	

May 19th, 1788.

I have been acquainted with Mr. Francis Hamilton twenty-six years, and found him a person of veracity and respectable character. ADAM STEPHEN.

I believe Mr. Hamilton to be a gentleman of integrity and character.

HORATIO GATES

I am of the same opinion. MOSES HUNTER.

I certify that the above signers are personally known to me, that they are men of good fame, and acknowledged their signatures before me, this 17th day of May, 1788.

CATO MOORE.

(No. 9.)

I do hereby certify, that in November, 1784, being at Richmond, attending the assembly as a representative from the county of Berkeley, I was in company with Mr. James Rumsey, he being an acquaintance, and from the same county, and that he then informed me (as I understood, in confidence) that he intended to construct a boat which was to be wrought altogether by steam; that he had tried the principles, some of which he mentioned, but I cannot ascertain the particulars; upon the whole of our conversation, I understood from him at that time, that his principal dependance, in the operation of his boat, was upon steam. Given under my hand, in Berkeley county, this 19th day of May, 1788. MOSES HUNTER.

Witnesses present at signing. JOHN MORROW.
ABEL WESTFALL.

(No. 10.)

This day came before me, Jacob Young, justice of the peace in and for this county of Frederick, and State of Maryland, Elizabeth Zimmer, and being duly qualified on the holy Evangelists of Almighty God, declared and said, that one week before the twenty-third of November, in the year of our Lord one thousand seven hundred and eighty-five, Mr. James Rumsey engaged my husband to make a quantity of copper work, among which was two round copper things of about three feet long, and better, and one foot wide, and may be better, all which parcel of work was finished before Christmas of the same year, and taken away. This deponent also well remembers of a certain John Peter, an artificer in tin work, to have been engaged to do some tin work, relative to the same machine, at the same time, and which was likewise finished before Christmas of the same year. This deponent likewise remembers to have seen three or four large cocks of metal, the same as still cocks, fixed to the same machine before it was taken away, and further this deponent understood, that the machine was to drive a boat, and that the round things was to raise water; this deponent likewise remembers of a certain gentleman, of a certain spare, thin complexion, and black hair, some time in April last, of this year one thousand seven hundred and eighty-eight, asked her, relative to the above subject, to which I answered in manner as herein recited, and further saith not. Sworn before

May the 16th, 1788. JACOB YOUNG.

I certify being present, when the above deposition was taken.

THOMAS PRICE.

Maryland, *Frederick County, to wit:*

I do hereby certify, that Jacob Young, gentleman, before whom the within deposition was made, and who hath thereunto subscribed his name, was at the time thereof, one of the justices of Frederick County Court, duly authorized and qualified, &c.

[L. S.] In testimoney, whereof, I have hereunto subscribed my name, and affixed the public seal of Frederick County Court, the 16th day of May, 1788.

WILLIAM RITCHIE, *Clk.*

(No. 11.)

State of Maryland, *Baltimore County, ss.*

On the 9th day of June, 1788, came Christopher Raborg, of Baltimore Town, coppersmith, before me the subscriber, one of the justices of the peace for the county aforesaid, and made oath on the Holy Evangelists of Almighty God, that when he gave his certificate to Mr. John Fitch, on the 26th of April last past, that he the said Christopher, had got four brass cocks made by Mr. Charles Weir & Co., in the Fall, 1785: but not having made any charge thereof, to ascertain the time exactly, could not be more particular, but that he, the said deponent, hath since been able to ascertain the time when the said four cocks were made, for Mr. James Rumsey, by order of Mr. Joseph Barnes, and doth swear and declare, that the said four brass cocks were made some time in the months of September or October, of the year of our Lord, one thousand seven hundred and eighty-five; and it hath since appeared to this deponent, that the said four brass cocks were for the use of Mr. Rumsey, to be employed in his steamboat, and further this deponent saith not.

Sworn to before me, GEORGE GOULD'TH PRESBURY.

Baltimore County, to wit:

I do hereby certify to all whom it doth or may concern, that George Gould'th Presbury, gentleman, before whom the within deposition was taken, and who hath thereto subscribed his name was at the time of the taking and signing thereof, and still is one of the justices of the peace, in and for the county aforesaid, and to all certificates by him given as such, due faith and credit is, and ought to be given, as well in courts of justice as thereout.

[L. S.] In testimony whereof, I have hereto set my hand, and affixed the seal of my office, this tenth day of June, in the year of our Lord seventeen hundred and eighty-eight.

WILLIAM GIBSON,
Clerk, Baltimore County.

(No. 12.)

STATE OF MARYLAND, *Baltimore County, ss.*

On this 9th day of June, 1788, came Charles Weir, of Baltimore town, founder, before me, the subscriber, one of the justices of the peace for the county aforesaid, and made oath on the Holy Evangelists of Almighty God, that when he gave his certificate on the twenty-sixth day of April, last past, of having made four brass cocks to Mr. John Fitch, he could not then recollect the exact time when; but that he, this deponent, by means of a receipt for money paid by him, which he has since found, can declare the time with precision, and doth positively make oath as aforesaid, that he made the said four brass cocks by the direction of, and for Mr. Christopher Raborg, (for the use of Mr. Rumsey's steamboat, as he has since learnt,) and delivered the said four cocks to said Christopher Raborg, on or about the 15th day of October, in the year of our Lord, one thousand seven hundred and eighty-five, and this deponent further saith, the money mentioned to be received in the receipt above alluded to, and dated the seventeenth day of October, seventeen hundred and eighty-five, was money received by this deponent, of the said Christopher Raborg, for the said four brass cocks; and further this deponent saith not.

Sworn before me, GEORGE GOULD'TH PRESBURY.

Baltimore County, to wit:

I hereby certify to all whom it doth or may concern, that George Gould'th Presbury, gentleman, before whom the within deposition was taken, and who hath thereto subscribed his name, was at the time of taking and signing thereof, and still is one of the justices of the peace, in and for the county aforesaid, and to all certificates by him given as such, due faith and credit is, and ought to be given, as well in courts of justice as thereout.

[L. S.] In testimony whereof, I have hereunto set my hand, and affixed the seal of my office, this tenth day of June, in the year of our Lord, seventeen hundred and eighty-eight.

WILLIAM GIBSON,
Clerk, Baltimore County.

(No. 13.)

STATE OF MARYLAND, *Baltimore County, ss.*

On this 10th day of June, 1788, came Isaac Cursten, of Baltimore town, founder, before me, the subscriber, one of the justices of the peace, for the county aforesaid, and made oath on the Holy Evangelists of Almighty God, that the certificate this deponent gave Mr. John Fitch, respecting four brass cocks made 29th March, 1786, by the deponent and Co. for Christopher Raborg, could not be the cocks alluded to, for, on further examination of my books, I find the price charged does not agree with the amount ascertained of the cocks made for Christopher Raborg, at the time he was employed by Mr. Joseph Barnes, neither does the time; for I am now satisfied, and do positively declare, and make oath as above, that the cocks were made some time at or about the 14th of October, 1785, that was for the use of Mr. Joseph Barnes, as we then thought; but have since learned, it was for the use of Mr. James Rumsey's steamboat, and from every circumstance, I find they have never been charged or booked, as it appears the cash was received at the delivery of said cocks; and further this deponent saith not.

GEORGE GOULD. PRESBURY.

Baltimore County, to wit:

I hereby certify to all whom it doth or may concern, that George Gould'th Presbury, gentleman, before whom the within deposition was taken, and who hath thereto subscribed his name, was at the time of the taking and signing thereof, and still is, one of the justices of the peace, in and for the county aforesaid, and to all certificates by him given as such, due faith and credit is and ought to be given, as well in courts of justice, as thereout.

[L. S.] In testimony whereof I have hereto set my hand, and affixed the seal of my office, this tenth day of June in the year of our Lord one thousand seven hundred and eighty-eight.

WILLIAM GIBSON,
Clerk, Baltimore County.

(No. 14.)

Berkeley County, ss.

I do hereby certify, that having an occasion of boarding with Mr. James Rumsey, in the month of January, in the year of our Lord one thousand seven hundred and eighty-five, where, amongst many of his curious experiments, one I remember very particularly, which was, he caused to be made a hollow square tube (made of pine boards) about eight feet long, and about one inch and a half diameter in the cavity of the tube, which he suspended upon fine cords, and having a common gimlet hole bored at the end of said tube, and on the one side of the same, and hanging some weights over a small pulley, by a thread tied to the end of said tube, whereupon

pouring water by hand into said tube, it drew up a certain weight; which being repeatedly tried, I asked Mr. Rumsey what he meant or intended by this experiment, to which he made answer, that by that principle he would make the boat go, and after some small matter of conversation, he took his pen and ink, and retired to make his calculations, as was his custom after experiments made, many of which he made during the winter; in testimony of which I have hereunto set my hand, this 19th day of May, 1788.

NICHOLAS ONICK.

We, the subscribers to these presents, do hereby certify, that we have been long acquainted with the within mentioned Nicholas Onick, and have every reason to believe him to be a gentleman of strict honor and integrity.

ADAM STEPHEN,	HORATIO GATES,	MOSES HUNTER,
GEORGE ROOTS,	PHILIP PENDLETON,	JOHN MORROW,
JOHN MARK,	JOHN COOK,	DAVID GRAY,
CORNELIUS WYNKOOP.		

Berkeley County, ss.

We do certify, that we received a letter from Nicholas Onick, saying that he drew the within certificate himself, and that if called on he would make oath to the same. Given under our hands this 19th of May, 1788.

CATO MOORE.
JOHN KEARSLEY.

(No. 15.)

I do certify, that Mr. James Rumsey, of Berkeley County, Virginia, in a conversation I had with him at the Warm Springs, in the latter end of July, or beginning of August, 1783, told me that he intended to construct a boat to go by the power of steam, and pointed out the great expenses it would save in water carriage.

JOHN WILSON.

PHILADELPHIA, July 4th, 1788.

(No. 16.)

I do certify that John Wilson, of Philadelphia, on his return from the Warm Springs, in the summer 1783, told me that Mr. James Rumsey was about to construct a boat that would go by strength of fire and steam, which the said Rumsey intended to have completed soon.

PHILADELPHIA, July 4th, 1788. JULIANA STEWART.

(No. 17.)

This is to certify, that at the time I gave my certificate to Mr. John Fitch, in April last past, respecting having made four brass cocks, as per my certificate in Mr. Fitch's pamphlet, No. 22, and page 28: that the said Fitch then urged me to prove what I had therein certified. I told said Fitch that I was not then positive of the time they were made, therefore could not prove it. Said Fitch persisted in soliciting of me, and said he would give me any thing I would ask, only to prove it, and I should be handsomely rewarded; but I positively refused. And further, that at the time Mr. Fitch called on me on his way to Annapolis, in May or June last, that I then showed him a receipt I had found since he had my certificate, that enabled me to be positive as to the time said cocks were made, and he said he was very sorry for it, that *they* would make a handle of it, and asked if *they* had called on me respecting it. I told him not.

CHARLES WEIR.

This certificate was voluntarily subscribed, and acknowledged in our presence, this fourth day of July, 1788.

her
ALICE × WEIR.
mark

BALTIMORE, July 4, 1788. JOHN LINOILD.

(No. 18.)

I certify, that Mr. Fitch came to our shop to get John Frymiller, an apprentice of Mr. Raborg's, to swear about something concerning a *steamboat* that Mr. Rumsey erected, for which he gave him, to the best of my knowledge, half a dollar, and treated him well, as the said Frymiller said: and after he had been gone the best part of the afternoon, he returned to the shop again, when he appeared to me to be somewhat in liquor, and said he would not care to swear in the same manner oftener, if he could be always so treated.

BALTIMORE, July 4, 1788. CHRISTOPHER BRUDENHART.

(No. 19.)

I also recollect well of John Frymiller being groggy, when he returned from the magistrate in the evening, where he had been to swear for Mr. Fitch, as per his pamphlet, No. 19, page 26. Given under my hand, this fourth day of July, one thousand seven hundred and eighty-eight.

CHRISTOPHER RABORG

[Dr. Thornton, the first Superintendent of the Patent Office, became associated with Mr. Fitch, and wrote a small pamphlet on the Origin of Steamboats. As it contains curious information, it is worth preserving.]

SHORT ACCOUNT

OF THE

ORIGIN OF STEAMBOATS,

WRITTEN IN 1810,

AND NOW COMMITTED TO THE PRESS,

BY

W. THORNTON,

OF THE CITY OF WASHINGTON.

WASHINGTON CITY:
PRINTED BY RAPINE AND ELLIOT, CAPITOL HILL.
1814.

ORIGIN OF STEAMBOATS.

City of Washington, Jan. 1, 1810.

Finding that Mr. Robert Fulton, whose genius and talents I highly respect, has been by some considered as the inventor of the steamboat, I think it a duty to the memory of the late John Fitch, to set forth, with as much brevity as possible, the fallacy of this opinion; and to show, moreover, that if Mr. Fulton has any claim whatever to originality in his steamboat, it must be exceedingly limited.

In the year 1788, the late John Fitch applied for and obtained, a patent for the application of steam to navigation, in the States of Pennsylvania, New York, New Jersey, Delaware, &c., and soon after, the late Mr. James Rumsey conceiving he had made some discoveries in perfecting the same, applied to the State of Pennsylvania for a patent; but a company formed by John Fitch, under his State patents, of which the author of this was one of the principal shareholders, conceiving that the patent of Fitch was not for any peculiar mode of applying the steam to navigation, but that it extended to all known modes of propelling boats or vessels, contested before the assembly of Pennsylvania, and also before the assembly of Delaware, the mode proposed by Mr. Rumsey, and contended that the mode he proposed, viz. by drawing up the water into a tube, and forcing the same water out at the stern of the vessel or boat, which was derived from Dr. Franklin's works, (the Doctor being one of his company) was a mode they (Fitch's company) had a right to, for the plan was originally published in latin, about fifty years before, in the works of Bernoulli the younger, and two of Fitch's company and I appeared without counsel and pleaded our own cause in the assembly of Pennsylvania, (the Hon. Messrs. Findley and Smiley, of Congress, were then sitting members of the assembly,) and after a week's patient hearing against the most learned counsel of Pennsylvania, we obtained a decision in our favor, and afterwards also in Delaware. We believed, and contended that our claim of propelling boats by steam, included all the modes of propelling vessels and boats then known, and that the patent was for the application of steam, as an agent to the propelling powers, and the decisions of the legislatures were in favor of this construction, as Mr. Rumsey's company (of which the late Messrs. Bingham, Myers, Fisher, and many other worthy gentlemen were members,) were excluded from the right of using steamboats on any principle. We worked incessantly at the boat, to bring it to perfection, and some account of our labors may be seen in the travels of Brissot de Warville in this country, and under the disadvantages of never having seen a steam engine, on the principles contemplated, of not having a single engineer in our company or pay, we made engineers of common blacksmiths, and after expending many thousand dollars, the boat did not exceed three miles an hour. Finding great unwillingness in many to proceed, I proposed to the company to give up to any one, the half of my shares, who would, at his own expense, make a boat go at the rate of eight miles an hour in dead water, in eighteen months, or forfeit all the expenditures on failing; or I would engage with any others, to accept these terms. Each relinquished one half his shares, by making the forty shares eighty, and holding only as many of the new shares as he held of the old ones, and then subscribed as far as he thought proper, to enter on the terms by which many relinquished one half. I was among the number who proceeded, and in less than twelve months we were ready for the experiment. The day was appointed, and the experiment made in the following manner: A mile was measured in Front street, (or Water street) Philadelphia, and the bounds projected at right angles, as exactly as could be, to the wharves, where a flag was placed at each end, and also a stop watch. The boat was ordered under way at dead water, or when the tide was found to be without movement; as the boat passed one flag, it was struck, and at the same instant the watches were set off; as the boat reached the other flag, it was also struck, and the watches instantly stopped. Every precaution was taken before witnesses, the time was shown to all, the experiment declared to be fairly made, and the boat was found to go at the rate of eight miles an hour, or one mile within the eighth of an hour; on which the shares were signed over with great satisfaction, by the rest of the company. It afterwards went eighty miles in a day!* The governor and council of Pennsylvania were so highly gratified with our labors, that without their intentions being previously known to us, governor Mifflin, attended by the council in procession, presented to the company, and placed in the boat, a superb silk flag, prepared expressly, and containing the arms of Pennsylvania,† and this flag we possessed till Mr. Fitch was sent to France by the company, at the request of Aaron Vail, Esq., our consul at L'Orient, who being one of the company, was solicitous to have steamboats built in France. John Fitch took the flag, unknown to the company, and presented it to the na-

* Yet Mr. Fulton asserts that no successful experiments were ever made with steamboats before his!

† Perhaps I here make a mistake; for in the patent taken out by Messrs. Fitch and Voght, for the company, I find the flag of the United States represented. The archives of the state will show it, if necessary.

24

tional convention. Mr. Vail finding the workmen all put into requisition, and that none could be obtained to build the boats, paid the expenses of Mr. Fitch, who returned to the United States; and Mr. Vail afterwards subjected to the examination of Mr. Fulton, when in France, the papers and designs of the steamboat appertaining to the company.

Finding that the works on board the first boat were not strong enough, we built another of twenty-five tons burthen, rigged schooner fashion, intended to go to New Orleans and mount the Mississippi. When the principal parts of the work were prepared, and ready to put on board, the author of this, thinking no mistakes could be made by the company, went to the West Indies on the 16th of October, 1790, to visit his mother for the last time, and expected to find on his return, the boat ascending the Mississippi at the rate of at least four miles an hour; but a spirit of innovation having seized some of the company, and their attempts to simplify the machine having ruined it, their unsuccessful endeavors to make it work, subjected them to debts which obliged them to sacrifice both boats and all the machinery; and on my return, after a two years' absence, I found, to my inexpressible grief, the whole of this very valuable scheme ruined. I had only then to wait till the patent taken out from the United States during my absence, (see No. 1,) for the benefit of the company, by Messrs. Fitch and Voight, in the year 1791, expired, and to take out a patent for these peculiar improvements which I had invented or suggested. Finding Mr. Fulton about to take out a patent, after he had examined every thing in the Patent Office relative to steamboats and steam engines, and not knowing whether he might recollect, among so many, those I had shown him of my own invention, I thought it proper to take a patent for them previous to a sight of his papers, or of any hint of what they contained; and I believe he will do me the justice to say I never saw one of his, nor had a hint of what they were, before my patent from the United States was issued. I find Mr. Fulton's patent rests principally on proportions, though the second section of the law expressly excludes proportions.* He uses Watts' and Boulton's steam engines, and wheels at the sides of the boat, but an engine on the principles of Watts' and Boulton's was used by us, the application of which was since patented; and the use of the wheels at the sides was known to us, and I often urged their use in our first boat, as can be testified by Mr. Oliver Evans; but the objection to them on so small a scale, was their waste of power by the fall of the buckets or paddles on the water, and their lift of water in rising, both of which objections would diminish as the wheel increased in size; but side wheels could not be claimed as a new invention, for their use in navigation had long been known and published to the world by Dr. John Harris, in his Lexicon Technicum, in 1710, just one hundred years ago. If Mr. Fulton should claim the actual application of steam to wheels at the sides of a boat, in opposition to the above declarations, I beg leave to offer, as a caveat against any such claim, the fire ship of Edward Thomason, in the tenth volume of the Repertory of Arts, which was laid before the Lords of the Admiralty in 1796. This contains wheels at the sides, operated on by a steam engine, and was intended to possess the power of moving given distances in all directions, according to the intention of the director, so that without any person being on board, it would conduct itself into an enemy's port, and by clockwork, at a given moment explode the combustibles; which plan, I also presume, might suggest to any person of even less original genius than Mr. Fulton, the mode of letting off torpedos, which were invented during the war for independence, by the late Major Bushnell, of Connecticut.

Mr. Fulton's have never exceeded five miles an hour in dead water, and he declared it impossible to make one exceed that velocity, and offered me $150,000 if I would make one that would exceed it. I agreed to his proposal at once, but he declined to write the terms. Our boat went at the rate of eight miles an hour, in the presence of many witnesses still living, and to comply with terms as before stated, which were completely and satisfactorily fulfilled; and yet he has nominally an exclusive privilege for navigating the waters of the State of New York; but not satisfied with this apparent violation of the rights of his fellow-citizens, he took out a patent from the United States, on the 11th of February, 1809, which act the legislature of New York must surely admit, supersedes their own, if they even thought its validity was before indisputable; and if Messrs. Livingston and Fulton attempt to shelter themselves under the expression of the seventh section of the patent law of 1793, by asserting that the provision only includes the grants of exclusive rights, by States, prior to the adoption of the present form of government, others may surely, on reversing the case, assert that the silence of the law is a clear proof that such a case was not considered as worthy of attention, because it could not be supposed to exist, being repugnant to common sense.

This silence precludes any construction favorable to the parties, and by making provision for the constitutional and general act, they are by a liberal and plain conclusion, excluded ipso facto from the prior advantage of the state act, even if it were valid, and that validity founded on proofs that these gentlemen were the inventors of the application of steam to navigation, or had made any essential improvements therein; but in the present circumstances to attempt an exclusive monopoly of these waters, is not merely to attempt to deprive others of natural and inherent rights; but without a shadow of reason to attempt also to deprive them of acquired rights under the general government, and as if the power and influence of individuals, which seem to have hitherto prevented an interference in vast monopoly, had encouraged to further acquirements of the rights of their fellow-citizens; and being discontented with the wise and equitable provisions of the Congress, in which all other citizens have rested satisfied, they have exhibited an avaricious

* Since examined, I find his boat is exactly in the proportion of the boat we used, and which was made known to him by Mr. Aaron Vail, viz. 8 feet wide, by 60 feet long; Mr. Fulton's 20 feet wide and 150 feet long; in both cases nearly 7½ times the length of the breadth. Other proportions may answer as well, but this is given to show whence he derived his original ideas.

desire of obtaining an universal monopoly of the waters of the union by addressing the different legislatures of the states; and were even in Virginia on the point of succeeding, and the final question about to be put, when my letter (No. 2,) was handed to the Speaker of the House of Representatives, and the bill was immediately negatived. So bold and unprecedented an attempt to infringe the privileges of the citizens at large, if successful, would probably have terminated in soliciting the Congress to grant to a combination of rich merchants, the monopoly of the seas by the promise of low freights.

The law already passed in the State of New York, in favor of those gentlemen, shews that in the most enlightened assemblies of men, there are cases which being brought forward by persons of high character, to whom no suspicion of incorrectness can possibly attach, are hurried through the house without doubting their legality, or seeing any injustice in their consequences, especially when the minds of the leading members are deeply abstracted or absorbed in the contemplation of important affairs. If those gentlemen had successfully pursued their monopolizing system, and had obtained exclusive rights to navigate all the valuable waters in the union, of what consequence would a patent obtained in a legal and regular way from the United States have been, and that for only 14 years, while excluded by those gentlemen for 30 years from every valuable water, and this too without any plea whatever? Such grants, it is true, would be deemed so illegal, so unjust, so unconstitutional and oppressive, that every person would be willing to contend for, rather than abandon his rights; but there are few men, especially those who live by their wits or invention, so powerfully supported as Mr. Fulton has been, or who would voluntarily enter into suits, that by protraction, would perhaps, only be their death or terminate in their ruin.

WILLIAM THORNTON.

[No. 1.]

To the Honorable, the Secretary of State, the Secretary of War, and the Attorney General.

The petition of *John Fitch*, of the city of Philadelphia, humbly sheweth,

That your petitioner in the spring of the year, one thousand seven hundred and eighty-five, conceived the idea of applying steam to the purposes of propelling vessels through the water; that fully satisfied in his own mind; of the practicability of such a scheme, of its great immediate utility, and the important advantages which would in future result therefrom, not only to America, but the world at large, if the scheme should be carried into effectual operation, he divested himself of every other occupation, and undertook the arduous task, not doubting that when perfected, he should be amply rewarded. In his first attempts to procure assistance from Congress, and the Legislatures of many of the States, from the peculiar situation of their finances and the seeming impossibility of the success of his scheme, he met with no relief. Not entirely discouraged by those disappointments, he continued his application to his project, and prayed several of the states for an exclusive right to the use of fire and steam to navigation: that New Jersey, New York, Pennsylvania, Delaware and Virginia, granted him an exclusive right, agreeably to the prayer of his petition for fourteen years.

That the impracticability of procuring experienced workmen in America, your petitioner's total ignorance of the construction of a steam engine, together with the necessary deviation from the form described in books in order to accommodate its weight and bulk, to the narrow limits of a vessel, have caused him not only to expend about eight thousand dollars in successive experiments, but nearly four years of some of his grants have expired before he has been able to bring his engine to such a degree of perfection as to be carried into use.

That having at length fully succeeded in his scheme, proofs of which he is prepared to offer, he trusts he now comes forward, not as an imaginary projector, but as a man, who, contrary to the popular expectation, has really accomplished a design which on examination, will clearly evince the many and important advantages which must result therefrom to the United States, some of which your petitioner begs leave to enumerate.

The western waters of the United States, which have hitherto been navigated with great difficulty and expense, may now be ascended with safety, conveniency and great velocity; consequently by these means, an immediate increased value will be given to the Western Territory; all the internal waters of the United States, will be rendered much more convenient and safe, and the carriage on them much more expeditious; that from these advantages will result a great saving in the labor of men and horses, as well as expense to the traveller.

Your petitioner also conceives that the introduction of a complete steam engine, formed upon the newest and best principles into such a country as America, where labor is high, would entitle him to public countenance and encouragement, independant of its use in navigation; he begs leave to say, that the great length of time, and vast sum of money expended in bringing the scheme to perfection, have been wholly occasioned by his total ignorance of the improved state of steam engines, a perfect knowledge of which has not been acquired without an infinite number of fruitless experiments; for not a person could be found who was acquainted with the minutiæ of Bolton and Watt's new engine; and whether your petitioner's engine is similar or not to those in England, he is to this moment totally ignorant; but is happy to say, that he is now able to make a complete steam engine, which in its effects he believes, is equal to the best in Europe, the construction of which he has never kept a secret.

That on his first undertaking the scheme, he knew there were a great number of ways of applying the power of steam to the propelling of vessels through the water, perhaps all equally effective; but this formed no part of his consideration, knowing that if he could bring his steam engine to work in a boat he would be under no difficulty in applying its force; therefore, he trusts no interference with him in propelling boats by steam under any pretence of a different mode of application will be permitted; for should that be the case, the employment of his time, and the amazing expense attending the perfecting of his scheme, would, whilst they gave the world a valuable discovery, and to America, peculiar and important advantages, eventuate in the total ruin of your petitioner; for a thousand different modes may be applied by subsequent navigators, all of them benefitting by the expense and labor of your petitioner, and thus sharing with him those profits which they never earned; such a consequence, he is confident will not be permitted by your honorable body.

Your petitioner, therefore, prays that your honors will take the subject of his petition into consideration, and by granting him an exclusive right to the use of the steam navigation for a limited time, do him that justice which he conceives he merits, and which he trusts will redound to the honor, and add to the true interest of America; and your petitioner as in duty bound shall ever pray.

JOHN FITCH.

New York, 22d June, 1790.

[No. 2.]

DEPARTMENT OF STATE,
PATENT OFFICE, 1810.

SIR:—I address you with extreme reluctance on the subject which affects very nearly the interests of many of my fellow-citizens; but being called upon by them, I consider it as a duty to represent to you and through you, to the honorable body over which you preside, that they view with very great concern an attempt to obtain from the legislature of your state, an exclusive right to navigate with steamboats the waters therein for a very long period; which, if granted, would effectually deprive many ingenious inventors and mechanics, of the benefits expected from their various inventions and improvements in steamboats, for which they have taken patents from the United States, under an impression, that the states had ceded by the constitution to the Congress, the right to grant patents or exclusive privileges for limited times to authors or inventors, thereby to promote the sciences and arts; on the expiration of which limitations their several inventions become the property of every citizen of the United States, by which tacit contract the individual is for a time benefitted, and the public forever after. But if the honorable, the legislature of your state, grant the privileges now desired, the example may lead to dangerous and oppressive consequences.

This is submitted to your consideration, with the highest respect and deference.

WILLIAM THORNTON.

To the Honorable, the Speaker of the House of Representatives of Virginia.

V.

ABORIGINAL ARTS.

GOLDSMITHING AMONG THE AZTECS.
SPINNING AND WEAVING BY AZTECS.
SPINNING AND WEAVING BY MODERN INDIANS.
REMARKS ON SPINNING.

ABORIGINAL ARTS.

THERE is a peculiar propriety, it is believed, in preserving in the reports of this bureau, remarkable relics of aboriginal inventions. Our government occasionally employs artists to paint the portraits of Indian Chiefs—works of transient interest and value. There can, therefore, be little ground on which to rear objections to the recording a few illustrations of the arts of the Aztecs, presenting as they do, vivid examples of ancient mechanical and industrial effort. In the present section will be found four uncouth figures—copies of old native drawings—sent to Spain by Antonio de Mendoza, the successor of Cortés, and first viceroy of New Spain, and copied into Lord Kingsborough's rare volumes on the Antiquities of Mexico. Than such pictures, few pages of history are more instructive, or impart a better insight into the character and condition of the half civilized races whom Cortés and Pizarro subdued.

Aztec Goldsmith at work—From Mendoza's collection.

In this figure the artist has represented a workman in the act of soldering or annealing a piece of plate. Except the rude style in which the native limners portrayed the human figure, the cut is a fac-simile of Pharaonic profiles of the same class of workmen, and of modern goldsmiths of Africa, Hindostan, Java, Sumatra, Ceylon, and Asia generally. The small portable furnace, blow-pipe, position of the artist, scantiness of apparel, and the ground his workbench, are common to all; the only observable difference is in the apron (suspended, too, by long shoulder straps) of the American, who, in this respect, seems to have advanced beyond his brethren of the other hemisphere.

Had the draughtsman possessed the skill of a modern artist, and painted the tools and processes used in fusing the metal, of spreading it out into plates, working it into shape, and chasing in the ornaments; of drawing wire, and fabricating the famous old Panama chains, &c., &c., many other problems of Aztec economy and art would have been solved.

The smiths of Mexico, Central America, and Peru, were expert in the use of the blowpipe; and this is not to be wondered at, if, as early Spanish writers report, the bellows was unknown among them. In specimens of their work extant, the soldering rivals any thing executed in modern workshops; seams often challenge, and sometimes defy the keenest scrutiny to detect them. Native smiths still use the pipe.

Every enlightened workman in metals, must feel interested in thus beholding an ancient red brother in the actual use of the blowpipe, to say nothing of the illustration the figure affords of the state of the arts in anti-Columbian epochs, and of ancient life on this part of the planet.

The use of the blowpipe has been inferred from metalline remains discovered in sepulchral tumuli of the Mississippi valley. In Caleb Atwater's Antiquities of the West—Columbus 1833, p. 92–3,—mention is made of sixty copper beads, found in one of the mounds at Grave creek, near Wheeling. "They were made of a coarse wire, which appeared to have been hammered out, not drawn, and were cut off at unequal lengths. *They were soldered together* in an awkward manner, the centre of some of them uniting with the edges of the others. They were encrusted with verdigrise, but the inside of them was pure copper. This fact shows that the ancient inhabitants were not wholly unacquainted with the use of metals." As it is admitted that *brass* was not known to the mound builders, an analysis of the alloy that constituted the brazen solder alluded to above, would be a positive addition to the little knowledge we have gleaned of these remote native artisans and of their arts.

SPINNING.

No matter how far man is separated from his fellows, either on the earth's surface, or by time, the general uniformity of his organization is stamped on all his normal devices. Primitive inventions are universally allied. Under similar circumstances and conditions, the same means are hit upon to reach the same ends. Kindred trains of thought, of resources and results, characterize the origin and early progress of the most essential arts everywhere: beginning in the same wants, they suggest the same ideas, which are carried out in substantially the same manner.

Still, when a primitive people is found shut out from communion with others; isolated from the rest of the world, and deriving no thoughts from it—some shades of difference, more or less strongly defined, often mark devices discovered by them in common with others; and this, whether occupiers of small islands or wide spread continents. But after all, this is nothing more than what may be named a variety *of expression:* the same general idea being differently brought out, just as in speech, utterance is given to the same thoughts after various idioms. All arts and all machines are but dialects of one language—reasonings and conclusions represented in tangible forms and figures—a universal speech, and understood by all men.

Of the diversity in the unfolding of a primitive and common suggestion, a more interesting example cannot well be adduced, than the phases in which the

fabrication of thread has been disclosed on this half of the globe. They appear so different from others, and so peculiar, if not unique, that it may safely be said, if the first spinsters were exotics, their mode of spinning was indigenous; however difficult, if not impossible it may be to reconcile the one with the other.

Spinning lies at the threshold of human culture. It was the first, or among the first born of the arts, and was doubtless the offspring of female cogitation. Throughout all ages of the past, it was under the peculiar province of the sex. In it, queens and even goddesses sought to excel: one of the earliest of useful efforts, it was one of the best. Till it was introduced man was a houseless wanderer, and where it is not, he is still a vagabond, roaming the forest. Home, and its softenings and soothing influences, were unknown, till women began to twirl the spindle; till then, the fair fount of the arts was unopened, unthought of, undreamt of: an universal acquirement, it is one in which little variations, in details, could be looked for among uncultivated tribes. It is, however, singular that the thread-making idea has been less skilfully developed by the red race, than perhaps any other of their mechanical conceptions; this is remarkable in people so far advanced as the Mexicans, Peruvians, and others were.

The distaff is identified with spinning in the old world, from the earliest times. It dates behind, far behind, historic, and was quite a common thing in heroic and mythic epochs. It pervades the most ancient of legends, and plays a part in the remotest of myths. No other instrument of domestic economy is clearer seen through the semi-historic mists that enshroud the infancy of human career; few others could be named as belonging to lower strata of time. Common in the other hemisphere through unknown periods, and yet utterly a stranger to this.

Of the province assigned to the fates, Clotho held the distaff, while Lachesis twirled the spindle, and Atropos determined the length of the thread. Then there was Hercules, who was playfully rapped over the head by Omphale, for his awkwardness in holding it. Sardanapalus, too, endeavored to rival the son of Jupiter, by spinning with it among his maids. Ancient Egyptian spindles and distaffs have been recovered from the tombs; and how common they both were among the Hebrews, appears in Solomon's portrait of a virtuous woman. "She seeketh wool and flax—she layeth her hands to the spindle, and her hands hold the distaff." Both spindle and distaff were frequently dedicated to Minerva, the patroness of spinning, and of the arts connected with it. The goddess was herself rudely sculptured with them in the Trojan Palladium.

A glance at these classic implements, before introducing the primitive American apparatus, will better enable one to perceive the difference existing between them, more correctly to appreciate both, and to judge how far one is allied to, or could have been derived from the other.

Distaff and Spindle—Ancient Greek and Roman.

This figure is from a series of bas-reliefs representing the arts of Minerva, upon a frieze of the Forum Palladium, at Rome. It shows the operation of spinning, at the moment when the spinner has drawn out a sufficient length of thread from the distaff, and just previous to the act of taking it out of the slit on the top of the spindle, to wind it on the latter. It is said by classic writers, that the spindle was always when in use, accompanied by the distaff, as "an indisputable part of the apparatus." The following particulars are gathered from Homer, Herodotus, Ovid, Horace, Catullus, Pliny and others. The spindle was a stick, ten or twelve inches long, having at the top a slit or notch, by which to fix the thread at the commencement; the lower end was passed through, and attached to a small but heavy disc or whorl, made of wood, stone or metal. The weight of this, and of the spindle, kept the thread at a proper tension, and the momentum while turning round, kept twisting the yarn or thread in the interim of repeating the operation with the fingers. When from the length of the thread, the spindle approached the ground, or descended below the reach of the fingers, the thread was wound on the spindle, except a short piece left for insertion in the slit, preparatory to the formation of another length. The distaff was about three times the length of the spindle, and commonly made of a reed, with an expansion near the top, over which the prepared flax or wool was placed, and secured by a ribbon or tape; the fibres being left sufficiently loose to be easily drawn out by the fingers and thumb of the spinner. Distaffs, as well as spindles, of gold and of ivory, were ascribed to goddesses, and were really presented to distinguished females.

It was quite common for ancient females to keep their spindles whirling while on their way to the fountain for water, or making short visits, &c. Some striking examples have been recorded by historians, and among them, the following one by Herodotus:—As Darius, king of Persia, was sitting publicly in one of the streets of Sardis, he observed a young woman of great elegance and beauty, bearing a vessel on her head, leading a horse by a bridle fastened round her arm, and at the same time spinning some thread. Darius viewed her as she passed with attentive curiosity, observing that her employments were not those of a Persian, Lydian, nor indeed of any Asiatic female. Prompted by what he had seen, he sent some of his attendants to observe what she did with the horse; they accordingly followed her. When she came to the river, she gave the horse some water and then filled her pitcher; having done this, she returned by the way she came with the pitcher of water on her head, the horse fastened by a bridle to her arm, and as before, employed in spinning.

In the rural districts of old Rome, women were forbidden to spin while travelling on foot. The prohibition arose from superstitious motives; but the practice has come down to our times, being found more or less common in Spain, Portugal, Hungary, Italy, Greece, and other parts of Europe; as also over the greater part of Asia. The shank of the distaff on such occasions being secured by a sheath or strap to the person; or, as in the following figure of a modern spinner, grasped under the left arm.

Distaff and Spindle—Modern Asiatic and European.

How differently the idea has been worked out by the ancient dwellers on this hemisphere, will appear in the two next illustrations. Coarse and uncouth they are; yet of unusual interest and value in an historical view of a people who at the conquest stood at the head of the aborigines; but whose nationality and power have been broken, and whose arts have all but vanished before those introduced by the whites.

Aztec girl spinning—From Mendoza's collection.

The figure on the foot of the preceding page represents a girl six years old, learning to spin in the presence of her mother, the portrait of whom is omitted. She is in the act of winding on the spindle the length of thread just spun. The spindle differs but little from those of the eastern world, its lower end being furnished with a conical weight or fly to promote rotation, and as it would seem for its pointed extremity to rest like a pivot in some small cavity while revolving; for the spindle when in use, was not raised from the ground—the reverse of the eastern practice, in which the motion ceased the moment the pivot touched it.

The basket-like base on which the fly rests, is the Mexican symbol of the ground, though possibly it may here represent an implement or utensil also. The bunch of cotton to be spun, after being suitably prepared, was held in the left hand, and the length of thread formed at one operation determined by the distance the bunch could be drawn away from the spindle, this being also the converse of the Asiatic and European practice, in which the distaff and cotton on it are at rest—the length of the thread depending on the descent of the spindle from them. We know that domestic industry was strictly enforced by the Mexicans, particularly on girls; and of this, these cuts are remarkable illustrations.

Aztec woman spinning—From Mendoza's collection.

In this, a female adult (as the head dress symbolizes) is at work, and portrayed at the moment when a full length of thread has been twisted, or in the act of finishing it. To this spindle, *two* conical weights are attached, unless the under one was fixed and had a cavity on the top to admit the point of the upper one to play in it. The process differs but little from that of the present Pimos and Maricopas tribes, as mentioned on a succeeding page, except in the hollow in which the spindle turns. It is obvious this practice is incompatible with walking; locomotion can only be associated with a spindle suspended by the thread, and whirling free above the ground. In this absence of the distaff, and especially in twirling the spindle like a top *on the floor*, the process can never be viewed as one derived from abroad; but rather as the sole result of native thought and primitive resource. No people, civilized or savage, of the eastern hemisphere, are known to have thus used and embarassed the movements of the spindle. The idea and the practice, appear to be purely American. No ancient American spinner is represented at work, either seated or standing—much less when walking.

For the following illustration and description, the office is indebted to Mr. Squier, late United States Chargé to Nicaragua. It is interesting as showing how little the old native process has been changed.

The common foot wheel is extensively used in spinning cotton in Nicaragua, but the primitive contrivance in use before the conquest, is not yet en-

tirely supplanted. It consists of a spindle of hard wood, sixteen or eighteen inches in length, which passes through and is fixed to a disc of heavy wood that serves as a fly, by adding momentum to the whirling spindle. The lower end of the spindle is rounded or rudely pointed, and when in use, the instrument is placed in a calabash or clean iron kettle.

Modern Spinning Apparatus of Central American Indians.

The modus operandi is as follows:—The spinster is seated in a stool with a bunch of loose cotton already prepared, in her lap. From this she twists a thread with her fingers, and attaches the end to the spindle at the top, giving it an energetic twirl that keeps it going for some time. Meanwhile she disengages and draws out the cotton from her lap with both hands. The length of thread spun (from two to three feet) is then wound around the spindle, which is again set in motion, and another length added in like manner.

In the accompanying sketch *a* is the cotton, *b* the spindle, *c* the thread already twisted, *d* the disc or fly, and *f* the calabash. When the spindle is not in motion the calabash prevents it from falling over, the fly resting against the sides

In the regions of the Gila and Colorada the natives have been little disturbed by white people. The Spaniards never extended their iron sway over them, and like the Americans of Peru, they have been supposed to retain many of the customs and arts of their forefathers. This is to some extent true. The country soon after the conquest, was reported to be occupied by a civilized people, one who followed agriculture and dwelt in stone houses. Colonel Emory, in his Notes of a Military Reconnoisance from Fort Leavenworth in Missouri, to San Diego in California, including part of the Arkansas, Del Norte, and Gila Rivers, [Ex. Doc. No. 41. Washington, 1848,] met with remains of stone and adobe houses, scattered over extensive tracts of ground—sometimes continued over ten, fifteen and even twenty miles. The Pecos tribe, he observes, have preserved alive till within a few years, the sacred fire that glowed on the ancient altars; nor is it certain that it is not yet preserved, for a few Indians took it with them to the Pueblos of Zuni. The name of Montezuma is said to be as familiar to those Indians, to the Apaches, Navajos, and others, as that of our Saviour or Washington is to us.

Turning from some old ruins towards the Pimos village—observes Colonel Emory—we urged our guide to go fast, as we wished to see as much of his people as the day would permit. We were at once impressed with the beauty, order and disposition of the arrangements for irrigating and draining the land. Corn, wheat and cotton are the crops of this peaceful and intelligent race of people. All the crops have been gathered in, and the stubbles show they have been luxuriant. The cotton has been picked and stacked for drying on the tops of sheds. The fields are sub-divided by ridges of earth into rectangles of about 200 × 100 feet for the convenience of irrigating. The fences are stakes wattled with willow and mezguite, and in this particular set an example of economy in agriculture, worthy to be followed by Mexicans, who never use fences at all.

The thatched houses of the Pimos are dome shaped, and of wicker work, about 6 feet high, and from 20 to 50 feet in diameter. In front is usually a large arbor, on the top of which cotton in the pod is piled for drying.

A Pimos spinster was observed at work. "Her apparatus was more simple than the preceding figures, but closely allied to them; in fact the same, with the exception of the calabash or basket, for which a more ready substitute, one always ready, was adopted. A woman was seated on the ground under the shade of one of the cotton sheds. Her left leg was tucked under her seat, and her foot turned sole upwards. Between her big toe and the next, was a spindle, about 18 inches long, with a single fly of four or six inches. Ever and anon, she gave it a twist in a dexterous manner, and at its end was drawn a coarse cotton thread. This was their spinning jenny." The application of the foot-fingers is akin to that of the wives and daughters of Hindoo weavers. The axles of their light cane reels are thus held when winding off the thread. The foot is however in front of its owner, and in a natural position, nor does the stick grasped by the toes revolve.

The Pimos and Maricopas are in their habits, agriculture, religion and manufactures, the same.

Indians Spinning Coarse Thread.

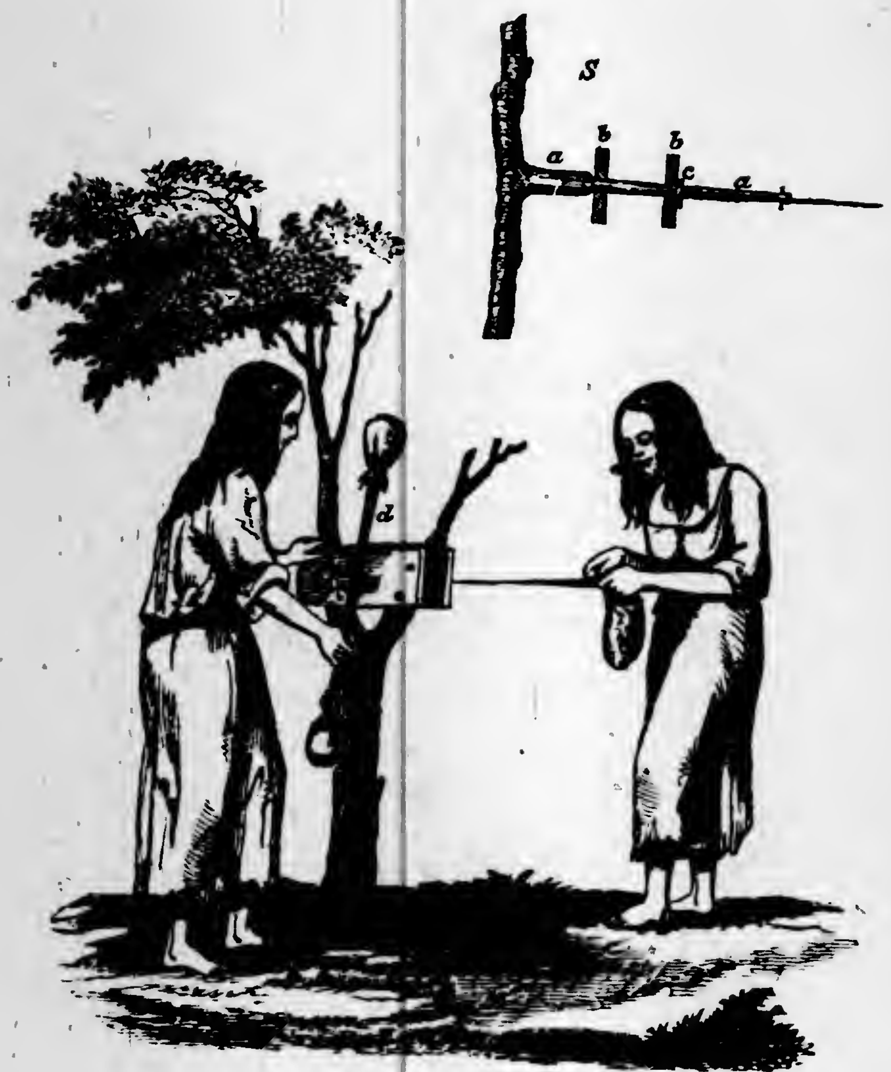
A process of undoubted antiquity, and occasionally followed by modern Indians, is shown on page 380. The spinner holds in the left hand, and horizontally, a short piece of hollow reed or cane, and within it the spindle is twirled by the fingers and thumb of the right hand. Sometimes a cross stick or handle is attached, as represented in the figure. A second person performs the part of a distaff, which, as the thread lengthens, recedes from the spinner, or the spinner from it; a section of this primitive apparatus is separately portrayed.

Mr. Van,—a delegate now in Washington from the Cherokee nation, to obtain a settlement of claims on the United States, for their lands in Georgia, Alabama, &c.,—states that the large old spinning wheel has, to his knowledge, been in the possession of the Cherokees, nearly fifty years. His mother, a Creek, and over a hundred years of age, he believes, used to spin with it in her youth. Mr. Van has seen Indians twist coarse thread with apparatus same as the above; an apparatus which, in all probability, formed one of the early contrivances that slowly led to the whirling spindle in both hemispheres.

For the next two illustrations of spinning by the Navajoes, Camanches, and other tribes of New Mexico, the office is indebted to Judge Peters, of Santa Fé, N. M. (See his letter in sec. VII.)

A Camanche Spinning.

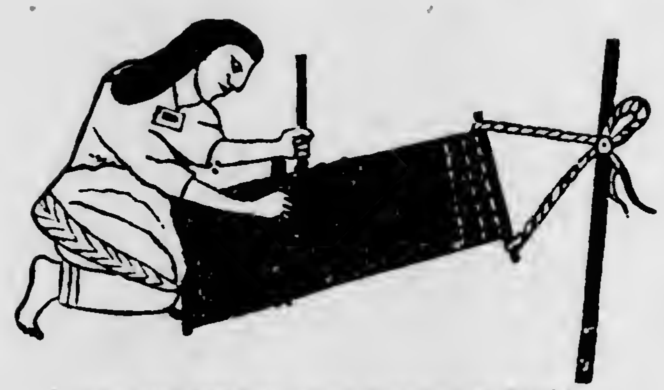
This is another phase, in which the thread-making idea has manifested itself among the red race, and an interesting one it is. The spinner has a small stick, which she holds horizontally in one hand, and on which she winds thread, as on a spindle, as fast as it is spun. The bunch of cotton is itself twirled round, by means of a short and small rod, passed through the lower part, with its ends projecting. A pebble is commonly fastened to the middle of this stick—see *d*—and serves as a fly to keep up the motion, and to assist by its weight, in drawing out the thread. To keep the stone and stick in their place, a piece of yarn is wound loosely round the bunch. The length of thread is seldom over six or eight inches, before being wound up on the stick. In this singular process, the classical mode is completely reversed—the spindle, or that which corresponds to it, is held at rest, and the distaff put in motion, in which respect the operation is unique. The idea of increasing the momentum of the whirling mass, by the introduction of a weight into its centre, is here realized.



Navajoes Spinning.

Two pieces of board, or shingles, are pinned to opposite sides of the fork of a small tree or stump. A spindle (being a smooth rod ten or twelve inches in length,) is passed through, and made to turn in them, as in two journals. See the section S, where *a*, *a*, is the spindle, *b*, *b*, the boards, and *c*, a pin to keep the spindle in its place. To whirl the spindle, a cross stick *d*, is tied to the large end, as represented. Sometimes a stone is folded in a rag, and fastened to each end of the cross stick, and answers the purpose of a rude fly wheel. When a suitable stick, having a branch at right angles, can be procured, the cross stick and spindle are of one piece, as at S. A notch is made at the small end of the spindle, where the thread unites to it, and thus, while one girl turns the spindle, another, with a bunch of loose cotton, supplies it, and as the thread lengthens, gradually draws backwards. As soon as a full length is twisted, it is wound round the spindle, and another length added, and so on 'till the spindle is fully charged. The thread is then wound off into a hank, and the spindle set to working again.

These illustrations of primitive art possess a deeper interest than their relation to a few Indian tribes, and a more extensive one; they are types of thought, more or less common to the species, to barbarians and semi-civilized [illegible] times: such as we ourselves would be led to adopt, were we thrown upon our own resources, without any knowledge or recollections of the subject.



Aztec girl weaving—From Mendoza's collection.

It is difficult to determine from this figure, whether the shuttle was developed in ancient Mexico. It is not represented, and appears not to have been attained any more than the distaff. The loom is like those now used by American Indians. Col. Emory, after speaking of the Pimos spinning, says: "Led on by this primitive display, I asked for their loom by pointing to the thread, and then to the blankets, girded about the woman's loins. A fellow stretched in the dust sunning himself, rose up leisurely and untied a bundle, which I had supposed to be a bow and arrow. This little package with four stakes in the ground was his loom: he stretched his cloth and commenced the process of weaving; he had no shuttle, the warp being passed across the woof, a thread at a time, by a long wooden needle. One of the rods in the preceding figure, was doubtless designed to represent a needle, and used in the same way."

If the figures here introduced, truly indicate the progress made by the Aztecs, in spinning and weaving, their advance was very moderate, and though very creditable work might be made with the weaving apparatus by individual skill and patience, it would seem that few or no attempts had been made to render it more facile and efficient. The same remark is, however, applicable to the loom of Asia and Africa. It is worth observing, that the dress of females pictured above, indicates a decided improvement on that of less civilized tribes. Aztec women and girls wore pantalettes and a species of tunic, with short sleeves and ornamental borders; not unlike Chinese female costume, save in the brevity of the sleeves. Amulets or keepsakes suspended over the neck, and resting on the bosom, seem also to have been common.

Modern Peruvian Indians spin without the distaff, and their loom is precisely like the ancient one just figured; the shuttle, or what answers the purpose of one, being a long thorn needle which is passed through the woof, thread by thread. Every piece woven is of the precise width wanted, whether for garments, coca bags, or aught else—no waste by cutting. Ancient specimens of cloth of excellent execution, have been found in tombs. The length of the needles varies with the width of the piece to be wove.

That very fine fabrics were produced in old Mexico, and by implements, little if any better than those here figured, is doubtless true. The highly colored accounts by the conquerors, are believed to have been no more so, than what the fineness of goods which they saw warranted. Indeed some of the richest of modern shawls and dresses, are turned out of looms of Persia, Egypt and Hindostan, but one degree advanced beyond those of the Aztecs. Personal tact and skill, are everything with semi-civilized artizans. The ancient spindle and loom of the east, singularly enough, are still preserved and used for special purposes in modern Rome, precisely as they were thirty or forty centuries ago. A recent writer on the Pallium, an ecclesiastical robe of lamb's wool, says, there stands about a mile outside the Porta Pia, on the road to Tivoli, an old convent of nuns attached to the still more ancient church of St. Agnes. These nuns are poor, and rarely do any of Rome's high-born damsels enter the cloister of this lonely and neglected sisterhood. They have got a small paddock attendant to the monastery, and therein keep a couple of sacred lambs, not necessarily of the Merino breed; but still proud and happy ministrants of their wool for the texture of this noble decoration. The sisters spin it, not by any new fangled jennies, but on the old patriarchal spindle, and weave it in a loom of which the pattern might date from the days of Penelope.

Concluding remarks on Spinning.—To the substitution of circular for straight motions, and of continuous for alternating ones, may be attributed nearly all the conveniences and elegances of civilized life. It is not too much to assert, that the present advanced state of science and the arts, is due to revolving mechanism. We may speak of the wonders that steam and other motive agents have wrought; but what could they have done without this means of employing them? The application of rotary in place of other movements, is conspicuous in modern machinery, from that which propels steam ships through the water, and locomotives over land, to that which is employed in the manufacture of pins and pointing of needles. It is by this, that the irregular motion of the ancient flail and primeval sieve, has become uniform in thrashing, bolting, and winnowing machines—hence, our circular saws, shears and slitting mills—the abolition of the old mode of spreading out metal into sheets with the hammer, by the more expeditious one of passing it through rollers or flatting mills—and hence, revolving oars or paddle wheels for the propulsion of vessels—the process of inking type with rollers in place of hand-rollers—rotary and power printing presses—and revolving machines for planing iron and other metals, instead of the ancient practice of chipping off superfluous portions with chisels, and the tedious operation of smoothing the surfaces with files. But in few things is the effect of this change of motion more conspicuous than in the modern apparatus for preparing, spinning, and weaving vegetable and other fibres into fabrics for clothing. The simple application of rotary motions to these operations has revolutionized the domestic economy of the world, and has increased the general comforts of our race a hundred fold.

The birth of the arts here, and not least among them that of the humble one of spinning, is related to a problem of American ethnology of great and increasing interest—the early occupancy or first peopling of this half of the earth. Were there through countless ages, no eyes and hearts here to respond to the smiling heavens—none to taste the teeming fruits and inhale the aroma of flowers—was the placid atmosphere never rippled by the prattle and laughter of children—nor the song of a bird, nor the movements of a quadruped arrested by the sight of one of the race ordained to rule over them; until a few straggling members of that race arrived (perhaps casually) from abroad, to claim the splendid heritage? If the red man was not indigenous to the soil—to the manor born—if the first settlers were aliens, how natural the desire to know who they were? whence they came? and how? and when? and over what spots the first pre-emption rights extended? To ask—have they left no memorials in the languages that have come down; in legends, manners, customs, traditions, religious observances and rites—no sign manual in arts—in utensil, arms, and other relics extant. Have they left not 'their

marks' in earthworks—those most lasting of records—in quarries and entrenchments,—in mines, tumuli and mounds?

It is reasonable to suppose—and difficult to suppose otherwise—that if no human form was ever reflected from the surfaces of the lakes and rivers of this vast expanse, no human voice heard in its glades and forests, the imprint of no human foot left on the sands, until colonized from another continent, the arts of that continent must have been considerably advanced ere the means of transport or inducements to emigrate were evolved: and under any circumstances a knowledge of the most essential would be brought over. Of these, such as related to the domestic habits and occupations of women would be prominent, and spinning among the foremost. When once introduced, this could not have become lost—indispensable as it is to the savage and semi-savage condition—while the original process or processes, whencesoever derived, unless superseded by better, would be continued in vogue by them and their posterity.

Now, if the first mothers of the American race emigrated from any of the early advanced sections, or outskirts of Eastern civilization, they brought the distaff and spindle whirling free in air, with them: yet nothing of the kind was found at the conquest. It cannot of course be imagined that they, or their descendants, could have been induced to throw the former away, and embarrass the movements of the latter in a calabash or basket. Efficient previous practice, and acquired habits and expertness, could never have been laid aside for such rude and laborious, and unproductive substitutes.

We know that the distaff and spindle have never been lost when once known in the old world: neither civil commotions, political revolutions, nor duration of time affected them—witness Egypt, Assyria, Greece, Italy, Carthage, Persia, Scythia, Asia-Minor, and all the great and small theatres of past history. The laws, learning, science, arts, and even races which once flourished in those countries, have mostly vanished, but women still spin there as they did from thirty to forty centuries ago—and so it is here also; the principal mechanical devices of the old Mexicans, Nicaraguans, Peruvians, Chilians, &c., are no longer known; the means by which the stone architecture, the basaltic and porphyritic sculptures of Cusco, Uxmal, Copan, Palenque, and numerous other Aztec remains scattered over the continent, were achieved, are a puzzle, yet the household labors of Indian females in those lands remain unchanged; they spin and weave with the same apparatus and embroider as did their kindred in and before the times of Atabalipa and Montezuma.

Admitting that repeated emigrations hither took place at periods remote as, or even behind that of the Illiad and up to the 12th century of our era—that arrivals, designed or fortuitous, thus occurred, and on both or either of the Atlantic and Pacific coasts—we might still more confidently expect to find the distaff and spindle of the other hemisphere domiciled in this. If they came at all they came in hands practised in their use and tenacious of their worth. But no—from the Cape of storms at the South to the limits of human abodes at the North, instead of them the most awkward contrivances prevailed when the white faces came, and such still are found to prevail. The inference would therefore seem to be that the first colonists and their successors for many ages came before spinning was known in their native homes, or at least before the distaff had been added to the spindle, and that the art as practised by the Aztecs and their successors in Central America at the present day, is purely of aboriginal development—is of remote antiquity, and had not before the conquest come in contact with the better processes of the other hemisphere.

Of the three epochs of human condition indicated by the materials of which implements and weapons have been made—stone, bronze and iron—it is uncertain whether the distaff was ever developed under the first—the probabilities are that it was not. In the remote periods in which it is mentioned, some of those who possessed it had progressed far into the second, and some had entered on the third. The great mass of the occupants of this continent at the conquest were found toiling in the cycle of stone; while the Mexicans and Peruvians, the most advanced of Red nations, had discovered and applied the properties of copper and some of its alloys: they had entered on the second, but had not progressed far in it. Had they possessed bronze weapons equal to those of the heroic ages, they might yet have preserved, in a measure, their independence and nationalities.

Clothing is second only to food, and clothing is woven thread. The magnitude and all but paramount importance of the manufacture of thread—including that made of flax, silk, cotton, worsted and other fibrous bodies—afford matter for great surprise. Compare the products of the distaff and spindle of old with that of our mills, and how difficult to realize the change which modern mechanism has wrought! The yearly amount—the lineal extent—of thread now made, who can measure it? It would reach from our planet to neighboring ones, and in time will suffice for a net-work to include the farthest in the system. Turn from the wood cut illustrations here given of ancient, and not yet obsolete, processes to modern manufactories, and it would seem that while Grecian Helens, Syrian Naahmahs, or Mexican Penelopes were preparing an annual supply of clews for their families, the myriads of spindles now twirling by steam and water, produce enough to use the Asteroids as balls on which to wind it, and as bobbins from which to reel it. Even a century ago, a single mill driven by water, is said to have spun or twisted 73,726 yards of silk—i. e.—between 40 and 50 miles at each revolution of the motive axle.

VI.

EARLY MACHINERY IN AMERICA.

To preserve the original forms and features of machines which have been among the foremost in changing the primitive wild aspect of the continent—of opening it to civilization's career,—is not simply a matter of passing interest, but one of present duty, and of future recompense; for when an account of the chief agents employed in working out the great things already achieved, and others yet greater in prospect, comes to be written, the principal materials will be looked for, and should be found, in reports of this bureau. As a part of American history, this ought to be done, because the true annals of a people, their most reliable, unmistakeable, unpervertible, durable and natural archives, are THEIR ARTS—their contributions to practical and productive knowledge; ideas they disclose and apply, to extend and refine the realities of life, compelling nature to yield up new treasures, detecting in matter new properties, employing it in new combinations, moulding it in new forms, putting it to new uses, and drawing from it novel and beneficent results;—all other knowledge of them might be lost, yet in these their genius, industry, morals, enterprise, and position in the scale of nations, would be seen and acknowledged.

We are careful, and justly so, to collect reminiscences of patriotic men of the revolution,—why not the venerable machines of that day, also; since the industrial arts themselves, were then on the eve of a change, more radical than at any previous epoch, and as marked, extensive, and fraught with blessings to the world at large, as those relating to the civil and political rights of man.

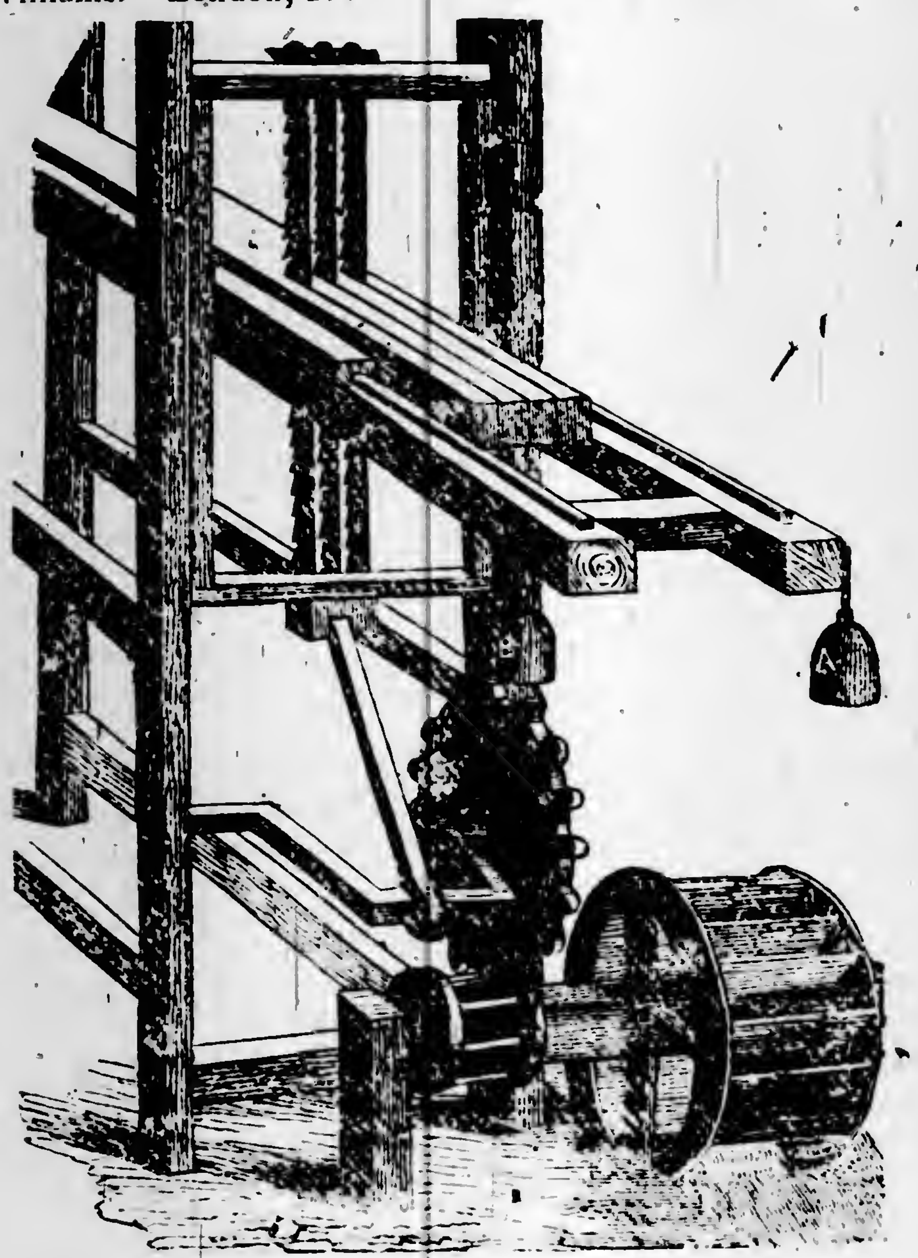
By putting on file our early mechanisms, we shall have in them, so many data or starting points, from which to measure subsequent advances—to mark off the distances we and our successors may leave them behind.

SAW MILL.

Who ever thinks of what this instrument has done for society—of the value of its services from the times of Colonial struggles to those of independence and of empire! How few call to mind the part it now plays, and the impetus it imparts in every upward movement! An invention almost contemporary with the infancy of civilization, it is among the favored few that in one form or another, are ordained to accompany man throughout his destined career.

The axe produces the log hut, but not till the saw mill is introduced, do framed dwellings and villages arise; it is civilization's pioneer machine; the precursor of the carpenter, wheelwright and turner, the painter, joiner, and legions of other professions. Progress is unknown where it is not. Its comparative absence in the Southern continent, is not the least cause of the trifling advancement made there during three centuries and a half. Surrounded by forests of the most valuable and variegated timber, with water-power in mountain streams, equally neglected, the masses of the people live in shanties and mud hovels, not more commodious than those of the aborigines, nor more durable than the annual structures of birds. Wherever man has not fixed and comfortable homes, he is, as regards civilization, stationary; improvement under such circumstances, has never taken place, nor can it.

The modern saw mill, driven by steam, differs from those set up by the pilgrims at the East, and by the first planters at the South. An original portrait is given in an old tract, entitled—"Virginia's Discovery of silk worms, with their benefit, and the implanting of Mulberry trees. Also the dressing and keeping of vines, for the rich trade of making wines there. Together with the making of the saw mill very useful in Virginia, for cutting of timber and clapboards to build withall, and its conversion to other as profitable uses." By Ed. Williams. London, 1650.



An Explication of the saw mill, an Engine wherewith by force of a wheel in the water, to cut timber with great speed.

"This engine is very common in Norway and mountains of Sweden, wherewith they cut great quantity of Dealbords; which engine is very necessary to be in a great Towne or Forrest, to cut Timber, whether into planks or otherwise. This heer is not altogether like those of Norway; for they make the piece of Timber approch the sawes on certaine wheels with teeth; but because of reparations which those tooth'd wheels are often subject unto. I will omit that use; and in stead thereof, put two weights, about 2. or 300. pound weight apiece; whereof one is marked A, the other B. The cords wherewith the sayd weights doe hang, to be fastened at the end of the 2. peeces of moving wood, which slide on two other peeces of fixed wood, by the meanes of certaine small pulleys, which should be within the house, and so the sayd weights should always draw the sayd peeces of moving wood, which advancing alway towards the sawes rising and falling, shall quickly be cut into 4, 5, or 6 peeces, as you shall please to put on saws, and placed at what distance you will have for the thicknesse of the planks or bords ye will cut; and when a peece is cut, then let one with a Lever turne a Rowler, whereto shall be fastened a strong cord which shall bring backe the sayd peece of wood, and lift again the weights; and after put aside the peece already cut, to take againe the sawes against another peece of wood. Which once done, the ingenious Artist may easily convert the same to an instrument of threshing wheat, breaking of hemp or flax, and other as profitable uses."

The idea of a thrashing mill here thrown out, nearly a century before Jethro Tull alarmed his superstitious neighbors by "wickedly constructing a machine for beating out corn without manual labor," will be new to many writers on agriculture.

The ancients used marble to an enormous extent, and according to Ausonius, mills driven by contributaries of the river Moselle, were employed in sawing it into slabs. But history has hitherto afforded no indications of timber having been slit into boards by water power, so early.

At the close of some general remarks on "Incomparable Virginia," "this ornament of the new world which nature has regarded with a more indulgent eye than she hath cast upon many other countreys,—whatever China, Persia, Japan, Cyprus, Candy, Sicily, Greece, the South of Italy, Spaine, and the opposite parts of Africa, to all which she is parallel, may boast of, will be produced in this happy country." "Duly considered for exactnesse of temperature, goodness of soyle, variety of staples, and capability of receiving whatever is produced in any other part of the world, Virginia gives the right hand of preheminence to no province under Heaven; she may, with as great justice as any country the Sunne honours with his eye-beames, entitle herself to an affinity with Eden, to an absolute perfection above all but Paradize," &c., &c.

The writer inserts a list of staples and prices, interesting and worth preserving:—

A valuation of the commodities growing, and to be had in Virginia: valued in the year 1621.

And since those times improved in all more or less, in some $\frac{1}{3}$, in others $\frac{1}{2}$, in many double, and in some treble.

Iron, ten pounds the Tun.

Silke Coddes, two shillings six pence the pound.

Raw Silke, 13s. 4d. the pound, now at 25s. and 28 per pound.

Silke grasse to be used for cordage, 6d. the pound; but we hope it will serve for many better uses, and so yeeld a far greater rate, whereof there can never be too much planted. Of this Q. Elizabeth had a silke Gowne made.

Hemp, from 10s. to 22s. the hundred.

Flax, from 22s. to 30s. the hundred.

Cordage, from 20s. to 24s. the hundred.

Cotton wooll, 8d. the pound.

Hard pitch, 5s. the hundred.

Tarre, 5s. the hundred.

Turpentine, 12s. the hundred.

Rozen, 5s. the hundred.

Madder crop, 40s. the hundred; coarse madder, 25s. the hundred.

Woad, from 12s. to 20 the hundred.

Annice seeds, 40s. the hundred.

Powder, Sugar, Panels, Muscavadoes and whites, 25s. 40. and 3l. the hundred.

Sturgeon and Caveare, as it is in goodnesse.

Salt, 30s. the weight.

Mastick, 3s. the pound.

Salsa Perilla, wild, 5l. the hundred.

Salsa Perilla, domestick, 10l. the hundred.

Red earth allenagra, 3s. the hundred.

Red allum, called Carthagena allum, 10s. the hundred.

Roach allum, called Romish allum, 10s. the hundred.

Berry graine, 2s. 6d. the pound; the powder of graine, 9s. the pound; it groweth on trees like Holly berries.

Masts for shipping, from 10s. to 3l. a peace.

Pot-ashes, from 12s. the hundred, to 14. Now 40. and 35s. the hundred.

Sope-ashes, from 6s. to 8s. the hundred.

Clapboard watered, 30s. the hundred.

Pipe Staves, 4l. the thousand.

Rape-seed oyle, 10l. the tun; the cakes of it feed kine fat in the Winter.

Oyle of Walnuts, 12l. the tun.

Linseed oyle, 10l. the tun.

Saffron, 20s. the pound.

Honey, 2s. the gallon.

Waxe, 4l. the hundred.

Shomacke, 7s. the hundred, whereof great plenty in Virginia, and good quantity will be vented in England.

Fustick yong, 8s. the hundred.

Fustick old, 6s. the hundred, according to the sample.

Sweet Gums, Roots, Woods, Berries for Dies and Drugs, send of all sorts as much as you can, every sort by it selve, there being great quantities of those things in Virginia, which after proof made, may be heere valued to their worth. And particularly, we have great hope of the Pocoon root, that it will prove better than madder.

Sables, from 8s. the payre, to 20s. a payre.

Otter skins, from 3s. to 5s. a piece.

Luzernes, from 2s. to 10. a piece.

Martins, the best, 4s. a piece.

Wild cats, 18d. a piece.

Fox skins, 6d. a piece.

Muske Rats skins, 2s. a dozen.

Bever skins that are full growne, in season, are worth 7s. a piece.

Bever skins, not in season, to allow two skins for one, and of the lesser, three for one.

Old Bever skins in Mantles, gloves or caps, the more worne, the better, so they be full of fur, the pound weight is 6s.

The new Bevers skins are not to be bought by the pound, because they are thicke and heavy leather, and not so good for use as the old."

VII.

COMMUNICATIONS.

Dyeing, Spinning and Weaving, by the Camanches, Apaches, Navajoes, &c.—In a letter from Judge Peters, of Santa Fé, N. M.

Thomas Ewbank, Esq., *Commissioner of Patents,*

Dear Sir:—Fully appreciating the heartiness and zeal, with which you direct your researches into the various branches of inquiry and learning connected with your important bureau, I with great pleasure, but with diffidence, accede to your request, and give you such information with regard to the manufactures of wool and cotton, as I have acquired in my rambles among our western Indians; and more especially, among the Navajoes, Camanches and Apaches of Western Texas and Southern New Mexico. I have not been further west than Paso del Norte, in Texas—nor further north than Sonora, in New Mexico, and the surrounding country.

It is known to every observing traveller in those parts of our country—now no longer remote—that the brilliancy and durability of the various shades of primitive colors, and the few semi-colors that those Indians dye their wool in, are probably not equalled by the learned and scientific chemists of Europe, and our own country—an important fact, that seems not to have excited the curiosity of our otherwise enquiring countrymen. Should I be able, through your instrumentality, to bring to the public notice, such facts as well lead to enquiry and investigation, I should consider myself as having contributed somewhat to our national advancement in one branch of the arts at least, and that one of the most important.

The Camanche, Navajoe, and Apache Indians, present the curious spectacle of marauding bands of well mounted men; seemingly always committing predatory incursions upon their civilized neighbors, the Texans and Mexicans, apparently constantly on the alert for evil, and yet, possessing great skill in the more peaceful and benevolent habits of the herdsman and shepherd.

The depredations of the immense number of sheep, almost daily chronicled in our gazettes, are not made to appease hunger only; but to add to the already immense flocks that overspread, as I have been told by them, the region of country lying west of the Sierra Madre, and east of California—a region as yet totally unexplored and unknown.

In the spring and summer of 1843, in company with an old friend—one of the Creeks who had emigrated west of the Mississippi soon after the treaty with them in 1832—I travelled westward. My guide and companion had acquired a good knowledge of the language and habits of the Camanches, Navajoes and Apaches, and had probably not altogether abstained from joining them occasionally in their irruptions upon the settlements of their timid neighbors of Chihuahua and Sonoro. I found him "as one having authority," and of course, very useful, both in the protection he afforded me, and the information he enabled me to acquire.

Among the first objects of interest to me, next to the matchless feats of horsemanship they perform, and which have so often been written of—was the number and variety of articles wrought by them, both useful and ornamental, and which might well vie with the skill of more civilized artizans. Among these were the beautiful fabrics composed of wool, and a kind of grass cloth, and some few of cotton. The object, however, of greatest interest to me, was the art of imparting to wool, &c. the beautiful colors I had often before admired, and to this I gave most attention. Like other Indians, I found them unwilling to impart knowledge voluntarily, and I had in my previous and long intercourse with the western tribes, early learned not to make inquiries that might excite their special attention to my designs. Our Indians are not disposed to impart to their white brethren, unless their citizens, any thing that might be useful out of their own country, in which particular, they are not unlike the Chinese, so that with the exceptions of their modes of dying and spinning, I will not now attempt to give you any certain account. The information I derived, and minutes made at the time, will now only enable me to give you the modus operandi of extracting their dyes, without being able to give you the names of the ingredients. The specimens I had been enabled to collect have become dried up, and many have been lost by crumbling, and I was not enabled to procure seeds or other means of re-producing the plant, and am not sufficiently a botanist to give you a technical description of them. I can give you the facts only, but these are of sufficient importance to awaken curiosity, and lead to the investigations of secrets by those more intimately connected with the subject treated of, and I think of sufficient importance to have that enquiry efficiently made under governmental auspices.

I may be mistaken, but to my apprehension, if Congress were to appropriate a sum of money sufficient to induce intelligent and competent persons to spend a year or two among the Camanches and Navajoes, and thus enable them to acquire an accurate knowledge of the plants used as dyes—procure seeds and plants—and obtain such practical information in their art of dying as would enable our manufacturers to acquire that art, it would be legitimately advancing the general welfare of our country in a greater degree than it does by applying to many uses the public treasure so often contributed.

The colors most admired by the Camanches and Navajoes are crimson, blue, purple and green; consequently these colors are the most common among them in all their shades; and though in their weavings they blend these with brown, yellow and other colors, with singular judgment and taste, yet it is the brilliancy of those that you most admire.

All their primitive colors are the products of the prairie and mountain flowers, and their semi-colors are composed of these and the inner bark and roots of but few other plants combined in such proportions as the hue intended to be produced. They have no mineral dyes that I am aware of. Many of these flowers are small, indeed most of them; and the plants of low size, and begin to bloom in February, March and April, and continue till summer. During the blooming, the flowers are gathered early in the morning, with the dew upon them, and dried of the dew under a shade. The leaves are carefully picked off, the stems and such as have their petals covered with pollen of another color—*e. g.*—such as are purple or scarlet with petals of yellow or white pollen, are carefully separated from it. Particular flowers only are selected; all flowers of purple color not used to dye purple, and so of every other color, but such only as are known to make an indelible dye.

When the desired quantity of leaves are collected they are carefully and cleanly bruised and into them a small quantity of ley (I shall hereafter describe it) is put, but only enough to make a thick paste—which has the property of loosening the dye from the fabrics, and facilitating its extraction. A small bag shaped like a money purse, and but little larger, made of new dog skin, deer or wolf skin, tanned by the Indians in a manner peculiar to them, is used to compress the juice from the pulp. This bag, a foot or eighteen inches long and three or four inches wide, is half filled with the pulp. Two small handles of wood are stuck through the ends of the bag, about the length of a corkscrew handle, and used to grasp a firm hold, and as levers by which the bag is twisted until the juice is extracted through the pores of the skin, which are very open.

Whether extracted or not for immediate use, the dye is carefully bottled, in glass if it can be procured, or in small bladders, if glass is not to be had. I say small bladders, because if put away in large quantities, the dye sometimes spoils, they say, and produces dingy colors. When put away for future use the light is carefully excluded by overwrapping with skins, or any thing else, and generally buried in the ground under a shelter in which fire is not used, so as to exclude heat. The dyes however, are generally used soon as extracted, as during the winter the women prepare their best wool, and have it ready in the spring and summer for the process of dying.

The pulp after compression is put into a small quantity of the same ley above spoken of, and permitted to remain several hours to extract any remaining dye that might be in it, and undergo the same squeezing process until no dye remains.

The ley is made with care of the ashes after burning, of the green wood of a shrub very similar to the *Auralia Spinosa*, if it be not the same of a stunted growth. So careful are they of procuring this ash unadulterated, that they have dry parcels of it laid by with which to ignite the green wood, that the ashes may not be commingled with those of other woods. The ley is usually made in a large gourd, well cleaned and dried, with the butt end cut off, and a small hole bored through the point of the neck to drip from. The gourd is three quarters filled with the ashes considerably compressed in it, and by a bale or handle suspended from a bar containing several of them. Each is then filled with rain or pure river water: the point is stopped, and the water allowed to remain on the ashes for a day and night, and then permitted to drip into the vessel placed to catch the ley.

This ley is a little colored, and is clarified by the same process of filtration through clean white sand, or sand that has been used for the same purpose before—when clarified, the ley is used as before stated, and especially to set the colors, which seems to be the principal use of it. It has no caustic quality

after filtration, but an astringency peculiar to itself—rather a pungent than burning quality. It is sometimes used to dilute the darker dyes and produce lighter shades.

The wool to be dyed is washed in warm water until perfectly cleansed of the natural oil—using the root of a plant very abundant in Texas and southern New Mexico, as well as most of the southern States, of a very saponaceous quality, and known as the soap plant. In all their best fabrics—blankets, belts, leggings, &c., made of wool, their finest fleeces are used, and it is not unknown to many of our army officers and others, that the Navajoes give great attention to their management of sheep, and often produce fleeces almost or quite equal to the merino in fineness and softness of texture, by their skilful crosses and selections made after long and minute observations and care. A Camanche and Navajoe are as much delighted with the possession of a superior ram and ewe as of a fine horse, to the breeding of which they also give much attention. Von Thaer would not be more so with the possession of his finest buck. All their wool is dyed before spinning, and this is done by submerging it in the dye and letting it remain ten or fifteen days, the dye-pot being left covered: but during this soaking the wool is turned over once every day. Sometimes the lighter shades are imparted to the wool by soaking a shorter time—they say this produces a clearer tint. If not dark enough, the same process is repeated with fresh dye. I have been told by my guide, that the Camanches fumigate the wool after dying, over a smoke of the above described wood, to deepen the color, but I never saw it done.

Their green color is produced from the leaves of several plants, the juice of which is expressed in the same manner as from the flowers, and used in the same manner.

Their brown color is made from the inner bark, roots and nuts of the walnut and of other trees, much in the same manner as our farmer's wives now dye their wool for home-made jeans.

After the dying is finished, the wool is dried in the shade, and when well dried, exposed to the sun for a few hours; the dying is then complete, and the wool ready for spinning, except sometimes, perhaps, not always, they oil the wool slightly, and diffuse the dampness through it by rubbing and rolling it in the hands. I do not know the precise object of this, but they say it works better. This does not impair the color, for washing restores them to their first brightness.

It seems to be the peculiar quality of the *set* that gives the lasting brilliancy of the color. I have seen the Camanche blankets, after being used for months, and abused by being put under the saddle, saturated with sweat, rained upon, slept in upon the naked earth, and when carefully washed, present the colors again, as bright as newly dyed silk.

THE SPINNING

Is what you would call twisting the thread; this is done altogether by the fingers, and somewhat similar to the ancient distaff, though reversing the order of operation. The distaff was used to wrap the raw material upon, and the spool or quill was used not only to wind the thread upon, but as the spindle to twist it. The Camanches reverse this order, and use the raw material for the spindle, and the spool only to wind the thread upon. See figure in Section VII. They use no distaff.

In spinning, a small portion of wool only is used at a time—a mess, say, of a quarter pound weight, and shaped like an egg, say four or five inches long, and two or three in diameter, is wrapped around with a string sufficiently tight to keep it together, but loose enough at the point to permit the wool to be drawn out for spinning the thread—a small stone, of an ounce or so in weight, is tied on the middle of a stick of about six inches in length, and inserted in the lower part of the bunch. This is to add weight to it without increasing the size, and is used as dead weight, to increase and continue the velocity when twirled round by the fingers.

The spinning is begun by first twisting a thread of five or six inches in length, which is wound around a stick of ten or so inches long, and half an inch in diameter, which is held in the left hand, and serves for the spool to wind the thread upon. After the thread is commenced, the spinning proper begins, and is then continued, by constantly keeping the bunch of wool swiftly rotating horizontally, by twirling it with the thumb and middle fingers; at the moment the twirl is given, a slight jerk downwards is made, to draw out the wool, and a simultaneous slight yielding of the left hand, to prevent the thread separating from the mass until the twist is given it, and when sufficiently spun, is wound upon the spool. They usually spin three or four or six inches at a time—and wind up every time. The thread is usually twisted hard, and always doubled before weaving. I have seen thread spun altogether by the fingers, and the spinning and weaving is by no means confined to the women; men are often engaged in it, and exhibit much taste and skill in devising the patterns, as well as blending the colors. After small parcels of the wool are well loosened by picking and straightening with the fingers, it is tied loosely together with a string, to prevent the bunch falling apart; or it is often put in a small bag, of four or six inches diameter, and drawn together at the mouth, leaving portions of the wool protruding from it in a point, to facilitate its being drawn out to form the thread. A weight of an ounce or two—usually a flat stone, is tied in the middle of a stick of six inches in length, and half an inch in diameter, and is enclosed within the wool, or the bag, near the bottom of it, and acts as a dead weight to facilitate the momentum when turning round. The ends of the stick project from the mass of wool like two handles, and are used to twirl it with the fingers.

The thread is usually about the fineness of our good Osnaburg, and spun sufficiently hard to twist readily when doubled, and makes the doubled thread not very hard. After the spinning is finished, and previous to weaving, the thread is measured, by *hanking* it over two pins a certain distance apart. This is only to ascertain the length of the thread required, and is then formed into a ball.

The Navajoes have another and a more artistic manner of spinning, for which it has been thought they were indebted to white instructors, but which they indignantly deny. Two boards, of two or three feet in length, and three to six inches in width, as may be procured, are pinned on opposite sides of the crotch of a tree of convenient height, or of two posts set in the ground near each other, or two trees growing near together. Two holes are bored in the boards, one opposite the other, and about one and a half inch in diameter. A limb of any kind of tree with a branch diverging at right angles, is procured. The larger limb is cut off about eighteen inches each way from the branch, so as to be about three feet long. The branch is trimmed off to fit the holes, and constitutes the spindle. The limb is used as the handle, and

as a fly to continue the momentum. The whole apparatus is unique, simple and efficient, and I would say an original one.

The spinning is commenced like the first process, by twisting with the fingers a short thread, then fastening it to the point of the spindle. The spinner has already prepared, by picking with her fingers, a quantity of wool which she has in her basket or bag, tied around her waist, or in a bundle like the one described in the previous process. A person twirls around the handle or fly, and the spinner keeps moving backwards as the thread is formed. The process is much the same as that by which our rope makers spin hemp by hand. A thread of six or eight feet in length, is spun before being wound up.

The Indian never spins until he or she has a specific work to perform. The size, plan, configuration, and every other requisite, is first determined. The quantity of thread required for any piece of work, is from long habit, pretty accurately known. I think I have said already, that all their weaving is done with a double and twisted thread. They waste no thread. They usually spin a small quantity and weave, and then spin again, and so on, until the work is completed. The process is the same for cotton, wool, grass, &c.

Weaving is the most elaborate of their arts, and they make beautiful work. Their blankets, or I should call them shawls, are often rich, strong and showy. Some have a resemblance to the Persian shawl. They frequently sell in Mexico for three hundred dollars, and I have seen them sell in New Orleans for two hundred dollars. I have one in my possession, taken by Gen. Houston at the battle of San Jacinto, which cost three hundred dollars. They are usually impervious to water, very heavy, and are rather plaited together than woven. The time occupied in making one of these, is from four to six, and sometimes eight months.

Very respectfully,

J. HENRY PETERS.

WASHINGTON, January, 1851.

Memorandum of Navajo Blankets, by R. H. WEIGHTMAN, *of Santa Fé, Senator elect of New Mexico.*

NAVAJO INDIAN BLANKET.

The Navajo Indians live west of the Rio del Norte, about the base of the Rocky Mountains, between parallels of latitude 32° and 35°. They are far advanced in the arts of peace—cultivate the soil, raising wheat, maize, melons, fruits, beans, &c. They own large flocks and herds, and in the cultivation of breeds by judicious crossing, are said to have made some progress.

They are *Manufacturists.* The blankets made by them are of wool, and dyed in bands of black and blue (fast colors.) The red bands are made of the English red Indian cloth, unravelled and worked up anew. These blankets hold water. A bucket of water may be carried in one of them for miles.

They are skilful diplomatists—the proof of which is that since 1846 they have negotiated with the American authorities four or five treaties of peace, of which they have availed themselves only during their cropping season, carrying on hostilities at all other times. These hostilities are carried on by them to gratify the feeling of avarice—to add to their wealth. They have driven off from New Mexico since 1846 stock to the value of at least $500,000 (half a million.)

A specimen of their blankets (one of the coarse sort) is at the house of Mr. R. S. Coxe, Esq., F street, between 6th and 7th.

R. H. WEIGHTMAN.

Washington, Jan. 7, 1851.

TYPE FOUNDING.

Of contributions by inventors and artizans to the great work of mental development, there are three that have been conspicuous in bringing out the modern outburst of thought. But for them the genius of refinement had never made the progress she has; nor without them could she advance a single step further. Successfully employed in hastening a present, they are securing the future elevation of our race. Preventing retrogation in intelligence, they add daily to the general stock, and are posting it up for the use of our successors. United, they have revealed a potency unknown to the ancients:—They are metallic types, paper and the printing press;—a triad of achievements in mechanical science unrivalled in importance and value. While water, wind, steam, electricity and the gases, serve to animate material mechanisms, these are the elements of a higher and mightier prime mover; one destined to agitate and expand the intellect of the world; to extend and perpetuate the peaceful reign of science and arts over the earth.

Type Founding in the United States, by George Bruce, *Esq., of New York.*

Type founding is not a business of great industrial importance, but is valuable as being the fundamental branch of the letterpress printing business, and interesting as the great discovery of the 15th century, by which books, which were before possessed by the rich only, were brought within the reach of people of moderate means, encouraging the learned, and promoting the arts and sciences, through the cheap diffusion of knowledge.

As soon as type founding had been brought to a moderate degree of perfection, by forming copper matrices from steel punches, and a variety of sizes of type had been introduced, it must have been separated from the business of the printing office and made a distinct art; for the same moulds and matrices, with the constant employment of a few workmen, could supply all the type that was required for many printing offices, and thus save the expense of separate moulds and matrices for each one. It would indeed require a demand from many printing offices to furnish the business necessary for a single type foundry and to keep it in activity.

In the year 1683, as Joseph Moxon states in his Mechanical Exercises, the number of different bodies of type cast in England was ten: the smallest having 184 lines in a foot, and the largest 17½. Each of these sizes or bodies required about 250 matrices. In 1789 the number of sizes or bodies in the British type foundries, amounted to upwards of twenty, of which the smallest, called Diamond, had 202 lines in a foot, and the largest, called 12-lines Pica, had six lines. Four foundries at that time furnished all the types used in Great Britian and Ireland, in all their colonies, and in the United States, which had become then independent. It is not probable that these foundries employed more than fifty casters and a hundred other persons, or altogether 150 persons. This must seem a very small number, though probably overrated. A caster's work is stated at from 3,000 to 4,000 letters in a day. Take the highest number, and supposing it to be of the body called Long Primer, having 90 lines in a foot, it will amount to 10 lbs., and in a week to 60 lbs. Ten such casters would produce 600 lbs. in a week; a quantity quite sufficient to print the largest newspaper published at that time, and to last twenty years, if used only for a weekly issue of 1,000 impressions.

The number of Printing offices in the United States, when independence was declared, could hardly have exceeded fifty, of which 37 published newspapers; and the annual importation of types could be supplied by the work of two casters. This constituted the difficulty of introducing type founding; the demand was necessarily too small for the proper maintenance of one, even if all the printers had united in support of a domestic establishment. Hence every attempt to establish before the revolution, and there were several, failed, as might have been foreseen. In 1790, the number of newspapers was 70, and some of them were published daily. The population and prosperity of the country after the revolution became actively progressive; and in 1796, when the exports of the year amounted to $60,000,000, the duties on imports were raised to 15 per cent. ad valorem, the inhabitants numbered 4,500,000, and the printing offices had increased to 150, the favorable moment at length arrived.

Type founding, unconnected with any other branch, was then commenced in Philadelphia, by Archibald Binny and James Ronaldson, natives of the city of Edinburg, where Binny had carried on the same business. Their assortment was not extensive, but it embraced the essential fonts, Brevier, Bourgeois, Long Primer, Small Pica, Pica, and Two-line letters. They were obliging and attentive, and in twenty years made a fortune. They improved their foundry according to the increase of printing and the consequent demands of the trade, extending their assortment from Pearl of 180 lines in a foot to 12-line Pica, having six lines. They made an important improvement in the type mould, by which a caster could cast 6,000 letters in a day with as much ease as he before could cast 4,000.

According to Holmes' American Annals, about 200 newspapers were printed in the United States, in the year 1801, of which 17 were issued daily, 7 three times a week, 30 twice a week, and 146 weekly. There must also have been at the same time as many as 60 offices engaged in miscellaneous printing. The whole business had increased three-fold in eleven years. Another type foundry was put in successful operation in Baltimore, about 1805, by Samuel Lower & Co. It had in it some moulds and matrices which had been used by Christopher Lower, who printed in Germantown near Philadelphia, and cast his own types, in 1740. He printed with German characters; but now the foundry was revived with excellent Roman and Italic letters, and among other extraordinary things it had the size called Diamond, with a smaller face than had ever been cast before. It was the smallest type in the world.

The demand for type was very brisk till the war of 1812 commenced, and the foundries were generally three or four months in arrears in their execution of orders. The names of the newspapers published in the United States, in April, 1810, are given in Thomas's History of Printing, and amount to 359, of which 27 were daily papers; 38 were printed twice, 15 three times, and 279 once in a week. Add those required for general printing, and the whole number of offices could not be less than 500, being an increase of 240 in nine years, and some of them using several thousand pounds of type for book printing.

In 1811, Elihu White established a Type foundry in New York. He had been long engaged, in connection with Mr. Wing, in the manufacture of printing types, at Hartford, Connecticut, upon a plan of their own invention, by which 20 or 30 letters were cast at once, and had brought it to a useful degree of perfection; but now, abandoning the invention, he adopted the old plan of casting, and having a good assortment of faces, and bodies, his removal to New York was a great convenience to its printers, and they gave him a very satisfactory support. But the principal business in type founding still continued for some years to be done in Philadelphia.

In 1813, another type foundry was begun in the city of New York, by D. & G. Bruce, principally to cast types for their own use. They had carried on book printing for seven years, and had now become acquainted with the stereotype art—Mr. David Bruce, having visited England, in 1812, and acquired it by purchase and actual labor. For ordinary printing, it was customary to level off the body of the type at the face end, or shoulder, as it is usually called, which unfitted it for making a strong stereotype plate in the most approved way: hence, the necessity for casting type expressly for stereotype. Their first font was Bourgeois, with which, they cast two sets of plates of the New Testament, the common school Testament, and sold one of these to Matthew Carey, of Philadelphia, retaining the other for their own business. But these were not completed till 1814. In 1815, they cast the plates of the 12mo. School Bible, on Nonpareil type, prepared like the Bourgeois, at their own foundry expressly for stereotyping. They thus gave the first stereotype School Testament and School Bible, to America; but not the first stereotype book. John Watts, of England, also commenced stereotyping in New York, in 1813, and completed the Westminister Catechism that year, a volume of 120 pages, 12mo. David Bruce, invented the planing machine for equalizing the thickness of stereotype plates, which is now used in every stereotype foundry in the United States. The process of stereotyping is, however, entirely different from that of ordinary type founding, and it is, therefore, generally carried on as a separate business, or connected with the composing department of a printing office. Twenty compositors, and two proof-readers, will furnish full employment for one moulder, one caster, and three finishers, who will, among them, complete on an average, 50 pages of octavo per day. There are now sixteen of these stereotype foundries in the city of New York, employing about 400 persons. Probably 600 more may be employed in the stereotype foundries of other cities and towns of the United States. Altogether, 1000 persons are employed in stereotyping, and cast daily, what is equal to 2000 octavo pages, in doing which, in addition to imported antimony and tin, they use up 3,300lbs. of good American lead.

In 1818, or soon after, a type and stereotype foundry was established in Boston, and another in Cincinnati, principally through the enterprise of the late Elihu White, who having the means of multiplying matrices with facility, took this method for the extension of his business. Others followed his example, and type foundries were established in Albany, Buffalo, Pittsburg,

Louisville and St. Louis, with several additional in New York, Boston, Philadelphia and Baltimore. The business in fact was overdone, and failures and suppressions took place, as competition reduced the prices of types.

The mode of type founding has latterly undergone some important changes, which must no doubt be considered improvements. First among them, is the introduction of machine casting, in which a pump forces the fluid metal into the mould and matrix, and gives a sharper outline to the letter than was formerly given by the most violent throw of the caster. The old practice of casting only a single type at a time remains. The first idea of this machine originated with Wm. M. Johnson, who obtained a patent for it in 1828. Elihu White, put it into use in his type foundry, and persevered in using and trying to improve it as long as he lived; but he did not succeed in removing the greatest fault, which was a hollowness in the body of the type cast by it, that inclined them to sink under the pressure of the printing press. Other machines for casting printing types, have been brought forward within the last ten years, and various modifications and improvements have been made in them, which have at last commended them to general use. By their use three times the quantity of type that was cast by Binney & Ronaldson's improved mould, is now cast in a given time, and nearly five times the quantity that was cast by the common hand mould, fifty years ago. This improvement has passed into Europe, and been adopted by some of the German type founders; but in Britain, it has found no favor, and types there, are still cast in the same kind of mould as was used two hundred years ago, or in the earliest known type founding, at the rate of 4000 letters in a day.

The next improvement to be mentioned, is the application of electrotyping to the formation of matrices, by which a great saving of labor is effected. In old fashioned type founding, the original of each character, is formed on a separate steel punch, which being hardened and tempered, is driven into copper a 16th of an inch or more to form the face of the type, called a matrix. This matrix being adjusted to the mould, which is to form the body of the type, is then ready for casting. If the punch with its matrix be of a very plain or simple character, it will have cost two dollars, and have occupied a day of one workman, though generally, the punch and matrix are made by different workmen. If the punch be of a fancy character, with scrolls and figures in it, requiring tedious engraving with much nicety and mathematical accuracy, it may occupy many days to cut it, and may be worth fifty dollars; but more commonly a fancy or ornamental character costs from five to ten dollars. Our type founders generally adhere to the old way of getting matrices for the fonts, commonly used in printing newspapers and books; but stereotyping is resorted to for many of the ornamental fonts and borders. The French have produced a great variety of fancy types within the last fifteen years, and offer to sell matrices of them for fair prices, but even such matrices without the punches come high. They also sell the type, which being brought to this country, are used by our type foundries, to produce electrotyped matrices, from which similar type can be cast, and thus a very great saving of time and money is effected.

It may seem unfair to the moralist, that the works of a laborious artist should be taken in this way without compensation, and used in competition with him in every market to which our manufactures are admitted. In that view it is a hard case, no doubt. But the type founders are not wilful wrong-doers in this matter. They have been accustomed to think, that when they buy an article, they may use it as they please, there being no law restraining them. They have been educated in this belief, having constantly before them the practice of booksellers, who buy a foreign book, and re-print it in a cheaper style than the original, and then thrust it into every accessible market to the exclusion of the author's sales, and the ruin of his pecuniary prospects. The bookseller, however, while cutting off the author's profits, contributes handsomely to the spread of his fame. This the type founder cannot do; and here, therefore, the parallel ends.

Not foreign articles alone are thus copied by the American type founders. Any article that is saleable, and got up in good taste by one type founder, is instantly electrotyped and cast by others; for there is no law to protect the peculiar property of the original producer, although the art for securing designs, &c. may seem to have a leaning that way. Types cannot have the date of the patent on each one as the law requires for a patented article; and to put the date on the wrapper would only serve to give the notice to the first purchaser. It might seem to be an evasion of the law, and not a fulfilment of its provisions, exposing the patentee to a fine of one hundred dollars upon every complaint, which of course would be made whenever he attempted to assert his patent right.

Perhaps, however, the law was not intended for the protection of printing types, and all this reasoning is useless. But, no doubt, there is a desire to protect every branch of industry, and type founders might be completely protected, by simply permitting them to file an impression of a new article with small expense, as the title page of a book is now filed to secure a copy-right. This is the practice in some parts of Europe, particularly in France and England, where it is called registering.

The demand for printing types in the United States, is continually increasing at a prodigious rate, both for newspaper and miscellaneous printing, and probably the number of printing offices amounts to 4,000. A writer in the New York Tribune, about six months ago, in a sketch of the newspaper press, estimated the whole number published at 2750, of which, nearly 250 were published daily, as follows: New York has 15; Boston, 11; Philadelphia, 8; Cincinnati and Pittsburg, 9; Albany, Nashville and Rochester, each 6; Baltimore, St. Louis, Charleston, Memphis, Buffalo, New Haven, Detroit and Chicago, each 5; Washington, Louisville, Richmond, Norfolk, Troy, Brooklyn, Hartford, Providence, New Bedford and Portland, each 4; Mobile, Savannah, Wheeling, Syracuse, Cleveland and Columbus, each 3; Portsmouth, N. H., Harrisburg, Newark, Oswego, New London, Lowell, Montgomery, Vicksburg, Zanesville, Milwaukie and Wooster, each 2; with some fifty other places which have one each. California is omitted in this enumeration, inadvertently of course, but it had on the 1st of September, at least 13 newspapers, of which 8 were published daily.

The writer in the Tribune estimates, on apparently good information, that the 15 dailies in New York, publish 125,000 papers per diem; the 11 in Boston, 70,000; the 8 in Philadelphia, 75,000; the 5 in Baltimore, 30,000; the 10 in New Orleans, 50,000; and the 201 other dailies, 1200 each. The aggregate makes 590,000 papers for the daily circulation, or 184,080,000 for the annual circulation of the daily papers of the United States. He then assumes that of the 2500 tri-weeklies, semi-weeklies and weeklies, there are 50 which circulate 30,000 each, making 1,500,000 in the aggregate; 50 which circulate 10,000 each, or 500,000 in the aggregate; and the remainder circulate 1000 each, on an average, or 2,400,000 in the aggregate. The whole annual circulation is thus estimated at 412,880,000.

It may be assumed as certain, that with the enlarged size of the present newspapers, each one, on an average, requires 800lbs. of type for its composition, or 2,200,000lbs. for the whole 2750 papers; and if it be also assumed that 1,500,000 impressions are all that can be taken from type on an average of large and small editions, then it will follow that in printing 412,880,000 papers in the year 1850, the type will sustain a wear equal to the destruction of one-tenth of the whole, or 220,000lbs., which may in great part be returned to the foundry, to be re-melted.

There are now four type foundries in Boston, seven in the city of New York, one in Albany, one in Buffalo, three in Philadelphia, one in Baltimore, two in Cincinnati, and one in St. Louis; in all twenty. The seven in New York cast about 2000lbs. of type per day, and employ about 350 persons. The 13 foundries out of the city of New York, are estimated to cast 2400lbs. of type per day, and to employ 450 persons. The aggregate production daily is 4400lbs., by the efforts of 800 persons. The metal used is a mixture of lead, antimony, and tin, in different proportions, suited to the kind of type to be cast, but containing on an average, 75 per cent. of lead. The consumption of lead, therefore, amounts daily to 3300lbs., and yearly to 1,029,600lbs., subject to a deduction for old type returned to the foundries to be re-cast, probably amounting to 20 per cent., or about 205,920lbs., leaving 823,680lbs. for the quantity of new lead consumed per annum.

These foundries not only supply the printers of the United States, but most of the printers in Canada, some in the British West India islands, the Spanish and Danish islands, Mexico and South America. The quality of the American type will bear a favorable comparison with the European, and in cheapness it is unrivalled. The following are the prices at which they have been sold for the last fifty years, given at eight different dates, and naming only the principal and most useful sizes.

Names of Bodies.	1801.	1806.	1811.	1819.	1827.	1831.	1841.	1850.
Pica, . . .	$0.35	$0.44	$0.55	$0.44	$0.42	$0.36	$0.38	$0.30
Small Pica,	.40	.48	.58	.48	.46	.38	.40	.32

Pearl,					1.75	1.40	1.40	1.08
Diamond,								1.60

I have thus endeavored to furnish an account of the rise, progress, and present state of type founding in the United States, agreeably to my promise; and although it may appear imperfect, I have not relied on my own recollections, which go back to Binny and Ronaldson's commencement; but have drawn some of the facts carefully, from various and well known sources.

PAPER MAKING IN THE UNITED STATES.

Ivy Mills, Pa., *Dec. 17th*, 1850.

Sir:—Your favor of Nov. 30th, came duly to hand. For want of documents and dates, my report of the rise and progress of the paper manufacture in the United States, must be very meagre, as I have to rely on my limited experience and observation, and on conversations with my father, long ago, to supply this deficiency.

About the year 1725, my grandfather, who was brought up to the paper business in England, came over and settled where I now reside. I have documents to prove that in 1732 he had erected a mill, and was manufacturing paper. The kind of paper then made, was what is called fullers' press-boards, such as are now used by clothiers to press cloth. I believe there was another mill a little north of Philadelphia, and one near Boston, similarly occupied. I believe also, there existed an act of Parliament at that time, prohibiting the manufacture of any other kind of paper in the colonies. As there were few books then published in the colonies, the progress of the paper manufacture was very slow, and so continued until about the dawn of the Revolution. My grandfather manufactured the paper for Dr. Franklin, who was publishing a newspaper in Philadelphia, and who was a frequent visitor at the mill. About the time my grandfather made the paper for the Continental money, he commenced making writing paper, supposed to be the first made in America. From the Revolution, until the year 1820, very little improvement occurred, that was important; very little machinery introduced for facilitating the operation. The mills increased in number in proportion to the increased quantity of newspaper and book publishing. About the year 1810, we began to experience a deficiency of raw material, (rags,) and were obliged to resort to Europe for supplies. These were obtained from all parts of Germany and Italy, and have continued increasing up to the present time. Whether the deficiency at home resulted from a real scarcity of rags, or their low price made it no longer an object to families to preserve them, I cannot say—but such was the fact.

At present we have an additional inducement to import our material. The article of cotton has here almost entirely superseded the use of linen for wearing apparel, and when much worn and reduced to rags, becomes a very tender substance; in fact, scarcely able to support its weight when made into paper. The foreign rags, we suppose average about 80 per cent. of linen, which, when mixed with the domestic cotton, imparts to the paper a strength and firmness, which it could not have without it. The best qualities of writing and printing papers, contain from 30 to 50 per cent. of linen, for which we are entirely depending on foreign countries. But as the use of cotton for clothing is yearly increasing all over the civilized world, we find the proportion of linen in imported rags, decreasing from 5 to 10 per cent. from year to year. We have an excellent substitute for this in our own country, did not its high price prevent its use—raw cotton—which makes a beautiful paper when mixed with the worn-out rags of the same material. In 1837–8, when the price was as low as 6 cents per pound, large quantities were manufactured into paper.

From 1820 to 1830, some efforts were made to introduce machinery from Europe. England and France were before us in its introduction. Several machines were sent out from England—some very imperfect, and the cost too

great for our manufacturers. The patronage then offered was no inducement to our own machinists to construct so expensive a machine; until 1830, about which time, Phelps & Spafford of Windham, Connecticut, made one which answered very well. Soon after, the country was supplied at a reasonable cost, and equal in quality to the best English. Not long afterwards, Howe & Goddard of Worcester, Massachusetts, commenced making them. I have reference only to the Foudrinier—the shaking endless wire-web machines. I believe these two establishments now make all these machines in the United States. The *cylinder* machine, more simple and less costly than the other, is in more general use; but the paper made on it, is not equal in quality. Notwithstanding, it does very well for news, and the various purposes which a coarser article will answer for. These are made in various places throughout the United States.

The interval from 1830 to 1840, was important for the vast improvements made in the manufacture by the application of this kind of machinery for that purpose. Also, by the introduction of the use of chlorine in the form of gas, of chloride of lime, and the alkalies, lime and soda-ash in bleaching, cleansing, and discharging the colors from calicoes, worn out sail, refuse tarred rope, hemp, bagging and cotton waste, the refuse of the cotton mills. These articles which heretofore had been considered only applicable for the manufacture of coarse wrapping papers, have, through the application of this bleaching and cleansing process, entered largely into the composition of news and coarse printing papers, and consequently have risen in value 300 per cent. A few mills possess machinery, and adopt a process by which they are prepared for the finest printing and letter paper. I have seen a beautiful letter paper made of cast off cable rope. Hemp bagging is an excellent material for giving strength, and is in great demand, especially for making the best newspaper. The cost of making paper by machinery, compared with that of making it by the old method, (by hand,) not taking into account the interest on cost, and repair of machinery, is about as one to eight. The present low price resulting from improved machinery; and the low price of printing by steam power has placed newspapers and books in the hands of all; and a great increase of production has followed within the last few years. I have no data by which I could furnish a report of the comparative increase within the last ten or fifteen years. The quantity now made, might be nearly ascertained, if the Deputy Marshals could report the number of *engines* in operation; I suppose 300lbs. of paper would be the average daily produce of each engine—taking into consideration the loss of time and power from a deficiency of water in the summer season. There has been a greater proportional increase of mills in the middle and western states within the last ten years, than in the east. Ten years ago, I suppose 80 per cent. of the supplies for Philadelphia, came from east of the North river; at present, I think there does not come 20 per cent. Formerly, a much greater quantity was sent west of the mountains, and large quantities of rags brought in return. In consequence of the greater number of mills in the west, particularly in Ohio, New Orleans, I am informed, is in a great measure getting supplies there. Formerly, they all went from the Atlantic states.

From the time of the Revolution, the quantity of paper imported has been gradually decreasing; and before the revision of the tariff in 1846, had dwindled to perhaps not more than 2 per cent. of the amount consumed, with the exception of wall papers, of which large quantities were imported and still continue to be from France. Since 1846, there has been an increase of cheap French letter paper, but the amount is small compared with the whole amount of letter paper consumed—probably not more than 3 per cent. There is also a small quantity of ledger and letter paper brought from England; but as the American is quite equal in quality, the importation is gradually diminishing. Within the last two years, great ingenuity has been exercised both in England and in the United States, in trying to make a paper by machinery, to resemble the old fashioned hand made *laid* paper, (yet preferred by many.) To the eye, it is a pretty good imitation, but lacks the toughness, firmness, and surface of the hand made. By an experienced judge, the deception is easily discovered. Notwithstanding, large quantities have been used under the supposition that they were hand made. The reduced price of machine paper, has forced almost all manufacturers to abandon the old method. I believe there are only two mills in operation in the United States, in which it is made by hand, one in Massachusetts, and one of mine. There is a limited quantity of particular kinds, that can be better made by hand, than on a machine. In mine, is made bank note, laid letter, deed parchments, and such as are used for documents, that are much handled, and require great strength and durability. Within the last few years some improvement has been made in the finish of writing and printing papers, by the introduction of iron and paper calenders, for the purpose of giving a smooth surface. The finish of American papers, I think, is now equal to any in the world.

Very respectfully, your ob't sev't,

JAMES M. WILLCOX.

Thos. Ewbank, Esq., *Washington, D. C.*

CHINESE MODE OF REPAIRING CRACKED OR BROKEN VESSELS OF CAST IRON.

Perhaps no device can be named more characteristic of oriental ingenuity—of the most mechanical people of the east—than this. It is one that could only have occurred where ages of experience in the treatment of the metals had elapsed. The idea of an ordinary artisan fusing *iron* with a handful of charcoal, and handling the glowing liquid as if it were but melted wax or tallow, would be considered by our founders as belonging rather to romance than to reality. Every year thousands of vessels, large and small, are with us thrown aside—costly sugar pans of planters, and the more capacious vessels of soap boilers and brewers, as well as culinary cauldrons—that might be restored to soundness by this simple method, and at the most trifling charge.

In 1794–5, Van Braam—the second in command of the Dutch embassy to Pekin, and who afterwards settled in the United States, bringing with him the chain pump and other inventions of the Chinese—was exceedingly struck with the operation—its simplicity and efficiency. He appears to have been the first European who observed it. His account is as follows:

"During our short stay this morning in the village of *Fan-Koun*, I had an opportunity of seeing a tinker execute what I believe is unknown in Europe. He mended and soldered frying-pans of cast iron that were cracked and full of holes, and restored them to their primitive state, so that they became as serviceable as ever. He even took so little pains to effect this, and succeeded so speedily, as to excite my astonishment. It must indeed appear impossible to any one who has not been witness to the process.

All the apparatus of the workman consists in a little box sixteen inches long, six inches wide, and eighteen inches in depth, divided into two parts. The upper contains three drawers, with the necessary ingredients; in the lower is a bellows, which, when a fire is wanted, is adapted to a furnace eight inches long and four inches wide. The crucibles for melting the small pieces of iron intended to serve as solder, are a little larger than the bowl of a common tobacco pipe, and of the same earth of which they are made in Europe; thus the whole business of soldering is executed.

The workman receives the melted matter out of the crucible upon a piece of wet paper, approaches it to one of the holes or cracks in the frying-pan, and applies it there, while his assistant smooths it over by scraping the surface, and afterwards rubs it with a bit of wet linen. The number of crucibles which have been deemed necessary, are thus successively emptied in order to stop up all the holes with the melted iron, which consolidates and incorporates itself with the broken utensil, and which becomes as good as new.

The furnace which I saw was calculated to contain eight crucibles at a time, and while the fusion was going on was covered with a stone by way of increasing the intensity of the heat."

Mr. Balestier, United States Consul at Singapore and United States Envoy to South Eastern Asia, during his recent visit to the United States, politely offered to procure any information for the Patent Office—agricultural and mechanical—that might be desired from the East.

Among other subjects of inquiry suggested to him, iron founding was named: an art of remote antiquity and brought to considerable perfection by the Chinese. The excellence and lightness of their hollow ware are proverbial; while the readiness with which they fuse and handle small quantities of the metal in the reparation of damaged wares excites surprise. The last operation Mr. B. had often witnessed, but without giving special attention to it. He promised, therefore, to minute down the particulars sufficiently in detail to enable any mechanic successfully to perform it. His letter is subjoined, and by it every thing is made clear. Van Braam leads one to suppose the sides of repaired rents are fused together or united as in soldering other metals, while from Mr. B's account, such is not the fact. The fluid metal in filling the crack is spread over it on both sides of the vessel, and thus forms a species of rivet.

Macao, *Feb.* 6, 1850.

To Thos. Ewbank, Esq., *Commissioner of Patents*,

Patent Office, Washington, D. C.

Dear Sir,—According to your desire, I have carefully observed the Chinese manner of re-uniting and joining together cracked or severed cast iron vessels, so as to make them as useful as ever after an accident, which is as follows: referring you to the utensils used, which I have numbered as at foot, and have had put into a box directed to you, and shipped per United States ship *St. Mary*, Commodore *Geisinger*, bound home, and which the Commodore will hold subject to your order.

I procured the accompanying cast iron pan, measuring 12 inches in diameter, by 4 four inches deep. A crack of 3 inches was made in it in the first place, and in the second a piece was entirely broken off: giving rise to two distinct operations.

The operator commenced by breaking the edges of the fractures slightly with a hammer, so as to enlarge the fissures, after which the fractured parts were placed and held in their natural positions by means of wooden braces. The pan being ready, crucibles made of clay, were laid in charcoal, and ignited in a small portable sheet iron furnace, with bellows working horizontally. As soon as the pieces of cast iron with which the crucibles were charged were fused, it was poured on a layer of partly charred husk of rough rice, or paddy, which was previously spread on a thickly doubled cloth, the object of which is to prevent the sudden cooling and hardening of the liquid metal. Whilst in this liquid state it was quickly conveyed with the right hand to the fractured part under the vessel, and forced up with a jerk into the enlarged fissure, whilst with the left hand a paper rubber was passed over the obtruding liquid, inside of the vessel, making a strong, substantial and neat operation.

You will thus remark that the art of the Chinese for re-uniting cracked or severed cast iron vessels, of all sizes, consists in cementing them with cast iron, whilst in the liquid state.

I have the honor to be, dear sir,

Your most obed't serv't,

J. BALESTIER.

The weight of this pot is 3¼ pounds. Except at the centre, where a part two inches over is left thick and flat for a base or foot to rest on, the thickness does not exceed, and in fact scarcely reaches $\frac{1}{16}$ of an inch. The handles are cast on, but appear to have been first formed and inserted into the mould. This does not seem to have been of sand, as the inner and outer surfaces are smoother, and of a different appearance from iron cast in that material. Of the metal used for repairing this pot, Mr. Balestier has forwarded a lump that was not melted. It is part of an old kettle, and differs but little, if any, from our pot metal.

The crucible, not much larger than a thimble, is made apparently of the same material as our common sand crucibles; except the shape, it could not be distinguished from one of them.

The amount of one fusion seems not to cover more than half an inch of the crack, and hence in the piece inserted, no less than nine distinct applications of the melted metal are seen—resembling in the inside so many ragged wafers touching each other, while on the outside, where the metallic plaster was applied, there are the same number of rude protuberances.

Dr. Gale, one of the examiners of the Patent Office, has made, at my request, a chemical examination of a portion of the basin, and finds it a very pure white cast iron, containing scarcely any foreign matter, except a little carbon and silex, ingredients always present in cast iron.

The subjoined figure represents the itinerant artist with his portable forge, at work in the street. The front half of the wooden chest is his *Fung Seang* or bellows, a description of which may be found in Ewbank's Hydraulics. Its principle is that of the double acting force pump, and it is constructed wholly of wood, except the valves and packing of the piston, which are paper, and singularly durable. The long coarse file, with a prolonged smooth extremity to slide through a ring, fixed on the chest, is a common accessory to a tinker's budget. By the arrangement, he possesses a tolerably good substitute for a bench and vise, and can increase or diminish the pressure of the file on the object operated on, at pleasure.

CHINESE TILE-MAKING—BRICKS, &c.

The following paper is by George R. West, Esq., of this city. Mr. West, in 1843, accompanied, as artist, the United States Mission to China, and returned recently, bringing with him a portfolio of graphic sketches, illustrative of the arts, manufactures, &c., of the Chinese.

No people, existing or extinct, surpass these in mechanical ingenuity and resource. To them the rest of the world is indebted for printing, gunpowder, the mariner's compass, porcelain, and a thousand minor contributions to modern civilization. In all their industrial operations there is something more or less new to us. In the process of tile-making, here described, some good ideas are manifested, and they are not confined to working of clay, by any means. In neatness, expedition, and saving of labor, it may safely be asserted that nothing can be found comparable to it in the manual operations performed in European or American tileries. The rearing of a prism (see *a*, in the cut,) of the kneaded clay, of such an outline as to furnish accurately shaped slabs or slices, ready to fold round the tapered and contractile core, is worthy of notice. So is the union of four perfectly modelled tiles in one short tube, which the workman finishes as fast as another cuts off slices from the prism of clay, and quicker than a single tile is made, in the ordinary manner, by other people.

Chinese Tile-Making.

SIR:—Agreeably to your request, I hand you with pleasure a sketch and description of the Chinese process of moulding earthen tiles, at Tinghae, Chusan.

The tiles used for roofing in China, are only partially burnt. They resemble in appearance and texture, terra cotta, and differ in form from those used in Spanish countries, in having no recurvature at either side, a cross section being a portion of a ring or circle; see the cut where a double row of short tubes is figured, drying in the sun. The manufacture is very extensive and important, from the fact of tile roofing, with one exception, (thatching) being the only style adopted in the southern part of, and I believe, throughout the whole empire. A novel and ingenious method is practised, of moulding four in the form of a short conical tube, in the same time that would be required to mould one separately—an illustration of the original and interesting methods these people have, of accomplishing their desired ends with ease and precision, by means rude and simple, but at the same time efficacious. [Not more so, however, than the process of moulding sheet tin for lining tea canisters, which is familiar to every person who has visited Canton, or the process of mending fractured porcelain and the most delicate glass-ware, with numerous copper clamps. Such examples are very common, and it is useless to cite them here, as the same may be said, with truth, of all their manufactures, and every thing they do, from the beautiful embroidered crape shawl, to the pork fat candle.]

With the aid of the subjoined sketch, the manner of conducting the process of making four tiles at one operation, will be readily understood. Three persons are here represented, but I have often seen one alone go through the operation with surprising rapidity. One of the figures in the foreground is represented in the act of cutting a slice of clay from a high mass before him, with a gauge knife; another bending and uniting a slice over the mould or core, which he holds in his right hand, upon a small revolving table before him; another removing a tube just formed, to the drying ground. Two figures are represented in the background, kneading clay, &c. The two detached views at the foot of the sketch, are representations upon a larger scale, of the

core and gauge knife. The core or mould consists of a circular conical hoop of the desired height and diameter, and is so constructed as to spring inwards, to allow of its being easily removed after the tiles have been moulded over it. On its outer periphery are secured vertically, and at equal distances, four thin bamboo slats, which divide the mould into four equal parts; these are for the purpose of making incisions half way through the clay, so that the four tiles will be united in the form of a circular conical hoop or tube, preserving them in their true shape, and from all injury whilst undergoing the succeeding processes of drying and passing through the kiln. When the tiles are wanted for use, it is only necessary to give each hoop a slight tap with a hammer or trowel, to divide it into four perfect tiles. The hoops are usually thus treated, when taken from the kiln, as the tiles then occupy less space in transportation.

The gauge knife consists of a piece of wood a little longer than the width of the tiles, having a handle projecting at right angles from its centre, and shoulders or projections formed on its face, from which is stretched a fine metal wire, serving as a knife to divide the clay. These, with the small table revolving upon a vertical shaft stuck in the ground, on which the operator places the core whilst moulding, and a small bit of wood to smooth the clay, and a pan of water close at hand, to moisten it, are the only tools used.

Before commencing, a high mass of clay, large enough to make several hundred tiles, is first raised and formed by a pattern; the sides curved, the ends tapered, &c., so as to give the desired length and breadth to the tiles. Slices removed from this mass by means of the gauge knife, in the same plane with its top and bottom, it is obvious, will correspond with each other in shape and size. The process is as follows:—The operator holds the gauge knife by its handle, in his right hand, and presses its face close to the top of the mass of clay, at the same time drawing it towards him, from end to end; thus a slice is removed of the desired thickness. This slice being the exact shape and size for forming a conical hoop, the operator has only to bend it over the core, which he holds by its handle in his right hand, turning it with the revolving table at pleasure, while with his left he joins and smooths it with a bit of wood dipped from time to time in the pan of water. The core is now contracted, by drawing one edge inwards past the other, and lifted from the hoop of tiles. This completes the operation, and a boy removes the hoop to the drying ground. Thus four tiles are completed in one operation, almost as quick as thought, and with perfect accuracy of form.

At the same yard where I witnessed the process above described, were to be seen a great variety of ornamental brick, for the eaves of houses, to cover and give a finish to the ends of the tiles; also large flags of various sizes and forms, and of different colors, some for paving, and others for facing the fronts of houses. Some of the moulds were of metal, and very neatly made. The variety of ornamental brick, adapted to their curious style of architecture, is very great, and I can mention here, only one curious form of brick, which I believe is truly original with the Chinese. It is well adapted to a variety of useful purposes, and might perhaps be used in this country to advantage.

This brick is denominated the "dragon ribbed" brick, is about six inches long, two thick, and three wide, with a half circle groove formed longitudinally on its edge. They are used principally for partition walls, upper stories of houses and pagodas, light pavilions, &c., and in all cases, where lightness combined with strength, is desired. The manner of constructing a wall with this brick, is as follows:—Uprights with grooves longitudinally cut in their edges, are placed, if for the first story, in the ground, at the distance of from six to ten feet apart, and if for a small building, only one at each angle of the wall. A number of slender bamboos are now cut to the proper length, so as to extend from post to post, and the ends fall in the grooves in the posts. The first layer of brick is laid with the grooved sides up, which will form a half circle groove the whole length of the wall; into this groove a bamboo is placed, the ends of which project into the grooves of the posts. The space between the bamboo and the brick in the groove, is now filled with cement, and another layer of brick with the grooved sides down, is laid over the bamboo, upon the top of the first layer, and cemented. The bamboo is now completely enclosed within the brick, and its ends projecting into the grooves in the posts, binds the whole together. Thus layer after layer of brick are laid with bamboos enclosed within the grooves, until the wall has attained the desired height; producing a very light, cheap and strong wall. A wall constructed in this manner, of only two inches thick, will resist, it is said, as much pressure within or without, as a solid brick wall of eight times the thickness; and if iron be substituted for bamboo, the strength would be increased vastly.

These walls are said to be a secure protection against burglars, Chinese thieves seldom if ever attempting to enter a house through the door or window, but by removing with a sharp steel instrument, brick after brick out of the wall, without the slightest noise, until they have made a hole large enough to give them entrance; before entering, however, they cautiously introduce an artificial head of a man secured to the end of a pole, to ascertain if the inmates are asleep, and every thing is favorable to their purpose.

PIN MANUFACTURE IN THE UNITED STATES.

During the war of 1812, in consequence of the suspension of importations, pins became very scarce. The prices asked for the few in the market, were many times the original cost—in some instances as high as a dollar a paper, by the pack. About this time an effort was made to introduce the manufacture in New York. Some pin makers came from England, bringing the necessary implements, and commenced the business at the old States Prison at Greenwich, (New York) employing the labor of the convicts. I think the establishment belonged to, or was managed by a man named Haynes. How much was done, I am not informed; but the low prices which prevailed very soon after the termination of the war, were fatal to the enterprise, and it was abandoned. In the year 1820, Richard Turman obtained the tools which had been used by Haynes. He made a contract for pauper labor, and undertook the manufacture in the alms-house at Bellevue. Mr. Turman carried on the business a year or two, when he died; having lost by the undertaking a considerable share of his property. Probably the trouble and perplexity of the business, together with the confinement consequent on attending to it, hastened his end. No further use was ever made of the tools. I recollect hearing Mr. Turman say at this time, that he had seen a *machine* for making pins, that it had made pins, but was too delicate, or intricate to be used with advantage. I suppose this machine was one which was invented and patented by Moses

L. Morse, of Boston, during the war. I think Morse's machine had been worked to some small extent at that time; but it had passed into other hands, and was never used afterwards. His specification showed him to have been a man of good mechanical talents.

Lemuel William Wright, of Massachusetts, patented a machine for making "*solid-headed pins*," both in the United States, and in England, at an early period. I believe his specification and drawings are published in the London "Repository of Arts." He never attempted to put it to use in the United States, but in London he formed a company with a large capital, for the purpose of operating with it. The company built a large stone factory in Lambeth, and constructed some sixty machines, at great expense. It is understood that the machines failed in pointing the pins, and for that reason never could be put into successful operation. To obviate this difficulty, Wright invented a machine for heading the shanks, pointed and cut in the ordinary way by hand. The company did not succeed, and broke up with the loss of a great part of the investment. D. F. Taylor, who had been ruined by this failure, afterwards came in possession of the machinery, and, by connecting himself with a capitalist, under the firm of D. F. Taylor & Co., was enabled to start a manufactory of "solid-headed pins" at Stroud, in Gloucestershire. This was in 1832, or 1833. Some pins of their make even sold as early as 1833; which were the first "solid-headed" pins ever sold in any market. They obtained a patent for the "solid-headed" pin by act of Parliament. They used (principally or solely) the machine for heading only. Some account of Wright's machine is given in Mr. Babbage's work on the "Economy of Manufactures."

In 1832, a patent for a pin machine was obtained for the United States, by John J. Howe, and in 1833 and '34, patents for the same invention were obtained for England and France. This machine was designed to make pins similar to the English diamond pins, the heads being formed of a coil of small wire fastened upon the shank by pressure between dies. No arrangement was made to use this invention in Europe; but in December, 1835, the Howe Manufacturing Company, was formed in New York, for the purpose of putting it in operation. This company removed to Birmingham, (Derby,) Connecticut, where its manufacturing operations are now carried on. In the spring of 1838, a second patent for the United States, was obtained by John J. Howe, for a machine for making "solid-headed" pins in 1840; and this is the machine which is now in use, by the Howe Manufacturing Company.

Samuel Slocum, of Rhode Island, obtained a patent in England, for a machine to make "solid-headed" pins, in 1835. His invention was not put to use in England; but he established the manufacture of pins, by means of it, in Poughkeepsie, in 1838, under the firm of Slocum, Gillson & Co. His machine has not been patented in the United States, but has been, as it still is, run in secret. At this period, and till the Tariff of 1842 came into operation, pins (under the "Compromise Act,") were free of duty; while brass wire of which they are made, was subject to a duty of 20 to 25 per cent. Under this discouragement, the business made but slow progress. But under the encouragement given by the Tariff of 1842, the two companies above named, went on increasing their production, and doing a profitable business, till 1846. In the meantime, it having been found that pins *could* be successfully manufactured by machinery—and exaggerated ideas both as to the extent of the business and the profits to be made in it, having obtained extensive prevalence,—many persons in different parts of the country, became engaged in scheming on machinery for making pins, and much capital was expended, and finally sunk in these projects. These attempts were attended with various degrees of success; in a few instances a good article was produced, but in most cases, the article produced was more or less inferior in quality. The consequence was, that at this time, within but a few years after the manufacture had been commenced, and before it was fairly established (at least on its present basis,) the market was overstocked with goods, importations were nearly or quite arrested, and the business was ruined by domestic competition. This depression continued about two years, from 1846 to '48, and during this period, nearly every party engaged in the manufacture, or attempting to engage in it, excepting the two companies before named, suspended operations. Slocum, Gillson & Co., sold out their establishment to the "American Pin Company," of Waterbury, Connecticut, and the machinery was removed from Poughkeepsie to Waterbury, where it is now used by the last named Company.

The "American Pin Company," and the "Howe Manufacturing Company," now manufacture nearly all the pins consumed in the United States. There is a party at Poughkeepsie doing a limited business, and a small amount imported. Since the depression of 1846 to 1848, the business at the two companies named, has been reasonably profitable, having been rendered so rather by reducing the cost of production and the expense of selling, than by the small advance in price which has been realized. Both companies manufacture the wire for making their pins. During the last year, the two companies have used principally Lake Superior copper, for making their wire; their joint consumption of copper, amounting to about 250 tons, per annum. The present weekly production of pins by the two companies, may be stated at about 8 tons.

In connection with the improvement effected in the manufacture of pins, by the introduction of self-acting machinery, superseding a process which formerly required six or seven different manual operations, important improvements have been made in the method of sheeting the pins, or sticking them on paper. This, as previously performed, by inserting a few pins at a time by hand, was a tedious process, at which some five or six dozen papers were as many as a good hand could do in a day. By the improved machinery now in use, one hand will stick from 75 to 125 dozen a day, and do the work better than it was usually done in the old way. There are three patents now in force for improvements in the machines in use for this operation, viz: one granted to Samuel Slocum, one to De Grass Fowler, and one to John J. Howe. These patents are held jointly by the "Howe Manufacturing Company," and the "American Pin Company."

The present price of American solid-headed pins, is believed not to exceed two-thirds of the lowest price at which imported pins of equal weight were ever afforded before the manufacture was introduced, and for service, they are undoubtedly better than the article of which they have taken the place.

The American improvements in both the pin making and pin sticking machinery have been for several years in operation in England, and probably in other parts of Europe.

SAN TORINO EARTH.

Department of State,
Washington, Dec. 19, 1850.

Thomas Ewbank, Esq., *Commissioner of the Patent Office,*

Sir:—I enclose herewith an extract from a despatch from H. L. Maxwell, Esq., United States Consul at Trieste, respecting the "San Torino earth," which is said to make "the best under-water cement." It is respectfully submitted to your consideration, whether it would not be well to publish it, for general information, in your next report.

I am sir, respectfully, your obedient servant,

DAN. WEBSTER.

Extract from a communication under date of Oct. 9, 1850, received at the Department of State, from H. L. Maxwell, *Consul of the United States at Trieste, Austria.*

There is a cement now coming into general use here, which, if not already known in the United States, is worth being tried. It is called "San Torino earth," and has been found to be the best *under-water* cement ever used in these parts. It is mostly used in the building of piers, moles, docks, &c. The island, where it is found, and from whence it takes its name, is situated in the Grecian Archipelago, latitude 36° 23′, and longitude 25° 26′. The name given to it by the Turks, appears to be "Kameni," or, "the burnt Isle," and it is generally considered to be the remains of a volcano not yet entirely exhausted. The earth is exceedingly dry and appears to consist of silicate of iron and alumina, with a large proportion of a light, porous and fibrous substance which floats upon the water, and is supposed to be "pumice." It has been very extensively used in Syria and in Algiers, in the building of fortifications, &c., where it has been found to answer admirably, and also here a Trieste, and at Venice and Fiume, with equal success. These works have been chiefly under water in the sea, in which the cement sets very hard in a comparatively short time. Trials however have been made *above water*, and exposed to the action of the air, which are said also to have answered very well. For use, the following composition has been prescribed for works *under water*, viz: 7 parts San Torino earth—2 parts lime, and 7 to 9 parts stone rubbish; and for works above water, 6 parts San Torino—2 parts lime, and 6 to 7 parts stone rubbish. The rubbish stone should consist of pieces not too small, and as rough and irregular as possible, thus binding better with the cement. Where economy is greatly desired, a portion of sand may be used instead of wholly San Torino earth, in proportion of 4 parts San Torino, 2 or 3 parts sand, 3 parts lime, and 6 parts stone rubbish. This is said to be just as good as the first mentioned composition, though requiring longer time to harden. For use, the San Torino earth, sand and lime must be well mixed and made with the necessary quantities of water into a very consistent mortar, then heaped together and placed under roofing for two or three days. In the meantime the foundation should be made with loose stones thrown into the sea at the spot required, and the caisson or form sunk on this. Into this caisson are to be thrown alternate layers of the mortar and stones. To every 2 or 3 feet of mortar the same quantity of stone rubbish, and so on to the water's edge.

The price of this earth at the quarry is said to be from 8 to 10 carantani, per stago beneto, equal to about from 6 to 8 cents per cwt. If desired by Government, I will order a barrel for trial from here.

VIII.

PAPERS AND ABSTRACTS

RELATING TO

EARLY AMERICAN INVENTIONS,

FROM THE ARCHIVES OF STATES.

The following interesting facts have been brought to light by the papers under this head in the last report. Some of them cannot fail to surprise inventors of the present day.

Steel Making: in 1728, in Connecticut.

Attempt at increasing speed of vessels in 1693, in New York. [The device not described.]

Tide Mills: "of such a nature as hath not yett been used." New York; by the same inventor as the above.

Heating the supply water of steam boilers, by passing the feed pipe through the furnace—by Fitch, in 1785.

Pipe Boilers: proposed by Henry Voight, of Philadelphia, in 1788, and adopted by Fitch.

Raising water by steam acting on two pistons—by Rumsey.

Tubular Boilers—by Rumsey.

Propelling Vessels by reaction of a stream of water—by Rumsey.

Improvement on Savery—by Rumsey.

Reacting Water Mill—by Rumsey.

Cylindric Saw Mill—by Rumsey. *et. seq.*

Card Making Machine—by Oliver Evans.

Improvements in Milling—by Oliver Evans.

Steam Carriage, or Locomotive—by Oliver Evans.

Carding and Spinning Machines—by Robert Lemmon, in 1786, (in Maryland.)

Printing Press—by Benjamin Dearborn, New Hampshire, 1787.

Balances, or Scales—by Benjamin Dearborn.

Hand Fire Engine—by Benjamin Dearborn.

Improvements on Chimneys.

Preparing Indian Corn, } patents granted in 1717.
Straw and Chip Hats, }

In the hope of eliciting further information, circulars were addressed to the State Departments of such States as had not been heard from: the following replies have been received. For the copious and characteristic extracts from the State papers of Connecticut, the office is indebted to the interest taken in

the subject by Hon. L. P. Waldo, of the House of Representatives. In these will be found information on Iron Works:—*Furnaces, Pig-iron, Slitting Mills, Kettles, &c., Iron Wire, Steel, Nails &c.*

Bell Founding,	Torpedo,
Polishing Crystals,	Water Mills,
Type Founding,	Perpetual Motion,
Pin Making,	Cloth Making,
Clock, *(winding up itself,)*	Stocking Weaving,
Steam,	Flax and Woollen Manufacture,
Drill Plough,	Silk Raising,
Pottery,	Linseed Oil,
Glass,	Sugar Refining,
Pitch,	Snuff,
Salt,	Cloth Dyeing, &c.
Paper,	

NEW JERSEY.

State of New Jersey,
Department of State,
Trenton, December 24, 1850.

Hon. Thomas Ewbank, *Commissioner of the Patent Office:*

Sir:—Your Circular of the 6th inst., directed to His Excellency the Governor of this State, has been referred to this Department, and at his request, diligent search has been made among the records, but no evidence has been discovered that Patents have ever been granted either by the Provincial, Colonial, or State governments of New Jersey.

I have the honor to be sir,
Your obedient servant,
THOS. S. ALLISON,
Secretary of State.

MASSACHUSETTS.

Commonwealth of Massachusetts,
Secretary's Office, Boston, *December 17th*, 1850.

Sir:—Accompanying this, you will find a memorandum of such matters as are found in the records of this department concerning patents or privileges.

We find no documents of which we can send you copies, which we would gladly do, if in our power. Should we find anything more on the subject, we will transmit to you at once.

Very respectfully, your ob't serv't,

Hon. Thos. Ewbank. W. B. CALHOUN.

1652.—John Clark allowed by General Court, 10s., for three years, from every family who should use his invention for saving wood and warming houses at little cost. After trial for this period, he was granted the same privilege during his life.

1641.—General Court Records: Samuel Winslow had invented a method of manufacturing salt. None are to make this article for ten years, except in a manner different from his—provided he set up his works within a year.

1656.—John Winthrop, son of the Governor, granted the sole privilege of making salt for twenty years in Massachusetts, after his particular method.

1671.—Richard Wharton, a lawyer of Boston, and Company, have certain special privileges from the legislature for the manufacture of tar, pitch, turpentine, &c.

1672.—General Court reply to several hatters, who wished to have as a Company, peculiar privileges, that there should be granted to them when they should make as good hats, and sell them as cheap as those imported were.

1722.—The Legislature offer, by an act passed, a premium for duck and linen made in the province, of domestic material.

1640.—The General Court offered 3d. on every 1s. worth of linen and cotton cloth made in the colony; but this was repealed in the same year, because of the public burdens.

1701.—The Legislature to encourage the sowing and manufacture of hemp, raised in the Province, engage to pay to any Company who purchase this article at 4½d. a pound, ½d. on each pound so purchased.

DELAWARE.

MILFORD, DELAWARE, December 12th, 1850.

SIR:—Yours of the seventh instant came to hand to-day, to which I hasten to reply, that I have directed a search to be made in the public archives of the state for the information desired.

I have the honor to be, your ob't ser't,

WILLIAM THARP.

HON. THOS. EWBANK,
Commissioner of United States Patent Office.

SECRETARY'S OFFICE, DOVER, January 3rd, 1851.

SIR:—His Excellency, the Governor, directs me to say in reply to your circular of the 7th December, that there are no records or documents in the State Department of this State relating to the subject of patents, or which would furnish any information of the kind desired by you—nor can he obtain such information by inquiry. It is not known that any patents were granted under the Colonial Government of the State. The evidences of such grants, if any there were, would more likely be found at Harrisburg. No patents are known to have been granted by the State Government, prior to the confederation of the States.

I have the honor to be, with great respect,

Your ob't serv't,

D. M. BATES.
Secretary of State.

HON. THOS. EWBANK,
Commissioner of Patents,
Washington.

CONNECTICUT.

EXTRACTS FROM COLONIAL AND STATE PAPERS, IN THE OFFICE OF THE SECRETARY OF STATE, HARTFORD.

Early Acts of the Colony to Encourage Discoveries and Inventions.

At a session of the General Assembly, at Hartford, March 10th, 1663 [4.]

"The court for the encouragement of any person that will lay out himself for the discovery of any mines and minerals, &c., do order that whosoever shall make such discoveries, and purchase it for the country, he shall be honorably rewarded out of what he doth discover, as aforesaid. (Colony Records, II. 193.)

In the printed statutes of 1672, the laws state:—For the encouragement of such as will lay out themselves upon the discovery of mines or minerals, for the public good:—

It is ordered, by authority of this court, that whosoever shall expend their time or estate upon such discoveries, and purchase them for the country, he shall be honorably rewarded out of what he doth discover, for the same. (p. 52.)

It is ordered that there shall be no monopolies granted or allowed amongst us, but of such new inventions as shall be judged profitable to the country, and for such time as the general court shall judge meet. (p. 52.)

And to the above was subsequently added,—

"*An Act for Encouraging Adventurers in Discovering Commodities.*"

Be it enacted, &c. That if any person or persons shall set themselves on work to discover any commodities that may be of use for the country, for the bringing in a supply of goods from foreign parts, that is not as yet of use among us; he that discovers it, shall have due encouragement granted to him, and the adventurers therein. (Statutes of 1715, p. 5.)

IRON.

The following paper, designed to be presented to the Parliament of Great Britain, being preserved on file, would indicate that it originated in this colony.

"Reasons against a general prohibition of the iron manufacture in his Majesty's plantations, intended by a clause in the bill now depending, entitled,—*A Bill for Encouraging the Importation of Naval Stores from America.*"

I. If the clause be taken in a strict sense, all iron work for building ships, houses, mills, and even what is necessary for instruments to till the ground, will be forbid to be made there; whereby it will become impracticable to live in the plantations, because this sort of iron manufacture must be made on the spot, that it may be framed and fitted to the size of the work.

II. To forbid his Majesty's subjects the making any sort of iron wares, when its for their own necessary use, and not for exportation, seems to bear hard on the common rights and liberties of mankind; especially when the ore is what their own soil yields, and what is found but in small quantities, comparatively, in the mother kingdom.

III. If such a prohibition be thought just, to prevent the plantations from interfering with the iron workers in this kingdom, all other tradesmen may expect, in their turns, to be forbid working at their respective callings; for by the same reason, the people may be forbid making cheese or cider, for fear of prejudicing the manufactures in *Cheshire* and *Herefordshire.*

IV. It is humbly conceived, there is no occasion for this clause. All labor is so excessively dear in the plantations, that no manufacture of the lesser iron wares can vend, or ever does there, but when it happens by accident that there is a great scarcity of the same commodity made in *Great Britain.*

V. The encouragement given by the bill for the importation of bar iron from the plantations, by taking off the duty, which is two pounds per ton, is not sufficient to bring it in; of which there needs no other proof, than that a ton of iron is worth sixty pounds in *New England*, their money, and but twenty pounds here, to say nothing of the chargeable freight thence; so that if the clause pass, the iron ore in the plantations will be of use neither there nor here.

VI. It seems a further hardship, that the subjects abroad should be permitted to forge their ore into bars, but not to run or cast it into pots and other implements, because the same fire, and even the same heat, will suffice for both.

It is therefore humbly prayed, that the clause prohibiting any kind of iron wares to be made in the plantations, though for their own use, and not for exportation, be left out of the bill. (Industry I. 98.)

IRON WORKS IN LYME.

To the Honorable General Assembly, &c.

The memorial of Samuel Southworth, of Lyme, in the county of New London, humbly sheweth:—

That he hath lately, at great cost and charge, built an iron work, and hath made considerable quantity of iron, and hath also built a refinery to refine pig iron, which is to be had plentifully at Philadelphia, which iron when refined, is as good for any use as Sweeds or Spanish; which if the same could be carried on to good purpose, would be a great advantage to the country in general, and hinder the importation of great quantities of iron. And your memorialist, being much reduced by his great cost in building said works, is unable to carry it on to good purpose, and the same will unavoidably sink and come to nothing, unless your honors will, in your wonted goodness to relieve the distressed, relieve your memorialist, by loaning him some money out of the public treasury, to the quantity of £2000. Which your memorialist humbly prays that your honors would, (loan) and that upon good land security or bond to your honors' or committee's acceptance; and that he may pay in interest and principal in iron, at as much less than the market price, as your honors judge reasonable. But if that cannot, by your honors, be complied with, then that he may have it on good security as above, on moderate interest, to be paid in some convenient time. And your memorialist, as in duty bound, &c.

SAM'L SOUTHWORTH.

LYME, May 15th, 1741.

(Industry I. 132.)

No legislative action on said petition.

General Assembly appointed a "committee to make a proper inquiry for obtaining an account of the quantity of iron made in this colony, as required in a letter from the Lords of the board of trade, dated June 9th, 1757, to the Governor and Company of this colony, and make report, &c., to this present Assembly." (Industry I. 174.)

IRON WORKS AT DERBY.

To the Honorable, &c.

The memorial of Ebenezer Keny, Joseph Hull, Jr., and John Wooster, all of Derby, &c., and Thomas Pirkins, of Enfield, &c., humbly showeth:—

That your honors' memorialists, being desirous of erecting and setting up iron works, on the falls of Nangatuck river, in said Derby, where there is a proper and convenient place therefor; and the Indians of said Derby, whereof John Howdee and Joseph Chuse are the head or chief men, [and] own about 40 acres of land, bounded west on said river, south on said falls, and running so far north as the head of said falls, which will impede the setting up said iron works, unless liberty can be obtained for purchasing the privilege of a highway by the river side, &c.

Whereupon your memorialists humbly pray, &c.

Dated at Hartford, this 12th day of May, 1760.

EBENEZER KENY.
et. al.

Petition granted by Assembly. (Industry I. 180.)

IRON WORKS AT CORNWALL.

To the Honorable General Assembly of the English Colony of Connecticut, in New England in America, now sitting, &c. Oct. 1761.

The memorial of John Patterson, Ephraim Patterson, and Thomas Russell, all of Cornwall, in the county of Litchfield, humbly sheweth:—

That your honors' memorialists are owners of a tract of land lying on the east side of Owesatunnuck river, and adjoining tract thereto, in said Cornwall, in which is a proper place for building a furnace for running iron ore into pigs fit for refinery, and are owners of land stocked with wood for coal, and have a good sufficiency of ore to supply said furnace; and being sensible of the great advantage it would be to the interest of people of this colony, and being advised that it will, in process of time, be somewhat profitable to the undertakers, are zealously inclined to set up such furnace, but have not personal interest enough at present, to carry it on to effect; therefore pray your honors to grant us the liberty of taking out of the public treasury of this colony, £1200, in bills of credit on this colony, and that we may have it for the term of four years, upon our giving land security double the value of said sum, or bonds with sufficient security, payable at the end of said time, with the lawful interest; said security to be according to the judgment of such committee as your honors shall appoint; said money to be taken out of the treasury, in case your memoria. go on and get such furnace at work within two years. And your, &c.

Dated in Cornwall, this 10th day of October, 1761.

JOHN PATTERSON.
EPH'M PATTERSON.
THOS. RUSSELL.

(Industry I. 204.)

Assembly continued petition to May next.

To the Honorable, &c.

The memorial of William Tanner, Benoni Peck, Elijah Steel, Heman Alling, all of Cornwall, &c., humbly sheweth:—

That your memorialists have purchased the one-eighth part of the great ore bed in Salisbury, in the county of Litchfield; and that your memorialists have in Cornwall, a very convenient and suitable place, on the Housatonuck river, to set up a furnace for the making of iron; which place is abundantly furnished with wood for the said purpose; and it is about nine miles distant from said ore bed, whereof four miles is good water carriage. And your memorialists have made preparation for erecting a furnace in said place, for the making of iron, and therein expended about £100 lawful money; and your memorialists beg leave to inform your honors, that they have been disappointed of a large sum of money, of which they were assured and depended thereon, at their entrance upon this design; which disappointment they have been unable to retrieve, and thereby they are rendered wholly unable to prosecute said design, which your memorialists really believe would be very beneficial to this colony, by supplying the inhabitants thereof with iron made in the colony, and preventing the exportation of moneys therefor. And your memorialists could easily carry on and execute said design with £1000 cash, which they have been unable to procure, unless they join with persons out of this colony; although they are willing to give interest and land security worth double said principal sum and interest.

Wherefore your honors' memorialists humbly pray your honors to loan, out of the public treasury of this colony, to your memorialists, the sum of £1000 to enable them to set up a furnace for making iron, as aforesaid, on their securing principal and interest as aforesaid. And your honors' memorialists, as in duty bound, shall ever pray, &c.

WILLIAM TANNER.
BENONI PECK.
ELIJAH STEEL.
HEMAN ALLING.

Dated at New Haven, the 11th day of March, A. D. 1762.

(Industry I. 205.)

No action by Assembly on petition.

IRON WORKS IN LYME.

The papers relate to a controversy about the use of water wanted for a gristmill. Extracts follow:

"That it is of much greater consequence to the public, that their gristmill should be kept going, than that said iron works should: yet your memorialists apprehend, that if said water, preserved in such large ponds, was prudently used, said iron works might go, without hurting the gristmills, many more months in each year, than they have ever done in any one year since they were erected; for that they, for many years now last passed, have been kept going but very little in the winter season, when there is water, &c., and have been kept going in the summer, or dry season of the year, when there is not water, &c.

And they petition General Assembly to regulate the matter.

Petition is negatived. (Industry I. 202.)

SLITTING MILL IN SUFFIELD.

Whereas, Mr. Ebenezer Fitch has represented to this court, that divers gentlemen, in company with himself, are willing and desirous to set up a slitting mill upon the river called Stony Brook, within the bounds of Suffield,* in the county of Hampshire, or elsewhere in the county of Hartford, within this colony, to slit and draw out iron rods for nails and other artificers in iron, their work and use; and since the charge and adventure of the first undertakers of such an affair must be considerable, hath therefore prayed this court for a private act in favor of himself and company, to grant them the sole privilege of such a mill for some time, in recompense of their expenses and adventure; and the court, considering the great advantage such a mill will be to this government, as well as the neighboring, have therefore thought fit to encourage the same.

Now, therefore, for the encouragement of said Ebenezer Fitch, and such as shall join with him in the said undertaking:—Be it enacted, &c., that no other person or persons whatsoever, shall or may erect any slitting mill or slitting mills in any part or place within this, his Majesty's colony of Connecticut, upon any pretence whatsoever, at any time during the space of 15 years, from and after this present session of this general court, upon pain and penalty of £10 per month, for every month that any such slitting mill shall stand within this colony, within the time aforesaid, to be recovered, &c.

Provided, that the said Ebenezer Fitch and company shall, within three years, &c., erect and set up a good sufficient slitting mill, &c.

Passed General Assembly, May 1716. (Industry I. 101.)

*Then claimed by Massachusetts.

ENFIELD IRON WORKS.

To the Honorable, &c.—The Petition, &c.

That Joseph Webb, of Wethersfield, in his life time, to wit, on the 19th day of September, A. D., 1759, bargained and agreed with Col. Timothy Dwight, of Northampton, &c., and Captain Samuel Dwight, of Enfield, to purchase of them one fourth part of their Iron Works, at said Enfield, together with one fourth part of the land in said Enfield, granted for building said iron works, and one fourth part of the dam, implements, &c., at the great importunity of said Timothy and Samuel, and upon their representation that the same might be paid for, and they would take their pay for the same in bar iron, manufactured in said works: whereupon the said Joseph was induced to agree and did agree to buy the fourth part of said works, &c., at the price of £100 money, to be paid in bar iron of that value at said works, &c.

(The remainder of the petition relates solely to the fulfilment of the terms of the contract. Mehetabel Dean was the widow of said Webb.)

Signed,

SILAS DEAN,
MEHETABEL DEAN.

Wethersfield, January 28, A. D. 1767.

(Industry II. 129.)

SALISBURY MINES AND IRON WORKS.

A Court of Election held at Hartford, May 14, 1674.

This Court grants John Bissell 100 acres of land, provided he take it up where it may not prejudice any former grant. (Towns and Lands VI. 82.)

At a General Assembly holden at Hartford, May 12, 1726.

This Assembly do appoint the surveyor of the county of Hartford, to survey and lay out the said 100 acres of land, in any of the ungranted lands of this colony, according to said grant. (Towns and Lands VI. 82.)

To the Honorable the General Assembly, sitting at Hartford, May 9, 1734.

The memorial of Jared Eliot, of Killingworth, Elisha Williams, of New Haven, Martin Kellogg, of Wethersfield, Robert Walker, Jun., of Stratford, John Ashley, of Westfield, Philip Levingston of Albany, and Ezekiel Ashley of Sheffield, humbly sheweth:

That this Honorable Assembly at their session on May 14th, 1674, granted 100 acres of land to John Bissell, late of Windsor, deceased; and at your session on May 12, 1726, ordered the surveyor of the county of Hartford, to survey and lay out said 100 acres in any of the ungranted lands of this Colony. In pursuance whereof, Jonathan Burnham, surveyor of lands for the county of Hartford, laid out said lands, as followeth, that is to say:—To begin at a stake and heap of stones west of Ousatonock river, and westerly of a large pond known to the Indians by the name of Wonoikopozo pond, said pond lyeth easterly of the road leading from Weatauge to Sackett's farm, and from thence measured south 13° 30′ west, 120 rods, to a stake and heap of stones; then measured east 13° 30′ south to a stake and heap of stones, 33 chains, 33 links and one third of a link, to a large black oak tree marked, and with stones about it; from thence measured north 13° 30′ east, 30 chains, to a stake and heap of stones; then measured west 13° 30′ north, 33 chains 33 links and one third of a link, to the place where it begins; and marked trees in the line between each monument:—Which said 100 acres of land laid out as aforesaid, is now by mean conveyances become the estate of your memorialists, and there being found in said lands, a bed of iron ore, we have advanced considerable sums to set up iron works for the improvement of it: Whereupon your memorialists humbly pray that this assembly, would allow us to take out a patent under the seal of the corporation, for the confirmation of our title to said land; and your memorialists as in duty bound, &c. (Towns and Lands VI. 83.) JARED ELIOT, *et. al.*

Upon the memorial &c., * * Wonokopoiko pond, which said 100 acres of land was surveyed and laid out by Jonathan Burnham, &c., unto John Pell and Ezekiel Ashley, as is set forth in the survey of said Jonathan Burnham, dated Oct. 27th A. D., 1731:

It is Resolved, That the memorialists have a patent as prayed for, provided they shew to the acceptance of the Governor and Secretary, that the right to the remainder of the 100 acres of land, (which is not yet made out) is well vested in said Philip Levingston, by lawful conveyance, before the said patent be executed. May 1734. (Towns and Lands VI. 83.)

ORE BED.

To the Honorable, &c., May 1784.

The memorial of Samuel Forbes, Henry Levingston and Nathan Hall, in behalf of themselves and the rest of the proprietors of the iron ore bed in Salisbury, &c., humbly sheweth:

That your memorialists, being owners of said ore bed, with the right only of digging and raising the same, have found, by long experience, that valuable body of minerals is constantly wasting, by the irregular method of raising the same, in that the canals or water courses (are stopped) which increase the quantity of ore, and care is not taken to keep them open, after the mines have exhausted a vein of the bed of ore, or from some other cause which your memorialists are convinced is occasioned by the irregular conduct of the miners, who are not under the possible control or direction of the proprietors, as each one digs and raises for himself, and strangers are constantly trespassing with impunity, whereby great injustice is done, not only to your memorialists in general, but to individual proprietors, who cannot derive the avails of their proportions of ore raised from said bed, and the public are in danger of losing that valuable resource of the most useful and necessary manufactures of this State. And your memorialists would observe, that in their present situation, a recovery at law for any trespasses is impracticable, being tenants in common, all suits for trespass must be brought in the name of all the proprietors, three eighths of which proprietorship is divided amongst near 100 persons, and is continually changing, whereby suits abate before any trial or judgment can be had thereon; and for each proprietor to commence a suit for his share or moiety of the ore raised by any of his fellow commoners, is attended with more expense than the avails are worth. Neither can your memorialists adopt any efficacious method of raising the ore, to prevent the injuries aforesaid, and many other inconveniences and losses which unavoidably attend their present tenancy, which your memorialists are confident can be provided against, were they properly incorporated, with power to appoint an agent or committee to superintend the raising of the ore, and employing miners according to the directions of the major part of the proprietors, at an annual meeting, with power of suing and being sued, by their agent or committee, and also the power of making and carrying into execution necessary by-laws for the benefit of the proprietors.

Whereupon your memorialists pray your Honors to take their case into your wise consideration, and grant them a Charter of Incorporation, thereby enabling the proprietors of the iron ore bed in said Salisbury, to regulate the raising said ore, and appointing an agent or committee to superintend and regulate the same according to the directions of the proprietors, at their annual meeting, and a power of making necessary by-laws, and of suing and being sued, by their agent or committee. And your memorialists, &c.

SAMUEL FORBES,
HENRY LIVINGSTON,
NATHAN HALE.

Dated at Salisbury, the 26th day of April 1784. (Industry II. 184.) Act of Incorporation granted, (186.)

In a petition for town privilege, May 13, 1736, petitioners of Salisbury say: "We * * are building iron works, and have plenty of ore, &c. (Towns and Lands VII. 232.)

To the Honorable General Assembly, &c.

The memorial of Charles Caldwell, of Hartford, &c., and George Caldwell, of Salisbury, &c., humbly sheweth:

That your Honors' memorialists have purchased the principal part of the furnace at Salisbury, aforesaid, for the making pig iron, potash kettles, and common pots and kettles of iron, &c, which cost them a very large sum of money; and that for sundry years last past, they have vigorously carried on the business of making pig iron, &c., to the very great advantage of the colony, as well as to their own private benefit, and have supplied many forges in this colony with pig iron to be made into bars, and have, over and above that, exported and sold abroad pig iron, and pots and kettles, annually to a large amount. And your memorialists have also erected a good new forge within 15 miles of the town of Hartford, [at Simsbury] for the making of bar iron out of pigs. And your memorialists would further observe to your Honors, that while they are pursuing that business with satisfaction to their own benefit, they also find by constant experience that it is of vast public advantage to the colony, as every bar of iron produced thereby is a saving of so much cash to the government, and keep that cash among ourselves which used to be sent abroad, for the purchase of iron, which is an article that the colony cannot subsist without, and which costs them annually about £20,000, a very large sum to be sent yearly out of the colony, which your memorialists suppose they have already put a great stop to, by means of said furnace, and suppose themselves fully able to supply the colony entirely with pig iron, which is easily wrought into bars fit for use by their own as well as the various other forges in this colony. 'Tis not unusual that matters of such public benefit and utility should meet with obstruction from those who find their advantage in keeping the colony dependent on foreign markets for their supply of such a valuable article. We, your memorialists, have met with and experienced very great hindrances, troubles and difficulties from persons of that character, many times to very great loss, though we have constantly kept our works in order and under improvement, at a vast expense, being obliged constantly to retain in our service for carrying on the business, about 50 hands, who are all employed in the different branches of the business, and we now have as large a stock on hand to be wrought up into iron, as we ever had since we owned those works, but find ourselves not able to make those works so extensively useful to the public as well as beneficial to ourselves as we might do, could we command somewhat more of the ready cash in this season of the great scarcity of money. And knowing your Honors' strict attention to whatever is for the public benefit of the colony; we your Honors' memorialists do thereupon humbly pray this Honorable Assembly to take the matters aforesaid into your serious consideration, and that your honors would be pleased to order and enact that your memorialists may and shall have the sum of £1,200 on loan, out of the public treasury of the colony, on interest, to be repaid again into the treasury, at the end of 2 years, on your memorialists procuring and giving good and sufficient security, that shall be approved of for the repayment thereof, in order that we may the more advantageously carry on said works: and we, as in duty bound, shall ever pray.

GEORGE CALDWELL,
CHARLES CALDWELL.

Dated in Hartford, this 7th day of Oct. A. D. 1767. (Industry II. 132.)
Loan is so made, and committee is appointed to execute the bonds. (131.)

To the Honorable General Assembly, &c.

And now your memorialists beg leave to represent to this Honorable Assembly, that they conceive themselves obliged, out of gratitude to your honors, and loyalty and friendship to the true interests and weal of this colony, to inform, that, notwithstanding the moneys graciously granted to your memorialists aforesaid, and received by them under the disadvantages it was, they find they cannot hold and carry on said furnace to advantage to the public or themselves;—for that some years past your memorialists were necessitated to hire £1,500 of lawful money in New York government, for which one Mr. John Rutsen was bondsman, to whom your memorialists were obliged to mortgage said furnace and bed of ore, &c. And that said Rutsen is sued and has judgment against him for said money by means of, and at the instigation of those who are seeking to engross said works and ore into their own hands,

out of this colony, whereby said Rutsen must and will (notwithstanding the utmost endeavors of your memorialists and the helps already afforded them) recover said furnace, and your memorialists' whole interest in said ore from your memorialists, for the sum aforesaid with the addition of about two years interest. not half the sum it cost your memorialists, whereby the whole interest of said ore bed and furnace will go from your memorialists, and fall into the hands of people living in the province of New York—whereby this colony will be deprived of the only means of supplying and carrying on the iron manufactory within themselves, which is of the greatest necessity and importance in almost every business of life. [Petition is here mutilated.] General Assembly to appoint a [committee to look into the] affair, or contrive some other way whereby said [ ] may be cleared from said ore and furnace by the colony, and to take a conveyance of said ore bed and furnace to the Governor and Company of this colony, in security, which your memorialists are willing to give, asking only that they may have the use and improvement of said furnace and ore bed for the space of four years; and till then allowed them to redeem said furnace and ore bed from said Governor and Company: or some other way devise means effectually to prevent the loss of so great, necessary and lasting advantage of furnace and ore bed to the colony, which your memorialists imagine can be done without advancing any money, by turns, orders, &c. And your memorialists &c.

CHARLES CALDWELL,
GEORGE CALDWELL.

Dated at Hartford, May 16th, A. D., 1768. (Industry II. 134.)
Referred to a committee.

The following is but a synopsis of papers:

Richard Smith of Boston, in the spring of 1768, was induced to supply Nathaniel Porter of Lebanon, with goods to the value of £862 for stores in Simsbury and Salisbury, to be vended to workmen in the iron works, and in the purchase of stock for the same, for which he was to receive pay in pig and bar iron of Charles & George Caldwell. In the fall, said Smith came into Connecticut, to see if it would be prudent for him to furnish said Porter more goods on the same account: When he was induced by the false representations of said Caldwells, to become a partner in said iron works in Simsbury and Salisbury, (at which time their affairs were in a most perplexed situation, and the furnace and premises were mortgaged to John Rutsey of Albany,) for half of which property said Smith agreed to give said Caldwell, £1,000 cash to clear Rutsey's mortgage, and £100 to be furnished in goods. But on a subsequent visit to Connecticut, Smith was surprised, that the fee of said property was vested in the Sheriff, Ezekiel Williams, by a deed of Caldwell's of anterior date to secure a debt in his hands: And to clear the same and claims of sundry other creditors, Smith was obliged to advance £1,200 L. M. additional. Finding himself thus deceived and traduced, he offered Caldwells a release, on giving him security for what he had advanced; as they were unable do this, he contracted to purchase all their interest in the iron works, for which he was to allow them £4,213 15s. He then, December 20th, entered into partnership with George Caldwell, in trade and the manufacture of iron; said George to take the oversight and management, and be at one-third of the expense, and share one-third of the profits. But at the earnest request of said George, on February 19th, 1769, Smith contracted to restore the whole works to him on his entering into bond to pay said Smith,

£8,663 9s. 5d. in three yearly instalments; which said Caldwell, utterly neglected to fulfil. Smith accordingly, in January, 1770, proceeded to oust said Caldwell, and took possession. (The forge at Simsbury, had been carried away by a flood.) As said Caldwells continue to harass him in every possible manner, Smith prays the General Assembly, April 21, 1770, to grant him a committee to settle their claims in equity, that he may be quieted in possession. (Miscellaneous III, 234.)

George Caldwell gives another version of the transactions, viz: That in view of the profitable investment, Smith offered to become a partner, with the ulterior design of getting the works out of their hands. That he promised on said Charles Caldwell's retiring from the concern, to set him up in trade to gain a livelihood; and that George Caldwell, was forced to enter into a bond, to release the property to Smith. And on July 3d, 1769, Smith's agent with others, forcibly made an attack on said George, in Salisbury, took away his books and papers, put a stop to the works; and on the entrance of said George with John McAlpin, on the premises, January 4, 1770, Smith entered a complaint against them for disturbing the peace; and on warrant, said Caldwell was thrown into prison, and on trial, he was found guilty and fined; and February 7, 1770, he was ordered by the court, to surrender the premises to Smith. Caldwell avers that said judgment was erroneous, and prays the General Assembly to set the same aside, and to restore him the property, and allow him £2,000 damages, April 28, 1770. (Miscellaneous III, 236 to 242.)

Caldwell's petition is rejected, and that of Smith's is referred to a committee, May, 1770; who, in October, 1770, report that no settlement can be made with Smith, but by assigning to him the debts. And the Assembly order said committee to proceed and finish a settlement with him. (Miscellaneous III, 235.)

Richard Smith carried on the iron works, under the agency of Col. Joshua Porter; but on the breaking out of the Revolutionary war, Smith not proving to be a friend to his country, his property was seized upon, and improved by the government of Connecticut. (See below.)

At a meeting of the Governor and Council of Safety, Tuesday, 9th January, 1776.

On representation to this board, that the iron furnace at Salisbury, belonging to Mr. Richard Smith, now in Boston, is in good repair, and capable of being improved to great advantage for the public by manufacturing iron, casting cannon, cannon balls, &c. On consideration thereof, it is voted and resolved, That Col. Jedediah Elderkin, be and he is hereby appointed a committee to repair forthwith to said furnace, and to the iron works of said Smith, at Sufferage, [Canton,] or higher up, and find the true state and circumstances of said furnace, and how they may be improved for the benefit of the colony, in either of the ways aforesaid, consult and advise in the best manner he can, as to the propriety of immediately improving and setting said works agoing for any or either of the purposes aforesaid; and make the best estimate he shall be able; and with his best discretion, if he shall find it expedient, give proper orders for executing any or either of said designs; and make report of his doings and opinion in the premises. (Council of Safety I, 59.)

At a meeting, &c., January 29th, 1776.

Col. Elderkin, gave in his account and report of the circumstances, &c. of the furnace, &c. at Salisbury, and the works thereabouts, Colebrook, &c.

Among other things, that a lot of about 200 acres of land lies near the furnace with about 150 acres of wood upon it, and may be bought in order for coal, and very difficult to get it in any other way. (Council of Safety I, 65.)

Governor and Council appoint a committee to purchase, &c. (65.)

At a meeting, &c., February 2, 1776.

Col. Elderkin is hereby appointed a committee to repair forthwith to Salisbury, and give proper orders and directions for procuring every necessary material for setting forward and promoting said business, and getting everything into the best readiness to carry on the same. (Council of Safety I, 74.)

Third February, 1776, &c., voted and ordered, that the committee of the paytable draw on the treasurer in favor of Col. Elderkin, for the sum of £100, to enable him to do the necessary to forward the works to be done at the furnace in Salisbury, whither he is going by order to prepare said furnace for the casting of cannon, &c. 'Tis done! and the Governor lent him the money, and his order is endorsed. (Council of Safety I, 76.)

16th February, 1776, &c. Voted, that Lemuel Bryant of Middleborough, as a cannon founder at Salisbury, and David Cawer, Zebulon White and David Oldman, in those parts as moulders, and that said Bryant, procure four moulders for shot, and he, to come by 15th March, and the rest by 1st April. (Council of Safety I, 86.)

18th March, 1776, &c. Lemuel Bryant and Zebulon White were present, who had been sent for, near Middleborough, &c. as cannon founder, moulder, &c. The first demands two dollars, and the other one and one-third dollars per day, and to be supported. And having great necessity of them, and they affirming that they have had and are offered the same near home; it is, therefore, and on that ground, agreed to allow them that pay and support; but it is agreed and understood, that if said Bryant does not succeed, he is to have no other allowance than his support. And they are desired and sent forward to Salisbury, for the purpose of pursuing the business of making cannon, &c.

It is voted, that Col. Joshua Porter be and he is hereby appointed chief provider and overseer of the works at the furnace in Salisbury, and to do whatever shall be needful and proper to promote the public service at that place, observing such orders as shall be given to him from time to time, by His Honor the Governor, and this Council or the General Assembly of this colony, and keep proper accounts to be rendered when required. And this sent in a letter to said Porter, by said workmen. (Council of Safety I, 96.)

To the Honorable General Assembly, &c.

The memorial of Joshua Porter of Salisbury, &c., humbly sheweth, That in March last, he was appointed overseer and manager of the furnace at Salisbury, for the purpose of casting cannon, shot, &c., by his Honor the Governor and his Council; that he immediately entered upon the business, went to procuring coal and ore, and putting in repair the furnace, and for that end, drew out of the colony treasury about £550 L. M., which money is all expended; and your memorialist wants about £800 more, to enable him to carry on said business with vigor and to the best advantage, which he will receive to be accountable for. Whereupon, &c.

JOSHUA PORTER.

May 14th, A. D. 1776. (Revolutionary war VII, 374.)

Allowed £800 on giving his receipt.

Committee is appointed to take into consideration the matter relative to the foundry at Salisbury, and to consider what is best to be done relative to the continuing and carrying on the same; and also to take into consideration

Mr. Paine's letter respecting the same, and report make, Oct. 1776. (Revolutionary war VII, 376.)

We, your honors' committee, &c.

Having considered the great utility and public benefit, which has already accrued by the foundry of cannon at said Salisbury furnace, in the summer past, and the great advantage which may hereafter arise by pursuing the same, notwithstanding we are apprehensive, that the cost may increase in procuring coal; yet, we are of opinion that every effort and exertion ought to be used to continue the present blast as far into winter as is possible, considering the season, and that every preparation ought to be made this winter, of provisions and all proper materials, for carrying on the foundry of cannon for the next season under the general direction of the Governor and his committee of safety, as has heretofore been. And as to the subject of Mr. Paine's letter referred to, we are of opinion, that it will not be practicable to add another furnace to the present, for the casting of large cannon; that the water would not be sufficient, and on many other accounts very inconvenient.

Signed per order, ELIPH'T DYER.

(Revolutionary war VII. 377.)

Whereas, the public safety makes it necessary still to continue the cannon foundry at Salisbury in blast, for the purpose of making a sufficient quantity of cannon, &c. for the public defence, &c.

Therefore resolved, &c. That Joshua Porter, Esq., who has the charge of the foundry, be empowered, &c. (378.)

Committee is appointed to consider what other and further measures it may be expedient to take, to continue the furnace at Salisbury in blast, and the foundry of field pieces and other cannon, so much needed for the use and defence of this and the other American states in the present war, and make report as soon as may be, December, 1776. (Revolutionary war VII. 379.)

The state continued to sustain the furnace, appoint managers, &c. for some years. (Revolutionary war VII, 380, &c.)

May, 1777. The overseers petitioned the Assembly, that the workmen might be exempted from liability to be drafted into the public service. (Revolutionary war VII. 387.)

The classes of men which must necessarily be exempted from military calls, which may impede the cannon foundry, are—

The managers and clerk,	3
Draughtsman of patterns and turners,	3
Founder, firemen and moulders,	10
Other workmen at the furnace, viz:	
Borers of cannon,	2
Dressers of cannon,	2
Clay Spanker,	1
Gutterman,	1
Filers,	2
Banksman,	1
Ore burner,	1
Ore pounder,	1
Ore wheeler,	1
Carpenter,	1
Colliers and ore diggers,	30
	59

(Revolutionary War, VII. 389.)

Assembly exempt 50 men necessarily employed, (388.)

The following are mere abstracts:

April, 1779. Governor and Council of Safety are authorized to lease the furnace for one year. (Revolutionary war, XIV. 281.)

William Whiting having leased the same, petitions the General Assembly to exempt workmen from draft, (284,) and they exempt 40 men, (285.)

Committee to take into account the circumstances of the furnace, April, 1780. (Revolutionary war, XVIII. 105.)

Report.—Governor and Council of Safety, leased the furnace and lands of Richard Smith to Wm. Whiting, to pay two tons of pig iron per month while in blast, &c., and Whiting proposes conditions for continuing. The wants of the state require that the furnace be kept in operation. (104.)

Joshua Porter says, he was appointed agent, March, 1776, and served 11 months, cast 300 tons of iron, and saved the state £8,306. His accounts were put into the hands of Wm. Whiting, his clerk; and he is surprised to learn that a committee have found him in arrears. He has in his hands £333 state money, but has received no pay for his services, &c.

On report of committee, he is allowed said £333 as compensation, and commended for his faithful services, May, 1780. (Revolutionary war, XX. 294 to 297.)

Richard Smith, late of Boston, now of Hamburgh, Germany, owner of the furnace and of large tracts of land, committed them to the care of Colonel Joshua Porter, Feb. 28, 1775, to lease and improve for said Smith's benefit. Since Col. Porter improved the premises for one year for the state, he says, they have been improved and leased to little advantage. The works are impaired and the utensils lost. He thinks, after the present lease of Mr. Whiting expires, it will be better for the state to relinquish all control,—as was done with Smith's refinery at Colebrook,—and leave the whole to private improvement. Oct. 16, 1780. (Rev. war, XX. 298.)

Col. Porter and Mr. Whiting both petition for a lease of the furnace, &c. Nov. and Dec. 1780. (Rev. war, XX. 302 and 299.)

General Assembly negative both petitions, and order governor and council to lease to the highest bidder, for one year, the furnace and lands at Salisbury, and the refinery at Colebrook, and take measures to have the iron at Salisbury refined. Nov. 1780. (Rev. war, XX. 303, 306.)

Sheriff Lord reports, that he attempted to lease the premises, for which £321,000 state money was bid; but becoming embarrassed, he stopped the vendue, and asks for instructions. Feb. 27, 1781. (Rev. war, XX. 309.)

Referred to a committee, who report that Smith joined the enemy, and his estate should be confiscated. March 3, 1781. (309.)

Ordered, that all persons holding property of said Smith, appear before the next assembly, to give reasons why his estate should not be confiscated.

Col. Porter and Jared Lane, each representing that they are attorneys, agents and factors of Richard Smith, petition general assembly, that after the expiration of the present lease, each of them may have liberty to improve the works for the owner.

Referred to a committee, who report that Smith went off from Boston with the British troops in 1775, and is a prescribed person in Massachusetts; and recommend that the furnace, &c., be improved by the state, until Smith's political character can be further investigated; and that taxes paid by said Lane, as agent, be refunded. Feb. 1781. (Rev. war, XX. 307.) Approved (308.)

Richard Smith states, that he left the country in 1775, on his private business, and was unable then to return. He petitions the assembly for liberty to return and possess his estate; the use of which he will lay no claim to, and will loan the state £1000 from the avails of goods he wishes to introduce. Jan. 1783. (Rev. war, XXIV. 101 to 103.)

He is so admitted a member of the state, on taking the prescribed oaths, &c. (104.)

COLEBROOK IRON WORKS.

Committee to call Mr. Ogden to account, Nov. 1780. (Rev. war, XX. 303.)

To the Honorable, &c.

The memorial of Jacob Ogden, of Colebrook, in the county of Litchfield, humbly sheweth:—

That in the night of 30th day of August last, the iron works and forge in the occupation of your memorialist, at said Colebrook, by some means, unknown to your memorialist, took fire and burnt to ashes, with the bellows and all the utensils thereto belonging: that your memorialist had laid out of his own money, in repairs from time to time, to the amount of about £200 L. M. which is now all lost: and the business of manufacturing iron and steel at said works, is at an end for the present. And your memorialist is willing and desirous of erecting a new forge in the same place where the old one stood, and of carrying on said business, provided he can be properly encouraged; and has already proceeded so far in said business, as to have set up a new frame; but from the difficulty of the times, and the lowness of his finances, he finds himself perplexed in getting forward with the dispatch he could wish, and that the public exigencies seem to require. He flatters himself that the utility of the business to the public, the acceptable manner in which he has performed it heretofore, and his determination to render it as useful as possible in future, will entitle him to the favor and patronage of your honors. [He then prays for a lottery to raise £300, or $1000, and adds] and he be enabled thereby to go on with dispatch in completing said works, and have them a going in about five or six weeks, and be able to work up his stock on hand, of which he has a large quantity provided, in the course of the year, which will furnish a large supply of iron and steel, for the use of the citizens of this state, and tend to render those articles plenty and cheap. Or that, &c., in some other way, &c.

JACOB OGDEN.

Dated in Hartford, Oct. 19, A. D. 1781.

(Industry II. 175.) Negatived.

IRON WIRE.

To the Honorable, &c.

The memorial of Nathaniel Niles, of Norwich, in New London county, humbly sheweth:—

That by reason of the present unhappy controversy between Great Britain and British America, and the consequent interruption of trade, it is become of very interesting importance to these colonies, that the article of iron wire on which the woollen and cotton manufactory so greatly depends, should be manufactured in these colonies, which hitherto hath not been done; and that it is of importance this should be gone into with the greatest expedition, since the makers of wool cards, quite from Philadelphia to Nova Scotia, are at present wholly out of proper employ. That your memorialist, desirous to serve his country in so important an article, has been at considerable expense of time, pains and cash, in acquiring the practical knowledge of this business; for which purpose he has attended, as far as he could gain advantage, either by men or books, to the European method; which he finds to be very tedious, it being necessary to carry each bar of iron through about 200 holes in a steel plate, before it is reduced to the size of card wire, and it being difficult and considerably expensive, and at the same time absolutely necessary to take the scale from the wire that is raised by heating, which operation must necessarily be frequent, in order to preserve the ductility of the metal. That in order to this article being afforded at the rate at which it has usually been sold by the importer, the apparatus must be very complicate, various and expensive, your memorialist apprehending the whole will amount to not less than £300. That your memorialist, considering the burdens that lie on the public at present, would undertake the business wholly on his own risque, notwithstanding the dangers into which his interest would, by this means, be thrown; had he a sufficiency first to make suitable preparations, and then to carry on this branch of manufacture, without involving himself in inextricable embarrassments. That not being able to do this, your memorialist, confiding in the zeal of this honorable assembly to promote American manufactures, humbly begs the grant of a lottery to raise £300, for the purpose aforesaid, not desiring, however, that the moneys so raised should be committed to him, to be applied by him at pleasure, any farther than such managers of said lottery, or such other persons as this honorable assembly shall see fit to appoint for that purpose, shall find evidence that the several sums they imburse have, bona fide, been applied to the single purpose of preparing to manufacture iron wire. The remainder of the proceeds of said lottery, if any there be, to be applied as this honorable assembly shall please to direct. That your memorialist apprehends he can, on such a grant being made, afford the several sizes of iron wire at the several rates at which they have most usually been vended in this and the neighboring colonies, by the importer. That if your memorialist finds, on experience, that he cannot afford it at such a rate, he will be holden to such prices as any committee appointed from honorable assembly shall judge reasonable, after an examination of the expense of making.

That if this honorable assembly shall not see fit, in their wisdom, to grant such a lottery, your memorialist begs such assistance as shall enable him to prosecute this business, either by a loan of money from the public treasury, or such other way as your honors, &c.

Hartford, May 17, 1775.

NATHAN'L NILES.
(Industry II. 151.)

On the memorial, &c.

Resolved by this assembly, that be and they are hereby appointed a committee to examine into the matters contained in said memorial, and the necessary expense of erecting the proper works for the manufacturing of iron wire, and what encouragement may be properly given the memorialist therefor. And if said committee, upon due examination, shall judge it reasonable and expedient, they are hereby empowered to draw their order on the colony treasurer for any sum not exceeding £300, to be paid by said treasurer, who is hereby directed to pay the same to the memorialist, upon his giving good security, to the acceptance of said committee, that such sum shall be improved solely for the setting up and carrying on said manufactory, and that the principal sum so received, shall be repaid at the expiration of four years after received, without any interest thereon.

May 1775. (Industry II. 152.)

Niles continued the manufacture of wire through the war. (See snuff.)

To the Honorable, &c.

The memorial of Samuel Bull, of Middletown, &c., humbly sheweth :—

That your honors' memorialist, being about to set up the manufacture of *wire*, hath turned his attention to the building and works erected at Middletown, &c., for the refinery of lead; which buildings and works, your memorialist is informed, by men skilled in the trade of drawing wire, would answer his purpose exceeding well, &c. The zeal which your honors have at all times, and especially since the commencement of the present war, shown to encourage and promote home manufactures, has induced your memorialist confidently to hope for your honors' patronage, in a branch of business which is likely to be very useful to the public. His only request is, that your honors would permit him to take said buildings and works, and use them for the purpose aforesaid, for the space of seven years, &c.

Dated at Middletown 28 May, 1782. SAMUEL BULL.

(Industry II. 176.)

Referred to a committee; on whose report a committee is appointed, to view the buildings and works at Middletown, and agree with said Bull for their use, &c. (177, 178.)

NAILS.

An Act for the Encouragement of Manufacturing Nails.

Be it enacted, &c. That there shall be paid out of the treasury of this state, a premium on nails manufactured in this state, of the following dimensions, viz: on all nails that shall weigh not more than 13lbs., nor less than 10lbs. per 1000, three-eighths of a penny; on all nails that shall weigh not more than 10lbs., nor less than 4lbs. per 1000, two farthings on the pound; and on all nails of less dimensions, a premium of one penny per pound;—from and after the first day of October next, for the term of 3 years. May 1786.

(Industry II. 215.) Negatived in upper house.

STEEL.

To the Honorable, &c.—May 1728.

The humble memorial and request of Samuel Higley, of Simsbury, and Joseph Dewey, of Hebron, &c., sheweth :—

That the said Higley hath, with great pains and cost, found out and obtained a curious art, by which to convert, change and transmute common iron into good steel, sufficient for any use; and was the very first that ever performed such an operation in America, having the most perfect knowledge thereof, confirmed by many experiments; and hath communicated the same to the above named Joseph Dewey, and jointly with him, have made further experiment and improvement, with considerable cost and labor; and we are thereby well assured, that the art, by good improvement, may redound to the public benefit and advantage of this colony, in that we have good reason to hope that we shall produce as good, or better steel than what comes from over seas, and at considerable cheaper rate. And that the affair be set forward

with the greater expedition and certainty, we propose to take into our company and assistance, four men, more able and of greater ability than ourselves to promote and set forward, to the honor of the British nation and prosperity of this colony.

Therefore we, the said Higley and Dewey, humbly pray this honorable assembly would be pleased to grant to us, your honors' humble petitioners, our heirs and assigns, free liberty to set forward said art, and practice the business or trade of steel making, for the space of twenty years next coming, and prohibit all others that may pretend thereto, within this colony, without our consent: provided we, your petitioners, or any under us, improve the said art to any good and reasonable perfection, within two years from the day of the date hereof, and so long as we shall well prosecute the same as above, and no longer, and your memorialists, &c.

SAMUEL HIGLEY.
(Industry I. 118.) JOSEPH DEWEY.

This may certify to all concerned, that Samuel Higley, of this town of Simsbury, came to the shop of us, the subscribers, being blacksmiths, sometime in June, 1725, and desired us to let him have a pound or two of iron, made at the new works near Turkey Hills, which we, according to his desire, let him have, shaping several pieces according to his order. He desired that we would take notice of them, that we might know them again; for, said he, I am going to make steel of this iron, and shall in a few days, bring them to you to try for steel. Accordingly he brought the same pieces which we let him have, and we proved them, and found them good steel, which was the first steel that ever was made in this country, that we ever saw or heard of. Since which he hath made farther experiments, taking from us iron, and returning it in good steel. As witness our hands, this 7th day of May, 1728.

TIMOTHY PHELPS.
(Industry I. 120.) JOHN DRAKE.

Whereas, &c.

We being willing to give all due encouragement to works of this nature, are pleased to condescend to their request; and do therefore by these presents grant to them, the said Samuel Higley and Joseph Dewey, our license and liberty for the sole practising the said art of steel making, to be and remain to said Higley and Dewey, &c., for and during the space of 10 years, next ensuing this date, strictly forbidding all persons practising the same within this colony, &c., without the consent and approbation of the said Samuel Higley, &c., under their hands and seals, as they will answer the country at their peril; the said Higley having power to take into their company, in and of himself, &c., three partners, and the said Dewey, in like manner, one partner.

Provided, always, that the said Higley and Dewey, &c., improve the art as above, to any good and reasonable perfection, within two years, &c., and so long as they shall prosecute the same, and no longer. May 1728.

(Industry I. 119.)

To the Honorable, &c. Oct. 1740.

The memorial of Thomas Fitch, George Wyllys and Robert Walker, Jr., all of said colony, most humbly sheweth :—

That your memorialists have been at the pains and expense of procuring the art and skill of making and converting iron into steel, and do judge it would be of very considerable advantage to this colony if the same be suitably encouraged and well performed in the same; and that your honors' memorialists are desirous to undertake the business aforesaid, if they may be suitably encouraged therein.

Whereupon, your memorialists most humbly move and pray this honorable assembly to grant us the sole liberty and privilege of performing the said manufactory of making and converting iron into steel, for the space of twenty years; and that your honors may more fully see the thing we desire, and the easier make the said grant, we have drawn a bill for an act for the purpose aforesaid, which we herewith present, and pray your honors to pass the same into your act, or something equivalent thereto. And your memorialists, &c.

New Haven, Oct. 1740.

THOMAS FITCH.
GEORGE WYLLYS.
ROBERT WALKER, JR.

(Industry I. 137.)

Granted for fifteen years, on condition that the said Fitch, Wyllys and Walker, &c., shall neglect to begin and perform said work, within two years after this date, and shall at any time after said two years, neglect to make half a ton of such steel in any one of the years within said term, then this grant and act, in every part thereof, shall be void. (138.)

To the Honorable, &c., October 1743.

Messrs. Fitch, Wyllys & Walker, in their petition add,—Whereupon, we with our assigns, one of whom was the Rev. Mr. Timothy Woodbridge of Simsbury, now deceased, expended a considerable sum of money in making a furnace, and providing other materials, in consequence of said grant, and in pursuance of said design, and had agreed to have made an experiment before the expiration of the said two years; but while we were preparing and before we had got ready, Mr. Woodbridge, on whom our dependence was to prepare and make the experiment, was removed by death, and thereby we prevented doing what we intended, within the limitation aforesaid: And as we are now got in readiness to make the experiment in a short time, and are willing to have the advantage of our risque and expense, and having been disappointed as aforesaid,—we pray your honors to renew the said grant to us and our assigns for the remaining 12 years, on the conditions before made upon, only we are willing that instead of two should be one year to effect the work in, &c.

New Haven, Oct. 18, 1743. Signed as above.

Assembly so renew the grant. (140.) (Industry I. 139.)

To the Honorable General Assembly,

Whereas, the General Assembly were pleased by an act bearing date, October 1740, to grant to Messrs. Fitch, Wyllys & Walker, the sole privilege of making steel, for the term of 15 years, upon this condition, that they should, in the space of 2 years, make half a ton of steel: The aforesaid 2 years being expired, and the condition not complied with,—application being made to the General Assembly in October last, they were pleased to renew the grant, upon condition that half a ton of steel should be made before the setting of the Assembly in October, 1744.

These are to certify and inform your honors, that after many expensive and fruitless trials, with which sundry of the owners were discouraged, the affair being still pursued by others of them, it has so far succeeded, that there has been made more than half a ton of steel at the furnace in Simsbury, which was erected for that purpose by the gentlemen to whom the aforesaid grant was made.

AARON ELIOT,
ICHABOD MILLER.

(Industry I. 141.)

To the Honorable, &c. October, 1744.

They add—And as a specimen of the goodness thereof, to answer the intentions of German steel, I, the said Aaron Eliot, who have had the care and oversight of said business, and performed said work, do herewith present to your honors for examination, instruments made with the said steel, made at Simsbury, aforesaid: And pray in behalf of said grantees and their assigns, that this Assembly would order a record to be made, that the condition of said grant appears to have been fulfilled to the satisfaction and acceptance of this Assembly: which will greatly oblige, &c.

AARON ELIOT, in behalf, &c.

(Industry I. 142.)

Assembly so declare and order, Oct. 1744. (143.)

To the Honorable, &c. May, 1772.

The memorial of Aaron Eliot, of Killingworth, humbly sheweth:

That your memorialist has, for a number of years, carried on the steel manufactory in this colony, and has made very large quantities, sufficient to supply all the necessary demand of that article in this colony, as well as to export large quantities for supplying the neighboring governments; and that the fortune of your memorialist has not been large enough to supply himself with a sufficient stock to carry on the business; and has therefore hitherto been obliged to procure his stock of iron at New York, on credit, and pay for the same in his steel when made, at the moderate price of £56 the ton, from whence it has been again purchased in this colony at the price of £75 and £80 the ton. And for several years past, almost the whole supply of steel in this colony has been from New York, of the manufacture of your memorialist at the aforesaid enormous advance: and your memorialist himself conceives, that the interest of the colony is to encourage necessary and advantageous manufactories within this colony, not only for the necessary consumption of the colony, but for export, which your memorialist will be able to effect, in the aforesaid article of steel, with some small assistance from your honors, to procure him a sufficient stock, and thereby save large sums of money within this colony which is annually paid to New York for the steel manufactured in this colony.

Wherefore your memorialist humbly prays your honors to loan him £500 out of the public treasury, for three years, without interest, whereby he will be enabled to carry on the aforesaid business to considerable public advantage. And he, &c. AARON ELIOT.

(Industry II. 144.)

Assembly granted him said loan, May 1772. (145.)

To the Honorable, &c. The memorial, &c.

Your memorialist further shews, that at present it will be very inconvenient for him to repay said sum, as he hath lost a large quantity of his steel in a store at Boston, where it was deposited for sale; his market at New York is interrupted, and he hath exerted himself to lay in a large stock to supply the demand for steel in this colony, which, in the course of the last summer, is greatly increased; and from the particular situation of public affairs, and from the great difficulty of procuring foreign supplies.

And thereupon he humbly prays that the loan of said money may be continued to him for the space of two years longer, or such lesser term as to your honors shall seem meet: And that a suit which the treasurer hath commenced against him and his surety, upon your memorialist paying the cost that hath arisen, may be discontinued: And your memorialist, if required, is ready to give any farther security that may be demanded.

Dated at New Haven, Dec. 21st, A. D., 1775. AARON ELIOT.
(Industry II. 146.)
Assembly extend the time of payment two years. (146.)

BELLS.

To the Honorable, &c.

The memorial of Abel Parmele, of New Haven, humbly sheweth:

That, whereas, your memorialist has been at great expense of both time and money, in order to gain the art and skill of casting large bells for the use of churches, schools, &c., and hath made such experiments as that your memorialist is well assured that he can perform, to good acceptance, and much for the public advantage of the government: Considering,—

1. Your memorialist can perform the work cheaper, allowing the discount of our currency with that of Great Britain, than it can be brought from foreign parts.

2. The best and principal product of our land will scarce, at any rate, make returns.

3. A great part of the materials of which such large bells are made, are the product of our country, and almost wholly useless for any other service.

4. If a bell should happen to be split, as many are, the recasting again here will save the great expense of transportation, the risque of the seas, &c.

And now your memorialist begs leave to remind this Honorable Assembly, that the performance of such as hath not been attempted, as yet, in the country, and the charge and expense of an undertaking so great; and calling to mind how ready your honors have been duly to encourage such undertakings, and your unwillingness that any suffer thereby; and your memorialist being desirous of reaping the benefit of his own study and industry, humbly requesteth of this Honorable Assembly, that he may have the whole profit and management of said affair of making and vending large bells within this colony of Connecticut, for the space of 20 years next coming: And that for the term aforesaid, no other person without the license of your memorialist, shall, within this colony, presume to set or make any bell of a larger size than 10 inches diameter, or for some shorter term, or some other way, as you, in your great wisdom think best, to encourage your humble memorialist. And your memorialist, as in duty bound, &c.

New Haven, Oct. 19, 1736. ABEL PARMELE.
Negatived in both Houses. (Industry I. 129.)

POLISHING CRYSTALS.

To the Honorable, &c.

The memorial of Abel Buell, of Killingworth &c., humbly sheweth:

That your memorialist having been convicted &c., of being guilty of altering the bills of public credit of this colony, &c. And whereas, this Honorable Assembly did so far compassionate the youthful follies of your memorialist as to give him enlargement from prison, where, by the laws of this colony, he was sentenced during life, and permitted him to dwell with his family in Killingworth, &c. Since which, duly sensible of his past error and offence, for which he justly suffered, he has with diligence applied himself to industry for the support of his family. And your memorialist would humbly beg leave to inform your honors, that in prosecuting the business of his calling, he hath discovered a method of grinding and polishing crystals and other stones of great value, all of the growth of this colony, and that without the aid or direction of any person skilled in the art, by which discovery, a great saving and advantage will accrue to this colony, by preventing the importation of such stones from abroad: And whereas, by the late laws of this colony, this Honorable Assembly were pleased to offer a premium to any person who should make any useful discovery for the advantage of this colony; your memorialist relying on the mercy and clemency of this Honorable Assembly in forgiving offences, on proper evidence of repentance and reformation, is encouraged to implore their gracious interposition, and that your honors would restore your memorialist to those liberties and privileges which he has justly forfeited, at least so far as may enable him to carry on the business, in all its branches, of so useful a discovery made by your memorialist, so as to render the same extensively advantageous to the colonies in general, and to this government in particular. And your &c. ABEL BUELL.

Dated in Killingworth, 8th day of Oct. A. D. 1766. (Industry II. 126.)

Certificate of justice of peace and townsmen, to his good behaviour, Oct. 8, 1766. (128.)

He is restored to all those liberties and privileges by him forfeited, on giving bonds, &c. (127.) [See the following memorial.]

TYPE FOUNDING.

To the Honorable, &c., October, A. D. 1769.

The memorial of Abel Buell of Killingworth, &c. humbly sheweth:

That your memorialist having experienced the great goodness of this Honorable Assembly, for which he begs leave to render his most grateful tribute of thanks, and to assure them from a grateful sense of their clemency, he has made it his unwearied study to render himself useful to the community in which he lives, and the American colonies in general; and by his unwearied application for a number of months past, has discovered the art of letter founding. And as a specimen of his abilities, presents this memorial impressed with the types of his own manufacture: And whereas, by an ancient law of this colony, this Assembly were graciously pleased to enact, that any one who should make any useful discoveries, should receive an encouragement therefor, from this Honorable Assembly; and as the manufacture of types is in but few hands, even in Europe, he humbly conceives it to be a most valuable addition to the American manufacture; and as the expense of erecting a proper foundry will be great, and beyond the abilities of your memorialist, he humbly hopes for encouragement from this Assembly, either by granting him the liberty of a lottery for raising a sum sufficient to enable him to carry on the same, or in some other, &c. ABEL BUELL.
(Industry II. 137.)

[The type, about Brevier with Bourgeois body, is more beautiful that any specimen we have seen of that period, and the impression better than the present average of Congressional Documents.]

Referred to a committee who report. (138.)

We have conferred with said Buell, &c., and are fully convinced that he hath discovered the art of letter founding; and that he is capable of making instruments necessary for the proper apparatus of letter founding, &c.

And on their recommendation the Assembly resolve, That the treasurer of the colony be, and he is hereby directed to pay out of the public treasury to said Buell, £100, upon his giving bond, &c. in the sum of £200 condition, that he set up and pursue within one year next after the receipt of said £100, the art of letter founding in this colony, and not depart therefrom to reside in any other province or colony within seven years next after the receipt of said money, and re-pay said £100 at the end of said seven years; and that in case said Buell pursues said business in this colony, the space of 12 months after receiving said £100, the treasurer is hereby further directed to pay said Buell one other £100, (payable as above,) &c. (139.)

Sir:—The long absence of my husband, makes me almost despair of ever seeing him again, &c. When he left me, it was unknown to me that he was so much involved as he was; and in a very few days, every thing was seized from me. I have by dint of industry got together so much, that I can now refund the money which he had of the state, &c. If, therefore, the £100 can be accepted in full for the demand against us, I am ready to pay it, &c.

I am, &c.,
ALETTA BUELL.

New Haven, August 8, 1777. (Industry II. 158.)

Assembly order the bond to be given up on the payment of said £100 August 1777. (157.)

(Abel Buell's name again appears among the petitioners of New Haven, for a tariff of duties on imports, October 12, 1785.) (Industry II. 201.)

PIN MANUFACTURE.

To the Honorable, &c.

The petition of Leonardus Chester of Wethersfield, &c., humbly sheweth:

Whereas, we are obliged totally to withdraw commerce from the parent state, and we have wantonly and negligently been dependent on them for most of the ornamental, as well as useful articles of life, to the almost entire neglect of manufactures and arts,—those stabilities of wealth and affluence—esteeming it a surer and easier method to gain wealth and riches by agriculture, yet drove to the last resource of breaking off all connection, which has, to mutual advantage, so long subsisted, we find that our dependence has been so great and universal, that we sensibly feel it in the minutest trifles. And to avoid the discomfitures and sufferings, we might otherwise subject ourselves to, it behooves every well disposed mind to parry the thrust by every lawful method in his power, as well individuals as societies of men.

Actuated by these principles, your petitioner has turned his attention to *arts* and *manufactures*, and while others have been industriously busied investigating some method to end the present grand dispute, your petitioner has been engaged as far as in him lay, and perhaps as far as any individual in this colony, to make provision for an easy contest, and has with great expense, erected a manufactory house, and engaged a number of useful and necessary manufacturers in various branches in a particular manner. The pin manufactory never before attempted in this colony, which at first blush to a person unacquainted with the work, would seem so diminutive and trifling as to the expense, that any person of a moderate fortune, might attempt and execute within himself; yet your petitioner begs leave to acquaint this Honorable House, that although he did most minutely and critically sit down and count the cost, it has, owing to innumerable embarrassments and difficulties, surpassed his calculation. Under all embarrassments, he has, however, thus far completed the works, that he can by samples, demonstrate, that they can be made as well as in London, and upon as fixed principles, saving the prime cost and charges of the wire; which to carry into an extensive execution, will demand a larger capital than your petitioner, exclusive of his other business is able to advance, especially at the dead crisis of collecting debts.

Your petitioner, therefore, by advice of his friends, and numbers of well disposed persons of worth, has taken this method, and humbly prays that this Honorable House will be pleased to look into the premises, and appoint a committee to inspect the works, and report the practicability of its execution, and certainty of an easy supply of that article, though trifling at first view, yet essentially necessary to the community, and on that principle *important*, as every individual will be affected by the want, which said committee may be vested with such power as to advance such a sum of money from the public treasury upon good security, as shall execute the design: Or, as the call is at present so loud, and a considerable sum of money might profitably be advanced for wire, which might immediately be worked up to advantage, judging, that at this time of stagnation of cash, your petitioner as aforesaid, not being able to collect his dues, this House would not wish that your petitioner should be obliged to part with his paternal interest for the service of his country; that they would encourage him by bounty, or a loan of a certain sum for a certain time, interest free; the way your Honors shall think most eligible, will confer a favor and advance the public good. And your petitioner, &c.

LEONARDUS CHESTER.

Wethersfield, December 21st, 1775. (Industry II. 153.)

Referred to a committee who report:—

That one method of encouraging said manufacture may be by premium or bounty.

** That a bounty or premium of 3d. on the pound may be proper to be given for every pound of good merchantable pins that shall be made in this colony within one year, &c.; and 1d. on the pound, &c., the next year after, &c.

We beg leave further to report, that Mr. Leonardus Chester, appeared before us, and represented that he had contracted with, and hired a workman and five hands well skilled in the pin manufactory, and hath already advanced £1700 towards providing buildings, tools, machines, and materials for carrying on the manufactory aforesaid. That the expense of setting up the same greatly exceeds his expectations. That his stock is so far exhausted in preparations, that he is not able to procure stock to employ said workman. And that in case he could be indulged with a sum of money for a term, interest free, he would be willing to submit to the following conditions, to wit: that his manufactory should be open to the inspection of the General Assembly, that he would be laid under obligation to sell his pins at a reasonable profit, to be determined by the General Assembly, and give security to apply the money received wholly to carry on said manufactory under penalty, &c. Whereupon, &c. a loan of money, without interest, to said Chester, is another method by which said manufactory may be encouraged, &c. (154.)

After disagreeing votes, the Assembly order a continuance to the next session. So it ended.

CLOCK THAT SHALL WIND UP ITSELF.

To the Honorable, &c.

The petition of Benjamin Hanks of Litchfield, humbly sheweth to your Honors :—

That your petitioner after unwearied trouble, pains, and study for a number of years now last past, in search of mechanical knowledge, not only for his own pleasure and amusement, but for the benefit of mankind, has made a large improvement thereon, by inventing, contriving and executing a clock or machine that winds itself up by help of the air, and will continue so to do without any other aid or assistance, until the component parts thereof are destroyed by friction; which will keep the most regular time of any machine yet invented, as it is ever wound without any variation or stop to her motion, and consequently not only a great ornament, but improvement in mechanism, which your Honors' petitioner will submit to your Honors, and beg them to take the matter into their wise consideration; and as he has been at great pains, trouble and expense, in accomplishing the same, that they would graciously grant unto your petitioner, the sole and exclusive right and privilege of making and vending said kinds of clocks for the term of 14 years, or some other way, &c.

BENJAMIN HANKS.

Dated at Litchfield, this 6th day of October, A. D. 1783.

(Industry II. 181.)

Lower House at first, negative his petition; but finally, such exclusive privilege is granted. (182.)

STEAM ENGINE.

To the Honorable, &c.

The petition of Barnabas Deane humbly sheweth :—

That your petitioner, for valuable considerations given to certain ingenious persons in Great Britain, the first and original inventors of the new improved steam engine, (who, by act of Parliament of Great Britain, have an exclusive right to construct and use the same within that kingdom, for the space of 25 years :) your petitioner has acquired a perfect knowledge of the construction thereof, with new improvements, and the application thereof to a great variety of important purposes; such as the raising of water, the manufacturing of iron, and to the working of corn mills, saw mills, and of mills of every kind. Your petitioner, therefore, humbly prays that an act of assembly may be passed, to give and grant to your petitioner, and to his heirs and assigns, the sole and exclusive right and privilege of erecting and making use of the aforesaid steam engine, for the purpose of manufacturing of iron, and of working of corn mills, saw mills, and mills of every other kind, for and during the term of 20 years from the date of such act or grant, in and throughout this state. And your petitioner, &c.

BARNABAS DEANE.

Dated in Hartford, May 27th, 1786.

Negatived.

(Industry II. 213.)

John Fitch, the inventor of the *Steamboat*, was a native of Connecticut, and it is said, made his first experiments in the Connecticut river.

Ship Building has ever been carried on from the earliest period in Connecticut, but no special privileges were ever granted.

DRILL PLOUGH.

To the Honorable, &c. Oct. 1771.

The petition of Benoni Hilliard, of Saybrook, humbly sheweth :—

That the society established in London, Anno Domini, 1753, for *Encouragement of Arts, Manufactures and Commerce*, in order to incite and stimulate persons to make improvements in the arts and in manufactures, and to the discovery of further advantages in commerce and agriculture, and every useful part of learning, from time to time, have given præmia on new inventions, proving useful either in the culture of lands, or in further promoting and advancing the arts, manufactures or commerce; and more especially, on the 10th of April, A. D., 1765, at a meeting of members of said society, in the *Strand*, in London, duly convened according to the rules and orders of said society, they voted a premium of fifty pounds sterling for the best drill plough that should drill, sow and cover the corn or seed at the same time, being an improvement upon such drill ploughs as were then already known or in use. And said society, on the 30th of May, A. D., 1764, resolved, that no member of said society should thereafter be a candidate for, or entitled to receive any premium, bounty or reward whatsoever, except the honorary medal of said society. And your petitioner, being under low circumstances, was moved and induced by the said offer of the premium of fifty pounds, as aforesaid, to undertake to make a drill plough, such as should be an improvement on all drill ploughs at that time known and in use; and after much time, study and perplexity of mind, effected the same, and constructed a drill plough, such as he judged would merit the premium offered as aforesaid. And your petitioner being a person of obscure life, and little acquainted with persons of rank and figure, in order to obtain said premium, applied to Benjamin Gale, Esq., of Killingworth, &c., a neighbor to your petitioner, and who was also a corresponding member of said society, to advise and assist him in procuring said bounty and premium. And said Gale undertook to negotiate and transact said business for your petitioner, so as to obtain said premium; and in consideration thereof, your petitioner was to give said Gale one-half said premium when received, as a reward for his services in procuring the payment thereof; and as it is contrary to the rules and orders of said society, for any member to receive a bounty; and also by the rules and orders of said society, if any person should be detected in any disingenuous methods to impose on the society, such person shall forfeit the bounty for which he is a competitor, and be deemed incapable of obtaining any premium thereafter: It was therefore agreed between said Gale and your petitioner, to keep secret the aforesaid bargain respecting the division of said premium, and that said Gale should solely transact all matters relating to the obtaining the premium aforesaid. And your petitioner, confiding in the honor and fidelity of said Gale, in the matters aforesaid, sometime in the year 1765, delivered the said drill plough, by him solely invented and constructed, unto said Gale, that he might transmit the same to said society, and obtain the premium therefor, if the same should be judged to merit the offered bounty, to be divided as aforesaid. And said Gale received the said plough for that purpose; and said Gale having so gotten said plough into his possession, in order to procure a great name and character of a person of skill and ingenuity, and to spread abroad his fame and reputation, did most unjustly and falsely write and declare to said society that he, said Gale, was the sole inventor and constructor of said plough; and said society having received said plough, adjudged the same to merit the offered premium, as aforesaid, and to be a great and valuable improvement on all drill ploughs before known and in use. But the said Gale being a corresponding member, by the rules and orders aforesaid, could not receive the bounty aforesaid, (he being supposed to be the inventor and constructor of the aforesaid plough) and therefore said society struck a golden honorary medal for said Gale, to perpetuate his fame and reputation as a gentleman of a fruitful invention, and very useful to his fellow-men in his day and generation; which medal said Gale has received, and the same is in value, in money, worth £7. 10s. L. M. By all which misrepresentations and fraudulent transactions of said Gale, your poor petitioner has lost the benefit of the premium aforesaid, is defeated in his expectations, by the fallacious and fraudulent doings of said Gale as aforesaid, and said Gale refuses to pay and satisfy your petitioner any part of said £50. Your petitioner would further represent to your honors, that as said Gale is and was a gentleman intrusted in many and important places of public trust, the execution of which, your petitioner conceived, would never be committed to any but such as your honors esteem to be persons of fidelity and virtue, he in his humble station was induced, by the public character of said Gale, to put great confidence and trust in him, and thereby, in some parts of the aforesaid representation, may not be able fully and clearly to evince the same, without the testimony of said Gale, or of your petitioner; although he is able, he conceives, to render the same highly probable in every part thereof, by other and disinterested witnesses, and in many of the material parts thereof, fully to evince the same.

Wherefore, your petitioner humbly prays your honors, by yourselves or a committee, to inquire into all the aforesaid matters, by the oaths of the parties, and other evidence, or otherwise, as shall be thought fit; and that said Gale may be, by your honors' decree, held to pay and satisfy your petitioner the sum of £50 sterling, or such part thereof as your honors shall think just and reasonable, or in some other way, &c.

Dated in Saybrook, August 22, A. D., 1777.
(Industry II. 148.) BENONI HILLIARD.
Petition was withdrawn.

POTTERY.

To the Honorable, &c.

The memorial of Samuel Dennis, of New Haven, humbly sheweth:—

That he is acquainted with the potter's business, and is about to erect a stone pottery; and there is in this country a plenty of clay, which he presumes of the same kind with that from which the queens-ware of Staffordshire is usually made; and that he wishes to erect a pottery for the purpose of manufacturing the finer kinds of ware usually made in Staffordshire, particularly the queens-ware; that the expense of this undertaking, of procuring the requisite information, and the workmen acquainted with the business, is too great for his property. Your memorialist conceives that the public would be so greatly benefited by a work of this nature, and particularly by obtaining and diffusing the knowledge of the business, that your honors will readily afford him some assistance. The manufacturing of those articles would be attended with not only the advantage of saving the expense in the country, but would probably, in a short time, very greatly reduce the price of them, as they now come to the consumer at two or three times the original cost, by reason of the high freight and other charges. Your memorialist thinks, that by the aid of £250 or £300, he could complete the business, and he would give sufficient security to lay out the money for the aforesaid purpose, and to repay the sum within three years. Your memorialist, therefore, prays your honors to loan him that sum without interest, for said three years, on those conditions, &c. SAMUEL DENNIS.

New Haven, October 9, 1789.
Negatived. (Industry II. 242.)

GLASS.

To the Honorable, &c. May, 1747.

The memorial of Thomas Darling of New Haven, in the county of New Haven, humbly sheweth to this Honorable Assembly:

That whereas, your memorialist has taken pains to inform himself in the art and mystery of making glass, and is persuaded that, by your Honors' leave and with proper encouragement, he can carry on the affair, so as to be beneficial both to himself and this government. The charge for setting up works for that business being great, and some considerable length of time required before they can be profitable—For

First.—He may be obliged to send to England for workmen, not being able to procure them at Philadelphia, and they main't be able to get here in a year or two, by reason of the difficulty occasioned by the war.

Secondly.—It will take considerable time to build the furnace, for it is dubious, whether the clay may be found here, either to build the furnace of, or to make the pots that contain the metal.

Thirdly.—There may be much time spent in experiments upon sand: for though all sand contains a glass, yet it may not answer either as to the quantity or quality; for some sand yields so little, that costs of fluxing and blowing could never be answered; and other sand, though it may yield in good proportion, yet it main't be sufficiently transparent, which is the peculiar excellency of glass.

Many other difficulties your Honors can easily perceive, may arise in an affair so great with so many dependencies, so that your memorialist main't be able to carry on the affair, either for his own benefit, or the public's in 4 or 5 years.

Wherefore, he humbly prays this Honorable Assembly, would grant your memorialist and his assigns, by your Honors' patent, the sole liberty and privilege of manufacturing and making glass within this government, for the space and term of 25 years next coming, or as long as your Honors shall think fit. And your, &c

THOMAS DARLING.

Hartford, May 1747. (Industry I. 159.)

On the memorial, &c.

It is resolved by this Assembly, That the memorialist and his assigns, shall have the sole liberty and privilege of making and manufacturing glass in this colony, &c. for the space of 20 years from this time; and all and every other person and persons are hereby forbid and prohibited setting up, erecting, and carrying on any works, buildings, or materials for carrying on the business of making glass as aforesaid, in this colony for the space of 20 years next coming, without the liberty of the memorialist or his assigns, on penalty that every such person or persons so doing, shall forfeit the sum of £1,000 money, to be recovered, &c.

Provided, nevertheless, that if the memorialist and his assigns shall neglect or fail to erect, set up and prepare suitable works and materials for the making of glass, as aforesaid, for the space of 4 years, or shall fail of making the quantity of 500 feet of good window glass, in any one of the remaining 16 years, after the aforesaid 4 years, that then this grant and every part thereof, shall be void, &c.

May 1747. (Industry I. 160.)

To the Honorable, &c.

The memorial of Elijah Hubbard of Middletown, Isaac Moseley of Glastenbury, Wm. Little, Jr. of Lebanon and Pickett Latimer of New London, &c., humbly sheweth:—

That they are desirous to erect a glass house, and set up and carry on the manufacture of glass of various kinds within this state. That upon inquiry, they find the introducing this manufacture into the state, will be attended with great expense and risque; and in case of success, will not be attended with sufficient profit to compensate the trouble and expense, if others availing themselves of the labors and experience of the first adventurers should establish rival works, as soon as they have collected workmen, and overcome the difficulties of a new adventure, in a manufacture hitherto unknown in this state.

Whereupon, they humbly pray your Honors to extend your gracious encouragement and protection to them; and upon condition, that they do within one year erect a glass house, and begin to manufacture glass within this state, for and during the term of 20 years next ensuing,—or for and during such term as to your Honors shall seem meet. And they, &c.

ELIJAH HUBBARD, *et al.*

Dated at Hartford, this 18th day of October, A. D. 1779.

(Industry II. 169.)

Granted during the pleasure of the Assembly. (168.)

To the Honorable, &c.

The memorial of Isaac Moseley and William Little, Jr., &c., humbly sheweth, &c.

..* That the said Hubbard and Latimer, upon consideration of the great expense and risque to be incurred, have declined to proceed further in said business; and that your memorialists, earnestly desirous to proceed in said business, have, at much expense of time and money, endeavored to inform themselves of the necessary cost of erecting works, and setting up said manufactory, and find that the cost of works, utensils and lands, will amount to about £3,000, L. M. as in 1774: That a number of able and experienced workmen may be obtained at a great expense, who are, nevertheless, slow to engage upon account of the expense and damage arising to them, by removing their families, &c. Your memorialists are willing yet to risk their time and fortunes in an attempt to introduce so useful and necessary a manufacture, but do not think themselves able to do it without some further encouragement from the public.

And thereupon, they humbly pray your Honors to grant them liberty [to raise] £2,000 in good and lawful money, or the value thereof in bills by lottery, as your Honors shall think meet, under such restrictions and regulations as may be judged proper, to enable them the better to set up and introduce said manufacture, or in some other, &c.

ISAAC MOSELEY.
WILLIAM LITTLE, Jr.

Dated in Hartford, the 8th day of June, A. D. 1780. (Industry II. 173.)

Upon the memorial, &c.

As a further encouragement to their undertaking and carrying on so useful and necessary a manufacture, [they] shall have and enjoy the sole and exclusive right of manufacturing glass within this state for 15 years, from and after the 1st day of July, 1780, upon conditions that they establish such manufactory as aforesaid, by the 1st day of November, 1781, and that, from that day forward, during the continuance of this grant, carry on in a regular manner, the business of such manufactory, so as to furnish for sale the usual quantities of glass, which are commonly made and sold at such kind of manufactories. (Industry II. 174.)

To the Honorable, &c.

The memorial of Wm. Pitkin, Samuel Bishop and Elisha Pitkin, humbly propose to your Honors—

Whether manufacturing glass in this state will not be for the public emolument of the same; and if it be thought an object worthy the attention of your Honors, they will, if properly encouraged, erect works and pursue said business. Money out of the public treasury in this distressing day, we do not expect; but an exclusive right to such manufacture, such length of time as may be thought proper to save them the great expense that will be necessary in buildings, &c. for said purpose, &c. And if the proposal meets your Honors' approbation, we pray a committee to hear your memorialists in the premises, and report, or any other way, &c.

WM. PITKIN
SAMUEL BISHOP.
ELISHA PITKIN.

Hartford, January 28th, 1783. (Industry II. 179.)

Referred to a committee, who report. (179.)

It will be a benefit to this state, to grant to the memorialists an exclusive right of manufacturing glass, for the term of 25 years, from and after the time they shall begin the first blast. And that the memorialists ought to be exempted from all assessments on account of the profits which may arise by manufacturing glass for the term of 10 years, from the rising of this Assembly.

Granted, on condition they begin manufacturing within three years.

(Industry II. 180.)

To the Honorable, &c. Oct. 1789.

The memorial of George Pitkin, Richard Pitkin, Wm. Pitkin, Jr., George Pitkin, Jr., and Richard Pitkin, Jr. of East Hartford, &c.; Aaron Bissel, Epaphias Bissell, and Daniel Ellsworth of East Windsor, and George Hale of Glastenbury, &c., humbly sheweth:

That your memorialists, conceiving that the erecting of glass works would be of public utility, and hoping they would prove to be of private advantage, have been at great expense in erecting buildings and furnaces, and providing materials, and procuring workmen for the purpose of establishing and carrying on a glass factory. That besides, &c., they have been subjected to great losses and disappointments, by means of one Robert Hughs of Boston, who entered into partnership with the memorialists, and engaged to furnish a large proportion of the stock for carrying on said factory; and who having induced your memorialists to believe, that he was a person well skilled in the aforesaid manufactory, was by them appointed and employed to superintend, and direct the business of their glass works; but the said Hughs utterly failed of furnishing stock, and also proved by his subsequent conduct, to be totally un-

skilled in the business of said factory. And the memorialists ...

skilled in the business of said factory. And the memorialists would further represent to your Honors, that the expense of carrying on said factory is greater than they expected, &c. That notwithstanding the aforesaid losses and disappointments, as the memorialists possess buildings, and have a considerable stock on hand, to be employed in said factory, they have proceeded to engage a number of workmen, and with such encouragement as might be afforded by the Legislature, without being burdensome to the public, they think they might prosecute their undertaking with success. The memorialists, conceiving that the prosperity of the State is intimately connected with the introduction and improvement of manufactures, and that the making of glass is one of the most important manufactures that can be introduced among us, &c., pray your Honors to interpose and grant them a lottery for the purpose of raising the sum of £400, &c. GEORGE PITKIN, *et. al.*

East Hartford, Oct. 6, 1789. (Industry II. 239.)

Lottery so granted, and managers appointed. (240.)

PAPER.

Upon the memorial of Christopher Leffingwell, of Norwich, &c., preferred to this Assembly, &c., May, 1768, and by continuance comes to this Assembly, shewing that he hath, at great expense, erected a paper mill in said Norwich, and procured workmen for the making and manufacturing various kinds of paper, &c., praying that a bounty may be granted him, on all paper made and manufactured in his said paper works, &c. And farther, it appearing to this Assembly that sufficient materials for making paper are and may be had in this colony.

Resolved by this Assembly, that the said Christopher Leffingwell be allowed and paid out of the treasury of this colony, two pence the quire on all good writing paper, and one penny the quire on all printing and coarser paper, that shall be made and manufactured in said paper mill, during the pleasure of this Assembly.

And it is farther resolved, that the said Christopher Leffingwell shall render an account annually, to the treasurer of this colony, of the quantity and kinds of paper made and manufactured in said paper mill in each year, duly attested upon oath, and upon his producing such account duly attested as aforesaid to the treasurer of this colony, the said treasurer is hereby directed and ordered to pay the said bounty as above stated, annually, at the expiration of each year, from and after, &c. May 1769. (Colony Records X. 439.)

At the end of the first year, May 1770, Leffingwell presented his affidavits and bill for manufacturing

4,020 quires of writing paper at 2d.	£33 10*s.* 0*d.*
10,600 " printing &c., paper, at 1d.	48 6*s.* 8*d.*

Which was paid him, and bounty discontinued.

(Industry II. 140 to 142.)

To the Honorable, &c.

The memorial of Hannah Watson and Sarah Ledyard, of Hartford, humbly sheweth:

That their lately deceased husbands, Ebenezer Watson and Austin Ledyard, in their lifetimes, and a few years since, had jointly, and at great expense, erected a paper mill in East Hartford, complete and excellent as any one upon the continent, and which had now begun to be of advantage to the owners, and great utility to the public, as it wholly supplied the press of

Hartford, (from whence issue weekly more than 8,000 newspapers) a great part of the writing paper used in the state for one year past, and had supplied large quantities for the use of the continental army, and officers: but most unfortunately for the memorialists, on the night after the 27th inst., in a manner to them unknown, (though suspected to be by means of some evil minded person) took fire and was wholly consumed, with all the effects therein, being about 20 reams of paper, and materials for 300 more, &c. Capital loss of more than £5,000, &c.

Dated at Hartford, Jan. 28, 1778. HANNAH WATSON,
(Industry II. 159.) SARAH LEDYARD.

Assembly grant them a lottery to raise £1,500. (160.)

TORPEDO.

(Of this important invention to destroy an enemy's shipping, but little appears on the files and records.)

At a meeting of the Governor and Council of Safety, Feb. 2, 1776—

Mr. [David] Bushnell was here by request of the Governor and Council, &c., and gave an account of his machine contrived to blow up ships, &c., and was asked many questions about it, &c., &c.

Voted, That we hold ourselves under obligations of secrecy about it. And his Honor the D. Governor is desired to reward him for his trouble and expenses in coming here, and signify to him that we approve of his plan, and that it will be agreeable to have him proceed to make every necessary preparation and experiment about it, with expectation of proper public notice and reward. (Council of Safety I. 73.)

Feb. 3, 1776.—Moved by the Governor, by motion to him from Governor Griswold, that some encouragement should be given to enable Mr. Bushnell to pay expenses incurred in preparing his machine for the design projected, &c., and to carry forward the plan &c., &c., it appearing to be a work of great ingenuity, &c. &c., a prospect that it may be attended with success, and being undertaken merely to serve the public, and of considerable expense and labor, &c. It is thought reasonable that something should be done, &c.

Voted and ordered, That the treasurer pay and deliver to his Honor, the Deputy Governor, the sum of £60, to be by him improved for the use of the colony and public, according to instruction from the board.

(Council of Safety I. 76.)

WATER MILLS.

To the Honorable, &c.

The memorial of David Bushnell, of Saybrook, in New London county, humbly sheweth—

That your memorialist, after long application to mathematical and philosophical studies and frequent and expensive experiments on mechanical improvements, hath discovered a new method of constructing water mills in such a manner,—by projecting the flume under the water wheel, so that the aperture through which the stream flows against the wheel, shall be advanced beyond a line let fall perpendicular from the extremity of that part of the wheel which is nearest the pond, and by placing the buckets of the water wheel obliquely to the radii of the wheel, and perpendicular to the stream which turns it,—that the force, action and impression of the same stream in turning the mill will be greatly increased, and in many cases, trebled beyond what it can be in mills of the usual construction: And has also discovered a further valuable improvement in grist mills, by fixing the rounds or leaves of the trundle head, so as to swivel or turn in the trundle head, whereby the friction in turning the mill will be greatly diminished: Which improvements, the memorialist conceives, will be of general utility to the public. And whereas, for perfecting and completing said invention and improvement, the memorialist finds it necessary to put himself to considerable additional expense, and employ his time and attention for a proportionable period.

Wherefore, your memorialist humbly prays this Honorable Assembly to grant him the sole right of constructing, altering and repairing water mills in the State, in the manner and according to the improvements above described, for such term as shall be adjudged reasonable, as a compensation to the memorialist; and further order and enact, that whoever, within this State, shall, during such term, construct, alter or repair any water mill, in the manner and according to the improvements aforementioned, either in part or in the whole, without license from the memorialist in writing first had and obtained, shall forfeit and pay to the memorialist such penalty as your honors, in your wisdom shall judge proper. And your memorialist, &c.

DANIEL BUSHNELL.

Dated at New Haven, this 28th of Oct. 1784.
Negatived. (Industry II. 189.)

PERPETUAL MOTION BY WATER.

To the Honorable, &c.

The petition of Harris Ransom, of Colchester, in said State, humbly sheweth:

That your petitioner, at great expense, with much pains, labor, and study, has obtained the art or mystery of making a perpetual motion of water, whereby he is able and can raise the water from any river, pond, spring or fountain, to the height of 30 feet perpendicular, and convey the same to any parts of any towns or cities, or return the same to the original fountain or head, which said performance will be of great advantage, not only to the petitioner, but to the public in general, by affording them at all times, good and wholesome water at a very trifle of expense; and also will provide all towns and cities with constant and unfailing streams, sufficient for the carrying any iron works and mills of all kinds:

Wherefore your petitioner humbly prays this Assembly to grant unto him and his heirs, a full power and license, under certain restrictions, to set up and erect his said works within this State, and that no person shall be allowed to set up any such works after the pattern of those by your petitioner so set up, within the term of 20 years, without a license first had and obtained from your petitioner; and that all such machines, mills, &c. set up by your petitioner for his own improvement, shall be free from all taxes and assessments for the term of 100 years, and that all such works set up by others licensed by the petitioner's license shall be free from all such taxes for the term of two years after erected. The petitioner being restricted in setting up his said works, not to obstruct any water to the damage of any individual person, or to the public in general. No action by Assembly. (Industry II. 216.)

Filed—"Prisoner in goal, memorial."

To the Honorable, &c.

As there is a new discovery of raising the water up, so as to turn it out of the valleys, and turn it into the hills to water the dry land, and to carry mills or to carry iron works or any other water craft, to water cities and towns, to drain dead swamps and ponds—since the thing is so profitable to this State, 'tis the earnest request of us all as one, that this petitioner's petition may be heard and granted him. Signed by ISRAEL NEWTON,
and 8 others.

(Industry II. 217.)

TIDE MILLS.

To the Honorable, &c.

The memorial of John Shipman, of Saybrook, in New London county, humbly sheweth:—

That by reason of extreme drought, the inhabitants of sundry towns in this colony, have been greatly distressed, as well for want of grinding grain, as in other respects; an instance of which is in the town of Saybrook, especially the first parish, where there hath not been, for four months next before the 18th inst., twenty bushels of grain ground in said parish; and the inhabitants have been obliged to carry all their grain out of town, in order to have it ground, and great part of it more than twenty miles, at great expense of time and money, and are now reduced to the necessity of carrying it to Long Island, and have been sundry times obliged to leave it, for want of wind to carry the wind-mills, and the inhabitants in the meantime distressed, for want of bread; by which your honors' memorialist hath been induced to turn his mind much on the subject of mills, especially such as might be made by salt water. And as the tides in the salt water creeks towards the eastern part of the colony, especially where they run near the uplands, don't ordinarily ebb and flow more than two feet and a half, it renders the use of salt water for the purpose aforesaid, very difficult. Yet your honors' memorialist is confident, that by close application and hard study, he has been so happy, though master of but little philosophy, as to hit on a plan on which he can build a grist-mill, though with something more than the ordinary expense, that will grind well and to good purpose, 12 hours in 24; and he verily believes, may be so constructed as to go continually, as long as wood and iron will last, without exhausting any considerable part of the water; and as such a discovery, if he should succeed, would be more beneficial to the people in general, especially on the sea shore, than to the particular owner, your honors' memorialist is encouraged to hope that your honors will do something to encourage him in such an undertaking. Therefore, your honors' memorialist, believing in your honors' good disposition to promote a design of such public utility, humbly prays your honors to grant him proper encouragement, either by way of a lottery to raise such sum as your honors shall think best, or a sum by way of premium, to be advanced on the completion of the proposed machine, in case he should succeed; and previous to the undertaking advance £100, or such greater or lesser sum as your honors shall judge fit, by way of loan without interest, for such number of years as your honors shall judge fit; or grant him the privilege of such a constructed mill, to the exclusion of other persons; or in such other manner as your honors, in your great wisdom shall devise. And your, &c.

JOHN SHIPMAN.

Dated at Saybrook, the 19th day of October, A. D., 1773.
Referred to a committee. (Industry II. 149.)
Upon the memorial, &c.

Resolved by this assembly, that the memorialist, &c., have the full and exclusive privilege of constructing, erecting and improving a tide grist mill, on the plan and construction proposed, for the term of forty years, at all places within said town of Saybrook, and within ten miles westward of Connecticut river; provided the memorialist, &c., do erect such mill within the term of five years next ensuing, and constantly keep up the same fit for use and improvement, so as to be beneficial to the public. And all persons are hereby prohibited from erecting or improving any tide grist mill, for the term aforesaid, within the limits aforesaid, without the liberty of the memorialist, &c., on the penalty of £50, L. M.

January 1774. (Industry II. 150.)

CLOTH MANUFACTURE.

To the Honorable, &c.

The memorial of Samuel Loomis, of Colchester, &c., humbly sheweth :—

That he has by great labor and pains, acquired a knowledge of erecting works for the manufacturing of wool, cotton, hemp, flax and silk, upon a new constructed plan, according to certain plans herewith exhibited, which may be done by hand or by water works; and that he can, by such machinery, perform the whole process of taking the aforesaid articles in raw materials, and making them into cloth, in a much easier manner than any now in practice, by which our manufacturers may be encouraged, the price of such cloth lessened, and vast sums of money saved in the state. And your memorialist would represent, that in case the raising of hemp in this state should succeed according to the encouragement given, that he should, by the aforesaid works, be able to manufacture a sufficiency of duck to supply a considerable part of the shipping of the state.

Your memorialist further represents, that said works cannot be erected without the expense of about £2000 L. M.; and that no individual will venture upon so great an undertaking without the public encouragement and security of enjoying the exclusive right and privilege of taking the profits resulting from such an enterprise, until he has reimbursed to himself the expense of erecting such works.

Your memorialist, therefore, prays your honors to take this matter into your consideration, and to grant to him the *sole and exclusive right and privilege* of erecting machines and works for the purpose of manufacturing the articles of wool, cotton, hemp, flax and silk, in the manner aforesaid, within this state for the term of fourteen years; and also grant to your memorialist the sole and exclusive right and privilege of manufacturing the aforesaid articles in such works by him erected, for the term aforesaid; or in some other way grant to your memorialist such public encouragement as the importance of the undertaking justly merits. And your petitioner, &c.

Dated at Hartford, May 28, 1787. SAMUEL LOOMIS.

(Industry II. 218.)

Plans or diagrams presented by petitioner.

For spinning cotton and wool, ... (219)
" Loom, ... (220)
" Carding, ... (221)
" Spinning flax and hemp, ... (222)

Referred to a committee, who report :—The committee conceive that the interest of this state is concerned to promote various manufactures, and particularly of this kind, as this will find useful employment for many who might otherwise be idle, give spring to industry and improvement, lessen importation from abroad, gradually turn the balance of trade in our favor, and eventually be the source of wealth and respectability, and therefore every attempt towards improvement in this respect, ought to be regarded in a favorable light.

It cannot be expected that any person would be at the expense and hazard of erecting works of this kind, which will probably cost not less than £2000, and be liable to be defeated of all prospect of advantage, by others who may think proper to do the same after him, but have not courage enough to begin the attempt.

In this view of the matter, the committee beg leave to give it as their opinion, that Mr. Loomis be allowed, for the term of seven years, the exclusive right and privilege of erecting machines and works for the purpose prayed for in his memorial, on the east side of Connecticut river, or within ten miles west of said river, and of using and improving the same for that term; and that for the second term of seven years next following, if he shall so long improve the said works, no person shall be allowed the privilege of erecting similar works within thirty miles of the works he shall so erect within the aforesaid limits.

Provided, that no privilege granted the present sessions of assembly, to promote the manufactures of wool, be affected thereby.

All which is submitted, &c.

Signed per order. JOHN TREADWELL.

(Industry II. 223.)

Corresponding act was passed May 1787. (224.)

STOCKING LOOMS.

To his Excellency, &c. May 1776.

The memorial of James Wallace, stocking maker, sheweth :—

That your memorialist has been in Wethersfield since December last, during which time he has exercised his trade of stocking making, which he professes himself master of, both in the silk, cotton, thread and worsted way, in all their different branches. That from a desire of serving this province, and settling therein, he prays your honors to lend him £100, to enable him to extend and carry on his trade, so that it may be of use to the public in general. He further intends, if encouraged, to erect an engine for the purpose of spinning cotton and woollen yarn, which will be of infinite service to several branches of the weaving business, and enable them, in a short time, to bring their goods to market, as cheap as they can in the old country. And as a security for the payment of the same, at such time as your honors shall think fit to lend it, he purposes to give a security on his frames, to any one or more gentlemen that will be good enough to take the trouble of the same. And your, &c. JAMES WALLACE.

Negatived. (Industry II. 155.)

To the Honorable, &c.

The representation and memorial of Benjamin Hanks, of Windham, &c., humbly sheweth :—

That he, relying upon a belief that your honors are ever desirous to promote and encourage every useful manufactory within this state, he hath taken encouragement to address to your honors upon the subject of fabricating stocking looms; to perform and effect which, he conceives that he is sufficiently skilled; that he, your memorialist, has been much used to and acquainted with laboring in iron, brass and steel, and every other material necessary to construct the proposed machine; that he is fully persuaded that he could, with some small encouragement, soon construct and finish a number of such looms, to the satisfaction of the public, and every skilful weaver therein; that he conceives that having completed his desires in that particular, that the public would be greatly benefited thereby, not only in more readily and cheaply supplying the soldiery with that necessary part of clothing, viz: stockings, but also the inhabitants of the state. But your memorialist being young, and not of sufficient cash to procure those materials which are necessary for the desired purpose, he is thereby unable and prevented from making the attempt. Whereupon, he humbly prays your honors to take the matter into your just consideration, and grant him such premium as your honors may think proper, upon his having completed a good and sufficient stocking loom, and upon such other conditions as are fit and suitable; and, in the meantime, entrust him, upon proper security, with a sum sufficient for the purpose. Or otherwise, &c.

BENJAMIN HANKS.

Dated in Windham, this 14th day of August, 1777.

(No action on it.) (Industry II. 156.) See clocks.

STOCKING WEAVING.

To the Honorable &c.

The petition of Thomas Hubbard and Christopher Leffingwell, both of Norwich, &c., humbly sheweth:

That your memorialists have, at very great expense and cost, procured 8 stocking frames for the weaving of stockings, and have endeavored to procure workmen to make use of said frames, to prevent, if possible, the necessity of sending away such large sums of specie to procure these articles, in hopes that by said business to make reasonable profit to themselves. But their workmen prove very unsteady and idle: Therefore your memorialists are constrained to take apprentices to find employment for said frames, which have not as yet, borne any profit to them, as they are assessed for said business, and said apprentices are rated for their polls in your memorialists' list, which has so discouraged your memorialists, that they must lay aside business, without the favorable interposition of your Honors. And your memorialists pray your Honors to patronize and encourage them by relieving them from any assessment on said trade, for the term of five years, and likewise release and exempt all persons that shall be, by your memorialists, constantly employed in said trade and business, from being rated for their polls, for the term of two years next coming. Or otherwise, &c.

THOMAS HUBBARD,
CHRIS'T LEFFINGWELL.

Dated in Norwich, the 20th day of May, 1789.

Granted in lower House. Negatived in upper. (Industry II. 238.)

WOOLLEN MANUFACTURE.

To the Honorable, *&c.* Oct. 1736.

The memorial of John Davis, of Lyon's Hall, in the county of Hereford, in Great Britain, now resident in Litchfield, &c., clothier, humbly sheweth:—

That your memorialist, about 13 months since, came over into New England from said Lyon's Hall, where he had practised and improved himself in

the art and mystery of a clothier, for the full space of 30 years and upwards, and then brought with him a considerable quantity of full cloths to the value of £300 or £400, sterling M. to sell and vend in this country, all of your Honor's memorialist's own manufacturing, which cloths well suited the country, and sample and specimen thereof your memorialist has here to shew your Honors. And your memorialist designing to have returned, but upon observation of the country, and view of the woollen manufactory, finds that the poorness of the cloth is chiefly owing to the unskilfulness of the inhabitants in the art aforesaid, whereby much good wool is in a great measure lost, and cloth confounded and rendered much less serviceable as well as fashionable for the people; which your memorialist humbly thinks your Honors are well aware is occasioned by the unskilful management of the wool, in mixing and preparing the same for as well as the unqualified practitioners in the mystery aforesaid; a due encouragement whereof under the present and prevailing extravagance of the price of cloths of the English manufactory at home, your Honors doubtless are sensible would commode and benefit the country in a very material article.

Thinking, therefore, there might be a disposition in this Honorable Assembly to give a proper encouragement to some private person that should appear, to set up the same for the cultivation of a trade so very necessary to the country (as far as may be consistent with the country's safety therein) would take leave hereby humbly to propound to this Honorable Assembly, that your memorialist would gladly set up the trade in such place as might best accommodate the people, if therein he might have the countenance and encouragement of this Honorable Assembly; and also, that his knowledge, practice and improvement in his said trade, which he has so long been improving himself in, might be extensively beneficial to the people of this government, (where he is minded to make his abode,) your Honor's humble memorialist would willingly communicate his skill and experience to the people, as to mixing their wool and preparing and qualifying the same for the wheels, by suitable cards for the country's wool; and the country's improving such wool cards as are altogether unsuitable for the same, is a great means of spoiling the cloth, as well as to its decency as duration; and the unskilfulness of the women, in their carding, chops the wool and breaks the staple of it.'

Which your memorialist could abundantly satisfy those in the least measure acquainted therewith, and could afford such directions as would facilitate the labor and pains in preparing their wool, with 4 times the ease at least, besides the vastly greater benefit of the cloth; and would instruct the people in such and so many places and towns and counties in the government, as your Honors in wisdom should direct, in any method that your Honors should think best, by public advertisements, and especially by personal instructions in mixing their wool, coloring, fulling, pressing and shearing their cloth.

And your memorialist's request is, as an encouragement thereunto, that he may have, by this Assembly, a grant of such a sum of money of the public treasury, that thereby he may be able to procure such utensils to use and improve in the directions of the people in the premises, and be under advantages to give his instructions to the country in such places, ways and methods as this Honorable Assembly shall prescribe, or of such a tract of the colony's land as may be a meet compensation to your memorialist, for so profitable an undertaking. Or some other way, &c.

JOHN DAVIS,
Clothier.

Hartford, May 20, 1736.

Negatived. (Industry I. 128.)

Your Honor's committee appointed to take into consideration the subject matter the memorial of William Crandall, and report what is expedient to be done, etc., beg leave to report,

That a woollen manufactory, in all its branches, would be very important to this State: but the sum proposed by the memorialist to be raised by a lottery, &c., being £6,000 L. M., is too large to be raised by said lottery; and your Honor's committee have not been able to devise any mode which they can with confidence recommend to your Honors for the purpose of introducing the woollen manufactory proposed by the memorialist. All which, &c.

Signed per order. WM. HILLHOUSE.

(Industry II. 214.)

The committee appointed to take into consideration what further encouragement might be given to manufactures and agriculture in this State,—

Report, That in a general view of the subject as relative to manufactures, the most direct and proper means of promoting them that occurred to the committee were by levying and collecting duties on imports, particularly on such articles as might, with great advantage, be manufactured in this State; but as a regulation of this kind might probably be superseded by the federal government before it could operate to effect, it appears to the committee, improper to adopt a system on this ground. In this view of the subject, the committee have thought proper to report only a temporary provision for the encouragement of the woollen manufactory, which more than any other at present, appears to merit particular attention.

The company formed by gentlemen in this city [Hartford] and its vicinity, for this laudable purpose, appears to be actuated by generous motives in the undertaking, though not without a reasonable prospect, in the ultimate progress of the business, of deriving profit to themselves. But as the first attempt to establish this manufactory must be attended with great expense, and the profits must be, at first, very precarious, the committee think proper to recommend the following encouragements, &c. (230.)

And on their recommendation, the buildings of the company are exempted from taxation, and also the polls of the workmen; and a bounty is granted of one penny a lb. on all woollen yarn that shall be spun and made into cloth at said manufactory before June, 1789. May, 1788. (Industry II. 231.)

To the Honorable, &c.

The petition of Jeremiah Atwater, Jr., and William Lyon, of New Haven, humbly sheweth:

That your petitioners, being desirous of promoting the manufactures of this State, have, in the course of the preceding summer, procured a large quantity of sheep's wool, and have also built at a considerable expense, machines and implements for manufacturing the same into woollen cloths of various kinds. That by this manufacture, they have given employment to more than 30 persons, male and female, and hope to be able to continue and augment the business. But as your petitioners are alone in the expense of this undertaking, and as a manufacture of this kind carried on in anywise extensively, is entirely new in this part of the country, and your petitioners find many difficulties therein, and, as they conceive that if it be prosecuted, it must be beneficial to the community, they request some encouragement of your Honors, that you would be pleased to grant to them some bounty on the wool they

have and may manufacture; or such other encouragement as to your Honors may seem just. And your, &c. JEREMIAH ATWATER, Jr.

New Haven, Jan. 5, 1789. WILLIAM LYON.

(Industry II. 234.)

Lower House refer to a committee. Jan. 1789. (235.)

LINEN.—*(See Hemp Below.)*

And further be it enacted, For the encouragement of making fine linen cloth, that whosoever shall bring to the county court, in the county in which he dwells, any linen cloth which in the judgment of the said county court, shall be in goodness equal to Garlick's of six or seven shillings per yard, according to the usual price thereof in our shops; and will make oath before the said court, that the said linen cloth was made in the said county, by their own industry or their proper charge, shall receive for their recompense, one-quarter part of the value thereof, which shall, by their order, be drawn out of the public treasury of the colony. This act to continue in force seven years. Oct. 1732. (Industry I. 48.)

(No vote on it.)

Committee to confer, consider and draw up, what may be proper to be enacted by this Assembly, relating to premiums on the manufactures and husbandry of this government. May 1735. (Industry I. 125.)

An act, &c, Be it enacted, &c. That there be paid out of the public treasury of this colony, a premium of one-sixth per yard, for all fine linen cloth made of yarn of six run to the pound and upwards to eight run, being full yard wide; and one-third for cloth of seven-eights of a yard wide, made of yarn of the size above said; and one-quarter for cloth three-quarters of a yard wide being well whitened; and for such cloth as above said being unwhitened, the same premium shall be paid, except three pence on each yard to be abated. And for all linen cloth upon which the premium is allowed in said act to be well whitened, being made of yarn, eight run to the pound and upward, the same premium shall be allowed for unwhitened cloth, except four pence per yard to be abated, as is there allowed for well whitened cloth, &c. May 1735. (Industry I. 126.) Not passed.

DUCK.—*(See Hemp Below.)*

To the Honorable, &c.

The petition of Richard Rogers of New London, humbly sheweth:—

That your petitioner having insight in the trade of making *canvas* for shipping, and having expended near £140 for the setting up the trade; and hath made of the cloth of good acceptance of those that understand the same. That your petitioner taking encouragement by the law, page 86, (see page 1, above) to venture upon so great an expense; and considering that the trade being set up, a market will much advance trade, in that so considerable a sum is expended to other governments to purchase of that manufactory, which might be improved in other trading, a market ourselves, as it will advance our own people, being improved in the raising of hemp and flax, and spinning the same; also bring into the government a considerable trade to have it made a market; and said canvas can be made much cheaper than it is now bought, coming from England and Holland.

That your petitioner doth humbly pray your Honored Assembly, that they would be pleased to grant the sole making of it to your petitioner, for fifteen years in this government. He keeping said trade going forward, for which he hath eight looms already set up, with what other encouragement your Honors will be pleased to grant. And your petitioner, &c.

RICHARD ROGERS.

(Industry I. 106.)

We, the underwriters, having viewed a certain piece of duck designed for the making sails for shipping, made by Mr. Richard Rogers, of New London, do adjudge the same to be very good and substantial cloth for that use; and that he having advanced a very considerable interest for the promoting this design,—it is our opinion, he well deserves all proper encouragement in that affair.

Signed by twenty-eight leading men in New London, &c.

New London, 20th May, 1724. (Industry I. 105.)

We, the subscribers, being weavers, and work in Richard Rogers, his shop, in New London, and we do declare, that a certain piece of duck, marked No. 4, RRER was wove in said Rogers, his shop, and do further declare, that it is good merchantable cloth, and of the best cloth that is made of that sort of duck.

Signed by six weavers. (Industry I. 107.)

Lower House grant petition. Negatived in Upper.

The next year, he renewed his petition at greater length: (Industry I. 109.) And was allowed the exclusive privilege of manufacturing duck for seven years. Oct. 1725. (110.)

To the Honorable, &c. May 1741.

The petition and memorial of Samuel Judson of Stratford, &c., humbly sheweth:—

That your Honors' memorialist did, some years since with considerable cost, set up and carry on the trade of weaving duck and canvas; and having made and vended about sixty or seventy bolts, the buyers and all others who saw the same, commended the same for good. But having had the misfortune in that affair, to sell to some persons out of this government, who have not to this day, made payment, for which reason, chiefly, I, for three years last past, laid aside the trade. But now, conceiving the carrying on the trade might be of advantage to myself, and much to the advantage of this government, had I a stock to carry on the same with, and being unwilling to break my landed estate to raise a fund, and having my looms and tackling by me, I have taken encouragement from the generous disposition your Honors have frequently discovered for the promoting of this branch of manufacture in particular,—to pray that your Honors, would grant that I may, for the carrying on said trade of duck or canvas, draw out of the treasury of this colony, the sum of £150 of new tenor bills of credit of this colony, upon my giving security, &c., with the interest, at three per cent., &c. And your, &c.

SAMUEL JUDSON.

Stratford, May the 12th, A. D. 1741. Negatived. (Industry I. 131.)

HEMP.

An Act for the Encouragement of raising Hemp and Silk, and of making fine Linen. Oct. 1732. (See Silk and Linen.)

Be it enacted, &c. That it shall be lawful for any and every town in this colony, annually to choose three discreet men in their town, to be surveyors of hemp. And it is hereby provided, that whosoever in the town where such surveyors are appointed as aforesaid, shall produce 100lbs. of hemp as shall be bright, well cured and water rotted, of four feet at least in length, and well cleansed, fit for use, &c., shall have a certificate thereof to the treasurer of the colony, of the quantity of hemp so raised and manufactured as aforesaid. The said treasurer is hereby ordered to pay out to him 2s. for every 100 weight, certified as aforesaid; and so pro rata for greater or lesser quantities. (Industry I. 48.) No action was had thereon.

An Act for the Encouragement of raising Hemp, making Canvas of Duck, and also for making fine Linen. May 1734.

This assembly considering the great profit and advantage that might in time accrue to his Majesty's people in this government, by the raising of hemp, making canvas and fine linen, &c., if the same may be sufficiently encouraged and promoted:

Be it enacted, &c. That there shall be paid out of the public treasury of this colony, to every person or persons inhabiting in this colony, as a premium, the sum of 4d. per pound for every pound of good, well dressed, water rotted hemp, that shall be by him or them raised or procured to be raised, and shall be the proper growth of this colony; provided, there shall be no premium allowed to any man, for any quantity less than 50lbs.

Be it further enacted, &c. That there shall be likewise paid out of the public treasury, the sum of 20s. for every bolt or piece of well wrought canvas of duck fit for use, of 36 yards in length and 30 inches wide, and weighing not less than 45lbs., made of hemp aforesaid, or well dressed, water rotted flax, to be paid to him that shall do, or procure the same to be done and manufactured as aforesaid.

Be it also further enacted, &c. That as a premium for the encouragement of making fine linen, there shall also be paid out of the public treasury of this colony, to every person or persons that shall make or procure to be made within this colony, any fine linen cloth, as followeth, viz: for every yard that is well spun, wove and whitened, and is a yard wide, and made of yarn that is eight runs to the pound, 2s. per yard, and so pro rata for wider or narrower cloth so made; and also for fine cloths of the same width, a proportion to the fineness thereof, to be determined by the number of runs to a pound, provided none be allowed to be narrower than three-quarters of a yard, and that no deceit or fraud be imposed upon the public, &c.

Provided, this act shall continue and be in force for the space of five years from the rising of this assembly, and no longer. (Industry I. 51.)

Act continued in force five years. May 1740. (Industry I. 67.)

Continued in force till May, 1750, as voted by lower house. Upper house dissent. May 1745. (Industry I. 77.)

An Act, &c. May 1787.

Be it enacted, &c. That all persons in this state may annually, &c., insert in their lists of rateable estate, &c., an account of the quantity of land which they shall have severally sowed with hemp, &c.; and listers shall deduct from the list of such persons respectively, at the rate of 40 shillings per acre, for any quantity of land sowed with hemp, &c., as aforesaid.

(A duty was to be laid on the importation of hemp, of 6s. per 100cwt., after May 1789.) (Industry II. 70.)

FLAX MACHINE.

To the Honorable, &c. May 1753.

The memorial of John Bulkley, of Colchester, in the county of Hartford, in the colony of Connecticut, in New England, humbly sheweth :—

That whereas, there are great quantities of flax raised in this colony, and that article is become so considerable a part of the staple thereof, that the encouraging the raising and manufacturing so valuable a commodity, by all proper ways and means, must conduce much to the public interest; and as the common way of dressing and cleansing flax here is so very laborious, and calls for so great a number of hands to be employed in that business, that in a country where laborers are so scarce, and labor so very dear, it is a great discouragement that attends the raising of that article; so any way that can be devised for the better and more expeditious dressing of flax, and with much less labor, would be serviceable, and tend much to promote and encourage the farmers in raising greater quantities of flax in this colony.

And whereas, your memorialist understands that the trustees of the society for managing the linen manufacture in Scotland, have advised to and encouraged the erecting and setting up there a late invented water machine, for dressing and cleansing flax, which does it in a better and more expeditious manner, and with a great deal less labor than the common way, and is found by experience to be a great encouragement to the linen manufactory there; and as your memorialist apprehends that the setting up such machines in this colony would have the same effects here; so he proposes, upon suitable encouragement, to be at the pains and expense of procuring the same kind of machines to be used in this government.

Whereupon, your memorialist humbly prays this honorable assembly to encourage him in so good a design, (which if it succeeds, he imagines will be greatly for the public advantage, though it cannot be effected without great charge and expense to the undertaker,) to grant to him and his associates the sole liberty and privilege of erecting and setting up machines for the purpose aforesaid, within this colony, for the space of twenty-one years next ensuing the rising of this assembly; and to prohibit all other person or persons erecting the same kind of machines, or any in resemblance or imitation of them, in this colony, without leave or license from your memorialist and his associates, during the full term aforesaid.

Provided your memorialist and his associates shall, within eighteen months next ensuing, erect and set up one machine for the purpose aforesaid, in some convenient place in this colony, as he and they shall think proper, for a trial or experiment.

Provided also, that if said attempt should prove successful, that then, if the said memorialist and his associates shall not, within seven years next ensuing after the setting up of said first machine, erect and set up in some convenient place in each county in this colony, for the purpose aforesaid, one such machine at least, that then in such case, it shall be lawful for any other person or persons to set up machines for the same purpose, in every such town where the said memorialist and his associates shall not, within seven years have erected one such machine as aforesaid, at least.

And your memorialist is willing that in your honors' grant, a clause should be inserted, that nothing therein should be construed or understood to prohibit any persons in this government from making or using any instrument or machine for the purpose aforesaid, that have been or are now in use in this colony. And as in duty, &c. JOHN BULKLEY.

Hartford, May 1753.

Negatived in lower house. (Industry I. 171.)

To the Honorable, &c. Oct., A. D., 1753.

The memorial of Jabez Hamlin and Elihu Chauncey, humbly sheweth :—

That whereas, there is a new invented water machine for the dressing of flax, brought into use in Scotland and Ireland, by the societies for managing the linen manufactures there, which is found by experience, to be a much more expeditious and less expensive method than that in use here.

And whereas, your memorialists are of opinion that the procuring the said machine to be set up in convenient places, and brought into use in this colony, would greatly encourage the raising larger quantities of flax, and conduce much to the public interest of this government,—we would propose to be at the charge and expense (which will be very considerable,) of procuring the said machine, to be set up and brought into use here, upon proper encouragement.

Whereupon, your memorialists humbly pray this honorable assembly to encourage them in so good a design, by granting to them and their associates, the sole liberty and privilege of erecting and setting up the said machine for dressing of flax, in such towns in this colony as they shall think proper, for the term of twenty-one years next ensuing; and that all other persons be prohibited setting up in this colony, any such machines, or any in imitation of them, during said term.

Provided the said memorialists shall, within eighteen months next after the rising of this assembly, procure one such machine, to be set up in this colony for an experiment.

Provided also, that if the said memorialists shall not, within seven years next ensuing, set up one such machine at least, in every town in this colony, that they shall forfeit and lose the benefit of setting up in all such towns as they so neglect, after the seven years are so expired, and the inhabitants of said towns may themselves set up said machines, as they see cause. And in all the towns in which the said memorialists shall set up said machine within said seven years, they shall keep the same up and in repair, during the said term of twenty-one years. And in case they shall let any of them be out of repair the space of fifteen months, they shall forfeit and lose the benefit of the monopoly herein granted, in such town where the said machine so lies without repairs.

Provided also, that this grant shall not hinder the use and improvement, or setting up hereafter, any mills or machines that are now used in dressing flax in this colony; nor any other that may be invented, if diverse from, and not in imitation of the machine your memorialists pray for liberty to erect and set up.

JABEZ HAMLIN.
ELIHU CHAUNCEY.

(Industry I. 172.)

Liberty was granted for fifteen years, &c. (173.)

SILK.

An Act, &c.

Be it further enacted, &c. That whosoever shall raise silk among us, and shall shew it to the county court in which county it is raised, at their nex sessions after the making thereof, and will, upon their oaths, declare before the said court, that by the silk worms which they have nourished and brought up since the last sessions of the said court, the said silk was made. That then said court shall certify the same to the treasurer of the colony, and order him to pay out of the public treasury, the sum of ten shillings per pound, and so pro rata for greater or lesser quantities, to him that brings such certificate. Oct. 1732. (Industry I. 48.)

Not acted on by the Assembly.

An Act for the Encouragement of the Raising of Silk in this Colony.

This Assembly, observing and being well assured, that good silk may be here made here, and that by proper improvements, a sufficiency thereof may be raised and produced amongst ourselves, whereby industry may be promoted and the wealth of this government in time much increased; and considering that the beginning of things beneficial and profitable, are attended generally with difficulty and charge, which use and experience may remove, abate, and render easy and profitable.

Be it therefore enacted by the Governor, Council and Representatives; in general court assembled, and by authority of the same, that there shall be paid out of the public treasury of this colony, as a premium for the raising silk; that is to say, for every ounce of good sewing silk, one-sixth; for every pair of silk stockings weighing 4 ounces, and so pro rata seven-sixths; for every yard of silk stuff, 1; and for every yard whereof the warp is all silk, two-thirds; for every yard of silk half yard wide, weighing less than one ounce, three-ninths; for every yard weighing one ounce, and less than two ounces, six-ninths; for every yard weighing two ounces or more, nine; all to be well wrought:—which premium shall be paid on an order obtained of the county court, on the public treasury aforesaid, to be given by the court in the county where the person dwelleth, that shall produce the said silk, and shew to the satisfaction of the said court, that it is bona fide, the growth and product of the silk worms, bred and nourished in this colony, and that no premium hath been before taken or allowed for the same or any part thereof.

This act to continue in force for the space of 10 years, and no longer. (Colony Records VI. 161.)

Continued in force 10 years longer, May 1745. Lower House dissent. (Industry I. 76.)

To the Honorable, &c.

The memorial of Nathaniel Aspinwall of New Haven, humbly sheweth:—

That from the experiments that have been made, there is great reason to believe that the cultivation and manufacture of silk, might become a source of much wealth to this state, especially as a principal part of the labor might be performed by persons aged, decrept, &c. capable of doing very little if any other business. But as the planting and cultivation of the mulberry tree would be attended with considerable present expense, without any immediate profit, the good people of this state cannot be induced to turn their attention to the business without some recommendation and encouragement from this Honorable Assembly. The importance of encouraging the manufactures of this state must be obvious; and as there is a fair prospect that the silk manufacture might be improved to great advantage and profit to the state—

Your memorialist, therefore, humbly prays your Honors to afford your patronage to the infant manufacture; and grant the small encouragement of exempting the polls of such persons from the list, for the term of one year, who shall plant, cultivate, and raise one hundred mulberry trees, and keep them well pruned and attended, and for a greater number of said trees an exemption in proportion; and also free the land whereon they grow from taxation, being set in the proportion of one hundred trees to an acre; or in some other way, &c.

NATHANIEL ASPINWALL.

Dated at New Haven, the 2nd day of October, 1783.

(Industry II. 184.)

Referred to a committee, who report favorably, Jan. 1784. (183.)

An Act to promote the making of Raw Silk within this State, January 1784.

Whereas, by the experiments which have been made, it is highly probable that the making of raw silk will be attended with much advantage to the good people of this state. Therefore,—

Be it enacted, &c. That from and after the first day of March, A. D. 1784, to the first day of March, 1793, whoever shall plant one hundred thrifty shrubs or saplings, of three or more years growth, of the white mulberry tree on his, her, or their land within this state, at such distances from each other as will be favorable for their growth and for collecting their leaves, shall receive at the end of every year, and during the term of three years from and next after the year in which such saplings shall have been planted as aforesaid, ten shillings, L. M., and so in proportion for every one hundred of such saplings, planted as aforesaid, upon proof and certificate thereof as hereafter directed, that such saplings were, at the end of every three years after they were so planted in a thrifty condition. Every such certificate shall be given in at the end of every of the three years as aforesaid; and no certificate shall be given for any number of such saplings, but for one or more entire one hundred as the case may be.

Be it further enacted, That whoever shall make any raw silk from worms and mulberry trees of his own raising within this state, by properly winding the same from the balls or cocoons, after the said 1st day of March, and for fifteen years next thereafter, shall have and receive 3d. L. M. for each ounce of such dry silk, which he, she or they shall make as aforesaid.

Every of which bounties given by this act, shall be paid out of some tax which has or shall be granted for the support of the civil government of this state.

[The remainder of the act provides, that on the certificate of two justices of peace, the collector of the tax may pay said bounty.] (Industry II. 62.)

An Act, &c., (Repealing the above, and providing;) That whoever shall make any raw silk from worms and mulberry trees of his own raising, within this state, by properly winding the same from balls or cocoons, after the 1st day of July next, and for ten years next thereafter, shall have and receive as a bounty from the treasury of this state, 2d. lawful money, for each ounce of such silk well dried, which such person or persons shall make as aforesaid; which bounty shall be paid out of the duties arising on the importation of foreign articles into this state, &c. May 1784. (Industry II. 63.)

MANSFIELD SILK COMPANY.

To the Honorable &c.,

The memorial of a number of the inhabitants of the town of Mansfield, within said State, whose names are hereunto subscribed, humbly sheweth:

That your memorialists, under a full conviction of the unhappy situation to which they and the other inhabitants of this State have been reduced by reason of drawing from us our circulating medium, and depriving the country of her wealth in purchasing articles of foreign growth and manufactures, have, for a considerable time past, turned their attention to the cultivating of mulberry trees, and the manufacture of silk. And your memorialists would inform your Honors, that from the encouragement of the Honorable Legislative body of this State, in the premiums which they have been pleased to grant, from the natural fitness of the soil for the production of the mulberry, and by your memorialists' own industry, they have been able to raise large quantities of raw silk, some of which has been manufactured into cloth, and the remaining part into sewing silk, which if properly made, is acknowledged to be equal to any that is imported. And your Honors' memorialists would beg leave further to state, that they live contiguous to each other, and from the nature of the soil which they possess, and from their situation, they have not the least doubt but that, under proper regulations, they should not only be able to supply the people of this State with sewing silk of the best quality, but afford a considerable supply of silk cloths, and in a short time, make the silk manufactory not only advantageous to themselves, but of utility and importance to the public.

Whereupon, your memorialists pray that your Honors would grant that they may be formed and incorporated into a company or body which shall be called and known by the name of the Director, Inspectors and Company of the Connecticut Silk Manufacturers, and that by that name they and their successors forever may have perpetual succession, and may be persons in law capable of suing and being sued, pleading and being impleaded in all suits, and also may have power of purchasing, holding and conveying any estate, real or personal, and may have a common seal, and that they have power of appointing or choosing a director, inspectors, and other necessary officers for said company, at such time or times, and in such a manner as to your Honors may seem meet, who shall be vested with such powers as your Honors shall judge necessary: And further, that said company have power of passing by-laws and rules for the well ordering and regulating themselves in and about the raising and manufacturing silk, and which are not repugnant to the laws of this State, which by-laws shall be binding on and among themselves; and likewise that they may make such regulations as to them shall seem necessary, respecting the admitting persons in, and making them members of said company: and that said company and the members of the same be exempted of and freed from every kind of tax or assessment for or on account of the profit or advantages which may or shall arise from or by means of said manufactory. Or that your Honors would grant your memorialists such other privileges and immunities as in your wisdom shall appear to be most conducive in rendering said manufactory both permanent and useful. And they, &c.

Signed by THOMAS BARRONS,
Dated at Mansfield, Sept., 1788. and 31 others.
(Industry II. 236.)

Act of incorporation, (requiring a vote of two-thirds to admit a member,) Oct., 1788. (237.)

LINSEED OIL.

At a General Assembly, &c, Oct. 1718,

At the humble suit of John Prout, Jr., gentleman, Moses Mansfield, mariner, and Jeremiah Atwater, brasier, and for their encouragement to set up a mill and other necessary furniture, to improve the flax seed of this colony for the extracting and producing linseed oil:—

This court hath therefore granted, and doth hereby grant to the said John Prout, &c., the whole and sole privilege of making linseed oil within this colony, and that no other person or persons shall set up any mill or other engines for that purpose, within the county of New Haven, during the space of 20 years next coming, nor in any other part of the colony, without the special leave asked of this court, whereof the parties above named shall be seasonably notified, within the 20 years above mentioned. Provided said John Prout, &c., shall set up such mill, and all needful furniture for the use aforesaid, in New Haven, within the space of 2 years next ensuing, and keep the same in good repair, at all times till the expiration of the said 20 years.

(Industry I. 121.)

To the Honorable, &c.,

The prayer of Samuel Burr and Nathaniel Burr, Jr., of Fairfield, &c., humbly sheweth,—

That the General Assembly at their sessions, Oct. 1728, &c.

* * Although the said undertakers have erected and set up a mill for the purpose aforesaid, yet they have not made so steady an improvement thereof as to use the flax seed even of the county of New Haven, much less of the other counties, nor to provide oil for the people thereof. Neither do they improve, of late years, any part of the seed raised in the county of Fairfield, nor furnish them with oil, &c. We, therefore, your humble petitioners, pray you would be pleased to grant liberty to us to set up a mill, &c., in the county of Fairfield, etc.

Fairfield, Sep. 13, 1732. SAMUEL BURR,
Negatived, Oct., 1732. NATH'L BURR, Jr.
(Industry I. 122.)

TEA.

To the Honorable, &c. Oct. 1765.

The memorial of Alexander Phelps, Amasa Jones, and John Coleman, all of said colony, humbly sheweth,—

That your Honors' memorialists have, with great pains and expensive pursuits, made discovery of a plant in a distant part of this continent, bearing such resemblance in figure and taste to the genuine foreign Bohea tea, that we are well assured 'tis the same kind. Whereupon, we now address your Honors, praying your attention to a discovery so highly interesting and beneficial to this community, to people of all ranks in this day of distress; as it will be not only much cheaper, but also more easily purchased by barter than that which is imported: and as this discovery has already been attended with great expense, and still must be much more so by transplantation, gaining the art of thoroughly curing, etc. We pray your Honors would grant us a patent of manufacturing, and also vending such plant or tea, within this colony, exclusive of all others, for the space of 20 years next coming, or for such other term as your Honors shall think proper. And your, etc.

Dated at Hartford, this 1st day of Oct. 1765.
Negatived. (Industry II. 123.) ALEX'R PHELPS, *et al.*

MOLASSES.

Upon the petition of Edward Hinman, of Stratford, praying liberty and a commission to make molasses of Indian corn stalks, in the county of Fairfield,—

This Assembly grant the liberty prayed for to the petitioner, within the county of Fairfield; and that any person or persons within said county, shall, within the space of 10 years, presume to set up any works for the making of molasses of corn stalks, without allowance from the said Edward Hinman, shall pay and forfeit unto the said Hinman the sum of £5 a month;—always provided the said Hinman make as good molasses, and make it as cheap as comes from the West Indies. Oct. 1717. (Industry I. 123.)

SALT.

To the Honorable, &c. Oct. 1746.

The memorial of John Jerom and Stephen Jerom, Jr., of Branford, etc., humbly sheweth:—

That, whereas, it would be a great public advantage to the inhabitants of this colony, if we could get into the method of making salt by boiling sea water, as practised in sundry places in Europe. And the charge of setting up convenient works for that purpose would be very great and the success uncertain, as appears, in that the General Assembly at Boston, about 50 years ago, granted to Elisha Cook, Esq., and others, the sole privilege of making salt in the province, for the space of 14 years; and yet either by reason of the freshness of the sea water, the coldness of the climate, or their want of sufficient skill, they were not able to effect the design to any advantage. Yet your petitioners having been instructed in that art are willing to be at the charge and risk of making an attempt of that nature, if they may obtain the favor and countenance of this Honorable Assembly.

Your petitioners, therefore, humbly pray that this Honorable Assembly would be pleased to grant to your petitioners and their associates, the sole license and privilege of making salt as aforesaid, within this colony, for the space of 14 years next ensuing. And so, &c. JOHN JEROM,
(Industry I. 182.) STEP'N JEROM, Jr.

Assembly grant the same for 14 years:—

Provided, nevertheless, that if the memorialists &c., shall neglect or fail to erect, set up, and prepare suitable works and materials for the making of salt as aforesaid, for the space of 2 years, or shall fail of making the quantity of 500 bushels of good salt in any one of the remaining 12 years, &c., then this grant &c., shall be void. Oct. 1746. (Industry I. 183.)

Upon the memorial of Stephen Jerom, Lyme, Oct. 1749, &c.

That he therefore speedily erected and set up salt works in the town of Lyme, in this colony, at very great expense and charge, and hath made considerable quantities of good salt, to the great benefit of his Majesty's subjects in this colony: and that he finds, by experience that said affair is capable of great improvements, had he money sufficient to carry on said business, for the want of which he finds himself much hindered in prosecuting said affair; and praying for a grant of £1,000, O. T., out of the colony treasury on interest. (Industry I. 184.)

Assembly loan him the same for 2 years, on his procuring security, &c. (186.)

He again petitions, Oct. 1751, and adds,—

Whereas, your memorialist lately came into this country from Great Britain; and upon my first coming into this colony, found salt to be scarce, and fetched a good price; and being willing, &c., undertook to raise salt works for the making of salt, and expended in so doing the sum of above £2,500, which sum exhausted more money than the value of all the estate your memorialist had in the world, &c. (But as the price of salt fell one half at the ending of the war, he asks, etc.) (Industry I. 187.)

Assembly continue the loan of £1,000 for 3 years, without interest. (188.) Upper House dissent.

After various efforts, seconded by assistants in Lyme, he petitions, and adds,—

He set up said business, and with the utmost diligence followed the same for the space of 3 years or more, and made more than 3,000 bushels of good salt, etc. He is desirous his bondsmen should be reimbursed; and prays for a lottery to raise £150 L. M., equal to £1,000 O. T. loaned.

Lyme, May 6, 1760. STEH'N JEROM.
Negatived. (Industry II. 193.)

Again he states he has paid all the £1,000 loaned, except £250, which he prays may be remitted.

May 12, 1769. Negatived. (Industry II. 136.)

SUGAR REFINERY.

To the Honorable, &c.

The memorial of George Phillips, of Middletown, humbly sheweth:—

That the consumption of loaf sugar imported into this state annually, amounts to a very large sum, which is, in general, paid for in cash; that the manufacture of that article has not been set up within this state, and the stock and buildings necessary to carry forward that business will amount to a sum not short of £6000; that your memorialist is desirous to set up the manufacture within this state, but in accomplishing his purposes, he will be obliged to adventure most of his property, which will greatly injure him, unless he has some public encouragement on this subject. He therefore prays your honors to grant him the exclusive privilege of manufacturing that article within this state, or such part thereof as shall be reasonable, for such term of time as your honors shall judge reasonable. And he, &c.

GEORGE PHILLIPS.

Dated in Middletown, Oct. 15th, A. D., 1784. (Industry II. 193.)

Assembly allow him the exclusive privilege of manufacturing for ten years, provided they set up their works by December 1, 1785; and provided the assembly may grant the same privileges to two other sugar works in this state within said ten years. (Industry II. 194.)

John Heyleger, late of St. Croix, W. I., now of New Haven, Elias Shipman and Lina Denison, of New Haven, and John Morgan, of Hartford, petition for a sugar refinery in New Haven. May 16, 1785. (Granted.) (Industry II. 197.)

A similar grant was made to Elijah Backus, Joshua Huntington and Dudley Woodbridge. Norwich, May 1786. (Industry II. 199.)

PITCH.

John Eliot, of Windsor, offering to this assembly, that he will undertake the making of pitch in considerable quantities, which may be of great advantage to those parts of the government where tar is to be obtained, and an addition to the naval stores, if he may be encouraged therein:

This assembly, being well satisfied of the public advantages of such a new improvement, never heretofore made in this government,—do grant to said John Eliot, &c., the sole making of pitch within this government, for the term of ten years next ensuing, &c. And for the better encouragement of the said undertaker, this assembly orders and grants the said undertaker, that if any pitch shall be made in this government, by any other person or persons, except for their own use, and not for sale, whereby the said undertaker will be more or less obstructed, hindered or disadvantaged, and the intent and good meaning of said grant frustrated,—it shall be lawful for said John Eliot, or his assigns, by warrant from authority, directed to any officer or indifferent person, to seize said pitch, one-half for his own use, and the other half to the use of the colony, to be tried and condemned in any of her Majesty's courts in this colony.

Provided always, nothing herein shall be taken to hinder the masters or owners of any vessels trading in this government, to boil up tar for the use of their vessels.

Provided also, that the said Eliot do set about and effect the said undertaking within the space of two years after this present session of the general assembly. May 1708. (Industry I. 99.)

Encouragement had before been given by the colony for the manufacture of pitch and tar; but no such general grant.

POTASH.

Upon the humble motion, request and representation of Samuel Williard, Jabez Hamlin, Seth Wetmore, Elihu Chauncey and Robert Fairchild, shewing their desire and design of undertaking to make and manufacture potash, if they may be suitably encouraged therein, and that the same, if performed, will be of great advantage to this government; therefore that all due encouragement be given to promote such profitable and useful manufacture in this colony:—

Be it enacted and granted, &c., unto the said Samuel Williard, &c., the whole and sole liberty and privilege of making and manufacturing potash within the bounds and limits of this colony, for and during the full term of twenty years next after this assembly, and that they, &c., shall have liberty to erect, build and set up any works, engines and machines for that purpose, within the limits of this colony, within the term aforesaid; and all other persons, &c.

Always provided, that this grant or patent is upon condition, that the aforesaid Williard, &c., shall make and manufacture two tons of good merchantable potash, fit for transportation, within the term of two years next after the rising of this assembly, and two tons annually, every year after, during the term aforesaid.

Provided also, that the benefit of this grant or patent shall not extend to the said grantees in such county in this colony, where they shall not, in the space of five years, &c., set up and erect proper works for the manufacturing potash as aforesaid. May 1741. (Industry I. 134.)

To the Honorable, &c. Same petitioners add:—

Your memorialists say that they have been at considerable expense and cost to be instructed in the art and skill of making of said potash, and have set up

works at Middletown, and made some trial of making the said potash, and have made several barrels of it; and have, for more than twelve months, sent the same home to England to have the same proved, and to know what the same is worth by one Mr. Joseph Scott, of New York, who has been gone for England above one year, who promised to send us an account thereof; and more, we have sent home, by way of Boston, and before now expected returns, that so we might be further satisfied whether it would be a profitable commodity, and worth our pains to make the same; but as yet we have had no returns; and the time is now near expired that we were to make said two tons; and we have now, in two counties more, provided and been at cost in procuring ashes and other materials, to set up in other counties; [we] would therefore humbly pray, that notwithstanding the said provision in said patent, that if your memorialists shall make two tons by the last of May, 1744, with what they have already made, that the said patent may not be forfeited, &c.

JABEZ HAMLIN, et al.

Hartford, May 13, 1743. (Industry I. 135.) Granted. (136.)

At the commencement of the revolutionary war, the manufactures of *potash*, *salt-petre* and *powder* were encouraged, and extensive works were erected, and large quantities of powder were made, through the war, particularly in East Hartford and Glastenburg, and Windham, &c.

No individuals were ever allowed to practice the art and mystery of *tanning* without license from the general court, although no exclusive privileges were granted.

SNUFF.

To the Honorable, &c.

The memorial of William Pitkin, of East Hartford, humbly sheweth;—

That he hath suffered great losses by fire, in manufacturing gunpowder for the use of this state, and a mill which cost about £400, is now altogether useless, which he wishes to employ for his own benefit and the emolument of the public, without injury to any individual. Your memorialist is confident your honors are fully persuaded of the importance of encouraging our own manufactory; and for that purpose, begs your honors to grant him the exclusive right and privilege of manufacturing snuff, such length of time, free from assessments and taxes, as will be sufficient, with other prospects, to induce a young man, skilful in said manufactory, to make it a business for life. And your, &c.

WILLIAM PITKIN.

Hartford, June 1, 1784. (Industry II. 187.)

At first negatived in lower house, but finally granted on those terms for fourteen years.

To the Honorable, &c. Oct. 1785.

The memorial of Elijah Lothrop, of Norwich, &c., and Timothy Donevan, late from Ireland, humbly sheweth:—

That the said Lothrop hath in Norwich aforesaid, an excellent stream of water for useful mills of all kinds that go by water, and owns a building which during the late war was erected and made use of by Mr. Nathaniel Niles for manufacturing wire, and said Mr. Niles being now gone into another state, said Lothrop hath purchased the same for the purpose of a snuff mill:

That the said Donevan hath contracted with the said Lothrop for the use of said stream, for a long time to come, viz: for the term of fifty years, with design to set up said manufacture of snuff, as also the business of a

CLOTHIER AND BLUE DYER,

and is well skilled in those manufactures, and hath large property, which he is desirous to bring into this state, sufficient to carry on the same, and purposes to settle his sons in those manufactures in said Norwich. That your memorialists have already been at great expense in preparing proper gear and engines for said business, and were pursuing their said design with speedy progress, until a few weeks passed, when to their great surprise and astonishment, they were informed that the Hon. William Pitkin, Esq., did in May, 1784, obtain, &c. (above.)

Now your memorialists beg leave to suggest to your honors, that the Hon. William Pitkin, Esq., not being the original inventor of the art of snuff making, nor skilled in that business, had no claim to that grant, in exclusion of those who well understood the business, and had a good right to exercise their skill in said art, for the support of themselves and families, by a lawful calling; nor was it known that any legislative body had a right to grant away the trade and professions of the subjects of the state, to any individual, for his private emolument, or to make exclusive grants to exercise any particular calling, unless to such persons as were the original inventors or prosecutors of such business or trade. And though exclusive grants are often made to the authors or publishers of useful books, for printing and vending the same for their own advantage, yet it is done as a reward for their labor, in which case, no man's right is taken from him; but people only who have no share in the invention, are prevented from taking the benefit of an author's labors before he can reap an adequate reward for his labor or discovery. And your memorialists having done nothing to forfeit their rights and estate in the business aforesaid, cannot be persuaded that this honorable assembly meant, by said grant, to deprive any individual of such right, but only to grant liberty to said William Pitkin, Esq., to carry on said business, free from all taxes thereon, which your honors had a good right so to do.

Wherefore, your memorialists pray your Honors to consider their case, and explain said grant to William Pitkin, Esq.; and grant liberty to your memorialists to carry on said business, together with the business of clothing and blue dyeing, and other colors in this state, subject to the same law of taxation as other manufactures in this state are subjected to; which will prevent the said Donevan from the necessity of moving with his property, into the state of New York, to carry on said manufactures, which will produce articles of commerce that may find their way into this state under the burthen of the merchants' profits. Or in some other way, &c.

ELIJAH LOTHROP.
TIMOTHY DONEVAN.

Dated at Norwich, the 8th day of September, 1785. (Industry II. 206.)
Negatived.

To the Honorable, &c. October 1785.

We, the subscribers, beg leave to signify our desire, that Mr. Elijah Lothrop and Timothy Donevan, may be allowed to carry on the business of snuff making in Norwich, and think the same cannot be of any damage to Col. Pitkin, as snuff is an article of trade, and will always find its way to the best market, it may be an article of exportation, or prevent it from being imported from the neighboring states, and from Europe. Said Donevan, also proposes to carry on the business of clothing and dyeing in the European manner, which must also be prevented, if he is not suffered to carry on the business of making snuff.

Signed by 243 residents of Norwich, Preston, Groton, Lebanon, &c. Dated at Norwich, September 8, 1785. [Industry II. 207 to 210.]

Mr. John Currie of East Hartford, testifies that Col. Wm. Pitkin applied to me about the month of July, 1784, to undertake the manufacture of snuff in East Hartford. In consequence of said application, I came from Philadelphia to said East Hartford, and assisted in laying the plan for the buildings, and saw the grant of the Assembly, and the engagements there made induced me to leave Philadelphia with my family,—where I am now settled to carry on said business. Every objection was thrown in my way to prevent my coming by intercepting letters, and preventing my business in Philadelphia, and offering high wages to prevent the manufacture in New England. The wages and encouragement given me, by Col. Pitkin for undertaking, I esteem better than £200, lawful money. I further say, that all the snuff made use of in the state of Connecticut, will not take the mill now erected, half the time it can work.

JOHN CURRIE.

Hartford, Oct. 17, 1785. (Industry II. 211.)

Builders testify, that Pitkin's buildings will cost £700. (212.)

Lothrop's petition is rejected.

[I, Wm. S. Porter, who have been some years employed in the office of Secretary of State of Connecticut, in compiling an analytical index of Public Documents, hereby certify that the above are true copies or abstracts of papers and records in said office, as per references.

Hartford, Feb. 28, 1851. WM. S. PORTER.]

Respectfully submitted.

In connection with the foregoing list of communications, it should be stated that some hundreds have been noticed under the heads of "Review of Crops," "Rearing Domestic Animals," and elsewhere. Many letters arrive at so late a period that it is impossible to get them copied and arranged ready for the press in season for the Report of 1850. The best of such will appear in that for 1851. It was expected that a large share of the agricultural statistics of the U. S. Census of 1850 might appear in this volume; but statistics relating to population being first prepared for the press at the Census Office, those relating to agriculture are unavoidably deferred.

REVIEW

OF

THE PRINCIPAL CROPS GROWN IN 1850.

WHEAT.

The circular issued from the Patent Office contains the following questions in reference to wheat: "Varieties in use? Average product per acre? Time of seeding and of harvesting? Preparation of seed, and quantity used per acre? How many times and how deep do you plough? Is the yield per acre increasing or diminishing? What is your system of rotation of crops? What the best remedies for Hessian-flies and weevils? The average price of wheat at your nearest market?"

The answers to the first question show, that from fifteen to twenty varieties of winter wheat and six or eight of spring wheat are cultivated in the United States at this time. These include not the whole, but the kinds most in favor with wheat-growers in all parts of this extended republic. A variety called Mediterranean is particularly commended for its early maturity and hardiness, and consequent exemption, in an unusual degree, from injury by rust and insects. It is, however, a cereal of inferior quality, and little cultivated in the best wheat-growing districts, because millers much prefer white wheats that yield whiter and more saleable flour. So far as gluten and strength of staple are concerned, the flour made from Mediterranean wheat is, probably, equal to the best produced under similar circumstances; but the intrinsic value of flour for nutrition has very little influence on the market price of the article. Seeds that contain a large per cent. of starch, which is whiter than gluten, and have a white and thin cuticle, or bran, are uniformly preferred by millers. Such grain yields the maximum of superfine flour. The wheat plant is attacked by so many insect depredators and parasite fungi, and is subject to so many casualties, from frosts in winter and spring, from sudden alternations of wet and dry weather, defective soils and bad tillage, that the more delicate varieties are not popular among the mass of farmers. In Western New York, Pennsylvania, Ohio, Michigan, Wisconsin, Northern Illinois, Indiana, and Iowa, the most extensive growers of wheat prefer the improved white flint, Soules, bald and bearded red-chaff, Hutchinson, Talavera, blue-stem, and other kinds, similar in character, but known by local names. At the South, Virginia May wheat and the Mediterranean are, perhaps, the most popular, although the above named varieties are also cultivated. In New England, spring wheat is grown much more than winter grain. The kinds usually cultivated are tea spring wheat, Italian, Black Sea, red-chaff, club wheat, Whintington, Canada, and others known by mere provincial names. Mr. Moses Newell, of West Newbury, Mass., says, that "little spring wheat has been sown here for four or five years, because the insects have nearly destroyed the crop.

The kinds in use here have been the red, the Black Sea, the tea, and the white bald." He adds: "Winter wheat, sown in August and September, is beginning to take the place of spring wheat. Upon some lots in this vicinity, nearly 40 bushels per acre have been obtained; and 20 bushels are not above an average crop. It has succeeded well upon sward land turned over, applying compost manure, spread on the sod after ploughing, and immediately sowed and harrowed. In some instances, the seed has been covered by a light one-horse plough, in some, by a cultivator, but more generally by the common harrow. The plough or cultivator is preferable to the common harrow, as it covers the seed deeper, and renders the young plants less liable to injury from frost. August sowing has given the best crops, other things being equal." In regard to the use of compost manure, guano, and other fertilizers, applied at the time of seeding, the practice is gaining favor in all districts where the soil is somewhat impoverished by previous cropping, or naturally not well adapted to wheat culture. A compost, consisting of well-rotted stable manure, wood ashes, gypsum, and a little common salt, is preferred. Mr. W. Fisher, of Franklin, Mass., says, that the Black Sea variety is most cultivated in that section; but, owing to a lack of mills for grinding, and other causes, little attention is paid to the production of this grain. Mr. Joshua Smith, of Hanson, in the same State, informs us that the legislature, some fifteen years since, paid a bounty on wheat; but the business proved unprofitable. The crop is now much neglected, and the bounty discontinued. Mr. Elisha Edwards, of Southampton, says, that the white flint is found to be the most profitable wheat for autumn seeding. Of this kind, he has raised 24 bushels per acre; but it was an extraordinary crop. About 12 bushels is the average yield. He prepares seed by "soaking three days in strong brine; pour off the liquid, and roll in as much air-slaked lime or plaster as the moist seed will receive, to make it fit for sowing. Time of seeding, early part of October; use two bushels of seed per acre; plough first in June, six inches deep; cross-plough the last of September. Not troubled with insects; average price, $1.38 a bushel." [Our correspondent soaks his seed too long in a "strong brine," and runs a great risk in destroying its vitality altogether. Five or six hours are quite long enough to keep seed wheat in any steep. It imbibes too much salt, which injures the growth of the plant for months after the wheat comes up, if the seed be long kept in strong brine, as the writer has found by experience.—Ed.]

Mr. Cyrus Holbrook, of Worcester, says that the average yield of spring wheat in that county is from 17 to 20 bushels per acre; amount of seed sown, 1¼ bushel; time of seeding, middle of April; time of harvesting, second week in August; plough twice; wash and lime seed; price of wheat, $1.25 a bushel.

Mr. Thomas Lincoln, of Washington county, Maine, writes, that "spring wheat is almost exclusively raised; varieties, bald and Black Sea. Winter wheat has been tried in a few instances lately, and succeeded so well as to increase the culture of this crop. Annual product per acre about 17 bushels." Mr. L. prefers to sow on land planted and manured the previous year; if green sward is used, the manure is spread before breaking, and is ploughed in spring; grain is sown about the 1st of May, at the rate of 1½ bushel per acre. The yield has diminished on the whole for a good many years. "Crop of late years much troubled with rust. Black Sea wheat is exempt from this malady, and is least injured by insects. Have never had the Hessian-fly, and seldom the weevil, in grain. Within seven or eight years, we have in some instances lost a large part of the crop by an insect called here the 'wheat-fly,' (probably the *cecidomyia tritici*,) which deposits its eggs on the end of each grain just after the blossoming, and stops the growth of the kernel by sucking its juices, without gnawing it like the weevil. Average price, $1.50 a bushel." Mr. J. S. Keith, of Oxford county, Maine, writes: "The average yield of spring wheat in this county for seven years past has not been above seven or eight bushels to the acre." "Winter wheat is being introduced into several counties with success." "Seed is soaked in brine from 48 hours to four days; best farmers have abandoned fall ploughing, and plough all they can in spring—the more the better, till the surface becomes light and porous."

Mr. Elijah Burrell, of Greene, in the same State, says: "In this vicinity, the culture of spring wheat has been for three years past nearly abandoned, owing to the ravages of the weevil, although in 1849 and 1850, wheat sown on light land produced well, and sustained but little injury from the fly. Red-bearded wheat is preferred, producing from 10 to 25 bushels per acre. Time of seeding, from 10th to 20th May. Seed usually washed or soaked in brine, and rolled in lime, to prevent smut. Quantity of seed from one to two bushels per acre. The crop is usually followed by corn. Wheat, corn, clover or timothy are grown in succession. Winter wheat is sown in August on a green sward fallowed. On land manured before breaking the sod, 30 bushels are sometimes harvested from an acre." Mr. Pruinton, of Portland, estimates "the average product per acre at about 35 bushels" in Cumberland county. His attention, probably, has been directed mainly to the crops of good farmers who make their lands rich by manure or clover, and cultivate their wheat fields in a superior manner. He says that "seeding takes place about the 25th of August; harvesting, the 1st of July." Very little wheat is cut so early as the 1st of July, so far north as Portland, we imagine. On light, warm land, well manured, wheat will ripen from 19 to 20 days earlier than on poor, heavy, cold soils. This fact is worthy of consideration by wheat-growers in Maine, and all the States where rust and insects attack the crop as it approaches maturity. One soil in the same field may be ten degrees warmer than another; and if so, the warmer earth will advance vegetation or growing wheat plants as much in 90 days as the colder in 100. The study of the temperature of soils and of the atmosphere just above the earth is too much neglected in all parts of the United States. Mr. Pruinton adds, on the subject of wheat culture: "Old ground should be ploughed twice, deep, with a subsoil plough. The yield per acre is increasing; spring sowing is going out of practice. Spring wheat is subject to blight and Hessian-fly. The average price in Portland of wheat is $1.40 a bushel." Mr. W. D. Dana, of Washington, says: "Wheat, which for a few years past, has almost ceased to be cultivated on account of the ravages of the wheat-fly, has this year proved remarkably good.

"The fly has left these parts; none having been seen this year, so far as I can learn, either in this State or the neighboring provinces of New Brunswick and Nova Scotia. The Black Sea wheat is almost the only variety in use—average product, 15 bushels per acre. Time of seeding, from April 20th to May 20th; of harvesting, from 20th to 30th August.

I prefer to cut it before the grain is hard, and let it ripen in the stock. Winter wheat is beginning to be cultivated as an experiment, and promises to become profitable. The preparation of seed usually practised here is to put it into a strong brine, and skim off what floats; then mix lime sufficient to dry it. I have never known *smut* where this course has been adopted. We sow 1½ bushel per acre. Hessian-fly and weevil not known. The wheat-fly does its mischief in the growing grain, for which we have no remedy but either early or late sowing—hoping that one or the other will escape. Price, $1.50 a bushel."

In Somerset county, as Mr. Edward Rowe informs us, the spring wheats most cultivated are a bald white-chaff, called tea wheat, and a bearded red-chaff, known as Malaga wheat. Owing to the depredations of the Hessian-fly and weevil, and injury from rust, the growing of wheat has been nearly abandoned for a few years; but the harvests of 1850 were more encouraging. Amount of seed, 1½ to 2 bushels per acre; harvest last of August or first of September. The growing of winter wheat is beginning to attract considerable attention. From reliable sources, information has been obtained that more than 10,000 bushels have been grown in 1850 in the two counties of Somerset and Kennebec, nearly all of which is sown for another crop; kinds in use are white flint, Kloss or banner, and Oregon. Sown in September, 1 bushel per acre; yield this season, 25 bushels per acre. Mode of culture: ground well ploughed once, harrowed fine and smooth, seed sown and covered with a small plough. Price, this season, $2 to $2.50 a bushel; price of spring wheat, $1.25 to $1.50. Mr. Elijah B. Stackpole, of Penobscot county, writes, that the crop of wheat is better in that county than usual; insects not so troublesome, and the average yield of spring wheat 15 bushels per acre. Time of seeding, middle of May; of harvesting, the last of August. Plough twice—first in autumn, six or eight inches deep, and again in spring.

Mr. John D. Lang, of Kennebec, writes, that wheat he imported from Poland, yields from 20 to 30 bushels per acre; this is a winter wheat. Black Sea and bald yield from 16 to 20 bushels. Winter wheat is sown from the 20th to 30th August; harvested from the 20th to 30th of July. Spring wheat is sown from 20th to 30th May, and harvested about the 1st September. Mr. L. ploughs green sward from 10 to 12 inches deep the first time; and instead of harrowing for winter wheat, the seed is ploughed in 3 or 4 inches deep, and not harrowed afterwards. Lime and plaster are applied to wet seed before sowing, which has been washed in simple water to free it from foreign and imperfect seed. For spring wheat, the ground is ploughed about 10 inches deep, and the seed harrowed in. The most successful dressing for winter wheat is a crop of clover turned under with the plough; in default of that, a compost of leached ashes, salt, and lime, spread evenly over the field. By sowing spring wheat on or after the 20th of May, the ravages of the Hessian-fly and weevil are avoided. Rust sometimes affects late-sown wheat, except the Black Sea variety. Mr. L. has sown as late as the 10th of June with good success. Wheat generally sells at $1.20 per bushel; seed wheat at $2. Mr. Ezekiel Combs, of Upper Freehold, Monmouth county, New Jersey, informs us that Mediterranean wheat is most extensively cultivated in that county, being less liable to rust and smut than other varieties. The next in public esteem is the Genesee wheat, which he regards as most prolific on rich, heavy land. The red-chaff is cultivated to a limited extent, and is considered best for late seeding, on a moist soil. Average yield per acre, 12 bushels; time of seeding, between September 25 and October 10. Mediterranean should be sown a little earlier than other kinds of wheat; early sown wheat, however, is frequently attacked by the Hessian-fly and yellows, while late sown suffers more from the fly in the spring, winter and spring frosts, and rust. Mr. C. calls attention to the well-known importance of letting seed-wheat stand till fully ripe before it is cut, and thinks, that wheat shrinks somewhat in weight by harvesting before maturity. He regards washing in strong brine and liming as a positive preventive against smut. White wheat, he sows from 1½ to 2 bushels per acre; Mediterranean, 2 to 2½ bushels; with Pennock's drill, 1 to 1¼ of white and 1½ to 1¾ of Mediterranean are sufficient. Plough deep; which is followed by a regular increase of product. Price, $1.10 a bushel.

Mr. Andrew Watterson, of Beaver, Pennsylvania, writes that the yield per acre of wheat in that region is increasing. Time of seeding, from 10th to 25th of September; harvesting, from the 4th to the 20th July. One ploughing is preferred, a little deeper each time. On land in good state of cultivation, a second crop is immediately taken after the first; then seed with timothy or clover. On poor land, a crop of oats succeeds wheat; and sow clover. Price, at the nearest market, 75 cents. Mr. Orange Johnson, of Franklin county, Ohio, informs us that there is very little variation in the yield of wheat in that section. He ploughs twice, not deep, sows 2 bushels to the acre, and gets about 20 as an average crop. He changes from wheat to corn, and from corn to wheat; is not troubled with flies or weevils, and obtains, at the nearest market, 62 cents a bushel for wheat.

Mr. Peter Fruttchey, of Northampton, Pennsylvania, says, that Whitehall, blue-stem, and Mediterranean wheats are most cultivated in that county; the first named is thought to yield the best, the crop being from 15 to 20 bushels per acre. Sow about the 15th September, and harvest near the 10th July. Plough three times about six inches deep. Yield per acre rather increasing of late. Wheat is generally sown on corn stubble; no preparation of seed except to have it clean. Price, $1 a bushel.

Mr. Jabez Bostwick, of Hamden, Delaware county, New York, says that since the appearance of the weevil, which destroys the berry of the head before it comes to maturity, we have nearly dispensed with the raising of either winter or spring wheat. The destruction of crops by the weevil within a year or two, has not been experienced, and the growing of wheat is increasing. Winter wheat is sown in the latter part of August, on summer fallowed meadow or pasture land, and yields from 15 to 25 bushels per acre. If spring wheat is sown so late as the 15th of May, it will escape the weevil; the egg-hatching season of that insect having passed by before the heads are sufficiently developed for the support of its larvæ; but in common seasons, the rust is very apt to attack late wheat. The white bearded is considered the best. Mr. B. sows 1½ bushel per acre.

Mr. Peter S. Reist, of Lancaster county, Pennsylvania, says that is a great wheat county—not because it brings sure crops, but on account of the great number of industrious people engaged in growing wheat, as a staple production. "We raise, as an average crop, from 20 to 25 bushels per acre; and not unfrequently, harvest 30 bushels. Sometimes we fail to get the amount of seed sown, from the effects of Hessian-flies, rust, and winter-killing. For insects and rust we know of no remedy. Late seeding keeps the flies off in the fall, but they often attack the crop in the spring, while rust and frost are usually more severe on late than early sown grain. Average price, $1 a bushel. Mediterranean and blue-stem are most cultivated." A correspondent, who signs "L. S. B., Warwick," in the same county, says, that the Mediterranean wheat is more cultivated than any other, because it ripens earlier, and is less subject to mildew and rust. The Hessian-fly rarely, if ever, attacks or injures it. The red blue-stem is a fine wheat, and much cultivated in the county, but it is a great favorite with the flies. The same is true of the white blue-stem, which is even less successfully grown than the red variety. Average product, about 15 bushels.

Mr. George Craft, of Brownsville, Fayette county, Pennsylvania, writes there was almost an entire failure of the wheat crop, except the Mediterranean, in 1850; owing, as I believe, to some two or three days of intensely hot weather about the 22d of June, when the berry was filling, or making. Many contend that the rust destroyed the crop, when there was, in fact, no rust upon it. The smooth Mediterranean is a white wheat, with large grains, yields well, and weighs 64 pounds per bushel. Average crop, from 15 to 20 bushels per acre. Sowing is done from September 20 to October 10; harvest begins about the 25th June; seed thoroughly cleaned, and sown at the rate of 1¼ bushel per acre. On fallow ground, plough and harrow twice; first ploughing from 6 to 8 inches deep. Lime is much used as a fertilizer.

Mr. Charles Ruggles, of West Vermilion, Ohio, who resides in a wheat-growing region, has the following sensible remarks on the production of this staple:—

"The varieties most in use are the white kinds—such as the Soules, Hutchinson, Crate, white flint, &c., with some Illinois and Mediterranean. There is but little of the latter, as it is a poor variety, a little superior to rye in quality, while the yield is good. The average product per acre, in this vicinity, is 20 bushels. This year it has gone far above that. Taking one tier of farms on the lake shore, six miles in extent, 548 acres were sown, from which 20,317 bushels were harvested and *measured*, being an average of 27½ bushels per acre. Little or no pains are taken in the preparation of seed, further than to clean it well. On strong lands, 2 bushels are sown per acre; the usual amount, 1½.

"Summer fallows are not often ploughed more than twice, and from 5 to 7 inches deep; but a few run a second plough in the furrow made by the first, and the two turn the soil from 12 to 15 inches. The result is *one-third more wheat per acre.* I think the yield is steadily on the increase. But little system of rotation of crops is observed—many sowing wheat after wheat for several years in succession, until the ground becomes so foul that it will no longer bear grain fit for market. It is then seeded to clover and timothy, and kept in meadow a year or two, or till it will do to undergo another series of cropping.

"This, however, is not done by good farmers. A great deal of wheat is grown after corn. The ground is well manured, ploughed deep, and the corn cut up at the root so soon as it is ripe enough for that purpose, and the ground well ploughed and sown immediately. This, when well done, gives a good crop, and is profitable; but the practice demands more manure than summer fallow. I know of no remedy for the Hessian-fly, only to sow early, and prepare the ground well."

The idea of Mr. R., doubtless, is not to escape the fly in autumn, but to have the wheat plants so vigorous that its larvæ can do but little injury. If this view of the case be correct, and sustained by experience, then early sown grain will have the additional advantage of standing winter freezing better, and of coming earlier to maturity in summer, and thereby escape injury from rust.

Mr. S. S. Boyd, of Jacksonburg, Wayne county, Indiana, writes that wheat has become a principal crop. It is oftener sown among corn than all other modes of seeding, when it yields about 12 bushels per acre. By breaking a fallow or clover field in June or July, ploughing again and sowing in September, harrowing in the grain, 25 bushels per acre is a common yield. The greatest enemy to wheat is rust: the Hessian-fly and weevil are seldom feared in this country.

To avoid the rust, the earliest varieties are selected, and sown about the 1st of September, so that it may ripen as early as possible.

Mr. Henry Daggett, of New Haven, Oswego county, New York, says that it pays to plough corn ground twice instead of once, in preparing it for seeding with wheat. It is quite subject to heave by frost, which often does great injury to the crop. Draining is the proper remedy for this evil.

Mr. F. D. Kingman, of Bergen, Genesee county, New York, says that his "crops of wheat for the last five years have averaged thirty-two and a third bushels per acre." We commend this fact to the notice of those who have been led to believe that the "Genesee country" was failing to produce the great staple for which it has long been celebrated. Mr. K. has the following remarks on wheat culture:—

"Time of seeding, from 1st to 16th September; of harvesting, from 20th to the last of July. Brine and lime the seed, and sow 1½ bushels per acre: sometimes I sow two bushels, but find it too thick. Plough three times: have this year procured one of Nourse & Mason's subsoil ploughs, and subsoiled a part of each wheat field. It takes three heavy horses to haul the surface plough 7 inches deep, which is my gauge. Subsoil with a yoke of oxen and a pair of horses, driving the plough 6 inches below the cut of the surface plough. The increase is from 8 to 10 bushels per acre. Within the last 10 years, I have not been troubled with the Hessian-fly but once. Price of wheat, from $1 to $1.12. At least one-third of my wheat is sown after spring crops, and clover always follows, being sown in April, at the rate of 10 pounds of seed per acre, with 100 of plaster. I turn nothing into clover fields in the spring; and when it is half in blossom, turn under with the plough. I now raise too much straw, and feel the need of understanding chemistry, to learn what to apply to increase the berry. We once had a chemist at Rochester, (Dr. Lee,) who would give the desired information, but I did not then know that it was needed by me. I have never kept any account of my corn crop, but it averages not far from 50 bushels per acre."

How to grow more wheat, and less straw, to the acre, is a problem not so easily solved as some may suppose. If the enterprising farmers of Western New York would maintain an experimental farm to test, in a thorough and satisfactory manner, the suggestions of chemical science, we have no doubt that the same land and amount of labor now employed in wheat culture might give them a quarter more grain at each harvest, on an average. Time will work out this improvement, when more agriculturists discover, as Mr. Kingman has, that additional knowledge is desirable.

Mr. Loring K. Tyler, of Lee county, Virginia, writes that the average yield in that county does not exceed 8 bushels per acre. Wheat brought from the North invariably does badly for seed; while the Mediterranean, brought from South Carolina, is succeeding well, after 4 years' trial. Time of sowing, from 20th October to 10th November.

Mr. William Mulks, of Cold Spring, Jefferson county, Wisconsin, writes that the "wheat crop in this section of the State has been exceedingly light this year, both spring and winter grain; the decrease below last year is probably 40 per cent." The culture of spring wheat is increasing, owing to the failure of winter wheat. The last-named averages about 12 bushels, the former 14, per acre. Average price at Milwaukie, 75 cents a bushel.

Mr. G. De Neven, of Fond du Lac county, in the same State, says:—"More winter wheat was sown in the autumn of 1849 than in previous years; but the yield was very poor, and of an inferior quality, owing to an exceedingly dry spring, cold winds, and continued rains during harvest. The average yield this year is about 9 bushels per acre; last season about 20. More spring wheat is grown this year than usual."

Mr. Ephraim Pickins, of Dodge county, Wisconsin, says that the average yield of wheat there is 15 bushels per acre, and that the crop is sadly injured by rust on low ground. Farmers are turning their attention to other crops, stock-growing, &c. Wheat is sown from 5th to 25th September, and harvested from July 15th to 25th. Quantity of seed per acre, 1½ bushel. Plough but once, 6 inches deep. Yield per acre diminishing.

Mr. James H. Gill, of Mount Pleasant, Ohio, after naming the varieties of wheat generally cultivated in that State, says that "defective crops originate from several causes: 1. The seed is thrashed by machines which break and injure the grain, so that it fails to germinate. 2. Seed harrowed in, leaves at least one-fifth on the surface, which never come to maturity, if they grow at all. 3. The want of proper draining. 4. Shallow ploughing, seldom going deeper than 7 inches, and scarcely ever subsoil. Frequently we plough but once; but generally lose the crop, from the fact that blue-grass takes possession of the ground and destroys the wheat. Our system of cropping is various; but the method of cropping should be—first, corn; second, oats or barley; third, wheat; then clover."

Mr. Stephen G. West, Jr., of Troy, Wisconsin, writes:—"The season just passed has been an unusually hard one for farming in this country. Winter wheat is generally a good crop; usual product, per acre, from 25 to 30 bushels on new land, where the yield is much more certain than on land long cropped. Method of putting in a crop on new land is as follows:—Break the ground between the 1st of May and the 1st of August; harrow once before sowing, and twice after. By seeding the 1st September, harvest will ensue about the 20th July. After the first crop, the yield is generally less, except on clayey land, which yields more the second and third crops than at first. We usually sow spring wheat after winter grain, with good success. The hedge-row variety is preferred."

Mr. James D. Bell, of Walden, Caledonia county, Vermont, states that the eastern range of the Green Mountains passes through that town, from south-west to north-east, forming the highlands between the Connecticut and Lamville rivers, being in latitude 44½° north, and having an elevation equal to any in the State. It snows there eight months in a year, and July is the only month exempt from frost. Fair crops of grass and grain are produced; crops come to maturity in about ninety days. Wheat is sown from the first of May to the first of June; harvested from 15th August to middle of September. Average yield, twelve bushels per acre. Best remedy for weevils, late seeding. Wheat is worth $1.25 a bushel. Mr. Bell estimates the cost of growing corn at only 20 cents a bushel in that cold, elevated region; yield, 40 bushels per acre. It is manured in the hill with a compost of muck and hog manure. It is worth $1 a bushel.

Mr. Coles Cook, of Addison county, in the same State, writes, that but little winter wheat is grown in that county; while spring wheat is raised in considerable quantities. Black Sea is the variety mostly cultivated; average crop, about 20 bushels per acre. Time of seeding is the month of May; harvesting, in the month of August. Quantity of wheat sown, 1½ bushel; prepared by soaking 24 hours in strong brine, adding as much recently-slaked lime as will cover every kernel. Excellent spring wheat is raised on green sward, either with or without manure. This crop also does well after corn, peas, and potatoes. Some prepare land in the fall for spring wheat, and seed as early as the ground will permit.

Mr. Joseph Parker, of West Rupert, Vermont, says:—"This formerly was a great grain growing country; but, owing to several causes, the consumption of wheat at present far exceeds the product. Our former method of growing wheat was to summer-fallow, and sow, from the 15th to the 20th September, 1½ bushel per acre; but that practice is now nearly abandoned, save occasionally on a piece of land recently cleared. Black Sea and tea are the kinds of summer wheat mostly grown. The seed is soaked in brine 12 hours and rolled in lime. Crops vary from 15 to 30 bushels per acre."

Mr. M. F. Palmer, of St. Albans, Franklin county, Vermont, writes that "the production of wheat is increasing both in the quantity sown and the yield per acre. Spring wheat of the Black Sea variety is mostly grown. This variety is preferred, especially for late seeding, as it is less liable to rust than other kinds. One bushel and a half is usually sown upon an acre, from the 1st to the 20th of May, mostly after corn or potatoes. I have, for eighteen years, prepared my seed by washing it in strong brine, and mixing it with fresh-slaked lime in sufficient quantity to render it dry enough to sow. From seed thus prepared I have never had wheat to smut in the least; and I regard it as an effectual preventive. The best and only remedy known here for the grainworm—sometimes called weevil—is late seeding. In this climate, we sow from 17th to 25th May, and the grain is not in blossom till the season in which the insect deposits its eggs has passed."

Mr. Jacob Shallcross, of Frankford, Pennsylvania, writes, that the Mediterranean wheat is preferred in that district, because it is least subject to injury by insects and rust. Farmers there plough but once, in preparing ground for seeding, and that but a few inches deep. The annual yield per acre is diminishing. Mr. S. recommends the following system of rotation:—First, plant corn, and sow clover-seed in February, instead of oats; plough in the clover when fully grown, (not ripe,) instead of manuring for wheat; then plant corn, in place of growing hay, which is the most unprofitable crop a farmer can raise in this part of the country. The average price of wheat in 1850, was $1.15, and the average product per acre, 25 bushels, with good farmers.

Mr. George H. Bucher, of Cumberland county, Pennsylvania, says the soil of that county is exceedingly variable in quality; some parts being strong limestone land, others slate, clay, or sandstone. The yield of wheat per acre differs as much as the fertility of the land and the skill of its cultivators. Mediterranean wheat is preferred, being more hardy, ripening earlier, and is less injured by mildew, freezing and thawing in winter, and insects. Mr. B. highly commends using a drill in seeding, rather than sow broadcast. Seed is placed at a uniform and proper depth when drilled, ripens evenly, is less injured by the heaving of frost, endures the winter better, and yields considerably more grain at harvest.

Mr. Asa Manchester, of Washington county, Pennsylvania, says that wheat ground is ploughed early in spring, so that it will freeze, frost being regarded as the best pulverizer. It is then sown early with oats; which being harvested, the stubble is turned in 8 or 10 inches deep, the land further cultivated, and seeded with wheat about the 20th September. Soil, a strong limestone clay. Crops harvested vary from 15 to 40 bushels per acre. He adds:—"Immediately after sowing wheat, and harrowing both ways, we sow timothy-seed, a bushel and a half to ten acres, for pasture, and bush it in, crossing the harrow marks, which fills them and prevents washing—a matter of some importance in a hilly country, liable to be cut up into unsightly gulleys. The bush is made by boring 10 or 12 holes in a beam 7 or 8 feet long, and filling them with brush. We have never missed a crop of timothy put in after this manner. The peculiar advantages are that it pulverizes the ground very fine, and buries the seed at just the right depth, so that it all grows. To keep our land, we plough it only once in 8 or 10 years."

[Bushing in grass-seed, including clover and flaxseed, is a practice universally commended by farmers who have fairly tried it.—Ed.]

Mr. George T. Powell, of Uniontown, Fayette county, Pennsylvania, writes that white wheat is worth from 10 to 20 per cent. more a bushel than Mediterranean and other dark varieties; but the first named is less prolific and more injured by insects, rust, and mildew. The average yield in Fayette county is estimated, by Mr. P. and several experienced farmers, at 13½ bushels per acre, which is obviously increasing. In seeding, they sow 1½ bushel of Mediterranean per acre, and 1¼ bushel of other kinds of wheat: knows of no remedy against Hessian-fly; but keeps weevils out of a mow of wheat by sprinkling the grain lightly with salt while mowing it away at harvest. "It is efficacious against weevil; and if it were not so, the salt in the straw would not be lost."

Mr. R. P. Stevens, of Cerestown, McKean county, Pennsylvania, informs us that the soil in that county is not well adapted to the culture of wheat, it being deficient in lime, and formed mostly of decomposed shales and sandy slates, underlying the conglomerate of coal measures. Whatever of lime the soil contains is derived from calcareous rocks at the north of us, in the State of New York. "We are, however, improving in the culture of wheat. Varieties grown are white bearded, Michigan flint, and Soules." The average yield is not far from 15 bushels per acre. Land is ploughed twice from sward, and once when buckwheat is ploughed in; depth of ploughing eight to ten inches. The yield is increasing. System of rotation from grass is wheat, oats or corn, buckwheat, and seed down with timothy or timothy and clover. We are not troubled with either fly or weevil; average price of wheat, $1.50. Wheat is not our principal crop.

Mr. Jeremiah Brown, of Luzerne county, Pennsylvania, writes that old land yields about 10 bushels of wheat per acre, and new 20, in that county. Sow 1½ bushel per acre in September, and harvest in July. Price, $1 a bushel.

Mr. Benjamin J. Passmore, of East Nottingham, Chester county, Pennsylvania, writes that the Mediterranean wheat yields much the best in that county. At the last harvest, other kinds were much injured by rust and mildew, while the first-named nearly escaped without damage. Average crop per acre, 18 bushels; time of sowing, latter end of September; average price, $1.

Mr. James A. Such, of New Lebanon, Mercer county, Pennsylvania, says the average yield of wheat in that county is 15 bushels per acre; and in preparing land for this crop, they plough twice, seven inches deep. The yield per acre is increasing; price per bushel, 85 cents.

Mr. John Blackfan, of New Hope, Bucks county, Pennsylvania, describes the larvæ of an insect, probably the true wheat-fly, (*cecidomyia tritici*,) developed in the seed of wheat when in the milk and dough state, which is less than a timothy-seed. When not preyed upon by insects, wheat turns out 20, and sometimes 30, bushels per acre in that county. Mr. B. is a great friend to frequent change of seed, having found it highly beneficial. In speaking of "plaster as a manure," he says: "Large quantities are yearly sown on grass fields in the spring; about a bushel is mostly sown. It is found, by experience, that its effects on grass are much increased by adding an occasional dressing of lime; and, if applied plentifully, a number of years in succession to land without liming, it almost entirely fails to have any effect. Plaster, mixed in the proportion of one part to ten of leached ashes, and a small handful dropped at every hill of corn before covering it, has been found by many of our farmers of great benefit."

Mr. John McSparran, of Fairfield, Lancaster county, Pennsylvania, writes that Mediterranean wheat yields 22 bushels per acre; white bluestem, 25 bushels; and "mountain" also 25 bushels. Time of seeding from September 1 to October 1; and of harvesting, from June 25 to July 15. Plough but once, four or five inches deep, and sow from 1¼ to 1½ bushel if put in with a drill, and from 1½ to 2 bushels when scattered broadcast. Price, 95 cents.

Mr. John G. Landis, of Lancaster county, Pennsylvania, speaks of that county as first in agricultural improvement and mineral resources, particularly iron, in the State. Its iron interest is greatly depressed. Wheat crop is 20 per cent. better than in 1849; his crop averaged, in 1850, 26½ bushels per acre, being about the usual harvest this season; yet an acre or so often yields from 30 to 40 bushels. Land is ploughed but once, eight inches deep, early in August; then cultivated with the harrow and cultivator. Time of seeding, from the last of August to the middle of October. The kind of wheat most successful and generally cultivated is the Mediterranean. Quantity of seed used, from one to two bushels per acre.

Mr. Thomas Stocks, of Oak Hill, near Greensboro', Georgia, writes:—"We break up our ground and put about 10 bushels of cotton-seed as manure per acre, and sow about a bushel of wheat any time before 10th December. Ground thus prepared will yield from 15 to 25 bushels per acre, according to the quality of the land. The only preventive against the weevil is sunning the wheat before it is stored away in the granary." [Mixing lime with it is said to be a sure remedy.—Ed.] Mr. S. says that the best rotation is for corn always to follow cotton; and wheat, corn; and after wheat, let the land lie idle a year, then plant cotton again, so making three crops in four years. A plantation well ditched on hill-sides and cultivated as above will never cease to make a remunerating return to the planter, particularly if he puts what manure he can raise on galled spots only.

Mr. Albert Hill, of Le Roy, Genesee county, N. Y., says that the average product of white flint wheat in that county is 27½ bushels per acre. This is a better account of wheat-growing in Genesee than has been given by gentlemen who knew next to nothing of the land and excellent farmers of that region. They sow from 1½ to 2 bushels seed per acre. Earth ploughed 8 inches deep yields better, as tested by experience, than when ploughed 6 inches.

Mr. A. A. Huntingdon, of Columbus, Wisconsin, writes that in that new country, 1½ bushel of seed is sown per acre; and that the crop of 1850 was quite poor. Early seeding does the best. Seed is washed and soaked in strong ley to prevent rust.

Mr. Ashbel A. Hosmer, of Riga, Monroe county, New York, a good farmer, sows his wheat without ary preparation, except to have it perfectly clean or free from other seeds, at the rate of 1½ bushel per acre. Clover and plaster are mainly relied upon to keep up the fertility of the soil—turning the clover when in blossom.

WHEAT AND OTHER CROPS IN OREGON.

Sir:—I have just received one of your circulars, and hasten to give you what information I am possessed of, in compliance with your request.

WHEAT.

We have three varieties in common use:—First, what we call the white fall wheat, which is considered the best for market, on account of making the whitest flour; but it is not generally preferred by farmers for bread, as it dries up in one or two days in summer, so that it is hardly eatable. But mixed in about equal parts with the red-bearded or Mediterranean wheat, a better article of bread is formed. White wheat is open and porous; consequently, it gathers moisture in the rainy season in this country, making it difficult to grind. The red-bearded or Mediterranean is very hard and flinty, and generally weighs from 8 to 7 pounds per bushel more than the white, which is better to grind in the dry season, and the red in the rainy season. The third kind is a bald red wheat, and there is a bald white spring wheat coming into use. The first mentioned variety is most common, having the advantage of producing the largest crops, and those most marketable. The time of sowing white wheat in September and October; and it may be sown any time during the winter when the ground is in condition, *i. e.* dry enough for seeding. I sowed, the last of February one year, on bottom land, and obtained a larger crop than on upland, sown in autumn, harvesting 38 bushels per acre. One of my neighbors sowed the same variety in May, (from the 8th to the 10th,) and reaped in August, about 27 bushels per acre; but it is not safe to seed so late, for it is not properly a spring grain. Our crops of white wheat may be 27 bushels, in ordinary seasons; but, taking all the land cultivated in wheat into the account, I do not think that the average exceeds 25 bushels per acre.

One year, I sowed about 4 acres with a mixture of white and red bearded, in April, hoping to obtain a crop of hybrid wheat. It all grew apparently well until about a foot high, when the red bearded shot up and headed most beautifully; but the white remained, and spread out over the entire ground in a perfect mat, and did not come to maturity that year. Some of my neighbors have sown the white wheat in August, but it did not come up till the showers of September, when it grew well, and produced a fine crop. The red bearded has a wider range, as to the time of seeding, than the white. It may be sown in August, September, and all the months of winter and spring. One of our neighbors sowed it on the 17th June, and gathered, the same season, about 18 bushels per acre. This, however, is an extreme case. I generally sow this grain about the 20th April—sometimes a little earlier. A good crop may be generally expected, if the seed is in the ground by the middle of May. This is naturally a spring wheat; but grows equally well in this climate, if sown in autumn, and sometimes yields better. In 1846, I sowed 15 acres in April, and, the season being dry, I got only about 16½ bushels per acre. The crop was uneven in ripening, owing to the drought coming on soon after it was sown. In harvesting, it shattered considerably, and the fall rain caused it to germinate and take root; and, without either plough or harrow, it gave a yield of 25 or 26 bushels per acre. This volunteer crop ripened in July, and the straw was from 5 to 5½ feet in length. A neighbor tried the experiment, and obtained 25 bushels per acre. No smut or chess was the result of this self-seeding crop, as we term it; but the ground was found to be more foul with weeds than that which had been cultivated.

Our harvest usually occurs in the latter part of July and fore part of August; although, I have seen wheat stand till October before it was ripe enough to cut. We make no preparation of seed, more than to have it free from other kinds of grain. The quantity sown per acre varies from 1 to 2 bushels; but most farmers sow from a bushel and a peck to a bushel and a half, according to the kind of wheat and season. The white, having a larger berry than the red, requires more to the acre. I always sow 1¼ of the red, and 1½ of the white.

We seldom plough more than once, sow on the furrow, and then harrow well. We plough from 4 to 7 inches deep, and sometimes 9 inches. No particular system is, as yet, adopted as to depth or time of ploughing, each one satisfying himself; yet those who are particular in preparing their ground, and putting in their grain well, are the most flourishing. No doubt, a few agricultural periodicals would benefit Oregon. Where crops are grown in rotation, with wheat, peas are the best. The fact that oats seldom winter kill in this country, renders this crop entirely unfit to either follow or precede wheat in rotation. The plan now generally pursued, is to let the land remain without any crop one or two years and pasture it, when it is ready for wheat again.

The climate of this country being so cool in summer, makes it a natural wheat-growing region. This alone, no doubt, has a great influence in respect to Hessian-flies and weevils. The former I have never known in this country; and the latter, I have not heard of but one season, and they were confined to two or three granaries of the Hudson Bay Company. I can give no other than hearsay information concerning the weevils. The general opinion at the time was, that the grain had been threshed and stored in the granary before it had undergone the sweating process, which always takes place in the mow or chaff subsequent to threshing. I have never known weevils to get in grain in this country while it remained in the field; and in only one instance anywhere. There have been large quantities of wheat stored in granaries, in different parts of Oregon, and particularly at the time those of the Hudson Bay Company were affected. Great fears were entertained by most of those having wheat in storage; while no apprehension was felt by such as had wheat in fields, or in the mow. The rust sometimes appears on wheat in Oregon; but I have never seen it injured by this malady. In the summer of 1845, in particular, as I walked through my wheat-field, my clothes would become entirely colored with the rust; but, during the season, I did not find a stem or head injured by it. The cause of the rust was frequent warm rains in June, and a hot sun shining upon the grain immediately after. The average price of wheat at Oregon City (our nearest market) is $1.50 per bushel; the range being from $1 to $2.

CORN.

So little corn is raised in Oregon that I shall say but few words on the subject. The climate is too cool for this crop to do well; and I have not seen a failure of frost in the fore part of May any year since 1839. Frosts are not uncommon in June, such as materially injure corn, but not wheat, rye, nor oats. If wheat happens to be in bloom then, it is seriously injured. One of my neighbors raised 15 to 20 bushels of corn to the acre; but it can never become a staple crop, owing to the climate.

OATS.

This crop is generally good, though not very extensively cultivated; and, therefore, we have a good home-market at a better price than wheat. Forty bushels is the average yield per acre. Oats are frequently sown in autumn, at the rate of two bushels per acre; the winter having but little effect on them. They grow self-sown, and are apt to come in wheat, if not guarded against. I have grown this grain on the same piece of land five successive years; but the last crop was a poor one, on account of the dry weather, yielding only about 16 bushels per acre. The fourth crop was 65 bushels, the season being very favorable.

Barley, rye, and beans grow very well, but are little cultivated. Peas are cultivated to clear the ground for wheat, and are admirably adapted to that purpose. They yield about 18 bushels to the acre, and leave the soil in a good condition for any crop. The ground appears much renovated by this crop in many cases, and, in truth, I may say, in all cases, though more perceptible in some than in others. We find the same soil will always produce a better crop after peas than without them.

CLOVER AND THE GRASSES.

This being a northern latitude, it is probably expected that quantities of hay are made to subsist the herds of cattle and horses found here; but information only is wanting to show that Oregon, at present, needs but little winter food prepared for cattle or horses. In the fall of 1849, I prepared about seventy dozen sheaves of oats to winter thirty head of cattle and six horses, which was sufficient to winter them, and all in good order in the spring. The winter was a hard one for this country. This fall, my oat crop being poor, I have prepared about two-thirds as many for my stock. This leads to another observation, which may not be out of place here, viz. that whenever we have a dry season and a light crop, we are sure to have an open winter. On the other hand, a wet season, which produces large crops, is always followed by a comparatively severe winter. But little hay is made in the Territory, in comparison with any of the Northern States. Timothy, red-top, and blue-grass all flourish here, and clover in some portions of the country. I have seen timothy, the second year from the seed, grown 6 feet, bearing a head 10 inches in length. The soil is generally of a close, firm texture, and better adapted to herds-grass than clover. I have seen about 2 tons of timothy hay cut from an acre. Hay is little used, as cattle in hard winters are fed mostly on wheat straw.

NEAT CATTLE.

In this country, we usually raise all our calves, and give them a part of the milk until they are six months old, and some have milk until the cows naturally wean them, in the fore part of the winter. My usual method is to give the calf from one-fourth to half the milk, according to the quantity which the cow gives and the size of the calf, up to the time it is four months old, and then gradually diminish the ration till it is six or seven months of age, when it is in good condition to stand the winter rains. The amount of food necessary for winter is small, as cattle do not need feeding over three or four weeks, all told, during the winter. I express the opinion, after ten years' experience here, that it will cost about as much to winter cattle in this country as the same number of sheep in my native place in New York, *i. e.* about a ton of hay to ten head, taking open and close winters together. Horses will be in about the same ratio, although many horses and cattle are never fed, particularly the Spanish breed. The actual cost of rearing, until three years old, is mostly while sucking-calves; and, as near as I can calculate, the milk and care, before weaning, are equal to $15; to which add the cost of wintering, and a little for salt and attention, and the expense of rearing a three-year-old steer is not far from $25. The value at that age is generally from $35 to $40 for steers, and $25 to $35 for heifers. Another consideration places heifers in quite a different light. With few exceptions, they produce calves when two years of age, thus becoming cows with second calves when three years old. Many have their first calves when eighteen months old; and some even as young as fifteen months. In some cases, instead of becoming a dam at three years of age, they are really *grandams*. There are more that produce calves under two years than there are that go till they are three; but these young cows are not at their best for dairy purposes before they reach four or five years of age, when they are valued at from $50 to $75. Some sell as high as $100. It will be understood that the prices above named are paid for American, not Spanish cattle; the difference between the two being about twenty per cent. minus the Spanish.

I have never known beeves stall-fed in this country, and yet the beef fattened on grass is quite as good for fresh as any stall-fed. For salting and foreign consumption, the difference is sometimes very great; inasmuch as the fat of the animal (the tallow included) is not so hard, and frequently appears quite oily. Trials have been made in salting for foreign markets, when it was found that the beef of American cattle, *i. e.* stock brought from the Atlantic States, would keep in a sound condition, while that of Spanish cattle would be so injured, after having been packed two or three months, as to be unfit for use. This difference is supposed to arise from the hardness of the former and the softness of the latter. Beef cattle on foot, are worth from 6 to 10 cents per pound; butcher's meat, from 7 to 20. Steers, from 3 to 4 years of age, usually weigh from 600 to 800 pounds, quarters only.

DAIRY HUSBANDRY.

As before observed, calves are nearly all raised in this country; and the quantity of butter and cheese produced is proportionably less on that account. Taking our dairy-cows together, I estimate the average yield per cow at 50 pounds of butter, and a corresponding ratio for cheese, when made. Butter has averaged, the past year, about 50 cents a pound; cheese, 40 cents. Labor is so high here that the cost of making these articles is nearly equal to the prices which they bring. It is very difficult to get at these things with any exactness; but I have formed as just an estimate as practicable, under circumstances so fluctuating.

HEMP.

Previous to the discovery of California gold, hemp was experimented upon by my neighbors who were acquainted with its culture in the Western States; and they reported the growth to be better and of a firmer texture than any produced where they were acquainted. It has not been cultivated since.

ROOT CROPS AND VINES.

The potato crop has been free from the rot until this season. I discovered that a small piece of potatoes, which I had manured in the hill, had black specks through them, of the appearance of particles of earth, which alarmed me; and, on inquiry, I found that the crops of my neighbors were similarly affected. I have tried experiments, by putting a few alone in the open air, and together in a body, and the tubers remain the same, without being more or less affected. It is worthy of notice, that potatoes immediately adjoining, manured in the new manner, were entirely free from those specks. Onions, parsnips, carrots, beets, turnips, cabbages, tomatoes, &c., all grow most prolific, but are not extensively cultivated. I usually grow a small portion of each for family use only, and I am not prepared to give any useful suggestions in reference to these crops. Squashes, pumpkins, and melons are not sure crops here, owing to the late frosts in the spring, unless covered at nights. When planted as late as the 10th May, in rich ground, they grow finely and bear well. The best way to prepare ground for culinary vegetables, in this country, is to make a yard, or fence a plot of ground by itself, and in the summer, when it is dry, say from June until fall, yard cattle on it at nights, instead of putting them into the barn-yard. This will give the soil a good coat of manure; and as soon as fall rains moisten the ground, plough well, about seven inches deep, still letting cattle run upon it so long as it is dry enough not to injure the ground by treading it. This plan of manuring I think highly of, where it can be done, and is preferable to hauling out stable manure. The earth receives all the urine as well as dung, which is a matter of more importance than many suppose. I have found, instead of injuring cattle to put them into a yard at night, rather than leave them in their pasture, it is an advantage. In the first place, they must have time to chew their cuds, which, of course, may be done as well in a yard as elsewhere: secondly, when cattle lie down in the pasture, the places occupied by them have received the peculiar smell or effluvia of their bodies, which, with their excrements, gives them a distaste for that part of the field or pasture. On the other hand, when shut up during the night, and especially where they have fresh yards occasionally, as they should have, every thing is fresh for them in the morning as they go forth with good appetites to graze and gather their needful food. This new process of manuring I have never seen in full operation, except in this country.* Last year, I raised about 4 large wagon-loads of squashes on a piece of land 26 yards long and 8 wide; and the largest kidney potatoes I ever saw, grew when manured in this way.

Yours, truly,

WILLIAM GEIGER, Jr.
Quality, Washington County, Oregon.

Hon. Thomas Ewbank,
Commissioner of Patents.

CORN.

The crop of corn harvested in 1850 was very unequal in different States. At the South, the yield was unusually small; the injury being done mainly by protracted dry weather in May, June, and July. In the Middle and Western States, the yield was not far from an average crop; some districts producing more and others less than an average. In New England, this grain was somewhat injured by dry weather, the depredations of

* The plan of manuring described by our correspondent is quite common in all the Southern States; and it was, doubtless, introduced into Oregon by emigrants from Missouri. Yards should be oftener ploughed than he suggests, to fix all the volatile matters voided by stock in the soil.—Ed.

insects, and other casualties to which corn culture is subject. Mr. H. H. Watson, of New Haven, Oswego county, New York, writes that the usual crop there is from 40 to 50 bushels. He gives "the preference to manuring in the hill," as a given amount will go farther than when applied broadcast to the land. The market price of corn there, is generally 50 cents. Mr. G. Bowdish, of Montgomery county, in the same State, says that yellow corn is sweeter than white, and generally preferred, from the popular belief that the meal of the first named is more nutritious. "Of the various kinds cultivated, perhaps there is none equal to the small eight-rowed yellow." It is generally sounder than larger kinds, and often weighs more than 60 pounds per bushel. Average yield per acre, 35 bushels. Corn and cob ground together is the favorite way of feeding domestic animals on this grain.

Mr. Asa Carter, of Champion, Jefferson county, New York, says:—"After trying all the various kinds I could obtain, a variety known as the 'red Blair' has proved to be the best. The ear is long, the kernel large and well set, the color white, with a red blaze on the tip of the ear, and the average product on my farm, for several years, has been from 40 to 50 bushels." Some of Mr. Carter's crop, this year, turned out 80 bushels.

Mr. Seth Severence, of Oswego, writes that crops of 135 bushels per acre have been several times grown in that county; and fifty bushels are not far from an average, among good farmers. Poor farmers harvest not more than half that amount. Increased attention is paid to the saving and application of manure, and to tillage. The Dutton corn (a 12-rowed variety) is commended by Mr. S. as valuable, and worthy of more extended cultivation.

Mr. J. Y. Berry, of Stafford Corner, New Hampshire, applied 4500 bushels of "marl mud" on 3 acres of land, in 1846, and harvested therefrom 100 bushels of corn in 1847. In 1848, the crop measured 140 bushels; and, in 1849, the yield was 60 bushels of oats and 25 of barley; and, in 1850, the crop was 6 tons of clover hay, with nearly the same quantity of after-math, mown in the middle of October. Another piece marled not only produced large crops of corn, but each stalk became more prolific in the number of ears that set and came to maturity.

Dr. Wm. Johnson, of Prospect Hill, Iowa, describes corn-growing in that State, as follows:—

"Corn is reckoned, and doubtless is, the most certain crop of this region. Some break the land in the fall; but the general practice is to plough early in the spring. The ground is listed with a plough each way, and the seed planted in the intersections, at the rate of from 2 to 4 grains in a hill. The usual method of covering seed is with a hoe; but many cover with a harrow. With but little attention, 25 to 30 bushels are the average yield; and hence this is, *par excellence*, the lazy man's crop. Where the land is well tilled and kept clean, the average is about 50 bushels; and it is no uncommon thing to gather from 60 to 70. The price, the past year, has been 25 cents per bushel."

Mr. H. Little, of Stoystown, Ontario county, New York, says that the small yellow corn is the only kind cultivated in that climate, and it yields about 30 bushels per acre.

Mr. Jonathan Talcott, of Rome, Oneida county, New York, informs us that the average yield of corn, in that vicinity, is 50 bushels, among good farmers—70 being often harvested. Planted in rows of from 3 to 4 feet

each way. Best method of feeding is ground into meal and cooked. Mr. T. advises seeding after corn with grass seed, (hardsgrass,) at the rate of 12 quarts per acre, sown with or after wheat, rye, or oats, adding 8 quarts of clover-seed. Previous to seeding, the ground should be manured, ploughed nine inches deep, and, when seeded, thoroughly harrowed.

Mr. Homer H. Winchell, of Shelby county, Missouri, writes that on land well cultivated, the average yield of corn there is 60 bushels per acre. Best system of culture, is to plough deep in the fall, harrow the ground well in the spring, and furrow off at the distance of 4½ feet. Plant the first week in April, keep the ground in good order by repeated ploughing, until the first of July, and an abundant crop will most generally be harvested. "Cost of production, as nearly as possible, 10 cents." The New England yellow flint corn has been tried, and proved a failure.

Mr. Wm. Zimmerman, of Keokuk county, Iowa, writes that more corn is cultivated there than any other crop. "We raise both the yellow and white. Manure is not used. Plough once, plant, and, if well tended, (ploughed four or five times,) it will produce 60 or 70 bushels per acre. The cost may be estimated as follows:

Rent of land	$1.25
Ploughing half day	1.00
Planting	75
Tending	1.00
Gathering	1.50
Total cost per acre	5.50"

Mr. George Groves, of Knox county, Tennessee, says that the large white corn is most esteemed in that section; and the yield per acre varies from 25 to 50 bushels. Often the extremes in crops are more distant.

Mr. Henry Merrill, of Marion county, Western Virginia, writes that "corn was never better than in 1850." Mr. M. describes, in glowing terms, the energy with which the Baltimore and Ohio Railroad is pushed forward to its completion. This great work will be invaluable to the farming interest of that fertile but sequestered region.

Mr. John H. Tarr, of Fayette county, Pennsylvania, informs us that the most esteemed variety of corn in that county is "the large rough gourd-seed, with from 12 to 16 rows. Cob white, seeds long; and the average yield is from 40 to 50 bushels per acre." "We generally plant on a clover ley; with long manure ploughed in; follow corn with oats and manure, and this crop with wheat." Previous to seeding with wheat, lime and coal-ashes are freely used as fertilizers. Corn is usually planted on or near the 25th April, in squares 4 feet from centre to centre. After-culture is done with cultivator and double-shovel plough. *Crop is kept free of weeds and grass till harvest.*" [A capital practice, and one too much neglected.—Ed.] "Price of corn in December, 1850, 40 cents. Cost of production, 8 to 10 cents a bushel, exclusive of interest and taxes on land."

Mr. Alonzo Dutton, of Windham county, Vermont, writes that "corn is considered one of the best crops" in that region. Average yield, 45 bushels per acre; cost of production, some 48 cents a bushel. Best system of culture is to spread manure broadcast, plough in, plant in rows 3 feet apart; four stalks should stand in a hill, and the ground should be kept free of weeds and light by tillage.

Dr. John H. Weir, of Madison county, Illinois, says: "Corn is produced in great abundance on the American Bottom. The yellow, and a mixture of the white flint and gourd-seed, are the best, and most productive. The Bottom averages 50, and the high prairie 40 bushels per acre. The cost of production is from 10 to 12 cents a bushel. Ground should be ploughed 6 inches deep, furrowed both ways 4 feet apart, planted with three grains in a hill, to be covered with fine earth 2 inches in depth, on or near the first of May. Cultivate with a plough, running the bar next to the corn; and, so soon as it can bear it, turn mould to it. Corn should be ploughed at least four times, breaking all the ground between the rows each time. It is fed here whole and raw; but whether the gain from grinding and boiling will pay cost in this part of the country, I cannot say. Corn sells in our market at 35 cents a bushel."

Mr. J. H. Harrison, of Sangamon county, Illinois, writes that corn is much more cultivated than wheat, and is of more value to the farmers in that region than all other crops. In preparing the land for a corn crop, the stalks of the previous year are cut up with a sharp hoe, at the rate of five or six acres per day. They are then raked into rows by a rake drawn by two horses, and burnt. A pair of horses will rake 30 acres in a day.

[This is a valuable hint to corn-growers at the South, where hands spend a good deal of time in picking up and carrying dry cornstalks into heaps, with a view to burn them, or let them rot.—Ed.]

Mr. Harrison says "the ground is well ploughed 3 inches deep," which is too shallow by at least 3 or 4 inches. "It is furrowed off 4 feet each way, and four seeds are planted for each hill, and covered from 1½ to 2 inches deep, with dirt from the furrow. When the corn is 3 or 4 inches high, it is ploughed with a small plough, throwing dirt from it. In eight or ten days it is cross-ploughed, with three furrows in a row; and in ten or fifteen days repeat the operation the other way, and so make the crop. The most esteemed varieties are a kind of yellow corn, very near the gourd-seed, and a white gourd-seed, which is about fourteen days earlier in maturing than the yellow. Average product per acre, from 45 to 60 bushels; better culture easily increases the yield to 80 or 90 bushels. Labor is now so scarce and high, that we cannot afford to expend more on a crop till there is some change."

Mr. A. Cleaveland, postmaster at Yankee Hill, in the same State, writes that the cost of growing corn in that region is about 10 cents a bushel, and the crops vary from 40 to 60 bushels per acre.

He recommends, in tillage, to turn the earth from the corn in the first operation, and to it afterwards. "Corn should be ground before feeding, and soured, for hogs."

Mr. Ralph Ware, of the "Buel Institute," in Northern Illinois, writes that the "corn crop is good, if not the best ever raised since the settlement of the country. We place the average at 45 bushels per acre. One field of 10 acres produced 110 bushels per acre; a number of pieces averaged from 70 to 80." Mr. A. Job, of Cass county, Illinois, estimates the cost of growing corn at 7 cents a bushel. He raises both white and yellow—the former for bread, and the latter for feeding stock. Feeds raw and unground, and husks the corn on the stalk.

Mr. Amos A. Hilliard, of Macoupin county, Illinois, says: "All that is required to grow 60 bushels of corn on an acre of common prairie land is to plough deep, pulverize the soil, and keep the weeds down—all done with the plough or cultivator. Here, where mills charge high for grinding, and labor is dear, we do not grind or cook feed for stock. Our best method is to cut up and shock the crop as soon as the grain is hard, and while both the stalks and leaves are green. In winter, the corn is daily hauled into a lot, to be first fed to fatting cattle; which being turned out, stock cattle follow to eat up the fodder, and these by hogs."

Mr. Joseph H. Merrick, of Franklin, Delaware county, New York, says that the Dutton corn is much approved, and that the average crops, with good culture, range from 40 to 60 bushels per acre. Greensward, well turned after it is manured, gives usually the best harvests. Seed is covered with tar, and then rolled in plaster, before planting, to keep off insects, birds, and squirrels. Before feeding, corn is boiled or steamed, so as to render it soft. In this condition, both seeds and cobs may easily be crushed and mixed together.

In his report of the products of agriculture for Delaware county, Ohio, in 1850, Mr. Henry Hodgden writes: "The average yield of corn this year is 40 bushels per acre—25 per cent. less in the western part, owing to a severe drought. Our best method of raising is to plough as early as the season will permit, and deep; plant by the first of May, and tend thoroughly with the cultivator and shovel-plough. Corn is generally fed to stock, and is worth 25 cents a bushel. Amount probably grown this year, 650,000 bushels. In favorable seasons, many portions of our country will average 50 bushels per acre. Defective farming is the main difficulty."

Mr. Elijah B. Stackpole, of Penobscot county, Maine, writes that "corn has been good the present year." The small eight-rowed yellow corn is preferred. Average crop, 40 bushels per acre; time of planting, 20th May; harvesting, 10th October; cost of production, 50 cents a bushel.

Mr. John D. Lang, of the same county, (Penobscot,) informs us that "the yellow eight-rowed corn, with long ears and small cob, called the early Canada, is most esteemed. The seed is occasionally renewed by importing it fresh from Canada. There is another kind, called the "brown," having a larger kernel, and ripening about two weeks later. The former averages about sixty, and the latter about seventy-five bushels per acre; and I raise from six to eight bushels of white beans in addition. The cost of production is not far from sixty cents a bushel. One method of cultivation is to turn in a crop of grass in the seventh month (July) from ten to twelve inches deep, cross plough in the spring, spread twenty-five to thirty cart-loads of manure to the acre, plough eight inches deep, and harrow well. Soak the seed in brine, and mix with plaster; plant ten kernels in a hill, which should be three feet apart in the rows, and the latter three and a half to four feet apart: add a spoonful of plaster to each hill. At the second time of hoeing, remove all but four of the healthiest plants; these will spread over the hill. Hoe twice or three times, top the stalks after blossoming, and let the crop ripen in the field."

Mr. W. S. Sparks, of Somerset county, Maine, writes that the crop in that county now averages about forty bushels with good farmers, and the yield might be considerably increased. He gives a decided preference to the yellow eight-rowed corn, and adds: "The drill system, as far as I have learned, is considered a great improvement in corn culture, although it is not practised here. I have seen the effects of it in other parts of the State, and the results were good. Compost manure is excellent for corn, especially if composted in the hog-yard—perhaps the best that can be applied to corn ground. Our farmers are much in the habit of manuring in the hill. Long manure is spread sparingly upon the ground, and ploughed in. Some plough first, spread manure, and harrow or cultivate it in, which, in my opinion, is the poorest kind of economy; and crops so raised are apt to run the farmer in debt. Lime, plaster, and ashes are used as a top-dressing, and in compost heaps; and they are found to be very beneficial. The method of feeding corn is ground and cooked. I should think the gain is at least 10 per cent. In my opinion, from fifty to eighty bushels might, with more care and skill in saving manure, and culture, become our average crops, in place of forty."

Mr. Peter S. Reist, of Lancaster county, Pennsylvania, estimates the average yield of corn in that county at fifty bushels. Some crops have been grown that gave eighty and one hundred per acre. The crop of 1850 was injured by dry weather, and sold at 50 cents a bushel. To destroy worms and insects in corn-ground, plough in the fall, and let the earth freeze through the winter.

Mr. James Harkness, of Jacksonville, Illinois, says that the large yellow corn is best for horses, mules, and hogs, the small yellow for neat cattle, and the large white for the consumption of man: average product, about thirty bushels per acre; cost of production, from 12 to 14 cents. Cultivation: "Break up the ground with a two-horse plough as early as it is fit for ploughing in the spring, then harrow, lay off the rows four feet each way, drop from three to five grains at each intersection, being careful to place the seed near the land-side of the furrow; then cover with a bull-tongue plough. As soon as the corn is fairly up, harrow it; then use a one-horse plough or cultivator, and go over the field three or four times. In the mean time, it should be weeded and thinned out to three stalks in a hill."

Mr. James Edgerton, of Belmont county, Ohio, says that the range of the yield of corn in that county is exceedingly variable, reaching the extremes of from ten up to one hundred bushels per acre. Mr. E. states that the Agricultural Society in Belmont county awarded a premium for a crop of sweet potatoes which measured eight hundred and forty-two bushels from an acre. The average of this crop is said to be about four hundred bushels per acre. "Sweet potatoes are usually worth 75 cents a bushel." In climates adapted to it, this esculent tuber is much less cultivated than it deserves. It is one of the best crops grown in the South for feeding milch-cows and other stock.

Mr. J. Widney, who dates his letter "Ohio Farm, Illinois," says: "Our corn crop is good and sound, but does not turn out so well to the acre as people generally expected." As we have no means of learning where his "Ohio farm" in Illinois is, (the envelope of his letter not being preserved, which might show the post-office at which it was mailed,) Mr. Widney is informed that the "keg of pure China wheat," which he says he forwarded to the Patent Office, was destroyed by weevils.

Mr. W. A. Bacon, of Bourbon county, Kentucky, writes that their average crop of corn is 50 bushels: but the present year it is about 40. For early feeding, large kinds are preferred, but they do not keep so well

through wet winters as smaller varieties. A severe drought during the month of June injured the corn crop in that State. Expense of production, about 15 cents a bushel. Culture: "Plant 4 feet apart; plough twice in a row each way; seldom use a hoe; some use a roller after planting, which, no doubt, is advantageous, if the ground is cloddy. Feed in the ear."

Mr. George W. Harrison, of Salisbury, Sangamon county, Illinois, estimates the cost of growing corn at 6 cents a bushel, and says that the crop might be made to average 100 bushels per acre.

Mr. Amos Benton, of Ross county, Ohio, says that "considerably more than 100 bushels have been harvested from an acre in large fields which received only ordinary cultivation." The manure made from corn and cornstalks seems to be the best for the growth of corn. Fields in which cattle are fed, although tramped until, from appearance, they would not produce any sort of a crop, yet, when the ground is broken early, so as to have it mellow, yield corn in the largest quantity. Manure made by fatting-hogs is the best, perhaps, that can be used; and its beneficial effects may be seen much longer than those of other manures. Mr. Charles Ruggles, of West Vermillion, Northern Ohio, writes that corn averages there 60 bushels per acre, and is grown at a cost of 12½ cents a bushel. Mr. Ezekiel Combs, of Monmouth county, New Jersey, writes as follows:—"The yellow gourd-seed corn is principally cultivated in this section, yielding from 30 to 35 bushels per acre. Some good farms produce from 60 to 75 bushels. The average cost of production, I estimate at 37 cents. A clover ley, with or without manure, according to the strength of the land, deeply ploughed, well harrowed, marked out four feet by four and a half, kept clean and mellow in the first stage of the crop, and tilled with the cultivator in the latter part of the season, is the management most successful. The best method of feeding hogs, that I have ever witnessed, is to have corn and cob ground together; boil the meal; let it cool and sour before feeding it. By this process, I have found not only great economy in the use of food, but also great gain of flesh. It is sweeter, more juicy, and of fine marbling. For cattle, it seems almost indispensable that corn be ground, except the offal at husking-time; but I have doubts as to the economy of grinding corn for horses, unless their teeth begin to fail."

Mr. Orange Johnson, of Franklin county, Ohio, says corn is grown at the rate of 60 bushels per acre in that county, and at a cost of 12½ cents per bushel. Easiest way of raising is on turf ground ploughed twice. For feeding, he uses a mixture of corn and potatoes cooked. Mr. J. G. Tyler, of Hillsdale county, Michigan, prefers the white dent corn to any other, for that climate. It yields from 30 to 40 bushels per acre. Cost of production, 25 cents a bushel; hoes the crop twice. Mr. Alexander Hamilton, of Penn Yan, New York, says:—"The yield of corn is much better than formerly," owing to the use of plaster applied in the hill, better tillage, and improving land with clover.

Mr. A. J. Willmarth, of Athens, Ohio, says that corn is grown there at a cost not exceeding 10 cents a bushel. He cultivates in drills, having a plant every 10 or 12 inches in the row, and these 4 or 4½ feet apart.

Remarks similar to the foregoing might be extracted and extended to almost any length from the great number of letters received at this office. There is not a State in the Union, east of the Rocky Mountains, in which corn is not an important crop; and it is rare to find a cultivator of the soil who is not familiar with the production of maize. We have elsewhere given all that our correspondents in the cotton-growing States have had to say on the subject. We are happy to know that this grain is produced cheaper per bushel, and more per acre, now, than at any former period in our history, by those farmers who keep pace with the increase of agricultural knowledge in the United States. The gradual improvement of all cultivated lands is an object which cannot be too often nor too earnestly pressed upon public attention. On rich soils, corn may be grown to an indefinite extent, at a price which will force its consumption by the millions in Western Europe. No other crop, not even cotton, has equal commercial importance, provided corn-culture be reduced to a perfect system, based on true scientific principles. As an article of every-day consumption, by man and beast, the seeds of Indian corn are without a rival. Slowly, but certainly, it must force its way into common use in England, Scotland, and Ireland; and to this end its most economical production in this country is a matter of the highest importance. One might suppose that commercial cities, which draw all their wealth from the soil, would be willing to establish agricultural schools for the purpose of diminishing the cost of producing the breadstuffs, provisions, cotton, tobacco, rice, grass and lint-seeds, which they export to foreign nations. But, somehow, the denizens of cities fail to see that they have a deep pecuniary interest in the productiveness of rural industry. They never consider the important truth that, when the natural fertility of land is impaired, the loss injures commerce, injures manufactures, injures professional occupations, and injures all educational institutions, quite as much as the farmer. It is a sad mistake to suppose that agriculturists are alone concerned in the practical results of tillage and husbandry. They have no more than a common and equal interest in maintaining or increasing the natural fruitfulness of the earth. Hence, all classes should unite to increase the professional knowledge of American farmers. All the sciences which illustrate the principles of agriculture should be placed within the reach of every youth who is to direct the cultivation of an acre of ground. Sciences are best taught and easiest learned in schools having all the appliances to develop and explain their elements and combinations. If an increase of knowledge would save only 5 cents in the cost of growing a bushel of corn, on an average throughout the Union, the aggregate annual gain would exceed twenty millions of dollars. We have given the names of intelligent practical farmers who vary in their estimates of the expense of producing this great American staple from 6 up to 60 cents a bushel. What is most needed, particularly in all the Atlantic States, is those elements of this crop which are least abundant in common soils. The raw material for making corn, and the professional knowledge how to obtain it in the cheapest manner, are the weak points in this branch of agriculture. The manufacture of manure in cities and villages, from animal and vegetable substances, and the importation of guano, are remedies for the evil which are beginning to attract considerable attention. Marling, liming, turning in green crops, and subsoil ploughing, aided by draining and greater care in saving and using manure, are efforts in the right direction, and rarely unsuccessful.

THE STUDY OF SOILS.

BY DANIEL LEE, M. D.

A General View of the Subject.

If four-fifths of the persons employed in agriculture, in the United States, work 250 days in a year, their aggregate labor exceeds one thousand millions of days in twelve months. The compensation realized for this immense amount of industry depends in a large degree on the fruitfulness of the soil under cultivation. Hence, the study of the sources of fertility, and of the causes of barrenness in improved land, has a direct bearing on the every-day employment of more than two-thirds of the labor and capital of the republic. It is almost impossible to over-estimate the importance of understanding all the elements and circumstances which affect the natural productiveness of the earth. To show what American soil and climate have done, and are capable of doing, we give below a statement of the premium crops of corn grown in Kentucky, in the year 1850. There were nine competitors; and the surface in cultivation, ten acres by each competitor. Their names, and the product of each per acre were as follow:—

J. Matson, 37 barrels, 4 bushels, and 1 quart.
Peter Pean, 37 barrels and 4 bushels.
S. H. Chew, 27½ barrels.
J. Hutchcraft, 23 barrels.
A. Vanmeter, 21 barrels and 3½ bushels.
H. Hedges, 21 barrels and 2 bushels.
E. W. Hockaday, 20 barrels.
Dr. B. W. Dudley, 20 barrels.
H. Varnon, 19 barrels and 3 bushels.

Mr. James Matson took the first premium; and his crop was certified to by Mr. Peter Pean, who was his close competitor—Mr. P.'s crop being only *one quart less.* The reader, not familiar with the barrel measurement of corn, is informed that a "barrel" is five bushels of shelled corn; so that Mr. Matson produced 189 bushels and 1 quart per acre, or, 1890 bushels and 10 quarts on 10 acres.

The 90 acres cultivated for premiums, yielded 10,960 bushels and 10 quarts; being an average of 121 bushels and 24 quarts per acre. Make all reasonable allowance for shrinkage in drying, and throw in something for the natural tendency of man to strain a point in a keen competition, and still the productiveness of the soil is most extraordinary.

CHAPTER I.

ORIGIN OF SOILS.

All *soils* are formed by the intimate mixture of the *debris* of rocks, in the condition of sand, gravel, or clay, with remains of plants and animals in the shape of *mould.* Earth that contains no mould, or combustible matter, is not a *soil;* nor will vegetable or animal substances *alone* form one. The proportions of sand, clay, and mould in a soil, vary indefinitely. Not only is this true; but the nature, composition, and value of different kinds of sand, clay, and mould vary in an equal degree. A very slight change in a soil is often adequate to double the reward of every day's labor expended in growing crops thereon. Hence the necessity of studying closely all defects in the surface which a farmer has to operate upon, whether his land be in tillage, pasture, or meadow. As the division of soils into *mould, sand,* and *clay,* is the most natural, we will discuss the subject under these three heads.

Vegetable and Animal Mould.

If the forest-leaves that annually fall to the ground did not rot, and become ultimately dissolved and return to their original elements, they would soon accumulate to the depth of many feet. The progress of decay in all vegetables and animals and their products, is governed by fixed natural laws; and these organized bodies decompose in that way which will best promote the growth of new generations of living beings. *Mould* is the half-way house between the living and the dead in the organic and inorganic worlds. It covers the surface of islands and continents like a carpet, and is a treasure of inestimable value when properly used by the husbandman. The fertilizing power of mould depends partly on its peculiar mechanical and porous structure, and partly on its chemical composition. All porous substances, like charcoal, platinum sponge, and well pulverized clay or loam, have the property of condensing *gases* and retaining *odors.* This is shown in the practice of burying dead animals in mould, charcoal, or earth, to prevent the escape of offensive odors and gases to poison the atmosphere. This property in mould is purely mechanical; but it is none the less useful in the economy of nature on that account. When intimately mingled with compact earths, by the use of the plough, harrow, and cultivator, mould increases their friability, and promotes the chemical action of atmospheric air and the development of all the latent elements of fertility in the soil.

The dark color of mould favors the absorption of solar heat, and thus warms the ground, while it is peculiarly calculated to imbibe dews and a large quantity of rain-water. That both heat and moisture are indispensable to the growth of vegetables, is known to every one; and to secure these, mould plays a conspicuous part. It is, however, as the food of cultivated crops, that the farmer should study the remains of former plants and animals with the greatest care. That the several atoms contained in one corn or wheat plant are well adapted to form another plant of the same kind after the first is decomposed, is a truth too obvious to be seriously questioned. But why is it that the remains of a turnip or potato form mould or manure adapted to the natural wants of all other crops?

This is the reason: all crops, including, of course, turnips and potatoes, consist mainly of three elementary bodies, called *carbon, oxygen,* and *hydrogen.* Thus, if we carefully burn, with the air mostly excluded, wood, starch, sugar, oil, gluten, fat or lean meat, *coal* may be produced. The essential element in this coal is *carbon;* and it is the prominent element in all mould. Carbon, whether derived from the decaying carcass of a dead horse, from rotting wood, or a diamond, is ever the same. It forms not far from half of the dry solids of all plants, and some 40 per cent. of all animal tissues. It is carbon that imparts the dark color to swamp-muck, mould, vegetable and animal coal. The supply of carbon in nature is abundant for all useful purposes. In every 100 pounds of lime-rock and marble, there are about 12 pounds of pure carbon; and, admitting these rocks to exist in the crust of the planet to the extent stated by geologists of high repute, the carbon locked up in the form of carbonate of lime would suffice to cover the whole globe with a stratum of pure coal to the depth of 400 feet. In mineral coal, the amount of combustible carbon is large; but the quantity of coal in the earth is altogether unknown. Ten thousand parts of atmospheric air contain four parts of carbonic acid, and over one of pure carbon.

The farmer's stock of available carbon in mould is rapidly consumed by tillage, just as a manure heap becomes smaller by constantly turning it over. When green crops of a luxuriant growth are suffered to rot on the ground, or are ploughed in, his stock of carbon and mould is renewed to a certain extent.

Oxygen is the next most abundant element in mould, forming ordinarily some 40 per cent. of the combustible matter in all soils. In the solid part of all plants and animals, it exists in a little larger proportion. When organic substances decay, they give off the elements of water (oxygen and hydrogen) faster than carbon is converted into carbonic acid gas. Oxygen is so abundant in nature that it forms more than half of the earthy minerals in the crust of the globe; and it constitutes eight parts in nine of all water and vapor, and 21 per cent. of the atmosphere. When wood or coal is burnt, under ordinary circumstances, 16 parts of oxygen in the air combine chemically with 6 of carbon in the fuel, and the two elements form 22 parts of a heavy invisible gas, called *carbonic acid.* From the same elementary bodies the same gas is produced in all fermentation, and during the decay of organic substances and the breathing of all animals. Oxygen is often called vital air, because it supports animal life; and it is equally indispensable to the life of plants. It derives its name from two Greek words, which signify to generate sourness or acidity. Oxygen is truly an "acid generator," but not the only one known.

Next to carbon and oxygen, an element called *hydrogen,* or "water generator," is the most abundant ingredient in mould. It is, when pure, the lightest gas known, being sixteen times lighter than oxygen, and about fourteen times lighter than common air. Under favorable circumstances it unites with oxygen in the proportion of 1 to 8, and forms water. In wood, starch, gum, oil, and sugar, and in the fat of animals, hydrogen exists in the proportion, or nearly so, to form water, i. e. one part by weight of hydrogen to eight of oxygen; and it retains about the same relation in mould, as will be shown by several analyses. Mould contains another element, called *nitrogen,* which forms 79 per cent. of the air we breathe. When animals and plants are undergoing decomposition, hydrogen, in what is termed its *nascent* state, combines with nitrogen in the proportion of 3 parts of the former to 14 of the latter, and the two form a pungent alkaline gas called *ammonia.* This substance also exists in mould. In addition to what are denominated "the organic elements" of plants and animals, mould usually contains an appreciable quantity of soluble flint, (silica,) sulphur, phosphoric acid, iron, lime, potash, soda, magnesia, and chlorine. These minerals will be more appropriately described when treating of sand and clay.

Dr. Anderson, of Edinburgh, chemist to the Highland and Agricultural Society, has recently made several critical analyses of different wheat soils in Scotland, which are published at length in the July number (1850) of the journal of that society. These soils were generally distinguished for their productiveness. The first ten inches from the surface was regarded as "surface soil;" the next ten inches as "subsoil." 100 parts of the surface soil from Midlothian gave 6.789 of combustible dry matter or mould. It had the following composition:—

Carbon	4.500
Hydrogen	0.215
Oxygen	1.806
Ammonia	0.268
	6.789

Although two parts of ammonia in a thousand appear very small, yet when we recollect that an acre of soil ten inches deep weighs a thousand tons, it will be seen that there are over two tons of ammonia in the soil of an acre of rich wheat land, as is shown by analysis. A large crop of wheat takes less than 60 pounds of this volatile alkali from the earth in which it grows. Not an element required by nature in forming wheat, both stems and seeds, was lacking in these soils. In the one above alluded to, an acre contained 45 tons of carbon within ten inches of the surface. This fact indicates the vast amount of vegetation that must have decayed to produce so much carbon. Nor should the fact be overlooked that the plants which formed all this organized carbon were rich in nitrogen. It is doubtless true that a part of the two tons of ammonia was formed by the union of nitrogen in the atmosphere with nascent hydrogen; yet plants, rich in organized nitrogen, like cabbages, turnips, clover, and lucerne, yield richer mould than such as are known to contain very little of this element. Thus, 1000 pounds of wheat will yield 24 of nitrogen; while the same weight of wheat-straw yields but 3 pounds. No sensible farmer would prefer the manure or mould formed by 1000 pounds of straw to that produced by 1000 pounds of wheat or corn. Mould, like manure, is very unequal in value. Decaying wood, the stems of flax, and buckwheat straw, yield mould poor in nitrogen; clover, peas, and beans form mould rich in this important constituent of animal food. Before a soil can produce good crops of wheat, it must contain, in an available condition, every substance consumed in forming the stems and seeds of this bread-bearing plant. The poorest soil, so far as its organic elements were concerned, analyzed by Dr. Anderson, gave the following results:—

Carbon	0.714
Hydrogen	0.033
Oxygen	0.286
Ammonia	0.089
	1.122

Although the organic matter present is small, being a trifle over 1 per cent., yet the ammonia indicates the growth of fertilizing plants, or the

application of good manure, to form the mould that really exists. If the fertility of land depended mainly on the large amount of the remains of vegetation in the soil, then a black mucky earth should be the best for growing wheat, instead of the poorest. Light, sandy soils, almost destitute of mould, have produced fine crops of wheat and corn by the aid of a little guano. This fact demonstrates the possibility of drawing largely upon the atmosphere for carbon, oxygen, and hydrogen, if not for ammonia, in feeding cereal plants. When gypsum or wood-ashes produce a fair crop of clover, on comparatively thin land, it is safe to infer that not only carbon and the elements of water are drawn from the air, but ammonia, or nitrogen, in some other form, also. Nothing of a combustible nature is applied to the soil, while it yields several tons of organized matter, including all in the roots, stems, and leaves of the two or three crops which the ashes or gypsum will produce. Calling the aggregate yield five tons, and the nitrogen consumed will be 240 pounds, while not an ounce has been applied in fertilizers. Leguminous plants appear to possess a similar power to extract nitrogen in some way from the atmosphere, as well as carbon, and the elements of water. Unless one has a large supply of cheap manure at hand, it is doubtless sound policy to grow green crops, with a view to form a rich mould for the production of grain, cotton, hemp, tobacco, or sugar-cane. The farmer should have a full knowledge of the increase or diminution of organic matter in each field every year. If it is cultivated in a hoed crop, and that removed, he may safely assume that the aggregate of mould has been diminished through the agency of tillage. Where a crop of small grain has been grown, and the ground seeded, either by art or nature, to a degree which gives a good return in grass, clover, or weeds, and this vegetation be allowed to rot on the field, the loss of organic matter effected by tillage and cropping may be fully compensated. When forest-leaves, weeds, insects, and cultivated plants rot on the ground, or in the soil, it may interest some readers to be told what substances are formed in the operation. To have a clear idea of the products of vegetable and animal decay, or putrefaction, one must not forget the fact that all vegetables and all animals are formed of only *four* simple elementary bodies, of which pure water constitutes two, viz. oxygen and hydrogen. It is true that both plants and animals have other ingredients in their tissues and structure, such as sulphur, phosphorus, iron, lime, chlorine, potash, &c.; but these are not endowed with the same indefinite and, apparently, infinite power of combination which characterize carbon, nitrogen, and the elements of water. Had the possible combinations of these constituents of all living things in the vegetable and animal kingdoms been as limited as those witnessed in metals, the present Flora and Fauna of the world never could have existed. There are some 200,000 (more or less) different races of insects and larger animals, and nearly 100,000 different plants, formed essentially of water, atmospheric air, and carbon. It is on this account that when one plant or animal dies and rots, its atoms will feed and nourish any growing plant, and that in turn will feed and nourish growing animals. Infinite wisdom is not less displayed in the economy with which matter is repeatedly endowed with life in the systems of plants and animals, than in the infinite variety developed from different combinations of only four elementary bodies. There is probably not an atom on the surface of the planet, which is capable of organization, that has not been many times endowed with vitality. Every time we breathe, our bodies lose a part of their solids.

Humic substances are divided by Mulder into such as are soluble in alkalies, and may be precipitated by acids, and such as are insoluble in alkaline solutions. The former he divides into three classes, according to their composition: 1st, such as consist of carbon, and the elements of water in the proportion that these elements exist in water. 2d, carbon and the elements of water, in which there is more hydrogen than the oxygen requires to form water. 3d, those in which there is an excess of oxygen. In all these compounds of carbon and the elements of water, the combining number of atoms of carbon is 40. Thus, *ulmic acid* (first obtained from elm, *ulmus*) consists of 40 atoms of carbon, 14 of hydrogen, and 12 oxygen. *Ulmin* has the same composition, with 2 atoms more of water. In the above compounds, there is an excess of hydrogen, taking water as the standard. *Humic acid* has 40 carbon, 12 hydrogen, and 12 oxygen. This is simply carbon combined chemically with 12 atoms of water. *Humin* differs from humic acid in having 15 atoms of water in place of 12. *Geic acid* has the same composition, with an excess of atoms of oxygen. *Formic acid*, (first obtained from ants,) differs widely from the above in having 2 atoms of carbon combined with 1 of hydrogen and 2 of oxygen. *Crenic* and *apocrenic acids*, which exist in all good soils, contain nitrogen in addition to carbon and the elements of water. These acids were first found by Berzelius, in spring-water, and took their name from *krene*, the Greek for spring. The following is the composition of these acids:

Apocrenic acid...........................	C 38	H 12	O 24	N 5
Crenic acid	C 24	H 12	O 16	N 4

C stands for carbon, H for hydrogen, O for oxygen, and N for nitrogen. Chemists disagree as to the atomic composition of these acids. Sir Robert Kane, at page 640, gives the following description of them:—"Crenic acid is a pale-yellow, gummy mass, of an astringent taste, very soluble in alcohol and water. Its formula is NC 14, H 16, O 12. By exposure to air it changes into apocrenic acid, which is brown, of an astringent taste, reddens litmus, and is much less soluble in alcohol and water than crenic acid; its formula is N 6, C 28, H 14, O 7." Mulder seems to regard whatever of nitrogen there is combined with these acids as a base or ammonia.*

The natural process, called "nitrification in soils," is more important, in a practical point of view, than many suppose. In this operation, atmospheric air, which costs nothing, and water, which is equally cheap, play conspicuous parts. The hydrogen in the water, and the nitrogen in the air, form *ammonia*, an article worth some 10 cents a pound for making wheat. Nitre, or saltpetre, consists of potash and nitric acid. The last named substance is composed of nitrogen and oxygen, united in the proportion of 14 parts of nitrogen with 40 of oxygen. How the alkalies, potash and soda, and alkaline earths, lime and magnesia, promote the formation of nitric acid or nitrification in porous soils, will be explained hereafter. At present we desire to give the agricultural reader a correct impression of the nature and properties of the organic or combustible elements of his

* The substances above briefly described all result from the slow decomposition of plants and animals on the surface of the earth and in the soil.

crops. In his Chemistry of Vegetable and Animal Physiology, at page 170, Mulder remarks:

"It deserves particular notice that hydrogen is *always liberated* whenever those substances which are the most generally diffused in the vegetable kingdom are changed into constituents of the soil—that is, when *cellulose*, starch, gum, sugar, &c. are in a state of decay. First, these substances are converted into ulmic acid, and that again becomes humic acid; from this, geic acid is formed, which again produces apocrenic acid; and from that, finally, crenic acid is derived. This whole series of transformations must be passed through before the organic substance is converted into carbonic acid and water. The whole process consists in an oxidation, (combining with more oxygen,) and so may be called a slow combustion. It is evident, from the composition of the five substances mentioned, that, during the formation of humus, a new quantity of oxygen is continually fixed."

The products of this slow combustion are partly soluble, and in a condition to enter the roots of growing plants to nourish them, and partly insoluble. If all mould was soluble in water, it would disappear in a heavy rain as readily as a mass of snow melts in a warm day. On the other hand, if the residuum of vegetables was quite insoluble, it could never enter the minute pores in the roots of plants, and would be worthless as food for all succeeding generations. Providence has made the solubility of the remains of all living beings *just right*.

Change but slightly the general law which governs their dissolution, and the extinction of all plants and animals would soon follow. Increase or diminish in any sensible degree the vital air which surrounds the planet, and all vitality must shortly cease to be. Change the relative proportions of oxygen and hydrogen in water from what they now are, and it would no longer be *water*, and all plants and animals must perish. Improvements in husbandry can only be effected by the more careful and diligent study of the laws of nature, and ever complying with all their requirements. Some plants and forest-trees are much better adapted by nature to live on a thin, sterile soil than others, and will, in skilful hands, augment the organic matter in the earth where they grow. In forest culture, a barren soil is often planted with small pines, which in the course of time create a covering of black mould. This mould is drawn from the atmosphere by the decomposition of carbonic acid and water. The economical production of a rich mould where little exists, is a point to be investigated with great care. To effect this purpose, one needs to understand the *mineral* or *incombustible* elements of plants, and the various conditions in which they exist in the soil. Although these elements may be found in the residuum of decaying vegetables and animals, yet they most abound in *sand* and *clay*.

CHAPTER II.

SAND IN SOILS.

Any earthy mineral in a granulated form in the soil is called *sand*. Grains of sand can be produced by the breaking up of almost all kinds of rocks, by frost, and other mechanical forces, and grinding and rolling their fragments over one another in moving water. In studying sand and clay, it is important to bear in mind the fact that all islands and continents have long been the beds of seas or oceans, and subject to the mechanical action of vast bodies of moving water for indefinite geological eras, or ages. The thickness of sedimentary rocks, which contain fossil plants and animals, is between six and seven miles. In Pennsylvania, fossiliferous rocks beneath the highest coal measures are 40,000 feet, or more than seven and a half miles in thickness. (See Professor Rogers's Report on the Geology of Pennsylvania for 1838, page 82.)

In the peninsula of Tauris, Pallas describes a continued series of primary strata inclined 45° over a distance of 86 miles, which would give a perpendicular thickness of more than 68 miles. (Lyell's Principles of Geology, volume 2, page 443.)

In New England, primary rocks have been measured to the depth of 20 miles. (Hitchcock's Geology, page 70.)

The same volcanic forces, deep in the bosom of the earth, which now elevate volcanic mountains, have, in the course of time, forced up from the depths of the sea all stratified and primary or igneous rocks. Volcanic heat, and the immense mass of water that surrounds the globe—a quantity sufficient to cover every part of it a mile and a half in depth—have been the prominent physical agents of Providence, acting in unison with other causes, to bring our planet into its present condition. As all sand and gravel are derived from the abrasion of rocks, the readiest way to learn the nature of the sand in one's soil is to trace it back to the parent rocks from which it came, and study their composition. All rocks have been formed either of melted minerals, cooled under greater or less pressure, or of sediment deposited in water. The former are denominated *igneous* rocks, from *ignis*, "fire;" and the latter *sedimentary* rocks. The latter are frequently called *aqueous*, from *aqua*, "water," and *fossiliferous*, or "fossil-bearing," because they contain an incalculable number of fossil animals and plants, and were deposited in water. Dr. Buckland estimates the thickness of fossil-bearing rocks over the continent of Europe at ten miles. (Bridgewater Treatise, volume 1, page 37.)

Nearly all sand in soils is derived from water-formed sandstone, or fire-formed granite and other rocks of an igneous origin. The purest and sharpest sand is called *silica*, from the Latin *silex*, "flint." Silica is a simple mineral, which has acid properties, and is formed by the chemical union of two atoms of oxygen with one of a simple elementary base called *silicon*, or *silicium*.* Silica is often denominated *silicic acid*, because it combines readily with potash, soda, lime, alumina, iron, and magnesia, to form permanent chemical compounds, called *silicates* of potash, soda, &c. In 100 parts of pure flint sand, there are 52 of oxygen and 48 of silicon. As some three-quarters—perhaps 80 per cent.—of all rocks, taken in the aggregate, are silica, the reader will see that the crust of the earth is more than half oxygen, or vital air. This fact will more clearly appear when we come to study the composition of clay. Every farmer knows that pure sand is remarkably insoluble in water; yet about 67 per cent. of the ash of the stems of wheat, rye, oats, barley, maize, and sugar-cane is pure flint, or silica. While a little sand is found in soils in the form of pure silica—derived, perhaps, from crystallized quartz or flint—its mass consists of silicates of alumina, lime, iron, potash, soda, magnesia, and

* Fresenius's Quantitive Analysis.

manganese, and usually in a condition to resist the solvent power of strong acids.

A knowledge of the character of the rocks which formed the sand will enable the agriculturist to judge of its probable composition. If the soil has been washed down from highlands, either mountains or hills, by a river or smaller streams, it is called *alluvium*, or *alluvion;* and the owner must study the nature of the rocks upon which the rains and snows fell that washed the sediment down to his farm. If this soil can be traced to no such source, and lies on an elevated plain, a hill, or mountain, it is probably *diluvion* in its origin, and must be traced either to the action of glaciers, as maintained by Professor Agassiz; to ancient tidal currents and icebergs, as contended for by Sir Charles Lyell; or to the upheaval of the earth at some point far north of the United States, which caused a sudden rush of waters southward, bearing with it granite boulders and a vast mass of loose earth, as is believed by Professor Emmons. It is foreign to our purpose to discuss, in this connection, the various theories advanced by geologists of the highest distinction to account for what is known as the "*drift formation*." That the loose earthy matter, which in many places has a thickness of several hundred feet, came from the north, both on this continent and that of Europe, is conceded by all. Thus the deep basin of Lake Ontario is mostly scooped out of a soft sand rock called Medina sandstone. Boulders of this rock, which is peculiar and well known, are found ten, twenty, and even thirty miles south of its bed, scattered over the earth in great profusion, and upon lime and slate rocks hundreds of feet in thickness. So much of the Medina sandstone, ground into fine sand, is spread over large areas of lime-rock, from one to ten feet deep, that the soil is as destitute of lime as it would be if the lime-rock were fifty miles distant. There is, however, a marked difference in the sandy soils north and west of the Alleghany mountains, and those lying on the Atlantic slope, from Maine to Alabama. The sand of the latter is derived mostly from rocks of an igneous origin, the former from rocks of an aqueous origin. The poorest sands can be found in the Atlantic States, where granite abounds; the richest in Western New York and Pennsylvania, and in the Western States, where the rocks are all fossiliferous, or abound in the remains of plants and animals. The extent or quantity of these remains in solid rocks and drift deposites, from which the surface of the earth is mainly formed, often imparts to it high and enduring fertility. There are districts in the Southern Atlantic and Gulf States where this fact is strikingly exemplified. When the earthy elements of crops happen to abound in a dry sandy soil, it is remarkable for productiveness; but the misfortune is, that such soils are usually too porous, open, and inclined to leach and part with their elements of fertility. Hence the importance of *clay* and *lime* to mix with sand in forming an arable soil. Vegetable mould alone will not answer a good purpose.

All sandstone rocks were once in the condition of fine loose sand. This was consolidated, partly by the pressure of a mountain weight to which beds or strata of sand are subjected in the depths of the ocean, and partly by the infiltration of soluble minerals, as iron, lime, or manganese, which are precipitated or crystallized among its particles. All sedimentary rocks were derived from those of an igneous origin, which atmospheric air, frost, electricity, water, solar light, and vegetation have disintegrated and converted into sand, or clay, or dissolved minerals. When we consider the fact that portions of the earth's crust subside as far below the common level of its surface as any part is elevated above in mountains, the opinion expressed by Lyell, that fossiliferous strata often sink deep enough to be melted and finally crystallized into granite again, seems not improbable. If this view be correct, then we may say that granite and all plutonic and volcanic rocks are formed by the subsidence, melting, and cooling of sedimentary strata. There are now some 300 volcanoes on the globe which are known; and so numerous are extinct ones, or their effects, that geologists find no reason to believe that the planet has ever been exempt from their powerful action. For the crust of the earth to be always rising up, and nowhere subsiding, must obviously create immense vacancies below its surface. No such spaces are believed to exist; and the evidence of the sinking of the surface, over extensive districts, below the level of the sea, is abundant and conclusive. (See Lyell's Elements of Geology, volume 1, page 430, and before.)

Rocks, the elements of which were melted by internal heat, are divided by this author into three classes, viz. *plutonic*, of which granite and sienite are types; *metamorphic*, of which marble and some slates and sandstones are representatives; and *volcanic*, which are subdivided into *ancient* and *modern*, and appear in a variety of forms. *Basalt* and *trap* belong to the ancient family; while the recent or modern volcanic rocks are found in the vicinity of all active volcanoes. When decomposed, all rocks yield either sand, clay, or both, besides other minerals. Plutonic rocks are *unstratified*, and often denominated "primary," because they were once thought to be in all cases older than sedimentary and stratified rocks. More careful and extended researches have shown that granite has been forced up, and, as it were, injected into masses of fossiliferous strata, in a way to prove that the latter are the older of the two. Indeed, metamorphic rocks are nothing but stratified, aqueous deposites, *metamorphosed*, (changed by heat,) from the action of plutonic or melted matter into a crystalline form. Thus common lime-rock, it is believed, may be transformed into marble, if it be placed in contact with a mass of intensely-heated granite, and both cooled under great pressure. In this operation, all traces of the remains of shell-fish and other animals in the limestone will be effaced. Few studies are so interesting as the phenomena exhibited by different rocks, whether we trace their origin and present condition to the action of fire, or water, or to the joint agency of both. The elevation of granite and other mountains is as slow an operation as their wearing down through the corroding influence of oxygen, carbonic acid, the growth of mosses, the expansion of freezing water, and the washings of rain and melted snow. In large districts of Auvergne, in France, the decay of granite is so rapid that Dolomieu called it the "*la maladie du granite*." The disintegration is produced by the escape of carbonic acid gas from numerous fissures in the rocks, which attacks the silicates of potash, soda, lime, and magnesia in granite and sienite, and liberates the silica or silicic acid. In this operation the silicate of alumina is not decomposed, but remains as pure pipe or porcelain clay, called *kaolin*. All organic substances which yield carbonic acid promote the elimination of potash and soda from their before insoluble combinations with silica; but the time comes when all the alkalies that can be separated by decaying vegetation or manure are consumed in the growth of cultivated plants, or washed out of the soil by tillage. The first decompounding of granite is

to separate it into three minerals, called *feldspar*, *mica*, and *silica*. Sienite differs from granite in having the mineral called *hornblende*, in place of mica, in its composition. The three minerals—feldspar, mica, and hornblende—are very complex substances, which yield not only alumina, (the base of all clays,) but iron, manganese, lime, potash, soda, magnesia, phosphorus, sulphur, chlorine, and fluoric acid, and doubtless other elementary bodies like copper, gold, and other metals. The elementary substances found in plutonic rocks are very variable. Their analyses ought to be repeated by some skilful chemist, with all the improved processes for detecting minute quantities of chlorides, sulphates, phosphates, and other salts, which in the old way were not noticed, or vaguely estimated. Mineralogists describe two kinds of feldspar: 1st, *potash feldspar*; 2d, *soda feldspar*, which is also called *albite*, from its whiteness.

	Potash feldspar.	Albite.
Silica	65.21	69.09
Alumina	18.13	19.22
Potash	16.66	
Soda	—	11.69
	100.00	100.00

Feldspar and albite are readily distinguished from quartz by the circumstance that they do not scratch glass, and generally may be marked by the point of a knife. In sienite, feldspar is the predominating mineral. *Porphyry* is a hard rock, having numerous crystals of feldspar, which give it a beautiful appearance when worked. Feldspar being an abundant mineral, and the source of much of the clay in soils, we give the formula of several varieties, as calculated by Berzelius:—

Feldspar............ $KO\ SiO^3 + Al^2\ O^2.3(SiO^3)$.
Albite............... $NaO\ SiO^3 + Al^2\ O^3.3(SiO^3)$.
Porcelain spar..... $NaO\ SiO^3 + Al^2\ O^3SiO^3 + 3CaO\ 2(SiO^3)$.
$+2(Al^2O^3SiO^3)$.

KO stand for potash; the words mean that the substance referred to consists of an atom of potassium (*kalium*) chemically combined with one of oxygen. Hence, the letters *k o* mean simple potash. SiO^3 mean silicic acid, or a substance formed by the chemical union of an atom of silicium or silicon with three atoms of oxygen. Fresenius makes silicic acid to consist of silicon and 2 of oxygen, instead of 3. Al^2O^3 stand for *alumina*, and mean that two atoms of *aluminum* unite with three of oxygen to form that substance. NaO stand for soda, and mean that an atom of pure soda is a compound of sodium (*natrium*) and oxygen. CaO stand for lime, and indicate the fact that an atom of lime is formed by the union of one of calcium (its metallic base) with an atom of oxygen. Divested of technicalities, potash feldspar is simply a silicate of alumina and potash, just as *alum* is a sulphate of the same bases. Soda feldspar (*albite*) is a silicate of alumina and soda; and porcelain spar is the same mineral united with lime and two additional atoms of silicate of alumina.

Mica is often called "isinglass," and is distinguished by its bright, shining appearance, and the ease with which it may be split into exceedingly thin scales. It is found of different colors, from coal-black to perfect whiteness. Mineralogists divide it into potash-mica, magnesia-mica, and lithia-mica. Rose has analyzed the first, Klaproth the second, and Gmelin the third, with the following results:—

	Potash M.	Magnesia M.	Lithia M.
Silica	47.50	42.50	49.060
Alumina	37.20	11.50	33.611
Oxide of iron	3.20	22.00	
Oxide of manganese	0.90	2.00	1.420
Potash	9.60	10.00	4.186
Magnesia	—	9.00	0.408
Oxide of lithium	—	—	3.594
Hydrofluoric acid	0.56	—	3.445
Water	2.63	1.00	4.184

The chemical composition of mica in any of its forms is not uniform. The above will give a fair idea of the general constitution of this mineral. It contains more alumina than feldspar, and forms very tenacious clay soils. Mica, however, is less abundant in granite than feldspar, and yields magnesia, which feldspar does not.

Hornblende is a dark-colored, weighty mineral, which is tough and not easily wrought under the chisel. It is sometimes found in regular crystals of various colors, and may be distinguished from mica by refusing to split when heated in the blaze of a candle, and from quartz and feldspar by its darker color. It abounds both in *basalt* and *sienite*. The following are the results of two analyses:

	Basaltic hornblende.	Sienitic hornblende.
Silica	42.24	45.69
Alumina	13.92	12.18
Lime	12.24	13.83
Magnesia	13.74	18.79
Protoxide of iron	14.59	7.32
Oxide of manganese	0.33	0.22
Fluoric acid	—	1.50
	97.06	99.53

We have only to assume the decomposition of a large amount of hornblende to account for the existence of the vast quantities of *lime*, *iron*, and *magnesia* known to all who have paid any attention to the minerals in the earth's crust. Before we proceed to study these and the other earthy elements of cultivated plants, it is proper to consider some of the peculiarities of *clay*.

CHAPTER III.

CLAY IN SOILS.

It has already been stated that the simple mineral called *alumina* is the base of all clay. In 100 parts of alumina there are 53.3 *aluminum*, (a simple metal,) chemically combined with 46.7 oxygen. Alumina contains, according to Sir Robert Kane, 5.3 per cent. less oxygen than silica. The effect of this seems to be that, while silica has *acid* properties, alumina has an *alkaline* reaction. Hence, these two most abundant minerals in nature have an affinity for each other, and, when united, form the purest porcelain clay, known in chemical language by the name of *silicate of alumina*. Pure clay (kaolin) is composed exclusively of silica and alumina, and usually in the following proportions.

	(1.)	(2.)	(3.)
Silica	54.5	57.4	53.4
Alumina	45.5	42.6	46.6
	100.0	100.0	100.0

Clay usually contains from 13 to 20 per cent. of water. The above figures indicate the composition of three samples of pure clay, after all the water was expelled. Ordinary clay in soils contains far more silica and less alumina. It is rare in the clay soils of this country that one finds so much as 10 per cent. of alumina. This mineral is easily obtained from alum and from aluminous earths. It is as white as lime or white earthenware, and has a remarkable affinity for water and organic substances. It combines readily with phosphoric, sulphuric, and other acids, and retains all alkaline minerals in solution with extreme tenacity. Not only all soils, but all sedimentary and igneous rocks, yield alumina on analysis. Even crystals of flint have been found to contain alumina, lime, iron, and potash, by Berzelius. *Greenstone*, a rock of ancient volcanic origin, has the following composition, according to Bendant:—

Silica	63.3
Alumina	14.2
Oxide of iron	5.8

It is rare, if ever, that one meets with either sand or lime rock which yields no alumina on analysis, while all slates and shales abound in this mineral. Few rocks form so productive a soil as *basalt*, which is of volcanic origin, and has the following composition, (by Gmelin):—

	Part soluble in acids.	Part insoluble in acids.
Silica	35.741	48.500
Alumina	11.121	6.792
Oxide of manganese	1.487	—
Oxide of iron	—	9.383
Protoxide of iron	16.015	—
Strontian	0.112	—
Lime	11.914	17.395
Magnesia	10.434	13.131
Soda	3.264	—
Potash	1.204	—
Water	6.530	—

The above figures show the interesting fact that basalt contains a large amount of silica, alumina, iron, lime, and magnesia, in a condition insoluble in acids. Not only these minerals, but potash and soda exist in soils in a similar condition, as will be shown when we come to study the latent resources of poor soils. It is generally known that alluvial clay lands are both durable and productive. *Why* they are so is a matter not so well understood. It arises from the fact that they possess all the elements of crops in an available condition, and so intimately blended with clay (which is not the food of plants) as to endure without exhaustion for an indefinite number of years. These elements are silica, lime, potash, soda, magnesia, chlorine, sulphur, phosphorus, iron, carbon, oxygen, hydrogen, and nitrogen. Other minerals are occasionally found in cultivated plants; but they are not regarded as indispensable constituents in their composition. It is known that neither of the four organic elements called carbon, oxygen, hydrogen, and nitrogen, can be dispensed with in the growth of any plant; nor can any of the others, except, perhaps, soda, in a few vegetables grown on the farm. Mulder gives very minute analyses of three specimens of clay taken from the Zuyder Zee, which were performed by E. H. Von Baumhauer, with the following results:—

	First.	Second.	Third.
Insoluble sand, with alumina	57.646	51.706	55.372
Soluble silica	2.340	2.496	2.286
Alumina (soluble)	1.830	2.900	2.888
Peroxide of iron	9.039	10.305	11.864
Protoxide of iron	0.350	0.563	0.200
Lime	4.092	5.096	2.480
Magnesia	0.130	0.140	0.128
Potash	1.026	1.430	1.521
Soda	1.972	2.069	1.937
Ammonia	0.060	0.078	0.075
Phosphoric acid	0.466	0.324	0.478
Sulphuric acid	0.896	1.104	0.576
Carbonic acid	6.085	6.940	4.775
Chlorine	1.240	1.302	1.418
Humic acid	2.798	3.991	3.428
Crenic acid	0.771	0.731	0.037
Apocrenic acid	0.107	0.160	0.152
Humin, vegetable remains, and water, chemically combined	8.324	7.700	9.348
Wax and resin	trace	trace	trace.
Loss	0.542	0.611	0.753
	100.000	100.000	100.000

Few river flats, or alluvial bottoms, show soils so rich in the raw material for making bread and meat as the above. It is unusual to find arable soils in which 45 per cent. are soluble in boiling acids, including the organic matter and water of absorption. It would have been instructive to be informed what elements, and how much of each, were soluble in rain-water, or in distilled water; but no information of this kind is given. The quantity of soluble alumina is small. The first specimen gives less than 2 per cent., and the second and third less than 3 per cent. It is generally characteristic of strong fertile soils to abound in the peroxide or red rust of iron. The river bottoms of the Zuyder Zee, so famous for their durability and fruitfulness, contain an average of more than 10 per cent. of this mineral. Of lime, the percentage is unusually large. An acre of common earth an inch in depth weighs about 100 tons; so that, estimating a soil to the depth of only 10 inches, we have 1000 tons of earthy matter to operate upon in tillage and husbandry. The average of lime in the samples given is near 4 per cent. At this rate a ton of soil will contain 80 pounds, and, of course, 1000 tons 80,000 pounds, or 40 tons. Allow 200 pounds of this mineral to be washed out of an acre in a year by leaching rains, and removed in crops, and the quantity above named would last 400 years. A soil, however, will cease to produce grain long before the last particle of lime is taken out of it. The supply of magnesia, though much less abundant, is sufficient for all useful purposes. Most crops consume more magnesia than lime, as will be hereafter demonstrated by trustworthy analyses.

The soils under consideration are remarkably rich both in potash and soda, and it is doubtless owing to this circumstance that so large an amount of silica is set down as "soluble." Estimating the potash at one per cent. only, and there are 10 tons of this alkali within 10 inches of the surface on an acre. By examining the figures, it will be seen that the supply of soda is nearly twice as large as that of potash. Consumed at the rate of 100 pounds each per annum, the soda would last four centuries, and the potash two. But before the alkalies in the soil were exhausted, subsoiling would be practised to render those 20 inches below the surface entirely available to needy crops. Particular attention is invited to the ammonia found in these soils.

The amount is not peculiarly large, but is an element of fertility too often overlooked in studying the sources of productiveness in cultivated lands. Probably the earths analyzed by Von Baumhauer have been cropped some two thousand years. One hundred thousand parts of these soils contain respectively sixty, seventy-eight, and seventy-five parts of ammonia. This gives 1200 pounds to the acre, estimating the weight of available soil at 1000 tons in the earth that contains the least of this volatile alkali. Doubtless the principal source of ammonia is the decay of organic substances in the soil, such as manure, plants, and insects; some is also derived from the atmosphere through the fall of rain and snow. There is another source which is worthy of consideration. Critical readers will see that both the protoxide and peroxide of iron figure in the composition of these fertile lands. The protoxide is literally the first oxide, and consists simply of an atom of oxygen chemically combined with one of iron. The scales that fly off from a heated bar when hammered on an anvil by a blacksmith, are the first oxide or protoxide of iron. The peroxide is the red rust of this metal, and consists of two atoms of iron chemically united to three of oxygen. Now, in converting the protoxide of iron into a peroxide in a moist soil, (a result greatly promoted by tillage,) water is decomposed. Its oxygen unites with the iron to form rust (peroxide), and its hydrogen combines at once with nitrogen in the atmosphere, and is always present in soils, to form ammonia. Most farmers have observed that soils often change their color within a few years after they are first broken up, assuming a darker hue, and sometimes a deeper red. Such soils contain a good deal of iron, and, if lime is not wanting, they grow more productive by tillage. In the virgin earth, more or less of this iron is united with sulphur, forming a mineral of a bright yellow color, called iron *pyrites*, or sulphuret of iron. Tillage decomposes this compound. Oxygen combines with the sulphur and forms oil of vitriol, called sulphuric acid. Oxygen also unites with the iron and converts it into the first oxide, when the oil of vitriol and oxide of iron combine and form a very soluble salt called copperas, or sulphate of iron. If the soil contains a sufficient quantity of lime, or the farmer applies it when needed, this mineral takes the sulphuric acid away from the iron by a stronger affinity, and forms gypsum, or sulphate of lime. The protoxide of iron, thus deprived of its oil of vitriol by lime, is soon changed into a peroxide, in which condition it is not only harmless to all crops, but a valuable condenser of fertilizing gases by reason of its porous nature.

In well-drained and long-cultivated soils, sulphuric acid is never abundant, because all its salts, except gypsum, are exceedingly soluble, and readily washed away in all water that passes over or through the soil into springs or creeks. When the oil of vitriol unites with soda, it forms glauber salts, which, as every farmer knows, are very soluble. With magnesia, this acid forms epsom salts, which are equally liable to be washed out of tilled earth. Alum, or the sulphate of alumina and potash, is subject to the same operation. It takes nearly 500 parts of water to dissolve one of the sulphate of lime, or gypsum. Hence, this is the best compound of sulphur for all agricultural purposes.

Phosphoric acid is an element of fertility of great importance, and one which is never wholly absent from any soil that yields either food or clothing for man. Baumhauer found from a third to a little less than half per cent. of this acid in the Zuyder Zee clay lands. In ordinary soils, most of this acid (which is formed by the union of an atom of phosphorus with five of oxygen) is combined with iron and alumina. The salts are called phosphate of iron and phosphate of alumina. In this form, the acid is sparingly, if at all, available as the food of plants. It is the phosphate of lime, not alumina nor iron, that forms the *bones* of all animals; and it is the phosphate of lime that they require in their vegetable nourishment. Of course, no crop can extract *bone-earth* from a soil in which no bone-earth exists. But, fortunately for the farmer, bone-earth can be formed by simply applying lime to a soil that contains phosphoric acid in combination with iron or alumina; for the more alkaline mineral, lime, will take the acid from iron and alumina, and thus produce the phosphate of lime, or bone-earth. Let us suppose that all the phosphoric acid had been consumed by previous crops, and by the long-continued washing and leaching of an arated soil; would the application of simple lime, or gypsum, create an atom of phosphoric acid where none existed? Certainly not. Hence the necessity of applying *bones*, or phosphates in some other fertilizer, when this acid is lacking. The *carbonic acid* found in the soils under consideration was doubtless mostly combined with the alkalies, potash and soda, and the alkaline earths, lime and magnesia, forming carbonates of those minerals. A part, however, must have been diffused through the porous mass in an uncombined state. When vegetables and animals complete their decay in the soil, carbonic acid, water, and ammonia are the ultimate products, not to name the incombustible minerals which exist in organized beings.

Chlorine, which abounds in the soils under consideration to an unusual degree, is a heavy gas, of a deep sea-green color, very pungent, and irrespirable. It forms not far from 60 per cent. of pure, dry (anhydrous) common salt, which is a compound of chlorine with the metallic base of soda, called *sodium*. Hence the chemical name of salt is *chloride of sodium*. Chlorine is an important element in the vegetable and animal kingdoms; and salt has been used as a fertilizer since before the time of Moses, and also with human food. We read of salt not fit for the dung-heap, in the Bible, indicating one use to which it was applied. "Ye are the *salt of the earth*," expresses a high popular appreciation of this compound of chlorine, many centuries before the chemical nature of salt was known. Chlorine combines readily with hydrogen, and forms a strong acid, called *hydrochloric*, formerly muriatic acid.

All the salts formed by this acid or chlorine in the soil, are quite soluble, like common salt, chloride of lime, magnesia, and potash, and therefore we seldom meet with so much as 1 per cent. of this element in any tilled land. One-tenth of 1 per cent., or 1 in 1000, is nearer the average in ordinary soils of a fair quality. *Humin*, *humic acid*, *crenic* and *apocrenic acids*, and *vegetable remains*, have already been described.

Several thousand specimens of soil have been analyzed by reputable chemists in Europe, the United States, and in Canada; and from the facts thus elicited, the following deductions may be fairly drawn:—

1. All the elements of vegetables, whether in the atmosphere, in water, or in solid minerals, are the same in all countries.

2. The elements of all matter, endowed with vitality, and performing varied functions in an organized condition, must for ever continue the same, without change, so long as the existing physical laws govern the mineral, vegetable, and animal kingdoms.

3. The *raw material* for making all crops being known, the accumulation of such raw material is as simple as to make brick, and lay them up into the walls of a house.

4. All the elements of human food and raiment must be well understood by the consumers thereof before these elements can be husbanded with reasonable economy.

5. It is unreasonable to expect that people will preserve from loss and waste any things, no matter how valuable in themselves, so long as they remain in profound ignorance of such value.

6. The least abundant and most precious elements of crops annually thrown away through sheer ignorance of their value involve a needless loss to this country, equal to two or three hundred million days' labor by the cultivators of the soil. When a farmer gives as much work for 50 bushels of corn raised on poor land as 100 would cost if grown on rich land, it is plain that he and the public lose half his labor if he needlessly impoverishes his soil, or neglects to improve it when or where he can.

7. Until he knows what are the things in the surface of the earth which render it, when present, exceedingly fertile, and, when absent, perfectly sterile, the husbandman can hardly *begin in the right way* to save and accumulate these elements of fertility.

8. There is reason to believe that good Peruvian guano (the dung of sea-birds) is the best known expression of the most valuable elements of crops, from the fact that practical farmers are able and willing to pay from $40 to $50 a ton for this manure to produce breadstuffs and provisions in this republic, where virgin soils may be cultivated to any extent, without buying the land, or paying taxes or rent of any kind.

CHAPTER IV.

THE CRITICAL STUDY OF THE ELEMENTS OF FERTILITY IN SOILS.

Having taken a general view of mould, sand, and clay, and incidentally explained the origin and chemical composition of soils, we propose, in this chapter, to investigate the science of fertility, in order to discover what portion of the constituents of plants the farmer should husband with the greatest care, and what part nature will supply in water and air to his needy crops. To be a skilful husbandman, one should know *what* to husband, and *why* he husbands it. The true principles of agriculture are found to be simple, like all the operations of nature, when fully comprehended. In forming a new plant or animal, no one has reason to suppose that a particle of new matter is created for the purpose. Whatever may be its weight, or form, or substance, every atom in its system existed before the life in the seed of the plant, or in the egg or young of the animal, had a being; and when its life ceases, and its body is dissolved into its original elements, not an atom will be annihilated. Having satisfied ourselves that in the growth of plants and animals nothing really new is created, we may reasonably assume that nature always consumes the same kind of elementary bodies to form the flesh and blood, bones, nerves, fat, and cellular tissues of animals; and hence, that their food should always contain substantially the same elements of nutrition.

If we examine the skeletons of the human family, as preserved in mummies for thousands of years, and the fossil bones and shells of inferior animals met with in rocks which appear to have been thirty or forty thousand feet in thickness, there is abundant evidence that the minerals used for making shells and bones are the same now that they were in the beginning; nor does it require any elaborate research to satisfy one that all the so-called organic substances in plants and animals, such as starch, sugar, gum, gluten, albumen, oil, fat, muscular and nervous tissues, have ever had the same chemical combinations which exist at this day. It is inconceivable how plants and animals can be organized and live, if formed of other elements than carbon, oxygen, hydrogen, and nitrogen, which alone the Creator has fitted to display all the complex and wonderful phenomena of vegetable and animal life. The things that feed and nourish plants and animals, that constitute their whole weight and substance, are substantial and ponderable matter. If these things were equally abundant in all soils, and equally consumed in forming all crops, then all land in the same climate would be equally fertile. But soils are not of equal fertility, nor are the elements of plants consumed in equal quantities, or supplied in equal parts.

Hence the study of soils, in their connection with cultivated plants and domestic animals, presents a wide field for experiment and critical research. The six most valuable elements of all crops, and valuable only so far as they chance to be deficient in any soil, are *ammonia*, *phosphorus*, *sulphur*, *potash*, *chlorine*, and *lime*. It may happen that lime is abundant, and magnesia is lacking, or that potash is more abundant than soda, and sulphur may be less lacking than soluble silica. When the facts are fairly considered, that a soil only five inches deep contains some 500 tons

of earthy matter to the acre, and that 200 pounds of guano will often add two tons to the weight of dry matter in a crop of corn, and nearly as much in several other crops, it seems but reasonable to conclude that the 500 tons of earth lack some elements which corn plants greatly need, and that guano supplies the lacking ingredients. The analyses of the fertilizer, of corn, and of soils, lead to this conclusion. If this reasoning be sound, then it is the guano in soils and in crops that the farmer ought to husband with the greatest care; for guano sells in market at $5 for 200 lbs., or at the price of good flour, and is brought by the cargo 10,000 miles, for no other purpose than to feed hungry plants now starving in the soils of the United States. Phosphoric acid, ammonia, and potash are doubtless the most important elements in guano, and these substances are least abundant in nearly all cultivated lands.* If we study the natural products of the earth in connection with the elements of fertility, we shall find that large, long-lived, and thrifty forest-trees grow only in soils which are rich in potash. When the farmer has occasion to burn maple, elm, oak, walnut, hickory, beech, and other hard-wood forest-trees, he finds them rich in this alkali; and he also finds that soils which produce this kind of timber are always good for agricultural purposes. Their productiveness is not to be ascribed to potash alone, for all the other elements of crops are equally present in an available form; but the existence of an abundance of magnificent potash-yielding forest-trees, will never deceive the farmer as to the natural capabilities of the soil. Hence, when a farmer can learn what amount of potash 100 pounds of his soil or subsoil contain in an available condition, (for this alkali exists in combination with flint or silicic acid in an insoluble form,) he may judge with considerable safety of the natural resources of his land. This alkali exists in some soils in a proportion as high as two per cent.—a quantity, however, rarely found—and in others, ten thousand parts of earth yield not one of potash. Such soils are always nearly barren. How far soda can perform the functions of potash in the growth of cultivated plants, there are no data in the practice of agriculture sufficient to settle the question. There is reason to believe, from a few experiments, that it may serve as a substitute in many cases; but to what extent, and in the organization of what crops, future experiments must decide.

To obtain a clearer idea of the importance of this element in farm economy, let us briefly examine the amount of it in good soils, and the quantity taken therefrom in ordinary crops. The report of the Geological Survey of Canada for 1849 and 1850, made by W. E. Logan, Esq., provincial geologist, (the analytical part of which was performed by T. S. Hunt, Esq.,) contains the following among other analyses of soils. First sample is taken from a rich clay soil, having an unusual quantity of vegetable mould; the original forest was maple, elm, and birch:—

* The London Gardener's Chronicle, of April 19, 1851, after stating that 18,000 tons of guano were imported in 1850 more than the year previous, adds:—"Mr. Way has demonstrated, in the Journal of the Agricultural Society, that the money value of a ton of good Peruvian guano was, in 1849, £12, 2*s*. 5*d*.; the ammonia being worth £9, 14*s*., the phosphate of lime £1, 13*s*. 9*d*., and the potash 14*s*. 8*d*."

When wheat is worth 5*s*. a bushel, a pound of ammonia is worth 6*d*. for making a bushel of wheat. A pound of bone-earth is worth about a cent and a half, and one of potash over six cents.

Sand	49.2
Clay	23.4
Vegetable matter	20.8
Water	6.6
	100.0

One hundred parts of this soil gave to hydrochloric acid—

Alumina	4.820
Oxide of iron	3.240
Lime (part carbonate)	1.033
Magnesia (part carbonate)	.749
Potash	.435
Soda	.795
Chlorine	.080
Sulphuric acid	.144
Phosphoric acid	.557
Soluble silica	.075

The quantity of ammonia is not stated; but, as the organic matter is large, there is doubtless a fair supply of this element of fertility. The above is an excellent soil. Wheat growing upon it would be subject to fall and to rust, from the lack of soluble silica or flint, and from the excess of mould. In a good climate, it would be remarkable corn land. Owing to the excess of organic matter, an acre of this soil, a foot in depth, would weigh not much over 1000 tons. In that quantity, there would be over ten tons of lime; seven of magnesia; four of potash; nearly eight of soda; sixteen hundred pounds of chlorine; about one and a half ton of sulphuric acid, (oil of vitriol;) five and a half tons of phosphoric acid; and fifteen hundred pounds of soluble silica. One hundred parts of this soil gave to distilled water .786 of soluble matter, principally organic. By burning, it left .104 of alkaline ash. 100,000 parts of this ash gave 8 of chlorine, a small portion of nitrates, and a trace of sulphates.

The soluble bases were potash and soda, lime and magnesia. The next sample of soil analyzed was at the other extreme, in point of vegetable matter, containing "but a trace." Rough analysis gave—

Sand	56.0
Pebbles	8.0
Clay	27.8
Water	8.2
	100.0

One hundred parts of this soil gave to hydrochloric acid the following substances.

Alumina	1.440
Oxide of iron	3.780
Lime	.650
Magnesia	1.036
Potash	.276
Soda	.840

Chlorine	.134
Sulphuric acid	.034
Phosphoric acid	.215
Soluble silica	.150

The above analysis shows a soil in which vegetable mould became exhausted sooner than the mineral constituents of crops. It contains less oil of vitriol (sulphuric acid) than of any other ingredient. Gypsum and clover, turned in with the plough, will bring up the land with good profit. Gypsum is a compound of lime and oil of vitriol. 2000 parts of the above soil gave 1 of soluble matter, three-fifths of which were incombustible, consisting mostly of the chloride and sulphate of lime, magnesia, and the alkalies. No trace of nitrates was detected. Organic substances favor the formation of nitrates. The small percentage of alumina in this soil is a defect.

Soils too poor to grow clover to any advantage in Canada, have been brought up by the aid of peas and gypsum. A similar result has been attained in the United States—a fact that should be universally known.

Soils in which alumina predominates are usually richer in the incombustible constituents of plants after the mould is consumed by excessive tillage, than such as contain but little of that mineral. The following facts stated by Mr. Hunt, at pages 81 and 82, elucidate this point:—On the farm of Major Campbell, the original layer of vegetable mould has, by long tillage, entirely disappeared. The general character of this clay seems to be nearly the same for the depth of five or six feet, except that it is a little lighter on going down—a difference, perhaps, due to the fact that organic matters have not infiltrated thus far. When brought to the surface, it breaks into hard, angular fragments; but, by the influence of the weather, it crumbles down into a comparatively mellow soil; still, however, becoming hard and dry in the heat of summer. In laying out a railroad, a bank of the clay was cut down and uncovered to a depth of six feet. The surface thus exposed (denuded) was entirely free from any organic matter; but was found, after a dressing of plaster, to yield an *excellent crop of peas and clover* upon the clays, generally. 100 parts of this clay yielded to hydrochloric acid the following substances:—

Alumina	12.420
Oxide of iron	7.320
Lime	.697
Magnesia	1.490
Potash	.591
Soda	.231
Phosphoric acid	.390
Sulphuric acid	.022
Soluble silica	.105

One may take the best authorities, and examine the analyses of soils in this country, England, Scotland, France, and Germany, and he will hardly find one sample in a hundred that yields so much alumina as the above. When associated with a good deal of the oxide of iron and silicious sand, it lays the foundation for an enduring and excellent soil. When combined with exceedingly fine sand and little iron, the earth becomes altogether too compact and impervious to air and water. Exhausted or naturally sterile lands usually lack phosphoric acid or other essential elements. The following is a case in point, (analysis by Professor Way, consulting chemist of the Royal Agricultural Society, England:)—

Water	20.56
Vegetable matter	6.17
Clay and sand	59.00
Phosphoric acid	—
Carbonate of lime	5.49
Magnesia	—
Oxide of iron and alumina	7.90
Potash	0.31
Soda	0.12
	100.00

The above was a "worn-out soil" on Mr. Pusey's estate, and yet it has an abundance of vegetable matter, lime, and the usual amount of potash and soda. In clay and sand, iron and alumina, the proportions are such as we find in many good soils; but as not a plant can grow without phosphoric acid, and few without magnesia, the absence of these ingredients induces sterility. Instances of this kind might be multiplied to almost any extent; but their repetition is deemed unnecessary. To suppose that one can produce a root, tuber, seed, or stem from other ingredients than such as Providence fitted for the purpose, is to assume that there is no difference between lead and gold; or that an atom of water and one of iron are the same thing. Finding, as we do, many different elementary bodies in all fertile soils and in all cultivated plants, and that they are the same in both, it is alike unphilosophical in science and unsafe in practice, to assume that any one mineral can perform the functions of other minerals in the economy of plants and animals. We may be profoundly ignorant of the office performed by an atom of lime, iron, sulphur, carbon, phosphorus, chlorine, nitrogen, potash, or magnesia, in any of the phenomena of vegetation or animal life; yet direct experiments and universal experience have proved the necessity of having all these substances in the soil, as well as silica in a soluble form, before it can be productive of cereal and other valuable plants. As a general truth, it may be stated that land which will bear good crops of wheat, will also yield all other crops adapted to the climate. Hence, to study the composition of wheat plants when ripe, will lead us at once to all the essential elements of fertility. In 100 parts of wheat, nearly 98 are combustible; in straw, from 90 to 96 per cent. is also combustible. The combustible or organic part of wheat has the following composition, (Boussingault:)—

	Grain.	Straw.
Carbon	46.10	48.48
Hydrogen	5.80	5.41
Oxygen	43.40	38.79
Azote (nitrogen)	2.29	.35
Ash	2.41	6.97
	100.000	100.000

The greatest difference in the combustible part of wheat and straw is in azote, or nitrogen, which is regarded as the flesh-forming element in the plant. One must multiply the nitrogen in wheat-straw by 7 to give as much as there is in wheat. Hence, if a wheat-grower had to rely on decaying straw for nitrogen to form his grain, it would require 700 pounds of straw to make 100 of wheat. If he depended on clover or peas, the case is widely different, as their organic analysis indicates:—

	Pea-Straw.	Clover-Hay.
Carbon	45.80	47.40
Hydrogen	5.00	5.00
Oxygen	35.57	37.80
Azote (nitrogen)	2.31	2.10
Ash	11.32	7.70
	100.00	100.00

It will be seen that pea-straw, or haulm, contains as much nitrogen as wheat; and, when timely cut and properly cured, it makes the best of hay and the best of manure. Clover contains a fraction less nitrogen, but is nearly equal as forage and for manure. By regarding carbon as charcoal, and oxygen and hydrogen as one form of water, we may proceed to consider the inorganic, mineral, or incombustible part of wheat and other crops, in their relation to the soil. The ash left on carefully burning the seeds and stems of cultivated plants is not perfectly uniform in its chemical composition in all varieties of wheat or straw grown on different soils, in different seasons and climates. The variations, however, are no greater than one might reasonably expect under the influence of a change of circumstances. The ash, or incombustible part of the plants, resembles the bones in animals. A poor animal, like a very lean pig or horse, has a larger per cent. of earthy matter in his system than a fat one—that is to say, his bones will bear a greater proportion to the weight of the whole carcass. Plants of the same species yield unlike quantities of starch, sugar, oil, gum, albumen, gluten, and other (so-called) protien compounds. The incombustible earthy matter in them differs in an equal degree. The following table contains the results of an analysis, made by Professor Way, of Hopeton wheat, (ash,) which is near an average of some 60 performed by that chemist at the Royal Agricultural College, Cirencester, and published in the journal of the Royal Agricultural Society, vol. 8, p. 624:

Silica	2.28
Phosphoric acid	45.73
Sulphuric acid	0.32
Carbonic acid, none.	
Lime	2.06
Magnesia	10.94
Peroxide of iron	2.04
Potash	32.24
Soda	4.06
Chloride of sodium	0.27
	99.94

The reader will see in the foregoing all the elements of fertility named in the preceding pages, as shown in the analysis of productive soils. By taking the results of the 60 analyses of the ash of wheat together, it will be found that *the amount of lime in the seed of this plant is about one-third as large as the amount of magnesia, and one-tenth that of potash.* The phosphoric acid is larger at all times than any other substance, and is chemically combined with lime, potash, magnesia, and with soda when present, as it generally is, but in less quantity than in the foregoing table. The silica is confined to the cuticle, or bran, and varies from 1 to 8 per cent. The amount of sulphuric acid is small, as is that of chloride of sodium, or common salt. The iron, set down at over 2 per cent., is unusually large.

The following is the mean of several analyses of the ash of wheat, performed by Boussingault:—

Phosphoric acid	47.00
Sulphuric acid	1.00
Silica	1.30
Potash	29.50
Lime	2.90
Magnesia	15.90
Chlorine, traces.	
Soda, traces.	
Oxide of iron, none.	
Charcoal, and loss	2.40
	100.00

Although no iron appears in the above, yet, when searched for critically, Boussingault did not fail to find it; but as nearly all soils abound in this element of crops, no one is under the necessity of applying copperas, or other salt of iron, to his land as a fertilizer. The reader will see that the per cent. of potash is ten times larger than that of lime, and that magnesia is more than five times as abundant. The best natural wheat soils in the Genesee valley yield a good deal of magnesia and potash on analysis. The ash of wheat-straw has the following composition:

	Per Cent.	Removed from an Acre.	
Silica	69.94	107 lbs.	5$\frac{5}{10}$ oz.
Phosphoric acid	8.53	13	1$\frac{4}{10}$
Sulphuric acid	2.33	3	9$\frac{1}{10}$
Carbonic acid, none.			
Lime	4.94	7	9$\frac{2}{10}$
Magnesia	1.43	2	3
Peroxide of iron	0.06	0	5$\frac{1}{10}$
Potash	12.48	19	2$\frac{4}{10}$
Soda	0.25	0	5$\frac{4}{10}$
Chloride of sodium, none.			
	99.97	153	5$\frac{2}{10}$

This crop was at the rate of 30 bushels per acre, and the grain contained 32$\frac{2}{10}$ pounds ash, which, added to that in the straw, gave 186$\frac{2}{10}$

pounds as the incombustible minerals taken from an acre in a single crop. It is worthy of particular attention that over 100 pounds of soluble flint, or silica, are required to form an acre of wheat-straw. Too little attention has been paid to this substance by the wheat-growers of the United States.

A judicious rotation of crops favors the accumulation of soluble silica in the soil, and how this result is attainable every farmer should understand. The system consists in making a wise use of all the silica contained in all straw, cornstalks, and hay grown on the farm, and in increasing the solubility of the finest particles of silicious sand in the soil. The former is simply a matter of good husbandry, i. e. carefully saving all straw, stalks, and grass or hay, or the manure derived from the same. There are farmers in England who make land, which is naturally poor, yield an average of 36 bushels of wheat per acre, take one year with another. In this operation, straw, hay, and turnips supply most of the raw material for making so large an average yield of wheat. The solubility of flint-sand, or silica, is increased by the aid of potash and soda. When these alkalies combine with silica in small quantities, insoluble silicates are produced, like common glass; but, if glass be ground fine and boiled in a concentrated solution of potash or soda, it will be dissolved in the water, the silica having combined with a large amount of the alkali. Wood-ashes and salt, abounding in potash and soda, have been found, by experience, valuable fertilisers for wheat; and even salt and lime, or salt alone, will greatly benefit the crop, as many wheat-growers in western New York have demonstrated. One reason why peas, beans, and clover rotate so successfully with wheat, is, that these crops extract comparatively little silica from the soil, and, of course, leave the more for cereals.

Composition of Peas and Beans on Clay Soil.—Analyses by Professor Way.

	1 ton of Peas.	1 ton of Beans.	2989 pounds of Pea-straw.	2270 pounds of Bean-straw.	Entire crop Peas.	Entire crop Beans.
Silica	0.42	0.22	4.62	2.95	5.04	3.17
Phosphoric acid	14.43	15.23	2.93	0.55	17.36	15.78
Sulphuric acid	2.93	1.62	5.38	1.58	8.31	3.20
Lime	2.28	2.75	86.80	22.25	89.08	25.00
Magnesia	3.48	3.66	13.62	2.85	17.10	6.51
Protoxide of iron	....	....	1.74	0.69	1.74	0.69
Potash	20.75	27.40	30.18	36.96	50.93	64.36
Soda	2.51	0.23	0.57	3.18	3.08	3.41
Chloride of sodium, (salt)	2.15	....	23.00	13.88	25.15	13.88
Total	53.16	51.16	168.84	84.84	207.79	136.00

It will be seen by the above figures that a ton of peas (2240 pounds) and 2989 pounds of pea-straw contain only 5.04 pounds of silica, and beans still less. Hence, an acre of arable land might yield a crop of 5229 pounds of peas one year, and one of 4510 pounds of beans the next, and not part with $8\frac{1}{2}$ pounds of silica in the two crops. Pea-straw consumes a large amount of lime and considerable potash. Land should be well stocked with lime for these crops. 3698 pounds of perfectly dry clover gave Boussingault 284 pounds of ashes, equal to 7.7 per cent. In these ashes, or, more properly, in this ash, there were 18 pounds phosphoric acid, 7 pounds sulphuric acid, 7 pounds chlorine, 70 pounds lime, 18 pounds magnesia, 77 pounds potash and soda, 15 pounds silica, and 1 pound oxide of iron. To the foregoing must be added 71 pounds carbonic acid, to make the aggregate 284 pounds. In the way that Boussingault burns clover, the ash contains 25 per cent. of carbonic acid. It will be seen that this plant, like peas and beans, draws slightly on the soil for soluble silica, but largely for the alkalies and lime. Scientific farmers realize great benefit in growing clover and beans in connection with wool-growing and wheat culture, because the first-named plants send down their roots in a permeable soil to a great depth, and bring up phosphates, sulphates, and chloride of lime, potash, and magnesia, which are ultimately consumed in forming generous crops of wheat.

The writer has frequently traced the roots of clover and beans to the depth of 34 inches into the earth in sandy and loamy soils. *Subsoiling and root culture* are profitable operations, when conducted on scientific principles. Care should be had that there is not an excess of moisture in the subsoil. Draining is the only remedy for this evil. The capacity of soils to take up and retain water without injury to crops by its excess, and the temperature of soils at different depths and under different circumstances, will be noticed before the close of this essay. The reader's attention is now invited to the minerals taken from the earth in the growth of potatoes, turnips, and carrots, which, under a good system of husbandry, are valuable crops.

About three-fourths of the weight of potatoes, when dug, are water; of the other fourth, twenty-four parts in twenty-five are combustible—the other part being ash. Estimating his crop at its dry weight, an acre gave M. Boussingault 2828 pounds of tubers, which yielded 113 pounds of ash—consisting of 13 pounds of phosphoric acid, 8 pounds sulphuric, 3 pounds chlorine, 2 lime, 6 magnesia, 58 potash and soda, 6 silica, 8 carbonic acid, and 1 pound oxide of iron. It will be seen that more than half of the ash of potatoes is pure potash, for it contains but a trace of soda. Dry potato tops yield 6 per cent. of ash. An acre (in which the growth of vines or tops must have been unusually large) gave to M. Boussingault 5042 pounds dry weight, and 303 pounds ash—consisting of 33 pounds phosphoric acid, 7 sulphuric acid, 4 chlorine, 7 lime, 5 magnesia, 135 potash and soda, 39 silica, 16 oxide of iron, and 57 carbonic acid. Taking the figures as they stand, there are few so exhausting crops as that of Irish potatoes, (*tuberosum solanum*,) when entirely removed from the soil. In the tops and tubers 416 pounds of incombustible matter are removed from an acre. Twenty bushels of wheat require 12 pounds of phosphoric acid for the grain, and 5 pounds for the straw; while an acre of good potatoes demands 13 pounds of this acid for the tubers, and 33 for the haulm or tops. This is equal to two large crops of wheat. In an acre of potatoes, 193 pounds of potash are consumed: one-sixth of that amount answers for an acre of wheat. Few farmers supply their growing potatoes with a sufficient quantity of potash and phosphoric acid.

Hence this plant and its tubers have become constitutionally deteriorated on most farms, and extremely prone to premature decay.

Professor Way gives the following figures to indicate the minerals required by nature to form twenty tons of bulbs and four tons of tops of the following root crops:

	Turnips. lbs.	Mangel-wurzel. lbs.	Carrots. lbs.
Phosphoric acid	45	21	39
Sulphuric acid	50	22	57
Lime	90	21	197
Magnesia	14	22	29
Potash	140	130	134
Soda	33	70	103
Chloride of sodium	57	160	85
	429	446	644

The above figures appear large; but it must be borne in mind that a crop of 24 tons of 2240 pounds to the ton is also large for an acre—at least, it would be so regarded in this country. Roots require rich land to do well; and, in turn, they yield a large amount of fertilizing elements. It will be seen that 24 tons of carrots consume 197 pounds of lime, and 287 of potash and soda, besides 85 of common salt, (chloride of sodium.) The large demands for phosphoric and sulphuric acids is also worthy of note.

The most successful improvers of soils and grain-growers in the world produce a vast quantity of roots, and mainly with a view to augment the stock of manure on the farm. The organic matter which 24 tons of roots furnish is immense; but many believe that the price of labor is too high, grain too low in the United States, and virgin lands too cheap, for the profitable adoption of the English system of husbandry. Before one can wisely adopt any system of farming, he must learn the natural capabilities of his soil, the elements of crops which he can command at the lowest price, and the cost of producing each article that the market calls for, as well as the probable compensation he is to receive for the same. Among the elements of production, *temperature* and *humidity* deserve the most careful consideration. The temperature of soils at different depths below the surface has been very little studied in the United States. Professor Emmons has made observations at Albany for twenty months, which are published in the second volume of his valuable work on the agriculture of New York, from which we condense the following:*—From May 14th to 22d, inclusive, 1847, mean temperature at the surface of the soil on grass land, at 5 o'clock, A. M., was 48°. At four inches below the surface, it was $53\frac{1}{3}$°; at nine inches below, 55°. At noon, the temperature at the surface was 85°; four inches below, $82\frac{1}{4}$°; nine inches below, 57°. At 7 P. M., at the surface, the heat was $77\frac{3}{8}$°; four inches below, $69\frac{3}{8}$°; nine inches, $59\frac{1}{4}$°. Four feet above the surface, the temperature, at the times above named was $49\frac{1}{3}$° at 5 A. M.; $68\frac{3}{8}$° at noon; 65° at 7 P. M. The above

* Albany is in latitude 42° 39′. Mean annual temperature, 48° 47′ at 130 feet above tide. Observations made 100 feet above tide.

figures reveal the interesting fact that the mean temperature was 29° higher at the surface than four feet above it, at noon; while the soil, four inches below the surface, at that time of day, was $17\frac{1}{2}$° warmer than the air four feet above the ground. At nine inches in depth, the mean is 10° below that of the air four feet above the surface. At 7 o'clock, P. M., the temperature is 2° higher than at noon.

From 23d to 31st of May, inclusive, the record is as follows:—Mean heat at the surface, $52\frac{1}{8}$°, four inches below, $55\frac{1}{2}$°, nine inches below, $56\frac{1}{2}$°, at 5 o'clock, A. M. These figures show a regular cooling of the soil during the night-time, from the surface to the depth of nine inches. At noon, at the surface, the temperature was $68\frac{1}{2}$°; four inches below, $61\frac{1}{8}$°; at nine inches below, $58\frac{3}{8}$°.* At 7 P. M., at the surface, the mean was $62\frac{1}{2}$; four inches below, $61\frac{1}{8}$°; nine inches below, $59\frac{1}{2}$°. During the same period, the mean heat four feet above the surface, at 5 A. M., was 54°; at M., $65\frac{5}{8}$°; and at 7 P. M., $63\frac{1}{2}$°. These figures indicate cooler weather than one would expect between the 23d and 31st of May, even at Albany.

From the 1st to the 7th of June, inclusive, the mean at the surface on grass land was, at 5 A. M., $54\frac{5}{8}$°; at four inches below the surface, $57\frac{3}{8}$; at nine inches, 58. At noon, at the surface, the temperature was $74\frac{3}{8}$; at four inches below, $64\frac{1}{4}$; nine inches below, $59\frac{1}{2}$. At 7 P. M., at the surface, 68; four inches below, $64\frac{3}{8}$; nine inches below, $60\frac{7}{8}$. At the period above referred to, the mean temperature of the air, four feet above the surface, was, at 5 A. M., $53\frac{1}{4}$; M., $66\frac{1}{4}$; 3 P. M., $69\frac{3}{4}$; 7 P. M., $64\frac{1}{4}$. From 8th to 14th June, the mean temperature, at 5 A. M., at the surface of grass land was 61; four inches below, 60; nine inches below, $60\frac{1}{2}$. At noon, the average was 69 at the surface, 66 four inches below, and $64\frac{1}{2}$ nine inches below. At 7 P. M. the thermometer gave a mean of 67 at the surface. In the air, four feet above the surface, at 5 A. M., the heat was $65\frac{5}{8}$; at M., $77\frac{3}{4}$; at 3 P. M., $78\frac{3}{4}$; at 7 P. M., $73\frac{1}{4}$.

The soil attained its maximum temperature in the third week of July, at the depth of nine inches, being $75\frac{3}{4}$ degrees. 81 degrees was the maximum mean at the depth of four inches, on grass land; and 85 at the same depth on naked soil.

In the fourth week of July, the mean, at nine inches below the surface, was near 72 degrees. In this week the mean, at 5 A. M., four feet above the surface, was $65\frac{1}{4}$; at M., $73\frac{1}{2}$; at 3 P. M., $70\frac{3}{4}$; at 7 P. M., $69\frac{1}{4}$.

During the first week in August, the mean temperature of the soil at nine inches below the surface, was $71\frac{1}{2}$ degrees. The mean, four feet above the surface, was 72.

During the second week the mean, at nine inches below the surface, was 73 degrees, being $1\frac{1}{2}$ higher than the preceding one. The mean in the air, four feet above the surface, was $75\frac{1}{2}$.

The third week gave a mean of $71\frac{1}{4}$ degrees, at the depth of nine inches in the soil; while the mean, four feet above it, was 69

In the fourth week, the soil had a mean of $70\frac{1}{2}$ degrees at the depth of nine inches.

The temperature fell to a mean of $64\frac{1}{2}$ degrees, at the same depth, during the first week in September.

* This footing is wrong in the table in the quarto volume from which we copy. The mean is there stated at $68\frac{3}{8}$°. It should be $58\frac{3}{8}$°.

The mean of the second week was 64 degrees; of the third, $62\frac{1}{2}$; fourth, $59\frac{1}{4}$.

In the first week in October, the soil, at nine inches, had a mean heat of 58 degrees; in the second week, of 55; in the third, of $52\frac{1}{2}$; in the fourth, of —. (*Note.*—This table is defective.)

At 2 feet below the surface, the temperature of the earth in Albany fell from 40 degrees, on the 1st of January, 1848, to 34 on the 31st of that month; and at four feet below the surface, the change, in the same length of time, was from 43 to 37.

In the month of February, at the depth of 2 feet, the reduction in temperature was from 34 degrees to 32; and at four feet, from 37 to $35\frac{1}{4}$.

In the month of March, the earth, at four feet, was cooled 1 degree, or to $34\frac{1}{4}$; at 2 feet, the variation was very slight.

During the first fifteen days in April, the temperature, at the depth of two feet, increased 11 degrees, or from 33 to 44; in the last fifteen days in April, the increase was from 44 to $47\frac{1}{2}$.

During the thirty days in April, the earth, at four feet in depth, had its heat increased from $34\frac{1}{4}$ degrees to 46.

During the thirty-one days in May, the earth, at the depth last named, had attained a temperature of $54\frac{1}{2}$ degrees; at two feet, it was $58\frac{1}{2}$; at nine inches, it was $60\frac{1}{2}$; and at four inches, 8 P. M., it was 62.

From the foregoing observations, it is obvious that the four months of June, July, August, and September furnish the warmest soil, to the depth of two feet, for the production of corn in the Northern States. There are many circumstances that modify the temperature of soils, such as being open, and permitting either warm or cold water to descend freely to a considerable distance into the earth. Standing water being a bad conductor of heat, a wet, compact clay soil may have boiling hot water poured upon it in large quantities, without heating either the water or ground below the surface to any depth. Solar heat encounters equal difficulty in penetrating a wet, compact clay, from the surface of which water evaporates and carries off much heat in a latent form. Different soils absorb unequal quantities of water, and retain it with unequal force. Dr. Sprengel, in his valuable work on soils, truly remarks that "the power of the earth to take up and hold back more or less water, mechanically, in its pores, is of the greatest importance for vegetation, not only because the water in and of itself contains the life of plants, but especially, also, because it carries to them means of nutriment from the soil." In the *want* or *excess* of moisture we frequently must seek the cause of the unfruitfulness of the earth. The capacity of the soil to hold moisture,* but especially the decompositions and combinations which take place, are of importance, since the decomposition of organic matter may be prevented either by an excess or the want of moisture.

The following table contains the results of experiments made by Professor Schubler, with such soils as usually come under the notice of the agriculturist:

* We have tried swamp-muck, or peat, which, when perfectly dry, would take up, without dripping, four times its weight of water.

Kinds of Earth.	Power of containing Water.		A Cubic Inch contains—		A Cubic Ft. contains—
	According to Weight.	According to Volume.	Grains of Water.	Cubic lines of Water.	Pounds of Water.
Silicious sand	25 per ct.	37.9 per ct.	121	655	27.8
Calcareous sand	29 "	44.1 "	141	763	31.8
Gypsum powder	27 "	38.2 "	122	660	27.4
Fine lime	85 "	66.1 "	211	1,142	47.5
Lime, precipitated	47 "	54.5 "	174	941	39.1
Fine magnesia	25.6 "	76.1 "	242	1,316	62.6
Sandy clay	40 "	51.4 "	164	888	36.8
Loamy clay	50 "	57.8 "	183	991	41.4
Stiff clay, or brick earth	61 "	62.9 "	201	1,088	45.4
Pure gray clay	70 "	66.2 "	212	1,145	48.8
White pipe-clay	87 "	66 "	211	1,142	47.4
Humus	181 "	69.8 "	228	1,207	50.1
Garden mould	89 "	67.3 "	215	1,164	48.4
Arable soil	52 "	57.8 "	181	980	40.8
Slaty marl	34 "	49.9 "	158	868	35.6

From this table we obtain the following general results:—

1. The sands have the smallest power of containing water, whether they are compared in weight or in volume with the other earths.

Silicious or flint sand has the least power of them all—the sands, moreover, differing according to the fineness of their grains. The finer the grains and particles, like precipitated lime, fine clay, and magnesia, the more water is taken up by the earth. Thus white pipe-clay absorbs 87 per cent. of its weight, and 66 of its volume of water, while common silicious sand takes up only 25 per cent. of water by weight, and 37.9 by volume. Coarse sand imbibes, when saturated, only 20 per cent. of water.

2. Gypsum powder very nearly approaches the sands in its hygrometric properties, taking up but 27 per cent. by weight, while fine lime absorbs 85 per cent. In this case the lime is specifically much lighter as well as finer. The lightness of fine magnesia is well known; hence the large per cent. of water absorbed by it. The same remarks will apply to humus, or pure mould.

3. It will be seen that 100 parts of arable soil take up 52 per cent. of water in weight, and over 57 in volume.

4. Slaty marl has a less capacity for containing water than one might infer from the fineness of its particles; it is, however, about 50 per cent., according to volume.

5. The large amount of water that a cubic foot of earth is able to hold, is worthy of note. We suspect that magnesia is rated too high. It is stated at 62.6 pounds per cubic foot, which is as much water as a cubic foot contains without any magnesia whatever. A cubic foot of common arable soil will hold over 40 pounds of water. The proportion of water which evaporates from the surface of leaves and the ground, and the proportion that penetrates the earth to appear again elsewhere as springs, and the part that runs off immediately from the surface when it rains, or soon after, are facts that have not been studied except to a very limited

extent. Considerably more water will evaporate even in the cool and damp climate of England from an acre of land than falls upon it, provided the earth is kept saturated all the time. One of the advantages of trenching—that is, of digging up the soil and subsoil to the depth of 18 or 20 inches over a whole field—is the increased quantity of water it will contain, and not be too wet for the healthy growth of cereal and other crops. On soils thus treated, they seldom suffer from drought, the supply of moisture from below being so enduring. Deep ploughing and subsoiling operate in a similar manner, only less in degree.

The Drying of Soils.

Kinds of Earth.	Ease of Drying.		
	Of 100 parts of Water absorbed, was evaporated in four hours, at 67° Fahrenheit—	Of 100 parts of Water absorbed, 90 parts evaporated at 67° Fahrenheit, in—	
		Hours.	Min.
Quartz sand	88.4 parts.	4	4
Lime	75.9 "	4	44
Gypsum, in earthy form	71.7 "	5	1
Stratified clay	52.0 "	6	55
Loamy clay	45.7 "	7	52
Pure gray clay	31.9 "	11	17
Carbonate of lime, in fine state	28.0 "	12	51
Carbonate of magnesia, in fine state	10.8 "	33	20
Humic acid	20.5 "	17	33
Loamy soil	32.0 "	11	15

On the drying of the deep layers of the soil in a longer or shorter time, the different looseness or consistency of the upper soil has also an important influence. Fine clay, for example, at 2 inches thickness, has a moist surface long after the surface of peaty soil is dried up at an equal depth.

If a soil contains many salts, particularly such as deliquesce, i. e. attract moisture from the atmosphere sufficient to dissolve them, like pearlash and common salt in damp places, it is characterized by peculiar hygroscopic power. All earths attract more moisture by night than by day; they also give back, through evaporation in the sunlight, the moisture absorbed at night. Schubler remarks:—"In order to ascertain how much moisture one kind of soil will absorb from the air, we laid a certain quantity of finely pulverized and fully dried earth on a plate, which was put under a glass bell made water-tight, and permitted to lie there 12, 24, to 48 hours, in a moderate temperature, (from 59° to 67° Fahrenheit,) and then weighed. The gain in weight shows the amount of water absorbed."

The following results were obtained in the manner indicated :—

Kinds of Earth.	100 parts of Dry Earth absorbed in—			
	12 Hours.	24 Hours.	48 Hours.	72 Hours.
Quartz sand	0 parts.	0 parts.	0 parts.	0 parts.
Lime sand	2 "	3 "	3 "	3 "
Gypsum	1 "	1 "	1 "	1 "
Carb. lime in powder	26 "	31 "	35 "	35 "
Carb. magnesia in powder	69 "	76 "	82 "	82 "
Potter's clay	21 "	26 "	28 "	28 "
Loamy clay	25 "	30 "	34 "	35 "
Pure gray clay	37 "	42 "	48 "	49 "
Humic acid	80 "	97 "	110 "	120 "
Plough land and corn soil	16 "	22 "	23 "	23 "

In commenting on the above table, Professor S. pertinently calls attention to the fact that "gypsum attracts scarcely no water from the air. But it is usually believed that gypsum, employed as a manure, especially promotes vegetation by attracting moisture from the atmosphere, which it transmits to plants. *Thus theories which are written down often fall to nothing when tested by experiment.*"

It is to be hoped that American farmers will soon see the importance of encouraging accurate experiments in the science as well as the practice of agriculture, and no longer dignify mere *theories* or *surmises* with the name of agricultural science.

Truth in the science, like truth in the art of tillage and husbandry, can only be established by numerous and reliable experiments.

The shrinkage of different soils in drying is thus given by this indefatigable worker. 1000 cubic lines were reduced to the following dimensions :—

Quartz sand	0 (i. e. no reduction.)
Potter's clay	940
Loamy clay	911
Pure gray clay	817
Humic acid, (mould)	800
Carbonate of lime, as powder	950
Plough land, loam soil	880

This table shows that the decrease in the volume of earth stands in direct proportion with its power of retaining moisture. The unequal contraction of earths in drying is a curious phenomenon, and produces the crumbling of clays, loams, and all compound soils, when turned up by the plough or spade.

According to Schubler's experiments, the following are the results as to the capacity of different earths to retain warmth for a longer or shorter time :—

Kinds of Earth.	Power of retaining warmth, that of limestone sand being fixed at 100.	Length of Time which 130 cubic inches of Earth need, at a temperature of 62° Fahrenheit, to cool from 145 to 70°.
Limestone sand	100	In 3 hours and 30 minutes.
Quartz sand	95.6	3 " 20 "
Gypsum earth	73.8	2 " 34 "
Potter's clay	76.9	2 " 41 "
Loamy sand	71.8	2 " 30 "
Pure gray clay	66.7	2 " 14 "
Carb. magnesia	38.0	1 " 20 "
Carb. lime	61.0	2 " 10 "
Humic acid	49.0	1 " 43 "
Plough-land loam	70.1	2 " 27 "

From the above table, it appears that limestone sand, and next quartz sand, excel all other soils in retaining warmth. In many climates, this is an advantage of great importance. Black mould (humic acid, or humus) radiates heat with the greatest rapidity. Hence, peaty soils, although sufficiently dry, being soonest cooled down to the freezing point, are the first to experience a frost in autumn. Carbonate of magnesia radiates heat with greater facility than mould, but no one meets with a soil all or nearly all magnesia; hence the radiating power of that mineral has little practical importance. In mixing soils to improve their texture and chemical properties, it is found by experience much better economy to add clay to a light leachy sand, to impart strength and tenacity to the soil, than to apply sand to stiff clay to render it more friable and porous. Experience of this kind gave rise to the old English doggerel maxims :—

> "Clay upon sand
> Makes land;
> Sand upon clay
> Throws money away."

Little land has been "made" in this country by adding a top-dressing of clay to sand; but in many localities the operation will pay well. The clay should be dug from the richest deposite within reach, and dried, to diminish its weight before it is hauled and spread. 100 tons will cover an acre an inch in depth, which will permanently improve any soil, whether sand or gravel, that is too porous and leachy. It is only, however, where land is valuable, that one can safely incur the expense of putting 100 tons of clay upon an acre; and the labor should be performed at times when the farmer has least work on hand for his teams, hired men, or servants. It is so much cheaper to grow crops on a soil that holds manure and other fertilizers well, than on a loose sand or gravel, that the skilful mixing of earths will pay better than one might at first suppose. Where lime can be had at a reasonable rate, it may be used as clay. This mineral is lacking in a large portion of the land under cultivation in the United States; but the misfortune is, that in sections where there is least lime in the soil, it is too expensive to apply an amount that will equal one per cent. of the mass, estimating the earth to the depth of ten inches. As the soil to this depth weighs 1000 tons, it will take 10 tons of slaked carbonate of lime, or 6 of caustic lime, to the acre, in case the earth lacks this mineral, to form one per cent. in the soil. There are very few soils on the limestone lands in Western New York that contain so much as two per cent. of lime. The writer has analyzed a great many of the soils that overlie limestone rocks, famous for producing good wheat, and he has found more that contained less than one per cent. of lime than that had over that quantity. A soil may, however, possess 30 or 40 per cent. of this substance, and still be productive. If it were quicklime, a much smaller amount would be fatal to vegetation; but as common lime (carbonate) is insoluble in pure water, requiring the presence of carbonic acid, or some other, to dissolve it, not enough of this alkaline earth is ever dissolved in its mild state to injure crops. On the chalk lands of England, and extensive marl deposites in this country, the fact has been abundantly demonstrated that the carbonate of lime is not otherwise injurious than in taking the place of soluble silica, potash, chlorine, or other elements of cultivated plants.*

CHAPTER V.

THE PHILOSOPHY OF IMPROVING SOILS.

It is a grave mistake to suppose that all soils can be improved with equal facility and profit. The best way to impart a high degree of fertility to any given area of earth, is a problem often very complex and difficult of solution. In some cases, a little gypsum scattered broadcast over a clover or pea field operates like magic to increase the crop; in others, this fertilizer produces no effect whatever. The same is true of bone-dust, common salt, lime, and potash. More compound fertilizers, like the dung of sea-birds, called *guano*, and stable manure, seldom, if ever, fail to improve the productiveness of land for one or more crops. Why this difference in favor of the latter?

While lime adds to the soil only one element, the excrements of domestic animals applied to it contain not only lime, but some twelve or fourteen other ingredients equally necessary to form cultivated plants. Now, unless a part of a thing is equal to the whole, the excrements of animals, no matter whether of birds, swine, sheep, neat cattle, or of the human species, must ever be more reliable to augment the productiveness of the earth than any one, two, or three simple elementary bodies, consumed in the formation of any crop. When a part of the necessary ingredients are present in the soil in an available condition, then the addition of the lacking ingredients, whether few or many, will effect the desired purpose. While this statement is strictly true, it does not militate in the least against the use of lime, bones, gypsum, salt, marl, greensand, and other popular fertilizers, whenever and wherever it can be done at a profit.

* Earths that contain a large amount of chalk or other calcareous matter are commonly very porous and dry, and support a feeble and stunted vegetation. Treading the surface with sheep, rolling it, and applying clay, are the principal remedies used on the chalk downs of England. Georgia contains a little, and Alabama a considerable area of land where there is an excess of calcareous mineral. Those that desire to study the economical value of lime in the Atlantic slope of the United States will find a vast fund of useful information in an extended "Essay on Calcareous Manures," by Edmund Ruffin, Esq., of Virginia.

In the very nature of the case, experiment or personal experience must decide this question for the farmer. Science can do no more for him than to establish general and correct principles to guide his practice and researches. But the agriculturist should weigh carefully all the facts that science and the large experience of thousands of other cultivators of the soil have recorded for his instruction and benefit.

In an able and interesting address before the Maryland State Agricultural Society, delivered at its third anniversary exhibition in October, 1850, the Hon. Willoughby Newton, of Virginia, gave the following as the results of his experience in the use of guano:—

"In the effect of *guano*, especially the Peruvian, I have never been disappointed. I have used it now for four years, with entire satisfaction, having each year been induced to enlarge my expenditure, until last year it reached $800; and for the crop of wheat this fall it exceeds $1000. I have observed with astonishment its effects in numerous instances on the poor 'forest land,' alluded to in a former part of this address. What the turnip and sheep-husbandry have done for the light lands of Great Britain, the general use of guano promises to do for ours. Lands a few years ago deemed entirely incapable of producing wheat, now produce the most luxuriant crops. From 15 to 20 bushels for one sown, is the *ordinary product on our poorest lands, from the application of* 200 *pounds of Peruvian guano.* I may remark, that it is not usual, in Eastern Virginia, to sow more than a bushel of wheat to the acre; and that I deem amply sufficient."

We regret that Mr. Newton does not state what quantity of wheat this "poorest land" in Eastern Virginia would yield without guano or manure of any kind. In the absence of such information, it is probably safe to assume that 5 bushels are about the average; if so, the gain is from 10 to 15 bushels by the use of 200 pounds of Peruvian guano. It is a philosophical question of great practical importance in farm economy to solve, *In what way does nature operate*, to make 200 pounds of manure produce 15 bushels of wheat, including, of course, the plants that bear this amount of seed?

Science, associated with practice, enables us to answer this question in a clear and satisfactory manner. Assuming the highest gain, or 15 bushels, the weight of that amount, at 60 pounds per bushel, is 900 pounds. From this 12 per cent. must be subtracted for water in merchantable wheat, which reduces the quantity to 792 pounds. Of this, 95 per cent., in round numbers, is water, or its elements, oxygen and hydrogen, and carbon, or coal. The other 5 per cent. is organized nitrogen and incombustible matter, called ash. This 5 per cent. is nearly 40 pounds in weight, and similar, in every respect, to the elements contained in the guano applied to the soil. If we may safely assume that growing wheat-plants can obtain most of their carbon from the carbonic acid in the atmosphere, and water from the same source, there is no difficulty in understanding how 200 pounds of a highly concentrated manure should supply 40 pounds of raw material for making this grain, and have 160 left for the benefit of the straw. To yield 900 pounds of wheat, requires from 1200 to 1800 of straw and chaff. As guanoed wheat usually contains less straw in proportion to the grain than wheat grown on ordinary rich land, probably 1500 pounds of straw and chaff are a fair estimate to 900 of seed. Of the combustible part of this straw and chaff, over 99 parts in 100 are carbon and the elements of water. The amount of nitrogen in straw is about one-third of one per cent. Guano supplies nearly all the wants of the stems of wheat plants in minerals, except soluble silica or flint. Potash is sometimes lacking in this fertilizer to a degree that impairs its value for growing wheat. As a crop of wheat is not taken year after year from the light sandy soils in Virginia and Maryland, soluble silica has an opportunity to accumulate, to some extent, between the large demands on the soil for this element. The power of wheat, corn, oats, and other cereal grasses, to extract carbon from the atmosphere, is one of the most pregnant facts in practical agriculture. If the essential elements of grain can be so much concentrated that 200 pounds of manure will produce 900 of wheat, *the fact* is of inestimable importance to the human family, and especially to all owners of arable land, no matter how sterile it is by nature, or poor by excessive cropping. Anxious to encourage investigations in this direction, we copy a few additional remarks from Mr. Newton's address:—

"I applied, last fall, $350 worth of guano, partly Peruvian and partly Patagonian, on a poor farm in 'the forest,' which cost, a few years ago, $4 an acre, and reaped 1089 bushels from 78 sown. Forty-six were sown on a fallow, (both guano and wheat put in with a cultivator, followed by a heavy harrow,) and yielded 790 bushels, or over 17½ per acre for one of seed. A considerable part of this was dressed with Patagonian guano, and was much inferior to the other portion. A lot on which 15 bushels were sown, and dressed with Peruvian guano, was threshed separately, and yielded 301 bushels, or over 20 for one. The cost of the farm was $1520, and I have good reason to expect, with a favorable season, from the crop now sown and dressed with guano, a bushel of wheat for every dollar of the prime cost of the farm. Many other instances from the use of guano, equally striking, have come under my immediate observation among my neighbors and friends, and I can vouch for their entire accuracy. It has been frequently objected to the use of guano, that it is not permanent. It would be unreasonable to expect great permanent improvement from a manure so active, and which yielded so large a profit on the first crop; yet, I have seen some striking evidences of its permanency in heavy crops of clover succeeding wheat, and in the increase of a crop of wheat on a second application. As an instance, I may mention that two years ago I sowed, upon a single detached acre of 'forest land,' one bushel of wheat, and dressed it with a barrel of African guano, costing $4, and the yield was 17 bushels. Last fall, the same land, after remaining one year in clover, was again sown with one bushel of wheat, and dressed with 140 pounds of Peruvian guano, costing $3, and the product was 22 bushels; yet I would advise no one to rely upon guano exclusively. Its analysis shows that it contains salts of ammonia, alkaline phosphates, and the other mineral elements necessary to produce the grain of wheat, but is deficient in most of the elements of the straw and roots of the plants."

If the last remarks were true, the dung of sea-birds and of common domestic fowls would be less valuable than experience proves it to be. Mr. E. F. Teschemacher, of Boston, gives the following as the result of an analysis of Peruvian guano made by him:—"One hundred parts consist of 9 parts of ammonia, combined with phosphoric, carbonic, uric, and organic acids; forming, of

Ammoniacal salts	40
Animal organic matter	6½
Sulphate and muriate of potash and soda	11½
Phosphate of lime and magnesia	29½
Sand	1
Water	11½
	100"

While there is but one per cent. of sand, or silica, and that insoluble, there is 11½ per cent. of salts of potash and soda, being about the same found in wheat straw.*

No fertilizers differ more in value and chemical composition than those imported and sold under the name of guano. We can no more judge from the analysis or practical effects of one cargo of this manure what the next will be worth, than from the composition of one man's soil in one locality what is the composition and what the value of a different soil in a distant locality. The true way to estimate the value of the excretions of any animal, is to learn the nature and constituents of the food on which it subsists. The mule that lives on sedge, thistles, and bushes, will yield manure vastly inferior to that of one fed on corn and oats. When a bird consumes 100 parts of dry organized fish, flesh, insects, or the seeds of plants, 80 parts, more or less, escape from its capacious lungs in the shape of carbonic acid and vapor; and 20 by the bowels, which constitute guano. It is because the food of birds is richer in the least abundant elements of plants, and their systems burn out nearly all the carbon and hydrogen in their aliment before it leaves the organs of nutrition and respiration, that the dung of this class of animals is so valuable. Every farmer knows that if 100 pounds of oats were rotted, they would form valuable manure; but how would the mass compare with 100 pounds of guano, suppose fowls had eaten oats enough to form 100 pounds of dry excrement? The composition of oats, according to Boussingault, is as follows:—

Carbon	50.38
Hydrogen	6.32
Oxygen	37.14
Nitrogen	2.24
Ash	3.98
	100.00

* Professor Way has demonstrated, in the Journal of the Royal Agricultural Society, that the money value of a ton of good Peruvian guano in England, in the year 1849, was £12 2*s.* 6*d.*; its ammonia being worth £9 14*s.*, the phosphate of lime £1 13*s.* 9*d.*, and the potash 14*s.* 8*d.* Ammonia is worth sixpence (11 cents) a pound for producing wheat at $1.25 a bushel; phosphate of lime is worth 1½ cent a pound, and potash about 6¼ cents, for agricultural purposes.

From a return printed by order of the House of Commons, it appears that 116,925 tons of guano were imported into the United Kingdom in the year 1850; being more than was imported in any year since 1841, excepting the year 1845, when 283,300 tons were imported.

It will be seen that nitrogen and ash or incombustible matter form only 5.22 per cent. of oats, and that 94.78 parts in 100 are carbon and the elements of water, carbon forming a fraction over half the weight of this grain.* Now, the best guano contains no more carbon than it does of nitrogen, and often not so much; but let us assume that the oxygen and hydrogen in oats are not estimated as fertilisers at all, and that guano made from the seeds of this plant contains as much carbon as the ash and nitrogen combined; then it is obvious that 100 pounds of oats will form but 10.44 of this most concentrated fertiliser; so that 1000 pounds of oats would yield only 104.4 pounds of guano. If a soil did not lack available carbon, oxygen, and hydrogen, but ammonia and the earthy elements of oats, who can say, in view of the chemical composition of this grain, that 105 pounds of the right ingredients might not produce 1000 of oats? To comprehend the philosophy of improving land, the farmer must have a clear perception of the existence and condition of the two tons of matter which forms that quantity of clover-hay and roots, when 100 pounds of gypsum are applied to an acre that needs sulphur, and, perhaps, available lime. When a mixture of wood-ashes, burnt bones, and common salt adds many thousand pounds to a crop of corn, where does all the carbon come from contained in the stalks, leaves, roots, cobs, and seeds of this luxuriant plant? Not a pound of carbon was applied in the fertilisers. In burning over prairies at the West, a thousand pounds or more of carbon from each acre are annually discharged into the atmosphere for centuries, while not an ounce is applied in manure of any kind. Instead of impairing the soil and robbing it of mould or carbonaceous matter, these prairies are remarkable for the dark color and richness of the earth. In this case, not only carbon and the elements of water are consumed in the annual burning of all vegetation, but whatever of nitrogen is contained in wild grass and other plants is also thrown into the air. Nothing but the ash remains to keep up the virgin fertility of the land, and that is sufficient for the purpose.

If these prairies had been *tilled*, as well as cropped by burning their products, there is no question but the exhaustion of the soil would ensue. Tillage *alone*, by increasing the solubility and solution of all the elements of plants, both organic and inorganic, hastens their removal from ploughed land. There is vastly too much land under the plough in the United States for the crops harvested. The proportion of the elements of crops which leave the soil without entering at all the roots of plants is much greater than is generally believed. No intelligent person can long study the combustible and incombustible matter that rain-water dissolves out of an arated or frequently stirred soil, in the course of the six warmest months of the year, and not be convinced of the truth of the above remark. The leaching and washing of tilled land are to be avoided by all practicable means, if one seeks to increase its productiveness from year to year. When manure enough to produce 17 bushels of wheat on poor, sandy land, can be put into a "barrel," and sold readily for "four dollars," farmers should contrast this operation with that of hauling and spreading tons of manure on an acre, which are not worth a dollar a ton. Facts like these are full of significance. We have long contended, and religiously believe, that the cultivators of American soil perform more unnecessary work every year, to obtain their crops, than the aggregate labor of all other classes combined. This prodigious loss of national industry and capital can never be prevented until the laws of nature, that govern the fruitfulness of the earth and the rewards of farm-labor, *are studied, understood, and obeyed.* The unwillingness of the people, of State legislatures, and of Congress, to foster the study of good husbandry, is the greatest marvel of the age. *Why* the dung of sea-birds is worth forty dollars a ton, and that of horses only the *fortieth part of that sum*, is a problem in farm-economy which every school-boy, fifteen years of age, should be able to solve at once. According to the analysis of the recent dung of a sea-eagle, made by Coindet, it contains uric acid and ammonia equal to 45 per cent. of that valuable fertilizer; while a horse, eating rations composed of two-thirds timothy and one-third oats or corn, would void manure that had less than one per cent. of ammonia. In all the higher animals, most of the nitrogen in their food escapes by the kidneys and not by the bowels. One hundred pounds of the dissolved salts contained in the urine of a horse or other domestic animal, dry, would be worth many times that amount of their dung.* It is not the *water* nor the *carbon*, in the liquid excretions of a cow, that make them worth $10 a year, in Belgium, for the improvement of land.

* There is reason to believe that no inconsiderable part of the carbon which enters the roots of plants from the soil comes from the atmosphere, absorbed previously by the soil, partly from the air, and partly derived from the carbonic acid contained in rain-water as it falls upon the earth. The fact, however, should be distinctly stated, that decaying plants and mould yield carbon to all growing crops.

The quantity of phosphates of potash, lime, and magnesia, of ammonia, chlorine, and other earthy constituents of crops, available to the farmer in his soil, is usually quite small. If this were not so, how could the application of only two hundred pounds of these salts in guano, to a thousand tons of earth in an acre, add fourfold to its productiveness? Estimating the soil as available to the roots of corn, wheat, clover, and other crops, to the depth of ten inches only, and it weighs two million pounds per acre. If we divide this sum by one hundred, (an amount of guano that often produces a great increase in a crop of corn,) it gives only one part in twenty thousand. The essential elements of crops constitute so small a part of the earth in which they grow, that it is not altogether improbable the time may come, when they will be carefully extracted and stored up for safe-keeping in vessels hermetically sealed, or as involatile salts. A fertiliser that will produce three pounds of wheat or six of corn for one on poor land, is as worthy of a granary as the grain itself. Why not? When two hundred pounds of guano have produced nine hundred of wheat, can the wheat be so managed, after its consumption in bread, as to form two hundred pounds of manure equal in ammonia and phosphoric acid to the original guano? Probably not; but, taken as a whole, the nightsoil may be quite as valuable as the guano. Researches in the preparation of nightsoil, and its economical value, are greatly needed in this country. Our cities and villages increase so rapidly in population, and draw so constantly from the soil its most precious constituents of human food and clothing, that unless we adopt the principle of restoring as much potash, phosphorus, sulphur, chlorine, and ammonia, as we take

* It is because 100 pounds of oats extract a little more nitrogen and earthy salts from the soil than a like quantity of wheat, that renders the former the more exhausting crop, estimating the yield in tons.

from it in breadstuffs, vegetables, cotton, tobacco, and provisions, it must become, at no distant day, too sterile for profitable cultivation. It is not necessary to return to the soil as many pounds of matter as it yields in crops; but there are few so rich in potash, chlorine, sulphur, and phosphorus, as to render it safe farming to take more of these substances in plants of any kind, than is restored to the earth. Soils often contain not over one part of phosphorus, in an available condition, in five or ten thousand; and to extract this mineral (without which not the first blade of grass, seed of grain, boll of cotton, leaf of tobacco, or crop of any kind, can be formed) and not make adequate restitution, is the extreme of folly. Pure phosphorus is worth from four to five thousand dollars a ton. This fact indicates the scarcity of the article, even in the richest virgin earths; for, like potash, it all comes from the soil. Whoever will examine the analysis of the ash of cotton-seed, or leguminous plants, will see that phosphoric acid and potash are large and indispensable elements. Except in cotton-seed, the fertilisers in most seeds are habitually wasted, or sent abroad to market. This practice, of throwing away in cities the most valuable food of plants, and then partially making up the loss by purchasing imported manure at $40 a ton, is discreditable to our national good sense and agricultural skill. If our crops need the elements of bones, ammonia, and potash, why waste these things by the thousand tons in cities and villages? If one-fourth of the weight sent to market in human food and raiment were returned to the country and the soil, (being the least abundant elements in the plants extracted from the land,) it would maintain for ever, under a good system of farm-economy, the highest fruitfulness of the earth. And who will say that the same vessels, railways, canals, and wagons, which convey four thousand pounds of breadstuffs and provisions to near or distant markets, cannot take back to the fields whence these products were drawn, one thousand pounds of the raw material for making similar organic substances? The 75 per cent. to be left in cities is essentially the carbonic acid and vapor thrown out of human lungs in ceaseless respiration night and day, which carbon and vapor came from the nutrient atoms in the blood-vessels, and from the food taken daily into the system.

All fermentation and decay in vegetable and animal substances, in town and country, discharge carbon and the elements of water into the atmosphere,—mould being the *residuum* of such substances, and containing less than 25 per cent. of the original organized matter. It is on this account that a rich mould formed from clover is worth more, pound for pound, than the clover which rotted to produce it; for four hundred pounds of the dry plants will yield only one hundred of dry mould. In the same way, a ton of dry forest-leaves is reduced to five hundred pounds of rich mould, when properly rotted and dried. Hence, five hundred pounds of good mould will suffice to grow at least a ton of cultivated plants, if it be not wasted by a cultivator who refuses to study the soil which he ploughs and hoes.

One may separate one hundred and fifty pounds of carbon and the elements of water from a barrel of flour, and still leave, with its nitrogen and incombustible matter, four times more of carbon, oxygen, and hydrogen, in weight, than of the other ingredients in the flour. If guano contained 95 per cent. of its weight in charcoal and water, as wheat does, it would never be worth $4 a barrel as a fertilizer. In one hundred pounds of dry corn there are ninety-seven of carbon and the elements of water; and it is generally easier to grow forty bushels of this grain on an acre than twenty of wheat. Experience shows that the same food of cereals which will produce twenty bushels of wheat will yield forty of maize. The prominent fact that guano and the best nightsoil operate equally to promote the growth of *all* cultivated plants, indicates that *all* require ammonia and phosphates; which is true. It also indicates that the things contained in nightsoil, and in the dung of birds, or in the excrements of flesh and fish-eating animals, are not abundant in ordinary soils; which is also true. As it takes not far from five pounds of corn to form one of beef, we should not be surprised to find that nature is as true to vegetable as to animal life, and so enables a pound of beef to produce five of corn. The quantity of different kinds of vegetable food consumed to form a given weight of flesh is an interesting study. Three and a half pounds of cooked cornmeal have yielded one of pork; or three hundred and fifty pounds have produced one hundred of the flesh and fat of swine. Thrifty sheep give quite as large a return; cattle a little less. This whole subject needs further investigation. The circumstance that some animal perchance eats the beef in advance of corn-plants affects not the purpose of nature in the least.

The reader may infer from the remarks offered on "the philosophy of improving land," that we regard good economy in feeding plants, and in saving the most valuable raw materials for making them, as the direct road to such improvement. We assume that the soil has been properly drained and limed, if it needs either, and that it does not lack vegetable mould. In addition to what has been said about the elements of crops, and their scarcity in ordinary soils, we desire to call attention to a few of the best plants for enriching land, which draw from the *subsoil and atmosphere* the most valuable atoms consumed in making human food and clothing. Some plants, like mosses, flourish on naked rocks; others can subsist on sterile sands; while by far the larger part of the vegetable kingdom would have no existence, unless the surface of the earth possessed nearly the degree of productiveness now exhibited. Destroy this productiveness by tillage or other means, and, in time, you make a barren, naked desert. But, instead of impoverishing the earth, a sound public policy demands that we should increase its natural fruitfulness, to meet the increasing wants of an ever-augmenting population. To achieve this result in the most economical manner, recourse must be had to the agency of growing vegetation. Among the plants best adapted to the improvement of land are the grasses, trifolias, legumes, turnips, and other root crops. In skilful hands, these can be so managed as to produce a great deal of cheap manure to enrich the surface of the earth, while the substance of the manure itself will be mainly drawn from the subsoil and the atmosphere. Peas have proved the best crop in the Southern States for the renovation of partially exhausted fields; but we are inclined to believe that a legume called *sainfoin*, *sanctum fœnum*, or "holy hay," which has long been cultivated in the South of Europe, and is remarkable for the length of its roots and the depth to which they descend into the earth, will be found, on a fair trial, a more valuable plant. The roots of the pea-plant do not descend so far as those of clover and lucerne, and, on that account, do not draw so much of the mineral food of crops from the deep resources of the earth as is desirable. In an interesting chapter on "St. Foin," Jethro Tull remarks:—

"The reason why St. Foin, *in poor ground*, will make forty times greater increase than the natural turf, is the prodigious length of its perpendicular tap-root. I have been informed, by a person of undoubted credit, that he has broken off one of these roots in a pit, and measured the part broken off, and found it fourteen feet. This tap-root has a multitude of very long horizontal roots at the upper part thereof, which fill all the upper stratum or staple of the ground; and of the thousands of St. Foin roots I have seen broken up, I never found one that was without horizontal roots near the surface, after one summer's growth."

In a note, the same author has these remarks:—

"There is a vulgar opinion that St. Foin will not succeed in any land where there is not an understratum of stone or chalk to *stop the roots from running deep:* else, they say, the plants spread themselves in the roots only, and cannot thrive in those parts of them which are above ground. I am almost ashamed to give an answer to this."

"It is certain that every plant is nourished by its roots as an animal is by its guts; and the more and larger roots it has, the more nourishment it receives, and prospers in proportion to it. St. Foin always succeeds where its roots run deep; and when it does not succeed, it never lives to have long roots," &c.

There is strong sense and plain Saxon in what this English farmer writes, who was about a century ahead of his time in agricultural improvement.

He says:—"Any dry ground may be made to produce this noble plant, be it ever so poor; but the richest soil will yield the most of it, and the best. If you venture to plant with the drill, according to the method wherein I have always had the best success, let the land be well prepared before you plant it." Tull was careful not to cover the seed over a half inch in depth, and not to have it thick in the drill, particularly on poor land. In France, with decent culture, two or three good crops of this "holy hay" are made in a year. In favor of thin seeding and the resources of the subsoil, Tull has the following remarks:—

"It is common to see a single St. Foin have a bigger tap-root than twenty thick ones, (thickly planted,) and their length is in proportion to their bigness; therefore, that single plant may well be supposed to have twenty times more depth of earth to supply it than all those twenty small roots can reach to. And though these under-strata are not so rich as the upper, yet, never having been drained by any vegetable, *they do afford a considerable quantity of nourishment to those which first enter them.*"

The above was written a hundred and thirty years ago, and before subsoiling and the analysis of soils were known. Science and experience have alike demonstrated the fact that the "under-strata" of an impoverished soil are richer than the earth or stratum at the surface. The following practical suggestions are worthy of attention:—

"Notwithstanding I commend the planting of St. Foin thin, that most of the roots may be single, yet I have fields that were drilled with but four gallons of seed to an acre, and yet, the rows being seven inches asunder, the roots are so thick in them that the ground is covered with the plants, which seem to be as thick (in appearance) as most sown St. Foin whereon seven or eight bushels are sown on an acre. I have other

fields that were drilled with about two gallons of seed to an acre, (which is five seeds to each square foot,) the rows sixteen inches asunder, *that produce better crops though the ground be poorer.* The drilled St. Foin, being regular, is more single, though as thick as the sown, and for that reason always makes a better crop, and lasts longer than the sown that is of the same thickness, but irregular." Again, he says: "I have now a great many single St. Foin plants in my fields that are near *thirty years of age*, and yet seem as young and vigorous as ever; and yet it is common for thick St. Foin to wear out in nine or ten years, and in poor lands much sooner, if not often manured with soot, peat-ash, or coal-ash."

Wood-ashes and lime would doubtless be the best fertilizers in most districts of the United States. We invite particular attention to the age or long life of this legume, or "holy hay." It reminds us of the "Tree of Heaven," (China tree,) whose multitudinous roots spread all over a small neighborhood, and whose leaves are devoured so greedily by cattle.

Tull learned to cultivate St. Foin in Languedoc, where he spent several years, and was able in England to cut his earliest crop in the beginning of May, before blossoming. He divides the crops into four sorts, viz: "1st, the virgin; 2d, the blossomed; 3d, the full grown; 4th, the thrashed hay." Although the following remarks are a little too ethereal, in the main they are true: "The first of these (virgin hay) is best of all beyond comparison; and, except lucerne, has not in the world its equal. This must be cut before the blossoms appear; for when it stands until full bloom, the most spirituous, volatile, and nourishing part of its juices is spent on the next generation; and this being done, all at once the sap is much depauperated, and the St. Foin can never recover that richness it had in its virgin state. And though in blossom, it be literally in the flower of its age, it is really in the declension of it. If it be said that what is not in the stalk has gone into the flower, it is a mistake, because the greatest part of its quintessence perspires thence into the atmosphere." The aroma, or "quintessence" of "holy hay" in blossom, is doubtless something very nice, but subsequent experience in hay-making and vegetable physiology does not sustain the practice of cutting forage plants before they blossom, to improve the food or crop. Our author says: "The owner of this hay, if he be wise, will not sell it at any common price, but endeavor to have some of it every year, if possible, for his own use." A full crop of this hay cut when in blossom, is three tons per acre. In stacking St. Foin, Tull recommends pulling up a basket in the centre of the stack, as the rick is made, to form a "vent-hole" for air to circulate through and carry off dampness. *Sainfoin* seed is cheap and abundant in France; and we should be happy to see the cultivation of this perennial, deep-rooted legume fairly tested in the Central and Southern States, where we believe it would be valuable. Its seed is worth more per bushel than oats, and is hardly inferior to peas as food for domestic animals.

Lucerne, the *herba medica* of the Romans, has maintained a high reputation in the South of Europe for twenty-five centuries. It has been successfully cultivated in Chili, Peru, and Brazil, and from the last-named country introduced into this, under the name of Brazilian clover.

If the Chilian clover-seed ordered from Valparaiso should turn out to be a variety of the *medicago sativa*, or sainfoin, we shall not be disappointed. Mr. Loudon, in his Encyclopedia of Gardening, says: "Lucerne is highly extolled by Roman writers; it is also of great antiquity in Spain, Italy, and the South of France; is much grown in Persia and Peru, and mown in both countries *all the year round.*"

We have traced the roots of this plant growing in the light, sandy soil of Georgia to the depth of 34 inches; and, like sainfoin, peas, and red clover, it draws largely on the atmosphere for its organic nourishment.

With a directness from the "well of English undefiled" which we cannot but admire, Tull speaks of its "tap-root that penetrates deeper into the *bowels* of the earth than any other vegetable she produces." He describes a plant on his farm twenty-two years old; and still in its youth. He says: "Its roots are abundantly longer than the roots of St. Foin; I have one that measures very near two inches in diameter; those which are higher than the ground have a bark like a tree. Upon this account, and by its stalks springing again just below the place where cut off, and by the woody hardness of its stalks when they stand too long without cutting, it seems that lucerne is of a nature nearly approaching to that of a shrub. It is the only hay in the world that can pretend to excel or equal St. Foin." This "medica" and classical hay, which was cultivated in beds by the Romans without iron-plough, hoe, or rake, is too well known to need any encomiums. It does best in a deep, permeable soil; and where the subsoil is compact, it must be broken, either by trenching or the use of the subsoil plough. Like St. Foin, it is best cultivated in drills, which should be far enough apart for a horse to walk between the rows to draw a hoe or cultivator.

If these plants shall prove as popular in this country as in Europe, it will be a very profitable business to raise their seeds for sale. After the farmers began to sow clover-seed in the Northern States for the purpose of renovating wheat lands, the production of this seed was for many years the most profitable branch of agriculture known in that region. At present, clover-seed is too cheap for the business to be very remunerative. We do not believe that lucerne or St. Foin is likely to take the place of clover in any district where the latter does well; but they are worthy of trial on "clover-sick" fields.

The pines that grow spontaneously on the impoverished and abandoned fields in the Southern Atlantic States, present a very instructive lesson to all that seek to understand nature's process for restoring fertility to the surface of the earth. Nature hauls no lime, nor marl, nor manure of any kind. She never ploughs, nor hoes, nor stirs the soil at all; yet she forms a black mould where man had robbed the ground of this necessary aid to the support of the higher orders of plants and animals. To study closely her operations in the process of enriching soils, is the highest wisdom of the practical husbandman. The seeds of pine-trees have a structure that peculiarly fits them to be carried a great distance by birds and winds, and scattered far and wide over the whole surface of the earth. Under favorable circumstances, these seeds germinate and grow into forests. We have studied only the sprouting and growth of the seed of the long-leaf pine on the poor sandy lands of Georgia. By the time its first two leaves have attained a length of 3 inches, its tap-root has descended 6 into the ground, and continues to penetrate into the earth, when unobstructed, any distance from 3 to 9 feet, and how much farther we know not.

Pines are endowed with a large quantity of foliage, and their leaves annually fall, to decay and form new mould. In 1000 parts of these leaves, when thoroughly dried, we found 40 of incombustible earthy matter; while the same amount of pine wood gave only 2½ parts of ash. If the trunks of pine-trees consumed as much of earthy minerals as their leaves do, these trees would always be very small, and could grow only on land rich in potash and the other elements found in wood-ashes. But while the exceedingly deep roots of this tree find the mineral constituents of vegetation far below the pasture of common plants, and the reach of the farmer's subsoil plough, these minerals, instead of being deposited in the substance of lengthened roots, in the trunk and branches of the tree, are nearly all contained in its innumerable and peculiarly long leaves, and with them, in the economy of Infinite Wisdom, go to enrich the surface soil, that it may again become fruitful in bread-bearing plants. No soil, naturally poor in potash, can grow a dense forest of oak, hickory, walnut, maple, beech, and elm trees; for all these store up potash in their trunks, limbs, and roots, to a large degree. But 100 parts of their leaves, which annually fall to the earth, contain from 7 to 15 times more of incombustible matter than a like weight of their wood. The bark of these forest-trees, and of all others so far as known, yields much more ashes than wood. In the tree called hemlock, this fact is strikingly illustrated; for, while its wood yields very little ash, its bark abounds in incombustible matter. This bark, like that on one variety of hickory, is cast off, and falls to the earth to rot, and feed vegetation. Professor Emmons has investigated this subject of the distribution of the minerals in forest-trees, in their heart and sap-wood, bark, &c. in a very satisfactory manner, and published the results in his "Agriculture of New York." Forest culture can be made more profitable in the United States than is generally supposed. There is very little land that will not grow the equivalent of a cord of good pine-wood a year, and much that will produce a cord and a half in twelve months. In connection with the improvement of soils, the cultivation of good timber can be prosecuted at a round profit. We are collecting facts on this too much neglected branch of rural economy, and hope to be able to furnish some useful information on the subject in our next Report. A forest cannot be grown in a day; and before seeds planted in 1850 can yield much valuable timber, the United States will contain fifty millions of inhabitants.

The overflow of rivers and smaller streams and artificial irrigation should not be entirely unnoticed in this review of the principal means employed by nature and man to impart fertility to cultivated soils. River bottoms like those of the Nile, Euphrates, and Ganges, which are annually inundated, were, doubtless, first cultivated in wheat, rice, and other cereals. Under the most favorable conditions, such bottoms or flats required neither tillage nor manure of any kind to yield an annual crop of grain. Pliny remarks: "How easy is the husbandry of Egypt; for there the Nile, serving the turn of a good husbandman, begins to swell and overflow at the first new moon after the summer solstice. He begins fair and gently, and so increases gradually, as long as the sun is in the sign of Leo, and rises to his full height. On entering into the sign of Virgo, his fury slackens, and then slowly decreases until he regains his wonted channel.

"It is always observed that, if he rises not above twelve cubits high, the people are sure to have that year a scarcity; and they make their account for the same if he exceeds sixteen cubits, for the higher he rises the longer he is before he is fallen to his level; by which the seedtime is past, and men cannot sow the ground in due season. It is generally understood that upon the subsidence of the deluge, they cast seed upon the flooded land, *and turn in their swine to trample it into the soil when moist.*"

Cereals are grown by the above operation without the aid of plough, hoe, or harrow. The water stood long enough over the bottoms to kill all ordinary weeds and grass; and the seed-wheat, trampled in by droves of hogs, had the advantage of all other plants. It is difficult to imagine a more primitive system of grain culture. But droves of swine could not always be at hand to tread in seed at the time when their services were indispensable. Some land would become too dry before the grain was covered, and the feet of hogs or cattle would fail to bury it in the earth. In this dilemma, the ancient Egyptian "*sarcle*," as the Romans called it, was invented for digging up the ground. This implement, from drawings and inscriptions, appears to have been something between a modern hoe and a pick-axe. A slight change in its structure converted it into a rude plough, which was first drawn by men and women. The subduing of cattle to field labor, hauling the plough by their horns or by their tails, was altogether an afterthought. Pliny remarks:—"In Lower Egypt, the straw is never a cubit long; the reason being that the seed lies *very dry*, having no other nourishment than the mud of the river; and there is nothing underneath but sand and gravel. But in Upper Egypt, about Thebes, they are far better farmers, and have better harvests; that part being, as indeed most of Egypt is, *low* and *flat*." He goes on to say:—"The same husbandry is practised in Babylonia and Seleucia, where the Euphrates and Tigris overflow their banks in like manner, but to better effect and greater profit, owing to their more general use of sluices and floodgates. In Syria, they have small, light ploughs on purpose for making these shallow furrows and stiches; whereas *with us in Italy*, in most places, eight oxen, at least, are required for one plough; and, indeed, to make speed with it, they must work till they blow and pant again."*

The breaking of American prairie of the West with eight oxen, panting and blowing, would, even now, look quite familiar to an old Roman, could he witness the operation. The early history of agriculture, and the kind of tillage that prevailed in Egypt when its husbandmen fed abundantly, through successive years of famine in surrounding nations, the population of such immense cities as Thebes, claimed a passing notice. It is a curious fact, that the comparatively independent wheat-growers of the inundated bottoms of the Nile, Euphrates, and Tigris cherished a sovereign contempt for the people who depended mostly on their herds and flocks for the means of subsistence. Joseph warned his brothers that, when they came before Pharaoh, they should say: "Thy servants' trade hath been in cattle, both we and also our fathers, that you may dwell in the land of Goshen; *for every shepherd was an abomination to the Egyptians.*" The rearing of "cattle" was more reputable than sheep husbandry; but corn culture was the glory of kings before the time of Abraham.

The science of agriculture and the true principles of tillage are no better understood now, by the mass of mankind, than they were five thousand years ago. Thirty years of unremitting labor to establish agricultural

* Pliny Hist. b. 18.

schools in the great State of New York have signally failed, from the lack of popular sympathy and countenance. Without the aid of chemical research, Jethro Tull, a century and a half ago, came as near to a correct knowledge of the use and value of mellowing frequently, and deeply stirring the soil, as one can. With all his genius, talents, and large experience, he fell inevitably into a false theory about "the pasture of plants," and "tillage being a perfect substitute for manure." No man in modern times has had a clearer or juster conception than Tull of the mechanical results which follow the deep and thorough "pulveration of the soil." Of the chemical effects of tillage, he knew next to nothing; and it was his lack of knowledge, as revealed by modern science, that led him into error.

"By tillage," says this distinguished writer, "we can enlarge our field of subterranean pasture without limitation, though the external surface of it be confined within narrow bounds. Tillage may extend the earth's internal superficies in proportion to the division of its parts; and as division is infinite, so may the superficies be. Every time the earth is broken by any sort of tillage or division, there must arise some new superficies of broken parts which were never broken before; for when the parts of earth are united and incorporated together, it is morally impossible that they or any of them should be broken again *only in the same places.*"

The above reasoning on mere mechanical principles is unquestionably sound; but when an indispensable ingredient for making a plant is absent from the soil, and not supplied by art nor by the atmosphere, how can any degree of stirring or pulverizing the earth create the lacking element? Can any human art or use of implements form a new atom by tillage? When all the available potash within reach of the plough is consumed, what then? While it is apparent that something more than tillage may be necessary, the father of drill husbandry to the contrary notwithstanding, it is proper to remark that but few farmers have brought their practice up to the full appreciation of the benefits of frequently stirring the earth, and mellowing it, to the depth of ten, fifteen, or twenty inches. The object of the agriculturist is to make the most of all the elements of crops which his soil contains. The raw materials of bread and meat at and near the earth's surface are the gift of Providence; and it is not less the duty than the interest of the husbandman to *husband* them with great care and wisdom. To break the undercrust, or subsoil, so that water, air, and warmth may freely descend and ascend about the roots of plants, and thus supply them at all times with their appropriate aliment, and enable them to grow in all directions, is the crowning glory of modern agriculture. In many places underdraining is also necessary. This is particularly the case where a field lies in a basin, having higher land near it, whose water-shed carries a part of that which falls in rains into the ground below and at a distance. In most of the States, if not in all, where a soil contains no more water than what falls upon it, underdraining is rarely necessary. But the unevenness of the surface, and the variable direction of many geological strata, operate to convey the water which falls on one acre or field into the earth of another acre or field. This of course gives an excess in certain localities, to be disposed of only by drains or open ditches. The growth of grasses and rushes peculiar to wet places will indicate where draining is required to sweeten the soil. Viewed as a mere mechanical operation, the farmer must see to it that his tilled ground is neither too open nor too compact; that its depth and friability are maintained by the due admixture of sand, clay, and vegetable mould, aided by draining where necessary. Sandy, porous soils are improved by the use of a heavy roller and the treading of sheep, hogs, and young cattle, which should be fed on fields of this kind. There are usually more fine particles of earthy matter from eight to twelve inches below the surface than at it, which, being brought up by the plough, mingled with the surface sand, and rolled after seeding, will much improve the texture of the soil. Old fields are more apt to become compact, heavy, and lifeless, than too open and pervious to air and water. How to renovate and rejuvenate an exhausted clay soil will be better understood after we have studied the next chapter.

CHAPTER VI.

CHEMICAL EFFECTS OF TILLAGE.

We have seen in the preceding chapters that the minute subdivision of the soil operates to condense atmospheric air and other gases within its pores. It enables water to descend and ascend with great freedom through the mass of tilled earth. We have now to consider the chemical effects which follow from the breaking and stirring of the ground. To render our explanations clear and satisfactory to plain, unscientific farmers, it is proper to give the meaning of several words unavoidably used in discussing this subject.

That important hidden changes do take place in the soil, in consequence of good tillage, not to be explained by any mere mechanical theory, few intelligent men will deny. What are these occult changes in the earthy matter operated on by the implements of husbandry? At what point shall we begin to study them?

1. All matter is supposed to be endowed by its Creator with certain *forces* tending to form compound bodies, which forces exist sometimes in an *active*, and at others in a *quiescent*, state.

To illustrate: if the two gases called *chlorine* and *hydrogen* be mixed in the dark, no combination takes place; but if brought into the light, under the direct rays of the sun, the slumbering forces in these two bodies are excited into action, and a chemical union occurs with an explosion. An intense acid is formed, called hydrochloric or muriatic acid, which differs widely from both of its elements.

2. Different substances are endowed with *peculiar* forces, the intensity and other peculiarities of which can only be learned by observation and careful experiment.

Thus, the metals called iron, nickel, and cobalt, alone possess the force denominated magnetism—other metals have no magnetic power. A knowledgo of the *forces* inherent in the elements of cultivated plants is invaluable to the husbandman; for he deals constantly with these elements, and labors to change them—now into manure and available food of plants, and now into grain, grass, milk, and meat, as food for man and his domestic animals. The chemist finds five pounds of pure sulphur in 100 pounds of wool. This well-known mineral can only come from the food of the animal and from the soil. We now bring the wool-grower directly to this point: Does your soil contain, in an available condition, sulphur enough to produce luxuriant crops of such plants as are best adapted by nature to keep sheep in good health? If not, then no amount of tillage, none of the chemical changes resulting from it, can give you good crops of clover, turnips, or cabbages. Why are 100 pounds of cabbage, exclusive of water, when perfectly sound, worth more as feed for sheep or cows, than a like weight of rye straw? That land too poor to yield a generous crop of cabbage will produce a fair one of rye or buckwheat, is known to most farmers. Although sulphur is not the only substance that exists far more abundantly in cabbage than in the other plants named, yet it is an element that seldom abounds in well-drained soils. Tillage can do much to promote fertility; but it cannot create something from nothing, nor change one elementary body into another. But tillage is usually more efficient to impoverish an arated field than to improve it; and it is this deteriorating effect of cultivation, irrespective of all crops, to which we desire to call particular attention. The chemical changes in the soil, produced by ploughing, are quite independent of the presence of plants. Tillage dissolves more silica, potash, soda, lime, magnesia, chlorine, iron, mould, sulphuric and phosphoric acids, than would be dissolved without this operation. If this were not so, the farmer would have as little occasion to plough, harrow, and hoe, as nature has when forming her most abundant products of the earth. After tillago has dissolved the elements of crops, they do not remain long in well-drained land, if no plants are present to imbibe the water that holds them in solution. Wherever the water runs, most of the organic and inorganic constituents of vegetables go with it, after they are fairly dissolved, like common salt in water. There are, however, several modifying chemical and physical properties in good soils, by which, when irrigated with water holding saline minerals in solution, a part of these fertilizers is retained. Thus, if the sulphate or muriate of ammonia in a weak solution be passed through a clay soil, the salt is decomposed, the ammonia is retained by the alumina, and the chlorine or muriatic acid, or sulphuric, as the case may be, will pass through as the chloride or sulphate of lime. Professor Way has published some interesting experiments on this subject, in a late number of the Journal of the Royal Agricultural Society of England. The effects of irrigation, both natural and artificial, and of tillage, on the chemical constitution of the soil, demand further research. A good deal more water will evaporate from an acre of land, than falls upon it in the course of a year. Hence a good supply of moisture in the subsoil, to rise by capillary attraction about the roots of needy crops in dry weather, to keep good the fluids circulating in plants when evaporation at their leaves is most active and profuse, is a matter of the highest importance. As a general rule, less water will ascend from the subsoil to the surface than descends into the earth—a part going to feed wells and springs or underground rivulets. What portion of the water that annually falls in rain and snow runs off into creeks, rivers, and swamps, on the surface; what portion sinks directly into the ground; and of this, what part rises again and is evaporated from the leaves of plants or from the naked earth, we are not informed; nor are there data sufficient, at present, to warrant an extended generalization on the subject. The common practice in England of placing numerous drains in the earth, at from 30 to 50 inches below the surface, and measuring the fall of water on a given area, and the quantity that percolates through soils of different texture into these covered conduits, has furnished nearly all the information we possess on the points under consideration. From one-tenth to a sixth of all the water that falls on a level or nearly level surface in the course of a year, will find its way into well-constructed drains in the climate of England; but a very humid atmosphere, with a low mean temperature, is ill adapted to the rapid evaporation of water from the foliage of plants and the surface of the ground. According to observations made by Charles Charnock, Esq., through a series of five years, and published in the Journal of the Royal Agricultural Society of England, for 1849, a soil which evaporated 33.61 inches of water in 12 months, had this quantity reduced to 22.48 inches when kept in the shade. This fact shows that shade and sunshine, as well as humidity and dryness, heat and cold, exert a powerful influence on the ascent and descent of water through the soil. In England, it is found, by experiment, that a quarter more water will evaporate from the surface of an acre than falls upon it, if artificially irrigated. Anxious that investigations of this kind should be prosecuted in this country, we will give a few of the results of researches and observations made by Mr. Charnock:—

In 1842, the fall of rain was 26.11 inches; the evaporation, in the sun, 30.02. In 1843, the fall of rain was 24.49; the evaporation, 31.19. In 1844, the evaporation was 37.85; while the fall of rain was only 19 inches. The evaporation was from a soil kept saturated by the frequent application of water in measured quantities. The quantity that fell was determined by a rain-gauge in the usual way. In 1845, the fall of rain was 28.18; the evaporation 31.09. In 1846, the fall was 24.24 inches; the evaporation, 23.28. The mean evaporation in the five years named was 32.686 inches; the fall, 24.402. The quantity of water that will percolate through a soil or common earth to the depth of three feet, depends so much on the physical properties and condition of the mass in each instance, that a large number of experiments on various soils can alone settle the question. The quantity of water that filtered through three feet of earth was, in 1842, 4.55 inches; in 1843, 4.28; in 1844, 3.60; in 1845, 4.92; in 1846, 6.76. These results were obtained by means of a leaden vessel three feet deep and one foot square, into which were put two feet of gravel and calcareous sand, so as to represent the substratum of the farm, and the remainder was filled up to an inch of the top with an average quantity of soil. At the bottom a pipe was inserted, which conveyed all the water that filtered through into a bottle, which was regularly emptied and registered. The leaden vessel was inserted into the ground to within an inch of the surface, keeping the level of the soil inside and outside alike, with an inch of the vessel above, to prevent any communication of water from without. The soil was kept free from weeds, and occasionally stirred, that it might not be more than ordinarily compact.

To determine the evaporation from saturated soil, a leaden vessel thirteen inches deep and a foot square was filled within an inch of the top with soil, and placed in the ground in the same manner as the previous vessel, with a pipe level with the surface of the soil to carry off the excess of top-water into a receiver. This soil was also stirred occasionally, to correspond with the tilled land which is wet and undrained. It will be seen that more water than falls upon a field must come into it, either by springs from below or by running over the surface, by filtering through the earth from the dip of its strata or the unevenness of the ground, to

supply as much as will evaporate. If heavy showers did not fall suddenly, it would be rare for the surface-soil to contain any considerable excess of moisture on common land. We have already stated that the earth on an acre weighs 2000 tons by going to the depth of twenty inches. This will hold from four to six inches of water without inconvenience, if equally distributed. An acre of water an inch deep is not far from 25,000 gallons, so that where forty inches fall in a year a million gallons are received on each acre. How to make the most of this water, whatever the precise quantity, and prevent all damage from washing and undue leaching, is a study that commends itself to the attention of every farmer.

We have known wheat sown the first of December to be harvested by the 20th of May, in Georgia; while in Maine, wheat sown the first of September is rarely ready for the cradle before the first of August. Why should five months and twenty days suffice to grow a crop of wheat—and they include all the cold of winter—in the State of Georgia, while eleven months are necessary in the State of Maine? We draw the following inferences from the facts named:

1. That as great *chemical changes* take place in the soil of the Southern State in six months as occur in the soil of the Northern State in eleven months. These changes consist essentially in decomposing both organic and inorganic substances which were before insoluble in rain-water, so far as is necessary to render them soluble and in a condition to enter the roots of plants.

2. That air, heat, rain-water, and probably electricity, are the prime agents in effecting the necessary chemical changes in the surface of the earth which supply, day by day, aliment to all vegetation.

3. As much water enters the roots and passes out of the leaves of wheat-plants in six months in Georgia as in eleven months in Maine. From the increased activity of all chemical, physical, and vegetable phenomena at the South, the intelligent reader will see why a defective system of tillage and husbandry there should impoverish the land faster than at the North. But the same agencies which rapidly exhaust the elements of crops when misdirected, will recuperate with equal facility and regain the lost fertility in the warmer climate. To ascertain the changes that transpire in cultivated and uncultivated soils in the course of three, six, nine, and twelve months in different latitudes, and under various circumstances, is not so formidable an undertaking as some may suppose. By leaching a cubic foot of rich earth six months with rain-water as it falls from the clouds, one may grow wheat, corn, or other plants in pounded glass with the fertilizers so extracted; and by applying a known quantity to the crop, and weighing it when matured and thoroughly dried, we can determine the relative weight of the plants organized, and of the food given to them. Thus, if a corn-plant weighs when dry eight drachms, and has received only one drachm of dissolved organic and inorganic matter extracted from a rich soil, it is plain that ground glass, heated to burn out all vegetable substances, and washed in hydrochloric acid, still further to purify it, could not yield the other seven drachms of weight in the corn. It must have drawn 87½ per cent. of its solids, which are carbon and the elements of water, from the atmosphere and water. There are other ways in which the writer has been able to demonstrate the important fact, that, in forming one hundred pounds of organized matter in cultivated plants, the soil

parts with less than fifteen pounds, and often less than ten, of its solids. Sand that has been burnt at a red heat for some time, and boiled in a strong mineral acid, will grow crops by feeding the plants on such of their constituents as good soils or the best manure furnish. In truth, the substance of the earth which does not dissolve when a crop is growing has no more to do in adding to its weight than ground glass has, or than cotton has, when plants are grown by extending their roots into its moist fibres. It is a knowledge of this fact which has led to the extensive culture of mere drifting or desert sands, with the aid of ashes and guano. The more we learn of the raw material of crops, as it exists in the soil, the less important is it that the surface of the earth abound in such raw material as is supplied by nature.* Science corrects these defects with constantly increasing facility. Bone-earth, or phosphate of lime, is a mineral less abundant in most soils than is desirable; but chemistry has demonstrated that all cities abound in phosphates of lime, potash, and magnesia, and in ammonia, which are derived from the breadstuffs and provisions consumed by their inhabitants, and the oats, hay, and other food of horses and cows kept within their limits. That fertilizers of this kind are generally allowed to run to waste, not only in cities, but in villages, and even on many farms, is a fact known to every agriculturist. There are, however, extensive natural beds of *apatite* (phosphate of lime) being discovered by the researches of geologists and chemists, which promise greater usefulness to agriculture than any deposites of gypsum known. Professor Emmons, of Albany, has recently presented specimens of this mineral from an extensive bed near Crown Point, New York, to the State Society, which is noticed in the December number, 1850, of the journal of said society. Dr. Buckland, Dean of Westminster, has an instructive paper on the "Causes of the presence of phosphates in the strata of the earth," in the tenth volume of the Journal of the Royal Agricultural Society, from which we will copy a few sentences:—

"Professor Liebig five or six years ago invited the attention of agriculturists to the possibility of applying to the same use as bone-dust and guano the fossil bones and coprolites† which occur together in certain beds of the lias formation. This invitation took place not many months after I had the honor of conducting him to the well-known *bone-bed* in the lower region of the lias at the Aust Passage Cliffs, on the left bank of the Severn, near Bristol, where two beds of lias (each from one to two feet thick) are densely loaded with dislocated bones and teeth and scales of extinct reptiles and fishes, interspersed abundantly with coprolites, derived from animals of many kinds, which seem to have converted that region into the *cloaca maxima* of ancient Gloucestershire at the time of the commencement of the formation of the lias. * * * In 1846, Professor Henslow laid a paper before the British Association, at Cambridge, on the abundant occurrence of the ear-bones of whales in the crag-beds of Felixstow, on the coast of Suffolk, together with large quantities of rolled pebbles of phosphate of lime, (which he then supposed to be coprolites,) among the miscellaneous gravel and shells that compose the bulk of the crag formation. About this time, also, Professor Solly's analysis of these supposed coprolites proved their chemical composition to be nearly identical with that of real coprolites from the lias; and the attention of agriculturists was invited to their use, as a manure of nearly equal value with guano or bone-dust. Mr. Solly's advice to agriculturists, to make use of this newly-discovered storehouse of fertility, has been duly responded to; and *many thousand tons* of these pebbles and bones have been collected from the shore near Felixstow, ground, and used as a manure."

* The idea advanced in the text is, that science and art are able to remedy natural defects in soils with ever-increasing economy as the positive wants of cultivated plants are more closely studied and better understood. In this way, knowledge is better than money or rich lands, for it is a perennial source of wealth, enjoyment and independence.

† "Coprolites" are fossil or petrified dung of sea-animals, amphibials, and birds, found in fossiliferous rocks.

When it is known that these fossil-bones of whales are many feet above the ocean, and that not an inhabitant of the tertiary sea in which they flourished is now found, we are constrained to acknowledge that science has taught farmers how to form bread and meat from the remains of animals that lived and died before the island of Great Britain had an existence. From the Hudson to the Rio Grande, the Atlantic and Gulf States contain many tertiary strata, having fertilizers of great value. French burr, greensand, chalk, and other valuable deposites, exist in Georgia.

Doctor Buckland thus graphically indicates the way in which fertile earths were formed, long before there was "a man to till the ground:"—

"I believe the essential condition was the admixture (in a fluid or semi-fluid state) of all the now consolidated ingredients of the marlstone and of the septaria, (which we use to make our Roman cement,) viz. of clay, *carbonate of lime*, and *protoxide of iron*, in a state of mud on the sea-bottom at the time of the disengagement of phosphoric compounds from the dung and putrefying bodies of fishes and of molluscous animals and marine worms at the bottom of the seas in which the deposition of the London clay was going on. These conditions that attended the deposition of the London clay were similar to those attending the deposites of sedimentary mud (subsequently converted to beds of clay and marl) in all geological formations since the waters were first peopled with swimming creatures of ten thousand kinds, with creeping things innumerable, both small and great beasts.

"From the first creation of fishes, to fill and multiply in the waters, there must have been a never-ceasing deposition of phosphoric compounds in every bed of mud that was in progress of accumulation at the bottom of all inhabited portions of seas, and lakes, and rivers; and thus the fecal dejections of all subaqueous animated nature must, by their decomposition, have supplied daily and hourly accessions of matter convertible to *phosphorite*. There must have been, also, a further never-ceasing supply of phosphates from the decay of the bodies of all these animals after their death—i. e. from the dead bodies of all fishes, and mollucss, and sea-worms that were not devoured by other animals."

The above reasoning will account as well for all the other elements of living beings necessary to fertility in sedimentary rocks having sand, clay, lime, and iron for their mass, as for phosphorus. This learned geologist and divine, who has done so much to popularize the great truths of science, remarks that, "where the bottom of the sea was covered only with silicious sand, no phosphoric combinations could take place; and hence the barrenness of the great silicious sandy deserts of the world; but where the bottom of the water contained, in an unconsolidated state, the ingredients of future marl, or marlstones, or septaria, conditions were present favorable to the formation of the new combinations of phosphorite."

Before tillage is applied to the soil, a large share of its phosphoric acid is combined with alumina and iron, and a large portion of its potash, soda, lime, and magnesia with silicic acid. In these forms, silicic acid, the alkalies, and phosphoric acid are insoluble, and unavailable as food for cultivated plants. Tillage brings oxygen gas, condensed in the pores or innumerable spaces in well-cultivated land, into a condition to act on the sulphur in iron pyrites and form sulphuric acid. This acid, as well as carbonic acid evolved by the rotting of vegetables turned under by the plough, attack the insoluble silicates of potash, soda, lime, and magnesia, and liberate their alkaline bases. So long as potash and soda exist to combine with nitric acid in a soil which abounds in decaying vegetation, or where stable-manure is applied to it, such acid is formed by the chemical union of oxygen and nitrogen, and it immediately combines with potash to form saltpetre, or with soda, to form nitrate of soda. Hence, so long as the mineral food of crops exists, *even in an insoluble form*, tillage and organic manures will operate to extract it, although latent in sand as hard as pulverized glass. Artificial nitre-beds consist essentially of a mixture of wood-ashes and manure.

The ashes furnish the necessary alkali, and the manure, in decomposing, starts the formation of nitric acid, which is continued at the expense of nitrogen in the air for an indefinite time, if potash be present to take up the acid as it is formed. This acid, as has already been stated, consists of fourteen parts of nitrogen chemically united with forty of oxygen. Phosphoric, sulphuric, nitric, hydrochloric, silicic, and carbonic acids, as well as the bases—alumina, iron, lime, potash, soda, magnesia, and ammonia—are all brought into active play through the agency of the plough, harrow, cultivator, and hoe. If we compare the aggregate weight of the earthy constituents of crops removed from the soil by tillage, pasturage, and mowing, with the weight of such ingredients restored to it, we shall find that the surface of our farms is constantly losing its alkalies, phosphorus, sulphur, chlorine, and soluble silica. If we obtain larger crops than formerly, by deeper and better cultivation, what is gained in crops is lost in their elements consumed in making them. The bone-earth, potash, and magnesia in the subsoil, are as certain to be extracted in time, as the loss of similar elements taken from the surface-soil in previous crops. The quantity can only be augmented by adding to the land such minerals as have been removed in water passing over or through the soil, in the stomachs of domestic animals, and in the several crops taken from the field. We dwell on this point, because, of the hundreds of communications sent to the Patent Office, estimating the cost of growing grain, cotton, roots, tobacco, hay, and other crops, no one has taken into the account the value of the raw material in the soil which is consumed to form the products of human industry.* It would be quite as sensible

* There are some soils so well stored with the earthy elements of crops, that we do not wonder that their value, in a commercial point of view, should be entirely overlooked. In a valuable communication, sent too late for insertion in this Report, Mr. Joseph Sibley, of West Rush, Monroe county, N. Y., (in the Genesee Valley,) says:—"I know lands that have been constantly worked for more than thirty years, which were thought at first to be too poor without receiving any manure, that now produce more than double the growth of any kind of crop that they would during the first five or ten years of their cultivation." He adds a fact or two, which deserve particular attention:—"Our soils are highly impregnated with lime,

to overlook the value of the coal, the ore, and the lime consumed in making iron, as to neglect the potash, ammonia, lime, magnesia, chlorine, phosphorus, sulphur, and mould, consumed in making a crop of wheat, corn, tobacco, cotton, potatoes, or hay. The best manure is only valuable because it consists of these substances. Strike out of a fertilizer every thing but water and carbonic acid, and it will be worthless to enrich a sterile soil. The salts in the ocean, of which Peruvian guano is the best representation, should be obtained and employed to add threefold to the productiveness of cultivated land. The same organized and disorganized elements in the sea that support its Flora and Fauna, are equally capable of nourishing all land plants and animals. Every river, and smaller stream, that falls into the ocean, carries with it an indefinite amount of both the mineral and organic constituents of all crops. All lakes and seas which have no outlet, except by solar evaporation, are salt; and, in many places, salts of lime, soda, and potash are precipitated. It is more than probable that the evaporation of sea-water in Florida and other Southern Atlantic and Gulf States, to obtain salts for manure, will pay a fair profit. The water should be let into shallow basins at high tide, and there retained till the sun and wind evaporate it. The more compound the salts, the better for all agricultural purposes.

A letter from the Chincha guano islands, on the coast of Peru, dated November 20, says that there were then a large fleet of vessels there, loading principally for England; but some few were up for the United States. "The guano is mostly taken from the north island, the southern one remaining untouched; and there are said to be on the three islands thirty millions of tons of guano. It is thirty feet in depth."

"At different points on the island are shoots or tunnels, made of heavy canvas, about three feet in diameter and 50 or 60 feet in length, reaching from the top of the island to the water, under which the boats are placed to receive the guano; and as it runs down with considerable velocity, they are soon despatched." As the consumption of this article is rapidly extending in the United States, we will give the results of a few experiments in England, where it was applied on much richer land than any manured with guano in this country and reported to this office. At a late meeting of the Sittingbourne Farmers' Club, Sir J. M. Tylden gave the following results of experiments with guano:—"Last autumn I set apart three pieces, of a quarter of an acre each, of Spalding wheat. On No. 1, I put no manure; on No. 2, applied guano at the rate of four cwt. (448 lbs.) per acre; and, on No. 3, guano at the rate of two cwt. (224 lbs.) per acre. The cost of guano on No. 2, £2; on No. 3, £1 per acre. The yield of No. 1, not manured, 28 bushels per acre; weight of straw, 1664 lbs. per acre; weight of wheat, 61½ lbs. per bushel. No. 2 had four cwt. of guano sown and harrowed in with the seed: yield, 38 bushels 6½ gallons per acre; weight of straw 3936 lbs. No. 3 had two cwt. of guano sown and harrowed in, as with No. 2: yield, 35 bushels, 6 gallons; weight of wheat, 61 lbs. per bushel; weight of straw, 3812 lbs."

and the most of them with the sulphate of lime, which accounts for their not becoming, like most other lands, so speedily exhausted without manure. With good husbandry, I have no doubt that most of our lands in this county will be as productive one hundred years hence as they now are. Much of the land which, when first improved, would not produce grass to any extent, now, after being worked for many years without manure, yields as fine hay and pasture as almost any in the country. Plaster is extensively used, as it abounds in the county, but its effects are less beneficial than formerly."

From the above data, it will be seen that on land so fertile as to produce 28 bushels of wheat per acre, 224 lbs. Peruvian guano gave an increase of seven bushels six gallons of grain, and of 1648 lbs. of straw. The additional two cwt. added only three bushels to the crop, when brought up to 35 bushels 6 gallons; which shows, that as the manure last applied cost a pound sterling, the gain did not pay. The straw and grain being more valuable in England than in this country, as well as clover and turnips, which follow wheat, of course higher manuring there than here is allowable. It is worthy of remark, also, that, taking every thing into the account, while 224 lbs. of guano paid a profit of 85 per cent. on its cost, 448 lbs. gave a profit of only 25 per cent.

The proper quantity of manure per acre which one ought to apply to obtain the best results, is a matter of great importance. In deciding this point, one must carefully estimate the value of the crop when grown, the condition of the soil, and the usual effects of any given amount of manure of a particular kind or quality. From the closest calculation of profit and loss that we can make, aided by the experience of hundreds of practical farmers, who have kindly answered all our questions, we reach the conclusion that lands should be made to yield about 30 bushels of wheat per acre in this country, to produce the grain at the least expense per bushel in a series of years. We have before us the London Agricultural Gazette, of January 4, 1851, in which it is stated that a field that gave 32½ bushels of wheat per acre without manure, yielded no more when guano, phosphate of ammonia, and potash were applied to parts of it; and we doubt if the largest crops of grain, whether wheat, corn, oats, or barley, pay for the last ten bushels per acre added to the same. The wheat-growers of Denmark, it is stated by the correspondent of the London Morning Chronicle, have brought up their lands to an average yield of 38 bushels per acre. If this be true, manure must cost next to nothing there, to go any further in the improvement of the soil. In the improvement of wheat itself, corn, and cotton, we think much may be done by the aid of science; but that is a subject which we shall not now discuss.

The burning of stubble has some advantages, and many advocates. A writer says:—"By burning the whole surface of one-half of a field, it bore last year an excellent crop of turnips, without the aid of farm-yard dung; and this year it has produced 10 bushels of barley and 13 trusses of straw more than any other part which received 18 loads of farm-yard manure."

Where vegetation is rank and the ground sour, burning tends to destroy all organic acids, sweeten and improve the soil. After lands are properly drained, caustic lime not only neutralizes all acids, but it attacks, and ultimately consumes, all organic substances. It operates most favorably when often applied, and in moderate doses. The farmer should proceed with caution, experimenting in a small way at first, watch results, and increase such practices as promise the highest pecuniary reward. Both the art and science of feeding cultivated plants are in their infancy; and we must devote years to the accumulation of new facts before we shall be warranted in saying how productive a soil should be made by artificial means, to yield the largest income to its owner and cultivator. To develop new truths in rural economy, every State in the Union should maintain a well-conducted experimental farm, the records of which would add largely to our knowledge of the capabilities of improved land to feed and clothe the human family. As tillage consumes both the organic and mineral constituents of crops, it should be applied to no larger area than is demanded for the highest gain of the husbandman. There are millions of acres annually devoted to the production of grain, cotton, and tobacco, more than are strictly necessary to obtain the quantities of these staples harvested. This involves the wasting and entire loss of an immense amount of vegetable mould, lime, magnesia, phosphorus, sulphur, potash, soda, chlorine, and ammonia. Although the departure of these things from arated land is not seen, and they do not appear in the crops, their loss is none the less certain. Some of them have passed into the atmosphere, and some have gone to the ocean. When a prairie is broken at the West, it often operates to make the neighborhood sickly for a season or two. Why is this? Because tillage greatly augments the decomposition of the vegetable and animal substances in the virgin soil. The air is loaded with fertilizing but poisonous gases that ploughing, harvesting, and hoeing discharge into it. Tillage is a most unnatural operation, and its effects on sand, clay, iron, lime, and other minerals, as they exist in the surface of the earth, can be understood only by one who is familiar with all the great truths revealed by the critical study of agricultural chemistry. So much preliminary knowledge of acids and bases, and the play of affinities, is needed, that one encounters almost insuperable difficulties in attempting to explain how carbonic acid derived from mould attacks the insoluble silicates of potash, soda, lime, and magnesia, and in the end yields to needy, growing plants soluble flint, soluble lime, magnesia, and all other elements present in the soil. One who has read with care Johnston's Lectures on Agricultural Chemistry and Geology, will have no difficulty in comprehending the chemical effects of tillage in consuming the food of plants, without such food ever entering their roots. Economy in saving the raw material of crops is only attainable by knowing all the results of tillage in decomposing mould and all compounds of silica, alumina, iron, lime, potash, and other bases. So soon as one crop is off the ground, another should succeed; not, indeed, further to exhaust the soil, but to collect in growing plants all the available elements of human food and clothing within their reach, to be carefully husbanded for future use. If the renovating crops be turned in by the plough, the soil gains carbon and nitrogen from the atmosphere; if consumed by domestic animals, the farmer has their manure, which costs him next to nothing. One that knows how to use growing plants to the best advantage can improve his land at the least expense. Indian corn possesses many elements of productiveness, and in skilful hands will add rapidly to the organic and inorganic food of other crops, where all such food is preserved from waste. Turnips are extensively used for a similar purpose in Great Britain, and may be equally so in this country.

FRUIT CULTURE.

BY J. J. THOMAS, MACEDON, N. Y.

After a lapse of two centuries since the settlement of the country, the cultivation of fruit is just beginning to assume a character its merits deserve. More trees have been set out into orchards within the past five or six years, even in those regions which were long since settled, than in all previous time. This rising estimate of the value of fruit is not founded on any false basis, and is not destined, like many other objects of general and eager interest, to endure only for a season, and then pass away. So long as substantial and cheaply furnished food, and the most desirable and wholesome luxuries shall be objects worthy of attainment, so long will fruit culture maintain its importance.

I. *As an article of food*, fruit, and more especially *apples*, have been proved of great value. Some farmers save annually, in various ways, from fifty to a hundred dollars by the use of green and dried fruit upon their tables—not merely by the amount of aliment afforded, but, adding to the variety and to the list of luxuries, enabling them to reduce the amount of other and more costly articles. By planting rich and high-flavored sorts for culinary purposes, instead of those of an inferior grade, a great saving may be made in sweetening and spices. The amount of sugar and other ingredients used for making bad apples good, is often more than enough to buy good apples, sugar and all. Fall pippins, for example, at fifty cents per bushel, have been found more economical than poor and insipid varieties at fifteen cents per bushel. By a free use of the best sweet apples through autumn and winter, for baking and for puddings, some families have avoided large expenditures. The aggregate saving in the million of American families who might enjoy the privilege of plenty of fruit, with a general cultivation of the best kinds for a succession the year through, might perhaps be set down, without extravagance, as more than the whole expenses of the General Government.

Not less important is the value of fruit as an article of food for domestic animals. Although direct and careful experiments by weighing and measuring are still wanting, enough has been ascertained to prove that apples, especially the richer sweet varieties, as food for cattle and swine, are fully equal to potatoes; and some of the most careful trials already made indicate their decided superiority, being about as seven to five. The chemical analyses of these two productions show the superiority of the apple in the aliment it contains, and also prove that some sorts excel others in richness and value. Hence the importance of ascertaining by careful trial those sorts best adapted to feeding and fattening.

For fattening swine, apples are particularly excellent. Some farmers have saved three-fourths of the expense of pork-making by allowing their hogs the run of a part of their orchards while the autumn fruit was falling from the trees. A neighbor sold forty dollars' worth of pork, fattened with the "droppings" of only half an acre of good grafted orchard. The process was completed by a week or two of feeding with grain. Even common seedling apples, if cooked, are valuable. In one experiment, 500 pounds of pork were made from 120 bushels. There is no doubt, however, that selected grafted varieties would have been found much superior. Even the hogs themselves are good judges, and show much discrimination in choosing the best trees whenever a plentiful supply is allowed them.

For milch-cows, sweet apples regularly and moderately fed, after being sliced to prevent choking, have been found to increase the milk one-third in quantity. They are also good for horses, as well as for nearly all other domestic animals.

While, therefore, the apple possesses a high value from its inherent qualities for feeding, the cheapness of its production far exceeds that of nearly every other article for this purpose. Taking, as an average, the value of land at fifty dollars an acre, we have the following estimate, giving the actual cost of one acre of orchard:—

Cost of land	$50.00
Cost of 50 apple-trees	10.00
Cost of setting out	5.00
	$65.00

The crops from the land will more than pay the yearly interest for the first few years, and the product of both land and trees will more than pay it as they become larger. An acre of full-sized bearing trees would, therefore, cost no more than sixty-five dollars. With the selection of the most productive sorts, in connection with the vigor imparted by good cultivation, the trees will yield, on an average, at least eight bushels each, or four hundred bushels from the acre. The annual interest on the orchard, at 6 per cent., would be about four dollars; the necessary cultivation and manuring, to maintain a most fruitful condition, would not exceed six more, making *ten dollars*, the whole yearly cost of the *four hundred bushels*, or *two and a half cents per bushel.* In the more fertile parts of the country, the only cultivation required would be one ploughing and two or three harrowings annually, reducing the cost of the ungathered crop to about one cent and a half per bushel—a sum much lower than the same value of nutriment yielded by grain or root crops. The only drawback is the time required for growth; and, as the immediate results are too often the controlling motive for exertion, the more remote and superior advantages of orchards, as a source of food, are but scantily enjoyed. No land-owner need fear to plant extensively for the purpose of a copious supply—needing not, like other crops, the yearly attention of procuring seed and planting. Such crops can never suffer by a glutted market, so long as the growth, maintenance, and fattening of domestic animals form an important portion of agricultural economy. Nor is the time required for an orchard to come into full bearing so great as common opinion regards it; for, through the vigor imparted by good culture, trees will attain a full-bearing age in a third of the time requisite where the soil is neglected and the trees are allowed to take their own course.

II. *As an article of comfort and luxury*, the value of fruit can scarcely be estimated. The few who have learned by actual experience the enjoyment of the best and most delicious sorts for the whole twelve months, would not willingly relinquish the privilege. Many, it is true, have furnished themselves with occasional supplies of their own raising—they possess only a few scattered fragments of the yearly circle of fruits; but the number is yet much too small, although rapidly increasing, who may place upon their tables delicious sorts on almost any day of the entire year.

Facilities for this annual round of delicacies vary in different portions of the Union. In the more northern States, where the culture of fruit has received the most attention, the earliest sorts of the cherry and strawberry ripen by the first days of summer; the later sorts, with the addition of currants and raspberries, extend the period for six weeks, or until midsummer. Apricots, in connection with the earlier pears, plums, and apples, immediately follow, and fill up the space till the rich profusion of autumn fruits, in all their kinds, keeps up an abundant supply till winter. Grapes and pears may be kept till spring; and by a proper attention to sorts and to good keeping, apples may be had every day of the year, or, at least, until the next strawberry season in early summer.

Is not an abundant provision for this yearly supply an object worthy of much exertion? What commodity is more calculated to increase the comforts of country life, and to add to the pleasures and to increase the attractions of home, to young people, than fine, ripe, and refreshing fruit, of one's own raising, during a whole season? The enjoyment yielded by a single bed of strawberries, supplying a few quarts daily for the table, we have never yet known to be despised; but this is but a single specimen in a rich and profuse cluster, when compared with the whole assemblage—embracing delicious and ruddy cherries, golden, perfumed apricots, juicy and refreshing apples, luscious bloom-dusted plums, buttery and melting pears, fragrant and crimson nectarines, clustering and transparent grapes—all diversified with their many and varying sorts.

III. *The value of fruit for market*, as a source of income, has been proved by many striking instances. Farmers, whose orchards do not occupy a tenth of their land, often make more by the sale of fruit than from all other crops besides. We have already seen in what manner 400 bushels of apples may be relied on as an annual crop from one acre of land. Admitting only half this amount of good fruit for market, and that the ungathered crop is worth only twelve and a half cents per bushel, (the lowest we have ever known for good winter apples,) then we have twenty-five dollars as the yearly interest on an investment of sixty-five dollars; or, deducting three dollars for cultivation, twenty-two as a net dividend. There has scarcely been a season, however, for a long series of years, when good apples have not been worth at least twenty-five cents, which, for the small crop just set down, would make the yearly net product forty-seven dollars per acre, or more than two-thirds the capital invested. With other fruits, the price is often much higher. Good late pears, after transportation to great distances, sell in our cities at three to five dollars per bushel. Single trees, producing eight to twelve bushels each, have, in a number of instances, afforded a profit of twenty or thirty dollars. Farms of a hundred acres are scarcely ever made to yield so much as a well-managed single acre of such pear-trees would produce.

A few well-attested instances of success will show that these estimates are not extravagant. Richard J. Hand, of Monroe county, New York, sold, in 1845, $440 worth of Northern Spy and Roxbury Russet apples from one acre. The land was well cultivated. Numerous cases have occurred under the notice of the writer, where one hundred dollars or more have been made from the sale of an acre of good winter apples; and a number of trees of the Rhode Island Greening have borne forty bushels each at a crop, yielding ten dollars from each tree. A fruit-raiser in Orange county, New York, sold in one year more than three hundred dollars' worth of plums from the fourth of an acre. These are only a few out of many instances which might be given.

Now, it is admitted that these are unusual cases; but they are so for no other reason than that good cultivation is unusual. No part, in the management of trees, receives more general neglect, and no neglect results in greater loss to the orchardist. It seems particularly unaccountable that while fruit-trees furnish larger returns than any thing else on the farm, they should be the very thing that the farmer most neglects. Nothing is more common than to suffer trees, both young and old, to weather the whole season through with scarcely a moment of labor or attention. Each has cost ten times more originally, and is worth now fifty times more, than a hill of corn or potatoes; yet, who thinks, for a moment, of planting a hill of corn in a grassy field, and of leaving it untouched by cultivation from spring to autumn? Yet this is the treatment of a large portion of newly transplanted trees. All the remarkable, and in some cases almost incredible, instances of young trees coming soon into bearing, and of older trees yielding enormous and lucrative crops, have mainly resulted from the same good manuring and mellowing of soil which every good cultivator gives for his potatoes, carrots, and cabbages.

Orchards which now yield $40 or $50 per acre without care, might be doubled in the value of their annual products by the appropriation of a sum not exceeding $5 to $10 per acre. The advantages of good treatment are threefold: young trees are thrown forward into bearing in less than half the time otherwise requisite; the products of large trees are doubled in amount; and the appearance and flavor are sometimes improved to a degree almost beyond belief. Some varieties of the pear, almost worthless under neglected culture, have been rich, melting, and delicious, when subjected to the genial influence of a deep, mellow, and fertile soil. Sometimes the same pear has been thus tripled in market value; and so has been the change in appearance, as well as in flavor, that we have known even experienced pomologists to be deceived into the belief that new sorts were before them, when they were really but old acquaintances grown under the most favorable influences.

Transplanting.—It has been estimated, that, of the hundreds of thousands of trees yearly set out in orchards in the United States, not more than one-third ever reach a good bearing condition. The delicacy in the organization of all the parts of a young tree appears to be overlooked or forgotten. The roots are mutilated when torn from the ground, or four-fifths of their length cut off by the spade. They are crowded into small holes, dug in hard soil, and often not large enough to receive all the roots, such as they are, without binding, and the earth is stamped hard upon them. A large number necessarily perish from such treatment, and those which survive often remain in a sickly or feeble condition, from neglect in successive years.

Very opposite is the management of the skilful and successful cultivator. The trees are carefully lifted from the earth, securing a wide circle of spreading roots and finely branching fibres; they are next immersed in a bed of mud, to coat the surface, and prevent injurious drying; ample holes are dug for the full extension of all the roots; fine and fertile soil is sprinkled in, while the small fibres are evenly spread out with the fingers; the earth is closely settled through all the interstices of the roots, not by stamping with the foot, but by pouring in a few quarts of water before the hole is quite filled.

As the subsequent treatment of the newly set trees is of the greatest importance, it may be well to enter more particularly into this branch of the subject.

Preparation of soil.—The first requisite of success and vigorous growth is a deep fertile soil. They may be secured for the tree, while young, by digging large holes and filling them (except in immediate contact with the roots) with very rich soil, or with short manure, well-mixed by raking with common earth. Young apple-trees, not larger than a carriage-whip, with holes seven feet in diameter, thus filled, have borne a bushel of fruit each the fifth summer. By the time the roots have run beyond the holes, the rest of the ground may have been enriched with manure, and deepened by ploughing. An admirable mode of deepening is first to loosen the soil as far down as practicable with a subsoil plough, and then to trench-plough this deeply loosened bed for the intermixture of manure. Trench-ploughing is effected by running a large common plough in the bottom of the previous furrow. The subsoiling admits this to a much greater depth than could possibly be attained without it. This preparation of the ground may be accomplished before or after planting the trees.

When the surface cannot well be prepared in this manner, a strip of ground eight feet wide, where the row of trees is to stand, may be prepared at less expenditure of labor. This method would indeed be always found of great use in clayey soils, which, otherwise holding water like a tub in the holes, would admit of drainage by means of the deep furrow through the centre. A small quantity of brush laid in the bottom of the furrow, before being filled, would allow the water to soak away for years afterwards.

Cultivation and mulching.—After a young tree is transplanted in the best manner, the first step only has been taken. Much will depend on the treatment it receives the first summer. Neither a tree nor a domestic animal can thrive and grow, if not well fed in its early years. The ground must be kept mellow and free from weeds for a distance of at least several feet around, because the new roots begin rapidly to extend themselves, and the roots of weeds and grass, if permitted, will also approach towards the tree, to rob it of its support. As soon as the dry summer season arrives, or sooner, the trees must be well *mulched*—that is, covered for several feet around with old straw, coarse litter, or leaves, not less than five or six inches thick. This keeps the top soil, throughout the hottest day, as moist as in the dew of morning, and consequently the under soil can never become dry. The moisture of the soil is thus preserved in the most even manner—incomparably better than by the irregular supplies of artificial watering, which not unfrequently do more harm than good, by causing the surface to bake, the water not penetrating to the roots below. For *cherry-trees*, more especially, which often perish at midsummer, after having made a good beginning, mulching is of the greatest importance.

The writer has restored a row of young apple-trees, which were so much injured by the drought as to cease growing and assume a sickly appearance, to freshness and vigor, by the simple operation of mulching, although no watering was given, and no rain fell, neither at the time nor for some weeks after the improvement in their foliage became visible. A correspondent of the *Horticulturist* mulched fifty trees out of a hundred and fifty, all of which had commenced growth alike. Those which were mulched all lived. Of the hundred others, fifteen perished.

On the approach of winter, to guard against *the attacks of the mice*, which work under the snow, a little mound of earth, about ten or twelve inches high, should be thrown around each tree, to remain till spring. This has proved a complete protection in hundreds of instances, even where trees have stood in thick grass, the most tempting of all spots to these little depredators. Nothing is easier, and nothing more efficacious, than this simple remedy, which has also the additional advantage of stiffening the newly set tree against the action of the wind.

Keeping the ground well cultivated has already been urged. A few examples of its influence may be interesting. Some years since, fifty fine peach-trees were set out, under the notice of the writer. The work was carefully done, and all lived. The ground was alike in quality, and a part was occupied with a crop of winter wheat, and a part with potatoes. The latter received, of course, good cultivation, with repeated hoeings; the former was not cultivated at all. On examining the trees after harvest, it was found that none of those standing in the wheat ground had grown more than *three inches*, and few more than one or two inches. On the other hand, of those in the potatoes, none had grown less than *a foot and a half*, and some had thrown out new shoots *two and a half feet long*. In another instance, the superiority of growth given by means of a hoed crop to the trees of a large bearing orchard of peaches, compared with those standing side by side in an unhoed crop of peas, was so striking as to be visible by the color of the foliage at a distance of more than half a mile. The worst piece of ground which it is possible for a young orchard to occupy is a meadow. We have observed whole hundreds smothered to death the first summer by the heavy grass which nearly enveloped them. Sown grain crops are not much better; but low cultivated crops, as potatoes, rutabagas, and carrots are the best which can occupy the land. But all plants in all cases draw upon the strength of the soil; and hence clean, mellow, unoccupied ground is the best. A skilful cultivator found that his trees made about double the growth on clean unplanted ground, compared with those which stood among his field-trees. Dr. Thompson, of Delaware, states that two rows of potatoes only, between the rows of bearing peach-trees, have been found not only to affect the fruit, but to injure the trees. Hence the best market-orchards in the country—those most famed for their splendid fruit, high prices, and heavy net profits—are kept clean by ploughing and harrowing, in connection with the application of manure.

Some are, perhaps, now ready to exclaim, "We cannot *afford* to give so much attention to our trees—we cannot devote all this labor to them!" What! not afford to be economical? Not afford to save trees, after having paid for them? Then, by all means, buy only half the number, and apply the other half of the purchase-money in giving them the best possible care. An eminent and experienced cultivator has given it as his opinion, in which, it must be admitted, there is a great deal of truth, that if nine-tenths of the orchards of the older States were cut down, and the labor of taking care of them expended on the remaining tenth, more and better fruit would be raised. No good farmer hesitates for a moment in bestowing all the required attention on his annually planted crops: why, then, should he not exercise the same wisdom in relation to that which is more valuable than any of them?

The difficulty of cultivation is usually much increased by the very inconvenient machinery used for ploughing near the rows. A two-horse team, with double whipple-trees, cannot safely approach nearer than three feet; and every ploughman dreads a task attended with lacerated bark on the one hand, and wide grassy "balks" on the other. A great improvement is made by placing one horse ahead of the other, like a canal-boat team, with a very short whipple-tree for the hindmost, whose draught-traces may also be considerably lengthened, to admit of steering the plough to the right or left. With this arrangement, the task is easily and handsomely accomplished.

A wide error is committed in cultivating and manuring orchards by those who forget that roots extend far beyond the circle measured by the branches. When the trees become large, the whole of the ground is filled with a network of fibres. The larger and more obvious roots are near the base of the trunk; but the finer ones, which contribute the nourishment, are spread at great distances. Hence the whole surface should be kept mellow and receive the manure, and not narrow strips or pinched-up circles just at the base of the trunks.

SELECTION AND PARTICULAR TREATMENT OF DIFFERENT FRUITS.

In planting every orchard or fruit-garden, the intended object must be kept strictly in view. For supplying a family, the selection will, of course, be quite different from that of a market-orchard. The former may be nearly the same in whatever locality; the latter will vary exceedingly, with the nature and distance of the market and the resources of the planter.

It will be most convenient to speak in the first place of the former.

To supply a family of moderate size, 100 well-managed and full-grown trees will afford an abundance with the best cultivation. At least, this number may be taken as a fair and full average, to be diminished or increased according to varying circumstances. They may be distributed among the different kinds in about the following proportion: 30 apple-trees, 20 pear-trees, 12 peach-trees, 10 cherry-trees, 10 plum-trees, 6 apricot-trees, 4 nectarine-trees, 8 grape-trees. As the apple and pear-trees are to furnish a large portion of the year, when other fruits are out of season, they compose one-half of the whole number. The cost of this hundred, at present nursery prices, would not exceed 30 dollars. To make the supply still more complete, a few additional rods of ground should be planted with strawberries, gooseberries, raspberries, and currants, the cost of which would increase the above sum to 40 dollars, the annual interest of which would not amount to the usual cost of replenishing a tobacco-box for a year. This number of each kind, if well chosen, would furnish strawberries for a month, cherries for two months, raspberries for nearly a month, apricots for one month, plums for three months, peaches for two months, grapes for four months, pears for eight months, and apples for the whole yearly circle.

These might all be planted on an acre and a half of land; but if two

acres could be appropriated it would be better, as new trees must be occasionally set out to keep up a succession of good thrifty bearers. Plums, apricots, and nectarines are to be so arranged that they may be easily fenced off by themselves for the confinement of pigs and poultry to destroy and repel the curculio, as will be noticed on a future page.

To protect such an orchard from that peculiar and most serious evil, which prevails to a disgraceful extent in this country, namely, fruit-stealing, a good secure thorn hedge should encircle the whole. In the extreme Northern portion of the Union the English hawthorn has succeeded well, and some of the American species have done well further South. But neither of them is to be relied on when there is danger of the ravages of the borer, which has wholly destroyed some beautiful thorn hedges in the Northern and Middle States. There are, however, two hedge-plants, not liable to any known disease or destroyer, eminently fitted to protect fruit-trees from the spoiler. These are the buckthorn and Osage orange. The former is extremely hardy and poisonously bitter to any animal that attempts to feed upon it; the latter, although somewhat sensitive of severe winter frosts, will succeed well as *a hedge* as far north as the peach and Isabella grape will mature their fruits, and it is so profusely set with sharp thorns as to form a most terrific barrier. The only objection to a hedge is the time required for its growth. Its advantages are thus summed up by one of our distinguished writers:—"It is like an impregnable fortress, neither to be scaled, broken through, nor climbed over. Fowls will not fly over it, because they fear to alight upon its top; and men and beasts are not likely to make more than one attempt to force its green walls. It shows a fair and leafy shield to its antagonist, but it has thousands of concealed arrows ready at the moment of assault; and there are few creatures, however bold, who care to 'come to the *scratch*' twice with such a foe."

The mode of preparing the soil for such an orchard has been already pointed out. The selection of the varieties is a matter of the greatest importance. The best and most delicious sorts are generally as easily grown as the worst; and some good varieties are more than twice as productive as others—an important quality to those who have but limited grounds.

THE APPLE.

This fruit, first in value for its easy culture, hardiness, general adaptedness to all places, and the long supply it affords, will grow on any land that will raise good crops of corn, wheat, and potatoes. No tree is more benefited by a deep and well-manured soil. If well managed, the young trees ought to bear half a bushel to a bushel each by the fifth year after setting, and several bushels annually by the eighth or tenth year.

The varieties should be so proportioned as to afford a constant supply of fresh fruit for the twelve months. Early sorts last only two or three weeks, and should, therefore, be fewer in quantity than such as keep through the several months of winter and spring. If the earliest sorts commence ripening at midsummer, scarcely four months will elapse before the time arrives for securing the remainder within doors; therefore, the remaining two-thirds of the year are to be furnished with winter and spring varieties. It, however, happens that during the whole of autumn there is a great profusion of other fruits, as peaches, grapes, plums,

&c., which reduces the number of apples for this season, and renders a still larger proportion of long keepers desirable. The following numbers, in a list of 30 sorts, may therefore be thus distributed through the different periods: 4 of summer varieties, 2 of early and mid-autumn, 4 of late autumn and early winter, 10 of winter apples, and 10 of long keepers. Among the best and most productive sorts which have been extensively tried are the following:—

Summer Apples.

Early Harvest, generally esteemed through the Northern and Middle States as the best very early apple; in Illinois and adjacent portions of the West it has not proved a good bearer, and in some of the eastern parts of New England it adds to this defect slowness of growth and liability to crack and blast. When the soil is not naturally of the most fertile character, it needs the best cultivation.

Sine Qua Non, a week or two later than *Early Harvest*—better, and more productive; not so extensively known, and being of a rather slow and crooked growth, not so popular among nurserymen.

Red Astrachan.—Remarkable for its great beauty, to which a part of its popularity is owing; rather coarse for the table, but unequalled as a summer stewing fruit. Introduced only a few years since, but appears to have done well whenever tried.

Williams's Favorite.—A very handsome summer variety, but hardly of the highest quality; very popular in New England, but has not been extensively cultivated elsewhere.

Summer Rose.—Small, remarkable for its delicate texture and agreeable flavor. In these qualities it is fully equalled and surpassed in productiveness by the *Early Joe*, a new variety, only proved as yet in Western New York.

Sops of Wine.—This has proved a valuable, fine-growing, and productive sort in the Northern and Eastern portions of the Union.

The *Sweet Bough* is generally esteemed in many of the States as the best summer sweet apple. At the West it has proved unproductive. This defect of Eastern sorts on very fertile soils may diminish as the trees grow older.

The *Carolina Red June*, unknown at the East, is regarded by many as the best summer apple for the West.

The *Bohanon*, a fine early fruit of Virginia and Kentucky, ripens during the latter half of summer.

In addition to the above, the *American Summer Pearmain* may be added as a fruit of much value, although very liable to blast in some localities; the *Early Strawberry* as a small, beautiful, and productive sort, not of the highest quality; and the *Golden Sweet*, as a fine growing, productive, and good summer sweet baking apple.

Autumn Apples.

Autumn Strawberry.—So far as yet cultivated in New York and Northern Ohio, this has proved a fine, beautiful, very agreeable, and productive variety. It ripens early in autumn, and will keep till winter.

Gravenstein.—Although not many years since its introduction, the

gravenstein has been widely disseminated, and has proved, both at the North and South, a variety of the highest excellence.

Porter.—Pre-eminently the autumn apple of New England; it succeeds well, but does not maintain fully its Eastern reputation in New York and Northern Ohio; though slow in growth, fruit very fair, with heavy crops.

Dyer, or *Pomme Royale.*—Perhaps unequalled in richness of flavor and fine texture combined, among all autumn varieties, but only moderately productive.

Hawley.—A new sort, proved as yet only in New York; large, with a mild and excellent flavor.

The preceding all ripen by the middle of autumn; the following late in autumn; and in the more Northern States, they keep till midwinter.

Rambo.—In the East and North, a fine, spicy, rich fruit, of moderate size; in the Western States, of larger size, and a great and general favorite, although sometimes inclining to be water-cored.

Fameuse.—Very beautiful; of a refreshing, but not high flavor; fine and productive at the West; much valued at the extreme North.

Fall Pippin.—Very large, very celebrated, and very excellent; moderately productive, especially at the West; much valued for stewing.

Belmont, or Gate.—This has proved very fine in New York, Michigan, Northern and Central Ohio, and Illinois, and worthless at Cincinnati. Varies exceedingly in its external appearance, with season and locality. An eminent pomologist at Cleveland says, that, were he confined to one sort, he would choose the Belmont.

The following are among the best *autumn sweet apples:—Jersey Sweeting, Autumnal Swaar, Haskell Sweet, Summer Sweet, Paradise*, and *Peach-pond Sweet.*

The *Gloucester Cheese, Fall Cheese*, and *Fall Queen* or *Horse Apple*, are among the best varieties peculiar to the Southern States.

Winter Apples.

Yellow Bellflower.—With the exception of some parts of New Jersey, and a few other localities where it fails, this apple is uniformly fine, and much esteemed from New England to the Mississippi valley. Too delicate for a market fruit, it excels in its fine texture and agreeable acid flavor.

Westfield Seek-no-further.—Appears to be uniformly fine in all localities, especially in the Western States. At the East and North it is a good-keeping winter fruit; at the West and South-west, it ripens late in autumn and during the first of winter.

Hubbardston Nonesuch.—This excellent and rich variety has not been much cultivated out of New England and New York, where it is a late autumn and early winter fruit.

Bullock's Pippin, or *American Golden Russet.*—Very popular through Ohio, Indiana, &c., on account of the extreme delicacy of its texture and its great productiveness. In some other localities it does not always ripen so as to become tender, and is too small for market.

Peck's Pleasant.—A new variety; a very fine, smooth, and fair, and productive sort, so far as tried in New York and New England, ripening during the first half of winter.

Baldwin.—The most highly esteemed, and most celebrated New England winter apple. It appears to succeed equally well in New York. Its productiveness is remarkable: single, full-grown trees not unfrequently bearing 40 to 50 bushels. In the Western States, it becomes coarser, inferior in flavor, and subject to the bitter-rot. It is an exceedingly variable sort, when grown under different influences, even on the same spot of ground; specimens are sometimes so different, as at first glance to scarcely resemble each other.

Rhode Island Greening.—As celebrated, in Western New York, as the Baldwin in New England, for its free growth and great productiveness. Forty bushels are not a rare crop for a full-grown, well-cultivated tree. In the West, it does not bear so well; but the trees may become more productive when they become older. As far South as St. Louis, it ceases to be a winter apple, ripening before the close of autumn; and in the Southern States, it is changed to an early autumn variety.

Red Canada, known also as the *Nonesuch*, or "true Nonesuch," in New England, has proved of great excellence, so far as it has fruited—from Maine to Northern Ohio—and will doubtless succeed well farther West. It is regarded, by many good judges, as unexcelled in its rich and agreeable qualities by any winter apple.

Jonathan.—A beautiful, very fair, and productive sort in New York; but not, as yet, much proved elsewhere. In quality it is fine, but not quite equal to the Red Canada, to which it appears to be allied.

Esopus Spitzenburgh.—Far-famed for the extraordinary richness and spiciness of its flavor, in which it is nearly, if not quite, unequalled. The flesh is too firm, and to some the acid is too high, to be wholly agreeable. It is excellent for stewing. It maintains its high character, through New York and the West, so far as tried; but is usually only moderate in the amount of its crops.

Swaar.—For a mild, agreeable, and very rich flavor, this is regarded by many as unexcelled, and by others as unequalled. It bears well, but on old and overloaded trees the fruit is apt to be scabby or blotched. In some parts of New England it loses its high character, becoming light and corky at the core.

Northern Spy.—Much celebrated in Western New York as a handsome, fresh-flavored spring apple, but not proved elsewhere. The young trees do not come soon into bearing, and the trees need higher and better cultivation than many other sorts, to prevent the fruit from becoming small and defective.

Roxbury Russet.—Succeeds well throughout the Northern States, and, although good at the West, does not always bear well there. It is the most celebrated of all long-keeping sorts. It succeeds well, and maintains its fair appearance in all soils and with all kinds of treatment; but with rich culture, it becomes larger and bears heavier crops. Small specimens are flat; larger ones become more conical, with short, thick stems. It is known in many parts of Ohio, under the name of Putnam Russet.

English Russet.—Fruit rather small, from overbearing; keeps a year without difficulty; bears profusely in all localities. In Illinois, six bushels have been produced from one tree the sixth year from setting out.

Newtown Pippin.—But little cultivated in New England; but well known from the Hudson to the Mississippi, for its high and long-keeping qualities, and for a part of the crop being undersized, unless grown under favorable influences. In New York it requires high culture to prevent most of the crop becoming small and scabby.

Pryor's Red.—This fine fruit is one of very wide adaptation, being very highly esteemed and widely cultivated in the South and West, and succeeding well as far north as 43° latitude, in Western New York.

Rawle's Jannet.—Like the last-named variety, greatly esteemed in the Western and South-western States. The fruit is very valuable for its long-keeping quality. The trees, by overbearing, produce many small or imperfect specimens. Not of the highest flavor.

Milan.—Known only at the West. It possesses a mild, pleasant, and agreeable, but not very high flavor, but is much esteemed, more especially in Illinois, for its fine growth and productiveness.

Winter Cheese.—Cultivated much in Southern Virginia, and is one of the best early winter apples of that region.

Among the best *winter sweet apples* are the following:—*Broadwell*, *Tallman Sweeting*, *Danvers Sweet*, *Baily Sweet*, *Ladies' Sweeting*, and *Sweet Baldwin*.

More space has been devoted to the preceding list, from the universal importance and the great value of the apple in all collections. In small gardens, the number, of course, must be greatly reduced; but with the remarks appended to each variety, no person need fail of getting good sorts. The following circumstance may be stated as a proof of the extreme difficulty of prescribing exactly those which shall suit every one. At the first meeting of the American congress of fruit-growers in New York city, a committee of nine was appointed to prepare select lists of fruits adapted to general cultivation. A vote in committee of over two-thirds was decided to be sufficient to place any fruit on the select list; yet, with all this liberal allowance, only *ten sorts* of apples could be agreed on "as worthy of general cultivation." The difficulty was not less with other kinds. When the pear, for example, was under consideration, (although nearly a *thousand varieties* have borne fruit in this country,) there were only *two sorts*—the Seckel and Bartlett—which received a *unanimous* vote in committee. The lists furnished in this article will therefore be understood as not intended to be perfect, nor as embracing all the best *local* sorts which may be known, but those generally which have received a *large vote* of the intelligent fruit-raising portion of the community. Most of them succeed well in the Southern States, where they mature one or two months sooner than at the North.

THE PEAR.

This fruit, greatly exceeding the apple in the delicacy and melting quality of its texture, and in its delicious flavor, and also possessing the very desirable merit of a continuance for many months, would stand inferior to no fruit for value and importance, but for its most destructive malady—*the blight*. There appears to be no certain protection against this disaster; but its ravages may be greatly lessened or mitigated. Whenever the leaves on any branches suddenly turn black as if *scorched*, not a moment is to be lost. The branches must be immediately cut off, a foot or two below the affected part, and committed to the fire. If this practice is promptly and perseveringly adhered to, it will in most cases soon check the spread of the disease. The best preventive appears to be a good soil, producing well-grown, healthy, well-ripened wood; too great a fertility inducing succulency and not hardiness, and a poor soil causing a feeble and not sufficiently vigorous growth.

Dwarf pears, made by pruning into a pyramidal form trees grafted or budded on the quince, possess several advantages. They come sooner into bearing, in most cases, than those on pear roots; they occupy but little ground, each tree not needing more space than six to eight feet, thus admitting many trees even in limited gardens; and they but slightly shade and injure adjacent crops. Hence, no person should set them out who is not determined to give them the very best culture. Many sorts do not succeed on the quince.

Varieties.—A vast number of varieties of the pear have been collected at home and introduced from abroad, only a small portion of which are worthy of extensive cultivation. An eminent New England pomologist, who has fruited about one thousand varieties, gave it as his opinion that all that is valuable may be secured by a careful selection of about *twenty*. The following are generally esteemed as the best:—

Summer Pears.

Madeleine.—The earliest good pear; needs house-ripening.

Summer Doyenné.—New; scarcely later; equal in quality; rather smaller.

English Jargonelle.—Large; good; but worthless unless ripened in the house.

Tyson.—A new sort, of great richness, delicacy, and excellence.

Rostiezer.—Perhaps the highest flavored summer pear; rather small.

Bloodgood.—Usually fine; but in some places insipid.

Dearborn's Seedling.—Always fine; but rather small.

Bartlett.—Ripening at the end of summer, and passing into autumn; a great and almost universal favorite; large, melting, and good; the tree grows vigorously, and bears well while yet very young. An instance occurred under the notice of the writer, where a young tree, about six feet high, the second year from transplanting, bore about a peck of superb fruit.

Autumn Pears.

Washington.—Very sweet and high-flavored; uniformly fine; refuses a quince stock.

Golden Bilboa.—Fair and handsome; flavor a notch below the best.

Urbaniste.—Fine, and very melting; tree does not bear young.

Seckel.—Renowned through the pomological world as the highest flavored of all pears, but quite small in size. Tree very hardy, rarely attacked with blight; growth, slow.

Heathcot.—A New England pear of high quality.

Louise Bonne of Jersey.—Famed for its productiveness, (on quince stock,) combined with a good flavor.

Onondaga, or *Swan's Orange.*—A very large, freely-growing, fine-flavored pear; somewhat variable in quality.

Beurre d'Anjou.—Newly introduced; quality excellent.

Autumn Paradise.—A new pear of exceedingly high flavor, and promising to become very valuable.

Beurre Bosc.—Of good size and of very high quality; rather slow in growth; will not grow on the quince.

Flemish Beauty.—Remarkable for its fair and attractive appearance, combined with fine flavor. If there is any defect in this pear it is in its slight lack of high flavor when not grown under the most favorable circumstances. Fails on the quince.

Belle Lucrative.—As an eminent pomologist remarked, "*when* this pear is fine, it is *very* fine;" but it not unfrequently falls to an inferior quality. The best specimens probably approach as near *perfection* for a truly delicious pear as any to be found.

The *White Doyenné*, (or *Virgulieu* of New York, *Butter Pear* of Pennsylvania, and *St. Michael* of New England,) although it fails in some parts of the Eastern States, is considered as the most valuable of all pears, all its qualities considered, in Central and Western New York, and succeeds finely at the West. The *Gray Doyenné* is similar to it in quality. The *Doyenné Boussock* is a newly-imported variety, resembling it in quality and appearance, but of larger size.

Beurre Diel.—Large, rich, but rather coarse; ripening quite late in autumn.

Winter Pears.

The *Beurre d'Aremberg*, (or *Aremberg*,) and the *Winkfield*, (or *Vicar of Winkfield*,) stand first for productiveness; the *Winter Neles* for high flavor.

The *Easter Beurre* is the best long-keeping sort, ripening in spring: the tree needs high cultivation. The *Glout Morceau*, *Lewis*, and *Prince's*, *St. Germain*, are also fine winter pears. The *Chaumontel* is an excellent old pear, but needs, at the North, the warmest and richest soil for the development of its good qualities.

The following succeed best on the quince: Louise Bonne, of Jersey, Beurre Diel, Steven's Genesee, Angouleme, Winkfield, Long Green of Autumn, Glout Morceau, Chaumontel, Easter Beurre, Tyson, and Beurre d'Amalis.

No fruit suffers more in quality from bad cultivation than the *pear;* and *winter* pears are rendered nearly worthless if neglected. Unless they grow in a good, deep soil, they cannot perfect their flavor. If the season is cold, the fruit will not attain maturity before the cold weather of autumn, unless subjected to the best treatment; or, if the soil be dry, its growth will be checked until too late to ripen well. Hence good management, even under an unpropitious sun, will generally give us much better winter pears than the most favorable skies without it. Manure, with a small proportion of ashes, well worked into the soil, will impart vigor of growth; and mulching, in connection with frequent digging, will preserve the soil moist during any season of drought. A single trial is sufficient to convince any one of the economy of all the labor thus applied, by the large crops of finely-swollen, rich, and delicious pears which are the result.

The Chaumontel, Easter Beurre, and some others, are not easily injured by autumnal frosts, and should be left on the trees till the approach of cold weather. The Vicar of Winkfield, on the other hand, should be carefully preserved from frost.

A very essential requisite to the successful keeping of winter pears is a good cellar or fruit-room. It should be just sufficiently moist to prevent shrivelling on one hand, and rotting on the other; and the temperature should be low. The want of such a room, added to neglected cultivation, is one great reason why so many have failed with this fruit. In this room the fruit is to be kept till the time of ripening approaches, or until near the time the fruit is wanted; it is then to be placed in a warm room, with a temperature of about 70°, where, in a few days, it will change to a fine yellow, and become ripe and melting. In this way, pears may be successively ripened off so as to furnish a supply through winter.*

THE PEACH.

The peach, usually regarded as the most delicious of all fruits, may be made to yield a supply, by a good selection of varieties, for more than two months. The earliest good sort is the *Early Ann*, but too tender for the extreme Northern peach region. It is closely followed by the *Early Tillotson*—an excellent, productive, and more hardy variety, and well adapted to all localities, from Lake Ontario to the Gulf of Mexico. In Mississippi and Alabama it matures within two or three weeks of the first of summer. The Tillotson is immediately succeeded and often ripens with the *Serrate Early York*, a peach not inferior to it in value; after which, *Cole's Early Red, Cooledge's Favorite, Large Early York, Grosse Mignonne, Early Crawford, Morris White, Nivette, Bergen's Yellow, Old Mixon Free*, and *Druid Hill*, form an admirable succession of the best sorts. The *Heath Cling*, which does not always escape the frost at the North, becomes, when the fruit is thinned and well cultivated, the best very late peach, keeping on shelves in a cool, dry room, for two or three weeks after being gathered.

Stunted peach-trees always produce much smaller fruit than those of vigorous growth; but the crop suffers even more in flavor than in size. No tree more imperiously requires regular pruning. If neglected, the branches gradually extend in length, the side-shoots perishing, until they become long, naked arms, bearing leaves and fruit only at their extremities.

To prevent this difficulty, and to preserve the trees for a long series of years in a healthy, vigorous condition, and in a neat, compact form, the *shortening-in* mode of pruning has been successfully adopted. It consists in cutting off, in winter or spring, about one-half or two-thirds of every shoot of the preceding year's growth all over the tree. If this is commenced about the time the trees begin bearing, and is annually kept up, they will always maintain a handsome, compact shape; the fruit will be larger in size, not less in quantity, and immeasurably superior in flavor. The work may be expeditiously done with a common pruning-knife, with a short standing ladder.

The *peach-worm* attacks the bark of the tree at the root, but, unlike the apple-borer, never enters the wood. It feeds exclusively on the soft or pulpy inner portion, leaving the outside or hard shell which conceals it. Its presence is therefore indicated by the sawdust-like matter, mixed with gum, which is thrown out at the surface of the ground. In depositing its eggs, the parent or winged insect prefers to insert them where the outer surface is soft, as in young trees, or where the base of the trunk is shaded by grass. The grub kills the tree only when it girdles the bark.

* The ripening, however, must not be attempted before the usual season of maturity. Unless the season has been long and warm, the Easter Beurre, for example, will not mature much before spring. If the store-room is quite cool, the ripening of early winter sorts may be retarded several weeks. Some require to be kept in tight boxes, when brought into the ripening-room, to prevent shrivelling.

It is easily destroyed by following it in its hole with a knife, and will always be found at the farther extremity. Hundreds of trees may be thus cleared by a single person in a day. Ashes or slaked lime, placed round the tree, although not an infallible remedy, and never driving out the grub when once lodged there, tends to repel its attacks.

The great and peculiar malady of the peach is the *yellows*. It is both contagious and incurable. Its first infallible indication in bearing trees, is the premature ripening of the fruit, often two or three weeks in advance of the usual time, accompanied with purple discolorations of the flesh. The tree afterwards assumes a sickly appearance, frequently with many small, wiry shoots near the centre of the head, and it soon perishes. The disease may be communicated by planting stones from affected trees, by the pollen from the flowers, by budding, by using a knife on a healthy tree previously used on a diseased one, and by contact of the roots. A tree, when attacked, should be grubbed up immediately and burned, and no peach-tree planted on the site for many years.

THE PLUM.

The great enemy to the plum is the *curculio*. It is a little beaked beetle, about as large as a pea-bug, which lays its eggs in the young fruit. The egg soon forms a grub or larva, which, eating into the pulp of the growing fruit, causes it to fall to the ground. If laid after the fruit becomes large, it induces premature ripening, and spoils it. This insect usually begins its work as soon as the blossom is off the young fruit. Its mark is a peculiar, little, crescent-like incision, termed by a certain Irish gardener, "the baby's nail," a most expressive phrase.

Out of a multitude of remedies, there are two which are more particularly useful and reliable. One is to confine pigs, chickens, and geese, in the part of the orchard occupied by plums. They should be sufficiently numerous to eat all the fallen fruit, thus destroying the grub, and lessening the danger of the next year's crop. Their presence also frightens away the beetle from depositing its eggs. Operating thus in two ways, they are usually sufficient, if in good numbers, to save the crop, unless the curculio is unusually abundant. When this is the case, the other remedy, which is jarring the beetles from the tree, must be combined with it.

The jarring is to be done with a wooden mallet; and to prevent bruising the bark, the blow should be made upon the short stump of a small branch cut off for this purpose. The insects drop at once upon white sheets spread beneath, when they are immediately detected and killed by a pinch of the thumb and finger. When crushed, this insect, unlike nearly every other, feels dry and crumbling, like Indian meal. The work is best done in the cool of the morning, when the beetles are more torpid and easily caught. In the heat of the day, they do not drop so readily, and often spread their wings and are gone before the thumb-and-finger manipulation can reach them. This method is sufficient of itself to save any crop, if unremittingly applied; but it is distrusted by many who have lost their crops by an occasional intermission of a day or two.

Single trees, planted in much-frequented places, where this timid insect is frightened away, are often loaded with fruit without any care devoted to them.

There is a remarkable shrewdness in the instinct of this insect. It will not deposit its eggs, (unless hardly driven for a lodgment, from great numbers,) where there is not a fair chance for the welfare of the young larva. Hence it avoids puncturing fruit over a pavement, or on trees which lean over the water. But as trees cannot often or conveniently be protected in this way, the swine and poultry remedy will be found best for general use. The jarring can be resorted to as an auxiliary, or as the main remedy, where these animals cannot be allowed to run.

A malady which has destroyed the plum in large numbers, is the *black knot* on the shoots and branches. The cause is not satisfactorily understood, but the remedy is sure. It is to cut off instantly, on their first appearance, all affected parts, and to commit them to the fire. It may be requisite, indeed, in some instances, to remove large portions of some trees, before the evil is checked; but it is better to cut away a part than to allow the disease to spread without control and destroy all.

The following *varieties of the plum* have mostly proved general favorites among cultivators, and they will furnish a successive supply from midsummer till autumnal frosts:—

Primordian, Early Royal, Imperial Ottoman, Early Orleans, Green Gage, Lawrence Favorite, Lombard, Columbia, Bleecker's Gage, Purple Favorite, Purple Gage, Huling's Superb, Imperial Gage, Jefferson, Red Diaper, Coe's Golden Drop, Coe's Late Red, Blue Imporatrice, Jackworth Imporatrice.

THE APRICOT.

This golden, perfumed, midsummer fruit has been singularly neglected in many places where it would flourish in perfection. Its eminent merit consists in early maturity, ripening a month before the first peaches, while it is but little inferior to the peach in flavor. Its unwearied enemy, the curculio, whose habits have just been described, has doubtless discouraged many from its cultivation. By care in applying the remedies, full crops may be obtained, as it is scarcely less productive than the plum. It becomes, like the peach, feeble and stunted by age, if neglected, and needs the shortening-in method of pruning. When grown on a good dry soil, *with a subsoil which never becomes soaked with water*, it proves hardy, and succeeds well in Western New York, as far north as 43 degrees of latitude.

Varieties.—The *Golden* or *Fishkill*, the *Breda*, and the *Black* are the hardiest, most productive, and reliable for the North. The *Large Early* and the *Moorpark* are larger and of finer flavor, but less certain as to productiveness. The *Black* apricot is a distinct species from the others, and apparently as hardy as an apple-tree; and, although of second-rate quality, is quite valuable in the Northern States.

THE CHERRY.

The cherry, in the Northern States, is but little liable to any disease or enemy except the *cherry-bird*, which usually destroys the crop as soon as it ripens. The only effectual remedy is powder and shot; they soon become fearful, and, after a few hours spent upon them for a day or two, have not unfrequently quitted the premises wholly for a week or two at a time. In the West, the cherry-tree often suffers from the burning of the bark, one of the best remedies for which appears to be in forming the head very low, or within a foot or two of the ground. The *heart cherries*, that is, the straight or regular growing sorts, do not succeed well at the South; the *Mayduke* and other *sour* varieties are much better adapted to that region. Dwarf cherries, budded on the *Prunus Mahalet* as a stock, often succeed where other trees will not, and they may prove valuable for this reason, in some localities. The following varieties of the cherry furnish a good succession for about six weeks, beginning with the first of summer.

Early Purple Guingue, Doctor, Boyer's Early Heart, American Heart, Knight's Early Black, Black Tartarian, Holland Biganean, Rockport Biganean, Black Eagle, Elton, Yellow Spanish or *Biganean, Downton, Mayduke, Downer's Late, Belle Magnifique, Plumstone Morello.*

GRAPES.

The American varieties are the only sorts, with one or two exceptions, which may be successfully cultivated in the open air, in many parts of the Union. The foreign varieties mature in great perfection, if sheltered by a glazed house, either with or without fire heat. The best American grapes for the North, *Diana* and *Isabella;* for the Middle and Western States, *Isabella* and *Catawba.*

The limits of this article preclude a particular account of the management and treatment of hardy grapes. It may be sufficient to observe, that, like fruit-trees, they need a deep, loose, and fertile soil; and that, unless annually pruned down, so as to give shoots not older than the second summer for bearing the crop, neither high quality nor productiveness can be maintained.

Grapes may be preserved for months, if simply packed in kiln-dried sawdust, in close boxes or casks, and kept in a cool place.

SMALL GARDEN FRUIT.

A very copious supply of table delicacies may be obtained for the first half of the summer, by a few rods of ground planted with strawberries, raspberries, and currants.

STRAWBERRIES,

Under good management, will yield twenty quarts or more to the square rod. They should be kept cultivated in drills or strips, treating the runners as weeds; and after having stood in this way for two years, the runners should be allowed to fill up the previously cultivated strips or spaces, and then the old rows are to be spaded in. By this treatment, we get new plantations without the labor of setting out the plants.

Strawberries are of two kinds, *staminate* and *pistillate;* the latter cannot be relied on for good crops without the fertilizing presence of the former, but, with their presence, they are usually the best. Hence, wherever a pistillate sort occupies a bed, there should be another bed, or at least one row, of some staminate variety, side by side, and separate by an alley of a few feet wide, to prevent the sorts mixing by runners.

The best staminate sorts are the *Large Early Scarlet* and *Boston Pine*; the best pistillates are *Burr's New Pine*, *Hovey's Seedling*, *Old* or *Cincinnati Hudson*, and, in some localities, the *Black Prince*.

CURRANTS

May be greatly improved and more than doubled in size, by enriching cultivation, and by a sufficient pruning annually to keep the shoots from becoming crowded or stunted. The best varieties are the *Red* and the *White Dutch*, and there are some newer sorts of considerable celebrity; but even the old red and white currants, under the best management, will far excel any of them treated with neglect.

RASPBERRIES.

The best are the *Red Antwerp*, (if genuine,) the *Fastolff*, and the *Franconia*. These all need a deep, rich, and sufficiently moist soil. Where the ground is gravelly, and liable to suffer from drought, it should be deeply enriched, and the plants mulched during the season of ripening. Raspberries are greatly improved on gravelly land by *irrigation* in connection with mulching. We have known the stems to make triple the growth in a summer when thus treated, compared with others managed in the ordinary way.

RAISING FRUIT FOR MARKET.

The reader's attention has hitherto been directed to the supply which each family may afford itself, by a well-planted and well-managed fruit garden and orchard. This is the most perfect mode of enjoying fruit; there is a freshness and a delicious flavor in such as becomes matured on the tree, and used when plucked with the fresh bloom upon its surface, covering the melting juice of richness within, not to be found in any gathered before fully ripe and conveyed to great distances. There is also a peculiar satisfaction in deriving this supply from the trees which one's own hand has planted and reared, and which have become an interesting appendage to a rural home.

But it is to be remembered that there are many families in towns and cities, and in some other localities, who cannot, from the nature of the case, raise their own fruit. These must depend, for these useful delicacies, upon the crops of those who furnish them for market. Hence, it becomes the interest of both cultivator and consumer that every facility should be offered for an abundant supply. There is, perhaps, but one kind of fruit that has reached a desired extent in culture for this purpose—the peach. The first extensive orchard of this fruit, which was planted by Reeves and Ridgway, in Delaware, occupying 120 acres, proved highly profitable when prices were high. In one year, when the fruit sold from one and a half to five dollars per bushel, their gross sales were about sixteen thousand dollars. Since prices have fallen, a less sum has been obtained from the thousand acres occupied by the Reybolds, of that State, whose crops give constant employment during the selling season to a schooner and two steamboats. There are other fruits which have afforded heavy profits in market. A single orchardist on the Hudson is said to have sold *twelve thousand* dollars, worth of Newtown pippins in a year, a large part of which were sent to London and Liverpool. C. A. Cable, of Cleveland, obtained, in 1845, from an orchard of one hundred cherry-trees, twenty years old, more than one thousand dollars. An extensive cultivator of the grape, above New York city, has obtained several thousand dollars per annum by the sale of the crop, after kept till winter.

The strawberry has been raised only at Cincinnati in sufficient quantities to supply the demands of all. Two hundred bushels per day as an average for the whole strawberry season, or four thousand bushels in the aggregate, have been sold in that city in one year. One cultivator alone sent in one hundred and twenty-five bushels in a day, requiring sixty hands to gather them.

The great number of trees which have been set out in all parts of the country, have led many to the inquiry, "Will prices be maintained? Will not the market be surfeited?" To answer these questions, let us glance at a few facts.

Perhaps the only instances which have already occurred of a fall in prices, are the peaches of the Eastern cities, and the strawberries at Cincinnati. But these are both perishable fruits—they must be consumed as soon as purchased, or else be lost. Fifty times the amount of *keeping* fruit would find consumers, for it may remain on hand for a month together. But a single city no longer becomes the limited market for long keepers; the whole country is open; and no night-and-day labors are needed to bring them into market before decay seizes them. Railroads and canals will carry them to any part of the Union—steamships will transport them to the millions of Europe. The only requisite is so to cheapen the supply that all may enjoy them. The Newtown pippin has already found its way to the London markets; but the present amount, compared with the quantities destined to flow there, when orchards are profusely multiplied and facilities for conveyance increase, are but as the dripping rill to the mighty river. The price of good winter-apples through the great apple region, Western New York, has rather advanced than fallen during the past thirty years; but it has been shown, in a former part of this article, that even at half the present prices, orchards would be eminently remunerative. How long it may be before such a result takes place, while hungry millions for the whole hungry year are ready to consume them, is very uncertain.

We may, therefore, safely conclude that the time has not yet arrived for land-owners to withdraw their attention to an increase of their orchards; and while the population of the country and facilities for conveyance are multiplying so rapidly, no investment is likely to prove more permanently profitable or beneficial to the public at large.

It is easy to give a list of varieties for the private garden, but much more difficult to name those which may be best for market in all localities. There are so many circumstances to be considered in adapting the supply to the public demand, that no person can well undertake it, with the greatest prospect of success, without a previous thorough acquaintance with the best varities, to be obtained only by their actual cultivation on his ground, and from observation.

MANAGEMENT OF WHEAT HARVEST.

BY EDMUND RUFFIN, ESQ., OF VIRGINIA.

In preparing the following statement, it was my purpose to present merely my own practice and the opinions founded thereon; and not the practices or opinions of other farmers, whether better or worse, unless by special reference. Neither do I presume to offer my practice as the best example for other farmers; but simply as the procedure which my circumstances have induced or compelled me to adopt, and which the general results have seemed to sanction or approve.

The proper time for reaping wheat is when the grains have just reached the "*doughy*" condition; or when they are so soft as to be easily mashed between the finger and thumb. The interior of the grain is then a soft, glutinous, adhesive pulp; but having no remains of the white fluid, or "milk," the presence of which indicates the preceding and too immature condition. But as no considerable space (if even the smallest spot) of wheat can have all the grain at once precisely in the same "dough state," I do not wait for it to be complete. It is safe to begin to reap when not more than one-tenth part of the heads (of latter growth) in any one place of sufficient size have still a little milk to exude from the mashed grains. And in the progress of reaping the more ripened wheat, the same indication and rule govern as to any greener spots or margins. The greener grain, still showing a very little milky fluid, and the pulp softer and less glutinous than of the "dough state," will doubtless lose something in shrinking. But such loss I have never found appreciable in the general result. When reaped in the proper "dough state," I do not believe there will be any loss of size or weight of the grains by shrinkage, more than if left standing until dry—while there is great gain from the earlier reaping, in forwarding and securing the harvest, and thereby avoiding the hazards of bad weather.

The thus reaping wheat as much as possible in so green a state, has been condemned by the opinions and even experiments of many farmers, some of whom I respect highly as authority. Most of such experiments were comparisons made of different heads of wheat, apparently equal in size or number of grains—or of certain larger numbers of grains separated, of two samples—the one cut off green, and the other suffered to stand until fully ripe and dry. All such results are liable to objections. 1st. It is very difficult, if not impossible, to make fair and accurate comparisons as to size and quantity of any two heads of wheat, the one cut off green, and the other left to stand until dry. 2d. Even if such comparison could be perfectly accurate, still it would be made of wheat saved from every damage or danger from bad weather—and not exposed, as a large part of every crop must necessarily be, even in the most favorable season for harvest.

Now, even if it were true (which however I do not admit or believe) that a head of wheat cut off in in the dough state lost something of the size and weight it *might* attain if left to stand until quite dry, and then secured without any damage from rain—still it might well be that such (possible) loss would be more than compensated in the avoiding, by early reaping, the heavier losses of wheat which *always* attend the latter part of a protracted harvest. This is the true question. Even with beginning to reap

wheat in the "dough state," it is rare that a full crop of wheat can be all secured before much waste has been suffered by over-ripeness, aggravated by bad weather. Under such impressions, I have not resorted to the tests of any comparative weighings or measurements, or particular experiments. But in my general experience of reaping thus early, extending from 1822 to 1851, I have never had reason to suppose that any loss, either general or particular (unless in the small proportion of "milky grains") has occurred. The general gain has been believed to be very considerable, and for every harvest; and one particular crop was by this early reaping nearly all saved, just in advance of a long rainy spell, which destroyed fully half of the neighboring crops, then mostly standing. This occurred nearly thirty years ago, when the general practice was to begin reaping later than is now usual on nearly all wheat-farms.*

Aiming then to reap wheat as early as is safe, the operation is usually begun as soon as the most forward spots, of a few acres in size, have reached the "dough state." Sometimes the straw and chaff are yellow, and riper in appearance than the grain; in other years, the green color of the plant and its sappy condition more or less remain. Different measures of time,

* From memoranda written at the time of the occurrences, I am enabled to state the days of beginning to reap wheat for a number of years. For the intervening years, omitted, no such note was made, or preserved. Coggins Farm, the first subject of my labors, is high, hilly, and mostly sandy land, on the south bank of James River, and about 24 miles S. E. from Richmond. Marlbourne Farm, 13 miles N. E. from Richmond, and on the south of the Pamunkey River, is low and flat land, the soil of various textures, but a large proportion very stiff. Vegetation generally, as well as the first ripening of wheat, is always some days more advanced on the former than the latter farm—though they are not more than 25 miles apart.

From 1822 to the present time, the same kind of wheat has been cultivated, first known as the "Mountain Purple straw," and more lately distinguished as the "Early Purple straw." During all this time, my usage and aim have been to begin to reap as soon as enough wheat had reached the "dough state." But a few of these beginnings (marked *a*, *a*) were not made quite so soon, because of the pressure of other work; and in some others, (*b*, *b*,) the ripening of wheat was much retarded by peculiarity of season or disease of the crop.

according to such different circumstances, will be required, previous to the subsequent operations of binding and putting the sheaves into "shocks."

I use for reaping only the scythe and cradle. Since coming to my present farm, I have had great difficulty in getting the wood-work of cradles made heavy enough. Cradles made as light as usual hereabout are more laborious to work in good wheat, and less efficient, than heavier cradles. My scythemen complained loudly of the lightness of the ordinary cradles, which I was compelled to use for several years.

When wheat through the country was generally a very light growth, the reapers were taught to catch the wheat cut by each sweep of the scythe, from the cradle with the left hand, and then let drop the handfuls on the ground. This was best for such very thin wheat. But for a heavy growth, it would be better if our men could empty the wheat from the cradle, or "strew" it regularly along the row, as is done in some other parts of the country. My practice, then, of "handing" the wheat from the cradle is not deemed the best, but is the result of the old and inveterate habits of the laborers. It would doubtless be an improvement if we could introduce here, for all heavy wheat, the "strewing" instead of "handing"—and also the cradles best suited for the former practice. Perhaps a still greater benefit may be found in the substitution of reaping-machines—which even now are used by most of the good farmers of my neighborhood. But because of their great liability to get out of order, the difficulties of working them, and especially my own ignorance of machinery, I have feared to attempt the use of a reaping-machine.

After getting into full operation, each reaper is followed immediately by a "binder," who ties up into sheaves all the wheat cut by the reaper. In light or ordinary wheat, this is light work for the binder. But it is heavy service, if well performed, in heavy wheat, or if following a scattering and wasteful reaper.

The wheat is thrown by the reaper, as "handed" from the cradle, in piles of one, two, or three handfuls together—evenly as may be, and the stalks lying at right angles to the direction of the reaper's row. Each binder carries in the right hand a very light wooden rake, with six teeth, and the handle 18 to 22 inches long, which is conveniently used to straighten and gather up the wheat for the sheaf, and also to rake up most of the scattered stalks. The sheaf is made no larger than a band, made of a single length of the stalks of wheat, can securely tie up; and, if the straw is very green, or moist with dew or rain, still smaller size of sheaves is required.

In the beginning of reaping, usually there is not much wheat ripe enough, and there is no need for the most rapid work; and the perfect safety of the first reaped wheat is more important than greater speed in the progress of the work. Then, contrary to the later and general practice, the reaping sometimes proceeds some hours in advance of the binding. When so separated from the reapers, the binders always work much more slowly. But this loss can then be submitted to, for the attendant benefits of giving some time for the straw (and any intermixture of weeds) to wither, and partially dry by exposure before binding. The bands then tie better; and, as the green straw has then withered and shrunk somewhat, the band will not become so much looser afterwards, by the further drying of the sheaf.

The sheaves are left lying on the ground, in the rows where bound, but none in the water-furrows. There they remain, in the beginning of harvest, and, if rain is not threatened, from 3 to 8 hours (besides the whole night, if intervening) after the binding—or about a day later than the reaping—when the sheaves are brought together and put into "shocks" or "hand-stacks." The delay of this operation (and which is only permitted for wheat still green, and also in settled fair weather) permits the wheat to dry something more, and thereby is safer from becoming mouldy in the centre of the shock. The sheaves also are of less weight to the bearers, (who are mostly small hands,) and they stand more firmly in the shock. If an unexpected rain should occur, there will rarely be any damage done to sheaves caught lying on the ground—and still more rarely if the wheat is green and fresh. And this observation applies to sheaves so caught by rain, in any state of dryness and any later time of harvest. If the earth is dry, and absorbs the rain as it falls, so that none shall continue to soak any heads of wheat—and if the rain, even if heavy, does not last more than a few hours—the sheaves will mostly dry as they lie, and without any damage. This result has been found after (undesigned) exposure for 8 days, during which a heavy rain had fallen, and had cleared off. But much delay and risk of exposure to rain need not be permitted. Should a drenching or long-continued rain catch sheaves lying on the ground, they should be soon afterwards set up in small "stooks" of 4 to 9 sheaves each. They will dry in that state, if drying weather follows: if the weather continues damp, the stooks must be shifted, so that the wet sides of the sheaves shall be turned to the outside of the stook. But such damage, or any danger of such, has never occurred to me, except in the remarkably wet harvest of 1846. Then, and in any such long-continued wet weather, no method and no precautions can prevent great loss. Then, indeed, the sheaves sprouted when left only 24 hours on the thoroughly wet ground. But also in stooks previously set up, and even in the still standing stalks, much of the grain sprouted.

The things most important for the perfection of harvest-labors are: 1st. That the wheat shall be cut well, and laid evenly and regularly by the reapers; 2d. That the binders shall gather up the wheat without too much scattering and waste, and tie the sheaves securely; and, 3d. That the shocks are built and roofed over well, so as to stand erect, and to exclude rain. Of course, there must be more or less of short-comings in the efforts to reach all these desired ends.

The operations of reaping and binding need not be described, and, indeed, would scarcely admit of description. As to the building of shocks, perhaps directions may be advantageously given to those who need such instruction. My own heavy early losses, which were suffered from my want of knowing how to build shocks, would be enough to impress on me the importance of better knowledge. And even at this much later time of generally improved practice in harvest operations, there are more than half the farms in Lower Virginia where a wheat-shock has never yet been properly built.

It formerly was my usage, as it still is of some other and better farmers, to put all the sheaves, (of green wheat,) as fast as bound up, into "stooks" of 8 or 10 sheaves each. These stooks are made by setting 3 sheaves on their stubble ends, about 12 or 15 inches apart, on the ground, and forming, by their position, a triangle—the heads of the sheaves being brought together to a central point. Then 8 other sheaves are set around and in close contact, each one on the ground, at the opening between two of the inner 3 sheaves. A few more may be added, to the outside, to give proper size and shape, as desired, to suit the weather. Each stook, when finished, presents, roughly, the shape of a small cone. In such stooks, the wheat will usually cure well; and, after a day or two of good weather, may be put into shocks of the largest convenient size.

But I object to, and have abandoned this plan of general stooking, (for green wheat,) because of the labor of twice handling and moving, and the greater waste, by shedding stalks from the sheaves, in these handlings. If the weather should be good, the sheaves would be as safe if left lying separately on the ground. A light or transient, though much heavier rain, would not hurt the sheaves, either in stooks, or lying on the ground. If a storm of rain and wind occurred, the stooks would be nearly all overthrown, and the wheat would be but little safer than if the sheaves had been lying on the ground. And, in case of such a storm, or of any considerable rain, stooks may and ought afterwards to be set up, to permit the sheaves to dry. It does not often happen, from such an occurrence of heavy rain, that I lose any thing from the omission of building stooks before the rain occurs.

In beginning to build a "shock," the first 3 sheaves are set up as in putting up a stook. Others are set around the first, in a circular form, the "butts" or stubble ends of the sheaves, set firmly on the ground and close to the inner sheaves, and the heads pressed inward towards the central point. This foundation is thus continued to be enlarged until of sufficient size, (according to the length and dryness of the wheat.) This first part of the shock approaches in form a truncated obtuse cone. The inward inclined heads of the opposite outside sheaves are about 2½ to (for largest sizes) not more than 4 feet apart. The sheaves of the latter rounds should have been firmly pressed inward, and all set closely together, so as to be as compact as possible. The roofing is begun by setting the stubble end of a sheaf upon and partly into the bands of two of the outside sheaves; and so continuing a course around—putting each sheaf over the joining of two others below it, when spaces permit. These sheaves, forming the first course of the roof, have also their heads pressed inwards to the centre; and they are prevented from slipping down by some of the stubble ends of every sheaf sticking into the bands of the lower sheaves. This first course serves to reduce the amount of *cutting off* before exhibited, but still preserves the general form of a truncated cone, rising higher than before. Another course of sheaves is then laid on in the same way, rising still higher and approaching nearer to a point. The sheaves are laid on in the manner of shingles or slates to cover the roof of a house. Each sheaf covers the "break" between the two of the course below; and the heads of every sheaf are covered by the straw end of the next course above—so that no heads (except of the "cap") are exposed to rain, so long as the shock does not tumble, or lean so much as to disorder its roofing, and admit rain.

The last course carries the sheaves to a point, as high as the builder, standing on the ground, can well place them. The shock is then (or ought to be) nearly a perfect cone, of height greater than the diameter of the base. The last 6 or 8 sheaves used to bring the top to a point, should be of smaller size. And as the greenest wheat (occurring in spots) is bound into particularly small sheaves, these serve well for this topping. Moreover, by being so exposed to air, if put up as soon as reaped, these sheaves of green wheat will cure safely.

The "capping" and finishing of the shock is next to be done. For this, a very large sheaf is made, by tying a band of double length securely around and near to the stubble end of the wheat, put evenly together. The sheaf is then placed on the ground, resting on its stubble end, and so held while the laborer bends down at the band, and outward, all the stems, by handfuls, beginning at and around the outside, and so proceeding around until reaching the central stems. Being bent outward, the heads then are the outside of a circle, lying on the ground. In this flat outspread shape, the sheaf is lifted by a fork stuck into the tied part, as high as over the point of the shock, then placed thereon, reversed, so that the tied stubble end shall make the pointed top of the cap, and the loose stems of the cap-sheaf shall fall upon and cover all the upper part of the cone. The sheaf is properly adjusted; and some of the heads of wheat, hanging downward, are fastened into the bands of the underlying sheaves, on four opposite points, so as to prevent the cap being easily blown off by high winds. A light ladder, 3 to 4 feet long, set against the shock, will aid the capping of large shocks.

If properly so built, no heads of wheat will be exposed to rain, except those (hanging downward) of the cap-sheaf. And though these few are wetted by every rain, they are also so exposed to the air and sun, that they soon dry—and will keep sound in any but wet weather of unusually long continuance.

According to the size of such shocks, and to the quality of the crop, they will hold from 2 to 5 bushels of wheat; or more usually 2½ to 4. If the weather is threatening, and if sheaves are very green, or are actually somewhat moistened by rain or dew, it will be safe and proper to put up the wheat in small shocks. When this has been done for fear of worse weather, I have found both green wheat and damp sheaves to cure well. And in other cases, where no danger was feared, and less caution used, I have had both green wheat and wheat damp (from previous rain or dew) to become mouldy, in straw and chaff, in the middle of the shock; but without any other apparent damage to the grain than some discoloration. Some of the most mouldy heads, and still moist, as found when beginning to thrash wheat, were tried as to their power of germination; and of 100 such grains, 95 sprouted.

But, though wheat may thus bear to be shocked in a green and even in a wet state—and though it is expedient to do so in particular cases, when a worse condition is feared, from the continuance or threatened approach of wet weather—still I prefer to avoid such procedure in ordinary practice. It is not only necessary that wheat shall cure and dry finally and thoroughly in the shock, and free from damage in passing through its "sweating," (which every shock goes through,) but it is also very important that the wheat shall be dry as early as the time to begin threshing. If this operation has to be delayed, because the wheat is not then thoroughly dry, the completion will be late, and the shocks exposed to much more damage from a rainy spell.

The intervals of time, as above stated, between the reaping and the binding, and between the binding and the putting into shocks, are deemed proper, and allowed only in the early part of harvest, when the wheat is green—or afterwards, in case of wheat being reaped when moist with rain or dew. Of all these causes of danger, or damage, the moisture remaining from heavy dew seems to be the worst. The thinnest growing wheat, and still more if it is "dead-ripe," and therefore cuts badly when dry, should be reserved for reaping in the mornings, while dew remains. A light dew need not stop binding. But if there is heavy dew, and it is necessary to reap during its continuance, the wheat ought to lie long enough to nearly dry before being bound, and still longer before being put into shocks. The heaviest dew need not delay the building of shocks, of sheaves bound dry the preceding day—as their moisture will be only on the upper outside.

Having considered these subjects of exceptions to general operations, the latter, though far the more important in amount, can be despatched in fewer words.

Usually, before half the harvest labors are over, the remaining wheat is so ripe, by the time it can be reaped, that it may be shocked immediately. Much earlier, (if, indeed, not from the beginning,) the binding should have followed immediately after the reaping. After being thus brought together, there is thereafter permitted as little interval between these different operations as possible. Still, in settled fair weather, there will be no objection to there being enough sheaves left on the ground over-night to occupy all hands, except the reapers, in putting them into shocks, the next morning, during the continuance of dew too heavy to permit binding. At such times, the younger men not yet accustomed to reap may learn to use the cradle, in the lightest wheat.

When the labors of harvest are in regular progress, there is but little to be feared from rainy weather, except so far as it will delay the completion of the work, and injure the standing wheat. All the reaped wheat may be (if desired) safe in the shock within two hours after being cut down. If sudden rain threatens, by aid of the reapers and binders, all can be secured in half an hour. But the danger from delay of reaping, and of rain, to the yet standing and already fully-ripe wheat, is very great; and this danger is tenfold increased by a late beginning of harvest. By beginning to reap the wheat when green, there is an advance of 4 to 6 days gained; and, if afterwards interrupted, even for as long a time during the latter part of harvest, by a spell of rain, the farmer is then precisely where he would have been without that delay, if waiting at first for his wheat to be fully ripe and dry. On the other hand, if after so waiting, such a rainy spell were then to occur, the crop would be nearly destroyed. If not actually sprouted, the quality of the grain would be injured by every wetting and drying—and, even if not lodged in mass, the wheat would have its heads so turned down, that the loss in reaping would be enormous.

My harvest labors are too heavy for my limited force, and therefore they cannot be executed very perfectly. Especially, there is always great scatterings and waste of wheat by badly-operating cradles, or some awkward reapers, and which cannot be, or is not, raked up and saved by the binders. No laborers, either reapers or binders, worth having, can be hired here; and all who seek for such employment in harvest, studiously avoid all farms where there is any heavy growth to reap and no whisky is permitted to be used by the laborers. I have ceased to seek for or to obtain any aid of harvest hirelings.

To the foregoing general statements of practice and opinions, I will append the particular facts, as to weather and operations, of two different harvests. The statements are extracted (in substance) from my farm-journal. The entries concerning or indirectly relating to harvest operations or difficulties only will be presented. The two statements are selected from the number contained in my farm-journals, for the following reasons: Both the crops referred to were harvested within the few past years, so that most farmers may recollect the weather and other general circumstances of each time: In one of the cases, the harvest was remarkable for the worst weather I ever had to encounter; and through the other there was generally fine

weather, but the crop was unusually heavy, and the labors were protracted, and thereby the difficulties and risks much increased. A tabular statement of my latest harvest will also be added. The manner of proceeding, in all cases, agreed with the foregoing opinions and directions:

Harvest operations on Marlbourne Farm. Extracted from my Farm-journal. 1846.

[The spring season of 1846, to the end of May, had been generally and remarkably rainy.]

"*June* 1. Thick mist all forenoon. At night, heavy rain.

"3*d*. Driest and lightest part of corn-field just fit to be ploughed. [Continued generally cloudy, or misty, and cool, with some light rains in all the next five days.]

"9*th*. Slowly raining from 7 A. M. until late at night. Very cool.—The wheat seems ripe enough to begin to-morrow; but, in the very bad condition of the corn-field, I must give it another day's work before leaving it.

"10*th*. Still cloudy—and all day nothing but variations of thick mist, thin drizzle, or, in the cessations of both, damp and cold air. [Of course, better weather to begin harvest was waited for.]

"11*th*. Steady rain from last night to noon, making the corn-field everywhere too wet for working. Afternoon, began to reap wheat, as soon as the rain had dried from the straw. Continuing cloudy—and several scuds of misty drizzle, which did not cause any cessation of the work. Binding the wheat into sheaves, as fast as reaped, and setting up in stooks immediately after.

"12*th*. Raining heavily last night—and continued at intervals and slowly for nearly all day, though worse in forenoon. Notwithstanding, despairing of doing better by waiting, reaped and bound wheat about 6 hours of forenoon. Then, fearing to proceed, discharged the hands, because there was no other work for them. Never had I a corn-field so much needing both ploughing and weeding, and yet it is too wet to be touched, when weather ought to forbid reaping wheat. The condition of both crops, but especially the wheat, is awfully alarming. It is now nearly throughout just in the state to begin reaping; and, even if good weather were now to come, the wheat must lose much before the harvest can be entirely finished. But there is every prospect of bad weather continuing; and if so, of ruin to the crop, whether cut down wet, or left to stand, waiting for drier weather. Besides all the previous rains, and cloudy weather, there has not been any sunshine during the last five days, and there has been more or less rain on all of them.—Quite cold.

"13*th*. Steady rain, and sometimes falling heavily, from morning until noon—and showers at intervals afterwards, into the night. Thick damp air, or otherwise mist, at all other times. At 2 P. M. began to stook the sheaves cut and bound yesterday forenoon, which in part had been left on the ground when the hands were driven off by increase of rain. I supposed it did not matter whether the wheat lay on the ground, in sheaves, or was in stooks, for 24 hours only after being reaped, remaining wet in both cases, and the weather being so cool. But it was found that some of the wheat on the ground had already sprouted—and the same surprising and disastrous result may now well be expected for all, without a speedy change to drying weather. Even of the standing wheat the grains are much swollen by moisture, as if going on fast to sprout. Yet it was but in the dough state, and yesterday, if weather had permitted continuing to reap, J—— doubted whether there was enough wheat then ripe enough. As soon as the little stooking required was done, again discharged the hands, having no work for them. At late bed-time, still slowly raining.

"*Sunday*, 14*th*. Misty, cloudy, and always damp air until noon. Afterwards, some sunshine. Light scud of rain in evening, with threatening clouds and thunder. Turning warmer, found the sprouting progressing in all the stooks—and more in those of the wheat cut and sheaved wet on the 12th, and stooked on that and the following day. Would have thrown open the stooks to-day, if clear and settled weather. As it was, the risk was too great.

"There are numerous sprouted grains of the ripest *standing-wheat!* And all the sprouting is not so alarming as the apparent condition of all the other grain of the crop; which is so swollen and softened by the continued moisture, that it seems like wheat which has soaked in water for the purpose of making starch. And even if it should now dry soon enough to prevent further sprouting, I fear much that the gluten may be mostly converted to starch, to the great injury of the wheat for sale, and also to its power of germination. The damage is greatest in the ripest wheat. As my kind [a forward purple-straw, red-grain wheat] is 5 to 7 days earlier in ripening than any ordinary kind, (except the May and Mediterranean,) it is now just so much advanced towards injury or destruction, more than the later kinds.—Warm.

"15*th*. Threatening all day, but no rain. But even the expectation of rain is a serious impediment to the operations desired, under such difficulties. Began early to reap—and (for fear of more rain) binding immediately, and putting into shocks soon after. After dew was off, opened all the shocks, turned the inner and wetted sheaves outside, in new and smaller stooks—reducing the number of sheaves in each from 8 or 9 to 4 only. The sprouting very bad—and no drying yet of the interior of the wet sheaves. The grain of the standing wheat was still very soft this morning. But the sunshine dried it fast; and before night, some grains were shattering under the stroke of the scythe. If this day had also been rainy, the crop must have been nearly or quite ruined, by the general sprouting or later rotting of the wet grains. As it is, the loss is already great. Shocked nearly all the wheat reaped to-day. All that reaped before, remaining still exposed, and wet, in the small stooks.

"16*th*. Warm, and generally clear—but sometimes cloudy, and one very sudden and transient shower, which fortunately did no injury. Kept today's reaping shocked nearly up to the scythes, except the wheat cut early in the dew, which remained in stooks.

"17*th*. Finding that the wheat reaped wet would not dry in stooks of more than 4 or 5 sheaves, set up the sheaves singly. Shocked all the reaped wheat by night. The wheat cut on the 11th, when dry, has kept, and dried in the stooks, with but little sprouting or other damage; and with no other care than shifting the position of the sheaves on the 15th, and reducing the size of stooks from 8 or 9 to 4 or 5 sheaves. The wheat cut wet fared much worse, and was not entirely dry even after being to-day exposed in sheaves standing singly—though generally it is now fit for keeping in the small shocks into which it was put. Very hot sunshine, interrupted by passing clouds. At night, light rain.

"18*th*. Clear until afternoon, and hot. Then, heavy cloud, with severe thunder and lightning, and violent wind. Slow rain began at 5 P. M., which stopped reaping for two hours. Afterwards, reaped about an acre, in the rain, without binding. The building of shocks kept so near the scythes, that all was done by the time the rain began to fall steadily. But the furious wind, just before, had blown off some caps and top sheaves of other shocks, and I fear has done much damage.

"19*th*. The violent wind of yesterday has been more injurious than was anticipated. Many stalks of corn are broken off. The standing wheat before had more or less leaning from N. E., the direction of the previous storm. The wind of yesterday was from the opposite quarter; and it has reversed and increased the leaning of all the wheat, and has broken numerous stalks everywhere, so that the heads are too low to be saved in reaping. The caps, and even some of the roofing sheaves, of many shocks blown off, or displaced, which will require much trouble to repair.—Clear through greater part of the day. In afternoon, another heavy and alarming cloud, which, however, mostly passed by, causing only slow and light rain, from before 6 P. M. to dark. The day's previous reaping all shocked, and no wheat exposed, except the shocks damaged by the wind, and not yet repaired.

"20*th*. In afternoon, again heavy and alarming thunder-clouds, and rain in sight, falling along an extensive line, for two hours. Fortunately, none reached here until nearly dark, and then but a light shower. Nearly all the wheat shocked up to the reaping. The waste very great, owing to the dead-ripe and dry state of the wheat, and the numerous broken and bent stalks. There is, however, but little shattering of the grain, owing to its being so generally shrivelled and badly filled. This defect being caused by the quantity of rain during the growth, is greater where the land is lowest and richest, and the straw most luxuriant. The very thin 'stand' of the wheat also served greatly to increase this evil. [Nearly all the seed-wheat had been more or less injured by being washed in brine; and about one-fourth, or nearly, did not come up.]

"*Sunday*, 21*st*. Very cool since last evening's rain. This the first day without some rain since the beginning of harvest, and for some time before.

"22*d*. Still very cool. The waste in reaping increases with its causes, the dryness and broken down state of the wheat.

"23*d*. Strong north wind, and still very cool. Afternoon, rain falling in sight, but merely a light scud here, just before night.

"24*th*. The first moderately warm day, of late.

"25*th*. Finished reaping by night, and the building of shocks very nearly."

This crop yielded enough straw for more than 3000 bushels of grain. The actual product of wheat was 2432 bushels. The quantity of land is 201 acres. The laboring force of the farm was 24 hands of all kinds. Such of the house-servants as could be spared, (about 3,) aided in the labors of harvest. The whole field force was not throughout engaged in the harvest. The shocks were 850 in number, of which about 100, put up wet, were very small.

When threshing the crop, it did not appear that damage had occurred to any of the wheat, after its being put into shocks. This result was better than expected, from the unfavorable weather and condition of the wheat preceding the putting of some of it into shocks.

Harvest of 1848.

[The weather of the spring of 1848 had been good. No important disease or disaster had occurred to my wheat crop, which appeared very good for the land. It proved, indeed, to be a much better product of grain than I supposed during harvest. The crops of wheat generally were better that year than in any other known.]

"*June 7th.* Afternoon—began to reap wheat, with 8 cradles only. The wheat is barely ripe enough [i. e. in the 'dough state'] anywhere; and yet it is so generally near to that state, that I fear most of the crop will be dead-ripe, and wasting, before my small force can half get through the harvest. Strong north wind—and still continues very cool. Reaping equal to work of 1½ days of one man.

"*8th.* From 3 to 6 reapers, at different times, [4½ days work ?] Before night, brought the binding up to the reaping. Sheaves shocked up to wheat cut down 8 hours preceding the last reaping. 41 shocks. Wind northerly. This morning, the air seemed cold enough for frost—but none visible. Earth now very dry. Clouds threatening rain—but again clear before night.

"*9th.* Work of 7½ reapers. Day hot, but again cool at night. 40 shocks built. This work now a little more than a day behind the reaping.

"*10th.* Hazy and cloudy. At 10.30 A. M. slow drizzle began. Suspended reaping—and continued putting up shocks until 12 M., and also bound the wheat reaped and left unbound while wet with dew. Both operations hazardous. After a cessation of 3 hours, (during which the weather continued cloudy and damp, but not rainy,) returned to wheat, and shocked all remaining, and which was still quite damp. 174 shocks, mostly small. Those put up before the beginning of the rain were of good size, and some of them larger than usual.*—[8 reapers. 5 days' work of reaping ?]

"*Sunday*, 11*th.* Threatening clouds, but no rain.

"*12th.* 8 reapers. The building of shocks within 2½ hours of the reaping—and desired to be as near as possible. 98 shocks, of large size. Windy, cool, and clear.

"*13th.* Very cool morning, and strong north wind all day. The wheat has ripened rapidly. Though still green in low spots, much the greater proportion is quite ripe, and the straw dry. The heads are beginning to turn downwards. Yet but little more than one-fourth of the wheat land has been reaped. The work gets on slowly. The harvest will be long on hand, even with good weather; and a storm or a spell of rainy weather will cause great loss. 8½ reapers. 110 shocks put up—and within an hour's work of the reaping.

"*14th.* Strong N. W. wind impeded the reaping, and required the moving to more sheltered ground. 7½ reapers. 95 shocks.

"*15th.* Wind S. W. Very warm. 8 reapers—but two of them young beginners, in place of two good scythemen who are sick to-day. Wheat now dead-ripe—and where longest ripe, the heads bent downward. Began to reap the rankest growth, of which very little is lodged, owing to the very favorable weather. 83 shocks.

"*16th.* 8 reapers. Clear, still, and very warm. Straw now so dry and brittle as to be an impediment to tying the bands. Shattering of grain to-day for first time. 53 shocks. The first hot night (or indeed otherwise than cool) this summer.

"*17th.* Strong S. W. wind. Clouds threatening rain. Have now finished reaping nearly all the wheat or clover-fallow, which includes nearly all of the heavy growth. About half of the land in wheat now reaped. So far, all well secured, but all still to reap is in great peril. 96 shocks. [8 reapers ?]

"*Sunday*, 18*th.* Heavy shower. Loose tilled land wet about 2 inches deep. This refreshing to the growing crops, and I hope of not much damage to the wheat. But in its present state, every wetting must do some harm.

"*19th.* Strong southerly wind, impeding the reaping. Four several scuds of rain—which did not stop any of the work, though perhaps the shocking of the damp sheaves may be hazardous. 70 shocks—nearly up to the reaping. 9 reapers. Cool at night.

"*20th.* Nine reapers. 96 shocks. Last night, another hasty shower, which did not prevent binding and shocking this morning. Reaping lightest wheat every morning as long as there remains any effect of dew or dampness on the straw. Afterwards, the reaping moved to thick wheat. Very hot.

"*21st.* 9½ reapers. 79 shocks.

"*22d.* The first calm day for some time—and oppressively hot, even when clouds obscured the sun, as was the case for most of the day. 9 reapers. 77 shocks.

"*23d.* High S. wind. Reaping had to be moved to more sheltered ground. 10 reapers. 63 shocks. Rain threatening. So many heads of wheat now are turned downward, and the straw is so rigid and brittle, that the binding is difficult, and badly done. The topping of the shocks also made bad, by the outspread heads of the wheat in every sheaf, and the rigidness of the straw.

"*24th.* 8½ reapers. 73 shocks. North wind—and at night quite cool.

"*Monday, 26th.* Finished reaping at 1.30 P. M. 6 reapers to that time. [4 day's work.] 37 shocks.

"This has been the longest harvest I have ever gone through, but with the best weather ever known throughout harvest. If a heavy rain had occurred, the loss of wheat, from the delay of reaping, would have been very great."

When threshing, all the small shocks put up moist with rain, on the 10th, were found dry, and the wheat in good order. Some other and larger shocks, put up greener, and in dry weather, were mouldy in the middle—though there was no loss of grain.

The crop grew on 256 acres, (as estimated,) and made 5127 bushels. The shocks, 1289, averaged very nearly 4 bushels. The days' work of reaping are estimated at 125½—and the average of quantity of land for each was 2.04 acres; and of grain, 40.8 bushels. The farm hands, of all kinds, were 26, to which were added 5 house-servants—very nearly that whole force being engaged all the time in harvest labors.—*American Farmer.*

* None of this wheat, shocked after drizzle, and when damp, or but partially drying afterwards, was found damaged, at threshing-time.

REARING NEAT CATTLE.

Mr. D. S. Caldwell, of Essex county, Massachusetts, offers the following judicious remarks on the subject of feeding and weaning calves:

"The most defective branch of farm economy in New England that has come under my observation, is the treatment of calves under the age of four months old. Many stock-growers allow their calves to have all the milk of the dam until six or seven weeks old, (which is frequently all the food they need,) and the young animals eat little or no grass or hay. They are then suddenly weaned, before they have acquired the habit of eating solid food of any kind, and are reduced almost to the point of starving, from which they seldom, if ever, recover."

Mr. Caldwell estimates the cost of rearing a calf till it is three years old, in Essex county, at $26.50; and the animal must be large and in good condition to bring the money. "Ordinary cattle," he remarks, "do not pay for raising, where pasturage is so high as in this vicinity, and most farmers have nearly abandoned the business. To learn calves to eat grass, hay, roots, or meal, at an early age, it is recommended to give them about half feed in milk, say at the age of three or four weeks, put finely cut roots into their mouths, and hold their mouths till they chew and swallow, or swallow without chewing, the food. In this way, a calf will soon acquire a taste for roots or meal, and eat of its own accord. One eating calf in a pen will soon learn others to do likewise. A calf should have milk till it is ten weeks old, and be gradually weaned. To allow a young animal to suffer from the lack of nutritious food is the worst possible economy, for it will be worth less when three years old, if poorly kept, than at two." By keeping his calves in a thriving condition during the first two years of their lives, Mr. Caldwell sells his two-year old heifers at from $22 to $25. In the spring of 1849, he sold three at the following prices: $30, $32.50, and $35. A three-year old heifer purchased by Mr. C., kept in the ordinary way the first year of her existence, brought only $26. A pair of three-year old steers, which had been used to the yoke two years, and not pampered, were worth $80. Their weight was 3040 pounds. Their extra keep, above ordinary young stock, did not exceed $10, while their labor had been worth $20 the past year. In the opinion of Mr. C., a given amount of food will yield more meat in a Durham than in any other breed of cattle. He says that "they make the best of oxen, but I cannot recommend them for milkers."

Mr. Geo. W. Drisko, of Washington county, Maine, says that upwards of 12,000 cattle were received at Cambridge market, Mass., from the western and central counties of Maine, during the year ending November 1st, 1850. This business has sprung up since the construction of the railroad from Boston into Maine, and it is likely to increase. There are many districts in which it will pay well to rear superior milkers, beef-cattle, and working-oxen; where the growing of ordinary stock is a losing business. Every close observer, who has paid attention to this subject, must know that the necessary cost of breeding fine animals and bringing them to maturity, does not exceed that of producing indifferent ones of equal weight; and yet, a good cow sells readily at three times the price of a poor one, and then yields a better profit to the purchaser than the latter. Beef-cattle, which furnish the butcher little besides heads and horns, legs and viscera, although a vast

quantity of food was consumed to form this mass of offal, are dear at any price. Farmers have too long and too generally neglected the art of breeding and keeping domestic animals. This branch of rural industry affords little profit to a majority of agriculturists, simply because it is not properly attended to. In Belgium, it is the general practice to market beef-cattle at two years of age—experience having taught the important truth that young growing animals give a larger return in meat for any given amount of food than adults can possibly yield. A steer, which is 1000 days old, should have a live weight of 1500 pounds. In rearing calves from dairy-cows, they should be fed on buttermilk and skim-milk sweetened with molasses. This saccharine substance is the best substitute for the butter taken from their mother's milk. A small quantity of molasses will answer the purposes of the animal economy. A gruel, made by boiling a little corn, oat, or barley-meal, is excellent feed for calves, and will pay a round profit, if the animals are worth raising. Pea and bean porridge are admirably adapted to promote the growth of calves. In England, it is a common practice to rear two calves on a single cow; a plan that is adopted by many in this country. At the South and West, calves and cows herd together, and, with care and good keep, fine stock may grow in this way. But the misfortune is, where cattle can be reared at so little expense, they receive scarcely any attention; and by propagating from inferior animals of both sexes, the herd soon degenerates. Cattle that have to pick up a precarious living the year round where they can find it, always deteriorate. By regular feeding 365 days in a year, or securing good keep and care, as to salt, water, shelter, and propagation, one's stock may be constantly improving. Too little pains are taken to provide fresh pastures for neat stock, horses, and mules, and in making good winter forage. Considered as a whole, three-fourths of the meadows in the United States are suffering a gradual exhaustion of the elements which form timothy, herds-grass, blue-grass, and clover. Not one farmer in ten thousand keeps an exact account of debit and credit in reference to the bone-earth and potash taken from any field in hay and grass, and restored to it in manure of any kind. If such an account were kept, the book would show that the soil parts with vastly more alkalies and other elements of crops, than it receives. Neat cattle should be so managed as to make this account balance.

Mr. Moses Coburn, of Whitewater, Walworth county, Wisconsin, says that the cost of rearing steers until they are three years old, in that region, is about $8 each; at which age a pair of well-matched steers command $40. The usual price of good dairy-cows in the fall is about $15; in the spring, they sell at $20.

Mr. James D. Bell, of Walden, Vermont, who is in latitude 44½° north, on the Green Mountains, says that the cost of rearing neat cattle till three years old, is $15; at which age the usual price is $20. Cows are worth from $25 to $35 in the spring, and in the fall from $15 to $20. "Our farmers grow but few sheep or hogs. Some first-rate horses are reared. A dairy cow yields, on an average, 150 pounds of butter a year, which is worth 17 cents a pound. The culture of turnips, carrots, and beets is increasing. Potatoes were rotted somewhat in 1850; common yield, 150 bushels per acre; 500 have been grown in this town. Agricultural interest slowly but surely advancing."

Mr. Joseph W. Dudley, of Madison, Connecticut, says that it costs about $20 to rear a calf till it becomes three years old, and a steer at that age is worth $25. Value of good cows in the spring is from $35 to $40; in the fall, $25 to $30. Cows yield, on an average, 150 pounds butter per annum; cost of production 16 cents; average price, "one Yankee shilling."

Mr. C. A. Spalding, of Windham county, Connecticut, estimates the expense of rearing cattle till three years old, at $30; which are worth $30 to $35. Good cows sell in the spring at from $30 to $35; in the fall, $12 less. Feed is often poor, and cows average only 100 pounds of cheese, and 40 of butter; the former being made in warm, and the latter in cool weather. Mr. Daniel W. Alford, of Hartford, Connecticut, writes that cows yield 200 pounds of butter in a year; of cheese, the same quantity. Cost of producing butter, 12 cents; that of cheese not stated. Cost of rearing neat cattle till three years old, $18 a head; price from $20 to $30. Mr. R. P. Stevens, of Cerestown, Pennsylvania, estimates the expense of rearing neat stock until three years of age, at $20; and says that the average price at that age is $30. This indicates a good business in McKean county, which is well adapted to grazing. He remarks "that it is generally conceded that a given quantity of food will yield more meat in a Durham, or Devon, than in common stock, or our native breed." Mr. Prescott Cutting, of Worcester county, Massachusetts, writes that "considerable attention is paid in this section to the rearing of stock: our heifers for the dairy; steers for the yoke; and both, ultimately, for the shambles. Breeds, natives pretty well crossed with Durhams, and lately with Devons. I have no doubt that a given amount of feed will produce more beef in a Durham than in a native." "Cost of rearing till three years old, I should say, at least $25, and they usually bring about that price, (heifers,) and steers a little more. System of rearing, is to let the calf suck till 10 or 12 weeks old, then put them in good feed. It is bad economy to stint a calf during the early part of its life, for he seldom, if ever, recovers from the injury. Pains are taken to raise good milkers from our best cows." Our correspondent urges the importance of selecting a male from a family of superior milkers, instead of looking so particularly to his size and form, regardless of maternity. By careful selections of both sexes for a few generations, a distinct family may be formed, which, with care and good management as dairy-cows, will be much improved from the original stock.

Mr. Joseph Sibley, of West Rush, Monroe county, New York, says, "On no subject connected with agriculture is there so great a difference of opinion as on that of stock. With some, every thing that is *new* is the best. To be far-fetched and dear-bought establishes a reputation, regardless of all defects. I am of the opinion that farmers often deceive themselves; when they get an animal of a new breed, they give it altogether better keeping than their old breeds receive, and such usage renders the new better-looking and more productive: the new breed is credited with advantages which are really due to increased care and feeding. My own opinion is, that if as much pains had been taken with our native cattle as has been bestowed on the imported races for the last 20 years, the former would by this time be quite equal to the latter. The cattle generally imported into this country are from stock bred in England for the shambles, and for show, rather than profit. These races have been kept so high and so extravagantly fed, that high-keeping has become constitutional, and their offspring must be pampered, or they fall below our more hardy native

stock; and this result is witnessed where both are kept together, summer and winter, on something less than full feed."

Mr. Sibley says that apples are grown to feed hogs and cattle to a considerable extent, and that good eating-apples are a profitable market-crop. His communication bears date February 21st, 1851, and after this report is mainly completed. At that time, he had apples which weighed 24 ounces.

Mr. Lewis T. Hoyt, of Danbury, Connecticut, says that the average yearly produce of butter, per cow, is not less than 200 pounds; which is worth from 18 to 20 cents a pound. Good dairy-cows sell at from $30 to $40 in spring, and from $20 to $30 in fall.

In some remarks on the cost of rearing neat cattle, Mr. George Boyer, of Schuylkill county, Pennsylvania, advises agriculturists to raise colts instead of neat stock. He says that he has had 30 years experience in the business, and finds no difference in the expense of rearing a colt or steer, till three years old. At the age named, a colt will sell for $75 or $80; and a steer at less than a third of the money. Good blooded colts bring readily $100 apiece, when three years old; and sometimes $200 or $300. He adds, "I have paid more than the sums named for colts, and think the production of horses far more profitable to the farmer than to raise cattle."

Colonel B. F. Bridgeman, of Bledsoe county, Tennessee, writes that the cost of rearing heifers and steers until three years old is $7.50; and ten dollars is the price at which they are sold. Good dairy-cows are worth from $10 to $12. He says that 100 pounds of corn will produce from 10 to 12 pounds of beef; and that Durham cattle will yield more good beef from a given amount of feed than natives. In seeding for meadows or pastures, Colonel B. uses 2 gallons red-top, 3 gallons timothy, and 1½ to 2 gallons clover-seed per acre. This is a good mixture. He estimates the cost of growing hay at $6 per ton, which most farmers at the North will regard as high.

Mr. Turner Vaughan, of Wilson county, in the same State, writes that "the cost of rearing neat cattle until 3 years, is as follows: 1st year, $1; 2d year, $2; 3d year, $3. On my little farm, this can be and is done, and pays tolerably fair wages. A short time since, I sold 35 head, at the above-named age, for $181, and did very well." One hundred and eighty-one dollars, divided by 35, gives only a small fraction over $5.17 a head for three-year old steers; which shows how cheaply neat stock is grown in Wilson county. Mr. V. remarks: "I am pretty well fixed for this kind of work; my yearlings fodder themselves after this wise: I put ricks or stacks of hay on platforms 18 inches high, made of logs or fence-rails, in each of which are two tons of hay—if hay it may be called, being composed of millet, wheat, and oat-straw. My weaned calves stand around these stacks all winter, and eat as they like. When the weather is very hard, I give them coarse cornmeal, in little troughs, manufactured (ground) at a chunck of a horse-mill hard by, which serves as a shelter during winter. My mode of raising cattle is my own; and in it I find remarkable safety from disease—not losing 2 per cent. The great secrets are, good shelter in winter and high salting in summer. I buy my calves at $1.50 a head; so you see my grass and hay fed beef costs me less than 2 cents a pound, and my stall-fed less than 3½ cents. Good dairy-cows are worth $15. A given amount of food will produce more beef in a Durham, Devon, or Hereford, than in any indigenous or native animal. I deem it wrong to cut the ears of stock: keeping them inside of fences is better. My plan of castration (if it is mine) is most successful for all kinds of stock: I draw the testicle a few inches from the groin, clamp the spermatic chord with two sticks tied at one end, and cut it off close to the clamp; pour on a spoonful of tar, grease, and salt, kept warm; then sear the chord well, and take all off. The emasculated animals should be kept out of the rain till well; and in this way I lose *none*. I change bulls every two years. Beef is worth from 2 to 4 cents; green hides, 5 cents; dry, 10; tallow, 6 to 8. I keep my yearlings, milch-cows, and other neat stock, in separate fields in summer, and apartments in winter; and warm and comfortable in cold weather, as far as practicable. This division of *caste* and *size* prevents the strong from robbing the weak, and, by carefully sawing off the tip of the horn, no mischief is done."

THE PREPARATION AND USE OF MANURES.

BY DANIEL LEE, M. D.

All manures, from whatever source derived, should be regarded as part and parcel of the soil, and studied in that connection. It is usual to consider them under the heads of animal, vegetable, and mineral manures. Animal manures are either animal substances, like the flesh of a dead horse or sheep, or the excrements of animals, voided by the bowels and kidneys. Vegetable manures differ from the dung and urine of herbivorous animals in being less concentrated, and containing in a given weight more carbon (coal) and more of the elements of water, (oxygen and hydrogen.) Decaying vegetables, not consumed by animals, yield vegetable manures. Mineral manures differ from both animal and vegetable in being in a wholly disorganized state, like gypsum, burnt bones, wood-ashes, ammonia, and carbonic acid. Of all animal manures, the excrements of dunghill-fowls and sea-birds, called guano, approximate nearest to those which are minerals, or in a disorganized condition. Comparatively speaking, guano contains very little carbon and oxygen, and a large percentage of nitrogen and phosphorus.

In no department of rural economy is American labor more unskilfully expended than in the collection and use of manures. This arises partly from the low price of crops, which discourages the critical study of fertilizers, and partly from the lack of good schools and experimental farms for teaching such labor-saving processes as may be best adapted to the peculiar circumstances of the cultivators of the soil in the several States. Different crops, prices, soils, climates, and variations in value and kind of farm labor, all modify practice, and render the effort to lay down general rules in manure-making exceedingly difficult and hazardous. We shall venture, however, to indicate two or three plans for collecting and applying manures, which experience has shown to be highly advantageous.

In all cases where it can conveniently be done, domestic animals should be fed under a shelter of some kind, to protect them from the sun and rains of summer, and the cold and storms of winter. In this way, their droppings may easily be gathered into heaps, keeping the dung and urine together, and both from loss by volatilization, and protecting the mass from the washings of rain or snow water, and natural drainage. Where manure has to be hauled any considerable distance, it is bad policy to add weight to it by applying water with the view to promote fermentation or the rotting of the heap. Suppose one has ten tons of dry straw or cornstalks, it will not pay to add, as is often done, forty tons of rain-water, so that the farmer actually hauls four tons of simple water into his distant fields to convey thither one ton of vegetable matter. If one's soil is so dry that straw and cornstalks will not readily decay when ploughed in, sound economy dictates the making of all compost-heaps in the fields where the manure is to be used. This will save the hauling of an immense quantity of water; for every ingredient used in making the compost may go into the field in a dry state. Leached or dripped ashes should be well dried to diminish their weight before hauling; the same remark will apply to swamp-muck or mud, to forest-leaves, straw, and trash of every kind. Rains are expected to supply the necessary amount of water; although it will often pay to dig wells in fields to have water for this purpose and for stock in all coming time. A large reservoir, dug in the ground, and made tight by water-lime cement or good clay, to hold surface-water in case living water is not readily attainable, will pay a good interest on its cost. The excrements of domestic animals, particularly their urine, will hasten the decomposition of coarse straw, stalks, and muck; but it is better to haul the dung and urine of domestic animals to distant compost-heaps than so many tons of valueless water. Without the admixture of the excreta of animals, all vegetable substances placed in the compost-heap will rot, and stable-manure may be more economically applied directly to the land that needs it. As a general rule, the sooner a plant designed to fertilize the soil is buried in it, the better. It can never yield a larger quantity of carbon, hydrogen, nitrogen, oxygen, or earthy salts, by passing through the digestive organs of any animal, or by lying a day or a year in a manure or compost-heap. In case one has poor land, and desires to produce a large crop in a few weeks or months, as in market-gardening, then the previous rotting of manure or vegetable substances is indispensable to feed many growing plants up to the highest point of vegetable nutrition. But on fair soils, in common field culture, this great labor of preparing food for crops is unwise husbandry. Let the entire decomposition take place in the soil, as is witnessed when clover, peas, or other plants are turned under with the plough. If it was convenient, all the droppings of animals should be immediately covered in the soils which most lack fertility; for they will lose more than they can gain by keeping above-ground. But so speedy and constant an application of manures would interfere with other necessary labors on the farm, and hence the safe-keeping of fertilizers until needed is a matter of importance. It is excellent economy to provide a bed of dry straw, forest-leaves, or peat, to absorb all the urine of domestic animals. In what is called "box-feeding," both the dung and urine of fatting oxen, sheep, and hogs are intimately mixed with straw, or some other good absorbent, and trodden under the feet of the animals. As the latter consume meal and roots, their excreta are obviously rich in the elements of fertility. The animal is turned loose in a small pen or box, being fed regularly and well supplied with litter for bedding. The mass of manure thus formed is rarely disturbed until it is applied to the ground, either as a top-dressing or to be mingled with tilled earth. As a general rule, it is desirable to cover manure with from three to nine inches of soil. If it is light, porous, and sandy, manure should be buried deep; if compact and impervions, a covering of two or three inches will suffice to retain all gaseous elements. Manure moves both downward and upward, as well as laterally, in tilled ground, and therefore on a medium soil it should be placed midway in the earth stirred with the plough. If the ground is broken ten inches deep, five inches of the soil should lie above the manure, and five below it.

All organic and mineral fertilizers dissolved in water will enter so far into a chemical combination with the soil when applied to it in irrigation, that nothing will be lost by atmospheric and solar influences, unless the quantity applied per square rod is needlessly large. This speedy and thorough incorporation of fertilizing substances with the soil when dissolved, has led many to attempt the complete solution of manure before it is applied to the land, knowing that it cannot enter the roots of plants to nourish them before it is dissolved in water, or reduced to a gaseous state. By bringing all fertilizers made in stables and yards into a liquid form, the manure is easily conveyed in wooden pump-logs or pipes made of burnt clay into the several fields on the farm. If the fields are lower than the barn or stable, the water will run to them in pipes by its own gravity; and if higher, horse-power or a small steam-engine will force the liquid up to their level. Operations of this kind are successfully practised in England. Hose is used to distribute the water over the surface in the fields; and thus they are both manured and irrigated at such times as the applications will do the most good.

REMARKS ON DAIRY COWS, &c.

BY H. S. JOHNSON, CANTON, N. Y.

Every dairyman should raise his own cows. In purchasing, it is not always easy to obtain cows of the best quality, and, where such can be bought, the outlay is so considerable, that, as a general rule, it is not advisable for the farmer to incur the expense. It will be more economical to wait two or three years, in which time he can raise them. The farmer will not feel the expense of raising ten, fifteen, or twenty cows from calves as he will the outlay of buying that number. Add to this, he is more sure to raise good cows than he is to get them by purchase. Heifers well kept will generally come in the spring when they are two years old, and three such heifers will make as much butter or cheese the first season, and give milk, as two full-grown cows of the same quality.

Cows of a good constitution and well kept will improve till they are eight years old, and many will grow better for butter and cheese till they are ten or even twelve years old. Good healthy cows do not ordinarily diminish their dairy qualities till they pass their fourteenth year. I have kept some cows till they were sixteen and even eighteen years old, without perceiving any falling off of their good dairy properties. From my experience, it is safe to keep good healthy cows in the dairy one milking season after they are fourteen years old.

I have a small dairy of twenty-two cows, all of which I raised from calves. Most of these gave milk at two years old. I do not allow my cows to go dry more than from six to eight weeks. December 20th:—We are now, in my family, making butter of the first quality for the table. Winter has been severe during the last four weeks: the cows are fed nothing but good hay. We milk every day at noon: at this time of the day we think we get more milk than we should at either night or morning, or at both night and morning. The milk is put into a common tin milk-strainer, then the strainer set into a vessel of boiling water over the fire, and allowed to heat till the milk is nearly scalded, when it is strained into pans and set in a warm stove-room for the cream to rise. About the second day, the cream is taken off, warmed to sixty-two degrees, and churned. It then churns in from ten to fifteen minutes, and the butter is good, rich, and yellow. By this means we make about half the amount of butter after winter has fairly set in that we do from the same cows in the months of September and October. My experience is, that, by this management, cows are quite as good for the dairy the following summer as though they had gone dry three or even four months.

As far as my information extends, it is a common practice with dairymen to kill their calves at about seven days old. The practice deserves and should receive reprehension: it tends to prevent all improvement in cattle, and it yields no profit to its abettors. My practice is to select for raising all my early well-formed calves. These are allowed to suck from three days to a week, when they are taken away from the cow and fed with skim-milk. When they are about one month old, we put into each mess for a calf about one gill of shorts or oatmeal, increasing the quantity, as the calf grows older, to half a pint for each mess. When such a number of cows come in that we think it desirable to make cheese, we commence cheese making, and feed the calves with whey and shorts or oatmeal, instead of skim-milk; taking care to have the calves in plenty of good fresh grass for feed. The late calves we let suck all the milk of the cow till they are from four to five weeks old, when they are sold for veal. When I do not wish to keep my calves after they are weaned, which takes place when they are three months old, there is always a cash market for them of more than the cost to raise them to that period. By pursuing this course, the amount of our butter and cheese is not perceptibly diminished, and we are raising the best to take the place of such cows as require to be turned off for beef, and the means also are used to secure the most desirable improvement in cattle.

In selecting individuals for breeders to improve dairy-cows, horned cattle, and, indeed, other domestic animals, the farmer should not be governed by any one breed. The excellence of the animal should decide its claim to consideration. That animal should be selected which is the nearest to perfection.

The efforts to bring into notice particular breeds of imported animals is doing much good to the agricultural interest, and great praise is due to those worthy men who have embarked in the enterprise. They should be encouraged to continue their philanthropic exertions. But then for every farmer there is something practical about this business. His interest is to select for breeding the most excellent animals, irrespective of every other claim. Perhaps it is not temerity to suppose that, as a people, there is a kind of propensity among us to follow some fashionable course in the selection of our breeds of domestic animals. Hence the introduction of a popular breed is often attended by a prevailing mania of greater or less intensity, according to the prices paid for these new animals. In the hurry which takes place to obtain the favorite breed first, trifling and accidental tests of excellence are established, and it would be difficult to decide whether the produced progeny owe their celebrity to the enthusiasm or empiricism of buyers and sellers. Trifling distinctive marks may, to a certain extent, present indicia of a breed or variety; but the shadow should not, as is too often the case, be mistaken for the substance. An animal may possess the slight peculiarities of a breed, without any of its excellences. In forming an estimate of the qualities of an individual, the marks of resemblance should not be regarded to the exclusion of excellences. Even pedigrees, without excellence, are of little value; and when they are puffed about, appended with lofty-sounding names, to give celebrity to inferiority, they are ridiculous.

Such are some of the leading considerations which should influence the discreet farmer to make his experiments with known and established traits of real worth. I take the liberty to offer a suggestion for the consideration of those desirous to improve dairy-cows. There is a breed of cattle, which have long been known in England and Scotland for the richness of their milk and the valuable flavour which it imparts to cheese. These properties are so well known, that many of the most eminent dairymen keep a few of them for this specific object. They are a small, hardy breed, with few properties to recommend them for beef or market, except that they are easy to keep, even thriving where other cattle would starve. Some of them have been imported into this country; but, so far as I am informed, they have not met with great favor, on account of being small. The prevailing taste is for large cattle. It will be understood that I allude to the breed called Alderney cattle. Now, would not a cross of these Alderneys with such stock as we have, be likely to be an improvement for dairy-cows? Did I know where to obtain a pure-blooded sire, I would try the experiment.

MANURE.

The subject of manure is one of unlimited importance to every farmer. There was a time when the fancied elixir of life drew the arrested attention of the nations. Its supposed value was all-engrossing. Happily for the world, the dark shades of that night of ignorance have retired. But still subjects that are perceived to be of high importance engross the minds and become the chosen hobbies of men. Not unfrequently the élite and the savans enter the arena and contend for the prize. The efforts to discover hidden truths or bring to light occult science not unfrequently exert an influence which conducts unthinking and bewildered men so far astray, that they either neglect their own interest, or else pursue it with such inappropriate means as are sure to defeat their most assiduous efforts.

But what bearing have these remarks on the humble subject of manure for the farm? Reflect, and you will perceive that they are not altogether inappropriate. By at least common consent, the subject of manure is admitted to be the foundation of agricultural prosperity. This is the true state of the case in both Europe and America. The admitted importance of manure to successful farming is so great, that the most laborious investigations of science are directed to it. Men deservedly in the highest ranks of talent and literature are bestowing upon it their untiring labors. On this subject, several of the most learned men that ever enlightened and adorned any age or country are gathering their most unfading laurels. In our own land, many of the first scholars of the age are awakened and electrified by

the commanding importance of this rustic subject. So far, all is well. Noble minds, men of undying fame, are in this particular giving their labors to a subject every way worthy of their regard. To increase the comforts and multiply the food for a world is no trifling concern.

This class of scientific men are exerting a wide influence—an influence that affects every agricultural society and every agricultural paper. Though their labors have developed many important truths and disclosed much valuable information, yet they have but just entered the wide field which opens before them, and much that they have communicated is theory, and not fact. Experiments, testing the true value of different kinds of manure, have as yet been very imperfect and unsatisfactory. After all that has been obtained, our knowledge on this subject is still in its infancy. There is some reason to apprehend that agriculturists may be so infatuated by the many theories as idly to seek after some substance for manure, as men formerly sought the philosopher's stone, or else, amid perplexity, to conclude that all is fancy, and leave their fields to barrenness and decay.

The farmer should be very cautious in regard to what some have been pleased to denominate special manure, and others, concentrated manure. This consists in burning the materials and using the ashes to enrich the land. No doubt such ashes, or any ashes judiciously employed, are a good fertilizer. But is there not a loss in the process of burning? Every man, who has been at all conversant with clearing new land, knows that, in a very dry time, there is danger of burning such land too much. When all the vegetable matter is consumed by the fire in clearing, there may be one fair crop after it, but the land will be rendered barren and subject to moss for a long term of years. The prairies of the West are rendered productive by partially burning the vegetable surface. But burn deep, consume all the accumulation of vegetables, and barrenness will succeed. Men of experience in clearing land are cautious about burning deep even green-timbered lands. If the farmer wishes to increase the efficiency of his manure, let him haul marl, clay, and leached ashes on his sandy land, but let him by no means burn his manure-heap, nor suffer it to become dry by fermenting.

To the farmer it is important that the investigations of agricultural chemistry should proceed. The farmer should wait patiently for the result of those labors, and, as fast as facts are established, he should profit by them. In the mean time, he should be diligent in using the means which all experience, since the earth began to be cultivated, proves will enrich his fields and increase the reward of his toil. Notwithstanding all that has been written on agricultural chemistry by the venerated names of Sir Humphrey Davy, Lampadius, Goeppert, Sprengel, Liebig, Fresenius, Boussingault, and numerous other worthies in both Europe and America, still it is clear that one of the best substances to enrich the land and increase the crop,—one upon which every farmer may rely with unwavering safety, is barn-yard manure. As a farmer, here lies his pearl of great price—here his mine of gold. Nor does he need another Solomon to instruct him how to use it. All that is needed is care and effort to accumulate it, discretion in preserving it, a liberal hand and common sense to spread it on his fields.

Twenty-five head of cattle will, in this climate, with proper care, make one hundred cords of manure during the foddering season. This, spread on eight acres, will cause each acre to yield fifty bushels of corn—that is, on land, which, without manure, would not produce more than twenty or twenty-five bushels to the acre. Thus there would be a clear gain of two hundred bushels of corn the first year, with no additional expense, only that of putting the manure on the land. The second year, the same manure would equally benefit a wheat-crop or some other grain. Nor would the manure then be exhausted. The land would still be in a good condition for grass or clover. Where corn is worth fifty cents the bushel, the farmer may with safety estimate each cord of his barn-yard manure worth to him at least two dollars in cash, besides keeping his farm in a productive state. The farmer who saves his manure with care and applies it with common sense will steer his course with safety, and not be lost on a barren waste. But neglect manure, and no part of the world can continue fertile under the exhausting process of agriculture. If, without manure, the father obtains good crops, he will surely leave desolation and poverty to his sons. Here is a case where the iniquity of the fathers is visited upon the children.

It then becomes a matter of no small interest to inquire what are some of the means well adapted to accumulate and preserve manure. The farmer should stable all his cattle during the foddering season. His stables should all be prepared with tanks or vats under them, to receive all the liquid secretions from his cattle. Into these vats should be thrown, in the fall, a quantity of some suitable substance to absorb and retain the liquids. This putting into the vats some absorbent should be repeated two or more times during the winter. He should also have a good yard connected with his stables, in which his cattle may run in the daytime, when out of the stables. His yard should be covered to the depth of six inches or more, in the fall, with swamp-muck, with leaves from the forest, with any turf from the highway or from his headlands. By lying in his yard during the winter, and being mixed with the droppings of his cattle, any of these substances will be as good in the spring as common barn-yard manure. All the coarse remains of the fodder, which the stock refuse to eat, should be thrown into the tanks under the stables; the manure from the stables should be thrown into heaps, and sheltered from the rains and snows, to preserve it from leaching; all the weeds on the farm, of every kind, should be collected while green, and piled in the yard for manure. The farmer's hogs should be kept at work making manure. Their pen should be so constructed that there will be a hog-laboratory in one part of it. In this apartment should often be placed swamp-muck, turf, or straw, all of which the hogs will manufacture into first rate manure during the season. They will work diligently if occasionally encouraged with a little corn and other grain sprinkled over their task, and provided they have a clean, dry place to which they can retire for rest after hard fatigue. Each hog will produce at least one cord of manure in the course of the summer. The privy, also, should be constructed with a bin or portable box under the seat, with handles, so that two men can remove it, as occasion may require, and empty it on the manure heap. This box should be supplied with some absorbent material, and often be the recipient of a liberal supply of gypsum. Every animal that pertains to the farmer should assist in accumulating manure—the family, cattle, hogs and all. A well-regulated method of doing this will essentially contribute to the comfort and health of all, as well as secure the thrift of the farmer.

In the spring, every place that contains manure should be cleared of its contents for the benefit of the field. Farmers, who cautiously secure all the manure they can, use it discreetly, and exercise becoming economy, with the ordinary blessings of Him who rewards the diligent hand, will soon be able to live in palaces, become money-lenders, and enjoy the appellation of the nobility of America—not made noblemen by the ever-wavering breath of monarchy, but constituted *the nobility* by their skill with the plough and their success in producing bread for the hungry.

ROTATION OF CROPS.

A proper rotation of crops is very difficult to obtain, and of high importance to the farmer. A rotation adapted to one section may be entirely injudicious for another. It should be particularly adapted to the place where it is employed, so as to suit the soil, the climate, and the market. As these will vary in different localities, the farmer should exercise his judgment in arranging the rotation so as to secure the best means of enriching the farm, and take that course which will yield the most profitable returns for his labor. To obtain these results, the first principles upon which rotations are based should be brought into the account.

One principle never to be overlooked is, that every plant exhausts certain constituents of the soil on which it grows. Every plant obtains a part of its support from the soil and a part from the atmosphere; and hence every crop diminishes the fertility of the soil where the plant is removed from the field. But if allowed to remain on the soil they enrich it, for all that they abstract from the soil, with all they draw from the atmosphere, is given back again; and hence the noted fertility of lands on which the accumulated succession of vegetables have decayed during many years. But on the farm, the crop is generally removed, and hence the necessity of making a return by manuring, to prevent sterility. By constantly cropping, the most fertile fields will become unproductive and barren. In this way, most lands become unprofitable in a few years. Several of the most fertile sections of the State of New York have, in this way, been so far exhausted as not to yield a remunerating crop. Again: Different plants do not take from the soil the same elements; and hence a succession of the same crop must soon deprive the soil of certain parts which are essential to its growth, and it must languish, while some other crop, requiring different food, would flourish luxuriantly.

Nor should the farmer overlook the fact that some plants favor the growth of certain kinds of weeds more than others; chess and cockle flourish with wheat. Weeds peculiar to a particular crop multiply greatly when that crop is raised on the same land for many successive years. The same is also true in regard to certain kinds of destructive insects. The Hessian-fly and the weevil pursue the wheat-crop. The wireworm and the grub make their choice among the crops of the farmer, and multiply rapidly with a succession of what they have chosen.

Every farmer knows that some crops admit of a heavier application of manure than others. Broad-leaved succulent plants admit of abundance of manure. Corn, beets, and turnips are of this class; likewise grass for meadows and pasture, with most plants whose value depends mainly on the quantity of green growth. But the crops of smaller grain, such as barley, wheat and rye, may be so heavily manured as to cause a too luxuriant growth of straw at the expense of the grain. For this reason, in a rotation, the manure should be applied to such as are immediately benefited by a larger application. Corn and oats will derive more benefit from manure less decayed than wheat requires. A field heavily manured in the spring with manure made in the barn-yard during the winter, will produce a larger crop of corn or oats, and the next season yield as large a crop of spring wheat as it would had the manure been piled in the yard through one summer and then been spread on the field for wheat. The manure should always be put on the field as soon as may be after breaking up the sward, that it may be thoroughly spread and mixed with the soil. This item is of no little importance, for, by leaving fresh manure in bunches, unmixed with the soil, it yields little benefit to the plants, and, by increasing the drought, it has diminished instead of increasing the crop.

Farming, wisely conducted, is a continued succession of exhaustion and replenishing. The best method of replenishing the land should, in all rotations, be regarded as the leading object. The crop which brings the most money is not always the best. Not a few look only to immediate profit, and their management of the soil perfectly harmonizes with this one idea. Future fertility is disregarded; every thing possible is taken from the field and nothing returned to it—nothing done to restore its wasted energies—nothing to check the progress of exhaustion. If the farm, when new, was rich and fertile, it soon becomes barren and sterile, and the misguided occupant is ready to abandon the desolation which his improvidence has spread around him, and seek more fertile lands in a new country.

That these evils may all be avoided is certain, if a rotation of cropping can be secured, which shall afford a sufficient change in the draft made by the plants on the different elements of fertility in the soil, and which shall return to the soil as great a proportion of organic matter in manure as is taken from it. Of late years, it has been proved by many skilful farmers, that by the application of manures produced on the farm only, there has been a constant increase of fertility.

In forming a rotation, a number of particulars should be carefully considered:—1. To exhaust the soil the least that can be done. 2. Restore back to the soil as much manure as practicable. 3. Take that course which will best prepare the field for a future crop. 4. Prevent, as far as possible, the growth of weeds and the increase of insects. 5. Adapt the application of manure to the respective requirements of the different crops which are to follow. 6. Select the several crops so as to adapt them to soil, climate, and market.

For a three years course, the following is found to do well:—First year—Corn, well manured. Second year—Wheat. Third year—Clover.

This rotation brings round a return of the same crop so frequently that there will be danger of exhausting instead of increasing the fertility of the soil. A more extended rotation, like the following, would be preferable:—First year—Corn, oats, and roots, with plenty of manure. Second year—Barley, or peas, or both. Third year—Wheat. Fourth year—Clover, from two to three years.

It is needless to furnish specific examples of rotation. The principles above laid down will enable the cultivator to vary the crops for rotation as circumstances require. The more the subject is examined, the more deeply interesting will its investigation and application appear. A rotation, the same as given above, has tripled the products of many farms, and some, which were exhausted and abandoned, it has restored to fertility rivalling the rich districts of virgin soil. Let the farmer carefully examine the subject of rotation, exercise his judgment in its practical application, and he will guide his operations with precision and with increased profit.

That the farms will not now produce such abundant crops of wheat as they were accustomed to yield, has of late become the common complaint of agriculturists in the Northern and Eastern States. This complaint is well-founded—it is the language of fact. While the great mass consider this fact mysterious and inexplicable, it is one of the most obvious things in the world. It is the natural result of the negligent method of farming that has done it. The fields have been cropped without being replenished, till they are exhausted. There is no more propriety in this complaint than there would be in the case of the man who should complain that his team would not work while he neglected to feed them. Feed the team properly and fully, and it will work. Feed the field and subject it to a judicious rotation, and it will produce more than its former abundance. The same field may be constantly cropped, and yet constantly enriched with the refuse of its own productions. Let farmers perform their part faithfully, and there would be no worn-out lands as long as the world stands.

A PLEA FOR AGRICULTURE.

The most splendid superstructure has its foundation either on the earth or beneath its surface. Though what is high, magnificent, and imposing may engross the whole attention and monopolize the entire thoughts, yet it is the humble foundation which sustains the mighty edifice. So all the splendor and glory of these United States, which extort the admiration of the old world and constitute this the most desirable of all lands, are sustained by humble agriculture. There was once a city delivered from the invading forces of a powerful king by a poor wise man, and yet no one, we are told in the sequel, thought of that poor wise man, but forgot him. Is it not something so with our government in regard to agriculture? Very little, even next to nothing, is done for this prime essential interest. The accumulated millions of our national revenue are mostly expended for the benefit and protection of commerce, and by that means almost directly to advance the manufacturing interest, while only a few hundred dollars, through the instrumentality of the Patent Office, are doled out as a pittance, or perhaps a peace-offering, to agriculture.

Now it may be asked in soberness, is this course wise? Is it the dictate of impartial justice? Is it *republican* thus to neglect that interest which sustains all others?

Will not candor give a negative response to each and to all these interrogatories? The vast extent and exigencies of our country will constitute agriculture the greatest interest of the United States, until all our vacant lands are brought into cultivation and made to enrich and feed the teeming millions who must eventually have their homes here, until every frontier section is occupied by a dense population, who will make these waste lands yield wealth to the nation, and be able to defend the borders in case of an invasion. Nor can a town, city, or village be built up and sustained otherwise than as rustic farmers become pioneers to provide them food. Neither does it require the eyes of an Argus to perceive that by the neglect of agriculture our country has already sustained some serious detriment. Under governmental neglect, agriculture has either sunk or remained in disrepute. While commerce has been the chief pet of the government, it has, with all its appendages, been regarded as replete with honor. As a consequence, a vast number of our young men, possessing talent and enterprise, have turned from the disrepute of agriculture and resorted to mercantile employment. That department has been overcrowded, and thousands, after a few years spent in that pursuit, have failed, and become the most pitiable and most helpless of paupers. How much better would it have been for the country, for these men and their descendants, had they been contented to till the ground! While agriculture has been treated as a detected impostor and loaded with obloquy, the exclusive patronage of the government upon commerce has operated as a lure to draw numerous thousands of young men of fine promise upon the fatal rock. Nor does this make up all the dimensions of the evil. One of the most useful and honorable of the learned professions stands intimately connected with commerce and the mercantile pursuit. As a consequence, that profession has been crowded to overflowing, and not a little out of repute. Thus, the evil of which we complain has, indirectly at least, blotted out and destroyed no small amount of the rising talent and promise of our country.

Nor is this neglect of agriculture in accordance with impartial justice. Our naval force has, with great propriety, been called the right arm of the nation. Agriculture nerves that arm and makes it strong: take away this aid, and that arm would become palsied and powerless. Not only so, but the agricultural class, more than any other, must defend our country, in case of an insurrection or invasion. Still further, in the State of New York, which is, probably, about a fair specimen of the other States, the agricultural interest pays near four-fifths of the taxes, and, of course, about that proportion indirectly towards the United States revenue. Is it republican thus to tax this interest, and then cast it off by neglect? Why should not the farming interest be allowed a bureau at the seat of government—an organ by which they might communicate with the councils of the nation, as their exigencies might demand? Might not a pittance of the nation's treasure be appropriated to establish and carry on an experimental farm in different States, where experiments, which exceed the means of nearly all the farmers, might be made with agriculture and with animals? The farmer, the manufacturer, and the merchant are allies, and should be treated as such by the government, without partiality. These unitedly have rendered our country independent by its own resources, and safe against foreign foes. All America is united in the bonds of internal commerce. Our exchanges at home exceed our foreign traffic. Were our ships driven from the ocean-highways of the world, our country has become competent to sustain itself. We have less to fear from war than any other nation. The farmers have done their part towards securing this happy state of things. Now we may pursue our career, vindicate our rights, and put forth all our energies, in conscious security. While we rejoice in our strength, that joy should be tempered with gentleness, and evince a spirit of love for all; a love that shall perpetuate tranquillity, and cause a continued development of the boundless resources of the country.

SHEEP HUSBANDRY AND WOOL-GROWING IN THE UNITED STATES.

BY HENRY S. RANDALL, OF CORTLANDVILLE, N. Y.

AMOUNT OF WOOL REQUIRED BY OUR POPULATION.

An ordinary laboring Northern farmer, in comfortable circumstances, annually consumes, in dress, bedding, &c., not far from 18 or 20 pounds of wool, in the condition in which our home-wools are sold to the manufacturer. Boys of sixteen, in the same class, who labor on farms, consume about as much as adults. Boys of eight, consume 4 or 5 pounds. Females will not probably average to exceed much beyond one-quarter of the consumption of males.

There is a large class of poorer laboring population which diminish their consumption of wool by the substitution of cotton; and, on the other hand, in the cities, villages, and even throughout the rural districts, there is a large class who entirely exceed the first estimate.

A laborer in the Southern States requires from 8 to 10 pounds of wool annually for his health and comfort; and this is about the ordinary amount received by slaves of an age to labor in the field.

The average annual consumption of the entire population of the United States has been generally estimated by agricultural writers at 6 pounds per head; I think that 5 pounds would come nearer the actual amount. But to place the estimates which follow, clearly and certainly within the bounds of truth, I shall assume 4 pounds as the average of individual consumption.

INCREASE OF POPULATION AND PROSPECTIVE DEMAND.

In 1790, the population of the United States was	3,929,827
" 1800,	5,305,941
" 1810,	7,239,814
" 1820,	9,638,191
" 1830,	12,866,020
" 1840,	17,069,453

The census of 1850 will probably exhibit a larger ratio of increase; but as the late emigration to our country has been greatly promoted by causes which may not continue to operate permanently, this will be left out of the account. By the first six censuses, it will be seen that our population increases at a compound ratio, exceeding 3 per centum per annum; and 3 per centum, annually compounded, would double it in 23 years and 164 days.

The circumstances which have led to the rapid multiplication of our population—cheap and healthy lands, and consequently abundant provisions at a moderate expenditure of toil—will not be materially diminished until our population considerably exceeds that of Europe, which is to say, between 220,000,000 and 230,000,000. But estimating the rate of increase from 1840 to 1890 at 3 per centum, which would double the population as above stated, and after 1890 at 2 per centum, which would double it in about

86 years, the following would be our population at the periods indicated, and the amount of wool which, according to the previous estimate, would be necessary for their annual consumption:

Year.	Population.	Pounds of wool.
1863–4	34,138,906	136,555,624
1886–7	68,277,812	273,111,248
1925	136,555,624	546,222,496
1963	273,111,248	1,092,444,992

Thus, in 112 years, our population is likely to outnumber the present one of Europe, and our annual consumption of wool to exceed *one billion and ninety-two millions of pounds!* Assuming that sheep average 3 pounds of wool per head—which exceeds the present average product throughout the United States—and it will require over *three hundred and sixty-four millions of sheep* to supply the demand! The States south of the Potomac and Ohio and east of the Mississippi (containing 450,000 square miles) would support all these, at a trifle over 1½ sheep to the acre!

FACILITIES FOR PRODUCTION.

The wool zones, the wool-growing countries—those where the product is sufficiently remunerating to economically constitute it an important article of production—are mainly comprised within latitudinal zones or belts on each side of the equator, about 15° in breadth, and encircling the earth. Their distance from the equator varies in different longitudes, owing to the various circumstances affecting the temperature: in other words, the wool-zones are bounded by isothermal instead of latitudinal lines. Beginning on the eastern side of each continent, the zone north of the equator includes the country lying between the 30th and 45th degree of latitude, and bearing thence westwardly and northwardly, it terminates between 40° and 55° on the western shores of each continent. I am not definitely informed what isothermal lines in the southern hemisphere would bound the regions of analogous temperature. From the narrowness of both continents, south of the equator in the corresponding latitudes, and their greater consequent modification by the temperature of the ocean, it is probable that the southern wool-zone may extend nearer the pole, and thus be bounded; but, even then, the area of land included in it would be inconsiderable compared with that in the northern zone.

It must be borne in mind, that although the general course of isothermal lines has been followed in giving the boundaries of the northern zone, these lines, and consequently the zone itself, exhibit many minor deviations, owing to the local conditions which affect the temperature, such as elevation, contiguity of large bodies of water, prevalent winds, mountain barriers excluding cold or warm winds, etc. To prevent misunderstanding in the minds of less-informed readers, an instance of each of these exceptions will be noted. A few hundred feet of elevation, usually from 350, diminish the heat equivalent to a degree in distance farther from the equator.* A lofty

* Three hundred feet is the rule given by Professor Leslie, but the experiments of Humboldt, Gay-Lussac, and others, show that this cannot be relied on. It usually requires a greater elevation to produce the effect. In New York, Prof. Emmons has shown that the mean is about 350 feet. See Nat. Hist. of the State.

mountain will therefore exhibit every variety of climate, colder than that of the plane of its base; and, if it stands within the torrid zone, it will consequently exhibit all the climates and their flora, from the torrid to the frigid. For these reasons, the Andes, in South America, must carry, on portions of their declivities, a mild climate, adapted to wool-growing, far north of 30°—even to the equator; and, from a parity of conditions, the Cordilleras of Mexico must extend the northern wool-zone far south of 30°. From the vicinity of large bodies of water, the peninsula of Michigan and the eastern portions of New England have been shown to be exposed to less extremes of heat and cold than the western portions of Wisconsin;* and England, in the latitude of Labrador, has a milder and more uniform temperature than the interior of New York. But in the case of England, the third exception, the effect of prevailing winds, operates in connexion with the one already named: the movement of the westerly wind is such as to prevent the accumulation of ice on the whole north-western coast of Europe, and to carry the ocean temperature *considerably* to the landward. Norway, in the latitude of Iceland and Greenland—and of the basic of the Dionid, where spirits freeze and quicksilver becomes malleable—exhibits the flora of northern Germany. The effects of mountain barriers are to be seen in the differences of the temperature in eastern and western Europe, and in different countries of Western Asia. The Carpathians, Alps, and Apennines are so many successive barriers against the cold north-east winds, which sweep, without obstruction, across the plains of Russia from the Arctic Sea. Southern Russia is therefore colder than France. The north of Persia and south of Independent Tartary are in the same latitude with Italy; but the former, uncovered to the north winds, are cold and inclement, while Italy, sheltered by the Carpathians, Alps, and the innumerable ranges in Turkey, (and the contiguous seas moderating the hot winds of Africa) possesses one of the most delightful climates in the world. The lofty Altays, by cutting off the south winds from Siberia, add materially to the rigors of its own climate.

The valley of the Mississippi, divided latitudinally by no mountain barriers for thousands of miles, is exposed to the free sweep of both the southern and northern winds, and consequently its excesses and fluctuations of temperature in the middle region, where neither wind has yet been materially modified by the prevailing local temperature, reach those enormous extremes which have been noted in the observations kept by the officers of the army. While the annual range of temperature at New London, Connecticut, averaged for 9 years but 78°, it averaged at Rock Island, Illinois, 106°, and at Council Bluffs, 120°.†

There are other considerations besides climatic ones, which practically influence the adaptation of countries to wool-growing. The most important of these are the density of population, and the consequent price of soil; and to these must be added various natural and artificial local peculiarities.

Sheep can never be economically kept to a great extent, for *wool-growing purposes*, amidst a dense population. They would thus be made to occupy lands which should be devoted to the growth of products for human food. Nor can wool be economically grown under such circumstances, and exchanged for the food products of other countries, because this husbandry

* See Forry on Climate of the United States. † Ibid p. 43.

requires so little human labor, that it would not give occupation to a dense population, nor would its proceeds be sufficient for the subsistence of such a population. An acre of land, worth one or two hundred dollars, in an old and thickly populated country, for the production of human food, would produce no more wool than an acre worth but one or two dollars, in America or Australia. The former cannot, therefore, sustain the competition. We see some partial contradictions to this in practice in some of the German states, but this is but temporary. Skill and habit will do something to countervail nature, but wool produced under the circumstances it is in portions of Germany, France, &c., when brought into *full* competition with *similar qualities* grown on cheap and sparsely inhabited lands, will not, for a moment, stand the competition in external markets, nor in domestic ones, unless ruinously forced upon the people of the countries where they are grown, by oppressive tariffs on the foreign article.

The German and French wools alluded to can yet be produced, because neither labor nor moneyed capital demand so good a return where they are grown as in newer countries, and because the supply of the world is short compared with the demand; generally and peculiarly so in regard to a corresponding style of staples.

The above considerations, with certain local ones pertaining to climate, national habits, institutions, &c., will effectually prevent Spain, Portugal, France, the British Islands, Holland, Prussia, Bavaria, the smaller German States, the Western portion of Austria, Switzerland, Italy, Turkey, Persia, Tartary and China, Northern and Southern Africa, in the southern wool-growing zone, from competing successfully with more favored regions, *as soon as those more favored regions are prepared to supply the demand of the world.* This subtracts so great a portion from the area of the *natural* wool-growing zone, that it leaves the United States in possession of, probably, a moiety of that part of it throughout the world, which is adapted also by artificial circumstances to wool-growing.

COMPETITION OF DIFFERENT COUNTRIES IN THE WOOL-ZONE.

South America.—South America, and more particularly Buenos Ayres, possesses great advantages for the cheap production of wool. Lands were here until recently, and are now, for aught I have learned to the contrary, granted by the government, in estates a league square (5760 acres), at ten cents per acre. Its vast *pampas* are plains like our prairies, covered with wild grasses and destitute of timber. Until recently, these were depastured almost exclusively by horses and cattle, which were often killed for their hides. Labor is cheap, and the population sparse.

The Gauchos inhabit the north, and tribes of mounted Indians the southern pampas, who are wild, predatory, and often engaged in war. The culture of sheep has extended of late, and some Europeans have purchased large estates for that purpose. I am not aware that sheep have to labor under any particular local natural disadvantages.* The restless and predatory character of the population and the unsettled nature of the government seem to constitute the main drawbacks on this as on every other branch of industry.

* Still there *may* be serious natural disadvantages. Very little is known of the interior of that country by citizens of the United States.

Australia.—The wool product of Australia and Van Diemen's Land has increased with vast rapidity within a few years. The following statements are from a table compiled from official sources, in Bischoff's Comprehensive History of Woollen and Worsted Manufactures, &c.

In 1810, the export to England was	1,670
1815,	78,171
1820,	99,415
1825,	323,995
1830,	1,967,309
1835,	4,210,301
1840,	9,721,243

Later than this, I am in possession of no official accounts, but suppose that the clip of 1850 more than quadrupled that of 1840. One of our most intelligent and best informed manufacturers (Mr. Samuel Lawrence) recently wrote me that the Australian flocks now number 20,000,000 of sheep, and he added, "from thence England receives a large proportion of her supply of fine wool." According to this, the present product should more than quintuple that of 1840.

Professor McCulloch states, that the bad land in this country "bears a much greater proportion to the good than in almost any other." Also, that it is subject to the recurrence of periodical droughts, which sometimes continue for two, three, and even four years together; that the last great drought began in 1826, and did not terminate until 1829; that during the whole of this period, there was often not a single shower in six months,—and that the whole surface of the ground "was so parched and withered, that all minor vegetation ceased, and even culinary vegetables were not raised without much difficulty."*

There was another drought in 1835, and another in 1841. The effects of the latter on the sheep are thus described by Mr. Hood:†

"It will scarcely be believed in England that the estimated number of sheep which have died within the last twelve months in the colony, from catarrh and drought, is 70,000!! that colonists are compelled, in order to save the dam from starvation, to cut the throat of her lamb; that no means are adopted for securing a stock of lambs for next year; or that a stockholder would offer 8,000 sheep to any one that would remove them from his runs, and, finding that no one could be prevailed upon to taint his own flocks by accepting so dangerous a present, had recourse to consuming them by fire, and had actually killed and burnt 2,000."

"The wild and poachy nature of a considerable portion of the pasture," says Mr. Youatt, "gives the foot-rot a peculiar character, and, if neglected, it becomes inveterate, and destroys the animal."‡

The scab is a prevalent disease, and the convict shepherd, who has a pique against his master, can easily, by bringing his flock in contact with a diseased one, subject them to this dangerous and troublesome malady.§

Epidemics, supposed to be owing to the astringency of the water, and some other causes, have, some years, cut off half the sheep.‖

‖ See Spooner, pp. 417–421.

The above extracts are all from *English* writers of reputation, and have not, so far as I am informed, been contradicted.

The minimum government price of lands in Australia is *5s.* ($1.15) per acre, and but a very little, if any, good land is sold at that price. Mr. Hood states, that the portion of Captain McArthur's immense estate, which was obtained by purchase, cost, on the average, *7s. 6d.* ($1.72½) per acre. Shepherds receive from £15 to £20, ($69 to $92,) *with a house and rations,* per annum; overseers of a superior description, £50 to £60, ($230 to 276,) also *with a house and rations.**

It is about four times as far (13,000 miles) from Sydney or Hobartstown to London as it is from New York to London; and the expense of conveying a passenger from England to Sydney is three times that of conveying him to Quebec.† Under all these circumstances, McCulloch (though he made at the time an error in the price of American lands) justly remarks:

"If slaves could be imported into a colony of this sort, there might be some chance of its succeeding. But, while land of the very best quality may be had in the valley of the Mississippi for about a dollar an acre, or less, we think better of the common sense of our countrymen than to suppose that any one able to carry himself across the Atlantic will resort to Australia."

Hungary.‡—In considerable portions of Hungary, the climate is fine, the soil rich, and, the feudal tenures remaining unabolished, the land is yet held in those large estates so favorable to sheep-husbandry. Prince Esterhazy, the former Austrian ambassador to England, says Mr. Paget,§ owns an estate of something more than 7,000 square miles, including 130 villages, 40 towns, and 34 castles. His sheep are said to amount to 3,000,000.‖ Other nobles own flocks of from 10,000 to 30,000. The demi-savage Magyar serf, whose labor costs nothing, whose principal garment is a sheep-skin, and whose miserable and scanty food is more than half stolen,¶ makes a most *economical* shepherd! Hungary lacks facilities for internal communication, and her convenience to the Mediterranean market, excepting Turkey, so as to first throw her agricultural products into ports where the demand is good, is decidedly inferior to that of France, Italy, and Spain. The Danube is the only natural outlet to her commerce, which, thanks to a liberality of policy on the part of Turkey, contrasting most favorably with that of several *enlightened*** nations under similar circumstances, she enjoys without limitation. To reach Trieste, a long land carriage is indispensable. Her exports, too, are embarrassed by the imposts and narrow restrictions of the imperial government. She cannot therefore export cheap heavy articles, such as provisions, to so great advantage as the Levantine nations; but every circumstance points to her as a country which should be one of the first on the eastern continent for the production of wine, silk, wool, &c.

Southern Russia.††—Separated from Hungary and Transylvania only by the Carpathian Mountains and Turkish Moldavia, lie the fertile provinces of South-eastern Russia, the basins of the Dniester, the Dnieper, and the

Don. From the Carpathians to the Caspian, across the entire extent of the plains of ancient Scythia, not an elevation which could be properly dignified with the appellation of a mountain breaks the immense expanse! The lower valley of the Dniester, or Borysthenes, formerly known as the Ukraine, has been celebrated for centuries for its pasturage, for its horses and cattle; and recently flocks of Merino sheep have been introduced there and successfully crossed with the native variety. In 1839, Mr. Slade states that many of the colonists on the Steppes and in Bessarabia had 20,000 sheep. Merinos were introduced into Crimea or Taurida by M. Rouvier, a French adventurer, in about 1802.* In this favored peninsula, which the learned Pallas describes as little less than an earthly paradise, they have multiplied exceedingly, and extended to Cherson, Ekatherinoslav, Bessarabia, and other provincial governments.† The export of wool from Odessa in 1829, was 3,402 lbs.; in 1830, 21,361 lbs.; in 1831, 35,058 lbs.; in 1832, 41,558 lbs.; in 1833, 65,457 lbs.; in 1834, 66,901 lbs.‡

In one respect, Southern Russia has the advantage over Hungary—it is more sparsely populated, and land is perhaps in still lower estimation. As in the latter, the land, much of it, is fertile and well adapted to pasturage, and the price of labor is next to nothing. But, for causes already adverted to, there is a wide disparity in the climates of the two countries, if we leave Crimea out of view. That of Russia, affected by the north and north-east winds—which the Carpathian Mountains exclude from Hungary—has a winter which for length and intensity is entirely unequalled in the latter, excepting in its northern mountainous regions. Sheep must be housed and fed for some months on dry food in Southern Russia. Taking into view the broad level Steppes,§ and their luxuriant natural verdure; taking into view the climate, warm in summer, cold and exposed to winds of great severity in winter, it strikes me that there must be no inconsiderable resemblance between this portion of Russia and our own north-western prairies in corresponding latitudes, (45° to 46°.) But when the cost of land and labor is taken into consideration, wool can be produced cheaper, in my judgment, in South-western Russia than in Spain, France, Germany, Italy, or any other portion of Europe, excepting Hungary.

The United States.—As already remarked, the United States probably possesses half the cheap fertile lands included in the wool zone throughout the world. Nearly her entire territory lies within it. Experience has amply proved that sheep are healthy in every portion of the United States. The terrible droughts and predispositions to certain diseases encountered by the Australian flock-master—the comparative insecurity of property in Buenos Ayres—the climatic vicissitudes of Southern Russia (with the exception of the comparatively small peninsula of Taurida)—are none of them known in our *most favored* wool-growing regions. Land is cheaper here, and more fertile, and much nearer the great wool-markets of the world than in Australia. Our lands are probably as cheap as those of Hungary and Southern Russia, and, for a long series of years to come, will be practically as cheap as those of Buenos Ayres, because the purchase of only a quarter section (80 acres) of government lands will give its possessor the use of all contiguous ones

* For the interesting account of this fortunate French Jason, see Slade's Travels in Germany and Russia. London, 1840.

† Slade. Also McCulloch's Com. Dic., art. Odessa.

‡ McCulloch, art. Odessa.

§ Plains, like the prairies, pampas, llanos, &c.

until they are occupied. Lands can actually be bought of the owners, in portions of our territories, at a price not exceeding the government minimum in Buenos Ayres; and in others (in Oregon) they are given to the settler.

Under all the above circumstances, we *ought* to compete successfully with South America, Hungary, and Southern Russia in external markets, to *undersell* Australia in these markets, and, with the discrimination of our tariff of duties against them, to drive *all* foreign wools from our own markets.

The enormously increasing quantities of wool necessary to keep up with the demands of the home market have been given, and we see how futile is the idea that there is any danger of over-supplying it. In fact, we have never grown enough wool to meet the home demand. The following tables will show the imports of the raw and manufactured article for the last few years:

Value of Woollens imported from 1821 *to* 1851.

In 1821	$7,437,737	In 1836	$21,080,008
1822	12,185,904	1837	8,500,292
1823	8,268,038	1838	11,512,920
1824	8,386,597	1839	18,575,945
1825	11,392,264	1840	9,071,184
1826	8,431,974	1841	11,001,939
1827	8,742,701	1842	8,375,725
1828	8,679,505	1843	2,475,154
1829	6,881,489	1844	9,475,762
1830	5,776,396	1845	10,666,176
1831	12,627,229	1846	
1832	9,992,424	1847	
1833	13,262,509	1848	
1834	11,879,328	1849	
1835	17,834,424	1850	

Value of Wool imported from 1837 *to* 1851.

	Wool not costing to exceed 7 cts per pound.	Exceeding 7 cts. per pound.	Total.
Average imports of 1837, 1838, and 1839	$558,458		
Average imports of 1840, 1841, and 1842	759,646	$801,087	$1,359,545
Import of 1843*	190,352	1,004.312	1,763,958
Import of 1844	754,441	54,695	245,047
Import of 1845	1,553,789	97,019	851,460
Import of 1846	1,107,305	136,005	1,689,794
Import of 1847		26,921	1,134,226
Import of 1848			
Import of 1849			
Import of 1850			

* The fiscal year 1842 ended on the 30th September. Since then, the returns of imports have been made up to the 30th of June. The imports of 1843 in the table are therefore only given for nine months.

The table of imports of woollens shows how far our manufactures fall short of supplying the home demand; and the last table, how far our wool product falls short of furnishing the raw material for even this insufficient supply. Each million of dollars in the right-hand column of the last table, represents (with the exception, perhaps, of 1840, 1841, and 1842) about 10,000,000 pounds of wool.

This very year (1850–51) many of the smaller manufactories are stopping *for want of wool.* There is not enough in the home market, and wools are now too high abroad for profitable importation. The general impression is, that less wool was grown in the United States in 1850 than the preceding year, (the causes of which will be hereafter adverted to,) and the Hungarian war, and, perhaps, some other causes, have diminished the foreign supply.

In as favored a wool-growing country as the sun shines on, and where the home production is favored by a discriminating duty of 30 per cent. ad valorem, we suffer not only foreign cloths and wools to come into our markets, but we *actually suffer our manufactories to languish for want of raw material!*

In 1847, Samuel Lawrence, Esq., the leading woollen manufacturer in the United States,* wrote me:

"*The business of manufacturing wool in this country is on a better basis than ever before, inasmuch as the character, skill, and capital engaged in it are such that* FOREIGN COMPETITION IS DEFIED. *A very few years, and all articles of wool used here will be of home manufacture.*"†

The same gentleman recently wrote me:‡

"*The manufacture of woollen goods is now so far advanced in this country, that it will go forward quite as rapidly as* THE PRODUCTION OF WOOLS WILL ALLOW."

PROFITS OF SHEEP-HUSBANDRY IN THE UNITED STATES.

The Northern States.—Let us ascertain the actual cost of producing wool in New York. Flocks of part Merino or Saxon blood, producing wool quite up to the average article in market, are worth, say, $1.50 per head in the fall, and lambs half that price. The annual product of wool is about 3 pounds per head, and of lambs, 80 per cent.; or, if the latter is less, by reason of the number of wethers in the flock, the *growth* of the latter will give a corresponding increase in profit. One hundred sheep, properly littered, and with shelters,§ will make forty loads of manure during five months confinement to dry food. Prime grazing lands, with suitable house, barns, shelters, fences, &c., for carrying on sheep husbandry, are now worth $20 per acre, in the most retired grazing districts. One acre of such land will give subsistence, summer and winter, to three ordinary-sized fine-wooled sheep. The following presents the fair ordinary debtor and creditor side of the account with a flock of sheep:

* Mr. Lawrence (in connection, I believe, with his brother, Hon. Abbot Lawrence) has far the most extensive woollen manufactories in the United States.

† For the rest of this important letter, see Sheep Husbandry in the South, pp. 124, 125.

‡ January, 1851.

§ If sheep are not sheltered, they make the same quantity of fecal manure, but it does not convert the same quantity of litter into manure, and a considerable portion of it is wasted by floods, evaporation, &c.

Dr.

100 sheep, to interest on purchase money	$10 50
To interest on 33⅓ acres of land, at $20 per acre	46 66
" curing and storing hay on 11 acres of above	13 75
" expense of shearing	4 00
" salt, tar, and summer care	4 00
" labor of foddering, &c., during winter, say	5 00
" loss by death, 2 per cent. above value of wool pulled from skins	4 00
	$87 91

Cr.

By 80 lambs at 75 cents per head	$60 00
" 40 two-horse loads of manure, at 50 cents per load	20 00
" summer manure, say	7 91
	$87 91*
" value of 300 pounds of wool to be added	

It would be absurd, as the least intelligent farmer is aware, not to estimate the manure among the important receipts of sheep husbandry; and sheep manure made under shelter, the richest of all other farm manures, excepting the dung of fowls, is worth *more* per load than the above estimate, as any one will ascertain who will make an experiment with it on a crop of Indian corn, turnips, &c., of the amount of it which 100 hundred sheep, properly littered, under shelter, will make. I speak from 20 years' experience in this branch of husbandry. What I mean by "properly littered, under shelter," is, that the sheep shall have a proper shed or house accessible to them at all times, and thus be littered down with a moderate thickness of straw, say twice a week—but the sheep not fed in the house. If fed in the house, they would make a much greater amount of manure than I have named. The summer manure is not commonly thought of, because it is scattered over the fields when made. But its effects in *enriching the pasture*, or in *preparing it for a grain crop*, are worth more than I have set it down at—between 23 and 24 cents per acre, per annum. The whole above estimate is intended for flocks numbering say 300 and above. For one single hundred, the cost would be a little more. The common estimate among farmers in New York, who keep small flocks, is, that it costs $1 per head to keep sheep throughout the year; but then in small flocks the returns are usually better. The sheep get a better range, more condition, and consequently more wool, and the lambs are larger and will sell for more. It is, therefore, also the common estimate among farmers, that the lambs and manure will pay for keeping the sheep, and that the *wool is net profit.*

According to a table formerly by me, the average price of wool per pound from 1832 to 1845, inclusive, was 39¾ cents.† This would give a net profit of $1.18⅝ per sheep, or $3.56¼ per acre—a fraction over 17¾ per cent. on the value of the land. Many excellent farmers in New York and New

* Note by the Editor.—Mr. Randall's calculations are very extravagant. One hundred sheep, (half males,) will not produce 80 lambs worth 75 cents per head, nor will the hay from 11 acres, after manuring the land to keep up the supply of mineral elements removed in the crop, yield dung and urine to the amount of $20. So much *value* in manure from hay, which it costs but $18.75 to gather, (which manure the meadow that produced the hay really needs,) cannot be realized.

† For Table, see "Sheep Husbandry in the South," p. 53.

England keep large flocks of sheep on lands worth $40 per acre—and still find, as will be seen, a better remuneration than the legal rate of interest on money.

Still, causes are operating which are rather diminishing than increasing this branch of husbandry throughout New York and New England. These are the extraordinary recent profits of dairying, and the prospect that they will be continuous—the far better adaptation of the climate to cows than to sheep—the perfect knowledge of all sensible agriculturists, that they cannot compete with the Southern or even the North-western States in wool-growing, and the strong temptations which frequently occur to part with sheep.

The comparative profits of dairying it is not necessary here to discuss. They have, recently, undoubtedly come to equal or exceed those of wool-growing: they are generally thought by farmers to exceed those of ordinary flocks of sheep. The impression also generally and justly prevails, that our climate is a severe one for sheep, where they are kept in any considerable numbers, unless they are well sheltered in winter, and receive considerable other care; and, when these expenses are added to those of foddering five months, every intelligent farmer knows that he cannot compete with wool-growers in a region where lands are far cheaper, the expense of foddering, shelters, &c. far less. The 5° of the wool-zone, north of 40° on the east and 45° on the west shore of the continent, may be considered the DAIRYING-ZONE of our country. Our farmers believe that south of 40°, (on this side of the Mississippi,) though the cost of keeping cattle may be less, butter and cheese can never be produced which will compete in quality with those articles manufactured in New England, New York, Northern Pennsylvania, &c.* Dairying is therefore regarded as not only as much or more profitable at present, but as holding out the greatest prospect of permanence in profit. The temptations which the Northern farmer has to part with his sheep are manifold. The consumption of mutton is vastly increasing in the cities and in the country. The average prices of the better qualities have become above those of *beef in the New York and Boston markets.*

Every small village even now affords an active mutton-market in the fall months, in proportion to the number of the population. I have put down the average price of lambs at 75 cents per head in the fall—but, so far as my experience extends, every fat earlyish lamb readily finds a market at $1 to $1.25 per head, with the country butchers. Ten or 20 lambs are thus killed for consumption throughout the country, where, a few years since, one was killed. And the same remark would apply in nearly as great an extent to fat sheep. Farmers very wisely kill more of them than formerly, to obtain their fresh meats. Pelts (skins with the wool on) have been so high this past fall, that vast numbers of sheep have been killed, because the pelts and tallow, and the meat of those fat enough to eat, would exceed the ordinary price of sheep.

The tendency of all these things is to break up great flocks kept for wool-growing purposes in the north, and to substitute breeds of greater size and earlier maturity, to meet the demands of the provision-markets. Within 20 years, and perhaps half that time, very few sheep will probably be kept in the old Northern States for wool-growing purposes. This husbandry

* And it is also believed that the States west of Pennsylvania do not now, at least, produce as good butter and cheese, if they ever can. I see no reason why they cannot, when the domestic grasses are generally introduced in the Western States.

may first flow west, but ultimately, as soon as *the population take the necessary steps*, it must go SOUTH of 40°. This is as inevitable as the laws of cause and effect.

The Southern States.—Other things beside climate being equal, the country lying south of 40° on our Atlantic, and from 45° to 50° on our Pacific shore, *are equally or more healthy for sheep* than the countries lying north of them. Sheep are there exposed to no more diseases than in the north—they are not so much exposed to catarrhs or colds—and late lambs, old or feeble sheep, &c. are less liable to be cut off by the winter climate. These facts I have learned from answers, received from gentlemen of the first character in nearly all the Southern States, to inquiries in regard to this and kindred topics which I have been pursuing for years.* Their replies have been uniform in tenor on this point, and, within the last few years, I have sent colonies of Merinos to a large number of localities—embracing almost every variety of Southern climate, soil, verdure, &c.,—and, although I have aimed, as far as practicable, to keep myself informed of the history of every such colony, I have yet to learn the first instance where the sheep have not thriven and been substantially free from disease.† Spain, the native country of the Merinos, and where they flourished most successfully for ages, though farther north than our most Southern States, is, at the same point of elevation above the sea, warmer than the latter.

The effect of warm climates on the staple of wool is to make it *longer and softer*, and thus more valuable. This was the concurrent testimony of the numerous wool-merchants, staplers, &c., who were examined at the investigation into the state of the woollen trade, &c., in the British House of Lords, in 1828,‡ as it is of the most eminent growers, manufacturers, staplers, &c. of our own country.§

And the Southern fine wools are in *all* respects of the most valuable and desirable quality. Mr. Samuel Lawrence, who has purchased largely of them, writes me, (January, 1851,) "The unprecedented success of 'sheep husbandry' in New Holland illustrates the truth that southern latitudes are favorable to the production of fine wools, and the superior flocks of Virginia, Kentucky, and Tennessee prove that those of the other South-western States of our country are peculiarly adapted for this invaluable staple."

After speaking of the "sheep husbandry" of England, where sheep are grown principally for mutton and manure, where wool is but of subordinate consideration, he adds: "My impression is it will be for the interest of the flock-masters in the Northern and Western States to pursue a similar course:" and thus, (for such is his meaning,) give up wool-growing to the Southern States.

The Western States, even north of 40°, can, no doubt, from the cheapness of their lands, raise wools at a better profit than New York and New England, but they have the same long winters and period of dry foddering;

* For some of the most interesting of these, up to 1848, see "Sheep Husbandry in the South."

† Besides the case of an individual in Virginia, who wrote me that two lambs sent him had been afflicted by some disease unknown to him, I have not heard of one being ill—not *even on the low rice-lands* of South Carolina.

‡ See Bischoff on Wools, &c., vol. ii. pp. 118 to 200; or, for an abstract of it, "Sheep Husbandry in the South," pp. 28 to 29.

§ Mr. H. Blanchard, of the Kinderhook Wool Depot, recently wrote me that he had observed this fact in the wools received by him. Other testimony of this kind will be found in "Sheep Husbandry in the South."

and consequently it places an insuperable and eternal barrier in the way of their competition with equally productive lands, as low in price, from five to ten degrees further south.

The profits of sheep husbandry in the South are multifarious, beyond those simply of direct profit on capital invested; as, for example, to constitute the basis of amelioration in exhausted soils, and of a system of convertible husbandry. But it is only with the first that we now have to do, and what are the direct profits on capital invested.

Lands containing more or less herbage, on which sheep will subsist and thrive, can be found in all the Southern States at $1, and often as low as 50 cents per acre.* These lands consist of worn-out cotton and tobacco lands, and those naturally unadapted to those staples, of mountain sides, and, west of the Mississippi, of the prairies: even the forests will subsist sheep. Mr. M. R. Evans, of Mobile, Alabama, recently wrote me that his own and some other flocks had subsisted throughout the year and kept in fine condition in the *pine forests* about Mobile, without being once fed. Eastern Virginia and Kentucky do not probably demand to exceed one-third, and certainly not to exceed one-half of the winter feed of New York and New England; and south of these, on large ranges, sheep will subsist the year round without fodder, unless on very high lands. But if the number of sheep were largely increased, it would become necessary to provide winter feed, either dry fodder or some green crop, like rye. Mr. Evans also wrote me the following exceedingly interesting facts:

"I lived three years in western Texas, before my location here two years ago. I had there 1,000 head of sheep, and can say without hesitation that the Musquvoit prairies of that section offer greater inducements for wool-growing and sheep husbandry than any country I know any thing about. Sheep are hardy as goats—no disease—no ticks—and they yean both spring and fall. Musquvoit grass is an evergreen. I have seen the prairies in winter as green as fields of wheat in April; and no shelters are necessary. And then the herbage and grass of those rich prairies are now nutritious, and much larger numbers of sheep may be kept together. Land is cheap there, and the purchase of a quarter section gives privilege over thousands of acres. The country is healthy, with an abundance of pure water. I could procure a fat mutton there at any season of the year. I knew one man who had over 2,000 head in one flock, and when the Mexicans were prosperous about San Antonia, twenty or thirty years back, some of them had flocks of five to ten thousand subsisting on the prairies the year round."

This reduces the cost of growing wool to a mere trifle! General Houston fully confirms the statement of Mr. Evans, and thinks that those evergreen prairies include the greater portion of a country six hundred miles long and three hundred broad!

It is difficult to fix on a proper estimate of the interest on those lands which should be devoted to wool-growing in the States south of Virginia, for, at best, it would be but nominal. Summer pasture costs *nothing*, now, on "*the range*" (unenclosed lands) in those States.† The rye or barley pastures for winter can scarcely be counted as an expense, because the crop

* I regret that limits do not permit me to give particulars and authorities here; but I must again refer to "Sheep Husbandry in the South," where these are pretty fully given, though I am in possession of later ones of great interest.

† See Report of Hon. R. F. Simpson, late M. C. from the Pendleton District, South Carolina. Sheep Husbandry in the South, appendix, p. 398.

is not thereby lost. Farmers in the Pickens, Greenville, and Spartansburg districts of South Carolina will winter sheep for ten cents per head, and often warrant against losses by death.* In many other regions, the cost would not exceed this, even where they were *hired* kept. But we will suppose *unenclosed* lands to cost $1 per acre, and that one acre will give subsistence to two sheep. It would require the labor of a man to oversee 600 sheep. This labor would be worth, in the South, about $75 per annum, and I put the extra labor of shearing half the price of Northern day-laborers, or $12½ per hundred. The account would then stand thus:

Dr.

To interest on 300 acres of land at $1 per acre	$21 00
" " 600 sheep at $1 50 per head	68 00
" labor of one hand	75 00
" extra labor for shearing	12 00
" salt, say	5 00
" loss 2 per cent. above value of wool pulled from skins	12 00
	$188 00

Cr.

By 1800 pounds of wool at 33⅓ cts. per pound	600 00
†480 lambs, at 75 cts. per head	360 00
	$960 00
Add, for manure	

Manure improves the quality of land and makes it susceptible of *carrying more sheep* or raising *more grain* in the same proportion in the South that it does in the North. To say that one acre, with privilege of range, will support but two sheep, is a low estimate: I have also put the average price of fine wools at a very low mark, lower than they have averaged for the last 20 years. I have done this to cover all contingencies, trouble, and expense of marketing, &c.

It would not probably cost any more in wooded regions to fence sheep-walks into very large fields. It would raise the value of lands, but it would dispense with the labor of a shepherd to every, say, 600 sheep.

By the above estimate, the cost of producing wool in the South is between 9 and 10 cts. per pound; in the North, *nearly three times that amount.* But I am satisfied that wool can be produced at 8 cts. per pound, to almost any quantity, in the South, and it frequently now is, as I know, at a cost not exceeding 5 or 6 cents per pound.

Can any portion of the world grow wools cheaper than this? And to show the unutterable absurdity of allowing South American wools, with a 30 per cent. duty against them, to drive ours out of our markets, let us look at a few facts.

The duty on wool costing 7 cents, is 2 cents and 1 mill per pound. This wool is imported in the grease and dirt, and will lose about half weight by washing, so that every pound of *wool* actually pays a double duty, or 4 cents

* Hon. R. F. Simpson. See his letter to me, in Sheep Husbandry in the South, pp. 59, 60.

† Note by the Editor.—Six hundred sheep (half males) will not rear 480 lambs; nor half of that number, one year with another, without unusual care.

and 2 mills. If, on the other hand, the wool is washed prior to exportation, the reduction of weight one-half would require a doubling of the price. A pound of wool, in reality, in either event, costs 14 cents, and pays a duty of 4 cents and 2 mills. To this, cost of transportation must be added. Thus, if the *revenue laws are not fraudulently evaded,** every pound of the so-called 7 cent wools costs not far from 20 cents in our market; twice and a half the cost of producing wools of *more than double the value*, (unless there is fraud,) in vast portions of our Southern territory, to say nothing of extraordinary localities, like those described in Texas.

THE BREED OF SHEEP ADAPTED TO WOOL-GROWING.

This topic requires little discussion, as, for general *wool-growing* purposes, there is but one breed in the world entitled to a moment's consideration. This is the Merino.

The Merino has, by breeding and cultivation, been divided into varieties, some larger and carrying more wool than others, some finer, and some coarser. Size, within moderate limits, is not *per se* a matter of any consequence: nor is the amount of wool per head, provided the smaller sheep bears as much in proportion to its consumption as the larger. By a universal law, the larger animal of the same species consumes a proportionably greater amount of food than the lesser;† and the true question for the farmer to ask, in determining his best variety, is not, how much wool will a given number of sheep produce, but how much wool will the herbage of a given number of acres produce? Deep, rich, luxuriant, and unfailing herbage will carry *large* animals; that which is less abundant or nutritious, or is liable to become parched or poor, is better adapted to those of moderate size. Precisely the same rules apply here that do in breeding horses or cattle; their size should *be adapted to their feed*—should *not be too large for their feed.* Very large or very small animals, of any kind, I never have thought so hardy, healthy, and capable of taking care of themselves, as those of medium size.

Shape is of much more consequence than size. This should indicate hardiness of constitution; and here again the rules are much the same that we would employ in judging of other animals where speed of motion is not required. A sheep should be broad and straight backed, round carcassed, cylindrical, rather than tunnel-shaped, (that is, carrying its breadth and depth into the fore-quarter, instead of tapering off in the shape of a tunnel,) with short and straight legs; the neck full, round, particularly so at its junction with the body, and set on in a line with the back; the head small, conical, and well carried up, the eyes lively, and the countenance bright and pleasing.

* As they no doubt most shamefully have been, by a fraudulent system of invoicing. A sends out B and C to Buenos Ayres; B buys a good quality of wools, and pays the true value for them, 14 cents, perhaps. He then resells these wools to C for 7 cents, and they are invoiced accordingly. C is not informed that there is any collusion, and therefore is *not* bound to know it! This is *said* to be the modus operandi; but, after all, if the revenue officers understand their duty, and rigorously perform it, there is no need of such a fraud becoming successful. No artifice of this kind could, for a moment, mislead a respectable judge of wools.

† Spooner put this at 3½ per cent. of their weight, daily, in dry hay or its equivalent; wet places at 2½. My experience would say, half-way between. But whatever the per-centage of consumption, it is *proportionable* to the weight.

The quality of the wool is a question of circumstances; but, in the South, the finer grades are indicated, because it is in these qualities that other regions can less contend with them, and have less inducements to attempt it. Merino wool ranges from the finest Saxon to medium. The Saxon Merino, or Saxon sheep, is ordinarily a comparatively tender-constitutioned animal, because, in his breeding, every thing else was, for a long time, sacrificed to the *quality* of the wool, and he degenerated in constitution. Merinos, descended from the original Spanish family, can now be found, which equal ordinary grades of Saxon in fineness, and they usually are thicker woolled, and are a hardy sheep. I consider them therefore decidedly preferable to the Saxons, for those who do not intend to pay a much more than ordinary attention to the care of their sheep, and especially for new beginners in the husbandry, who require a hardier sheep. Whatever the grade of the wool, economy demands that it be *thick* on the animal, not only to make a good return for the food consumed, but as a protection from the weather. It should extend evenly all over the animal, except on the legs below the knees, and on the face; on the latter it is unsightly, of little value, and frequently impedes the sight of the animal, so that it falls an easy prey to any enemy. It should be as even as practicable in length and *quality*, all over the animal. The wool should open a pure, glittering white, with some, but not an excess, of oiliness, and the skin should be mellow, and of a bright pink, as contradistinguished from a livid or tawny hue.

Pure-blooded sheep are, of course, more desirable than any other, and, in the male progenitor, it is the height of folly to use any but a pure-blood animal, under any circumstances. But, to attempt to fill up our unoccupied sheep lands exclusively with pure bloods would be a matter requiring much time and expense; and it is perfectly well known to all practical breeders, that sheep of a most desirable quality are readily, and in *three or four generations*, produced by crossing any good, strong, healthy stock of ewes with pure-blood rams of *the proper stamp*. The readiest and most economical method, therefore, is to select from the stocks to be found in the country, and thus cross them; and it is always well to have a small supply of pure-blood ewes, both to supply rams and to gradually grow a pure-blood flock. In obtaining these, great care should, of course, be had, not only to *individual excellence*, but to *absolute and undoubted purity of blood.*

With good Merino rams, the second or third crop, with the most ordinary ewes, will produce decidedly more wool per head than I have estimated, as the average of our country and the quality will be fully up to the average of those now ranked in the general class of fine wools. At the third or fourth cross, it may be made to rank almost in the first class. These facts I have practically demonstrated in innumerable instances. The practice of crossing with existing or coarser breeds has been that of Australia, the Cape of Good Hope, Buenos Ayres, Southern Russia, and all other new wool-growing countries.

AGRICULTURAL EDUCATION.

We have received from the Hon. Marshall P. Wilder, chairman of a board of commissioners appointed by the Legislature of Massachusetts, an extended and interesting report on the subject of agricultural education. It contains an instructive account of the principal colleges and schools in England, Scotland, Ireland, France, and other continental nations, designed to teach the several arts and sciences which pertain to rural affairs, from the pen of Professor Hitchcock, who devoted some months, while abroad, to collecting the information given. The Royal Agricultural College at Cirencester has six professors and 700 acres of land for agricultural purposes. The object of this institution is to prepare young men to become intelligent proprietors of farms, or to superintend in the most skilful and successful manner the farms of others. From the unhappy operation of *caste* in English society, says Professor H., and from the want of governmental patronage, this college is not so well attended as its founders anticipated. There are accommodations for 200 students, but only 50 now belong to the school. Those residing in the building pay $355 annually; those who board elsewhere, $175. Formerly, the school was open for the sons of the smaller farmers, but could not find support on that plan, and it was found that, if these attended, the wealthier classes would not send their sons. The price, accordingly, has been raised, and none but the sons of gentlemen, such as clergymen and wealthy laymen, now attend. None of the nobility send their children, although many give their money for its support.

The impassable barriers of *caste*, happily, do not exist in this republic; and it would be impossible to establish an experimental farm of 700 acres, erect suitable buildings to accommodate 200 students, appoint six able professors, aided by museums to illustrate natural history, comparative anatomy, vegetable and animal physiology, and provided with a chemical laboratory for making original researches, cabinets of minerals, and all other needful appliances, and not have the institution crowded with students.

The agricultural school at Grignon, near Paris, is in a much more flourishing condition. "In going through a stable," says Mr. H., "containing a number of fine cattle, I observed one young man, with water and a broom, cleaning the legs of an ox which had lain down in his leavings. The director whispered to us that that young man was the son of a wealthy banker. Indeed, the pupils all appeared as if they had not been accustomed to labor. Formerly pupils were admitted from the laboring classes to attend the lectures, without residing in the institution, but they are now excluded. They now pay 750 francs, or $138, for board, and receive nothing for their labor. This institution receives $1,100 annually from government."

Already it has sent out nearly 600 pupils, and the present number is about 80. The farm connected with the institution contains 750 acres. The system of instruction and study is extensive and thorough, embracing algebra, geometry, mechanics, surveying, levelling, stereometry, (measuring solid bodies,) linear drawings, in the mathematical sciences; meteorology, mineral chemistry, mineralogy, geology, and botany, in the physical sciences; organic chemistry, or agricultural technology, agriculture, arboriculture, sylviculture, veterinary art, agricultural zoology, and equitation, in what are denominated technological sciences; and rural architecture, forest economy, farm accounts, rural economy, and rural law, in the noological sciences. There are six professorships, and three years are required to go through with a course of study.

At Versailles there is a National Agronomic Institute, employing nine first-class professors and 3,650 acres of land. The report of Professor Hitchcock fills over ninety octavo pages, and we regret our want of room to give copious extracts from this truly valuable contribution to the agricultural literature of the United States. It is a work of great labor and condensation. Without the text, the thirteen tables would be nearly unintelligible. The following summary, however, will indicate the territory surveyed:

"But though my list is doubtless deficient, I have been amazed, as I doubt not the committee will be, at its extent. The following summary will bring the whole subject under the eye:—

SCHOOLS.	Superior Schools.	Intermediary Schools.	Inferior Schools.	Special Schools.	Connected with Colleges and Universities.	Total.
In England	1	...	4	...	...	5
In Ireland	1	25	34	...	3	63
In Scotland	...	...	...	...	2	2
In France	5	...	70	...	...	75
In Italy	...	...	1	...	1	2(?)
In Belgium	...	3	2	1	3	9
In Prussia	3	2	12	13	2	32
In Austria	4	...	3	25	1	33
In Wurtemberg	1	2	1	3	...	7
In Bavaria	1	1	32	1	...	35
In Saxony	1	3	...	1	...	5
In Brunswick	...	1	1	...	...	2
In Mechlenberg Schwerin	...	1	...	...	...	1
In Schleswig Holstein	...	2	2	...	...	4
In the Principality of Anhault	1	1	...	...	...	2
In the Grand-Duchy of Hesse	...	2	...	...	...	2
In the Grand-Duchy of Weimar	...	...	...	...	1	1
In the Duchy of Nassau	1	...	...	...	...	1
In the Electorate of Hesse	1	...	...	...	...	1
In the Grand-Duchy of Baden	...	1	...	...	...	1
In the Duchy of Saxe Meiningen	...	...	1	...	...	1
In Russia	2	10	51	4	1	68
Total	22	54	214	48	14	352"

The 22 "superior schools" in the above list will rank with our best colleges in the extent and variety of sciences studied, while the 54 "intermediary schools" will compare favorably with most American colleges. It is remarkable that the United States should not contain a single institution of the kind, and that all efforts to establish one in the great State of New York, for the last thirty years, should prove unsuccessful. Nor has the report of the Massachusetts commissioners been favorably acted on, even in a State so distinguished for its liberality to all other educational institutions. One serious impediment has been the lack of well-qualified gentlemen to fill the several professorships. These must be educated in Europe before we can establish a first-class professional school. When medical schools were first founded in this country, nearly all our teachers of anatomy, physiology, surgery, theory and practice of physic, &c. were educated abroad.

Professional schools of a high character could be established in no other way. Doubtless, Congress might establish an institution of the scientific grade of West Point Academy, and procure such gentlemen as Leibig, Agassiz, and Boussingault, to serve as teachers until a reasonable number of talented Americans could be prepared to fill professorships in State agricultural colleges. At present, we not only lack institutions of this kind, but gentlemen duly qualified to teach all the sciences that legitimately appertain to the noble profession of agriculture and husbandry. The people of the United States have over three hundred millions of dollars invested in domestic animals, and if a young farmer engaged in stock-growing wishes to study the digestive organs, the muscles, nerves, or blood-vessels of the horse, cow, sheep, or hog, there is not a museum in all America where this can be done, and he must cross the Atlantic for the purpose, or remain in ignorance. We do not depend exclusively on books to teach the anatomy and physiology of man, but make dissections, have ocular demonstrations, and valuable museums still further to illustrate all parts of the system, both in a healthy and diseased condition. Why should we be so unwilling to form agricultural museums? Why so reluctant to provide facilities for the successful study of the organization of valuable domestic animals, with a view to preserve their health, increase the growth of flesh, fat and wool, and the production of milk, butter, and cheese? Will it be said that a knowledge of all this living machinery can be of no value to the country? Is there no chance for additional improvement in thirty millions of sheep which elaborate wool and mutton, nor in the five or six millions of cows which yield all the products of the dairy in the United States? On the contrary, is there an intelligent man in the Union who does not know that nine-tenths of all our domestic animals, from the horse down to dung-hill fowls, are susceptible of very great improvement?

In 1818, William King, of Wurtemberg, established an Institute of Agronomy and Forests on the royal domain, of some 825 acres, having one director, six professors, four functionaries charged with various labors, besides two tutors who hear lessons in the school. The instruction given is embraced in *forty courses*, divided into three groups: 1. Agricultural matters. 2. Forest matters. 3. Auxiliary sciences. In the 1*st* course are included—1. Of climate; 2. Of soil; 3. Of manures; 4. Of tools and implements of tillage; 5. Of clearing up of ground; 6. Of meadows and pastures; 7. Of agriculture in general: this is divided into ploughing and other tillage, seed-plots, of grain and root-culture, threshing and preservation of grain, &c.; 8. Of special agriculture. All cultivated plants are treated of particularly. 2*d* course—Viticulture; 1. Culture of the vine; 2. Wine-making. 3*d* course—Culture of fruit-trees. 4*th* course—The rearing of cattle; the races; the crossing; the young. 5*th* course—The rearing of the horse; natural history of the horse; different methods of raising; choice of animals for reproduction; treatment of mares; treatment of colts. 7*th* course—Rural Industry in *winter*, the manufacture of beet-sugar; of liquid manure; of malt beer and brandy. In *summer*, manufacture of beer, vinegar, cider, lime, and draining tiles. 8*th* course—*Rural Economy:* Valuation of real estates; general circumstances of the country; of farms in general; of different parts of the same farm; of the home means of maintaining its fertility; of systems of culture; of labor and the internal organization of a farm; relation between the number of beasts and land worked; of capital of the undertaker or farmer; of the different modes of working a farm. 9*th* course—Agricultural book-keeping, &c.

We omit all the details on "Forest Matters," although forest-culture is destined to become an important interest in this country much sooner than many suppose.

3. AUXILIARY SCIENCES.

1*st* course—Higher arithmetic. 2*d* course—Algebra. 3*d* course—Planimetry. 4*th* course—Stereometry. 5*th* course—Trigonometry. 6*th* course—Applied geometry. 7*th* course—Mathematics applied to forests: 1. Of the culture of trees and of the entire forest; 2. Of the increase of trees; 3. Of the valuation in money of forests. 8*th* course—Physics. 9*th* course—Mechanics. 10*th* course—Chemistry. 11*th* course—Oryctognosy. 12*th* course—Geognosy. 13*th* course—Vegetable botany and physiology. 14*th* course—Special and rural botany. 15*th* course—Zoology. 16*th* course—Veterinary medicine; 1. Natural history of our domestic animals; 2. Anatomy of do.; 3. Animal physiology; 4. Care to be taken of animals; 5. Of the medicines proper for slight diseases; 6. Description of diseases, pathology, and therapeutics; 7. Veterinary surgery; 8. Internal diseases of animals, and murrains. 17*th* course—Of forest law. 18*th* course—Rural constructions. 19*th* course—Of preparing plans. 20*th* course—Drawing of machines.

To illustrate these courses of instruction, the means seem to be very ample at Hohenheim. They are as follows:—

The operations on a large farm annexed to the Institute. A forest of 5000 acres. A botanic garden. A library open twice a week. A geological collection. A mineralogical do. A botanical do. A collection of woods, seeds, and resins, from the forest. A collection in comparative anatomy. Do. of specimens of wool. Do. of agricultural products. Do. of models of instruments for tillage. Do. for physical science. Do. for chemistry and laboratory.

Students board where they please, at a price from $24 to $120 per annum, but lodge at the Institute. The number of students in 1849 was about 100, but it had been 140 for many years. No less than 1650 finished their education at this seminary within 31 years. Dr. Hitchcock pertinently asks—"How is it possible that so many, having gone through such a thorough system of instruction, should not exert a powerful influence upon agriculture throughout the community?"

If the number of students appears small, it must be borne in mind that the small town of Hohenheim has 7 agricultural and horticultural schools of an inferior grade.

In Saxony, there is a superior school, with 9 professors, and a domain of 7,355 acres. Brunswick has a superior school with 13 professors. This practice of subdividing the business of teaching among so many professors, each of whom gives his undivided attention to the advancement of a particular art or science, secures that pre-eminence in German universities and scholars for which they are distinguished. Is it not possible for the United States to have one school worthy of the republic?

MISCELLANEOUS COMMUNICATIONS.

Delaware County Institute of Science, Pennsylvania,
Hall of the Institute, January 7th, 1851.

Dear Sir:—I am directed by the Institute to communicate to you their thanks for many packages of valuable seeds, reports, &c. from your office, and to say that the institution has directed a large share of its attention to agricultural subjects, (a majority of its members being thus practically engaged,) and will receive with pleasure, and test by suitable experiments, any seed or grain, &c. you may forward in future. The lively interest felt in the agricultural department of your office, will, at all times, secure the hearty co-operation of the institution, to the extent of its limited means.

I have the honor to be, &c.,

JOSEPH EDWARDS,
Corresponding Secretary.

To Hon. THOMAS EWBANK,
Commissioner of Patents, Washington, D. C.

Lima, Delaware County, Pennsylvania, January 7th, 1851.

Sir:—Your Agricultural Circular, dated August, 1850, was duly received, together with a note acknowledging the receipt of our communication in 1849. The Delaware County Institute of Science, under whose instructions that and a former report were made, having received the circular through our representative in Congress, directed the undersigned to prepare a reply in conformity with your suggestions. Many of the queries in the present circular are but slightly variant from a portion of those of former years, which, though then answered in detail, may, under the probability that each report will reach the hands of other readers, justify a review of our agricultural experience and condition, even if it shall involve the necessity of occasional slight repetitions. To enable the practical agriculturist to appreciate fully the information furnished by your correspondents, a general view of the local natural conditions, such as the character of the soil, climate, elevation, general humidity, &c., so materially influencing the result of any system or experiments, should, we conceive, in all cases, be particularly given. Delaware County, Pennsylvania, is situated on the west side of the River Delaware; the centre at about 15 miles W. S. W. from Philadelphia, and crossed north of the centre by the 40° of N. latitude; territorial area, 177 square miles; population, 24,640, or 140 to the square mile, containing the earliest settlement in the State. The surface is undulating, with a general inclination to the S. E., and rises gradually from tide-level to a mean elevation of about 450 feet at its N. W. boundary. An alluvial belt, bordering on the River Delaware at tide-water, is succeeded north-westward by a band of primitive rock formation, covering the remaining surface of the county, first, by a zone of gneiss, some 4 miles in width, extending from N. E. to S. W. nearly, followed by a belt of serpentine, of nearly equal width, and the latter by a band, some 8 or 10 miles wide, characterized by various modifications of gneiss and kindred rocks, extending beyond the limits of the county to the slate-ridge bordering the primitive limestone-valley of Chester County. Trap-rocks, in a few localities on either side of the serpentine belt, have protruded to the surface in the eastern sections of the county; mica slate near the centre, and limestone in a few detached spots in the extreme west. Interspersed throughout the serpentine belt, are comparatively large areas of silicious rocks, in various forms and compounds, requiring large and frequent supplies of fertilizing agents to maintain a satisfactory degree of productiveness. The more generous qualities of the soil, in other and adjoining sections, need much less artificial aid. The whole surface of the county, with trifling exceptions, is, however, in a high state of cultivation. In common with all the territory bordering on, and contiguous to the west bank of the Delaware, this county is traversed by numerous mill-streams, generally having their sources north-westward beyond its limits, and, by channels deeply-indented, nearly parallel, and from 2 to 3 miles asunder, which discharge their waters into tide-water, in the Delaware, on the S. E. The valleys of these streams are intersected on either side by continually recurring minor valleys and their accompanying streams, deriving their sources from springs on every farm, and frequently in every field, up to the dividing-ridge, at a mean elevation of about 200 feet above the creeks. This rolling character of the surface, with scarcely any declivity too abrupt for cultivation, or a single acre too low for drainage, with everywhere an abundant supply of streams and springs, is well-adapted to the business of dairy husbandry. These streams, great and small, meander through valleys of various widths, moderately fertile, of rapid descent, with gradually sloping sides, generally admitting of irrigation almost continuously throughout their extent. Thus almost every farm in the county has, or may have a portion of natural meadow, watered by the overflow of streams, or artificially by irrigation: in either case they are highly productive, and furnish two crops for hay annually, and perpetually, together about 2½ tons per acre, of the very best quality for dairy stock, without exhausting the soil, or other cultivation.

The character of the soil varies essentially in different localities, as may be inferred from the description of the rocks already given, embracing every variety, from nearly sterile to highly fertile. Clay predominates in the S. E., in the vicinity of tide-water, (except the alluvial of the river flats,) and also in a few detached localities inland; but the largest portion of the surface consists of soil formed from the disintegration of the local rocks, and may be termed a sandy or gravelly loam, impregnated everywhere by more or less ferruginous matter, and nearly destitute of lime; this latter defect has, however, been to a great extent corrected within the last 30 years, by a liberal admixture, applied in the course of cultivation. In the serpentine belt, magnesia and chrome exist to an extent, in many spots injurious, if not destructive to vegetable life. To neutralize the defects, and render available all the advantages now afforded by our varieties of soil and situation, have taxed the ingenuity and the industry of our ancestors through the five preceding generations. The entire territory of the county, except in the vicinity of villages and manufactories, is divided into moderate-sized farms, varying from 20 to 200 acres each, but principally from 60 to 100 acres; and these, whatever their size, into from 7 to 12 enclosures, viz. one natural meadow, one in timber, and the residue, more or less, for cultivated crops. The farm-buildings are mainly constructed of stone, and sufficiently capacious to admit the storage of the whole produce of the farm, and shelter for all stock, carriages, farming utensils, &c. In all cases, when practicable, the farm buildings are located in the immediate vicinity of a spring of water, over which is erected a substantial stone structure, and other appliances suitable for conducting the operations of a dairy, and, when convenient, the stream therefrom passes through the barn-yard, for the use of stock in the winter. The high estimation in which the fresh butter, veal, and poultry produced in this section of the State, are held in the markets of Philadelphia, New York, Baltimore, and Washington, and the present facilities of reaching them at a trifling expense, have rendered the production of these articles the most profitable application of the soil. To furnish the greatest quantity of suitable provision for dairy stock is, therefore, the leading object of the farmer, and gives character to our entire system of cropping. Experience has proved that land laid down in grass will not produce the maximum quantity beyond 4, or at most 5 years, in succession, without reploughing, whatever may be the natural or artificial stimulants; and as this has become the most profitable and desirable crop, the cultivation of the several grain crops follows as a matter of expediency, rather than choice. Thus influenced, our system of cropping may be briefly stated as follows, viz.: First, Indian corn, succeeded in the following order, by oats, wheat, and grass; the latter depastured the first year after the wheat has been removed, cut for hay the second and third years, and then appropriated to pasturage until reploughed; each field receiving like treatment in all respects as that preceding it. Thus every farm presents at all times the following phase:—One field under cultivation with Indian corn, one with oats, one with wheat, one or two producing grass for hay, (as there may be more or less natural meadow,) and the residue as pasturage. On small farms, the oat crop is usually omitted, and the corn followed in the same year by wheat. This would in all cases be adopted in practice, but it involves a heavy amount of labor in removing the corn crop from the ground, and time, in covering it with manure, which cannot at all times be effected in due season. The culture which experience has proved the most profitable for each of our course of crops is as follows:

INDIAN CORN.

Of the cultivated crops, this is the leading and decidedly the most important and profitable to the Delaware county farmer. Aside from the quality more or less used as food in various forms, in almost every family, it enters extensively, in as great a variety of forms, into the entire system of the farmer, furnishing in large proportion the most economical and desirable *extra* food for working-cattle, horses, beef-cattle, hogs, dairy stock, and poultry, and from the comparative certainty of obtaining a crop, under all the vicissitudes of season and accidents, it would be hazarding little to say that 50 per cent. of the entire profits of our agricultural operations (exclusive of dairying) flow directly or indirectly from the production of Indian corn alone.

In autumn, winter, or spring, old pasture ground (the older the better) is broken up, from 6 to 8 or more inches in depth, and so remains till near the planting season, when the surface is thoroughly broken with the harrow, laid off into squares, by furrows, with the plough, 4½ feet apart, and 4–5 or more grains planted with the hoe, and covered to the depth of two inches, at the intersections, between the 20th of April and the 10th of May. When the plants are some 2 or 3 inches above ground, the cultivator is used freely in each direction between the rows, and when 6 inches high, the number of plants in each hill is reduced to 3, or at most 4. Supplying any deficiency by replanting, and stirring the surface every third week (or oftener, if the weather is dry) with the horse cultivator, until the ear sets, comprise the usual and generally the only after-culture required. The depredations of *birds*, the *wire* and *cutworms* are generally limited to the first 4 weeks after planting. The most effectual remedy for the cutworm consists in ploughing the ground during the preceding autumn or winter; for the others, none is known. Injury by moles can be in a great measure prevented by frequently stirring the ground. About the 15th of September, when the *husk* of the ear gives signs of ripeness, and the grain is *nearly* hard, the whole crop is cut off, and shocked 48 hills together, around 4 hills left standing for the purpose, and secured at the top to prevent the admission of rain. After standing thus some 3 or 4 weeks, the corn is husked and stored in open lathwork cribs, 3 feet wide, of any length and height, and covered with a water-tight roof, exposed to the open air on every side. The stalks, with the husks and leaves upon them, are bound in convenient-sized bundles, and stacked or secured under shelter, if possible, until used. The occurrence of drought or early frost frequently causes the appearance of premature ripeness in the stalk and the leaves, and the grain, though it acquires a degree of hardness, is shrunken and movable on the cob, under the finger. Experience has proved that the sap-vessels in the stalk continue to act, and, if permitted to stand, will generally mature the grain satisfactorily. Almost every known variety of corn has been introduced and cultivated here experimentally to a sufficient extent to develop their respective character and general adaptation to our soil and climate: in all cases, however, after a few years' cultivation, the effect of the latter, or, possibly, occasional contact during their growth with the cultivated varieties, tends to reduce them to a general conformity in habits, appearance, and quality, with the common standard type already in use, viz. ear from 8 to 13 inches in length, cob white, 1½ inches diameter, from 12 to 20 rows of grain, compactly seated on the cob, and weighing from 50 to 60 pounds per bushel. A yellow variety, called Oregon corn, at the Patent Office, whence the seed was received, has become a favorite with many, and its cultivation is increasing, and three varieties of white, viz. Baden, Lloyd, and Rowsie, also received from the Patent Office, have been experimented upon sufficiently to establish the character with which they came recommended; but it is questionable whether either of them offers any permanent advantages over that already in use.

The corn crop until recently has been required to depend entirely for its support on the natural fertility of the soil and stimulants derived from a fresh-turned sod. The latter is indeed an indispensable requisite for a full crop, under any system of management, or on any of our varieties of soil, however productive they may generally be. No moderate amount of manure is adequate to sustain a second consecutive crop, nor indeed a full crop from any ground under cultivation the preceding year. Light manuring *in the hill* has long been practised on small parcels with marked benefit, but the recent extension of the use of *guano* on wheat ground has enabled those using it to dispose otherwise of a portion of their barn-yard manure. Land destined for corn has recently participated in this surplus with most decided advantage, and it is highly probable that the increasing use of that article (guano) will thoroughly revolutionise our system of manuring, and that the corn crop will eventually be the exclusive recipient of the home-made manure, as that of wheat has hitherto been. The sandy and gravelly loams on the more elevated land, distant three or more miles from the river, are better adapted to the production of this grain than the clay soil below, over nearly the whole surface of the country. However, the soil, solar heat, moisture, and length of season are so favorable to its cultivation as to produce, in average years, from 35 to 65 bushels per acre, (as the quality and natural strength of the soil may vary,) with suitable attention, *without* manuring, and a fourth or a third more if manured. The cost per bushel to the producer, when delivered at the mills, under the treatment sketched above, after making a reasonable allowance for the value of the stalks, is estimated closely at from 20 to 25 cents per bushel of 56 pounds, and the present value for new crop, 55 cents. The most recently-approved method of feeding to horses is in the whole grain; to horned cattle, in the form of meal, frequently mixed with an equal quantity of oatmeal; to hogs, the the same, after fermentation, except in the last stages of feeding for slaughter: then whole grain, and pure water for drink. Cooking the meal, and also the grain, is frequently practised on a small scale with decided advantage, but no experiments are known to have been made with sufficient accuracy to serve as data to estimate the extent of its economical advantages. The whole crop finds a ready demand at home—at the mills, factories, public houses, and dairymen, and also for feeding the large droves of beeves during their transit through our county from the South and West to the Eastern markets: in this case, it is fed in the ear, as the most advantageous and economical for the drover. The crop suffered severe injury the present year, from the violent storms of the 19th of July and later; and the great quantity of rain during the season was detrimental to crops generally, and particularly on clay soil, retarding the ripening some ten days. It escaped the frost, however, and the crop altogether is above an average one, and has been well secured.

OATS.

The oat crop, in our system, is almost invariably restricted to land cultivated with corn the previous year, and, owing to the common opinion that it is a great impoverisher of the soil, is in no great favor with the farmer. But for the small expense attending its cultivation, the convenient time of sowing and harvesting, and also the necessity for cultivating the ground preparatory to the wheat and grass crops in the succeeding autumn, which perhaps it serves well, it would be generally abandoned. Corn ground of the preceding year is ploughed at any convenient time, when the frost will permit, in the spring, not later than the 1st of May; 3 bushels of seed per acre are sown immediately, well harrowed, frequently passed over with the roller, and left without further attention, until it ripens, generally late in July, when it is cut with the cradle, bound in convenient-sized sheaves, and secured in the barn. The whole crop of 1850 was entirely prostrated by the storm on the 19th of July. Much of it could not be bound, but was stored in the barns in bulk. The quantity was about equal to an average, and the quality fair. No manure is applied to this crop: thin soil, if the season is favorable, is well adapted to this grain. On strong ground, the straw grows rank and weak, is liable to fall, and the grain perish. The crop is very susceptible of injury from drought, during any stage of its growth, but singularly exempt from the depredations of insects or other enemies. Under favorable circumstances, from 30 to 50 bushels per acre are the usual yield, if cultivated with proper care, without strict regard to the quality of the soil. A white, and also a black variety, have been cultivated here many years, and esteemed the best adapted to our locality. The cost of production is estimated to average 21 cents per bushel: the usual value from 30 to 50 cents; at present 44 cents. The whole crop finds a ready market in the county, and is used as food for horses in the whole grain; for dairy cows and hogs, in the form of meal, usually mixed with equal parts of cornmeal.

Barley and Rye, formerly cultivated extensively here, have been superseded by oats and wheat respectively. A blight attacked the latter some fifteen years since, and has continued to affect the small quantities occasionally cultivated, except on serpentine soil; if otherwise, however, the highly improved condition of our farms renders the cultivation of wheat more profitable. The cultivation of beans and peas is restricted to the garden, exclusively for table use. Wheat is one of our standard crops, and uniformly takes its place as that last cultivated in our system previously to the grasses. The thorough working of the soil and the high manuring necessary for both of these, admitting as they do of the simultaneous introduction of their seeds, render this arrangement at once the most judicious and convenient. All our varieties of soil, when highly manured *at the time of sowing*, will produce wheat satisfactorily under favorable circumstances of season, &c. On naturally strong ground, and particularly on clay soils, a heavy growth of straw frequently proves detrimental to the crop of grain, increasing its liability to fall previous to maturity, and especially so when abundant. Rains are highly beneficial in promoting a full crop on lighter soil in more elevated situations. The favorite practice until recently has been, to manure the ground but once during the usual course of cultivation, and that *always* at the introduction of the wheat and grass crops, the last of the series. Experience has abundantly proved that manure applied to corn-ground in the spring of the year, is not sensibly beneficial to a wheat crop, if following in the autumn, though the grass crop succeeding bears evidence of the usual durability of its effects. Thus, a direct and invariable proof is furnished that the first virgin virtue of fermented manures is essential to a full development of the wheat crop; or possibly from a continued fermentation in the vicinity of the roots the necessary stimulant is drawn. Various opinions prevail in respect to the most judicious mode of applying manure to secure the best results, at once, to the wheat and the succeeding grass crops, the latter esteemed the most important; and as various methods, with this object in view. Spreading it on the surface and turning it under with the oats stubble in August, where it is suffered to remain until seeding-time, when, by reploughing, it is returned to the surface, has many advocates. Spreading it after the first ploughing, and turning it under when preparing for seeding, is also extensively practised. These are the methods generally in use, but experiments are continually being made to solve this interesting question. Observing the superior growth and yield of wheat, and the flourishing condition of grasses, on a small portion of a field, where, merely from convenience at the time, the manure was spread on the surface *after* the last ploughing, and harrowed in with the grain, the writer was induced to use the like treatment with the entire crop in 1849. The result to both the grain and following grass crops was so highly satisfactory, that the same method has been continued with the present growing crop: the manure (from the barn-yard) was well rotted, and, together with the grain and grass seeds, mixed with the surface some two or three inches deep, by using the corn-cultivator instead of the harrow for that purpose. The present appearance of the crop warrants the opinion that both the wheat and timothy need, and are receiving, at the shallow depth to which their roots have penetrated, the greatest possible amount of benefit from the manure at this tender stage of their growth; and the inference is fair that any surplus, after supplying the wheat crop, will be much longer available to the succeeding grass than if placed at the outset at the extreme depth to which the mature roots shall penetrate. Some forty years back, a white, beardless variety of wheat, called "Jones," after enjoying exclusively the favor of farmers of that day, ceased to yield satisfactorily, and was discarded. A variety, still cultivated by a few—the "red-chaff bearded"—supplied its place, and continued without a rival until some fifteen years since, when its productiveness began to fail. It also fell into disrepute, and gave place to almost every known variety of winter wheat, which by turns succeeded each other, and had their year of eclat, to pass into oblivion as their predecessors. The "Chinese," "blue-stem," "Genessee," "Henderson," "Stewart," "Mountain," and "Mediterranean," have each walked over the course, and, except the two last, have nearly disappeared. The "Mountain," introduced about the year 1844, soon led to high hopes of its adaptation to our locality. The first, second, and third years of its general use, it succeeded to admiration; but last, and the preceding year, owing to its late ripening, (about the 10th of July,) it was struck with mildew, and simultaneously attacked, while in the milk, by a small, wormlike, reddish insect, whose depredations on the grain almost literally annihilated the entire crop of that variety, in a large portion of the county, and, with it, its former popularity. The "Mediterranean," introduced some twelve years since, has become a steady dependence under all vicissitudes. Its exemption from the "fly" served at once to extend its fame—a character which, unfortunately, departed early. Yet, notwithstanding the fancy article above-named passed over the scene in the mean time, its comparative excellence, by contrast with them, is more thoroughly appreciated, and at this moment it reigns in public estimation without a peer. Its good qualities consist in admitting of early or late sowing, more productive than other varieties on thin soil, early ripening, (about 10 days in advance of other kinds,) by which rust and mildew are nearly uniformly escaped: it probably escaped the ravages of the insect described above for the same reason. Flour, white and excellent; grain, large and full, weighing from 60 to 65 lbs. per bushel. The objection urged against it is the weakness of the straw, which causes it to fall occasionally, on very fertile land, before perfectly ripe, and renders the harvesting troublesome and expensive. Various modes of preparing the seed have from time to time been recommended, and in some instances practised, such as soaking in ley of wood-ashes, lime-water, salt-water, &c., but no advantages have resulted to induce a continuance: the only caution observed is to select the fairest portion of the recent crop, clear of blight, and to thoroughly separate any extraneous substance. The main dependence is placed in the preparation of the ground rather than that of the seed. In very rare instances, and these as a matter of convenience, wheat is sown on small lots of fresh-turned sod, and frequently on ground from which a potato crop has been removed, in both instances with moderate success; but the usual course, as before given, consists in preparing recent oats-ground, by some of the modes described, by mixing thoroughly with the soil from 25 to 30 ox-cart loads of stable manure, or 400 lbs. of guano per acre; then sow, broadcast, from 7 to 9 pecks of seed, harrow the surface thoroughly, and sow from 4 to 6 qts. of timothy-seed, immediately before rain. On flat ground, inclining to clay, covering the grain by light ploughing is frequently practised with advantage.

When the drill is used, from 5 to 7 pecks of seed per acre are deemed sufficient. The corn-cultivator is, in some instances, used for covering the grain, instead of the plough, harrow, or drill, as the condition of the soil or surface may render preferable. In all cases where guano is used, the plough is preferred, to prevent, as far as possible, its contact with the atmosphere. The usual time for sowing embraces the last 20 days of September and the first 20 days of October. The advantages of any time intermediate are wholly dependent on the after state of the season. When very dry, the early sown is attacked by the Hessian fly, and the check it receives from this and the lack of moisture is seldom entirely overcome. The principal advantage of early sowing consists in the opportunity afforded to the timothy to acquire sufficient root to resist the injury inflicted by alternate freezing and thawing during the ensuing winter: it is the more important crop, and very susceptible of damage from this cause. If the autumn continues mild and moist, with but little early freezing, that sown so late as the middle of October, or even later, frequently produces the heaviest crop, and but a few days difference in the time of ripening is observed to result from as many weeks difference in the time of sowing. The Mediterranean ripens usually about the first of July; other varieties, about the 10th. When harvested, the crop is stored in barns, and recently the threshing-machine is employed, as early as convenient, to anticipate the usual depredations of rats and mice. The crop of 1850, up to the middle of June, progressed favorably; but the constant humidity of the air and the large quantity of rain caused rust and mildew to attack all late varieties. This, in connection with the destruction by the unknown insect referred to, reduced the entire yield some 20 per cent. below our usual average. The whole crop of the county but partially supplies the local consumption, and finds a ready market at our mills, at Philadelphia prices ranging from $1.25 in August, to $1.04–$1.10 subsequently. The general yield of wheat per acre is progressively increasing in this county, owing to the constantly improving condition of the soil. From 15 to 20 bushels per acre, twenty-five years ago, was deemed a full crop, on our best soils. Under our improved system of cultivation, and greater attention to liming and manuring, less than from 25 to 30 bushels, on like soils, in favorable seasons, is not satisfactory. About that time, wheat had become an exceedingly uncertain crop, by the constantly increasing injury inflicted by the Hessian fly. The old "red chaff" was almost the only variety then in use, and generally sown early. The fly became so destructive as almost to deter farmers from further attempts to cultivate wheat. It was found, however, that, by late sowing, say from the middle to the last of October, for a number of years, it almost disappeared from the county; but that variety of wheat ceasing to yield satisfactorily, other more productive kinds were introduced, and they were proved to be most prolific when sown from two to four weeks earlier. The "Mediterranean" was one of these, the first; then followed the "mountain" and others, all of which escaped the fly for a time, even when thus early sown: they were consequently deemed fly-proof. The usual time of sowing was anticipated, in many instances, to the last week of August. The fly has returned again, and they attack indiscriminately every variety, thus inducing the belief that the previous exemption from the ravages was not owing to the kinds of wheat in use, but to *their absence*. Reflecting farmers are of opinion that their return is consequent upon very early sowing, and that the only relief will be found in a return to that practice which formerly proved effectual. The *weevil* is not known to us as a scourge to the growing crop. They frequently infest barns and mills. The remedy for the farmer is easy, and consists in stacking at a distance for about three successive years, and they entirely disappear. Our last crop, particularly the late-ripening varieties, and especially the "mountain," were attacked by a little reddish-yellow worm in the grain, *while in the milk*, and the destruction, in many instances, was almost complete. Its ravages were at an end when the grain became hard; and it was probably owing to the grains of the "Mediterranean" being in this situation when it made its appearance, that it alone escaped. This insect was called by some the "red weevil;" but it had none of the appearances nor characteristics of a weevil. It came with the mildew. Under the microscope, no legs were discoverable, nor any thing like a mouth for biting, but only for sucking; nothing like teeth, or any thing calculated to answer their purpose, could be discovered: the organ reminded every one who thus examined them of the mouth of the fish called sucker; hence they cannot be classed with the weevil family. From 10 to 50 were to be found in each head of wheat; often a dozen in the same pod. The number was so great, that the floors of the wagons and the barns, when storing the crop, bore the appearance of being covered with red dust. They continued to live, without sensible alteration in appearance, or further injury, many weeks. Their presence in the former crop is supposed from a similarity of its general appearance and light yield, attributed, at the time, to mildew alone; but they were not noticed. They are strangers to us, and no remedy for their ravages is known, save in sowing the earliest ripening varieties, and hence but little other than the "Mediterranean" was sown last fall.

CLOVER AND GRASSES.

The paramount importance of our grass crops, and the necessity for stirring the soil, at intervals of not exceeding 6 or 7 years, to insure the greatest aggregate yield, are the inducements to pursue as short a rotation of cultivation of the cereals as is found compatible with this main object. A three-years course of corn, oats, and wheat, has been reluctantly adopted as serving the desired purpose, and admitting of a convenient distribution of the farming operations equally throughout the business season. A most desirable modification would be effected if the wheat crop would admit of following that of corn directly, in the same year, with safety to it and the grasses, without an intervening oat crop. The principal difficulty to be removed is the additional labor and time necessary to haul and spread some 25 to 40 loads of manure per acre, after the heavy work of removing the corn from the ground, the commencement of which is not usually earlier than the 12th or 18th of September, thus delaying the *act* of *sowing* beyond a safe season for either grain or grass seed, particularly the latter. The well-established necessity for the application of manure, in some form, *at the time of sowing these seeds*, has, hitherto, rendered this large expenditure of labor and time essential conditions of such modification. It is now believed that the use of guano as a substitute for stable-manure may enable our farmers to make this desirable change without unusual risk to the after crops; some progress has already been made in its support. Guano, in quantities of from 300 to 400 pounds per acre, has been used frequently within the last 3 or 4 years, instead of stable-manure, on wheat ground, with effects entirely equal in benefit to that and the succeeding grasses. In a few instances, when sown very late, and particularly after the removal of corn, uniform success has resulted. If no serious objection shall present itself in further practice, and the hope entertained from this partial experience be realized, the stable-manure may be applied to the corn-ground in the spring, by which its ripening season will be accelerated some 10 days, to be followed in the fall by wheat and timothy, treated with a light dressing of guano, *in good season* for the security of both: the oat crop omitted and a return to grass crops, at the end of the second instead of the third year, as heretofore. Timothy and clover (together) are the grasses cultivated for hay and pasture, nearly to the exclusion of all others. Herd and orchard grasses are, in a very few instances, cultivated in orchards and moist situations, but the difficulty of eradicating them when desired is a serious objection to their use. The treatment of timothy has been noticed:—that of clover consists in merely sowing from 4 to 6 quarts per acre of seed, on the growing wheat-ground, in the month of March or early in April, after severe freezing has passed; the surface at this time, in drying after winter frosts, is divided into numerous small fissures, into which a portion of the seeds falls and takes root at once, thus receiving the necessary moisture, and protection from frosts and the drying winds usual at that season. If the weather continues dry after the wheat has been removed, both the timothy and the clover will languish, and care is required that they shall be protected from close pasturing—if wet, a heavy growth will follow, and admit of pasturing freely. In the following year, the proportion of the clover to the timothy will be larger than is desired for first-quality hay, and is frequently devoted to pasturage; the second and succeeding years, the relative proportion changes, until about the fourth, when the clover will have nearly disappeared, and the timothy be no longer in quantity to furnish a satisfactory crop of hay: it is then appropriated to pasturing stock until reploughed for corn. The production of these grasses, and particularly clover, may be greatly promoted, and the latter in moderate quantity indefinitely continued, by occasionally top-dressing them with about one bushel of plaster per acre, say every second year. The chief dependence of the farmers of this county for winter support for the comparatively large farm and dairy stocks, everywhere kept in number up to the extreme limit of subsistence, is on the clover and timothy hay thus produced, assisted as far as possible by that procured from natural meadows, corn-fodder, straw, &c. Previously to the introduction of clover and timothy, about the commencement of the present century, and within the recollection of our old farmers, the only supply of hay was limited to that procured from natural meadows, watered by the overflow of streams or by irrigation: hence the value of farms bore a close proportion to the quantity of such land on each: those destitute of such a resource were esteemed of little comparative value, having been already exhausted by continued cropping, and no means of resuscitation could be drawn from the soil. Necessity thus induced a resort to mineral substitutes: lime and plaster were applied, at first cautiously and hesitatingly, subsequently in profusion; and, at this day, *uplands*, with the assistance of home-made manures thus produced, are made as productive in grass as the best meadow-lands, and full crops of the cereals are obtained. In the course of the necessary preparation, no attention is required to natural meadows, except to regulate the flow of water when irrigated, and, when the utmost possible amount of hay is desired, to avoid pasturing them at any time. The quantity of fertilizing matter deposited from the overflow will fully sustain the constant cropping, and, with care, will largely increase the productiveness: leached ashes is found to be the best known top-dressing for portions not within the reach of water, and plaster on every part has proved highly beneficial. The quantity of clover and timothy (mixed) hay, produced as above, will vary from 1 to 3 tons per acre, as the soil and season may be adverse or favorable, and estimated to average, in a series of years, 1½ tons annually, from all cultivated and meadow ground: from the former, in one crop harvested from the 20th of June to the 10th of July; from the latter, in two crops—the first from the 15th to the 30th of June, the last in September. The late crop, (1850,) owing to the great abundance of rain and high temperature during the growing season, is believed to be equal to the largest ever produced in the county; and, as a consequence, the market value is about 20 per cent. below the average, say from $10 to $12 per ton at the close of the year. Timothy produces but one crop of seed or hay annually: the seed ripens about the 20th of July, and is harvested as wheat. The growth of clover is continued throughout the season: the seed is procured from the second crop, permitted to ripen late in August or in September. As pasture, timothy is highly relished by all kinds of farm-stock—clover is a great favorite with horses and hogs, but becomes loathsome to horned cattle if confined to it even for a few days; when depastured in connection with the natural grasses, and free access is permitted to either at will, its full value is realized. There is difficulty in arriving at a correct estimate of the cost of growing hay per ton, on upland, since it would necessarily include a portion of the expense and value of the manure applied to the preceding grain crops. Apart from these, however, the cost would be limited to the interest on the value of the ground, taxes, &c., and the expense of securing, amounting together to about $8 per acre, or $5.40 per ton, on upland, and $9 per acre, or $6 per ton, for meadows, the latter including two separate crops.

After the second or third year's crops of clover and timothy hay have been taken the diminution in quantity progresses rapidly, and its place is supplied with like rapidity by a spontaneous growth of white clover and green grass. These grasses furnish the most grateful food in the form of pasture and hay to all kinds of stock, and are estimated more valuable for beef or dairy cattle than any other known to us; the growth is rapid when moisture is abundant, but they languish in drought, owing to the slight depth penetrated by the roots. The clover is said to be an introduced grass—when, or by whom we are unable to say; the yield of seed is large, but none is secured. Every part of our land is charged with it, and to whatever length of time cultivation may be continued, when permitted to rest white clover will make its appearance at once, and, in the space of two or three years, these grasses occupy the ground, to the exclusion of nearly every other. Their productiveness is greatly promoted by top-dressings of plaster, wood ashes, and other manures. At the end of 6 or 7 years from the previous ploughing, the surface becomes hardened by the feet of cattle, in common parlance "sod-bound," and the regular course of cropping is repeated.

ROOT CROPS.

Turnips, Carrots, Beets.—Turnips are grown in small quantities, for table use alone; generally sown in gardens and borders of cornfields late in July or early in August, when the corn needs no further work upon it. The crop is a precarious one, and frequently fails from partial drought. Ashes, rubbish from the wood-yard, and other refuse and rich earth were, until recently, the usual manures applied. A few recent experiments with guano have proved it to be incomparably superior to any other for this crop, and it is probable further trial may induce greater attention to it.

Carrots and beets are also produced in small quantities for table use. Some ten years since, a spirited attempt was made to introduce sugar-beet as a standard crop. Their cultivation was attended with success in almost every instance, and their value as food for cattle and hogs was generally admitted. The yield was from 400 to 800 bushels per acre in field culture, but ripening too late in the season to be succeeded by wheat and grass without interfering with other important operations on the farm was an objection, and but few are now to be seen in the country. As winter food for store hogs they are preferable to grain, and their cost less than one-third. The usual practice was to plant in ground suitable for potatoes, laid off by furrows 18 inches apart, treated with a moderate quantity of well-rotted manure on very rich earth, two or three seeds deposited together at 6 inches distance, and covered with the hoe; when the plants are some 3 or 4 inches above ground, thin out, leaving one only; as their growth progresses, feed off every second beet, and leave the number to ripen 12 by 18 inches. The season for planting and harvesting, and also the treatment throughout, are similar to that of the garden beet. The usual way of preservation in winter is the same as potatoes. When fed to hogs, no preparation is necessary; to cattle, they are required to be washed clean, cut into pieces, and, when desired, dusted with any kind of meal. When fermenting manure is used, cover it two inches deep with earth, then plant and cover again. When fed to horned cattle, owing to its slight purgative quality, a simultaneous use of hay, straw or corn fodder is required.

Potatoes, Common and Sweet.—The common potato is cultivated in this county to the extent of consumption, and, in the eastern section, for the Philadelphia market. The planting season is from the 10th of March to the 1st of June. Early planting, say from the 10th to the last of April, has been generally preferred since the prevalence of the "rot;" by admitting of harvesting previous to the usual copious rains late in September, loss by that disease has been to a good degree avoided. Late planting, when the months of July and August are wet, succeeds well, and, before the appearance of that disease, was chiefly practised for a winter supply. Apparently, owing to the unusually large quantity of rain in the months of July, August, and September, in 1850, the early planted crop was backward and the quality indifferent. The disease became very prevalent in September, and continued, causing a heavy loss. After being gathered and stored, they were attacked by another disease called "black rot," for which no remedy is known. When stored in confined cellars, its progress was rapid and destructive, and the quantity left by both diseases is small and the quality very inferior. Altogether, this season has been more disastrous to this crop than any since 1846. The latter disease was observed immediately after the potatoes were stored away, presenting a slightly shrivelled skin and numerous small specks of white fungi on the part affected under the skin; the substance became slightly hardened and of a dark brown-color; thus it progressed till the whole was destroyed and dry. No evidence is afforded of the disease being communicated to another by contact, but the inferior quality of all favors the opinion that none are in a strictly healthy condition. The usual cultivation consists in spreading about 40 cart-loads of slightly fermented stable manure upon an acre of *sod* ground, (if convenient,) or that cultivated the previous year with corn or oats, at any time in the spring. For planting, plough the field as usual, and drop the potatoes 8 or 9 inches apart in every second furrow; harrow the surface, or permit it to remain until the plants are some 4 or 5 inches high, when the surface is thoroughly broken by the harrow, without regard to the tops; before the tops fall, pass the corn-cultivator freely between the rows until all grass and weeds are destroyed; if the surface is flat or inclined to clay, throw a light ridge on each side with the plough: proper care afterwards to prevent the growth of weeds, &c. is all the attention required until the crop is ready for gathering. The manure, in some instances, is placed in the furrows under the potato as the planting proceeds, but with no visible advantage. Soil inclined to sandy is esteemed preferable for this crop, and it is less liable to suffer from disease. About 500 lbs. of guano are found to equal the usual quantity of manure, and its use for this purpose is increasing. Lime also is much used, and is believed by many to improve the quality of the potato sensibly. No preparation of the seed is practised beyond reducing to the proper size, if too large; but small tubers about 16 to the pound are generally used whole, and preferred by many to large ones divided. The "Mercers" are cultivated almost to the exclusion of all others; some of the latter are occasionally introduced and tried, but none are found to be preferable, and soon disappear. The average of our crops for a series of years may be placed at 100 bushels per acre. In favorable seasons and soil, 150 bushels are obtained, but it is doubtful whether there is any progressive increase since the "rot" made its attack in 1843, or that by the present practice any very material increase in the product per acre can be obtained. The writer of this, a few years since, made an experiment to test the capacity of ground equally manured, to produce potatoes when planted in rows at less than the usual distance apart. On one-fifth of an acre, eight cart-loads of manure were spread in the usual way on the sod; one-third was planted with potatoes in every third furrow; one-third in every second furrow, and the remaining third in every furrow, at the distance of 9 inches apart in the furrows; dressing the crop was performed in the usual manner until it required the last culture; the last third received a thorough dressing with the hoe, and the others with the plough. The result was 60 bushels of prime potatoes, exclusive of small ones, or about 300 bushels per acre. The product of every row was measured separately, and the average found to be the same. Thus proving, in this instance, that ground equally manured will produce one-third more if planted two feet apart, or two-thirds more if planted one foot apart, than if at the usual distance of three feet; in other words, three bushels if planted in every furrow, to one bushel if in every third furrow, as is the present practice, with only the additional cost of seed and extra labor of the last dressing with the hoe, when planted so close as to yield the greatest quantity. The present year, (1850,) the most unfavorable of many years past for the potato crop, from 1½ acres of ground, 278 bushels of potatoes, large and small, were gathered, grown in rows two feet apart; usual cost of production estimated at 36 cents per bushel.

FRUIT CULTURE.

Considerable attention is given to the varieties of fruit suitable for table use at home, and for the Philadelphia market. These include apples, pears, peaches, plums, cherries, and grapes: apples are grown in quantities sufficient to meet those demands; but the more profitable use of the land for other purposes restricts the orchards to a few acres. None are cultivated for exportation. Much care has been recently observed in selecting the most valuable varieties and in their management: proper trimming, and yearly washing the bodies and principal branches with soft-soap, mixed with a solution of saltpetre, and also the removal of the earth, 6 inches deep and three feet in diameter, from the stem of the trees, and occasionally *ploughing the soil*, is the usual and necessary treatment practised. A white worm, infesting the body at and below the surface of the ground, is the great enemy to the apple-tree. Its seat is believed to be in, and its presence owing to the wound inflicted in grafting: it generally manages, with all our care, to produce premature decay and death to the tree. The only known remedy practised is to expose the part attacked to the frosts of winter. Hogs and cattle thrive well on the fruit when green, in connection with other food; but the unlimited use by dairy-cows, in some instances, almost suspends the secretion of milk, destroys their appetite, or deprives them of the power of eating other food, and nearly paralyzes their legs and feet. Horses become fat in a very short time when permitted to range in the orchard. For winter feeding, they are very nutritious, and relished by all kinds of stock, but no experiments are known to test their comparative value with potatoes. Our locality is well adapted to the pear-tree, and by quite spirited exertions we continue to avail ourselves of the advantage. The new and choice foreign varieties have been added to our former catalogue, with a fair prospect of success: a solitary instance of the blight, with the supposed cause and remedy, will exhibit in a nutshell the result of general experience. A young pear-tree, growing in a grass-sod, near the dwelling-house, bore fruit abundantly from an early age until 1842. It was then included in a newly located garden; the grass-sod was permitted to remain some 20 feet in diameter, under the tree; until 1844, the tree continued healthy and fruitful as before; in that year, the sod was removed and the ground cultivated; one of the principal branches was blasted the same year. The following year, the tree was fruitless for the first time, and wore a general sickly appearance, with a few small blasted branches. The greater exposure of the roots to the vicissitudes of extreme heat and cold was the supposed cause, and the surface was again covered with the sod; the tree recovered slowly, and has since become healthy and very prolific; other trees near it, but not included in the garden, have continued uniformly healthy and fruitful: the soil is a rich sandy loam; the situation, a south-eastern exposure, inclined at an angle of about 5 degrees. Peaches are cultivated for market in moderate quantity, with about the usual success. The trees are uniformly attacked at an early age by the worm, in the stem at the surface of the ground. Many devices have been put in requisition as preventives: exposure of the parts to winter frosts, a bank of earth around the stem during summer and removed in winter, straw-covering for the stem, white-washing, ashes, tan, salt, lime, &c., around the stem at the roots: all, however, have alike failed to preserve the tree, beyond the sixth or seventh year. The yellows also performs a full share in the destruction, for which no remedy or palliative is known. The past 20 years have witnessed the introduction of many excellent varieties of plums, but their cultivation is discouraging; the fruit is frequently attacked when nearly full grown, by the "black rot," and perishes before maturity. This disease varies in intensity in different seasons, but comparatively few escape at any time. The injury inflicted by an insect on the branches has almost annihilated it in many localities. Some 12 years since, the writer was surprised by a few of the unsightly blotches on his young trees, but strict vigilance in removing them on their first appearance during 2 or 3 years was sufficient to destroy them; none have since appeared, notwithstanding at the distance of one-third of a mile many trees continue to be disfigured by them. Cherries are numbered among the valuable fruits that flourish in this county with complete success, and almost without an enemy. Many of the most excellent varieties known have been introduced, and succeed to entire satisfaction in situations elevated 80 feet or more above the creek valleys: cherries are also, in common with pears, found to succeed best where the earth near and under the trees is permitted to remain uncultivated. Grapes, suitable for table use, have within the last 20 years obtained a place in almost every garden in the county: some of the more delicate varieties are cultivated under glass, but generally those more hardy and native to our climate are preferred: among which the Catawba, Isabella, and Schuylkill are the favorites. These, when the season is moderately dry, ripen satisfactorily; when otherwise, they scarcely arrive at maturity before being overtaken by early frost; this was especially the case the present year, (1850.) All kinds also suffered seriously from the rot: the Catawba least, and the Isabella to the greatest extent here, as elsewhere. We perceive no remedy is known, and fears are entertained, from its progressive increase, that at no distant time we shall be deprived of the enjoyment of this delicious fruit. Its appearance has not been noticed in the wild-grapes in the forest, and a few choice kinds transplanted into our gardens, though greatly improved, have thus far escaped. No wine, except for family use, is made in the county. The preceding includes all articles of field-culture with us, and the processes, application of manures, &c., in general practice. But few particular instances have been given, for the reason that in the anxiety to make the most profitable use of every discovery or improvement, they are, when established, at once adopted into our system, and their influence mingled in producing the results given under the foregoing heads respectively.

MANURES.

The improvement of the soil is progressing by every practicable means throughout the eastern counties of this State. In this county it is, beyond all other considerations, the leading object of the agriculturist. Every fertilizing agent in reach is put in requisition for that ultimate purpose; lime, plaster, bone-dust, poudrette, and guano, are each, to a greater or less extent, drawn upon as aids to the large quantities of domestic manures made at our barns, stables, hog-pens, &c. Lime is used indiscriminately on all kinds of soil in this county, with decided advantage; nearly the whole of our arable land has been treated within the last 25 years, with liberal dressings of from 50 to 100 bushels per acre, and much of it repeatedly. The form of applying it is merely to slake and spread it as nearly uniform as possible over the surface, either of sod or broken ground, at any season of the year, or in any quantity desired. In every instance its effects are immediate, decided, and permanent. The opinion has many advocates, that, while it continues in the forms of caustic and hydrate, its energies are much more active as a fertilizer, than after its return to that of a carbonate; hence, that dressings of 30 to 40 bushels per acre, repeated periodically at the end of 8 or 10 years, are preferable to a larger quantity at longer periods. Plaster is used extensively as a top-dressing on grass grounds, in quantity from 1 to 2 bushels per acre. Its advantages on clay soils are not so decidedly marked as on others. The benefit received by all the grasses, and particularly clover, is at once evident after copious rain, and is continued, at least to the fourth year. An increase of one-third in the quantity of clover, and a fourth in that of the native grasses, together with earlier and later vegetation, and their uniform deep-green color, are the common proofs of its value on the sandy and gravelly loams of this county. It is also used extensively on the young plants of Indian corn, but by many its benefit in this case is doubted. Bone-dust and poudrette have also been used to some extent, the former with entirely satisfactory results: spread over or mixed with the soil in the course of cultivation, the benefit received from it is immediate and lasting. Their use, however, has been checked by the recent introduction of guano, which, from the high character it has already acquired as a fertilizer of the soil in every form and under all conditions, promises fair to withdraw attention from these, if, indeed, it shall not materially diminish the usual exertions in accumulating the ordinary stock of domestic manure. It is probably too early to pronounce definitely upon its relative value, in comparison with the mineral and vegetable resources thus far relied upon, and which have changed many large districts of our previously exhausted Atlantic border to a highly productive condition, within the recollection and under the persevering industry of the present generation. But that it will form an important epoch in our agricultural history, the brief experience already had leaves no room to doubt. The most judicious form and mode of applying it are yet the subject of experiment, and opinion is not yet established on this interesting point. The volatility of its fertilizing properties has, however, suggested the necessity of mixing or covering *at once* with the soil, and this is the present practice. To secure uniformity in spreading, it is previously pulverized finely, and mixed in any proportion with plaster, fine earth, &c., and spread with the hand; plaster is preferred by many under the impression that a portion of the volatile salt becomes thus fixed and secured from loss, while it is otherwise well suited to the purpose. Plaster, in the proportion of 1 peck to the bushel of guano is generally used; some experiments go to show that *ashes* wholly neutralize its volatile qualities, and that lime does so partially. On corn, oats, wheat, turnips, potatoes, carrots, and the succeeding grass crops, its effect is immediate and highly satisfactory. On all our soils, and particularly on thin and those exhausted by long cropping, its productive energy, when used to the extent of 300 to 500 pounds per acre, is equal to a heavy dressing of stable manure. Its use is increasing rapidly, notwithstanding the price has advanced 50 per cent. since its first introduction. The importance of securing the largest possible quantity of domestic manure, as the most reliable source of agricultural prosperity, is

well understood here, and every convenient means is resorted to, to effect it: all refuse vegetable matter is collected and deposited in the cattle-yards and hog-pens; earth from ditches, hedges, &c. is frequently used to pave the yards, stables, and pens, where it remains through the winter, to absorb the urine and other valuable liquids. The corn roots with the earth adhering to them, after the removal of the corn crop, are in many instances used for the same purpose. The whole of these, when the manure in the yards is turned and heaped in the following spring, are mixed with it, and form a covering to protect it from exposure to the weather, and to imbibe the volatile matter thrown out in the process of fermentation, and thus acquire a value equal to the vegetable matter with which they had been associated. The manure heaps thus protected remain until fermentation has ceased, and until the land intended for a wheat crop is prepared to receive it. When convenient, the manure is kept under sheds or other shelter, and is esteemed one-third more valuable than if exposed to the weather.

METEOROLOGY.

The state of the weather, throughout the year 1850, has been the most favorable, in this region, for the agricultural interests, within our recollection. The quantity of rain was abundant, and distributed in suitable quantity and time for every growing crop, except potatoes, which are believed to have suffered from the excess. Under the influence of abundant moisture, accompanied by high temperature and unusual electric disturbance, vegetation was impelled to an extent rarely witnessed, if indeed it has ever been exceeded; a brief suspension of rains occurred very opportunely at harvest and seeding-time, but was not productive of serious check to vegetation, owing to the large quantity of moisture previously collected in the soil. The violent storm on the 19th of July almost entirely prostrated the oats and corn crops. The former partially, and the latter satisfactorily recovered from its effects, without serious loss, except additional expense in harvesting the oats. The loss of life and property occasioned by the lightning was large beyond precedent, and its frequency and severity without a parallel. The months of October and November were mild and comparatively dry, and the farmer was enabled to close his out-door operations in good season, without obstruction from frost or wet.

The accompanying table has been prepared from the meteorological journal kept for our Institution, and is believed to conform to your "suggestions," and may embrace all that is interesting to the agriculturist.

Meteorological Table for 1850, *at North Latitude* 39° 55′ 18″, *Longitude* 1° 36′ 10″ *East from Washington City.—Elevated* 175 *feet above tide-level.*

Total number in the year.

DAIRY HUSBANDRY

Engages the attention, directly and indirectly, of a large portion of our population, and the high character of the produce, and particularly of butter, in the New York, Baltimore, and Philadelphia markets, sufficiently attests not only a judicious discrimination in the choice of stock and their general management, but intimate knowledge of the most approved method in the delicate operations of its manufacture. In the selection of cows for the dairy, (almost exclusively from those driven into this county from the midland districts of this State,) preference is usually given to fair specimens of our native breeds over any pure blood or cross of imported stock. A stock thus selected, dry and comfortable shelter, a sufficiency of good hay and corn fodder, in the winter, with about 6 or 8 quarts of wheat bran, or its equivalent in corn and oat-meal per day, when in milk, free access to water, and general cleanliness, are the necessary preliminaries to a successful year's operation in the business of dairying. The usual management in a well-conducted dairy is nearly as follows, viz.:—At four or five weeks old the calves are slaughtered and the process of butter-making commences. The cows are milked in the morning and evening, and the milk strained at once into pans from 4 to 6 quarts each, and placed in a well-aired milk-house, in water, to the depth of 4 or 5 inches, at a temperature of about 52° Fahrenheit, there to remain *but* 36 *hours*, until the cream is separated. If the cream will not "ripen" in that time, the process should be accelerated by the addition of milk previously soured, to be placed in the pans previous to their receiving the new milk, that the latter shall become thickened at the end of that time, and the cream removed. If permitted to remain in contact with the milk longer than 36 hours, that peculiar sweetness and freshness which characterize Delaware county butter will almost invariably be destroyed. Great care is required in separating the cream from the milk, to prevent, if possible, even the smallest quantity of milk from passing into the cream-cans. These cans should contain about from 4 to 5 gallons, and when filled, placed in water as deep as they will stand steady, and their contents stirred twice daily. The cream should be churned at the end of three or four days at farthest, in a revolving churn, without stoppage during the process, or permitting the escape of the accumulating gas. The temperature should not vary much from 60° Fahrenheit, nor the process be completed in less than 30 or more than 60 minutes. The desired time can be very nearly attained by close attention to the temperature of the cream and to the velocity of the churn. When the butter has gathered to the size of peas, the churning should cease, the butter-milk be withdrawn, and about one-fourth the quantity of clear, cold water returned into the churn. After 3 or 4 turns, draw off the water, and return one half the quantity, as before, and repeat a few turns of the churn. Drain the water well off by a few direct and reversed motions of the churn. Add fine, clean Liverpool salt, at the rate of 11 oz. to 30 lbs. of butter, or, which is nearly equivalent, to 30 quarts of good cream put in the churn. Turn the churn 3 or 4 rounds, and reverse, and the butter will be thoroughly salted for use *while fresh*. It should remain in the churn in this condition for half an hour, that the salt may all be dissolved, when it will be ready for working and sponging. The operation of freeing it from moisture is performed by placing it, when taken from the churn, on a table with a lever attached, and pressing and turning it frequently, using a sponge covered with a cloth, to absorb the moisture, till no more appears, when it will be ready for weighing and printing in any desired form. The most material points in the manufacture of butter are, first, that, to secure the maximum quantity without injury to the quality, *the cream shall be separated from the milk at the end of 36 hours;* secondly, that the cream in the cans shall be kept at a temperature of about 52°, and stirred twice in 24 hours; thirdly, that, in the process of churning, *gas or air generated in the course of the operation shall not be permitted to escape from the churn.* It is believed to contain all the rich aroma of the cream, and by thus confining it in contact, it is imbibed by the butter while forming. In summer-feeding dairy stock, a principal object is to induce the cows to eat the largest quantity compatible with full health. This is most readily accomplished by frequent change of pasture, with free access to water and salt. The natural grasses furnish the most grateful and richest pasture, and produce the best quality of butter. Clover, as has been said, is relished by horned cattle but for a short time only, if confined to it; but when allowed to range at will in it and natural grasses together, its full value as pasture is realized. The annual production of butter per head, in our dairies, fluctuates, with the abundance or scarcity of summer pasture, from 125 to 150 lbs., and occasionally something above these numbers. The quantity produced the present year (1850) has been above the average, if not the very highest. In a few instances, above 200 lbs. have been obtained from small dairies of choice cows. These instances occur, however, under extraordinary care and cost, but may nevertheless furnish valuable hints to the dairyman. The value of fresh butter in Philadelphia market varies, during the season, from 16 to 40 cents per lb., and will average 25 cents or upwards for all qualities. The cost of butter to the producer, interlaced as it is with our entire system of agricultural operations, cannot even be approximated, and we are deterred from the attempt. No cheese is made at our dairies. The sour milk is fed to hogs, and estimated to produce 80 lbs. of pork for each cow in the dairy. The average value of calves is about $5 at 4 or 5 weeks old.

Neat Cattle.—But few of these are raised in this county. The more directly profitable application of provisions when fed to dairy cows induces a dependence for recruiting their numbers on those driven from districts in this State north and west of us, not in convenient reach of a market for fresh butter and veal. A few, however, from choice cows, are occasionally reared, and prove that our dairy stocks would be highly improved in appearance and quality if more generally resorted to. The usual practice is to permit the calves to remain with the cows until 5 weeks old, then separate them into adjoining fields, to prevent the usual fretting of both, and leave the calves to take care of themselves. Clover pasture is preferred to any other until they are 3 or 4 months old. Their value at 3 years of age, or with their second calf at their side, varies from $25 to $35, according to their promise of future profit. These limits in price will also apply to fair and good cows at the drove-yards in March, April, and May, and indeed, in limited number, at any time: dry cows of like quality command about $10 less per head than those accompanied by a young calf, or approaching that condition. We possess no data for estimating the precise value of corn in producing beef, or the comparative value of the different stocks of cattle named as feeders.

Hogs.—Various breeds of hogs have been introduced into this county, and much attention has been given to improving the stock by crossing them

in every direction. The present favorites are the result of these efforts, and inherit a liberal and perhaps barely predominating share of the "Berkshire" introduced some 15 years since. The comparatively small bone, and the disposition to take flesh and fat readily at all ages under light feeding, compensate satisfactorily for a lack of growth to a size common to some others. Their usual weight, when fat, at the age of 12 or 14 months, will average something less than 300 lbs., on the usual fare, but may, by high feeding, exceed that weight by a fourth or a third. They depend mainly on the refuse of the dairies and on pasture and nuts for their summer subsistence, until 4 or 6 weeks previously to being slaughtered, when they are fed liberally on *whole corn.* A large number of hogs are fed at our dairies wholly on sour milk, placed in pens at 4 or 5 weeks old, in March, April, and May, and kept until September and October, when they are slaughtered and sold at the Philadelphia market at from 7 to 10 cents per lb.

The foregoing embraces all the important operations to which our agricultural industry is directed, and the conditions under which it is pursued. If not too lengthy and tedious for your examination, we trust some things may be found serviceable to you in making your annual report.

Very respectfully yours, &c.

JOSEPH EDWARDS,
JOHN MILLER,
Committee of Del. County Institute of Science.

London, July 11th, 1850.

My Dear Sir:—Mr. Francis Bonynge has addressed to me a communication upon the cultivation of tea, which I transmit to you, and beg that it may be placed in the hands of some one from the South who takes interest in multiplying the productions of our soil. I believe the experiment of raising tea is now being tried in South Carolina. I sent, a few weeks since, a communication from a gentleman upon the subject of the production of the silkworm. This paper, with samples of silk, &c., was addressed to the Secretary of State. I have heard nothing from it. Will you do me the favor to ascertain whether the box containing the silk, with the papers that accompanied it, was received? It has appeared to me that silk can be produced in the United States with profit. With respect to the cultivation of tea, it would be satisfactory if some of our friends in the South would try the experiment. Will you favor me with your opinion upon the above subjects?

I am, my dear sir, most respectfully, your ob't serv't,

ABBOTT LAWRENCE.

Hon. Thomas Ewing, &c. &c. &c., *Washington.*

TEA CULTIVATION.—ASSAM, INDIA.

London, July 8th, 1850.

To His Excellency ABBOTT LAWRENCE, &c. &c.

Sir:—With reference to the subject of the interview with which you honored me a few days ago, I beg to submit the following observations on the cultivation of tea in India and China.

I have been cultivating the tea-plant, and manufacturing tea for five years in India, in a district east of Assam, called Namroop, and also in Assam itself. The tea-plant has been found in an indigenous state in the valley of Assam. Assam extends from 25° to 28° north latitude, and from 94° to 97° east of Greenwich, being within one degree of the western province of China, Yun-nan.

The valley is one of the most fertile in India, and enclosed on all sides by the Himalaya Mountains. The Great Bramapootrah, which is the united channel of the Dihing, the Dibong, and the Dihong rivers, divides the valley in its centre, which is also fed by numerous tributary streams, in its course to Goalparah, stated to be as many as 60. From the diversity of its soil and temperature of its climate, almost all European and eastern products might be raised within its circle.

TEMPERATURE.

The mean annual temperature is ....67°
The four hottest months ....80°
The colder or winter months ....57°

RAINS.

Rain commences in March, and continues until October, giving fully seven months of wet weather.

PRODUCE.

Rice, which is the food of the people. Yams are found in great abundance (uncultivated) in the jungles; some of them weigh as much as 16 pounds, and are a very good substitute for the potato. There are several kinds. The natives rear the silkworm, and weave the silk into cloth, which is the principal, I may say, their only clothing. Cotton of a superior East India kind, is produced, but only cultivated with other crops at the same time. The erea copera is a course kind of silk, from an insect reared on a plant of that name, resembling a nettle. There are stick-lac, gum, the India-rubber tree, the tea-tree, the wild coffee-plant, and the nutmeg-plant. There are salt springs, petroleum springs, and coal in abundance, all over the country. Gold-dust used formerly to be collected in the streams when slavery existed in the country.

THE INHABITANTS OF THE FOREST

Are the elephant, rhinoceros, tigers, leopards, the jungle-dog, the jackall, the elk, deer, musk-deer: the bison is found higher up to the north, and also the buffalo and wild-hog.

THE NATIVES OF ASSAM

Are, without exception, the most demoralized of all Indians, the cause of which may be almost wholly attributed to the use of opium. Until 1839, they had scarcely any idea of money: their diet is rice, sometimes boiled, but oftener simply steeped in water. They eat fish, fowl, the wild-hog, and, when killed in the chase, they eat the buffalo, rhinoceros, and elephant.

The evil consequences of the use of opium, which sometimes sells for its own weight in silver, are, that the natives are dwindling away. An opium-eater is not long-lived, and his life is one continuous scene of misery. He is a thin, emaciated being, has no energy, no care for aught but to procure opium; if he cannot get it, he casts himself on the ground, rolls about in the most gloomy horrors, crying, in a heart-rending voice, "Khane ne! Khane ne!" "There is no opium." In this state he would sell his nearest kin for this honored drug; he would freely part with wife or child, if he had a child, which seldom the opium-eater has, for it destroys the generative powers, and there are seldom more than one or two children in any family, and sometimes whole villages of women are to be found with scarcely a man. I have been somewhat out of the latitude of my subject, in thus bringing the valley of Assam immediately under your Excellency's observation, as the indigenous locality of tea in India.

SOIL FIT FOR TEA.

A reddish loose soil, in which ochre is pretty abundant.

Localities.—Table-lands and around the bases of hills are best. Lands which are low and on which water rests, such as paddy lands, or slightly elevated lands among paddy grounds, being always cold and wet, are unfit for tea. High table-lands, which are of dry and stiff soil, sides of mountains, after a moderate elevation, are also very unsuited, and the produce will not pay for the cultivation. However, the plant will grow in all the above places. Moisture is very necessary for the plant; that is, such moisture as will pass away and not keep the ground cold. In Assam, there are seven months of rainy weather, and therefore irrigation is unnecessary. On the Kamaon hills, where the government of India are carrying on tea-planting, no success will or can attend the speculation. There are three years of irrigation required, and the plant takes, consequently, seven to eight years to arrive at its full yield, and even then the produce is very poor with regard to quantity, though in quality it may be superior.

The plant in Assam arrives at its full yield in four or five years, and will with care continue in a healthy state for 20 years, and there is no irrigation required because of the long duration of the rains. There are, however, in March, only a few necessary showers, and April is not what may be called a wet month. The rains are heavy in June, July, and August, and wear away by the end of September.

PRODUCE OF THE PLANT, AND AGE.

The plant is raised from seeds. Plants might be raised from slips also, but it would not answer beyond the mere fact of an experiment. Tea-seeds being sown in December, the plants therefrom could be transplanted during the following rains; that is, from June to the end of the year. The plant should be transplanted before it is two years old.

Seeds may be sown in November, December, and January. The young plants should be planted the following September, October, and November —this would be the first year. A few leaves ought to be taken off the young plant the second year. Thus, it will yield about 40 lbs. per acre on the third year. On the fourth year, the produce per acre would be about 150 lbs. On the fifth year, the produce should, in a rich soil, be 320 lbs. per acre of 43,560 square feet, *and so continue for at least* 20 *years*.

In the following *estimate*, I have made the second year the first, because the expense of putting the seeds into the ground is little or nothing. The estimate is made out of what the cultivation of 1000 poorahs, or 1250 acres, of land, and the manufacture of tea thereon, would cost for four years, with the probable return in Assam, India.

ESTIMATE OF EXPENSES AND RETURNS ON A CULTIVATION OF 1250 ACRES, OF 43,560 SQUARE FEET EACH.

First Year, that is, the year of transplanting, say from Nov. to Nov.:	
1 superintendent, at £600 per annum	£600
1 first class assistant, at £300 per annum	300
1 second " " at £180 " "	180
Clearing 1250 acres, transplanting, and keeping clear for the year	975
Elephants and horses	120
Buildings, tools, &c.	400
Total	£2575
Second Year:	
European superintendence, and native head establishment, &c.	£1440
Weeding and hoeing	475
Manufacturing, say 40 lbs. of tea per acre, 50,000 lbs.	500
Chests, packing, and transit to Calcutta, 1200 miles	200
Total	£2615
Third Year:	
European and native establishment, elephants, &c.	£1740
Hoeing and weeding	470
Manufacturing, say 200,000 lbs. of tea	150
Chests, packing, and transit to Calcutta	1000
Total	£3360
Fourth Year:	
European and native head establishment, elephants, &c.	£1800
Hoeing, weeding, &c.	470
Manufacturing, say 360,000 lbs. of tea	1575
Chests, packing, and transit to Calcutta	1800
Total	£5645

Produce first year, none of any consequence.	
" second year, 40 lbs. per acre, say	50,000 lbs.
" third year, 160 " " " "	200,000 "
" fourth year, 300 " " " "	375,000 "

It will be observed that the clearing of 1250 acres, transplanting, and keeping clear for the year, is put down at £975. This is what it would cost in Assam. This item in America would probably vary very much—but of this your excellency will be the best able to judge.

Wages in Assam, as herein estimated, are about seven shillings a month, without food or any other allowance. There will be a very material difference, therefore, if we calculate the amount of American hire of labor by that of Assam: but other matters must be also well weighed, viz. the amount of work an American laborer will do, and that an Assamee will perform.

I see the cost of hoeing an acre of land 12 inches deep, under the Fermoy Farming Society—the laborer earning 1*s.* 2*d.* per diem—is stated to be 13*s.* 4*d.*; however, one-third of the labor would not be necessary for land, to fit it for the tea-plant.

There is another consideration: miserably poor and indolent as the Assam laborer is, he is also dishonest, and, without constant supervision, will not work at all. Hence, there is about £1600 of the £5645 for such supervision, or about 29 per cent. This would be greatly reduced in America, —if we also take into consideration the intelligence and energy of the Americans, and the probability there would be of all the rolling being performed by machinery.

In the estimate I have given, I have only made the Assam laborer work about 5 hours per diem, and that in such a manner as he does work.

Your excellency will see, by this estimate, that the expense, when the tea-plant is in full produce—that is, the fourth year after transplanting—of cultivating the soil and manufacturing the tea, packages, and packing, and transit by the rude country-boats of India, 1200 miles on the Bramapootrah, is about three-pence farthing (3¼*d.*) the pound.

Taking the above considerations together, as well as the cheapness of timber in America, and the little expense at which it may be cut up by the sawmill, I have no doubt the American tea should not cost more than what it has been made to appear in my estimate for Assam. Even admitting that it cost one penny a pound more, which would be a great deal, still I suppose you cannot have your teas at the ship-side, at Canton, for less than one shilling per pound: I mean, of course, the average. You take a far superior tea from the Chinese to the English, and the average of English teas, being some 40 millions of the inferior black kinds, and 13 millions of green and superior black, was, in 1848, at the ship-side in Canton, one shilling per pound.

TEA CULTURE IN CHINA.

Having made, for your excellency's consideration, these brief remarks on the expense of cultivation, I will now proceed with a brief notice of the tea localities of China, in the following order:

1*st*. Temperature.
2*d*. Soil.
3*d*. Geographical position.
4*th*. Whether, if the cultivation diverge from that position, the tea will be of good quality, and profitable for commercial purposes.

Temperature.—Mr. Bell, in his book on the tea cultivation in China, says, a temperature of a mean annual of 62° to 67° is the best. From my experience, I can state that tea will not produce, or rather will not be productive, so as to pay for labor, under excess of heat or cold.

The temperature of Jogan, in the Tokeen provinces, N. lat. 27° 4′, nearly agrees with that of Assam with regard to cold—the heat being somewhat greater, viz.:

		Assam.
Mean annual	70°	67°
Four hottest months	82° 15′	80°
" coldest "	57°	57°

Mr. Bell states, "The Bohea country, in Tokeen, lat. 27°, differs little from the Hyson-green districts in point of temperature. The tea-men," he says, "describe the fall of snow, as well as the thickness of the ice, as somewhat less, and the cold generally less severe; that it is a mountainous district, with sheltered valleys, fenced and protected from the cold north-easterly and north-westerly winds by the lofty and continuous range of mountains which forms the barrier between this province and those of Che-Keang and Keangse."

"In the green-tea districts, lat. 29° 58′, the leaves," says Mr. Bell, "of the first gathering were injured by the frost and snow which had fallen in April of 1809."

Shanghae, which is about 90 geographical miles to the north of the green-tea district, that is, N. lat. 31° 20′, must evidently be too unfavorable for the economical cultivation of the tea-plant for commercial purposes, although, for domestic use, it may be cultivated in sheltered places. Mr. Fortune states that, in July, the thermometer stood, in the shade, at 100°. This is 6 degrees of heat greater than that of Calcutta; and the sun of Bengal is too powerful for the tea-plant. Mr. Fortune further adds, that the thermometer was as low as 26° in 1844–45, and that the remains of the cotton and other tropical plants were destroyed by the frost; and that the Chinese asserted that the year was a mild one—"therefore," says Mr. F., "I have little doubt that in the worst years the thermometer may be found at 20° below freezing-point, or at 12° Fahrenheit, and perhaps lower."

At Pekin, N. lat., Mr. Bell saw the plants in a garden, as big as a currant-bush, unproductive, and kept as curiosities. Therefore, I should say that, from Shanghae northwards, tea would not answer for commercial purposes. Again, if we go down to N. lat. of Amoy, 24° 30′, and Quangton, 30°, it is well known that the leaves are very inferior. Mr. Bell says the Amoy (Ankoy) teas are very inferior, and those of the province of Quangton of still greater inferiority.

I would observe, therefore, that China cannot very materially increase the exports of tea, and that the country, being subject to greater degrees of heat and cold than any other kingdom under the same latitude, would be less suitable than many countries in which it has never been thought of.

Soil.—It has been supposed that the Chinese bring their barren mountains and hills under cultivation. They may do so; but they can never make barren or sterile mountains or any unfavorable soil bear productive tea-trees. It is a physical impossibility for the tea-plant to be productive in any other than a rich, deep soil. Hill plants, but not barren hill plants, may produce a small quantity of a fine description of tea, but it will be at a heavy expense.

The plant has but a single root, which grows directly downwards, and, if any article opposes its direction, it remains dwarfish and sterile, or otherwise it dies. I have taken up a tea-tree some 40 feet high, and its branches extending over a space of some sixteen feet in diameter: its root was about 3 feet 9 inches in length, with a few straggling fibres growing out from the main one.

The Catholic missionaries replied to some inquiries made of them, (these missionaries, and they only, make their way into the interior of China,) that "the soil should consist of a vegetable mould, sprinkled with sand, light and loose, and rather moist." And again, "the tea may be planted either in a rich or a poor soil, sandy or garden-soil, but that which is moist is most suitable, and the eastern aspect the best; but garden grounds and the embankments of gardens and fields are the most favorable."

Gutzlaff says: "Tea grows on the most sterile grounds, on the sunny ridges of hills, principally between north latitude 25° and 30°, in the province of Tokeen, Che Keang, and Keang-see, and almost all over the Chinese empire. Like the vine, the quality of its leaves depends very much on its soil. It grows in the most barren soil, but the leaves are coarse and unfit for use."

Mr. Fortune states that "the soil in the tea districts is of course richer in the northern provinces than in Quang-tong. In Tokeen and Che Keang it is a rich sandy loam." "Tea-shrubs will not succeed well unless they have rich soil to grow in."

What is the geographical position?—Mr. Bell states that "it has been observed that the Chinese universally agree, from remote antiquity to the present time, that only the Bohea Mountains produce the highest-flavored black tea. They moreover affirm that it is only in the central division of these mountains, which are known to the Chinese by the appellation of Vuy-shan, (inner mountains,) where the highest-flavored teas are produced; and that the teas deteriorate in quality, till, in some of the remote districts, the leaves are thin and poor, have no fragrance or sweetness in infusion, and no labor can make them good." And, "the Ankoy teas, grown in the vicinity of Amoy, 24° 30′, are for the most part inferior; and the Honan and Waping teas, of Quang-ton, may be given as examples of still greater inferiority. The vast inferiority of the flavor of Twankoy tea, the product of the green-tea hills, (with little or no attention paid to its culture,) to that of the Hyson, of the highly cultivated plant of the plains, would be apparent and interesting to any one disposed to try the experiment." Also: "The towns which extend 70 ly (23 miles) from Vu-ye Shang, are called Py-keen-tien, Cza Ty, Tang-moa-kown, Nan-nang, &c. &c: the leaves are thin and small, and of no substance; and whether green or black, or made with much care, yet they have no fragrance. Tea is also produced as far as Yew-ping Shang, Gen Nong, Kien Yang, Hew Shang, and other places, but is unfit for use."

"The extent," says Gutzlaff, "that produces the best Bohea, is no more than 40 ly, or 12 miles, in circumference. The total of the tea-plantations, as taken from official statistics, are 500,273, which may be set down as varying from a few perches up to a few acres."
