Whether, if the tea-plant cultivation diverge from certain localities, the tea will be of a good quality?—The latitudes for the tea cultivation in China are 27°, 28°, 29°, and 30°, and probably extend from the east to the west of China along these latitudes, over through the Singphoo country, Kooking, and Assam. I have never heard of it being discovered on the west side of the Burampotree or Bramapotree, in an indigenous state. But I cannot conceive that there is any obstacle against it being extended far to the west, through these latitudes, until the hot winds of Hindostan would interfere with its progress.

Valleys seem to be the favorite places in the east, being protected from the great extremes of temperature, and from the clouds being driven into the valleys and retained there by the contrary winds entering into them from the different breaks in the amphitheatre of mountains around, causing a greater and more incessant fall of rain. However, as already stated, China is subject to greater extremes of heat and cold than any other country, perhaps, in the world, placed in the same parallels of latitude; and therefore must be less suitable than more temperate climates for the production of this plant.

From the 31st degree of north latitude, northwards, the winter is too severe, as well as the heat of summer too intense, for the profitable cultivation of tea. Even in the green-tea district, lat. 29° 58′, the trees have to be bound round with straw to protect them from frost and snow. And, again, if we go down to the 24th deg. of N. lat., we find the teas of (Amoy) Ankoy very inferior, and those of Quang-ton, (Canton,) N. lat. 23°, of still greater inferiority; and also, that "tea deteriorates in quality, as the plantations diverge from the Bohea hills, till, in some of the most remote districts, the leaves are thin and poor, and have no fragrance or sweetness in infusion, and that no labor can make them good."—*Ball.*

"Teas of the neighborhood of Canton—the quality is such that no process of manufacture would render them suitable for the British market."—*Mr. T. A. Gibbs, evidence before the British parliamentary committee.*

"The tea viridis," says Mr. Fortune, in writing on Chusan, "is cultivated everywhere, but, if we except a small quantity sent over to the mainland, the whole is used by themselves. Every small farmer and cottager has a few plants on his premises, which he rears with considerable care, but seems to have no wish to enter into its cultivation on a larger scale. Indeed, it is questionable whether it would answer, as the soil is scarcely rich enough; and although the shrub grows pretty well, it is far from being as luxuriant as in the large districts of the mainland." Chusan is in N. lat. 30°. Thus we see, whether the exportation of tea be at Canton, some 1000 miles from the Bohea district, of a very difficult inland transit, or at Shanghae, or by caravans to the north and north-west, that the export, in these different directions, to Great Britain and America, and to Russia, Lama, &c., is supplied from the 28th, 29th, and 30th degrees of north latitude.

ITS INTRODUCTION INTO AMERICA.

I have so far entered into this subject to show your excellency not only the conditions of soil and temperature necessary, but also what ought to be avoided. Superficial observers of the tea-plant suppose, because the plant is to be found over nearly the entire extent of China, that therefore it will be productive everywhere. Such statements ought to be carefully guarded against.

What has defeated its successful cultivation in India? Erroneous ideas, coupled with a discouraging government.

Therefore, such should be carefully avoided, in introducing tea into America. A first failure would probably throw it back for a series of years, and this would be a serious loss. Taking into consideration the mighty extent of America, its great and commanding position, its tremendous strides towards being not only one of the greatest nations on the globe, but one of the richest, most populous and considerable of the five divisions of our earth,

I have no doubt, nor can there be any doubt, that there is a vast field in America for the cultivation of tea, coffee, indigo, &c.

Should your government undertake to introduce it, I beg to offer you my humble services. The cost would be but trifling, and the great requirement of America for this object is, that its government do get up gardens for the growth of tea-seeds. This necessary step toward this important object is easy, and requires, as I have already stated, little outlay. I feel an earnest wish that your excellency consider this paper attentively, and that your excellency would, immediately, and without waiting for reference to your government, take on yourself to forward this cultivation in America; because, by your delaying for a reply from Washington, the years 1850 and 1851 will be lost; and the *onus* of your acting on the suggestion which I would, if these papers meet your excellency's approval, offer you for your guidance, would not be as much as £100, probably not £50; and you would, for this sum, have some value for the money, in case your excellency's government declined taking up the subject as a government matter. Therefore, leaving these considerations for your excellency's minute and grave reflection, I will beg, as you have been graciously pleased to direct me, to give you a slight account of myself.

I am one who, as many of the children of the fair Emerald Island, had to seek a livelihood in a far distant land. I left, seventeen years ago, the domestic fireside of my foster-father, in the Town's lands of Ballentuber, four miles from Ballemahon, in the county of Longford, and proceeded to Dublin. After being placed under the Rev. Mr. Barrows, to get some little education, in addition to the very little I had, I was sent out, in April, 1835, in the bark Enmore, of Liverpool, commanded by Lieutenant Swanson, R. N., a connection of my mother. I was nearly wrecked off Liverpool, and ultimately arrived at Madras, in August, 1835. From Madras, I proceeded to Calcutta, where, after a stay of three weeks, I was put into a boat on the Ganges, to proceed upwards of 1200 miles, with native servants and native crew. Rustic as I was, I had greater disadvantages still to contend with. It was the first time I had ever been thrown on my own resources, and for the first time, too, I found myself alone, to deal with men of whose language I did not understand one word—nor did they of mine. However, what I could not make them understand by signs, I had to do myself; and by the time two months and 16 days had passed, when we reached Turackabad, on the Doab, I could explain some of my ideas to them.

In the districts of Turackabad, or Tully Ghen, about 90 miles above Cowanpoore, I remained till the end of 1839, engaged in making indigo and manufacturing saltpetre. I then returned to Calcutta, and was induced to proceed to Assam, to enter into tea-plant cultivation. I got some 8 or 10 acres of land, down in Assam, and was quietly proceeding in my labors to do the best I could in that wild, depopulated region.

Government, the Honorable East India Company, had military possession of Namroop, to the east of Assam Proper, and was desirous to take actual possession of it; and, with this view, induced a native chief to work some tea-lands on government advances, and undertook, through its own superintendent, to cultivate other lands, called Koojoo. The superintendent was not a very active man, and failed. Government then applied to the Assam Tea Company to take up the cultivation of the land, proposing to them to build a brick building for the military guard at Koojoo. The Assam Tea Company declined, whereupon the government did a second time propose to that body to cultivate the lands, waiving the above request. The company again declined. Government then induced me to cultivate the lands, and verbally promised me the protection and the good-will of government, and directed me to put in an application as usual for the lands, in a written reply to which they stated that I would get a lease of the lands as soon as surveyed, and that there was a guard to protect the place. For the space of four years, the government permitted me, in every confidence in its sincerity and good faith, to cultivate the lands; but, after these four years, withdrew the guard, which, a few months prior, I was given to understand, by the governor-general's agent, would not be removed, and without giving me any notice whatever of the removal. Within the then five years, these Tartars had twice rebelled against government, and only a few months before was the last rebellion put down; and at the time of depriving me, unprepared, of the protection of the guard, the chiefs around me were in irons in their powder-magazine of Debroo Ghen. I was thus exposed to a savage, infuriated people, attacked at midnight, and escaped through a most miraculous incident. The Tartars got into the verandah of the house before I saw them—in fact, it was only that instant that I providentially awoke. When I saw them, I started out of bed, and cried out to the two men who should have been watching at the door, but who, unfortunately, went to sleep. They were instantly cut down, and a rush made at my bed. I met the party with the discharge of one of the barrels of my gun, one of whom, receiving its contents, fell into the bed, and, in the dark, was cut in pieces, under the supposition that it was me. While this was going on, I was standing on the other side of the bed, considering what was to be done; but finding some of the party was coming round in my direction, I laid the gun, which was heavily loaded with three pistol-balls and shot, across the bed, and fired a second time into the party, who, terrified, rushed out of the house—except the man on the bed and two more, who then fell—but placed a guard at the door to prevent my exit. The table on which I kept my ammunition was upset, my Tartar swords had been carried off, and there was nothing left for me but to escape. The house was a mat-house, and I got out over the matted wall and clung to the roof until the party, who were on the same side of the house, looking for a light, passed round to the front, when I dropped down, and wandered that night and the following day, pursued by these savages; and at last, faint from loss of blood by the leeches, and suffering from enlargement of spleen and intermittent fever, I reached a guard-house some 16 miles distant. Government refused me any compensation or amends whatever, and told me there would be no guard placed at Koojoo again; nor would they fulfil their promise to me to give me a lease of the lands. The consequence was, I lost, of £5,000 outlaid, £3,000 and my five years' time. And the reprehensible and unmanly falsehoods were put forward by the local authorities, with which the whole body of the government has identified itself, that I irritated these people to attack me by beating them and not paying them their wages. When I showed them that throughout Assam wages were paid in advance, then they told me that I beat them and pleased them afterwards. These are the verbal statements to me by Mr. Shepherd, the chairman, a month ago. I have applied to get these charges made openly, and in writing; and, as yet, government has not replied to my application. Thus it is, that, under plea of ill-treatment of a third party, they violate their written and verbal engagements to me.

Under these circumstances, I am placed in a painful position—for Mr. Shepherd and his co-directors, having the full consciousness of the wrong that has been done me, instead of dealing openly with the matter, throw every obstacle in my way:—first, they oblige me to send my papers out to India, after retaining them two months in Leadenhall street; then, when they come home, they keep them two months more before they give me a reply; then they make the above statements, and, when I wish to have them in writing, keep silent for another two months, and, lest I should trouble them again on the subject, refuse me my documents, which they had twice directed me to call for, and twice declined to give up—and then come out with the statement that they were left in Bengal. After much difficulty, I could get only unattested copies—copies pretended to have been received from Bengal; but which had not even the usual signature of the clerk who copied, nor that of the head of the office in which they were stated to be copied.

Under these circumstances, I may well turn my thoughts to your land of liberty, and, like my countrymen, seek an asylum and a home in its bosom; and, for this purpose, I trust I may meet your kind offices, for which I will feel duly grateful.

I beg here to copy a few extracts from a letter of the governor-general's agent on the east frontier, dated,

"*On the River*, 24*th July*, 1849.

"*To* Frank Bonynge, Esq.

"*Dear Sir*:—I was favored with your note of the 11th, from Kedgeree, last evening, and, in reply, I have simply to say, that I was not aware of any thing like a feeling on my part to keep you out of any tract you could fairly be put in possession of; and you will have found, the moment I knew the Assam Company were willing to resign the plantations you wished for, I immediately wrote you to that effect.

"You may remember that I took much interest in your first commencement of operations, and was willing to assist you to the best of my power, and have never ceased to regret the circumstances which caused you to retire from manufacturing; as it always appeared to me, that of all the persons who have embarked in these speculations, you were the most likely to succeed, and to do justice to our indigenous tea and capabilities of raising China tea, by your untiring activity and the ability and zeal in the cause which you evidently had evinced. * * * *

"I am, dear Sir, faithfully yours,

"FRAS. JENKINS."

I will, with your permission, submit to you a copy of a letter I am now about to draw up, on my case, to the East India Company Directors, so that your excellency may know my case the better, and clearly understand my position. I have the honor to be, Sir,

Your excellency's most humble and obedient servant,

FRANK BONYNGE.

Litchfield, Conn., December, 1850.

Sir:—In reply to a few of the inquiries in the circular issued from the United States Patent Office, under date of August 26th, 1850, (one of which I have received per mail,) I have only given my own opinion, or estimate, without consulting with the farmers in other sections of this town. I know not how extensively the above-named circular has been distributed among them, or how extensively such or similar inquiries have been answered and published in former reports, as I have had only the one for 1848; but, in that, I observe very few statements either of the farming or mechanical interests of this State.

CORN.

The varieties most esteemed in this section are the eight-rowed yellow flint, and white flint, as they are earlier and less liable to be injured by frost. I think the average product per acre to be about 40 bushels. Some extra fields go as high as 80 or 90. The average cost of production per bushel is probably *more* than 50 cents. The practice has formerly been to plough the land in ridges, by turning two furrows together, and plant on the ridges, about 3 feet apart, and 4 or 5 kernels in a hill; but the system of clean ploughing is now practised a great deal, and to advantage. We hoe our corn but twice, although a third hoeing would be highly beneficial; but then our haying is upon us, and must be attended to.

The best method of feeding corn, decidedly, is to grind it. If for beef, ground with the cob, and fed dry; if for pork, shelled and mixed with about one-third as much other grain, and scalded.

OATS.

I think the average yield of our oat crop is something less than corn. Three bushels are usually sown on an acre of land. Oats, mixed with corn, for hog-feed, are coming into favor very much, as the animals like it better than clear cornmeal, and will fatten faster, fed with it.

CATTLE.

The cost of rearing neat cattle till three years old may be put down as follows:—1st year, $7; 2d year, the same, as they will live on coarser fodder; and, the 3d year, at about $9; making $23 at three years old, which is as much as ordinary animals will sell for at that age. But those heifers which promise fair for cows will bring from $25 to $30, and fairly matched steers, $60 or $80 a pair. Extraordinary steers, sometimes $100 or $120 a yoke, at that age.

Cows for the dairy average about $30 in the spring, and $18 to $20 in the fall of the year.

FATTENING PORK.

The cheapest method, in this section, where grain is comparatively high, is, I think, to take spring pigs and feed them with the slops of the dairy, with a little provender mixed in, until September; then, in addition, boil the refuse potatoes and apples together, and feed for 6 or 8 weeks; afterwards for a few weeks, with provender scalded.

Weight.—275 or 300 lbs. of pork, is a fair weight of a pig of 9 or 10 months old, but one cwt. added to that, is no uncommon occurrence.

The comparative value of apples with potatoes, when fed as above, is, perhaps,—one bushel of apples boiled with two of potatoes is worth as much as three bushels of potatoes, although *not* worth as much when fed alone.

With respect,

CYRUS CATLIN.

Hon. Commissioner of Patents.

Louisville, Kentucky, December, 1850.

Sir:—Having by request prepared the accompanying meteorological table for insertion in several publications about to be issued, I have sent you a copy, although the tables embrace more than would seem to constitute a proper answer to the inquiries propounded in your circular. It will be an easy matter to glean out what may be deemed useful for your report, and reject the balance.

It is gratifying to the lovers of accurate knowledge to witness with what rapidity the science of meteorology is winning the confidence and favor of the agriculturist. But as the number of co-laborers in the field of exploration is yet quite too limited, I shall perhaps best subserve your wishes by confining my few remarks to details suggestive of the advantages which may be expected to accrue to the arts of husbandry, pomology, and horticulture, by calling in this science to their aid. In horticulture, what may be considered the greatest triumph of the present, if not of any age, is the successful growing in northern Europe of the new water-lily, a gigantic native of the equator, one single leaf of which measures more square inches than a farmer's dining-table, and which said single leaf contains airducts and vesicles enough to displace more than 20 gallons of water—thus enabling it to buoy up the weight of a man. But this triumph has been won by a meteorological analysis of the conditions with which this lily is surrounded in its natural habitat, and a copying of the same in its new abode, not even omitting in the waters of its new home the almost scalding temperature and whirling motion of that leviathan of rivers, the Amazon, in whose broad waters this remarkable plant delights to dwell.

In agriculture, there are many plants grown that are exotics, that are introduced either from the north or from the south, and that will mature best as grown in the colder or warmer portions of the growing-season; indeed, I think there are very few, that fully answer the farmer's wishes, planted without regard to this fitness of season. It is true, we cannot now follow all these plants to their native wilds, in order to ascertain how much of water and how much of heat best promote their thrift. But, by the aid of a series of well-conducted meteorological observations and the simultaneous thrift of cultivated plants, nearly the same ends are accomplished. There is no fact plainer than the truth that this knowledge is desirable. The true inquiry is, do we possess it? I think not; and I will refer to the culture of a single article, both to prove a want of this knowledge and the agency of meteorology in leading us to truth. The article referred to is the sweet-potato. I think, in the neighbourhood of Louisville a great deal of labour is thrown away by anticipating the season for planting this esculent—by forcing it into the open air before the mean temperature has risen to summer heat, the plants remaining stationary or dying, and weeds taking possession of the ground; thus giving occasion for at least one hoeing more than a later transplanting would require. This opinion is founded upon the following facts: that is to say, I have grown the potato for market for some 20 years, and I think the planting this season may be said to range between the middle and last of May, sometimes a little sooner or later. Once only in that time have I known the sweet-potato to do well planted in the open air before the first of May. Again, it has been a practice, in my family, to give the sets in the hot-beds too small for use at the general planting, to the servants, for their patches or family gardens. It has been again and again remarked, during this 20 years experience, that these very late plants, in the family-gardens of the servants, have secured a better "*stand*" —a more uniform growth—and, when the cultivation has been good, a yield nearly, if not quite, equal to that of the main crop. Again, the summer of 1846 was one of the longest and hottest experienced in this climate, the mean heat, from April to October, being about 71°. This season was too long for the growth of the red sweet-potato, planted in May; and it was in housing this crop that I was first taught to know that potatoes may be "*frost-bitten*" before it is yet cold enough to freeze; or, what is the same thing, acquire that flavor generally supposed to result from the action of frost. I take the following extract from my diary, under date of October 11, 1846: "Cooked, on the 9th and 10th, two lots of red potatoes, supposed to be over-ripe—the root plump, but skin blotched with dark spots; eyes, at point, decayed—from whence I conclude that a sound sweet-potato has all its eyes plump, however little developed, whilst a decaying of the eyes, either at the side or end, will impart a bad flavor to the whole tissue." These facts themselves appear to me sufficient to warrant a belief that the whole of a long summer is not needed for growing this potato, and that, if so, it is false economy of labor to be in too much haste to plant. But a history of this year's crop is to the point, and conclusive. The past spring has been cold, dry, and backward. No living man, perhaps, has an experience old enough to have seen summer crops so unpromising at any former harvest as they were at the last; sweet-potato sets had hardly begun to vegetate at the period they were transplanted in former years; yet, under the growing influence of a temperature, although not remarkably high, yet uniformly so, throughout July, August, and part of September, the yield of this crop brought to perfection in less than 90 growing days is considerably above an average in quantity and of good quality; nor is any part of the result ascribable to increased fertility of soil, the field cultivated being an old potato-ground, unmanured.

The pomologist, in search of useful facts, will from this science derive no less assistance than the farmer or gardener; and I will close this article by a single experiment, in illustration. In 1840, strongly suspecting intense cold to be one of the causes producing blight among fruit-trees, and aware that (in consequence of the power on the part of trees to grow for one season after receiving a death-blow in the trunk or large branches) the only symptoms capable of pointing to the true harm-producing agency are often obliterated by time, before the casual observer suspects the presence of injury, I then determined to invoke the assistance of the unerring instruments of meteorology as sentinels to sound the alarm on every visitation of intensity of heat or of cold, hoping that, if either of these violent powers were the culprit, I should be able to detect him "*flagrante delictu*," or that, by a continued record of facts, the case of his guilt might be made out upon the evidence of circumstances.

In Kentucky, the first remarkable spell of intense cold occurring within the last ten years, happened in December, 1846, a month which would have done credit to a New-England winter, its mean being 26°, and the thermometer at one time, for the space of forty-eight hours, not rising above 10° above zero; for some days the expansion of trees in the forest produced a continued cracking, not unlike the promiscuous firing of small arms.

On the occurrence of a thaw, and immediate examination, many peach-trees were found to have the bark burst throughout the extent of the trunk: the bark on the branches of one or two pear-trees was found to give way to the touch, and, out of a lot of 60 hardy young cherry-trees, about half were entirely killed, or so injured as to produce death. In a small orchard of plums measuring six inches in diameter, and very thrifty, about half a dozen had the bark entirely separated from the alburnum—in most of them the fact not being discernible except by pressure, and, when touched, the bark being found to hang loosely on all sides of the trunk. In two cases the bark was burst, as in the case of the peaches, and, on making any two horizontal sections on the trunk, the intervening bark might have been rolled off. It is needless to add that these plum-trees all died, and that the first outward evidence of disease or injury in those cases where the bark was loosened, but not burst, was a gradual shrivelling of the bark on the coming of hot weather.

Very respectfully, L. YOUNG.

A TABLE

Showing the Monthly and Annual Mean Temperature for Nine successive Years, beginning in October, 1841, and closing in September, 1850; also the Monthly and Annual Fall of Rain for the same period, in the vicinity of Louisville, Kentucky.

WHEAT.

Different kinds of summer wheat have been universally cultivated in this vicinity until recently, and the farmers have been under the necessity of abandoning it almost entirely, for the reason that it has proved almost an entire failure. Within the last three or four years, the farmers have been experimenting with winter wheat, and have found their experiments crowned with success beyond their expectations.

I have now before me the statements of Robert Johnson, of Gorham, Cumberland County, Me., in which he states, that he has raised this season, from one bushel's sowing, 29 bushels; said one bushel was sown upon 157 square rods of ground, upon which were spread two cords of compost manure, and sown in the month of August, 1849. In conversation with Mr. Johnson, he says, "I should recommend sowing with the wheat two bushels of oats the acre, as the oats would get quite a growth before the frost would kill them down, and then make a covering for the wheat through the winter."

CORN.

The most esteemed varieties are the large yellow, 10 to 20 rows, and the long eight-rowed, both of which are good varieties; but by observation I have found that the greatest crops come from the large variety.

The average product from an acre is about 35 bushels, although in some instances the product has trebled it. The best method of culture is to spread the manure, plough immediately, and harrow well, and plant in squares about 3 feet and 8 inches apart, and cultivate both ways with a horse. For feeding, I grind the ears and wet up with hot water for hogs; and for cattle and horses, mix with chopped feed and wet up together.

The manure formed by hogs, while consuming 20 bushels of corn, if they are well supplied with loam and muck, will add greatly to the crop, say one third.

HOGS.

The best breed, as has been proved, in this vicinity is the cross of the Berkshire and grass breeds.

The cheapest method of making pork is to procure early pigs and keep them until about nine or ten months old.

The best method of putting up pork that I have ever found is, first, to let the hog remain long enough after slaughtering for the animal heat entirely to subside. This I consider of great importance. I then cut and salt in sweet barrels, with Turk's Island salt, ground, and I use three-fourths bushel to the barrel, and then make a strong pickle, and fill up. For hams, immediately after cutting up, I pulverize saltpetre and rub the fleshy parts thoroughly with this powder, and let them lie 12 hours. I then pack them in barrels, using one-fourth bushel of the same kind of salt as for pork. I then make a pickle, by using one gallon of the best of molasses, ½ lb. saltpetre, and as much salt as will dissolve. After lying long enough for the salt to strike through, I smoke with corncobs, and find it to be nice.

APPLES.

The cultivation of fruit is receiving increased attention, and it is found that the raising is a profitable business. The best varieties for winter use are the Baldwins and Russets, and are found to keep sound longest when kept as cool as can be and not freeze.

GRAPES.

Some few individuals have bestowed some attention to the culture of the grape with good success. I saw, the past fall, four vines of the white Sweetwater, which had been cultivated four years, and upon the four vines I should judge there were 4 bushels of very fine grapes. Some clusters would weigh upwards of a pound.

JOHN SAWYER RAYMOND,
Cumberland County, Maine.

Thomas Ewbank, Esq.,
Commissioner of Patents.

Meadville, Franklin Co., Miss., Dec. 25, 1850.

Dear Sir:—Your agricultural circular of the 26th of August was handed to me some time since. I have delayed responding to your queries, to collect the desired information. I proceed to give you the result of my imperfect inquiries in relation to the agricultural interests of this section of country.

We raise no wheat, barley, or rye. Cotton and corn are the principal productions. In fact, we raise so little of any thing else, that we call these our only crops. We generally plant about half and half, that is, one half corn, the other half cotton. The number of acres thus planted is about 16 to the hand. So one hand is said to cultivate about 8 acres of cotton and 8 of corn. The average crop per hand is about 200 bushels corn, and about 5 bales of cotton. An acre planted in corn seldom produces more than 25 bushels; nor does an acre of cotton often produce more than ⅝ of a bale. There are lands that produce more; but there are others that produce less. Five-eighths is about a general average. The weight per bale is averaged at 400 lbs.

We sell nothing but cotton; that is, we carry nothing else to market. For this we get 13 cents per lb., making $52 per bale. The cost of conveying to market is about $2 for each bale. When we sell cotton, we purchase supplies for the next year. Those supplies consist of meat, for which we pay $13 per bbl., negro clothes, sugar, coffee, &c. &c. The whole *outlay* for each negro, per year, is about $25, not including herein the costs of corn, potatoes, garden vegetables, &c., consumed by each. The whole cost of supporting each negro here cannot be less than $35 per annum.

When we plant 8 acres of corn to the hand, we seldom fail to make plenty. But cotton, for a few years past, having borne a good price, many of our farmers have gone half mad; planted nearly all their land in cotton, and but little corn. The consequence is, that corn has become scarce, and commands a high price. I paid, on the 20th, almost as high as $1.25 per bushel. We could, were we not so absorbed in cotton raising, raise hogs enough for our own meat. A few sensible old farmers do this, but the most of us abandon every thing for the sake of cotton, and so we depend almost entirely upon the more northern States to furnish us with this most essential commodity. We might raise many things we do not—and which we will not, so long as cotton brings its present price. Sheep would flourish here with a little attention; but, as it is, we raise but few for home purposes. Cattle and horses might be raised to advantage. We raise no horses, at least so few, that we may count them none. We are indebted to Kentucky and the other more northern States for our supplies of horses and mules. Great droves are brought down and sold among us every year. The price, this year, for a good working-horse is no less than $100; for a good mule, $120; saddle-horses of the best quality at from $200 to $275.

Milk-cows sell for $10 and $12 per head. We have but few, and make no cheese—a little butter for family use. Cattle are little or no trouble: they raise themselves. We seldom feed them, and it is only the cows and oxen we ever feed, and these only in the severe winter months. We use oxen principally for drawing our cotton to market. Four yoke can draw 6 bales. Oxen sell for $35, $40, and sometimes as high as $50 per yoke. We gather a little crab-grass for hay, and sometimes a few pea-vines, with which, together with the shucks of the corn, we feed the oxen while working. We also give them a little corn. We gather all the blades from the corn for fodder, upon which we feed the horses during the working season.

The usual mode of feeding horses while working is to give them 15 good ears of corn and 2 bundles of fodder three times per day—morning, noon, and night. We employ, or ought to employ, one horse to every hand. It is not much trouble to make corn, but cotton requires a great deal of ploughing and hoeing. We are compelled to work it all the time we are not engaged in our corn, to make a good crop. When we have finished working it, we then have to pick it. No time is then to be lost. This keeps us busy until near Christmas.

We raise no tobacco or hemp; we raise a little rice about in the wet spots; also a little sugar-cane, more for the curiosity of the thing than for any real profit. We never make sugar. We sometimes mash the cane and make a little molasses for home use. A negro man hires for $135 per annum; a white man for about $15 per month. Overseer wages range from $20 to $25 per month.

We manure nothing but corn. This we manure with cotton-seed, at the rate of one double handful of seed to the hill of corn. Corn thus manured will produce large and fine ears in the poorest land.

Yours, &c.,

D. C. GRAHAM.

Clarksville, Red River County, Texas, Dec. 16th, 1850.

Sir:—The "Agricultural Circular" issued from your office, and bearing date the 26th of August, was this day handed to me by the postmaster at this place.

In the outset, it may not be improper for me to remark that agriculture, *as a science*, is with us yet in its infancy. Very little attention is paid to the quality or kind of seed, except cotton; and such a thing as fertilizing or manuring land is never dreamed of. This county possesses a variety of soils—from the black, sticky land in the prairies, to the light, sandy soils of the "barrens." Wheat is grown to some extent—none, however, for transportation; the crop being generally about sufficient for home consumption. The time of seeding is from the 1st of October to the 15th of November; though many plant much earlier than that—say, 1st of September, provided there are seasonable rains enough about that time to cause the wheat to come up early. This, however, is not generally the case, inasmuch as the beginning of our autumn is unusually dry.

Thirty bushels are the average yield per acre.

We harvest from the 15th of May to the 1st of June.

During a residence here of several years, I do not remember having ever seen a single bushel of wheat in the least damaged by weevils.

CORN.

The most esteemed variety with us is the yellow. The average yield is about forty bushels per acre. The land is first prepared by very deep ploughing, and is most generally planted in drills. Very little is consumed in feeding hogs. Oats, barley, rye, peas, and beans grow well, and yield abundant crops. Oats and rye yield astonishingly. The cost of raising cattle amounts to nothing more than the time consumed in marking and branding. Cattle are penned once a fortnight and salted, which is necessary to keep them gentle.

Cattle require no feeding. In spring and summer, the grass upon the prairies furnishes excellent grazing, and the wild rye, cane, and winter-grass in the bottoms, furnish food during winter.

From 8 to 10 dollars is the usual price of cattle, at 3 years old. The value of good cows in spring is $10—in fall or winter a trifle higher, say $12. The cattle here are all native animals. Many are turning their attention to cattle-raising. Two thousand head or upwards are annually shipped to New Orleans. They are shipped down Red River, which is the northern and eastern boundary of this county. The cost per head of shipping to New Orleans is from 5 to 6 dollars. The price of prime fat beef, butchered, is from 2¼ to 2½ cents. On foot, any quantity can be purchased at 2 cents. *Hogs.*—We have several different breeds and crosses. The Irish graziers, I think, do best here—at least, they are, among hog-raisers, preferred to any other. Hogs are never fattened upon corn, from the fact that they fatten themselves in the woods, upon acorns, which, of course, is the cheapest method of producing pork and bacon. Bacon or pork fattened upon acorns is considered by many as being much sweeter and better flavored than that fattened upon corn. There is one objection, however, which I have to mast-fed pork, and that is, the lard is never so firm, hard, and good, as that of hogs fattened upon corn. The acorns of the post-oak and over-cup trees are considered the best mast for hogs.

COTTON.

The average yield of clean cotton in the prairies is about 1000 pounds, and about the same in the wooded uplands and barrens. In the river bottoms, however, (Red River and Sulphur,) where most of our large cotton plantations are situated, the yield is from 1600 to 2000 pounds per acre.

It must be borne in mind, however, in connection with this fact, that the bottom lands of Red River, as cotton lands, are not surpassed by any in the world.

RICE

Has not been cultivated to any extent, most of the crops having been planted merely for experiment. I am fully satisfied, however, from the specimens which I have seen, that rice can be successfully cultivated upon our uplands and prairies. Potatoes, both Irish and sweet, grow well. I do not now recollect the average yield. The best manure for Irish potatoes is rotten chips, decayed wood, straw, &c. The best system of planting is in rows—cutting the potato—leaving an "eye" upon each piece. Sweet potatoes yield more planted in hills. With us, the Spanish potato is the most prolific.

Very respectfully yours, &c.

FRANK H. CLARK.

Erie, Pa., December 27th, 1850.

Mr. Ewbank—*Dear Sir*:—I have received your agricultural circular, asking for information on various subjects. I shall endeavor to answer some of them.

First, *Wheat.*—The kinds most esteemed here are those that ripen early—as the Mediterranean and Etrurian. This last is a wheat I received, a few years ago, from the Patent Office. It is a very superior wheat in every respect. It is a bald, white chaff, white wheat—ripens early. I sow two bushels per acre—plough but once, 8 or 10 inches deep—go over with the large cultivator—sow, and harrow in.

The yield per acre is on the increase. I average about 25 bushels per acre—this year, over 25 acres. I have no one settled rotation of crops; sometimes we sow on clover-sod, once ploughed—then corn, then barley and seed down. At other times—first corn, then barley, then wheat and seed down. Wheat is worth $1 per bushel.

Corn.—The most esteemed variety here, is red-cob gourd-seed. The best system of culture is to drill and work entirely with the cultivator.

Rape.—I have cultivated this crop for several years, and find it very profitable.

The soil for growing rape on should be rich and clean. A thorough old-fashioned summer-fallow is probably the best for the rape crop. It should be sown the last of August—three pints of seed to the acre. It will be ready to cut in the last of June, or first of July. We cut it with large reaping hooks, and lay it in small bunches to dry, for eight or ten days. Then, with a large cloth spread over the hay-ladder, we proceed to haul in, and thresh with a flail immediately. The greater portion of the chaff is to be raked off, and the remainder left, with the seed, one or two weeks, on the barn-floor to dry.

It will produce from 30 to 50 bushels per acre. I have raised the highest figure. It is worth $1 per bushel in Erie.

Rape-straw is useless, except for manure.

These few remarks I submit.

Truly yours,

ROBERT EVANS.

Potosi, Grant Co., Wisconsin, December 24th, 1850.

Sir:—I have the honor to acknowledge the receipt of your circular of August 26th, 1850, through Hon. O. Cole, and, in answer to your inquiry in relation to fattening pigs, &c., I beg leave to communicate the result of a careful experiment.

In October last, I selected from my stock two pigs, of the same age, and, apparently, alike thrifty; one, however, weighed 260 pounds, the other 247 pounds. Immediately after being weighed, they were put in different apartments of the same house, kept dry and warm, and fed with great care for 40 days; then they were again weighed, and slaughtered. The heaviest pig was fed with cornmeal, mixed stiff with cold water; the other, with shelled corn, with plenty of pure water for drink. The one fed with meal consumed 425 pounds, and gained 63 pounds, live weight; the pork weight, or weight after dressing, was 267 pounds. The other ate 308 pounds of corn, and was found to have gained only 33 pounds, live weight, his pork weight being 231 pounds. By subtracting the pork weight from the live weight, the amount of offal is ascertained, which, in this experiment, proved a fraction less than one-fifth of the live weight. If one-fifth be deducted from the amount each pig gained, we then have the true gain, in pork weight, produced, which was *six and three-fourth* pounds for every 56 pounds of meal, and *five* pounds for every 56 pounds of corn.

The pigs were a cross between the Byefield and Berkshire, the best and most profitable breeds—the corn, yellow-dent, or Cleveland, a variety held here in great esteem.

Very respectfully yours, &c.

J. E. DODGE.

Hon. Thomas Ewbank,
Commissioner of Patents.

Fair Water, Wisconsin, December 12th, 1850.

Sir:—Let me inform you, and the public, a little concerning my method of building a fence. Not that I am presumptuous enough to believe that I have hit upon the *best* method under all or even most circumstances; but because I imagine that it may be of "real practical value" to *some* farmers in this wide-extended Union. In the first place, I get rails as long as convenient, say from 10 to 12 feet, and strew them, 7 in a bunch, so that the ends will touch the whole length of the line on which the fence is to be built. (If the rails are small, more will be necessary.) Then, I prepare stakes and caps, after the following manner, viz.:—The stakes I cut 7½ feet in length, and split them out, say 4 inches square. Sharpen one end for driving into the ground—the other is fitted to a 3 or 3½ inch auger-hole, about 3 feet from the end. These should be made of the most durable timber to be had. Charring the part driven in the ground will prevent decay wonderfully. If your fence is 6 rails high, you will need ½ as many stakes as rails. The caps should be cut 20 inches in length, and split-out 6 inches wide by 1½ or 2 inches thick. The distance between the inner edge of the holes should be about 5 inches. You will need one-half as many caps as stakes, and, perhaps some more, unless you have good timber, and are careful to try every stake, so as to be sure that none are a size too large. After making a good bench to stand upon to use the sledge, you can commence putting down the stakes: about 2 feet in the ground will be sufficient. If the ground is hard, a "crowbar" will be necessary to make a hole. You will lay the bottom rail as you desire the stakes. When you get the fence 5 rails high, put down the cap, laying the top rail above it. For 12 feet rails, about 3 feet "worm" will be sufficient, or 18 inches from the centre each way to the outside stake. Do not make the fence entirely straight; for, in that case, the rails will slip by at the ends, and your fence will be all in a heap in one year. A fence 6 rails high, built in this way, is better and more secure than one 7 rails high, of old-fashioned zig-zag fence. The difference in the number of rails required is nearly enough to pay for the stakes and caps; but the greatest advantage is, that the winds will not affect it, and it is an "impassable barrier" to cattle, &c. When built, it looks farmer-like, and, indeed, it is so. It may be no new "wrinkle" to many—yet, I presume, there are thousands who have never thought of it. Without adding more, let me subscribe myself a friend to improvement.

Yours, &c.,

H. B. EVEREST.

THOMAS EWBANK, Esq.
Commissioner of Patents.

Golden Grove Tea Plantation, Greenville, S. C., Jan. 9th, 1851.

Sir:—I have received your favor of the 7th ultimo, together with a copy of a communication from Mr. Frank Bonynge, for which I am much obliged. The history of China is an imperfect record of past events. The curiosity of the public mind, in its researches, is soon bewildered and lost in its attempts to unravel the fabulous and unauthentic stories of a semi-barbarous nation. No satisfactory accounts relative to the time when the use of tea was introduced into the empire have been transmitted to us. It appears, however, that it was in use during the Tsing dynasty, in the latter part of the fourth century, and how much earlier no record shows.

During the Tang dynasty, in 780, a duty of 10 per cent. was levied upon all tea brought from beyond the mountains, where it grew spontaneously. During the reign of Moor Tsand, 824, this duty was raised to 50 per cent. in order to replenish the imperial treasury; not an unusual excuse for taxation in more modern and enlightened times. In 1023 to 1063, large factories were established, and tea became an article of extensive commerce in the empire. The use of tea was introduced into Thibet in the ninth century, when Chang-loo was sent thither by the emperor, as ambassador; for, at that early period, there seems to have existed a greater freedom of international association than at present. The Thibetians, observing the ambassador's preparation of tea in his tent, inquired about its qualities. "It is," said Chang-loo, "a drink which relieves thirst and dissipates sorrow." A recommendation of greater accuracy could hardly have been given by any Chang-loo of the present day. A disposition to possess this sorrow-healing beverage soon manifested itself, and a distribution of several packages, just sufficient to establish the use and create a demand, was made by the ambassador among the courtiers.

In Japan, the use of tea was known in 810. The plant was not introduced until 815, when two Buddhist priests brought some young shoots from China. These flourished, and the use of tea became general in Japan.

Soon after its introduction into England, in 1657 to 1666, the tea-leaf was a court luxury, and sold as high as \$25 to \$45 a pound. In 1678, the English East India Company commenced the importation of tea, as a regular article of commerce, and the annual quantity received from China at that time, amounted to 4718 pounds. For ten years, from 1700 to 1710, the importation amounted to less than 800,000 pounds, or an average of less than 80,000 a year. It was still a luxury confined to the wealthy, and used in small quantities, with cautious economy, out of cups containing about a table-spoonful. Since that period, the quantity of tea imported from China into England amounts to between 50,000,000 and 60,000,000 pounds annually.

As we indulge curiosity in looking back for many centuries, and inquiring by what means, at what time, and under what auspices the tea-plant was introduced into foreign nations, so our posterity may have the same curiosity to learn at what time and under what circumstances it was introduced into our own country; nay, we need not wait for posterity to disclose a kindred curiosity of this inquisitive character. It is now actively alive and looking for an authentic solution. As the history is short, and may gratify the wishes of some, and perpetuate a record of facts, and especially as I am now in health, and hold the evidence in my hands which has not been communicated in writing, I feel it of sufficient importance to give to the public.

An unbelieving world would call the introduction of the tea-plant into the United States as an article of commerce, an accident. A Christian would call it an unequivocal mark of the special providence of God, leading to events unlooked-for, unexpected, undesigned, and so entirely alien from any human calculation, that the weakness and humble condition of the agents employed would seem to be inconsistent with a favorable result of such a great undertaking.

I have an only child, a daughter, born in London, who married the Rev. Edward K. Maddock, in Sydenham, near London, where I then resided, in 1840. In 1842, he was appointed, by the East India Company, a chaplain in the British army in India. He sailed with his little family in November for Calcutta. After a short residence at Barrackpoor, about sixteen miles from Calcutta, the bishop appointed him to the military station at Meerut, north-west provinces of India. The heat of the plains (latitude 29 to 30 north) was so oppressive, that Mrs. Maddock was, for the security of her health, advised, during the summer months, to remove to the Himalayas Mountains, about eighty miles from Meerut. By the English overland-mail, we corresponded monthly. On the 30th of October, 1846, she wrote me a familiar letter, which I received in New York, the 22d February, 1847. In that letter she gave me the first intelligence I had received of the formation of the tea plantations in the north-west provinces of India by the East India Company, as follows:—"In my next, I shall be able to tell you something about the tea now growing on these mountains. We are going to stop with the superintendent of the botanical gardens, Dr. Jamison, on our way homeward: he has promised to let us taste the tea. We hear that it surpasses the China tea, and is likely to become a most valuable speculation to the East India Company. The present tea plantations are near Almarah.

Some of the tea has been sent to London, and sells there for $1.50 the pound." Thus, we see, that we owe the whole of American tea enterprise to the familiar letter of a lady, writing without the slightest idea and wholly unconscious that it was designed to be the instrument of conferring upon the United States the greatest agricultural boon recorded since the introduction of the cotton-plant. No sooner had I perused that letter, than the idea burst upon me, that if the tea-plant could be successfully cultivated upon the mountains of Himalaya, as well as in the territories of Assam, there could be nothing in the ordinary course of vegetation to prevent its growth in the United States. From that hour, I devoted myself to the introduction and cultivation of the tea-plant in the United States. I did not seek the employment. It sought me. After three years' labor, and repeated disappointments, I have the satisfaction to inform you that I consider the greatest and most trying difficulties surmounted. The year 1849 was fatal to my imported tea-plants and tea-nuts. All perished in transportation; but Providence directed events to a different issue the last season. My plants and nuts came to hand in the finest possible condition, and I have availed myself of the blessing by greatly extending my plantation of the first quality of tea-plants, and still continue to enlarge the boundaries of tea-nut cultivation. The art of transporting plants and nuts securely, so great a distance, was entirely unknown, because without a precedent. All failed in their various attempts to accomplish the end. Final success rendered it absolutely necessary for me to devise a plan of operations more likely to prove successful. In this attempt, my views were carried out in China, and crowned with signal and complete success. The nuts arrived late, and but few germinated before summer closed. Those few, together with a good proportion of the tea-plants, thrive remarkably well, and now look strong and healthy. Experience has taught important lessons, and more are to be learned in this interesting art, before we can bring tea cultivation to its ultimate perfection in this country,

Your obedient servant,

JUNIUS SMITH.

Courtland, Lawrence County, Alabama, December 4th, 1850.

Sir:—Accompanying this, I send replies, in part, to questions contained in a circular from the United States Patent Office. The replies are not of a character to add much to our reputation as agriculturists or planters, and it is to be regretted that our country is not managed in a manner calculated to reclaim the lands and make them as productive as they no doubt would be under an improved mode of culture, which they are undoubtedly susceptible of. Should the communication be acceptable to you, I shall be gratified.

Wheat.—The crop is too uncertain, and is only cultivated principally for the use of those who have produced it. The early varieties are preferred—average yield, 10 bushels per acre: no preparation previous to sowing: the wheat is sown broadcast, and turned under with a one or two-horse plough, as the disposition of the person seems to suggest, and left to its fate. The crop is rarely interfered with by the fly. It is sown in September, and harvested in June: price $1.50 per bushel.

Corn.—The large varieties of white are preferred—product per acre, 30 bushels; culture very defective, as it is generally where cotton is produced. Much the greater proportion is fed in the ear; no attention paid to collecting manure—the cotton-seed not used for planting, being the principal dependence for manuring in the hill of corn in the exhausted portions of the land.

Oats.—There are three varieties cultivated here—the rupple, very productive, and well adapted to cotton plantations, as it is later than any other variety; the black oat, several weeks earlier, and very desirable because of its great weight and yield. The common, a mixture of white and black. Quantity of seed per acre, one to one and a half bushels is generally sown—yield, 15 to 20 bushels per acre. The small yield is to be ascribed to the careless manner of putting in the seed, which is generally on rough land and ploughed in.

Barley not cultivated; only used for winter pastures. Rye is similarly used.

Peas.—A very valuable crop, excellent for all kinds of stock, and the best reclaimer of land known to us. The vines that are left, after feeding the peas, improve the land in a remarkable degree: product per acre not known, as they are rarely gathered in a manner to ascertain.

Clover and Grasses.—The land here is admirably adapted to clover, if once firmly set. The yield is abundant, and the land much improved by the deposit of leaves and stalks, as it is rarely, if ever, saved as hay. The herds-grass and orchard-grass are best suited to the soil and climate, as far as ascertained.

Dairy.—But little attended to, as there is no market convenient for any surplus.

Neat Cattle.—Not desirable, unless for milk and beef to a limited extent; are considered injurious to the land when pastured during the winter.

Hogs.—Those most highly esteemed are the Berkshire, grazing, and Woburn, or a mixture of the best stock of the country with the above kinds. The course pursued in producing pork here is by no means cheap, requiring feed until slaughtered; the corn and attention required generally being of more value than the pork. The climate is changeable, and it requires strict attention to save meat that will be palatable.

Sheep and Wool.—Sheep thrive well, if attended to, and produce good wool, and a fair yield. Peas and vines are superior, for winter food, to any thing I have known them to be fed on. The county is well adapted to produce all that sheep require, and, with proper attention, there is no doubt that the raising of sheep and wool would be profitable.

Cotton.—Average yield of clean cotton per acre, 180 pounds. Cost of production, 6 cents per pound, when the same hands cultivate the usual quantity of land in corn, say 7½ acres. Crops are best grown in rotation, with cotton, corn, and peas; the next year in oats. The rust is by no means common here. Preventives against the army and boll worms: the army-worm has appeared but one season, and then so late as to do no injury: the best preventive against the boll worm is to make the ridges for the cotton in the early part of winter, so that the worm that makes the fly may, if not destroyed the next summer, be exposed to the cold, and be killed. Early ploughing for cotton at all events is considered preferable, and, if done as above-mentioned, much will be gained. In making the ridges, 4 or 6 inches are the usual depth for ploughing with two-horse ploughs.

The subsoil plough has not been used to any extent, but is spoken favorably of by those who have used it. Cotton-seed is very superior as a fertilizer, if rotted, or the vegetative principle destroyed. Cotton lands can best be improved by planting corn and peas after cotton, and oats after the corn and peas, leaving the oats on the exhausted portions for stock. It is believed that cotton does not require deep tillage until the land becomes too close to admit of the absorption of water from the rains to promote vegetation.

Root Crops and Potatoes.—Irish potatoes are an uncertain crop. Sweet potatoes are cultivated to a considerable extent: product large, but rarely measured. Turnips are the principal root crop. It is produced by most of our farmers, but not offered for sale.

Fruit Culture.—The climate is better adapted to the production of the peach than any other kind of fruit. Apples are to be met with of good quality, but the trees are short-lived, and would not be profitable unless in particular situations. There is more attention paid to orchards now than formerly. No grapes, unless to a very limited extent, and no wine.

Very respectfully, your obedient servant,

JOHN M. SWOOPE.

Hadley, Hampshire County, Mass., January 6th, 1851.

Sir:—An agricultural circular from the Patent Office, bearing your signature, has been sent to me by the Northampton postmaster, requesting me to contribute to the objects of which it treats. Feeling deeply my incapacity to answer, satisfactorily to myself, even the questions contained in the circular, much more that of giving information to the agricultural community, is my only apology for thus postponing a duty, which, although difficult to perform, yet has a bearing upon a great cause that has ever been to me most interesting and precious.

In enumerating and remarking upon our staple crops in this section of the Connecticut River valley, permit me, sir, to call your attention to one which is not noticed in your circular, but which ranks among the first in our list of staple crops. I refer to broom corn, the culture of which is by no means confined to this valley. The virgin soils of the West furnish their hundreds of tons annually for the manufacturers here. A rich, warm, alluvial soil is best adapted to this crop. It can be raised any number of years in succession, on the same ground, without a deterioration of soil or crop, provided 8 or 10 ox-loads of good rotten manure are placed in the hills at the time of planting. The average product per acre is about 700 pounds of brush and 70 bushels of seed. The cost of labor on an acre is about $15. Very few crops leave the soil in better condition.

The kind of Indian corn raised here is yellow and eight-rowed. Average product per acre, 40 bushels. Cost of production per bushel, 50 cents, exclusive of rent. A good system of culture, and one which is approved by our best farmers, I will try to state in a few words. The land intended for corn should have been turf the preceding season, and, if clayey or wet, should be ploughed in the autumn. In the spring, 15 ox-loads of well-fermented manure should be spread on the inverted soil and well harrowed in. Mark the ground at right angles for rows, so that the hills may be 3 feet apart each way. Plant, about the middle of May, 4 kernels in each hill, with a moderate handful of ashes. Ten bushels will suffice for an acre, and

they may be applied in the hill, on the hill, or near the young plants, after the first hoeing, with like effect. Cultivate and hoe three times at suitable intervals. The corn should be cut at the ground about the middle of September, or after it has become a little hard, and put up in stacks to dry. In about 4 or 6 weeks it will be ready to draw off and husk. In feeding to hogs, there is, doubtless, a saving of grain in grinding and cooking; but to make pork quick, cooking is needless.

Oats are sown principally with grass-seed, two bushels per acre producing about 30 bushels. All land that is heavy, or that was stiff sward the year previous, should be ploughed in the fall rather than in the spring. Oats are considered very exhausting, and, if possible, had better be dispensed with in a rotation of crops. The quantity of hay cut per acre varies from 1 to 4 tons. Two tons are considered a good crop. When land produces but one ton, it is ploughed for corn, or, if it is low ground, where corn will not flourish, it is ploughed in August, dressed with compost manure, sowed with a peck or half a bushel of timothy, nicely harrowed and rolled. The ploughing is done after haying, and the next year we have a crop greatly improved in quality and quantity. This method is strongly recommended by the Massachusetts Ploughman.

If any of the above remarks may be considered of any worth, they are at your service. I have applied to Prof. Snell, of Amherst College, for answers to the questions relating to the weather, which I hope to enclose in this sheet. A copy of your Report will be gratefully received and highly prized by, Sir, your's truly,

THEOPHILUS P. HUNTINGTON.

Answers to the questions under the head of "Meteorology," as derived from the journal kept at Amherst College, by Prof. E. S. Snell:—

Sweet Home, Bond County, Illinois, January 1, 1851.

Sir:—Being favored with a circular from your office, soliciting information respecting the agricultural interests of our region, I give the following in reply.

Wheat.—The red chaff, velvet, and golden straw, are the most common varieties here, and have been cultivated ever since the first settlement of the country. These varieties are of course nearly run out, producing only 10 or 15 bushels per acre, and are generally sown among corn at the last time of ploughing, or later, as the case may be. More recently, the May wheat has been introduced with some promise of success. Its advantages are, 1st. It is much earlier than other kinds, say from 1 to 3 weeks. 2d. It has a small growth of straw, but stiff and firm, and on these accounts is less liable to rust or fall. The rust and want of proper tillage are the greatest obstacles in the way of a good crop. With this variety, the former is avoided, and the latter may be learned. As this kind is ready to cut before the rust strikes it, it might, with good management, be made a sure crop. The Hessian-fly rarely troubles us, and the weevil never. Of the last-named wheat, I would further remark, that though the straw is short and the head small, the grain is uncommonly heavy and plump. I raised a few bushels of it last year, which was cut with Hussey's reaper. Several of our most experienced farmers came to witness the operation of the machine, and assisted in taking up the grain, and said it was the heaviest wheat they ever handled for the quantity of straw. I threshed the same with one of Emery's overshot machines, the only one of the kind here, and is generally believed to be the best in use. I sold what I had, for seed. Its weight was 67½ pounds per bushel. Others raised of the same kind, which weighed about the same. As to the number of bushels it will yield per acre, I do not know, but my opinion is, that on the same ground, and with the same culture, it will produce as many bushels and more weight than any other kind. No pains have been taken to introduce other new varieties here. The general practice of farming is to plant and sow the same seed on the same ground, from year to year. If a man puts in a piece of meadow, he will cut the grass for 15 or 20 years without manuring, scarifying, or reseeding. There are farmers here who have planted corn on the same ground ever since they commenced farming, say for 25 years, without changing their seed or ploughing deeper than at the first. Corn, corn, without manure, is their rotation. Corn is their motto from beginning to end, barely splitting the rows. And should any one presume to do differently, he would be denounced as a *book*-farmer, and thought to be incapable of getting a living by farming. Still, there are some who are bold enough to differ from them, and who, after their grounds have become a little worn, venture to let their plough in to the depth of from 6 to 10 inches, and thus, without manure, obtain double the crop of their old-fashioned neighbors. This, and the use of machinery, they look upon as an innovation, while they pursue their old course, and manage to raise corn enough "to do them," and are content. Cost of raising corn is from 5 to 10 cents per bushel, and sells at St. Louis (our principal market) for from 20 to 60 cents per bushel. Wheat brings from 60 cents to $1 per bushel. Our corn is generally fed to stock in a raw state, and unground, with no other crib than the ground for them to eat from. And, when taken into the stomach

of the animal in this hard state, it affords but little nourishment, much impairs their digestive organs, and, of course, must produce disease in many cases. As I omitted to say what I intended to in relation to the best mode of putting in wheat, I would here remark, that I believe a summer-fallow of clover, or fresh-broke prairie, is indispensable to the raising of a good crop. It may do to sow after other crops, if the land is well manured, for the ground must possess the elements of wheat—otherwise, none will grow. In the next place, it should be put in with the wheat. Drill or plough as soon as the 1st September; and, in the spring, it should be well harrowed and rolled. This I consider to be good wheat culture.

Oats are extensively cultivated, and produce from 28 to 40 bushels per acre. They are worth from 25 to 50 cents per bushel.

Rye yields from 10 to 20 bushels per acre, and sells for 37½ to 50 cents. It is a sure crop, though but little raised.

Beans are not extensively raised here, though they do well. They are worth from 50 cents to $1.25 per bushel.

The castor-bean is raised here, and produces from 10 to 25 bushels to the acre. They are worth from $1 to $1.25 per bushel.

Grasses of all kinds do well here, producing from 1½ to 3 tons per acre, according to the land, cultivation, &c. The best fertilizers for meadows are leached ashes, and barn-yard manure, spread on evenly as a top dressing. No land retains manure longer than ours, or gives a more bountiful return for the expenditure. The kinds of grass preferred here are red clover and timothy, mixed. Quantity of seed per acre, ½ a bushel of timothy, and 4 quarts of clover. Hay can be raised, cut and put into the mow or stack, with the aid of Hussey's grass-cutter and a good revolving rake, for $1 to $1.50 per ton. The usual price here, is $4 to $5 in the stack; but, if pressed and taken to St. Louis, (about 50 miles,) it brings from $15 to $30 per ton. The prairies are our pastures, and our cattle come from them to our barns, in the fall, as fat as they well can be, and this, too, without any expense, except for salt. The produce of the dairy from the prairie is equal, if not superior, to the best tame pasture, making richer milk, and as much or more butter and cheese for the year. Our dairies are managed only in connection with stock raising, and with nothing but dry food in winter. The value of butter and cheese per year, for each cow, is from $15 to $20. Treatment of milk and cream, various; also the mode of putting down butter for market. The best plan I have found for large dairies is to set the milk for butter in a cool cellar, of the right temperature, without scalding, and take off the cream, which I churn in a large rocking-churn, and, after the butter comes, which is in from 10 to 20 minutes, draw off the buttermilk, and dash in a bucket of cold water, which, by churning a few minutes, helps to wash out the buttermilk; after which, we work in the salt, and set it away for a few hours; then work it over the second time, adding more salt, with saltpetre and loaf-sugar, and pack away in firkins made of mulberry or ash. This will keep any length of time in any clime. Average price here, 10 cents. At St. Louis, 20 cents. Cheese, from 8 to 10 cents.

Neat cattle cannot be raised till three years old for less than from $6 to $7 each; but, with suitable blue-grass pasture for winter feeding, might be raised for one-half that sum, and would attain a larger size, consequently bring a better price. Average price now from $10 to $15. I can raise a horse or mule to the same age (three years) for less money than I can a hog or a steer; though Durham cattle, possessing every advantage in market, without any additional cost of raising, might do better.

Sheep and Wool.—The raising of sheep is the most profitable branch of husbandry in which the farmer of this region can engage. One hundred per cent. can with certainty be realized in the raising of wool and lambs, on any amount of investment the farmer has a mind to make, with proper care, shelter, and blue-grass pasture for winter feed. I can raise a pound of wool of any description as cheap as any other man can a pound of pork, and I can raise a pound of fine wool as cheap as I can a pound of common, coarse wool. The different breeds here are the Merino, Saxon, Cotswold, Blakewell, and Southdowns, the latter of which, with their crosses, I prefer. All sheep grow larger here than in the old States, and will yield more wool per head with the same care, and will produce a greater number of lambs in proportion to the ewes. Experience has proved this most conclusively; also that the same kind of sheep will produce a finer quality of wool in this or any other mild climate. This is the fact respecting furs; for those coming from warm climates are much finer and richer than those from cold ones, as every fur-dealer knows. The same that causes the fur to grow finer will operate the same on the wool of the sheep. As to mutton, every man knows that a large fat sheep or lamb is better than a small poor one. Sheep will get fat on the prairies in summer, and, if changed to blue grass and timothy in the fall, will remain so all winter, with good shelter. Hemp and tobacco can be raised to any extent here, but are not. The same may be said of roots. Potatoes do well here, both sweet and Irish, when the latter do not fall a prey to the bugs.

Fruit.—In this line we stand No. 1, both as to quality and quantity. Notwithstanding the extent and number of our orchards, new ones are being planted every year. The raising of fruit is the surest source of profit to the farmer in this section. Our market nor crops do not fail more than once in ten years, and the net profit is often above two hundred per cent. So long as our market remains as good as it has been for the last ten or twenty years, we shall not need to make other arrangements to dispose of our fruit; but if this should fail, we should still find it profitable to raise it for stock. Thus far, I have answered as well as I am able, and I believe accurately, although not as fully as I could have wished. Yet, if I have subserved the interests of agriculture, it is most cheerfully submitted, for you to dispose of as you may think proper, while I remain

Your most humble servant,

SAMUEL COLCORD.

Cinnaminson, Burlington Co., New Jersey, 12th mo. 18th, 1850.

Sir:—Having received one of your agricultural circulars, soliciting such information as might be useful in the Annual Report to be issued from the Patent Office, I proceed to give some account of the crops and management of farm-land in this locality. The kind of crop most profitable for cultivation in any section of country must depend, not only on the soil and climate, but the convenience of conveying the same to market. The extensive cultivation of perishable articles is necessarily confined to the vicinity of large cities, and situations having steam communication with them. Our land being a sandy loam, is very favorable for the early ripening of fruits

and vegetables, and, situated within a few miles of Philadelphia, and having railroad communication with New York, fruits and other perishable crops, gathered one evening, may be served out in either market the next morning. As a consequence, the farmers in this section of New Jersey find the raising of fruits and vegetables for the great markets, Philadelphia and New York, to be the most profitable use to which their lands can be applied, and vast quantities of such produce are daily despatched, by cars, steamboats, and sloops, during the market season. Whole fields of asparagus, peas, melons, cucumbers, &c. may be seen during the season of cultivation, resembling vast gardens. Strawberries, raspberries, and grapes are now coming into general cultivation, and bid fair to remunerate the husbandman richly for the labor bestowed thereon. Rotation of crops is not strictly adhered to, yet the system most approved is to turn down a sward or grass lay for corn; if it is old, and likely to be infested with worms and troublesome insects, it should be ploughed early, so that the frosts may kill all vermin that would otherwise prey on the kernels when deposited in the hill. We usually plant about the first of the fifth month, and cultivate the yellow gourd-seed variety, which yields an average of about fifty bushels per acre, costing thirty cents per bushel for cultivating, which cost varies inversely with the yield per acre; a strong argument in favor of plenty of manure and careful treatment. The practice of cutting up corn near the roots before it is quite ripe, while the blades and stalks are full of nutritious matter, is coming generally into favor, thereby saving a large amount of fodder, which is rapidly wasted when unprotected from the bleaching winds of autumn. The stalks from an acre of ground, when properly cured, are considered equivalent to a ton of hay for feeding stock. Grinding the grain, and sometimes crushing the cob with it, is greatly preferred to feeding whole; but little steaming or cooking of corn for stock has been practised. Oats and barley are sometimes sown the next spring after corn, but more frequently the ground is occupied with potatoes, peas, melons, and other garden vegetables for market.

Potatoes.—The failure of this crop in many parts of the country, where the land is clayey and tenacious, thereby holding the heavy rains in immediate contact with the tubers, until the hot sun, coming upon them while thus thoroughly saturated with water, completes their destruction, drying and baking the ground over and around them, so as to exclude the air, that, if they were so near ripe at the time as to retain their form until harvested, they soon give way after being exposed to atmospheric influence. The same cause that has heretofore prevented the cultivation of the more delicate sweet potato on heavy land, now operates against the Mercer or Irish potato, which seems to have degenerated in vigor, and has at length yielded to those adverse influences (which the sweet potato never could withstand) that had been imperceptibly, though no less certainly, impairing its constitution for many years previous. And sandy loam,—open and porous soils, that allow the excess of moisture to pass off freely from the plants, whereby severe storms act like gentle showers, merely to moisten the roots and invigorate the plants, and the genial rays of the sun thereafter meliorate the land, to the great benefit of the growing crop,—being the most certain land in which to grow the potato successfully, has induced our farmers to cultivate them almost to the exclusion of oats and barley; and fifty or sixty acres may be seen growing on single farms. Potatoes are invariably planted in drills, about thirty to thirty-six inches apart, manured with stable manure, or marl, which is abundant, and containing portions of lime, potash, &c., is preferred by many to any other manure, and can be obtained at the pits at 25 cents per ton, the additional cost depending on the distance to which it is carried. Planting is generally done during the fourth and fifth months, using about 10 bushels of seed and 15 horse-loads of manure or marl per acre. The digging commences in the ninth month, and is hurried through, so as to seed the same ground with wheat before cold weather sets in. Average yield per acre, 100 bushels; cost of producing, 30 cents per bushel; current price for last season, 60 cents per bushel. Hauling the crop to market, or to some navigable stream from whence they can be shipped to any of the seaport towns, commences soon after digging, and is continued at intervals through the winter and spring, as they are wanted for transporting to distant markets.

Sweet potatoes are also extensively cultivated, in the lightest and most sandy portions of this district, (stiff, unyielding soil being unfit for them.) The yield per acre, and market value, about the same as the Irish potato; but greater care in cultivating, storing, and preserving them through the winter is necessary, they requiring a temperate and uniform atmosphere, both as to warmth and moisture.

Wheat.—The third year of the rotation is usually devoted to wheat, which had been sown at the close of the second, after the crop of that year, such as potatoes, melons, cucumbers, &c., had been removed. Many varieties have been introduced here, as having some particular merit, which entitled them to preference over others; but of those that have been subjected to the test of several years' cultivation under all circumstances, the "blue stem" has the preference among white, and the "Mediterranean" stands unrivalled among red wheat, being early and less liable to suffer from rust, fly, and other maladies to which the cereal crops are subject. Seeding is mostly done in the tenth month, and harvesting near the first of the seventh month. The seed is generally sown dry, as it comes from the winnowing-mill, though it is sometimes soaked in strong pickle with beneficial results. Average product per acre, 20 bushels; cost per bushel of cultivating, 80 cents; market value, $1 to $1.12 per bushel.

Rye.—This crop is not cultivated to any great extent here. Three pecks are usually sown in the ninth month, and about 12 bushels harvested per acre in the latter part of the sixth month following. Price, 75 cents per bushel. The straw is valuable to farmers. Being long and pliable, it is convenient for many purposes; but this crop has disappeared rapidly from our fields since the introduction of Mediterranean wheat, which succeeds admirably on light sandy soils, yielding 50 per cent. more in quantity than rye, and commanding 33 per cent. more in price.

Grasses.—Clover and timothy are the principal grasses in cultivation, and are usually sown on young wheat or rye, about 1 bushel of each on 8 acres of land. Lime, marl, and plaster are extensively used, and are excellent fertilizers for meadows and pastures. Wood-ashes, guano, and poudrette are sometimes used with beneficial results. There might be a great saving of useless experiments, if farmers, instead of groping in the dark, and waiting years for the results that might be produced by different treatment, could bring to their aid the light of science, to show by mere analysis the constituent properties of their soil, and the kind of application necessary to supply the exhaustion caused by various crops.

Peas and Beans are only cultivated as vegetables, and are picked and sent to market while green.

Hogs.—Several breeds have been introduced and much mingled together; the Berkshire, however, has held a prominent place in the estimation of the people. Hogs are kept principally for the purpose of consuming the slops and offal produce of the farm, which would otherwise be wasted, but may thus be turned to good account, and, by keeping the sties well supplied with litter, muck, &c., large quantities of manure may be obtained: further than that, the price of corn will not warrant the feeding of swine on a large scale.

Root Crops.—Carrots and beets have been cultivated as a field crop to some extent, but, not meeting the expectations of the people, they have been mostly discontinued. Turnips are still largely cultivated, both for market and for feeding stock, yielding about 500 bushels per acre.

Dairy Husbandry.—Milk and butter are the principal articles sold from the dairy. One hundred and fifty pounds of butter to each cow is a fair yield for the year, worth 20 cents per pound. There is a limited demand for milk, which commands 8 cents per quart in the neighbourhood, and 6 cents in Philadelphia market.

Fruit culture is claiming increased attention. Many people have found that a few trees of the best selected fruits, planted around the house and yard, have yielded more profit than as many acres of land cultivated with ordinary crops. If proper care be taken in the transplanting and after-treatment, for a few years, until the trees get established in their new location, it will be fully repaid by the additional quantity and quality of fruit produced. The holes to receive the roots should be excavated larger and deeper than merely sufficient to let the roots in without bending, and rich earth or prepared soil should be filled in, so as to plant the tree as deep as it previously grew in the nursery. All wounded or bruised roots should be pared with a sharp knife; the tree should be held upright, and the roots extended in their natural position, and covered carefully with pulverized soil, which should be brought in contact with every fibre, so as to leave no hollow or cavities among the roots. A little water should be poured on, so as to settle the earth and retain moisture around the roots, after which throw on a little more surface soil, to prevent its baking, and leave a little hollow to hold the rain. Stake each tree and tie it carefully, to prevent the wind from shaking it, which greatly retards the young roots from striking in the ground. Young orchards should be cultivated for several years, and have vegetables grown therein, in preference to grain or grass.

The *Plum* is a valuable fruit, and, being liable to several maladies, particular care should be taken to cut off and burn the large black bunches when they appear on the limbs. One of the best preventives against the depredation of the curculio is to allow swine to have free range among the trees, as the insect is found to avoid places so dangerous to its offspring, which is contained in the fruit that has been attacked on the tree, which falls prematurely to the ground, and is destroyed by the hogs feeding below.

Peaches are of easy culture, but the trees should be examined two or three times during the season, and all worms removed from their roots, which may be readily indicated by the gum oozing from near the surface of the ground.

Quinces succeed best in a rich, mellow, moist soil, and, when thus situated, produce abundant crops of fine, sound fruit. Coming into bearing early, they bid fair to be a very profitable market-crop.

Grapes.—The native varieties are the only ones to be relied upon for open or field culture; and the Catawba, Isabella, and Elsinburgh have proved the most valuable for that purpose. Poles or stakes have heretofore been used for supporting the vines, but what is greatly preferred now, is a cheap and substantial trellis, made by erecting upright posts, eight feet high, and extending wires (No. 11) from one to the other, for the tendrils to cling to, and support the fruit and foliage.

Raspberry.—The cultivation of this fruit is claiming much attention, and many thousands of them are annually planted. Having over six acres devoted to their culture, I have found them to be one of our most profitable crops. There are many highly esteemed varieties, but, so far, the red Prolific, a native kind, has answered better than any of my imported ones. It is a medium-sized berry, great and certain bearer, and very hardy, needing no protection during the severest weather. The Antwerps and Fastolffs bear superior fruit, but the canes are so tender as to require careful protection from the sudden changes in the weather, or they may be so injured as to affect the crop. A moist situation, free from the extreme of drought or surface water, is desirable. The rows should be six feet apart, and the plants three feet apart in the rows, and cut down to within a few inches of the ground, soon after being planted, that the roots may become well established before they are required to supply nourishment for a long top of green foliage; otherwise the exhaustion of sap would be greater than the amount furnished by the roots in their new situation, and many of the plants would wither and die at the approach of dry weather. After the bearing season is over, the stems that have borne fruit should be cut down to the ground, to give strength to the young suckers which are to produce fruit the next year, as those which have once borne will never bear again. All superfluous suckers should also be cut out, and not more than five or six of the strongest stems retained in each hill. Stakes or rails are not necessary in field culture for sustaining the plants, but where they are too slender to bear their own weight, the tops of several may be tied together, whereby they will support each other. The ground should be thoroughly cultivated, and have a coat of manure every fall. A new plantation should be formed every seven or eight years. The fruit is picked in small square boxes containing one pint each, at a cost of one cent per box, mainly by the wives and children of laboring men in the neighborhood, who, instead of being a burthen to be supported by the head of the family, as heretofore, can each of them earn from fifty cents to one dollar per day, being quite as much as the principal himself generally obtains. The extensive use to which the raspberry is now applied in making jams, pies, tarts, sauces and preserves, raspberry cordial, syrup and wine, which "is a good reviving draught in ardent fevers," in addition to the large quantity used as a dessert fruit, creating a great demand, and the supply being limited by the number of pickers in each neighborhood, maintains a price much above the cost of growing them.

Strawberries.—This delicious fruit being so extensively cultivated as a field crop, yielding as many bushels per acre as corn, and commanding six times the price in market, scarcely needs any direction at this time for its culture; but, as some may wish to engage in it, who are not acquainted with the manner of growing fair crops of large berries, I will merely state the mode of cultivation that I most approve, after several years' practice. The ground should be prepared as for other crops; if not already rich, make it so by manuring: mark the rows four feet apart, and set the plants twelve

to fifteen inches distant in the rows. If the plants are of the female variety, put one hermaphrodite to every ten of the others, entirely rejecting the purely male or barren plants, which produce no fruit, but blossom and grow vigorously, and soon overrun and crowd out their more fruitful neighbors; some hermaphrodites bear abundantly themselves, and are amply sufficient for all the purposes of fertilization, by which treatment every plant may bear a perfect berry to each blossom. The beds should be kept mellow and free from weeds the first season, and the runners carefully distributed over the ground, so as to form the beds with regularity, after which but little culture is needed. A new plantation should be formed every four or five years. Plants are less liable to suffer from drought when set in the spring than in the latter part of summer, though either is a suitable time for transplanting.

I have extended this communication beyond my first design, and have no doubt embraced much superfluous matter, which, I hope, thee will curtail, and publish only what may be useful. Believing that the great interest of agriculture will be advanced by collecting and disseminating information on all matters pertaining thereto, I shall be happy at any time to contribute what little lies in my power towards the general good, in part return for the benefits which I have received from the experience of others. With sentiments of the most perfect regard, I subscribe myself,

Very respectfully, thy friend,

WILLIAM PARRY.

West Chester, Pa., December 24th, 1850.

Sir:—In answer to the queries contained in your printed circular, issued the 26th of August last, I beg leave to confine my remarks, at present, principally to the cultivation of the apple.

The apple will, for a long time, continue to occupy a prominent position among the fruits cultivated in Pennsylvania, either for home consumption or exportation. Its adaptation as a table dessert, in connection with its cooking qualities, and the great length of time to which its season of usefulness may be prolonged, will secure it a prominence in the culinary catalogue that no other fruit can easily reach. But a very limited quantity has hitherto been cultivated in this section of country for exportation; the principal markets for the surplus, over the consumption of cultivators, are the inland and river cities and villages. The proportion of arable land in eastern Pennsylvania under apple culture is about 2 per cent.; it might be 10 per cent. with profit to the cultivator. At least, three-fourths of the trees are past the prime of bearing, with a rapid tendency to decay. Most of the old orchards were planted for the purpose of making cider and apple-brandy, and the varieties of fruit selected with special reference to those objects. The association of horticulturists, by holding exhibitions, and awarding premiums, have, within a few years, given an impulse to the growing of such varieties of the apple as are better suited for the table; hence, plantations have been lately made with reference to that object; but a small proportion of which has yet come into bearing. The ball of improvement is, however, in motion, and continues to roll. Experience has demonstrated that certain varieties of the apple cultivated with the greatest success in one section of the United States are very inferior in other locations. This remark holds good in relation to most other fruits. It will hence be seen that it is impracticable to give a list that would be worthy of cultivation in all parts of the country. It is better, therefore, that those who are about to make apple plantations should select such varieties as are known to do well in their own vicinity for the larger part of their orchard: at the same time, plant a smaller proportion of other varieties of standard reputation elsewhere. If any of these should prove to be inferior, the heads can be top-grafted, and the variety changed, with a loss of only two crops. I would here remark to the young orchardist, that the nursery-man, from the nature of his profession, is always the best able to give advice in relation to the varieties most worthy of cultivation in his vicinity. A northern slope is the best for an orchard; any deviation from this should be easterly or westerly; a southern aspect should be avoided, if possible, as the very worst. Although some compositions of soil are better than others, I would say to every landholder, plant on such soil as you have; but avoid, if possible, a low, flat, or wet location, unless you first give it a thorough draining. Most horticultural writers advise the digging of holes, 3 or 4 feet square and 2 feet deep, in which to plant trees; the holes thus dug being first filled with rich earth or well-prepared compost. This preparation will undoubtedly give the trees a rapid growth for a few years, while the roots are confined to the narrow space prepared for them; but when they are compelled to go beyond those narrow limits in search of food, I fear the consequence will be like a spoiled child, fed on "roast-beef and plum-pudding" at home, and then sent out into the cold world to seek a living for himself. I do, however, most earnestly recommend subsoil ploughing. Let the subsoil of the whole field to be planted be loosened and pulverized as deep as possible. Without this preparation, the good results contemplated by digging deep holes are, to my mind, very questionable. I planted an extensive apple-orchard, a few years ago, without even the advantage of subsoil ploughing, which I very much regretted, there being obstacles in the way, which I was unable at the time to overcome. To make amends, as far as possible, for the want of subsoiling, I planted my trees *on the top of the ground.* A boy held the tree upright, while a man, with a shovel, covered the roots with such topsoil as he could collect convenient to the tree, raising a mound about the stem, to the usual depth of planting, extending the slope some 3 or 4 feet from the tree, the ground having first been well ploughed in the usual way. I did not lose one tree to the hundred—they not only lived, but grew; and their growth, so far, is quite satisfactory. There is great difficulty in making a fair estimate of the quantity of apples that may be grown annually on an acre of ground—the age of the trees, the mode of pruning them, the number on an acre, the composition of the soil, its culture, the aspect or slope of the ground, with other contingencies—all have a bearing on the productiveness of the orchard. A good distance to plant apple-trees, is 33 feet apart each way, which will place 40 trees on the acre; this disposition will give the trees sufficient room when they come to full growth; but if the planter wishes to devote his ground principally to the growth of apples, and bring it into profit as soon as possible, he may plant his trees 1 rod apart each way, which will put 160 trees on an acre. When the heads grow so large as to become too close, cut out every other tree in each row—not the trees opposite each other in the adjoining rows; but so as to leave the orchard in the quincunx order. When they again

become too close, cut out one-half of the rows alternately, which will reduce the number to 40 trees to the acre, and give ample room to expand and develop their utmost fruit-bearing qualities. If apple-trees are planted on good ground, and well cultivated, they will commence bearing on the fourth or fifth year, (some varieties sooner than others.) The tenth year, they will yield 3 bushels to the tree, which (if planted 1 rod apart each way) will be 480 bushels to the acre. The fifteenth year, they will yield 5 bushels to the tree, which will be 800 bushels to the acre. This may be considered a fair average crop for 20 years afterwards. If apples are worth 20 cents per bushel on the tree, (which is a very moderate estimate,) then an acre, planted as above advised, will produce $96 the tenth year, and $160 annually after the fifteenth year. All that a farmer gets for his apples on the tree, over 5 cents per bushel, is clear profit. To produce these results, it will not do to merely plant an apple-orchard, and let it take care of itself. The ground must be cultivated and manured, the trees must be annually pruned, caterpillars and other insects destroyed; in short, such a course of culture is needed as will keep the trees in good health, with plenty of nourishing food at their roots. The crops grown between the trees, before they come into bearing, will remunerate all this labor and expense. Indian corn and root crops are the best for orchard culture; cropping with small grain is injurious to fruit-trees. Red clover is the only grass that ought to be permitted to grow in an orchard; and it should be ploughed under, the second or third year.

Pruning.—Minute directions for this operation cannot be clearly given, without occupying too much space. A few hints, in outline, will be sufficient for the purpose. Pruning should commence with the planting of the tree, and should be continued, more or less, every year. The upper surface of the head of the tree should be in the shape of an open umbrella: this will permit the rays of the sun to reach the fruit, without which it would not ripen well. The upright centre branches must be shortened, or "headed back," the outer side-branches be encouraged to take a horizontal position, and the whole head should be so thinned that light and air can have a free circulation. The facilities incident to hand-picking the fruit should also be kept in view when shaping the head of the tree by pruning.

Some pomologists prefer winter, and others summer pruning. My experience is in favor of winter pruning, for the purpose of thinning-out and shaping the head of the tree. Suckers or offshoots may be removed at any time—the sooner the better. When young trees are well cultivated and manured, they sometimes become too growthy, at the expense of fruit-bearing. To remedy this, it is well to go over the trees, in the months of July or August, and, with a sharp knife, cut off about one-third of the present year's growth of each shoot: this will check the growth of the tree, and induce the formation of fruit-buds for the next year's crop. Summer pruning for any other purpose cannot be recommended, as the removing of any part of the foliage has a tendency to check the growth of the tree. By pruning every year, small branches only are cut, which soon heal over, without any deleterious effects from the wound.

There is nothing to be gained by those who wish to plant fruit-trees, to begin by propagating and raising their own trees. It is better to go to the nursery at once and buy those they want, of the proper size for transplanting, which will be five years in advance of trees they would grow themselves. Five years advance in the fruit business is a matter of some importance. If the above remarks are deemed worthy of a place in your Report, and prove to be of any use to the community, the writer will be amply compensated.

Very respectfully, &c.

A. MARSHALL.

Canandaigua, N. Y., December 27th, 1850.

Sir:—In answer to the Agricultural Circular which you were pleased to send me, I beg leave to make the following remarks:—

Wheat.—The varieties most in use are Soules and white-flint, the former is sown to the greatest extent, but the latter has many recommendations. It will make at least an equality of flour, and, being less liable to shell out, there is less loss in harvesting; and, if there should be a scarcity of help, it can stand until quite ripe without any damage. On this last account, I have sown no other for several years. Where much wheat is grown, I think it advantageous to sow both kinds. Since I have grown the flint-wheat, my average has been about 25 bushels per acre. I am not an advocate for early sowing, but from the 10th to the 20th of September, I consider the best time. By sowing late, I think I stand a better chance to escape the ravages of the fly. I formerly limed my seed, but of late have sown without any preparation, and, by being particular in selecting clean and pure seed, have not found it necessary to pursue any other course. Where I fallow, I plough three times; but I put in a great portion of my wheat with one ploughing after clover. My favorite rotation, where the nature of the soil will allow, is, 1st. Corn or roots, on which I apply all my manure; 2d. Barley or oats, at the same time seeding-down with clover; 3d. Clover, mowed or pastured; 4th. Wheat, with one ploughing. Under this system, there is no dead year for fallow; my crops are good and my land is not exhausted. Of course, this system will not apply in all soils, for, on some, fallow seems absolutely necessary; but such I do not consider the most profitable to cultivate. Average price for 1850, at our nearest market, one dollar per bushel.

Corn.—I have tried several varieties, and consider the large eight-rowed yellow the most profitable. My manner of cultivation is as follows, viz.:— As soon as the manure is spread, I plough it under, and, without any harrowing, plant along the furrows made by the plough, taking every fourth furrow, which gives a little over 3 feet between the rows, and I allow the same distance between the hills. I would say that this plan requires good ploughing and favorable soil. As soon as the corn is up, I cultivate between the rows lengthwise, and drop some plaster on each hill. In a short time, I go through again with the cultivator, first cutting down all weeds with the hoe, which grow among the corn, and the next and last time I go through with the plough, throwing up the soil to the plants and covering up all weeds, which will as effectually kill them as cutting them up with a hoe. After this, I go through with a hoe and draw the soil about the plants, and release their leaves when fastened down by ploughing.

Hogs.—I only fatten enough for my own use, and this I do by throwing to them the corn on the cob, which is not, perhaps, the most economical way, but it is the least troublesome. For my horses, cattle, and sheep, I grind corn and cob together.

As to the increase of corn from the application of manure made from corn fed to hogs, I cannot speak; but, having made a small experiment on manure applied to ruta baga, I will here state the result. November 17th, 1842, measured three drills of ruta baga, 30 feet long and 30 inches apart, and weighed the product, with the following result:

From common barn-yard manure,	45 lbs.	of roots,	=	435[illegible]	per acre.
" hen-house	do. 99	do.	=	958[illegible]	"
" rotted hog	do. 108	do.	=	1045[illegible]	"

From this I think it fair to infer that a very material increase of the corn crop might be expected from the use of hog-manure.

Oats.—Average crop per acre, about 50 bushels. Quantity of seed per acre, 4 bushels.

Barley.—Average yield per acre, about 35 bushels. Quantity of seed per acre, 3 bushels.

Peas and *Beans* I consider the least exhausting.

Clover and Grasses.—Average quantity per acre, about 2 tons.

Plaster is undoubtedly the best fertilizer for clover; but I do not think it has an equal effect on other grasses. In laying down meadows, the kind of seed should be suited to the land, for, on low, wet land, red-top is considered to be the best, while, upon higher land, timothy is more suitable. I am now using orchard-grass with clover, on account of its ripening so much earlier than timothy, which is not fit to cut when clover ought to be. I have tried rye-grass, but did not like it.

Sheep and Wool.—My sheep are all Southdowns. They are not profitable merely for wool-raising, but their mutton is very superior, and we are now brought near the Eastern markets by railroads. I consider them the most profitable sheep to keep. I have known them to be sold before 12 months old for slaughtering, in our village, at \$3 per head. I generally rear as many lambs as I keep ewes.

Root Crops.—For many years, I have been a successful cultivator of roots. My greatest crop of mangel wurtzel was 1846 bushels per acre, and of ruta baga, 946. I consider mangel wurtzel, sugar-beets, and carrots to be the most profitable. I do not think there is any decided increase in these crops, nor will it ever be profitable to grow them to a very great extent in this climate, owing to the necessity of having them protected during our long and severe winters. It is very different in England, where the winters are so mild that the greater portion of the crop is consumed upon the ground. I look upon corn as the grand substitute for roots, and as the farmer's main dependence to carry him through our long winters. Having noticed your queries, so far as I have a practical knowledge of the subjects, and being invited not to confine myself strictly to those queries if any other subject bearing on agriculture should suggest itself to me, I take the liberty to call your attention to a subject which I consider of the first importance to agriculture. I allude to a thorough system of draining. The wheat crop in this section of the State of New York is the principal one upon which the farmers depend in order to meet their cash engagements. Any plan by which this crop can be materially and permanently increased must be of great benefit to a large class. Now, I consider the greatest enemy to the wheat crop to be a surplus of surface-water. Nearly every spring we hear farmers complaining that their wheat is winter-killed, and in almost every instance of this kind which has come under my personal observation, I have felt assured that draining would have proved an effectual remedy. I know that upon my own farm, where wheat used invariably to heave out, a thorough underdraining has effected a complete cure. On many parts, which were mere swamps, and too unsound to bear a horse, I now grow my best wheat, and those fields which were formerly so wet as to be the last in a condition to work in the spring are now dry the earliest. To carry off mere surface-water much may be done by judicious ploughing and furrowing. Of so much importance do I consider it that the surface-water should have a free egress, that I am not satisfied merely to draw a plough where it is necessary, but I follow with a spade or shovel and clear out the furrows completely, and, after the first rain, I go to see if there be any lodgment of water, and if so, lower the trench so as to give more fall. As to ploughing, I have suffered so much inconvenience in getting the surface-water from my land, owing to the custom, so prevalent, of deeming it absolutely necessary, if a field had been ploughed north and south, that the next ploughing should be east and west, that I have, for a number of years, given up cross-ploughing. I have my fields ploughed into lands of 30 feet wide, taking care that the furrows run with the natural inclination of the land. By adopting this plan, I obtain a good fall for all the surface-water. After all this attention in carrying off the top water, there will remain lands to a very large extent unfit to bear wheat without underdraining, and a still larger extent which might be greatly benefited by it. It would be difficult to lay down any general rule for draining, as different situations require different treatment as to direction and depth of drains. It is a disputed question, whether deep or shallow drains are best. I advocate the former, never having had to repent of making drains too deep. My drains have varied from two to three feet in depth. In some instances, I have drained every dead furrow, which, according to my plan of laying out my lands, would be 30 feet apart. This is rather an expensive operation, but it has proved very satisfactory, as the nature of the soil, which was before a stiff clay, has undergone a great change for the better; and the field, from being the wettest and most difficult to work, has become the driest on my farm. With regard to the best materials for laying drains, stones, if abundant on the farm, (and, of course, it would be an object to remove them from the surface,) make good and permanent drains. If you have not stones at hand, drain-tiles are the best and cheapest material for that purpose. These are now made of good quality, and at a reasonable price, at Waterloo, Seneca County, N. Y. In this county, draining is comparatively a new operation, but I am convinced it is one which may be very beneficially pursued, and several farmers in this vicinity have entered into it with spirit, and with perfect satisfaction as to results. If, by these imperfect remarks, I shall be the means of calling attention to this most important subject, and of having it introduced into the next Agricultural Circular, when more minute and satisfactory statements may be elicited, my object will be attained.

I am, sir, your ob't serv't,

CHAS. B. MEEK.

Aurora, Cayuga County, N. Y., 12*th mo.* 18*th*, 1850—*lat.* 43°.

Friend:—Thy circular of the 26th 8th month last is before me, and in answer—

Wool-growing is most profitable for persons who are obliged to hire laborers; but for those who work for themselves, a variety of agriculture is more profitable. Cost per lb. for growing fine Saxon Merino wool is about 28 cents per lb., and sells for 38 cents per lb.; average weight of fleece 2½ lbs. Cost of growing Spanish Merino wool, 22 cents per lb.; sells for 31 cents per lb.; average of fleece, 4 lbs. It is not any more, if as much expense, to raise Spanish Merino wool per pound, as to raise common coarse wool. The Saxon Merino is much the finest wool, but not as strong constitution as Merino. The wethers of the latter are worth 50 per cent. more than Saxon; are equal to Southdown for mutton. My flock is very fine Saxon, but I am crossing them with Merino, such as I kept years since. One ton of hay will produce 28 lbs. of Saxon Merino, or 36 lbs. of Spanish Merino wool. One ton of hay is sufficient for 11 Saxon, or 9 Merinos, during our winter-foddering of 17 weeks. Merinos will eat coarser provender than Saxon; the former are rather more profitable than the latter, and 40 per cent. more profitable than such sheep as were common in America previous to the introduction of Merinos. The proportion of lambs annually reared, to the number of ewes, is, of Saxon Merino 40 per cent., of Spanish Merino 60 per cent., if they have lambs at two years of age; but better not have them until three years old; the flock will be stronger, and produce more wool.

The soil of this county is a rich, calcareous loam, producing good crops of wheat, corn, or grass. The above statement is estimating land worth $1 per acre, annually, subject to taxes and repairs, or double that sum, if in grain culture. Laborers, $125 per year, and board.

I have kept a flock, averaging two thousand Spanish or Saxon Merino sheep, during the last twenty-five years. The foot-rot was introduced from Saxony 17 years since, and, after applying for years several caustics to their feet, &c., and other things, as directed in European and American books, with great labor, without success, then commenced giving the sheep about three ounces flour of sulphur, (cost in New York 3½ cents per pound,) in one peck of fine salt, each week during warm weather, which, if I had known years ago, would have saved me some thousands of dollars, for it effected a permanent cure without labor.

Respectfully, HUMPHREY HOWLAND.

Jeffersonville, Fayette County, Ohio, December, 1850.

Sir:—In compliance with a request made in your Agricultural Circular of the 25th August, 1850, I have thought proper to make a few suggestions relative to the culture of the Irish Potato. Having experimented considerably on a limited scale, for some years past, in the above business, I give the result, hoping it may be of advantage to others. By planting in the month of May, say towards the latter part, in ordinarily rich, loose soil, with the addition of a little long manure, prepared by ploughing and harrowing, plant in hills three feet apart each way, with from two to three small potatoes in each hill, and cover four to six inches deep. Till, by ploughing each way, without adding fresh dirt to the plants, but elevate the soil on all sides above that first made, (i. e. above the hill,) and thin to three or six stalks to the hill, just before they bloom. By this process, the yield is 400 bushels per acre. But the same process, in rich sod land, with the same manure, may make a yield of at least 600 bushels per acre. The varieties are the pink-eye and red meshannock.

H. CREAMER.

Westmoreland, December 28th, 1850.

Sir:—Having received a circular from you soliciting information upon the subjects therein named, I will proceed to give my opinion in answer.

Wheat.—There are three kinds in use—the bald, which averages about 25 bushels per acre; Black Sea, average 25 to 30 bushels, and red-chaff, average 20 bushels per acre. Time of sowing, September 20th; harvest, July 20th. Preparation of seed, wet and roll in plaster; quantity per acre, 2 bushels. We plough but once, depth 6 inches. Yield diminishing. Rotation, corn, oats, and wheat. Remedy for the weevil, air-slaked lime sown while the wheat is in the blow. Average price in market, $1.13 per bushel.

Corn.—Varieties, yellow and white; average crop, 50 bushels per acre; cost of production, 40 cents per bushel. The best system of culture is to plough the ground in the fall, and in the spring furrow it and dung in the hill with compost. Best method of feeding corn, have it ground and scalded. The manure of 10 bushels of corn made by hogs, if carefully saved and applied in the hill, will add 5 bushels to the crop.

Oats, average yield per acre,			40 bushels;	quantity of seed,		3	bushels.
Rye,	"	"	" 35	"	"	" 1½	"
Peas,	"	"	" 20	"	"	" 1	"
Beans,	"	"	" 20	"	"	" ½	"

Peas may be considered a renovating crop.

Clover and Grasses.—Average product per acre, 2 tons; best fertiliser, manure; kind preferred, timothy; quantity of seed per acre, ½ bushel; cost per ton to raise, $3.

Dairy.—Average product of butter per cow,	150 pounds,	cost	12½	cents.
" " cheese "	300 "	"	7	"
Average price of butter per pound			14	"
" " cheese			6	"

Neat Cattle.—Cost of rearing till 3 years old, $23; usual price, $25. Value of dairy-cows in the spring, $30, and in the fall, $18. Number of pounds of beef produced from 100 pounds corn, is 19½. A given amount of food will produce more meat in a native than in an imported animal.

Sheep and Wool.—This branch of husbandry is profitable, and on the increase. Cost of coarse wool per pound, 18¾ cents, and that of fine, 31 cents. One ton of hay will produce 15 pounds of wool. Large sheep are more profitable for mutton, and small fine-woolled sheep the best for wool. The proportion of lambs to that of ewes is two-thirds. The best breed of hogs is the Berkshire. The cheapest method of producing pork is to feed scalded meal. One hundred pounds of corn will produce 24 pounds of pork.

Potatoes.—Average yield per acre, 200 bushels; cost of production, 12½ cents per bushel. Varieties, red-field and pink-eyes. Best manure is a compost of muck, lime, and dung.

Fruit culture is receiving increased attention. Apples are a profitable crop, but, when compared with potatoes, are not profitable to feed. The best mode of preserving manure is to keep it under cover till wanted for use, then draw it out and plough it under as soon as possible. The quantity used per acre is about 20 loads.

ROBERT WATERMAN.

Morrissania, Amherst County, Va., December 28th, 1850.

Sir:—I had wished to see the agricultural part of the Patent Office Report before replying to your circular, that I might see what I had written last year, and avoid unnecessary repetitions; but, as I understand it will not be published in time for that purpose, I have concluded to delay an answer no longer.

Wheat.—The varieties cultivated in this county are the white-flint, white blue-stem, the early and late purple-straw, the white-bearded, Mediterranean, and Zimmerman. The May wheat, both white and red, and the red-shuck, which were formerly cultivated here, have been almost entirely superseded by the first-mentioned varieties. The white blue-stem was more productive the past season than any other cultivated by me. This fall, I sowed a part of my crop with early purple-straw and Zimmerman wheat; as these varieties are highly spoken of by those who have tried them. The average produce per acre in this county, the past year, cannot be estimated at more than 10 bushels. We usually sow on high land from 1 to 1½ bushels per acre, and on low lands from 1½ to 2 bushels; and we commence seeding about the 25th of September, and complete this operation about the 10th of November. Fallow ground I usually plough twice, corn and tobacco land only once, and cover with the harrow. The ploughing is usually from 6 to 8 inches deep for wheat. The yield per acre I consider as on the increase, for a much better system of agriculture is practised by our farmers; more attention is paid to manuring the land, and more guano, plaster, and other fertilizers are used than formerly. My system of rotation in crops on high land, is the six-field: 1st, corn or tobacco; 2d, wheat or oats; 3d, clover; 4th, clover, partially grazed; 5th, wheat; and 6th, clover; and on my low grounds, the three-field: 1st, corn or tobacco; 2d, wheat; 3d, clover, taking care to graze the clover, after harvest to closely beat down the weeds and prevent them from destroying the young clover. The best protection against Hessian-flies, is to make the land rich, and sow in the month of October; and that against weevils, is early threshing and grinding. The price of wheat, the present year, in Lynchburg, has been from 90 cents to $1 per bushel.

Corn.—The only variety I have cultivated for many years is what is called the "double-eared," a white grain, between the gourd-seed and the flint. The best system of culture for corn is to make the land rich, plough deep, plant early, and not work the corn after harvest. I usually plough my low land in beds of 21 feet wide, on each of which I make 5 rows, plant the corn 2 feet apart, and leave 2 to 3 stalks in each hill. My low land produces from 5 to 15 barrels (of 10 bushels of ears) to the acre, and my high ground about 5 barrels. The average of the county is not more than 4 barrels per acre. There is certainly great economy in the feeding of stock by having the corn ground, for I am satisfied that from one-fourth to one-third will be saved by this operation. As to cooking food for stock, I am unable to give any information.

Oats.—This grain will yield about double that of wheat to the acre; but as the poorest land is generally selected for oats, the average yield may be put at 15 bushels.

Rye.—The Poland rye, a new variety, is said to be much more productive and hardy than that previously grown; but I do not cultivate this grain, in consequence of the difficulty of keeping it from mixing with my wheat.

Peas and *Beans* are only raised for family use in this vicinity, and barley not at all.

Clover is regularly sown on all my land after the small grain crop, and I save largely of the hay: indeed I consider it necessary for my farming operations. This, and my corn-fodder, are the only kinds I make use of. I suppose the clover yields from 1 to 3 tons per acre.

Dairy husbandry does not receive much attention, as we are satisfied if we have plenty of milk and butter for family use. We make no cheese. It costs us but little to raise our cattle, as we have a sufficiency of straw-fodder and shucks to feed with, and we keep no more than we can feed with advantage. We never feed our sheep except when the ground is covered with snow, which, in our coldest winters, does not exceed a few weeks. Wool-growing, therefore, might be profitable, if it received sufficient attention, as the expense of keeping sheep is inconsiderable; we keep only enough, however, to clothe our families and to furnish us with mutton and lambs.

Hogs are generally raised by keeping in the woods during the winter and spring, and feeding them on corn till about the first of June, when they are turned into the clover-fields, where they remain until the wheat is removed, and they are then suffered to glean the wheat-fields; and about the first of October they are put up in pens, and fed with corn, pumpkins, &c., till December, when they are killed. This we consider the cheapest method of producing pork. I have but one suggestion to offer as to the best method of curing bacon-hams, and that is, to remove the bone from the point of the ham to the hip-bone, and round it off. It is under this bone that the ham usually spoils, and this removal is attended with but little trouble, and the appearance but little changed.

The crops which we grow in rotation to maintain the fertility of the tobacco land, are wheat and clover. It is also desirable, in the three-field system, to put that part which was in tobacco one rotation, in corn the next, so that the land will not be in tobacco but once in six years. This I consider necessary, as the food of the tobacco-plant differs from that required for grain. To prove this, all kinds of products grow well after tobacco; and wheat after it will yield twice the quantity that it will after corn on similar land. The average yield of tobacco per acre, may be estimated at about 700 or 800 pounds on old land, and on new at about 500 pounds. The reason why old lands produce the largest yield is, that they are generally manured. Sometimes, however, much larger crops are made, for I have grown as much as 1200 pounds per acre. Root crops are not on the increase, as we only cultivate them for family use, except a few for market. Fruit culture is receiving increased attention among us, for orchards of apples, peaches, pears, apricots, &c. are being planted, of the best varieties, which produce well, unless nipped by an "untimely frost;" and I have no doubt that apples will be exported from Virginia in a few years, instead of being brought from the North. Grapes are also grown of many varieties, and produce well, both native and foreign; the former, however, succeed the best; and among these are the Norton seedling, a fine bearer, and is a most delicious table grape.

Manure.—My plan for making manure is to place my pens for wintering stock near the land intended to be manured for corn or tobacco. Into these pens I haul all my corn-stalks, and feed with straw, shucks, &c. The cattle eat as much as they want, and trample the remainder under their feet. In the spring, this manure is spread and ploughed under, and the stable manure is used in the same manner. That which is made in spring, summer, and fall is either spread as a top dressing on clover or wheat in the fall and plastered. I have spread lime on my land, but never have been able to discover any benefit from its use. I use plaster freely and with beneficial effects. I spread it weekly over my stable-manure heaps, also over the manure when spread. It is sowed on clover and used with seed-corn. The use of guano has just commenced in this county, and gives general satisfaction.

Respectfully yours,

RICHARD G. MORRISS.

Warsaw Prairie, Kaufman County, Texas, December 26th, 1850.

Sir:—My absence from home for some time past has prevented me from answering the interrogatories propounded in your circular until the present time, and I shall now have to beg you to excuse me for the brief reply which I am compelled to make. From the newly settled state of the country, it is almost impossible to make a correct report of the amount of products now raised in this and the adjoining counties, for it is now only a short time since when "nought else was heard but the yell of the Indian and the tramp of the buffalo." As to the capacity of our soil and climate for the production of cotton, corn, wheat, and other cereal grains, as well as that of many other agricultural products, I think it cannot be excelled; in short, as was stated in the Report of the Trinity Convention, which met at Huntsville a year or two since, and which was composed of delegates from the whole Trinity Valley,—"The rich black prairie country of the Upper Trinity, in an agricultural point of view, must necessarily become the garden of Texas. The immense grassy plains of prairie and woodland, the cane-bottoms, with never-fading verdure, and the immense fields of wild rye, green in midwinter, all show that the constant labour and toil of man are not necessary in order to rear stock of any kind, for they grow and flourish without his care."

Wheat.—Most of that formerly grown here has been of the bald varieties. Very little of any bearded variety has as yet been introduced among us. I regretted exceedingly that we had not sown the "Mediterranean," or some other good variety of bearded wheat, the past season, as the little we had remained unharmed, while whole fields of bald wheat were almost entirely destroyed by myriads of small birds resembling the rice-birds of the south, and which have never before visited us. It is unnecessary for me to say more at this time concerning these birds, as I am apprized of your having noted down my remarks to the Hon. Mr. Kaufman on this subject. Our black prairie land generally produces from 30 to 40 bushels of wheat per acre, and is of a very superior quality, weighing about 70 lbs. to the bushel. Five bushels of our wheat are equal to 6 raised in Ohio, for it contains the nutritious quality called gluten in that proportion, as has been proved by actual experiments. From my experience in seeding, I prefer to sow from the first to the middle of October. Our wheat is ready for harvesting from the first to the middle of May, which gives us the advantage of having our flour in market one or two months earlier than that from any of the Western States. We generally sow about 1 bushel to the acre; but I prefer rather more. It is not common to plough our ground but once, and this at the time of sowing. I usually plant my ground with corn, preceding a wheat crop. I sometimes make a good crop of corn on the same land after taking off a crop of wheat, and then sow with wheat again the next fall. We are not troubled much with weevil, and not at all with the Hessian-fly. The average price of wheat is about $1 per bushel.

Corn.—The average product per acre is from 30 to 40 bushels. The cost of production is about 20 cents per bushel. I do not know that I can point out the best system of culture, for, having too much land to cultivate for my force, I am sometimes obliged to do many things different from what a scientific farmer would recommend. I suppose it is unnecessary for me to state the process of putting in a sod-crop. If any of your readers want any information on this subject, I would refer them to the letter of the Hon. H. L. Ellsworth, published in the Patent Office Reports for 1845. After this first crop, if not sown with wheat in the fall, I usually let the land remain without any further ploughing till I am ready to plant again in the spring, when I lay off my corn-rows only one way, and 3½ feet apart, with a plough. I drop my corn in the furrow, 1 grain in a place, about every 2 feet, and cover by turning a furrow from each side on the corn. When it comes up, I go through with a harrow, which levels the ridge and leaves the ground loose and in good order for giving the corn a good start. I usually give my corn one or two more ploughings after breaking out the middle, and then lay it by.

Oats.—The average yield on my land is about 40 bushels per acre. The quantity of seed per acre is 1½ bushels. Barley, rye, peas, and beans are also cultivated with good success. Peas are the best for renovating the soil, though as yet we have no need to cultivate them for that purpose. The cost of rearing neat cattle here is comparatively nothing, and the value of a heifer at that age, with her increase, is usually from $12 to $15. They usually commence breeding at two years old, and continue every year after until a very advanced age. We have no occasion to fatten beeves on any thing else than what our prairies and bottoms afford. Many of our citizens complain that the beeves are too fat, though the flavor is very fine. Some yearlings of the common breed have been killed in this neighborhood, which weighed about 400 pounds. Beef is worth $2 per hundred. Our high undulating prairies are peculiarly adapted to wool-growing, though no great attention has been paid to this business among our farmers; but from the experiments made, there is no doubt of its being a profitable branch of husbandry, for we have no trouble in feeding at any season. The raising of horses and mules is also profitable with us, and for the same reason. The large cotton and sugar plantations of Louisiana, as well as some portions

of our own State, always afford a ready market and good prices for all we can send them. If there is any one kind of stock that succeeds better than another, I would say that hogs have always exceeded any thing I have ever seen in any country, if we except the past year, for we have always before had an abundance of mast. This failure, together with the unprecedentedly long drought of the summer and fall, has proved very detrimental to our pork interests, for we have never before been obliged to feed our hogs on corn in order to make them fat, the mast (acorns) always being sufficient for that purpose. I think the meat thus fattened is better flavored than that fed upon corn, though the lard is not so hard: still, I believe it to be as good for all culinary purposes.

Cotton is one of the great staples of the Upper Trinity country, though, for the want of navigation on this part of the Trinity, it has not been cultivated so extensively as it would otherwise have been; yet we have tested this branch of agriculture sufficiently to prove that the quality of our cotton is equal to that of any other country, and, for the shipments we have made to Galveston and New Orleans, the highest prices have been paid which those markets afforded. I suppose a bale of 500 pounds would be a fair average produce to the acre. I have not heard any complaints of the rust or the bollworm. My system of culture is to throw up my land into beds, by ploughing four furrows (two on each side) together, leaving the middle unbroken. When ready to plant, I open a furrow with a small plough, and drill the seed sufficiently thick to secure a good stand, which I cover with a harrow, though a simple contrivance made of wood, which packs the earth close to the seed, I think, is better. As soon as the cotton is up, I thin it out to one plant for every two feet, the rows being four feet apart. The after-culture is very simple, the main object being to destroy the grass and keep it clean. Deep ploughing is not necessary. Should our land require renovating or improving, I should pursue a somewhat different course, which would be to bed up my land as early in the winter as possible, by first opening a deep furrow in the middle of the old rows, which is called the water furrow, into which I would put the stalks of one row, and whatever litter might be on the ground, and then bed immediately over it. This should be done early, in order that the ground may have time to settle close over the stalks beneath. A great many more hints might be given on this subject, but time will not permit. I have already extended my remarks on this topic to a greater length than I should otherwise have done, did I not believe the time had now arrived when the citizens of the Upper Trinity will engage with spirit in the cultivation of this great staple. The obstructions to the navigation of the river having been removed, there is now no difficulty in navigating it with steamboats. I do not know that the sugar-cane has yet been tried in our prairie country, though I am induced to believe it would succeed quite as well as it does in Harrison county, which is in about the same latitude as this, and where I have seen cane that had ripened well to the tenth or twelfth joint. The first year I moved here, I brought some sugar-cane with me, for the purpose of testing whether it would grow here. I planted it, and it came up and grew vigorously till the rabbits, which were then very numerous, began to eat it, and finally destroyed the whole. I have procured more, and shall try it again the next year.

Rice, as yet, is but little cultivated, though, from experiments which I have made, I am satisfied it might be a profitable crop.

Tobacco is also cultivated here by most of our farmers, on a small scale, merely for domestic use; yet those who have raised it in Missouri and other Western States, say that it succeeds equally well here.

Root crops, such as beets, turnips, carrots, &c., are easily produced, but are not cultivated as a field crop.

Irish and *Sweet Potatoes* are also cultivated with good success.

Fruit culture is receiving increased attention among our farmers, many of them having now considerable orchards of peach and apple-trees; also many other kinds of fruit.

Not having kept a meteorological table since I came here, I cannot answer the questions propounded under this head, but think there is very little difference in the temperature here from that of Louisiana and Mississippi, in the same latitude. I think the aggregate fall of rain, during the year, to be about the same also. I have thus, sir, glanced over most of the items named in your circular, in a very hasty manner, and, should any thing I have said, have a tendency to benefit the agricultural interests, it will be a source of gratification to me to think that I have been of any service to your department, which I look upon as being one of the first importance.

I am, sir, with high esteem,

Your obedient servant,

S. G. PARSONS.

Philips, Franklin County, Maine, December 25th, 1850.

Sir:—Having received a circular from the Patent Office, soliciting information upon agricultural subjects, I would, in reply, make a few observations relative to some of the crops cultivated in this vicinity. Of all the products of the soil in this State, that of grass is the most important. From this source arise at least three-fourths of all the profits of the agriculturist. Maine exports, annually, vast numbers of neat cattle, horses, sheep, the products of the dairy, wool, &c.; consequently, it is all-important to produce the greatest possible amount of grass, both for hay and pasture. The pastures of this State will compare favorably with those of any other in the Union, especially for sheep, as they are generally elevated. The common method of seeding ground for hay is to sow the seed with grain, in the month of May. The grain is wet, and sometimes soaked in blue-vitriol water, 2 oz. of vitriol to the bushel, in order to prevent smut in wheat; the grass-seed is mixed with the grain in this wet state, to which it readily adheres, and thus it is sown evenly over the ground. The quantity sown is about 10 pounds of clover and 8 quarts of herd-grass (timothy) to the acre. These are the principal kinds of seed sown, though some add 1 or 2 qts. of red-top seed. The quantity of hay per acre varies from 1 to 3 tons. When it falls short of 1 ton per acre, the land is ploughed, and treated in the following manner:—We plough after the hay crop is taken off, or early in the spring, and sow with oats, which will yield a crop of from 30 to 40 bushels per acre; and immediately after this crop is harvested, the ground is manured and ploughed; and in the spring it is ploughed again, and planted with corn or potatoes, and sometimes sown with wheat, and seeded down to grass, but more frequently planted as above stated: the next spring it is ploughed, and sown with grain, and seeded to grass. The hay crop, for the past season, was rather above the average and secured in good condition. Our wheat crop was of an excellent quality and a fair yield for late years. For the last ten or twelve years, the yield has materially diminished. The variety most in use in this vicinity is the red-bearded, which is much less subject to rust than any other variety that we have tried. An average yield per acre, is about 12 bushels. The time of seeding is in May, and of harvest in September. We generally sow 1½ bushels per acre. Good wheat is worth $1 per bushel.

The corn crop was very good the past season both as to quality and quantity. The yellow eight-rowed variety is most esteemed, the cob is small, and kernel larger than any other kind among us. Average product, 40 bushels per acre.

The last autumn was unusually mild: no frost to injure any thing till all the products of the farm were secured, except in some low situations.

Very respectfully,

Your obedient servant,

B. F. EASTMAN.

Waterloo, Granville, North Carolina.

Sir:—In reply to your circular, soliciting information on the different branches of agriculture, I will state such facts as have come to my own knowledge.

Our wheat crop, which, in this State, is generally small, was this year an unusually short one, having been attacked, a few days before harvest, with the rust, which cut it short in quantity at least one-third, and rendered it, in most cases, almost unfit for use. The state of the weather, at the time our wheat was attacked by the rust, has most sorely perplexed all the theorists who have attempted to account for the cause. The most generally received opinion of the cause of rust is, that it is induced by the superabundance of sap in the stalk, which, not being taken up and assimilated by the grain as fast as formed, exudes through the ruptured skin of the stalk, there drying and forming the rusty brown blotches or spots from which it takes its name. The weather heretofore considered most favorable to the formation of the rust is warm and damp, when vegetation generally flourishes best. The rust attacked our wheat this year, during an unusually cool and dry season, with cold dews at night. The wheat generally raised in this section is golden-chaff, a red wheat. The white varieties, of which there were some grown here, though the stalk was nearly as badly rusted as the red-head grain, were of far superior quality. Early sown, and the early varieties, seem generally to be less injured by the rust. Though the white bearded, (the only name by which it is known here,) a very late wheat, was the best in quantity and quality. Why the white varieties should escape the rust, I have not seen or heard satisfactorily accounted for. This crop has increased annually in this part of North Carolina, for the last ten years, with great benefit to the farmers, and manifest improvement to the farms. The average product per acre will not exceed 10 bushels, though, in some cases, I have known from 20 to 25 made on the acre. The time of seeding is from the 1st of October to the middle of November. Harvest, from the 15th of June to the 1st of July. The wheat is generally sown on land after tobacco, and turned in with the single-horse-plough: when sown after cane, and the land is foul, harrowed in on a deep furrow.

The best preventive of Hessian-fly is to wait for a hard frost before seeding. This was the advice of the late Judge Buel. I have followed it for the last 20 years, and never had my wheat injured by Hessian-fly. Salt, sprinkled thinly over a bulk of wheat, prevents its being injured by weevil, or covering it with sassafras or alder bushes. The average price of wheat at our market, Petersburg, Va., is about $1 per bushel.

Corn.—The variety of corn preferred by myself is a mixture of the gourd-seed and rare-ripe. It is early and very sound, generally. Great advantage may be derived by selecting seed-corn from the largest and most prolific stalks. The average product per acre is from 10 to 20 bushels. The most important part of the cultivation of the corn crop is the preparation of the land before planting. It is my opinion that all land should be first furrowed deep, and then harrowed before planting with corn. The early cultivation should always be deep, and shallower as the crop increases in size. Our corn crop this year is quite small, owing to the long dry spell of weather, from May to November. It is now selling higher than for 10 years past, 80 cents per bushel. Peas are considered the best renovator now in use in this section of the State; are more generally used for this purpose, and for fattening hogs, than any other crop; but are seldom raised here for market. But little attention is here paid to the grasses, although they are coming more generally into cultivation. Our all-absorbing crop is tobacco, which takes precedence of all others. The average yield per acre is from 800 to 1000 lbs. It is generally considered the most profitable crop when the soil and climate suit; and particularly in places far from market. I believe the crop made in this State stands as high as that made in any part of the United States for manufacturing into chewing tobacco. The method of curing has undergone a great change within the last five years. It is now cured mostly by the sun and air. After it is housed, very small fires, made with seasoned oak, hickory, sweet gum, or sassafras with the bark taken off, are preferred to dry it in damp weather, when the tobacco is soft, or, as we say, in high order. The wood should be split in small pieces about two feet long, and not larger than a man's arm. The object is merely to dry the tobacco, not to smoke it. Our crop was cut short this year, three-fourths, by the long-continued drought, freshets, and frost. The quality this season is generally very inferior; the price in market higher than for several years past; so that it is believed that the income from the tobacco crop, this year, will be as great as usual.

Much more attention is now paid to wool-growing than formerly. The number of sheep in this neighbourhood has doubled during the last five years. Wool is now becoming an article of export; most of our winter clothing is manufactured at home; and in our dwellings you may see some carpets as nice as can be found anywhere. Where lands are so cheap as they are in most counties in this State, I think wool-growing might be made very profitable. Sheep here cost nothing but attention in summer, and not than 10 cents per head during the winter, as they never require feeding here except in unusually bad weather.

As to hogs and cattle, we only raise enough for home consumption. Fruit is now more attended to than formerly, and, instead of being gathered for distillation into brandy, is now grown for the purpose of feeding and fattening hogs. As to manures, we may truly be called Rip Van Winkles; for I am sure no people could pay less attention to raising it than most of us do. For information on this subject we must be your debtors.

Yours, very respectfully,

F. R. GREGORY.

Burlington, Vermont, January, 1851.

Sir:—The culture of fruit has been for many years much neglected in Vermont, though apple-orchards were planted on almost every farm on its first settlement. At present the culture of fruit, particularly of apples, is exciting much attention. Old orchards are receiving more culture, and great numbers of young trees are yearly planted. Some portions of the State, particularly the valley of Lake Champlain, produce apples equal to any part of the United States, which are found to be one of the most profitable crops a farmer can raise for exportation. There has not been a failure of a fair amount of apples any season since I have been a resident of this valley, (twenty-five years.)

No other article grown pays *one-half* the profit to the farmer as good varieties of apples; and, even for feeding to his stock, an acre produces more value than any other crop, and with less labor. Of the comparative value of apples and potatoes for feeding stock, I cannot speak from accurate experiments. I have, for the last two years, fed apples, both raw and boiled, with and without meal, to hogs from the middle of August to December, and am satisfied they are equal to potatoes fed in like manner. I have also often conversed with farmers, who fed large quantities both to hogs and cattle, and find their general opinion to be that apples and potatoes are of about equal value for feeding.

Vermont, like other States, has many favorite seedling apples, both for autumn and winter. In the northern part of the State, the Fameuse for autumn, and the Pomo-Gris for winter, both from Canada, are much cultivated, and are great favorites. The Early Harvest, Bough, Red Astrachan, Porter, and Gravestein are among the best summer and autumn fruit; and the Greening and Roxbury Russet are among the best for winter use and exportation. The Esopus Spitzenberg is much cultivated; but neither this nor the Newtown Pippin, which is also common, is so well adapted to our climate as the Baldwin and Roxbury Russet.

Pears grow in most parts of our State in great perfection. One of our best is the old white Doyenne. (St. Michael's, of Boston; Virgalieu, of New York; and Butler pear, of Philadelphia.) This grows in great perfection, while it fails near the Atlantic coast.

Plums are abundant: in many parts of the State, found growing wild.

Peaches are but little cultivated, though not uncommon. As to disease, the blight on apple and pear trees, black knots and yellows on peaches, are so rarely seen, that no attention has been given to them.

The *grapes* mostly cultivated are native varieties of New England, which, including seedlings, are very numerous. The Isabella, Miller's Burgunda, white Sweetwater, and many others ripen, but require slight protection.

Spring planting in this cold climate has many decided advantages over fall planting, and should be adopted for all fruit-trees, vines, and shrubs.

As to planting and cultivating fruit-trees, the best advice that can be given is to study vegetable physiology, so as to have a slight knowledge of plants and trees, with the chemical properties of the different kinds; then manure accordingly, with thorough cultivation, and drainage when necessary.

But little wine is made in the State from grapes, though many families make small quantities. Wine is also made from currants. I have had from 50 to 100 gallons made yearly in my family, from red and white Dutch and black Naples currants, from the following receipt:

To make currant wine.—The fruit should be gathered when fully ripe. The juice may be expressed by washing the currants in the house, and straining through a common strainer. A man or a strong woman, accustomed to washing, will easily prepare the juice for a barrel of wine in a day. Have a clean cask, of the size you want to fill; let it stand on one end, and have a hole 2 inches in diameter in the other, to allow the scum to pass off. For every gallon your cask will hold, put in 1 quart and 1 gill of currant-juice, 3½ pounds of clean light-brown sugar; fill with water, and thoroughly mix. Shake the cask daily for 2 weeks while fermenting, filling the cask with diluted currant-juice as the scum passes off; then stop tight, and let it stand in the cellar until December, when it may be drawn off and bottled. It may be kept any length of time without the addition of alcohol; but 2 or 3 per cent. of pure brandy is added when bottled. It may be kept in the cask, though bottling is commonly thought best. For white currants, white loaf-sugar is used, making a clear white wine. We have also 50 gallons in a season from the berries of the common white elder, which resembles a rough port wine. This is made like the currant wine, except that 1 gill more of the juice of the berry is used for every gallon. This and the currant wine improve by age.

C. GOODRICH.

Hon. Thomas Ewbank.

Rock Haven Point-Office Farm, January 15th, 1851.

Sir:—Some time since, I received a circular from the Patent Office, requesting information respecting my experience in agriculture. My farm is situated on the bank of the Ohio River, on the Indiana side, about 30 miles below Louisville; and consists of 300 acres of cleared land, all of which is under cultivation, and 140 acres woodland, which is in pasture, making 440 acres under fence. My staple crop for a number of years has been hay, of which I raise about 200 tons annually, which I bale for the New Orleans market. I raise from 1 and 1½ to 2 tons per acre. As yet I have used but little fertilizing matter, the soil being very productive without; but barn-yard manure or straw, ploughed in, has, so far as I have tried it, doubled the crop on a stiff soil. The pure timothy-seed, unmixed with any other grass, is preferred for hay intended for the market; but, for my own use, I prefer a mixture of clover and timothy. Two gallons of timothy-seed is the amount sown on an acre of ground, when sown separate; and, when a mixture of clover is wanted, I would sow with the two gallons of timothy one gallon of clover. I have succeeded best in the fall and winter sowing, the ground being prepared for wheat in the month of September. I prefer to sow my seed, giving it one harrowing; then, to sow the grass-seed, harrowing again, so that the grass-seed gets one harrowing. I prefer this process to that of leaving the seed on the surface, wholly dependent on the heavy rains to imbed it in the surface. If, however, I fail by this process to get a sufficient quantity of young timothy in the fall, I resow during the winter, on the snow; and, between the two, I have never, as yet, failed to get a sufficient stand of timothy-grass, for a swath of hay, the season following the crop of wheat. If, however, grass is wanted without the wheat, the grass-seed may be sown alone, on the ground prepared as for wheat, and can be mowed the following season; but, usually, the first crop will be lighter than when sown with wheat and suffered to stand a year longer before it is mowed. Spring sowing is hazardous, unless sown in February, and then not so safe as fall or winter sowing. As to the cost of raising hay, I consider that, when sown with wheat, the cost of setting an acre of grass will consist of the following items, viz.: Two gallons of seed at 50 cents per gallon, $1, and the sowing of the same, at a cost of 25 cents, make the sum of $1.25 per acre, without rolling, which should be done in the month of February or March preceding the mowing; for, if the roller were passed over the ground when the sowing was done, it would assist the vegetation of the grass-seed very much, by compressing the soil, thereby retaining the moisture. The cost of rolling, per acre, would be, for driver 75 cents per day, and team $1.25, making $2 per day. Eight acres would be a fair day's work, making the cost 25 cents per acre. Harvesting the hay is estimated at $2 per ton, and baling $1. Thus, one acre of grass, producing two tons of hay, would cost as follows:—

Seed	$1 00
Sowing	0 25
Rolling	0 25
Harvesting	4 00
Baling	2 00
	$7 50

The average price of baled hay, at the river, is $10 per ton, amounting to $20 per acre, deducting expenses, $7.50, leaves $12.50 as the net proceeds of an acre of grass. I consider my grass crop worth to me, on an average, $10 per acre. The best baling fixture in our county is called the Mormon press, consisting of a beater to beat in the hay as the screw is receding, and an iron screw; the cost of the same, aside from the building in which it operates, is $175, and the building will cost $100, making $275 outlay for baling fixtures. It will also require an outlay of $500 to build suitable housing for 200 tons of hay. My screw has been in use 6 years, and looks as if it might last 6 or 10 years, or, it may be, 15 years longer. I put up the bales, about 4 feet long and 2 feet square in thickness, weighing, on the average, 250 pounds. This kind of screw will make it much lighter; but the above-named way is tight enough to be saleable and convenient. My press puts up 40 bales per day, in long days, working three hands and a boy to drive. Three hands prepare the poles, bale the hay, and stack it in the house, from which the loose hay is taken.

I have also on my farm some 1500 bearing apple-trees; but, for the last 10 years, the fruit has been nearly unfit for market, on account of the bitter rot, but, during the last year or two, the disease seems to be subsiding. The crop this year has rotted considerably on the tree, as heretofore, but the rotten part of the apple has not been bitter, as formerly. Before this disease attacked our fruit, I sold, in one season, from 500 trees, $1000 worth of fruit, besides what was used in the family. Since that period, my sales rarely exceed $100 per season, notwithstanding the enlarged size of my orchard. I have tried the application of lime to the surface of the ground about the roots of the trees, at the rate of 1 to 5 barrels per acre; but without any apparent success. I have also scrubbed the bark with a solution of potash, and inserted various drugs into the tree, by tapping and plugging; but without success. This has been a prevailing disease in all locations in this county; but it seems to be subsiding. I also had 100 pear-trees, bearing fruit, which, a few years since, died of fire-blight. I now have about a dozen, which seem free from disease, and have been bearing abundantly for three years. The fire-blight in pear-trees, after having prevailed here for the last 20 years, seems to have run out. My grain-raising has been without any system up to this time; but I now have a crop on hand, of which, another year, I expect to give a better account.

Yours respectfully,

JACOB L. KINTNER.

Henry County, Farmille, Virginia, January 24th.

Sir:—Your request would have been noticed sooner, but the Agricultural Circular was only received a few days ago. On only a few subjects will I submit a few remarks, leaving to others, of more leisure and superior knowledge, a full discussion of the important inquiries you make. In relation to ploughing, by far the most important work on the farm, I will observe, that every year's experience has convinced me more and more of the great advantage of ploughing *deep*, while I would by no means depreciate the utility of the various manures or other means of fertilizing the soil; yet, for this purpose alone, "deep ploughing" is invaluable. Not only by this means are larger quantities of the soil exposed to the fertilizing action of the atmosphere, rains, dews, or frost, but, by imbibing the rains that fall, the soil that is ploughed *deep* retains not only what it already possesses, but whatever it may gain through the decomposition of vegetables, &c. It will be admitted, that if a dam were thrown across a ravine, so as to catch and retain the soil that is washed off by the rains from a certain area above, in a few years' time, the accumulation would be sufficient to enrich the entire land from which it came; yet the land from which it was washed might remain as productive as before. In this case, the restorative processes of nature would repair the injury as fast as it was produced. Now, suppose any method could be adopted by which both the regular supplies of nature and the original soil could be retained, it is obvious that the land would be doubled in fertility. The hill-side ditches, however well graded, cannot answer this purpose; for whilst they may prevent the formation of galleys, they still allow the rain-water, impregnated or charged with the lighter, richer, and more soluble particles of the soil, to pass off. The "solid," or unploughed space, left between the rows of the growing crop, to prevent the "crushing of the land," will not answer, for a similar reason. As far as I know, there can be no remedy for this evil but deep ploughing; ploughing to a depth sufficient to allow the imbibition of all the rain-water that falls. This may appear impracticable to those who have not tried it; yet, it is well known to those who have, that if the soil be well broken to the depth of 15 or 20 inches, with a large turning plough, and subsoil plough, none, except the most hasty rains, if any at all, will run. Within the last winter, I have seen, on my own farm, this fact fully illustrated. A rain, unparalleled in this country, by which the water-courses were raised higher than they had been known for many years, fell on a piece of land that had been recently ploughed to the depth of 12 or 14 inches, yet not a drop escaped, and consequently no part of the soil was borne off. Another advantage of deep ploughing is, that when the surface has been exhausted to some extent by continued cultivation, many "earthy matters" that existed some 15 or 20 inches below are brought up and combined with the surface, so that a new soil is formed. One of the most productive fields I have, was made so by this means, after having been greatly exhausted. Another great advantage of deep ploughing is, that, to a great extent, it corrects the destructive effect of extremes in the seasons on the growing crop. Had we command of the clouds, so that we could stay their torrents when in excess, or provoke their genial showers in times of drought, there would be but little difficulty in making abundant crops, even on lands of common fertility. This power the great God of nature will never transfer to his ungrateful creatures; yet, he has permitted us, to a very great extent, to escape the effects of those apparent extremes, with which, for some wise purpose, he is ever visiting the earth. Through land that is deeply and well ploughed, water readily percolates. If it fall in excess, by means of a greater evaporation from a loose soil, but especially by its rapid percolation downwards, it soon disappears: a crop escapes all injury. If, on the other hand, there should be a deficiency of rain, the moisture from the subjacent clay more readily rises; the roots descend deeper to meet this moisture, and thus a crop, that might otherwise suffer from the want of rain, maintains its luxuriance and health throughout the driest seasons. One other advantage I will mention. By this means, a larger quantity of soil is rendered capable of producing, and consequently the crop may be grown much thicker than it otherwise could. We suppose a soil 6 inches in depth. A plough that runs 8 inches in depth, will certainly cultivate and prepare double as much soil in the aggregate as one that only cuts 4 inches, and thus, while the extent of surface may be the same, double as much soil is prepared and exposed to the action of roots of the growing crop in the one case as in the other, since the crop may be almost in the same ratio planted thicker. There is yet one other advantage, which I will mention. It is known that many soils abound in the roots of briers, sassafras, and other shrubs. These are more effectually exterminated by deep ploughing than by perhaps any other method. And, instead of their growing and taking from the crops much of the nutriment of the soil, they are killed, and, by their gradual decomposition, converted into valuable manure.

I will now add a very few remarks on the culture, &c. of the tobacco crop, confining myself only to those parts of the process that are less generally understood, and in which most planters are greatly deficient. It is well known that there is no part of this whole process more important than the raising of plants. The success of the crop depends, in a great measure, on the supply of early plants. The season here is short, and if, from any cause, the crop should be planted late, the plants are not only more difficult to live, but there is not, unless the seasons are more propitious than usual, full time for the crop to mature. The tobacco crop here is usually large and important, and is perhaps surpassed by none in its quality for manufacturing purposes, and the best methods of raising plants are as well understood here as in any other part of the country. Last spring, notwithstanding the general failure, and the very unfavorable character of the season, and the great depredations of the fly, we had an abundance of early plants.

A suitable place having been selected, (of which every good planter is a judge,) it should be burnt thoroughly. The surface should be exposed to the action of a hot log-fire, for two and a half or three hours at least. Then the ashes should be removed, and the bed deeply hoed, dug without being turned, to the depth of 8 or 10 inches. It should then be well manured with fresh stable manure, clear of seeds of all kinds, (that made from wheat chaff is perhaps the best,) and afterwards sowed. The bed should then be covered well with brush. Should the seasons be dry, the covering should be very thick, and, on the other hand, should the seasons be wet and warm, less covering will answer. Should, however, the plant be endangered by frost or the fly—two common sources of injury, if not entire destruction—a thick covering of pine brush, together with a second covering of manure, will be found most effectual remedies. There being nothing peculiar or worthy of remark either in the planting or culture of the crop, I proceed at once to the best method of curing. On this subject there is a great diversity of opinion, yet I think the method I am now about to propose will always insure a superior article, especially for manufacturing purposes. The plant should be allowed to become thoroughly ripe before it is cut. Tobacco, unless it become thoroughly ripe, can never be made of good quality, whatever may be its color. When cut, it should be hung on the scaffold, with its tails very near the ground, surrounded or covered on its sides with brush, so as to exclude the air, until it acquires a yellow color. It then should be removed to the house, (taking care not to hang too thick,) and immediately exposed to the fire. If common wood should be used instead of coal, thoroughly dry, yet sound, wood should always be taken. Small fires of this wood or coal should be made over the floor of the house, sufficient to raise the temperature to 90° of Fahrenheit's thermometer, or that of the sun of a moderate summer's heat. This should be continued 4, 5, or 6 days, until the leaf is thoroughly dried, then the fires should be suddenly increased so as to cure the stems in 12 or 16 hours. This process will insure a beautiful yellow or nutmeg tobacco, without the least color of green, or that "green taste," which is so peculiarly offensive, and which, by no process in its subsequent management, can be remedied. Should the flue be used—a peculiar method of curing here—the same rules as it regards color and temperature, &c. should be observed.

Respectfully, ANDERSON WADE,
Henry County, Virginia.

North Anson, Somerset County, Maine, December 7th, 1850.

Sir:—Being situated as we are, in the valley of the Kennebec, near the operations of the *lumbermen*, our efforts in agriculture are, as a matter of profit, chiefly directed to supply the market afforded by that branch of business; therefore, in past years, experimental farming has been practised

only so much as would tend to furnish *bread* and *pork* for the men, and hay and provender for the oxen employed in obtaining lumber. Lately, however, since the failure of spring wheat and potatoes, the agriculturists have been making experimental trials, in order to remedy, as much as possible, the loss of those important crops. Purely scientific farming is not known in this region. A hard flinty slate-ledge, the strata running north-easterly and south-westerly, underlie this section of country. The intervals or meadows which lie quite extensively along the river and large brooks, are fertile alluvial deposits. The upland is diluvial, and in many places considerably covered with boulders, the larger of which are granite.

The following analysis, made by Dr. C. Jackson, state geologist, in 1838, of soil taken from a plain elevated some 60 feet above the river, shows a large proportion of carbonate of lime. As there is no lime-rock to be found in the vicinity, it must have been brought hither by a diluvial current, from *limebeds* lying some distance to the north of us. Indubitable evidences of there having been such a current running south, 10° or 15° east, are found in many places.

Analysis of 100 *grains of the fine soil was found to contain—*

Water	7.6
Vegetable matter	5.6
Peroxide of iron	6.1
Carbonate of lime	4.6
Insoluble	75.0
	98.9
Loss	1.1
	100.0

We have, however, all the varieties of soil to be found in a broken country, from the fertile intervale to the barren mountain-tops.

I will now reply to your schedule of questions, rather by approximation than otherwise, regretting that our practice and results cannot be more definitely stated. The crops of *spring* wheat, the only kind formerly cultivated here, have been greatly diminished by the ravages of the weevil, which commenced its destruction eleven years ago; since that time, the average quantity raised per acre is not over 10 bushels, and that of an inferior quality. We know of no *remedy* for the pests, except to sow no grain for them to destroy, though late sowing, as late as the 1st of June, will avoid the weevil; then there is great risk of its being cut off by rusting: the last evil, is, perhaps, the lesser one, and more grain may be raised by sowing late than early. The varieties most in use are the tea, and Black Sea, or red-chaff wheat: two bushels are sown upon an acre, on the older cultivated ground, and five pecks on the newly cleared, usually sown dry, but sometimes wet and rolled in lime or ashes, from April 10th to 10th of May. Price in market, $1.84. A railroad to Waterville, 27 miles from us, has a tendency to keep the price proportionate to that of imported flour. Since the weevils commenced their depredations, attention has been turned to the cultivation of winter wheat, and, for a few years past, the Kloss Blue-stem, or, as it is popularly called here, "Banner wheat," has succeeded remarkably well, producing generally 25 bushels per acre. This variety, as I understand, was first received in this State from the United States Patent

Office, and cultivated by Mr. Drew, editor of the Gospel Banner, Augusta. A great quantity of this variety has been sown this season, and, should it succeed as well as it promises, we will soon return the flour-barrels, which are so plenty around us, filled for the sustenance of those who are unable to raise their own wheat, as we have been. It should be sown the last of August, or first of September. We can raise *wheat straw* in abundance, and, were it not for the accidents to which the berry is liable, a proportionate amount of the grain also.

Corn is now considered to be one of our surest crops, not having failed for a number of years. The 8 and 12 rowed yellow corn are usually preferred; other kinds, as the Brown, Dutton, &c., are planted by some. The former varieties are the ones adapted to the climate, having been cultivated in this vicinity by the Norridgewock Indians, a long time previous to the settlement of the Europeans upon the river. To succeed here, it must ripen before the 20th of September, as we generally have frosts about that time. The average product is 40 bushels of shelled corn from an acre, (100 have been raised,) costing 56 cents per bushel for raising. The best method of cultivation for it, is to spread 12 ox-cart loads of well-rotted manure upon an acre after it is ploughed, and work it in with a cultivator or harrow, then put as much more into the hills; plant, covering it just enough to prevent the seed from becoming dry, and hoe it twice: then you may safely trust in Providence for a remunerating harvest. An acre of corn planted upon hog manure will yield twice as much as when put upon manure from the barn-yard. It should be ground and cooked in order to be fed most profitably. *Pumpkins*, such as *pumpkin-pies* are made of down East, are raised among the corn. Hogs are seldom fed exclusively on corn, other grains and roots being used for that purpose.

Oats are an exhausting crop. The only *safe* method for their cultivation without manure, is to plough up grass-land and take off but one harvest, seeding down again to grass at the time the oats are sown, thus having one set of roots decaying whilst there is another forming on the top. Three bushels of seed are sown upon an acre, which will generally produce 30.

Peas yield 30 bushels per acre—never cultivated here as a renovating crop; but are often sown with oats, seeded half-and-half for feed for hogs and cattle. Spring and winter rye are sown with varied success, producing, one year with another, about 12 bushels per acre. Sometimes it yields exceedingly well, but is too much of a chance crop to be firmly relied on. Price, $1 per bushel.

Barley flourishes well, producing 30 bushels from an acre.

Buckwheat is cultivated quite generally, especially the rough variety, usually called Indian wheat here. Fritters made of it are thought to be "good enough for company." Besides, it makes good pork when fed to a "porker:" 40 bushels may be raised from an acre.

Beans are most frequently planted with the corn; but it is called better to plant them separately in drills. Land made as rich as for corn, will produce 30 or 40 bushels. They are sold here for $1 a bushel, and sometimes more.

Maine is decidedly a good State for grazing and hay, one of its most valuable products; and, without much difficulty, it may be raised in great quantities. One ton is near the average product per acre from all the lands producing grass; but two or more may be easily raised in cultivated fields. The land is not exhausted when it fails to produce English grass, but only needs turning over and new seeding, with *eight* pounds of clover and a *peck* of herds-grass seed, taking off a crop of oats, in the time, to pay for the labor. Or, what may be called a better renovator and fertilizer for *pastures* and *meadows*, spread upon them, in the fall, a *compost* made of equal parts of swamp-muck and barn-yard manure. Hay costs $4.50 per ton, when in the barn, unless the season be a very good one: then it would cost less. A drought in June lessens the quantity of grass.

Land is considered as "put through" a regular rotation of crops when the sward is broken up, and sown in the spring for oats; the next spring manured and planted with corn or potatoes; and, the following spring, sown to wheat, and seed down to grass again.

Corn and potatoes are planted, and wheat sown successfully on sward land-ploughing. Corn is more apt to be injured by the *cutworm* when thus planted, than when upon stubble-land.

But few have paid particular attention to *dairy husbandry*. Almost every family makes butter and cheese enough for their own consumption, and often a surplus for market besides. The average price of butter is 14 cents, and of cheese, 8 cents. Those who have made it their business, however, find it profitable.

There has been, of late, considerable care and commendable rivalry in the management and rearing of neat cattle for market—the result has been a great improvement upon the old breed, and, consequently, an increase in their value. The *rule* for cost of rearing cattle is, $4 for keeping a calf from spring until fall, and $4 a year thereafter until 3 years old, making a cost, at that age, of $16, which is the price of an ordinary one here. Our surplus stock is readily bought up by drovers, and driven out of the State, chiefly to the Brighton market. Oxen command a good price, if they are fit for service in the woods, bringing $100 a yoke. Good dairy-cows valued at $15 in the fall, and $30 in the spring.

The advantages of wool-growing to the agriculturist are not fully appreciated by a majority of the tillers of the soil; because sheep are peculiarly adapted, by their habits, to render important services as pioneers to the plough, reducing, in a few seasons, lands that have been mortgaged to weeds and briers to arable fields, and, while doing it, thrive so that their sides will stick out with fatness; or will scale the rough hill-sides, and glean food where the implements of husbandry are useless. They invariably leave a pasture for having been kept in it: an old sheep-pasture that can be ploughed may be looked upon as but one step from a well-filled granary.

When the desideratum is to obtain mutton, the large coarse-woolled breed should be selected; but, if the raising of wool is made paramount, the Merino is superior to all others introduced among us. They will *grow* more wool from the same weight of sheep, will eat a greater variety of vegetables, are more peaceable,—therefore requiring less watching to keep them within enclosure; and, taking all the items of expense and care into consideration, will *produce wool as cheap* per pound as any of the coarser breeds. Any pedigree of fine-blooded sheep requires more tending through our five months winter than the coarser native, but the compensation for the extra care is more than made up by the less amount of food consumed, by the finer, in producing the same quantity of wool.

Our flocks, young and old together, average $3\frac{1}{2}$ pounds per head—instances of shearing 8 or 10 pounds from a sheep are not uncommon; the more Merino-blooded the sheep are, the more is the proportionate weight increased. Among us, there is difficulty of obtaining a fair proportionate price for the different grades of wool. Our wool-merchants seldom make more than 8 or 10 cents difference between the finer and coarser staple; a difference which does not compare favorably with other sections of the United States: a *fact* which our wool-growers should take cognisance of, since we can and do raise the finer qualities, having obtained the stock from the best Merino flocks of Vermont, and other places where it was obtainable. A ton of hay will winter sheep enough for a clip of 17 pounds. The yearning time for our northern latitude is the last of April and the first of May, about the time vegetation commences. The lambs raised are, in proportion, two-thirds the number of ewes. After an experience of 30 years with a flock of fine bloods, and observation, during the time, upon the efforts of others in wool-growing, I am fully convinced of there being more profit in raising fine wool-producing sheep. Capital invested in them is available twice a year; in the fall, lambs and mutton are readily turned to cash, and, when spring comes, they tender their fleeces for all arrearages.

It is truly said that "a sheep may die indebted to its *purchaser*, but *never* to *him* who raised it."

As for the *breed of hogs*, we have had a great many different kinds, and they have been mixed and crossed until their *given names* "are used up," and no other left but *hog*, after all. They are important assistants in making a good cornfield. Three hogs, properly supplied with chip-manure, swamp-muck, or horse-stable manure, will make dressing enough to raise 80 bushels of shelled corn from an acre of land. The *cheapest* method of obtaining pork is to feed well from the pig upwards. Weight, when dressed, from *three* to *five* hundred. *Price*, average for round hog, 6 cents per lb.

Roots.—Since the rotting of potatoes, the root crops have been advantageously cultivated, *turnips* and *carrots* being chiefly sown. One farmer in this vicinity has raised, the present year, *carrots* at the rate of 1000 bushels upon an acre, by spreading a quantity of manure upon grass land, ploughing it, and sowing the seed in the seam between the sods.

Irish Potatoes.—Here, again, we can use "the language of complaint;" for we once thought that potatoes would never fail us; but the rot came and taught us the uncertainty of raising potatoes "in particular." It pays but little respect to kind. Some years, one variety will succeed better than others; but in the result, they are about equally affected. Early planting on dry soil does best, by spreading the manure on the top of the ploughed land, harrowing it in, and planting the seed in hills on the surface. The yield is now about 50 bushels per acre where it used to be 200. All the tubers that grow late in the season are liable to rot, and the vines die early.

Attention has lately been given to fruit culture. Many young orchards of choice fruits have been recently set, and older ones improved by grafting.

Apples are considered to be a profitable crop, and are an important item in the luxuries of a living. It is thought that hogs thrive as much by being fed upon an equal weight of *sweet* apples as upon potatoes.

Manures of a vegetable origin are chiefly used; but *plaster* and *lime* are considerably used. They produce beneficial results when applied to light sandy or gravelly soils, but are inert when used upon clayey lands.

Strawberries, raspberries, blackberries, and blueberries are indigenous here, and, in some seasons, may be gathered in great abundance. Should it be desirable, they could very easily be cultivated in gardens or yards.

We are located pretty well north, besides being "a long way down

east." The parallel of 44° 47′ 40″ crosses the village in this town. For this latitude we have the long range upon the thermometer of 110° F. Some of our hottest days raise the mercury to 102° F.

With due respect,

Your obedient servant,

WILLIAM R. FLINT.

Hon. Thomas Ewbank, *Commissioner*.

Chester District, South Carolina, 1850.

Answers to questions sent me by the Hon. Thomas Ewbank, Commissioner of Patents:—

Wheat.—The varieties in use in this locality are, yellow Lammas, blue straw, Virginia white May wheat, and a few others with local names. The average product is about 7 bushels per acre. My neighbors talk of a higher figure, but I give you my experience and belief as to what we make now; and no wonder it is not more, as you will readily perceive when I come to state our system of cultivating it. The first two varieties require being sown early, say in September, or they will be likely to ripen late and be struck with rust in the spring, whilst the white May wheat is not usually sown before some time in November; for, although not always free from rust, yet, if sown too early, it is still more liable to injury from late frosts in the spring, from prematurely shooting out the ear. We harvest the early white May wheat, which alone is what I sow, from the end of May to the middle of June; the others, from the middle of June to the beginning of July. We prepare our seed by soaking it in a solution of bluestone (sulphate of copper) for 12 hours, as a preventive of smut, and, if well done, it is very effectual. We make the solution at the rate of 3 oz. of bluestone to the bushel in the first water used. The water left when the wheat is taken out to be sown is preserved and the wheat thrown into the same vessel, with 2 oz. more of bluestone to the bushel, and additional water put in, so as to cover the wheat, and which is well stirred in it. The wheat, previous to being sown, is rubbed in as much good ashes as will adhere to it, and is then sown broadcast, at the rate of 1 bushel to the acre. We do not usually plough for wheat, but our system is to scratch it in hurriedly with a grab or gopher plough after corn, without manure, not as a crop, but to get what we can; and well may we be thankful when we get any in return: 'tis truly a godsend. Our rotation, when regularly conducted, is cotton, corn, wheat, and rest, perhaps, for 2 years, though that rest is too often converted into pasture, eaten bare, and the yield per acre certainly averages less than what it used to do. We are not often troubled with the Hessian-fly, and know of no remedy; neither are we much annoyed with the brown flour-weevil, but are very much incommoded and seriously injured by the little miller-fly weevil, which deposits its egg in the seed whilst in the field, is hatched out in July and August, and, eating its way through, leaves the grain a mere shell. Our only remedy is to thresh early, grind early, and sun for 2 or 3 days what we reserve for seed and spring family use. Our hot sun destroys the embryo in the berry. Our usual average price is $1 per bushel. This year (1850) it sells for $1.50. Our crops were eaten up by rust. I must be allowed to say one thing, though, in favour of us poor Southern farmers, on the subject of growing wheat. Our lot is cast in a cotton region, and no man can be a successful wheat cultivator and cotton planter at the same time; they interfere materially with each other, from beginning to end. Wheat is not cultivated for a crop, but a little is put in for family use; and cotton, cotton, cotton won't give us time to do that little well.

Corn.—Our seed is so generally mixed, that it is hard to give it any known name; the old gourd-seed kind is gone very much out of use, and that which I commonly use now is a Tuscarora—a mixture between the old gourd-seed and the low country flint-corn. I have now, for upwards of 30 years, been selecting every year my seed-corn in the field, from stalks not bearing less than two ears to the stalk; and it is now more difficult to find in my field a stalk with less than two good ears on it, than it was at first to find them with two ears—the average product about 25 bushels. We break up our lands as early as cotton will allow us; of course, it ought to be deep; but I believe I am the only man in this neighbourhood who uses the subsoil plough, and I have been doing so now for many years, with great benefit. Others say cotton will not give them time. Last year, when my neighbor, one of our best farmers, too, made 20 bushels of corn to the acre, I made 70, chiefly from the use of the subsoil plough. I lay off my land in furrows, at 4 feet apart, with a large, long shovel-plough, deep as I can get it done, and in the same furrow run my subsoil-plough with two horses, from 8 to 10 inches deep; in this furrow, where I have manure enough, I strew my manure, and then back up upon it with a two-horse Ruggles plough, running a furrow from 5 to 7 inches deep, and this is again followed by the subsoil plough in the same furrow: the whole bout is finished in the same manner. I then check off at 4 × by 2½ or ¾, and leave but one stalk in a check. In these checks is usually deposited my manure, and, where that is cotton seed, it is always deposited in the check before planting. I keep my land level, use coulters and cultivators, and lay by with the cotton-sweep, leaving a good water-furrow in the middle: my land is a stiff clay, and my greatest enemy is drought. I never cook any of my grain, except for my milch-cows, and sows and pigs, and find it to be highly beneficial to them; but the most of my corn used is crushed on the cob, in one of Hussey's corn and cob crushers, a good machine, but the plates, which are the crushers or grinders, are not very durable, and are difficult to be got, far as I am in the interior. It now makes slow work; I have used up one or two sets of plates, and would freely pay the price of new ones, could I readily obtain them.

Oats, &c.—Average yield of oats per acre is about 20 bushels; barley, 15 to 20; rye, 6 to 10. Peas, by themselves, in beds 3 feet apart, and in chops on the beds, 18 inches apart, about 10 bushels; where among corn, 4 to 5: this I know will be considered a very low estimate by many; but, perhaps they never measured the peas after they were thrashed on the land. Beans are not cultivated here. Peas are decidedly the least exhausting to the land—indeed, rather benefit it. I have never known them cultivated here as a renovating crop to be ploughed in. Cotton hardly gives us time to gather our seed.

Clover and Grasses.—We have a little rough meadow, in strips, along our spring branches, which give 1 or 2 tons of a coarse meadow-grass hay per acre. I have but little of that, and no bottom land, and have never been able to succeed with any of the cultivated grasses upon our uplands, though I have been trying them for upwards of 30 years. I have had as fine clover in the spring as I ever saw anywhere, but it could not stand our

July droughts and hot September suns: it may probably succeed better on our rich, deep, mellow bottom lands.

Dairy Husbandry.—We have nothing under this head, having no meadows or grasses; and cotton having cut up our ranges, we scarcely make more than butter enough for family use; and home-made cream-cheeses are only to be remembered, and talked about by the old grandmothers of the district, as the occurrences of the good, abundant, happy old times, before cotton came in to be a crop.

Neat Cattle.—We really raise them with so little care, that it would be a shame to charge any thing for their keep up to 3 years old, when they will sell for about $5; a cow and calf in the spring, are worth $10 or $12; in the fall, from $15 to $25; to the rest I can give no answers; we have no improved stock here; no grass to raise and fatten them on; no market here to encourage one to exertions for improving stock, and come too high to feed for a distant market; when the railroad comes, it will perhaps be better.

Sheep and Wool.—Sheep might certainly be raised with profit, both for mutton and wool, but again we have no market for either. My neighbors generally will not eat mutton, and as there are as yet but few manufactories that use wool, scarcely more is produced than what is required for domestic use. I have made all of my negro winter clothes and blankets for 30 years. I long kept a little flock of grade Merinos for mutton and wool for family use, and have raised full-blood quite as fine as my original Escurial stock; but found the full-blood too fine for our farmers' use; they cannot card it. I now keep from 80 to 100. I raise my sheep at little expense, but have never made any estimate of the cost. I have shelter for them in winter, and give them hay in sheep-rack, or rather open frames, and sometimes a little oats, and have usually a green pasture of rye or barley for the ewes and lambs to run on: the price we get for our wool is just the same, whether fine or coarse—about 25 cents per pound. I do not doubt that the time is at hand when wool will be more, much more attended to—more discrimination be made in the quality and price; a market for it is rising up in the manufactories, that are rapidly growing in the Southern States; and it will, ere long, become an important and profitable branch of Southern husbandry. For 20 years, I raised as fine wool as Spanish stock, or any samples I could obtain from the North; it was highly approved by the Messrs. Dupont, of Delaware, and sold in Philadelphia at 50 and 60 cents; and the railroads will soon open to us a way of reasonable transportation.

Hogs.—The breed we find to suit us best is a cross between the black Siamese or China, and the Berkshire; they thrive upon less feed: but I should say that the Suffolk, Sussex, and other late imported English breeds are unknown here. We raise our hogs by allowing them to range in our woods, where they get fat in the autumn on acorns, and call them up at nights, giving them a little corn to keep them tame, and to help them on when the acorns are consumed. In November, they are usually put in pens to fatten, where they have water and as much corn thrown to them on the ear as they will eat. I also see that they are well supplied with charcoal, rotten wood, and ashes, all of which they consume with great avidity and benefit—no doubt as absorbants and correctors of acidity. I have never known of any experiment made of the quantity of meat made by a given amount of corn. I cure my flitches in the usual way of dry salting; my hams I rub the first day with salt, to draw off the blood; the next day, they are packed loosely in casks, and cover them with Pocock's pickle, viz. 6 lbs. salt, 2 oz. saltpetre, 1 to 2 lbs. brown sugar or molasses, and 4 gallons of water, boiled together and well skimmed, in sufficient quantity to cover the hams well, pour it on them cold, and let them remain in it from 3 to 6 weeks, according to their size, and then hang them up and smoke them for a fortnight; and I will warrant, if you have one that has been well kept till this time, it will fill your dish with essence. As soon as you are done smoking, and which ought to be by the middle of February, bag them in a loose bag, but which has been previously soaked in a strong size made with wheat bran and water, and hang them up in a dry place with the string tied tight around, with the hock side down, and then keep free from bug or skipper, and remain juicy to the end. My smoke-house is 16 feet high, divided into two stories; the bottom one has an earthen floor, on which the fire is made; the second story, in which the meat is hung, is divided from the bottom one by a plank floor, which protects the meat from being heated by the fire, while the smoke is allowed to pass freely up to the meat through a double range of six-inch holes in the floor the whole length of the house, and which I think conduces very much to preserve the hams from becoming rusty.

Cotton.—The average yield here is from 150 to 200 lbs. of clean cotton per acre. I am no cotton-planter, and plant it only as a matter of necessity, to make a little money: it is with me a scourging, starvation crop, to land and every thing else. I leave you, for information about its culture, to those who like better, have better lands, and cultivate it better than I can. Drs. Cloud and Phillips will, no doubt, ably supply my deficiency.

Sugar-cane, rice, tobacco, hemp, are not cultivated here.

Root crops are not cultivated here as field crops. Turnips are merely sowed for domestic use on cow-penned patches, and are a very uncertain crop; our droughts in the end of August and throughout September burn them, even when they do come up. I have to depend on my spring sowing, even in my garden, for my supply of beets, carrots, parsnips, and salsify, and they are therefore frequently woody. Mine is a stiff clay soil, and I have to haul into my garden a good deal of sand to procure a due supply of them; but even in the most favorable soil here, they are never cultivated as field crops.

Potatoes, Irish.—Irish potatoes are only cultivated in our gardens and in patches, and, under good management, yield well, good, large, mealy potatoes; but I have not known any estimate made of what they would yield to the acre; we have no market to induce us to raise more than enough for our own immediate family use; for those raised from our spring planting in February, and which we usually begin to use out of the beds in May, and dig in in June, won't keep. By the end of July or middle of August, they shrivel up, sprout, and rot. Almost every year I make a second planting of them about the middle or end of July. If the season is favorable, I make good potatoes, which keep well all through the winter; but they most frequently fail to grow from the drought: those which I planted this year, never came up until in October, and but few of them then.

Sweet Potatoes.—The sweet potatoes do better, much better on sandy soil, and though not to be compared in quantity and quality with the low-country sweet potatoes, yet yield a fair crop: I have heard of 200 bushels to the acre being made; but they are never planted up here in any quantity, whereas, in the low country, where the climate suits them much better, they are cultivated extensively, being depended upon largely for provisions for

the negroes, and for fattening hogs; and I have even used them, when in great abundance, and with great benefit, in feeding my working mules, horses, and oxen:—big crop of potatoes, and every thing fat. Up here, we have to depend upon the root potatoes grown by planting the small potatoes, and which are called the seed; the product of these, called root potatoes, are much more difficult to keep through the winter, than such as are produced in the low country, as their principal crop, from what they term slips, which are cuttings, not of the potato itself, but of the vines. In the low country, they plant only a few acres of roots to raise vines for their principal crop; these vines are cut off throughout June and July, and stretched out in handfuls, lengthwise, on the tops of large beds prepared for them, and partially covered by hoefuls of earth thrown at intervals upon them; if rain follows, they take root, shoot them down into the beds, and produce there abundant crops of fine potatoes, superior in sugariness, and keep through the winter much better. I have known 600 bushels made to the acre; but I have travelled out of my province, or at least out of my district. You will probably ask why we do not do here as they do in the low country: the answer is simply, the climate will not allow it; the season up here in June and July, the time for setting out *slips*, is usually too dry to allow them to strike roots, which they won't do without rain, and allow them to grow in time to produce tubers of any size larger than merely for seed for another year, and oftentimes not even that, that few persons risk their labor even for that. The ground ought to be broken up well, deep, and early, and plentifully manured with straw, pine trash, or leaves, or any other vegetable matter, but ought not to receive stable or other stimulating manure, which will cause them to run too much into vine, and only produce fibrous roots instead of tubers. Cotton seed is a good manure, when it can be spared in sufficient quantities from the more important crop of corn. The best mode to preserve them for use is, after gathering them carefully in dry weather, soon after the vines are killed by frost, and their growth is consequently stopped—to pick out all decayed, cut, and bruised roots, pile them up in conical heaps, where they will be free from frost, and let them remain so to sweat for a few days—then pour over them well-dried sand till it covers them two or three inches deep. Preserved in this way in the basement story of my house, I have kept them sound and good, and unsprouted, until fresh potatoes came in again.

Fruit Culture.—The culture of fruit is certainly receiving much more attention than formerly. When I first came to spend only my summers up here, there were no orchards except of peaches for the still, nearly 40 years ago—there were but few apple-trees, and pears were quite a rarity—now every farmer has a small apple and peach orchard, though pears are still rare. One good thing cotton has done for the country, to make some amends for the destruction of our lands, has been to drive the stills out of the country; it does not leave the people time enough hardly to raise a sufficiency of corn for their own consumption, and without raising their meat, and, therefore, none for the still, and no time to carry peaches to the still, even in good and abundant seasons. I could write much upon this subject, but know you will have much of this kind of trash to wade through, and endeavor to condense as much as possible, and to answer your queries intelligibly. I have imported fruit trees from the North, largely and at different times, and grafted, too, wherever I could procure scions of good repute; the peaches and plums have done well, but pears badly; and apples from the

North have not succeeded with me at all. Both of these trees are short-lived with us when so obtained, and none of the apples from Prince's nursery, Newtown pippins, Rhode Island cooper, russet, &c., have ever perfected their fruit, though grafted and regrafted. I am still trying, however, some of the more modern kinds. Yet I have a few good summer and autumn apples, got from North Carolina, under various local names, but no really good winter-keeping apple. The farmers are just becoming aware of the importance of apples to their stock, but their orchards are quite too small yet, to draw any comparison between the use of apples and corn for stock; none are raised for exportation—freight has been too high; but I do hope that the completion of the South Carolina and Charlotte Railroad will bring with it a reduction of freight, and all the benefits attending such improvements, and so enable us to obtain a market for the various little articles we could raise, and an additional incitement to improve our orchards. I have paid a good deal of attention to the pear-tree, and have now 85 different kinds on my list, that I have either imported or grafted, but they are now a short-lived tree. I say now, because there are some very old, old-times pear-trees in this settlement. The imported tree will grow and bear well for a few years, and then die, most commonly with the real fireblight; suddenly —the whole tree blasted at once—some in full bearing, and some before they had ever fruited; and within a few years past, that disease, which commences with the dying of the limbs at their extremities, has done me great injury. I have lost upwards of 50 trees, of all ages, from a foot in diameter to a two-year old graft, and have had many others seriously injured by it; have tried all prescribed remedies and preventives in vain, without even benefiting by a change of location. Others have suffered nearly as badly, probably quite as much so, proportionably. I have not as yet had sufficient experience with the later varieties to test their durabilities, but the age of the variety does not seem to have much effect, for the old St. Germain does as well with us as any, while the Jargonelle (English) suffers severely. Our peach-trees are not liable to the yellows, but are dreadfully injured by the worm in the root, the best remedy for which, that I have experienced, is spent tanner's bark, piled up around the tree at the root; best when done in June and July, say a peck to a tree.

I have cultivated the grape for nearly 40 years, with very variable success. My soil is most unfavorable, and the drought and sun bake my stiff clay so hard that the leaves drop, and the berries wither up before the time for their maturity, though I cover their roots with leaves, and train them conically, that each vine might shade its own roots. I prune severely, and find the best manure is surface-mould from the wood, and ashes. Barn-yard manure makes them run too much to wood. I cultivate with the plough and prong-hoe, and, in good seasons, make tolerably good crops, but not to compare with Mr. Longworth, Weller, &c. The foreign grapes do not succeed with me any better than elsewhere. I have several varieties, but the Lenoir, Herbemot, and Bland Madeira do best with me, and it is chiefly from the last I have been making my wine for 30 years, and a very good wine it is. The birds and negroes are so destructive to my grapes, that it is difficult to keep those the drought spares me until they come near to maturity. I am obliged to gather them early in September, whilst those which hang around my piazza, and are preserved to the middle of October, are quite another thing. My juice strikes from 7° to 11° of Beaume's saccharometer; at 9°, one pound of good dry St. Croix sugar added, per gallon, gives me a pleasant, dry wine, within 2° as strong as Madeira, and which has kept and improved to 10 years old, and would have kept much longer, had there been enough of it.

Manures.—I have but little to say on making and preserving manures; it is a subject but little attended to but by a few, and it is much wasted, our mild climate not obliging us to house our cattle. We have no cellars to throw our manures into, and but few have even sheds around their cattle-yards. The breadth of land we cultivate, and the few cattle we are able proportionably to keep, seems to paralyze efforts. My yard is scooped out in the centre about 2 feet lower than the external borders, have cattle-sheds 12 and 16 feet wide, furnished with mangers to feed in, and the whole is well littered with cornstalks, straw, leaves, weeds, and whatever roughage I can procure; and this way, and from my stables and mule-pens, I make about 200 wagon-loads of manure a year, and which, with the help of my cotton-seed, enables me to help a portion of my farm every year. It is quite too little for the need of my farm, and far less than I see others write of making, but it is more than any one makes about here, even with a larger stock and larger force. Lime, plaster, and guano have been but sparingly tried: the enormous price we have as yet to pay for carriage, renders them quite too expensive. I cannot get lime delivered to me under 65 and 75 cents per bushel; and plaster, which could be had in Charleston at $5 the ton, would cost $20 more to bring it up here: we could buy three acres of fresh land for what it would cost to lime one.

Meteorology.—The thermometer ranges highest in July. The hottest day this year was the 20th of July, with the thermometer at 78°, 88°, and 82°, at 8 o'clock A. M., 3 P. M., and 10 at night. I have known the thermometer to rise as high as 92° here, though very seldom. The thermometer ranges lowest in January and February; the coldest day this year was the 5th of February, when the thermometer stood at 18° at 8 A. M., at 34° at 3 P. M., and at 28° at 10 P. M. On the 8th of January, 1847, it fell as low as 8° in the morning, and I once, since I have been living up here, have known it down to 4°! No register has been kept of the mean temperature, or of the quantity of rain that falls.

I shall be very glad to receive a copy of your Reports, and have the back volumes up to 1848. They contain a mass of valuable and instructive matter; and I shall be happy if I shall in any way assist you in accumulating materials for your heavy labors.

Respectfully,
WILMOT S. GIBBS,
Chestnut Grove P. O., Chester District, South Carolina.

December 16*th*, 1850.

WINE-MAKING NEAR CINCINNATI, WITH PLANS OF A WINE-HOUSE AND MACHINERY.

[From the Western Horticultural Review.]

Our frontispiece for this month is a view of the wine-house of Messrs. Corneau & Son, located on their place, at Latonia, in Kentucky, about four miles from this city; it is probably one of the most complete establishments of the kind in the country. The great and increasing interest that is felt, not only here, but in all parts of the United States, in reference to the culture of the grape and the manufacture of wine, induces us to devote some space to this subject, particularly as the vintage season is about over, and our vignerons are now able to determine the result of their labors and skill. Improvements upon the methods and practice pursued during the earlier periods of the manufacture of wine from the Catawba grape, are being made every year, and the result is, that a very superior wine is now obtained from this grape, and one that bids fair to rival the most celebrated brands of the old country. The wines manufactured by the Messrs. Corneau, as well as by Messrs. Yeatman, Longworth, Buchanan, and others, will not suffer in comparison with those which are imported in large quantities from the Rhine countries; but, on the contrary, are frequently preferred by those who have been most accustomed to the use of the Rhenish wines. Its perfect purity and mild tonic properties render it an important addition to our materia medica; and its use as a gentle and nourishing stimulant is prescribed by some of the most distinguished of our medical faculty.

One important improvement which has been successfully introduced by the Messrs. Corneau, is the stemming of the grape, by a very simple and rapid process, and which also increases the peculiar aroma, or bouquet of the wine.

Many attempts have been made to accomplish this result heretofore, but they have either failed entirely, or have been found impracticable for large crops. The method of the Messrs. Corneau is remarkable for its rapidity; two men being able to stem, mash, and place in the press, near 80 bushels of grapes in about 8 hours. We understand that they intend introducing some further improvements during the next season, which will facilitate their operations to a greater extent than those which they now possess.

A sketch of the details of wine-making, as pursued at this establishment, may not be uninteresting to our readers, and which will be readily understood by a reference to the accompanying cuts of the plan and arrangement of the wine-house.

A. Door, opening to the vineyard, by which the grapes are brought into the wine-house.

B. Back-door of wine-house.

C. Front-door of wine-house.

D. Opening through which the stones are thrown from the machine.

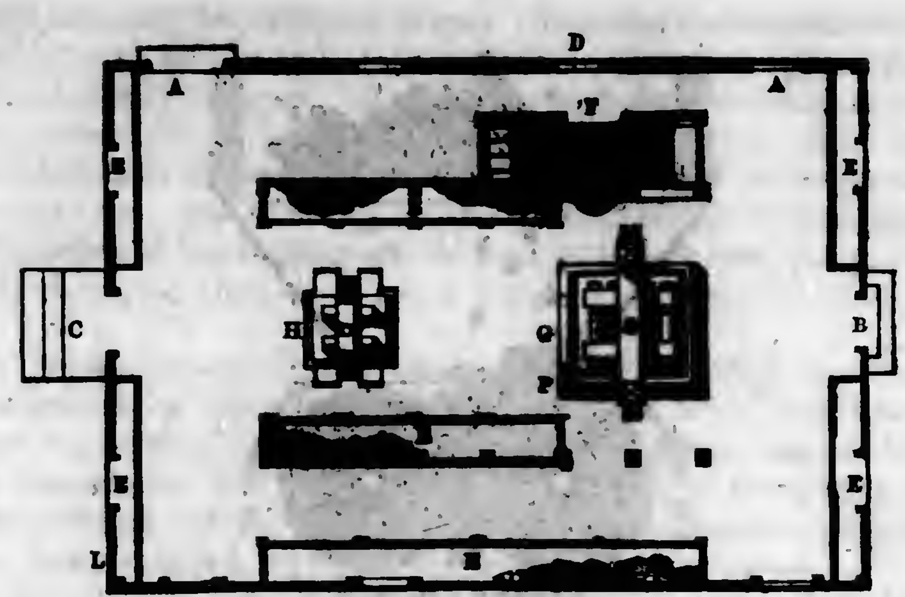
E. Tables for picking over and assorting the fruit previous to being stemmed.

F. Stemming and crushing apparatus.

G. Large press—capacity of 100 bushels.

H. Small press—capacity of 40 bushels.

L. Door opening into the basement.



Plan of a Wine-house.

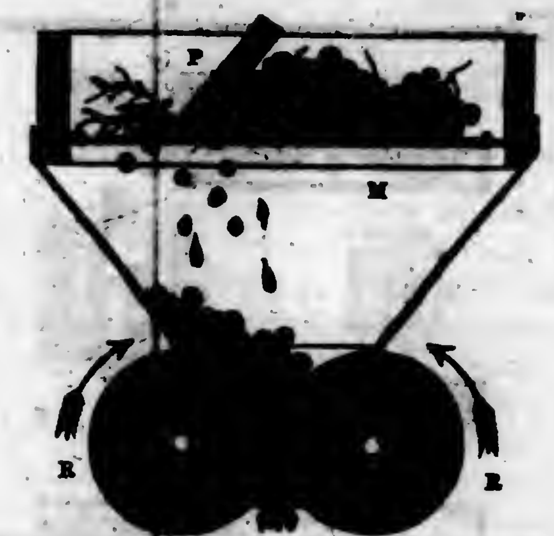
The following are the various operations of the manufacturing process, from the gathering of the grape to the bottling of the wine:

1. *Gathering.*—The grapes, when fully ripe, are gathered in baskets containing about a bushel, as well as in a sort of "pannier" of wood, made very light and strong, and which is supported by straps or thongs of willow, on the back of the picker, as represented in the frontispiece; they are brought from the vineyard in this manner and thrown upon the picking tables, where they are carefully assorted.

2. *Picking.*—This consists in removing by hand all green, shrivelled, or decayed grapes, which are thrown into tubs or barrels and pressed separately, to make a common wine or vinegar. The finest grapes are carried thence to the stemming apparatus, where they undergo another operation.

3. *Stemming.*—Beside the improvement in the quality of the wine which this process imparts, there is another material advantage derived from it, which consists in the diminution of the bulk or volume of any given quantity of grapes in bunches—the large press of the Messrs. Corneau being capable of containing upwards of 100 bushels after the stems are removed; from which about four hundred gallons of wine may be obtained. "Stemming" consists in separating the berries from the stem; it is done in F, (of the ground-plan,) by means of the apparatus, of which a wood-cut is appended.

The grapes are thrown on the wire sieve, M, which is open enough to allow the berries to pass, but retains the stems; a little plank, P, is held in an inclined position, to which a backward and forward movement is given by the operator, as shown in the next cut, so as to force the berries through the sieve, and to remove out of the way all the stems as they are stript: with the aid of this apparatus, two men can, in the course of 8 hours, if regularly supplied with grapes, stem from 70 to 80 bushels. Improvements might be made, by which the manual labor would be diminished; but this simple and cheap apparatus, which Mr. Corneau has introduced, is generally used by the wine-manufacturers of France.



Stemming Apparatus.

4. *Mashing.*—After passing through the stemming process, the grapes fall into a wooden mill, consisting of two rollers ridged obliquely, to one of which is attached a set of screws, by which the distance from each other may be graduated to the proper degree; it being desirable that every grape should be crushed, but that the seed should not be broken.

The rollers are turned by hand: the above wood-cut exhibits, in R R, a section of these rollers, and that which follows shows two men, one stemming, the other mashing the grapes.

Stemming and Mashing.

From the rollers, the grape (being entirely separated from the stem and thoroughly mashed) passes into the press, where the final operation of separating the juice is performed. The wine passes from the bed of the press, by means of a conductor, into the basement, from whence it is conveyed into casks containing 260 gallons each; these, though by no means of so large a size as those used by some of our wine-manufacturers, are of a very

convenient capacity for ordinary crops. The first fermentation takes place immediately, and, at the end of 6 or 8 weeks, the wine becomes clear—or, what is technically termed "fine;" a second fermentation takes place in the spring, about the period of the blooming of the grape. The wine should not be bottled until it is at least one year old, though it is frequently bottled for immediate use, just previous to the second fermentation: this may be done with safety if the bottles can be kept in a very cool place. There are many who think the Catawba wine is better at this period than ever afterwards.

Mr. R. Buchanan, of Clifton, whose beautiful vineyard has been so universally admired by all visitors, and whose wine is so excellent, has also introduced an apparatus for separating the stems from the mashed grapes, which is remarkable for its simplicity, being a large sieve, with meshes of about three-fourths of an inch aperture. The grapes are passed through this after being mashed, and thus separated from the stems.

Mr. Yeatman also uses the sieve to separate the stems from the mashed grapes, before he puts the pulp in the press.

WINE-MAKING IN CLERMONT COUNTY.

Mr. George Weir, of this neighborhood, has made, this season, 4800 gallons Catawba wine, from 8 acres of land—over 600 gallons to the acre. Judges say it is a superb article.

Thomas Williamson, we are told, has made over 1800 gallons; the precise amount we have not learned.

William Carnes made nearly 70 gallons on 2½ acres, first year's bearing.

Charles Burkheart made 150 gallons, on a little over an acre of ground, first year's bearing.

Michael Male made 240 gallons on 2 acres, first year.

Benjamin Light, about 1700 gallons on 8 acres.

Peter Light, about 1400 gallons on 3 acres.

This makes in all, 12,960 gallons, including Mr. John Williamson's. This, at the lowest price offered, will make $6480.—*New Richmond (O.) Age.*

Quincy, December 4th, 1850.

Sir:—Enclosed I hand you answers to some of the questions contained in the Agricultural Circular, dated August 26th, 1850.

The replies given are confined to such matters as come frequently under my observation; and I have been careful to reject any thing in reference to the subjects about which the opinion of practical farmers was not obtained. The profession of agriculture is, in this region, sensibly and steadily approximating towards its proper consequence and dignity, though, as yet, there is a great number of its members deficient in intelligence and enterprise. Our section of country is new—the average settlement of our farms will not reach 12 years: no part of the Union has a population more diversified, either in homebred or imported stock of the genus homo. It will be, therefore, unreasonable to expect much of us until we have attained more homogeneity in habits, peculiarities, and even in tongue. There are, however, indisputable evidences of awakened spirit and emulation among us.

General improvement, the most valuable, is seen in the roads, fences, farm-buildings, and better, neater, and more thorough cultivation of the country.

Agricultural statistics command greater attention than formerly. Experimental farming, with a view to test the extreme point of production the lands are capable of, will be entered into. Experiments are in contemplation, designed to ascertain whether the importation of seed of the staple grains from different latitudes will be productive of advantage, either in quality or time of ripening. Rotation of crops begins to receive some attention, through the example of some who have met with eminent success through its practice. (This is a most important improvement.) Crops are, in general, tolerably well saved, though vast quantities of straw, tops, fodder, and manure are still entirely wasted, in consequence of the short-sighted opinion that the land does not require its use. Many are unprovided with suitable accommodations for stock during our severe winters; yet, in this respect, a gratifying improvement is perceptible. Little disposition exists to introduce new crops, such as flax, hemp, barley, hops, &c., though it is believed many may be grown to advantage. Considerable machinery is used in the field; I think fully seven-eighths of the small grain is cut and threshed thereby: there are some mowing-machines also in use. Much interest is manifested in all sorts of improved implements and machines. The drill is not yet introduced, but will answer admirably, in my judgment.

Horses are almost universally used in the field—very few mules are seen—oxen are not numerous.

The average intelligence is worthy of particular notice, being inferior to no section I have seen in the Union.

Moral character is highly appreciated. Good-fellowship among neighbors, and general interest in country affairs, are marked strongly in our society. Neatness about the homestead is receiving gratifying attention, evinced by the cultivation of shade-trees, shrubbery, flowers, and garden-fruits, such as berries, &c. The means, however, of a great number are insufficient yet to enable them to erect such dwellings as are desirable. Economy, too, is a Sucker virtue. Labor is, in the main, fairly employed, and the laborers treated with deserving consideration: average wages, about $8 a month, with boarding and washing.

The German (chiefly Hanoverian and Prussian) population are generally excellent farmers, and, with the help of their wonderful frugality and industry, almost invariably succeed rapidly. Though not enterprising, they rank among our best farmers for clean fence-rows and well-tilled fields. Much of the field-labor is supplied by them. A desire to educate their children is characteristic with most of them.

The American population is composed of persons from every State in the Union, the mass losing nothing by the mixture, whatever. The country is indifferently supplied with schools, though they are increasing. Teachers' pay is too small entirely, and their responsible vocation not sufficiently appreciated. A disposition prevails to establish societies for the advancement of agriculture, and it is much hoped and desired that the national government will regard, with continued and increasing interest, this department of national industry.

Very respectfully, yours,

JOHN C. COX,
Quincy, Adams County, Illinois.

THOMAS EWBANK, Esq.
Commissioner of Patents.

FRUIT CULTURE.—BY MR. J. C. COX.

"Is the culture of fruit receiving increased attention?" Yes, very much, particularly the culture of apples. "Cannot apples enough be grown on an acre to render the crop a very profitable one to the farmer?" Yes, undoubtedly.

"What varieties are best to keep for winter use and exportation?" They are numerous. I prefer the annexed list:—Newtown Pippin, Golden Pippin, Rhode Island Greening, Jeanetten, Winter Pearmain, Baldwin, Roxbury Russet, Wine-sap, and Jonathan.

There are several excellent varieties of seedlings produced here, not yet named or classed by orchardists.

Apples generally are good. Some varieties are improved much upon the original stock; with reasonable care and attention, their cultivation amply repays the labor invested. In appearance, size, fragrance, and excellence, we can equal any farming locality I know of.

I have observed that some varieties change their colour when transplanted from abroad. The Kentucky Jeanetten and Pearmain, though retaining the original shape and flavor, assume a different shade of color, becoming much darker, and entirely losing the white and yellow.

"Do you know any preventive or remedy for the 'blight' on pear and apple trees, &c.?" No, I wish I did. Have tried close pruning, washing the tree with weak ley; topping, that is, taking off all the branches, stimulating with ashes and other manure, repeated digging at the roots, girdling the diseased limb, slitting the bark—but without avail.

I have observed that orchards in cold, dry, elevated situations are not nearly so much injured as those in more sheltered places. Have a young orchard on a very bleak spot untouched. My neighbors within a quarter of a mile, on a ridge less exposed, very greatly injured. The yellows in peach-trees is not very common here. I have no information on the subject.

Apples.—Best method of transplanting:—For this locality, move the tree before its diameter reaches 2 inches; take as many of the roots as possible; mark the tree, so as to set it in the same position as to north and south; take off a small portion of the stem or upper branches, handling very carefully. Plant a little deeper than the tree stood before, taking care to loosen the earth at the bottom of the hole in which you place it. Shake the earth well down upon the roots, avoiding the injury of the smaller ones as much as possible.

Let your ground be dry, clean, and cultivate in corn, with as much manure as you please. Avoid trimming, as much as you can, and let your trees grow without posts to help them. Weak ley is an excellent wash for the bark of fruit-trees. Forty feet apart is an excellent distance for the trees: less than 2 rods is too close. Plant in the spring, the sooner after the frost is out of the ground the better. Use leached wood-ashes for manuring the trees.

Peaches are abundant and of excellent quality, requiring little care in culture.

Pears.—A considerable number are planted; but, being of slow growth, very few have bearing trees. They have suffered more from blight than any other fruit.

Plums.—Not much attention paid to their culture, in consequence of the attacks of the curculio. The tree grows well.

Cherries.—We have abundance of the common red pie-cherry. The finer sorts are introduced, but few bearing trees. The tree thrives excellently.

Apricots, nectarines, quinces grow well and yield finely. Grapes are only cultivated as fruit. The Isabella stands our climate best.

Currants, gooseberries, strawberries, raspberries thrive very well and are plentiful.

Would any communication resulting from observation of forest-trees, shrubs, &c., together with natural fruits, grasses, &c., be of any value, confined, of course, to this locality?

Wheat.—Varieties in use: Red Chaff, smooth ear, much used.
White " "
Red " bearded, much used.
White " " summer, not much used.
Mediterranean Red, not much in favor.
White bearded Tennessee, (so called,) lately imported.

Average product per acre for 1850, about 19 bushels, of good quality. (Note.—I do not think this average would be correct for any previous year during the last six years.) Largest known yield, 36 bushels per acre.

"Seeding time," best from the 20th of September until the 25th of October for winter wheat.

"Preparation of seed" is much neglected. It is usual to select the seed from that part of the field where grow the most vigorous plants, or to take the seed from the pile having the heaviest and plumpest grains after cleaning.

"Quantity used per acre?" One bushel and a peck. If late, 1¼ bushels.

"How many times do you plough?" Twice if possible. Wheat, covered with the plough, stands our winter better, branches more, and is less liable to injury from falling before it ripens than when covered with the harrow. Depth of ploughing: flush the ground about 4 inches, and plough for seeding about 8 inches.

"Is the yield per acre increasing or diminishing?" I am of the opinion that it is increasing, decidedly, owing to improved farming, and increasing inducement in value, as well as the subdivision of large tracts into smaller farms.

Rotation in Crops.—The most approved system is to follow a crop of wheat with clover and timothy grasses; follow the grass with a corn crop the first year, and wheat the next, or other small grain. The custom is, for the most part, to break the prairie, then put in corn or wheat for ten years successively, reckless of injury to the soil.

Diseases and Insects.—I have heard no complaint of any in this county

this year. There was less cheat than usual at our last harvest. Thorough tillage and winter-fallowing are recommended for the destruction of the Hessian-fly.

Loss of crops sometimes happens from freezing out, from rust, and cheat; the first and last from indifferent farming, generally, however.

Wheat is considered a good crop as to certainty of remuneration.

Corn.—"The most esteemed varieties?" A species obtained by mixing the large yellow corn of Kentucky with the yellow flint, called here smooth yellow; it is prolific, full, smooth grain, covers the end of the cob, hard, sweet—cob brittle. The gourd-seed corn is most planted, both white and yellow. Very little care is taken in selecting seed, particularly as to variety, most farmers merely preferring the color.

"Average product per acre?" Fifty bushels; (have grown more than 100, which is not uncommon.)

Cost of production will vary with the crop. I think corn cannot be properly cultivated for less than $5.25 per acre, estimating labor at $8 per month. A fair average would be not less than 12½ cents for dry corn per bushel.

"Best system of culture?" Land should be ploughed deep during the fall, if possible; this secures the following advantages: 1st. It destroys a great number of weeds, and, at the same time, turns under the surface a considerable amount of fertilizing matter, in the shape of decaying vegetation, which would otherwise be lost. It destroys many insects which live upon the crop; it renders the soil more easy of cultivation at seed-time, and, by exposing more or less new soil, recuperates that already taxed for one crop. It should be again deep ploughed in the spring, after the frost is fairly out of the ground, and planted in rows, about 4 feet apart. Two plants are enough to stand in one hill—three may do well—more than this is too many. Plough till there are no weeds visible after the plants appear, throwing the earth against the plants, and then plough again, to be sure. Corn can't be ploughed too much in this climate. Planting depends much on the season, of course, as to time. I prefer late planting, in order to avoid the frost and the stunted character of the plant when its development is checked by unfavorable weather, such as cold, wet spells, &c. When the plants are quite small, use a cultivator instead of the plough, and when too large to use the plough, use the hoe. In thinning the plants, regard the color and thickness of stalk more than the height. Should the land be lumpy after spring ploughing, smooth with a harrow.

Oats.—Average yield, (5 farms, in fair season,) 36 bushels. Quantity of seed used, 2 bushels and 1 peck. Is an uncertain crop.

Rye.—Scarcely any raised in this county.

Barley.—None cultivated for a crop.

Peas.—None cultivated for a crop—are not cultivated as a renovating crop.

Beans.—Very small quantity raised—are very prolific. Oats are considered the most exhausting crop.

Clover and Grasses.—Quantity of seed used, about 14 pounds to the acre.

"Quantity of hay cut per acre?" With reasonable farming 2 tons; I have known 2½; average, 1½ tons. Cost of production $3 per ton.

"Best fertilizers for meadows?" Stable manure is the only one in use here, and answers every purpose. Will increase the yield surprisingly, even upon first-rate land.

"Grass seeds preferred for laying meadows?" Timothy, clean, is first. Timothy, with very little red clover, second. It is supposed that a meadow will thrive better with mixed grass, as the clover shades the young growth of the timothy during excessive heat, and preserves it thereby. Kentucky blue-grass is our best pasture grass. White clover grows spontaneously upon close-pastured land, in timber and prairie, most luxuriantly at this time. I am credibly informed that in the early settlement of the country it was unknown.

Dairy husbandry is much neglected; very little cheese produced.

Root Crops.—Some turnips are raised as a field crop, and are the only one of the list that are so cultivated. No disposition is manifested to engage in their culture as a crop. All of those named thrive excellently as garden vegetables.

Potatoes, (Irish.)—Average yield, 70 bushels. Most prolific variety, Neshanac—most profitable, pinkeye—most edible, Mercer. Cost about the same as corn; say 22½ cents average. Some experiments are being made in their culture: if any improvement be elicited, will report it.

Jefferson Township, Fayette County, Pennsylvania, December 5th, 1850.

Sir:—I have been at some pains to get what information I could from my brother farmers, and I herewith send you the result of my inquiries.

I live in a section of country every way adapted to the raising of wheat, corn, oats, and clover; the soil is a limestone clay, susceptible of the highest degree of cultivation.

Wheat.—Our average product per acre is from 20 to 25 bushels, and, in some instances, 30. Our varieties are the Mediterranean, the Cape, the red smooth, the red bearded, and latterly the Zimmerman; our mode of culture is varied; we sow on a fallow with two ploughings, which mode invariably insures us good crops. Sometimes we cut off our corn and sow wheat of a late variety, but our principal crop is sown on oats stubble, with lime or manure on the top; our time of seeding is from the 15th to the last of September; the yield of our land is steadily increasing; the land which, 15 years ago, produced from 12 to 15 bushels of wheat, will now, with lime and manure, produce 20 to 25, and could still be made to produce a greater quantity. Our rotation is, first, corn on a clover lay; second, oats, with manure; third, wheat with lime; fourth, clover sown on the wheat in the spring. Our nearest markets are Brownsville and Pittsburgh; prices range this season from 70 to 75 cents per 60 pounds. *Corn.*—Our most esteemed variety is a large, rough gourd-seed, with from 12 to 16 rows, a white cob and long grains. Our average yield is from 40 to 50 bushels per acre. We generally plant on a clover lay, with long manure, ploughed in early in the spring. We then commence about the middle of April to haul on lime, coal-ashes, and any other fine manure we may have, harrow fine, and mark out in squares of four feet each way, and plant from the 25th to the last of April, 3 grains in the hill; our after-culture is to work four or five times with cultivator and double-shovel plough. We keep our corn clear of weeds and grass till harvest. The National Road affords a good market for corn and oats, so that we feed but little to stock; the price this fall is 40 cents per bushel.

Corn can be raised at the rate of from 8 to 10 cents per bushel, exclusive of interest and taxes on the land. Oats we mostly sow after corn, once ploughing; we raise 40 to 50 bushels per acre, and sow 1½ to 2 bushels per acre. We consider oats an exhausting crop, and always lime or manure after oats, to insure a crop of wheat. Barley, rye, peas, and beans are not cultivated with us as field crops; neither are roots for feeding stock. Clover is considered as indispensable to good husbandry. We sow from 10 to 12 pounds of good seed, per acre, on our wheat; we sow in March, and always try to sow on frozen ground, or on snow. We raise from 2 to 2½ tons of hay per acre; cut in June, and reserve the second crop for seed; we cut two crops in succession, and then plough for corn. We sow timothy for permanent meadow on bottom land; hay is now selling for $10 per ton. Cattle and sheep are not raised to a great extent; if we feed cattle or sheep for market, we purchase from a distance, feed during winter, and dispose of them in the spring, when fat. Potatoes are raised in limited quantities, farmers have been deterred by the rot from planting them. *Manures.*—Our farmers are only just beginning to turn their attention to making and preserving their manures. We have, for several years, used lime as a manure, to which we owe the increase in the production of our land. Lime, in quantities of from 50 to 100 bushels per acre, sown immediately before we sow the wheat, increases the wheat crop, and insures us a crop of clover, which we consider the best renovating crop we can sow.

I have given you short answers to some of the questions proposed in your circular: if they will be of the smallest use to you in making out your Report, I shall be highly gratified; if not, you can lay them aside, and give no offence.

Yours, respectfully, JOHN H. FARR.

Rivesville, Marion County, Virginia, December 10th, 1850.

Sir:—I had the honor of receiving, through the politeness of the Hon. Thos. S. Haymond, your agricultural circular for the present year, (1850.) With the expectation of getting the necessary information from the marshal's books, I have delayed completing my report for more than two months, and, for want of their returns, shall be able to give you nothing more than a mere historical sketch of the improvements that are at this time progressing within our county. Our soils are naturally fertile, and highly adapted to the production of the various kinds of grain, as well as grasses. We have hitherto given but little attention to the improvement of our lands, either by any regular rotation of crops or otherwise; and while it yielded an ample supply for home consumption, we were satisfied with the present state of things. The principal market for the sale of our wheat and other produce heretofore has been Pittsburgh, Pennsylvania, the prices being barely sufficient to defray expenses of transportation and other incidental charges, the distance being over a hundred miles. The Monongahela river affords the necessary facilities for transportation, at least in the spring season of the year, by which the surplus of produce is conveyed to the above market. Lumbering, or supplying timber for steamboat building, has, for many years, engaged the attention of many of the citizens of Harrison, Marion, and Monongalia, and been a source of considerable revenue to those counties.

But I may say, with much propriety, the rearing of live stock, horses, cattle, sheep, and hogs have formed the staple of Western Virginia, and been the principal source of the wealth and prosperity of this section of our State.

The surface of the country is undulating and healthy, but its insulated position has heretofore proven unfavorable to the introduction of experienced and practical farmers locating among us. But a new era in the history of our county has at length opened. The time was, when it would have been thought impracticable for a wagon and team to cross the barriers that lay in the way on every side. But behold the change that has been effected within the last six months! The mountains are made to tremble from their very base, by the constant and tremendous explosions in blasting rocks, whose deafening reports arouse the sleeping echoes from their placid retreat, and send back a wild response in tones of thunder. The great railroad from Baltimore to Wheeling is now under a rapid state of being made through the centre of our county, and an active interest in all the departments of industry are favorably conspicuous among the people, especially the agricultural portion of its population. The wheat crop of '49 was extremely light, owing to the rust striking it a few days previous to harvesting. Nothing discouraged, the farmers, in anticipation of the public works that were all centering through Fairmont, our county seat, employed themselves with renewed energy, and perhaps no former year ever witnessed so large an amount of soil turned, or so much grain sown. The result was a favorable experiment, and an abundant yield of small grain of superior quality was our reward.

Corn was never better; oats not so good as '49; but potatoes were better, both in quality and quantity, than they have been for the last 5 years. They were not the present year injured by the disease termed the rot, though the yield was less abundant than before the disease was known in western Virginia. The red-chaff bearded, until a few years past, has been, with few exceptions, the only wheat cultivated in this section of country. The Mediterranean, though of recent introduction, promises a fair yield; being thought less liable to the ravages of the fly and other casualties. Besides raising an amount of produce sufficient for home consumption, there will be more than enough, it is thought, to supply the great number of hands at this time employed on the public works.

I am, dear sir, yours respectfullly,

HENRY MERRILL.

Hon. Thomas Ewbank, *Commissioner.*

Bloomfield, Somerset County, Maine, December 5th, 1850.

Dear Sir:—In answer to questions propounded in your circular, handed to me by the postmaster, W. S. Parks, of Skowhegun, I would say: 1st. The variety of wheat sown now is principally the Black Sea wheat, the red-bearded wheat, and the bald white, for spring sowing; and the average product per acre (unhurt by rust or weevil) is, or rather has been, about 8 or 10 bushels. The past season has been better. The time of seeding varies from the 25th of April, or as early as it can be sown, to the 10th of June; although, in general, farmers prefer sowing as early as it can be done, or to the 10th of May, or defer it to the last of May. Harvesting is done from the 1st of September, onward—done before the 20th. Seed is pretty generally washed clear, and lime or wood-ashes added till dry enough to sow, and allowed to stand 12 hours. It is now customary for most farmers to sow 2 bushels to the acre, some even more, on land planted with corn previously and manured, ploughed once or twice from 4 to 6 inches deep. The system of raising wheat has been changed somewhat of late, and considerable has been sown on "broken up" pasturage, which has succeeded well, using no manure: the plaster or gypsum is good. This, with rather better seasons, gives an increasing yield. The system of rotating has never been carried to much extent, as the country is not old, and land plenty, and two or three crops are all we get before seeding down, say one of corn and potatoes, one of wheat and grass, or one of oats or oats and peas, one of corn, and then wheat. No particular remedy for the fly, except having the wheat ripen in the season which is too early or too late for their accommodation. Market at home, and average price from $1.25 to $1.50—1850, $1.50—governed by imported flour. We have succeeded this year in raising a long neglected crop of winter wheat; none having been sown but what has yielded well, some as high as from 35 to 40 bushels to the acre; all that has been sown looks well. This crop succeeded well 30 years ago, but having failed several successive years, it was abandoned. We have for the last 20 years labored under great disadvantages in raising wheat, which began with the fly, then the weevil, and then "blue-neck," blight and rot. Forty years ago, wheat was a sure crop, and the quantity sown to the acre was just 1 bushel, the same as is now sown in the fall; and the yield was uniformly from 20 to 30 bushels, and it may be a question now whether 2 bushels to the acre is not too much: a farmer of my acquaintance began with Black Sea wheat, at the rate of 2 bushels to the acre, and found his crop pinched; he reduced to one and a half, and it was better; and then to one and a quarter, and found it right. Several experiments have been put in operation to test the quantity of seed-wheat in this State, which have elicited what may be valuable information on this important subject. It has been suspected for a long time that our seed was in fault, at least for a part of the deplorable deficiency in the crop, and if, "as you sow, so shall you reap," and every seed shall bring forth its kind, then it follows, if we sow defective seed, we should expect defective crops. I could not see why a flour-mill cleanser should not be the best thing to prepare wheat for sowing, till an experienced miller told me it would kill one-half of it. Reflecting on this fact, I was led to see what effect the common threshing-mill would have, when many kernels are broken in the operation. These suggestions have been experimented upon, and it is found, on repeated trials of samples sown in common saucers and broadcast in the ground, that one-fourth or more of the largest kernels are killed, and never germinate, and some will produce a shoot, but no root—the root-sprout being killed by the machine. This accounts in some measure for our wheat coming up thick enough, but shortly becoming thin. Many kernels, from native strength, shoot up, but, having no strength, die. In our flour-mills may be seen the caps of the root-sprout, blown out by the blower or fan, under the hopper, by quarts at a time, besides that which is blown out above. One farmer told me he had tried the experiment, by accidentally having a barrel of wheat threshed by hand and sown with another barrel threshed with the machine; and the difference was at least one-quarter. Thus it is seen that one-quarter of the seed is killed by the machine for threshing, and then the whole is run through an ordinary winnowing-mill, all together, and sown from the mass; we raise our wheat, year after year, from about three-quarters of the seed sown, and that of the poorest quality; the best and fullest being killed. Now, to my mind, this is enough to account for the diminution of the wheat crop, from 20 to 30 down to from 5 to 12 bushels. No seed on earth could stand such a test. Formerly, the wheat was threshed with flails, and winnowed in the north-west wind, and then the seed taken carefully from the north-west end of the pile, so that very little was sown but the first order of kernels. What a contrast! Some even went so far as to select heads of the largest and best growth, by pulling them from the sheaves. A gentleman, now on the Supreme Bench of this State, informs me that his uncle followed that course, and had no occasion to change his seed for 40 years in succession. A gentleman of this town informs me that he tried the experiment by selecting a few heads, enough to give a quart of wheat, which was carefully kept and sowed on a corner of the field, and he assures me that he could see the difference in the grain 40 or 50 rods, the plants being a darker green, broader leaf, and taller growth.

A question has been raised whether smut is raised from smut in the seed: and I am informed, by a friend, that he sowed some wheat in a bed in his garden in rows; two rows of good seed produced all good wheat; next two rows, of middling wheat, produced a poor quality, with some smut; next two rows, of the poorest wheat, which was mostly smutty; next, the very smut itself, a small part of which came up, but was all smut. This proves the necessity of improving the quality of seed-wheat, in this climate at least, if we would raise fair remunerating crops. A recapitulation might be well; but I will only say, let every farmer who sows wheat have a sufficient quantity threshed by hand, at least, for seed, and winnowed in a good strong north-wester, if he would have good crops of good wheat.

As for smutty wheat, I would say, with Capt. H——, there is no more need of raising it than of wearing a dirty shirt. In my younger days, when agriculture was not studied, but "*went on itself*," I was on a farm where, for years, smutty wheat had been successively raised, till my ambition rose above it, and, though at the time quite young, I bought 2 bushels of clean seed-wheat, and prepared it, by washing, liming, &c., for sowing; the consequence of which was that I got a crop several shades lighter than usual. Some of this crop I saved for seed, prepared carefully again, and sowed it, from which I got a very tolerable article; and, after the third year, I had no trouble in raising good white wheat and enjoying good white bread—a blessing which I wish every man to enjoy.

Corn.—There are several kinds of corn raised in this vicinity, from the old Indian blacksmith kind to the Massachusetts large eight-rowed, including the Brighton, the Dutton, the sparkled, and threaded. The Brighton is a kind got up by the legislature of Massachusetts, before the State of Maine was set off, and given to the members, by which it became pretty generally disseminated. It is considerably planted, grows large, and produces well; but has a moist cob, so as not to be very easily dried. The Dutton is much like it, ears a little shorter, from 8 to 14 rows, grows well, and is productive. The sparkled is a good variety, much like the old eight-rowed, and produces well. The blood-red is a soft, damp kind, not worth putting in competition with others. There is another kind, called here Piscalaquin corn, eight rows, good ears, small kernels, cob very small, ripens early, and is *the* kind for a bad season. But such are the changes in corn, that a description is

not worth much. I planted the Brighton kind on a light, sandy, alluvial soil, and the second year I had nearly all eight rows, small variety; and the same, put on a clay soil pretty rich, went back again; and the same stalk will produce eight, ten, and twelve-rowed ears. The old Indian corn remains nearest to its pristine state, tall and straight, two ears to the stock, half bluish and half yellow. An average crop per acre may be measured or estimated variously. An average of all the corn, from the drunken blacksmith to the accomplished farmer, would give an idea of the country and manners, but not of the agricultural capacity. An average crop of well-cultivated land may be reckoned not far from 40 bushels per acre, running from 20 to 100 bushels, but may be more under 40 than over. The cost per bushel, on the same estimation, may be put at about 42 cents per bushel. The mode of culture has been materially changed, and much corn is now raised by spreading manure and lime on grass-land worn out and "bush-furrowed," the seed put where the furrows join, by which little labor is required in hoeing. Pasturage and mowing, broken in the early fall, and manured with long manure, and then go over it, before planting, with the cultivator, gives good crop, and the old mode of planting on the stubble-ploughing. In the last case, a mixture of two parts ashes and one part lime, with one-half to a pint in each hill, covered one inch in dirt, especially on light land, gives a good crop at a fair paying rate. Cooked vegetables are generally best; but, in regard to corn, it may be questioned whether it will pay the expense: I think it will. Grind and cook corn, formerly planted 4 feet apart, in rows by three in hills, but recently 3, by crop a doubtful expediency—one ear for two to the stalk.

Oats yield very small, on account of threshing-mills, same as wheat; seed 2 to 5 bushels; naturally exhausting; 5 years kill the land; formerly 20 to 50 per acre, now 6 to 25.

Barley.—Rather uncertain; well sown, will produce from 12 to 30 bushels per acre; not very exhausting; a good article for pork, &c.

Rye.—Mostly sown in fall, and yield all the way per 10 to 30 bushels per acre.

Beans.—Seldom raised alone to any amount; planted with corn; raised per 50 cents; generally sold at $1.

Peas do not exhaust land, rather improve; not sown for the benefit of land; from 10 to 40 bushels per acre.

Butter and Cheese.—Very much neglected; average to the cow, 100 pounds cheese and 100 of butter; many cows kept for stock-raising, and nothing else.

Neat stock.—For 3 years old, prices vary greatly; from 15 to 50 in market; giving 15 for raising, the large ones cost more. Cows worth in the fall from $12 to $20; in the spring from $16 to $30; extra, $50 to $100. The kinds of cattle are not kept apart, but much attention is given to stock, and successfully; all fine yoke oxen must be 7 feet in girth, and many come to that standard.

Sheep.—Wool is considered worth raising as a business when worth 25 cents the pound. Coarse wool, on the same kind of sheep, is not so good as a paying business; but the coarse-wool sheep need a little less attention, and are as good mutton.

The large Dishley sheep produce good mutton and great fleeces—very hardy; but the Merino sheep are generally kept for profit. The difference in price is about equal with the cost—say from 24 to 34 cents from the sheep.

The subject of raising is badly understood and badly attended to, on account of the fluctuations in the prices produced by partisan legislation. Well might Mr. Hamilton say to Mr. Calhoun that a certain eight years had cost the nation $500,000,000. Sheep are too often kept for the purpose of killing the bushes in the pasture—consequently poor, the lambs are allowed to run with the dam till they wean themselves, the best sold off, and the flock kept good from the remainder: allowing for death and accident, no small amount. In this way, flocks soon run down, and well they may, and must be changed. Instead of this, if sheep could be kept well in winter, and bring their lambs by April, and let the lambs be taken off by the 1st of September, the sheep would all get fleshy by fall, and go into winter capable of standing the rigor of climate. The lamb would not be seen gazing at hay and provender, not knowing what to do, but go right to eating and winter vastly better; and by this means the ram is kept from them, if you please, so they do not yean the first year. The old sheep are in good case, and very little feeding will fit them for market.

The proportion of lambs to the ewes is, probably, about two-thirds, and, with the above rules observed, might be raised to seven-eighths. Sods of turf should be piled where sheep can get them in long snowy winters. Soot and salt, with a quantity of meal, are very good. Hogs are of all varieties and mixtures. We can't compete with the West in this article.

Cotton we wear out, but raise none.

Sugar-cane the same.

Rice the same.

Tobacco.—Everybody uses it, but produces none to count. It used to be raised considerably here, and is raised in Canada now.

Hemp.—This article has been tried, but did not succeed very well. Rather exhausting as a crop. It may come up again when we get railroads and have less lumber.

Potatoes.—Irish potatoes were one of the staple articles of the farm till the general blight, and numerous starch-mills were erected, which promised a lucrative business; but our hopes are blown to the moon for the present. The best kind of potatoes, every thing considered, is the old Spanish or English white, or the pinkeye, nearly alike. Most other kinds have objections: the Chenango rots more, the red is not good for the table, the Christri wants very rich soil, and so on of Butnene lady. The best method in raising them is to plough pasture land in the spring. Harrow and plant all good-sized, either cut or whole; put on gypsum or plaster of Paris. A thousand conjectures have come to light as to what constitutes the disease; but facts seem to baffle every one. No two fields, no two hills, no two positions of the same seed or location, high or low, dry or wet, produce the same results, but right contrary. My own opinion is, that the same disease attacks potatoes that does wheat, and they both came suddenly and may go as suddenly. I observed that something ailed potato-vines several years before the rot commenced; the tops rusted and died where they used to keep green till frost came. I had pens of potatoes near my stercorary, (hog-pen,) on which the vines grew large; and, wishing to dispose of them, I put them into the low wet ground in the yard, on which I piled a quantity of pamplain vines, making a cart-load. In November, I pitched the whole over, to give them some chance for rotting, and in the mass I found attached to the stalks of the potatoes thousands of maggots, resembling, in shape, color, and size, the weevil. It would seem that the fermentation had produced the requisite

amount of heat to hatch them out. They were in rows on the stalks, and appeared to have been deposited along the little raffle on the stalk. What would seem to corroborate the hypothesis is that, where corn and potatoes have been planted one year, and wheat sown on the whole ground the next year, that part where the potatoes were planted will be doubly injured to that of the corn.

Sweet potatoes are not cultivated nearer than about Boston, to my knowledge, and there they assimilate to the Chenango, so that little or no preference can be given. I think that they are the Irish potatoes varied by climate, little else.

We have a native ground, not exactly resembling the sweet potato in vine-leaf and blossom. I think that might be mistaken.

Fruit culture is new business and in infancy. Much is going on in the line, and will give ample results in a few years. Orchard lands have been too prevalent. When I was a boy, I have heard the remark, that we could raise apples to eat and some cider, but could not have cider like Massachusetts. Every one set out trees to try it; now, were the trees in good condition, and not killed by ploughing, we could expect a million bushels of apples in a year. I am entirely against cutting off the top roots with the plough share. Enrich the ground with coarse any thing, and cut out the middle of the top, so as to let the sun in.

Manures.—We are beginning to use lime considerably for manure, and salt and alkali, on Baumer's plan. Every farmer uses all his manure, and spreads it on all his cultivated land, probably one-eighth of what should be used. Good farmers put on all the way from 20 to 60 loads per acre.

Thus I have hastily gone over with most all the questions propounded, very imperfectly; and, if you find any thing worth notice, you are free to use it. The remarks on wheat are very strongly set in my mind, and, I think, worth perusing in the Northern States and the older Southern. In the virgin West any thing will grow. The remarks on sheep, too, are applicable to the North and Middle States, but not to where no winter is.

Very respectfully and with much esteem,

Yours truly,

EUSEBIUS WESTON.

WOOL AND WOOL-GROWING.

Nashville, Tennessee, October 21*st*, 1850.

Sir:—Your favor was duly received, and I cheerfully make a communication for your Annual Report, on the subject of wool-culture and sheep husbandry in the low latitudes of the United States. Observation and many years' experience have brought me to different conclusions from all others who have written on this subject, upon the effects and influence of warm climates on wool-growing, and especially upon the finest Saxony wools.

In a letter addressed to the Commissioner of the Patent Office, and published in the Report for 1848, page 627, I expressed the opinion "that the United States are a better wool-growing country than any portion of Europe; that the *low latitudes* have an advantage over the high, and will produce finer wool; and also, that as fine wool is now grown in the United States as can be found in the world."

I stated further that I had studied this subject with diligence and devotion for 35 years, and thought I had come to correct conclusions; but the Commissioner, Hon. E. Burke, decided that I "was wrong, and most decidedly mistaken in the whole matter," and that Mr. Fleischman's views, who had said that we must go to Germany for sheep, if we hoped to succeed, were no doubt correct. Still confident that my long study and experience had not misled me, when the Commissioner published his Report and remarks, I addressed him a letter, which may be found in the "Plough, Loom, and Anvil," page 366, December No., 1849, offering to exhibit selections from my own flock, in latitude 36°, against any sheep which could be found in all Silesia, or any high latitude in Europe, and especially above 50° north latitude. This offer has not been accepted, and I have no fears of the result, if it ever should be.

It is gratifying now to refer to the impartial evidence of science in favor of the positions then taken. I was certain the facts existed, but I did not know that the researches and inventions of our countryman, P. A. Browne, Esq., of Pennsylvania, would so soon present the testimony in so satisfactory and tangible a shape. Mr. Browne practised law for more than 30 years in the city of Philadelphia; retired from practice, he has devoted years to the study of hair and wool, aided by the lights of others and his own inventions. I consider his examinations, therefore, entitled to full faith and credit.

From two letters addressed to the Hon. R. R. Reed, of Pennsylvania, and myself, published in the May No. of the "Plough, Loom, and Anvil," 1850, I beg leave to make a few extracts, which show important results to the United States, because it places her at the head of the list of all countries for fine wools.

Mr. Browne examined 65 samples, or collections of samples, from all parts of the world, and especially the 18 samples brought over by Mr. Fleischman, from the most renowned flocks of Europe, and distributed, through your office, to the several States, as the standards of excellence, and worthy of imitation.

The quality is expressed by the number of fibres which will cover an inch; or, the diameter of one fibre is that fraction of an inch. The low figures indicate the coarser wools, and the high figures the finer.

		To an inch.

" "	Flock of Mr. Robert Allen, Virginia	1875
" 65.	Five specimens from the flock of Mr. Mark R. Cockrill, Tennessee, as follows:—	
" 1.		1572
" 2.		1875
" 3.	This is a beautiful even wool	1875
" 4.	This is a clean even wool of the extreme fineness of	2186
" 5.	Not uniform	2186
" 5.	Some strands in this specimen	2500"

The above is the evidence of scientific instruments in the hands of a gentleman devoted to the investigation of this subject, and fully sustains my position, that the United States are growing as fine wool as Saxony, Silesia, or any other part of the world.

Mr. Fleischman recommended, in his report, that wool-growers should go to Chrezelitz and give Mr. Heller $1500 for such bucks as "Napoleon," for the purpose of improving the *quality* of our wool. Compare the sample from Napoleon with the samples in Mr. Brown's cabinet, from New York, Pennsylvania, Virginia, and Tennessee:

United States samples	·1875, ·2186, and ·2500
Napoleon—rival flock to Prince Lichnowsky	·1200

Was I mistaken, then, when I said that as fine bucks could be purchased in the United States for $50, as those in Germany which are valued and sold at $1500? What improvement in *quality* of wool would such a buck as Napoleon be to the flocks of New York, Pennsylvania, Virginia, and Tennessee, which grow the samples in the above collection, running from 1500 to 2500, whilst he wears a coat, grown in the snows of Northern Europe, of only 1200 to the inch?

The sample from the flock of Prince Esterhazy, of Hungary, is 1572. This Hungarian prince, it is said, owns a flock of 3,000,000 sheep, and 4,480,000 acres of land. We have a right to suppose that he has done every thing that wealth and leisure could accomplish in *that latitude*, to improve his flock. Yet, would a buck with a fleece of 1572 be an improvement upon our ewes in the low latitudes of 36°, which bear now the "beautiful even fleece of 2186?" The same remarks apply with equal force to the flock of Prince Lichnowsky, of Kuchelna, whose samples are 1250 and 1562.

I cannot omit a notice of a remark of Mr. Fleischman, at page 306. He says: "It has been found that the highly improved sheep do not last well in America, and that the wool grown in America by the German sheep does not at all compare with that grown in Germany."

I can excuse Mr. Fleischman's partiality for his "fatherland," but I should do injustice to our own country not to challenge a test of such statements. I hold directly the reverse of both these propositions, and, on the subject of wool, refer to the testimony of Mr. Browne, who deserves from our wool-growers a service of plate and a suit of clothes from the "beautiful fleece of 2186," for his investigations in this important product.

There is a traditional belief entertained by the greater portion of the world, that sheep by nature belong to a *cold country;* and that when they are removed from a cold to a warm climate, the wool will grow coarser. My observations and reflections on this point have convinced me that, when the latitude is not below 30° N., the reverse of this tradition is true. I believe that the improved Saxony sheep, brought from the snows of Russia to Texas, in the United States, will produce a finer, evener, and fuller fleece than while in Russia. I think the evidence is pretty conclusive that the Merino sheep are natives of the orange groves, and are fitted by nature for the warm climates generally. Climate is a law of nature, and her laws are in harmony. The animals fitted for warm climates are most healthful and vigorous under the action and influence of these laws. The elephant, lion, and camel are organized to bear with healthful influences the long-continued heat of Africa, and the white bear grows fat on the ice of the Arctic seas. I can with confidence say to all husbandmen in the cotton districts of the United States, that, for growing fine wool, they have nothing to fear from climate.

I consider Texas an admirable location for wool-growing, as there is a scarcity of timber, and it is not so well adapted to other agricultural pursuits. The prairies are productive of grass without the labor of man. The winters are mild, open, and warm, furnishing green food, with a regularly growing fleece throughout the year. Population sparse, and lands cheap, requiring but a small capital to engage profitably in the business. Our population is rapidly increasing, and must continue to do so; and last year we imported nearly 20,000,000 pounds of raw wool, besides the woollen goods which we annually take from foreign countries. These are strong facts in favor of a continued demand for wool.

Though cotton, the happy gift of heaven to that class of men blessed with the fewest comforts of life, is steadily in competition with all other materials for coarse goods, yet there are appropriate uses for wool which nothing else can supply. The cotton district, embracing 10 States, and about 500,000 square miles, presents a wide field for the growth of wool. The resources of the South are but partially developed, and I am happy to see Southern opinion awakening on this subject. The spindles and looms are coming to the cotton fields, and when they are up, the cotton crop alone will yield $150,000,000 per annum. The wool crop, at 20 sheep to the square mile, will yield 30,000,000 pounds, besides rice and sugar. We have spread over our cotton territory, and the great enterprise of opening new cotton States is nearly closed. We have about $750,000,000 invested in the growth of cotton, an enterprise of comparatively but a few years, and the addition now of the spindles and looms in the cotton fields will double the product of this great growing capital, and insure consumption by furnishing coarse goods for the laborers of all the world, at cheaper rates than they ever have been or ever can be furnished elsewhere.

The cotton district of the United States is to become, in a few years, the dispenser of a great public charity, by furnishing the laborers of many portions of the world with the cheapest clothing made in Europe or America. The wool crop may be grown in the cotton district, without diminishing the latter, and thus add to the resources of the South. All the cotton region is adapted to wool and sheep.

In my estimation, the South is not dependent and not weak; but rich in natural advantages, and now ready to say she will turn to account the gifts of nature, and show the strength of her position. No power at home or abroad has any just right to interfere with our domestic relations, and thereby disturb our quiet, and arrest the full development of our resources.

I have said that the low latitudes of the United States will grow the finest Saxony wool, finer than Silesia, the boasted province of Europe. I am also satisfied that the intellect of the Caucasian race, under the genial influences of our southern sun, and the effects of our domestic relations, is more rapid, more polished, and more brilliant than it is in the higher latitudes of our own country. Mind is power; and the South may add this to its other natural advantages; and these powers, when developed and understood, and associated in harmony, point to a prosperous destiny.

I am, very respectfully, yours,

MARK R. COCKRILL.

HON. THOMAS EWBANK,
Commissioner of Patents.

Spring Cottage, Marion County, Mississippi, Nov. 6th, 1850.

In reply to a circular of the United States Patent Office, forwarded to me by the Hon. A. G. Browne, I take pleasure in answering such questions as apply to the production, manner of cultivation, &c., of this section of country.

Cotton.—The average yield, on the bottom lands, (no worm,) 400 pounds clean cotton, on uplands, 150 to 300 pounds; cost of production per pound, 6 to 7 cents. Corn yields best after cotton, and, to keep up or improve the fertility of land, sow down between rows of corn from 3 pecks to a bushel of peas to the acre; plough them in lightly, or harrow them over. The next season, sow the same land down in rye or oats, which may be fed off, first by horses or cattle, and then by hogs, so as to tread the straw down. About the 1st of July, sow the land down with peas again, pick or feed them off, and the land is again in good condition for cotton. The oat or rye stubble and straw and pea-vines decompose in less time, perhaps, than any other vegetable matter, and lighten and improve the soil. In regard to subsoil ploughing in the cultivation of cotton, so far as my experience extends, and from observation, I am satisfied that subsoil ploughing will prove beneficial only in strong clay and prairie lands, and upon light and sandy soils will prove injurious.

My mode of cultivating cotton is to bed up with turning-ploughs, in January or February, 3 or 4 inches deep, 5 feet rows on bottom land, and 4 feet on upland. At planting-time, 10th to last of March, sweep the top of the bed with a broad sweep; follow the sweep with a heavy harrow on the bed; then open the bed with a small, light scooter-plough; sow the seed moderately thin; cover the seed with a light harrow. In the first ploughing of the young cotton, commence in the centre or middle of the row with a turning-plough, and turn to the centre, forming a bed between the drills, until the young cotton is scraped; second ploughing with the turning-plough, commence near the drill, raising the bed as much as the cotton will permit; third ploughing, run one furrow on each side of the drill, still raising the bed, and finish the row with shovels; then harrow and sweep the residue of the season alternately, as may be necessary.

The object of bedding up the land in January or February is, that it may settle down by planting-time to an ordinary firmness, so that chilling winds, cold dews, and the rays of the sun will not penetrate so deep about the roots of the plants and kill them, as is frequently the case, when the earth is light and fresh at the time of planting.

Cotton should not be ploughed after the 20th June, if it can be avoided, as it shoots out many small fibrous roots; and to plough deep and cut its roots after it commences forming and maturing, will cause it to drop its forms, check its growth, and seriously damage the plant.

Boll and Army Worms.—Some experiments have been made, and several things recommended as preventives against the army and boll worms; but none has as yet proved effectual. From observation, I have discovered that the army-worm makes its appearance about the farm first, in the shape of the *grass-worm*, as it is called, and generally at particular points on the lowest basins, hollows, or levels; from that it spreads over the farm, maturing usually two generations, by which time they will generally consume the grass. They next appear on the cotton, at particular points, as on the grass, if the season is favorable for their production; but if it be dry or showery, and a change occurs about the time of their coming to maturity, from wet to dry, or from dry to wet, it destroys them. If, however, they so mature as to commence on the cotton, no change of weather will then affect them until they consume it entirely; the cotton protecting them effectually against all changes of weather.

The worm is deposited on the cotton-leaf, by a small bug, or light brown-fly, (resembling the ordinary candle-fly,) at twilight, in the evening, and morning, a live, kicking mote of a worm, and commences its ravages immediately, attains its growth in 10 or 12 days, furls itself up in the leaf, and forms a chrysalis, from which a fly hatches out in 9 or 10 days, and commences depositing the little eggs again.

I this season, having noted the points in my farm where the worm usually first assails the cotton, had torch-fires raised on stumps and other places, elevated a little above the cotton, in a circle or line about these points, to burn from twilight to full dark at night. I noticed that great numbers were singed down by the torches, while the grass-worm was consuming the grass. My cotton has not been touched by the army-worm, and very slightly by the boll-worm, this season: but I would here remark, that plantations around mine, where no fires were raised, have also escaped the ra-

vages of the army-worm this season, though more injured by the boll-worm, than mine. The antidote this year has been, I conclude, in the dry season, commencing about the time the worm usually quits the grass and assails the cotton. I am, however, still of opinion that the use of torch-lights about the points and at the time designated will prove beneficial to farms, not only against the boll-worms, but many other insects that damage the crops to a great extent. There is scarcely any kind of insect injurious to plants, grain, or any other crop, that is not in the form of a fly or bug, between the 20th June and 1st of August. All are attracted by fire-light at that season of the year, and will hop or fly into the fire when near it, and thus be singed down and destroyed. In support of the position here assumed, I will cite two or three small experiments upon insects that have proved effectual preventives, to wit: the carrying of a pan of fire or large torch, at parallel lines near the surface, slowly through a garden or turnip-field at night, while the plants are small and being devoured by a small black bug that most persons are familiar with, will so consume the bugs by their hopping into the fire, as to relieve the young plants entirely.

I this year tried the torch in my smoke-house, by passing it at night, once a week, between my ranges of bacon as it was hanging, and succeeded beyond my expectation, in clearing it of skipper-flies, and bugs, and their effects—*it should be commenced early in the spring.*

I have also exterminated the fleas about my barn-yard, by having a number of small fires made on the ground about the yard, into which they hop at night. These uses of fire should be attended, or superintended, with due care. I shall continue the experiment about my cotton fields until I am satisfied of the effect. This I conclude will be but a partial and limited preventive, until a general and simultaneous effort is made throughout the whole cotton-growing region; as I well recollect how rapidly the worm spread when it first made its appearance.

Corn.—The most esteemed variety in this section of the country is the white, long-grained gourd-seed, as it is called. Average production of upland 15 to 20 bushels per acre; bottom land, 25 to 30 bushels. Cost of production per bushel, 50 cents.

Manure.—Little is done or attempted in this country in the way of manuring. The principal reason is, that the grants of lands, as made by the French, British, Spanish, and first land sales here by the American government, were of large tracts. The holding of large bodies of land encouraged the planters to plant extensive crops of cotton, making heavy crops of which gives the planter no time to manure. As his land becomes exhausted by cultivation, he clears more, rather than manure. Holding large tracts, as most planters do, the only efforts made to renovate the lands reduced by cultivation are to change the cultivation occasionally from cotton to corn, and to rest portions. Cotton-seed is used as a manure, but is frequently poorly managed, and with but ordinary success; it is an excellent fertilizer, if properly applied and well managed. The proper method of using cotton-seed as a manure, is to sow it down on the land in January, 20 to 30 bushels to the acre, and plough it under: thus the seed will be sufficiently decomposed to give support to the crop as soon as the grain gets up; thus the support is gradually attained by the expansion of the roots of the plant, until it is matured, and the crop is not injured by too great heat in the decomposition of the manure or seed. Cotton-seed, when applied on the hill, as many do, if the season proves drier than usual, either fails to decompose, or produces so much heat as rather to injure the crop than benefit it. On the hill, it only gives a good crop in very fine and uniform seasons.

Plaster and Lime.—I have used plaster two seasons, by dropping an ordinary spoonful on the hill of corn when two or three blades high. I believe it paid me about 25 per cent. above what the land would otherwise have produced. I also, with a view to a preventive against worms in the ground, soaked my seed-corn in strong copperas-water, 1½ to 2 pounds to the bushel, 18 to 24 hours immediately before planting; I then rolled the grain in lime. As the result of this experiment, I will say that I never saw corn come up better, or look better; and I think this an effectual preventive against all insects, such as ants, woodlice, worms, &c., that assail the seed in the ground.

Sweet Potatoes.—Average yield per acre, 150 bushels; cost of production per bushel, 20 cents. The *red* are most prolific and profitable to feed to stock; the *yam* and *Spanish* are best to keep, and for family use.

The best mode of manuring and culture for sweet potatoes, upon old land, is to rake up trash, straw, and leaves, in the forest bordering upon the farm, haul them in carts or wagons, and spead them in lots intended for potatoes 3 or 4 inches deep. Keep and feed cattle on them in the early part of the winter, until the straw and leaves are trod to small particles; then take the cattle off, plough the matter under, and let it lie until spring. Plant in April, run the ground off at 3½ feet, turn it up into beds with turning-ploughs, draw up one side of the bed with hoes, make chops with the corner of the hoe on the bed, at about 8 inches apart, drop two cuts of the potato in each chop, draw up the opposite side of the bed with hoes, and cover the potato. When they require working, plough the bed down, turning the earth off to about 6 inches, that is, leaving 6 inches of the line as the potatoes stand, and scrape the grass off with the hoes. In 10 or 15 days after plough the earth up to the bed again, and draw the earth with the hoes up to the bunch, barely leaving the bud or top clear. They will then require no more working until ready to dig. The last-mentioned mode of manuring is preferable, in this climate, for all root crops and all varieties of vines.

Cattle.—Upon the pine region of south-east Mississippi, covering about eight counties of Mississippi, two parishes in Louisiana, and two counties of Alabama bordering upon Mississippi, forming a square of about 200 miles, there have been raised, I suppose, for 20 years past, one million head of cattle yearly. The beef is sold, at 3 to 4 years old, from $10 to $12 per head. There has been considerable falling off in numbers for a few years past, and some degeneracy in the stock, by reason of the winter range being overstocked, and, to some extent, exhausted.

Sheep and Wool.—Throughout the pine region, as before referred to, sheep are as healthy and prolific as in any other climate, and the various breeds yield wool as well. They require no feed, summer or winter; the winter herbage and evergreen shrubbery are as abundant in winter as in summer. With all these advantages, there are but small flocks of sheep kept, barely for domestic or family use. The Merino and Saxony are preferred for wool, and the Southdown for mutton. No effort is made here, as yet, to improve the breeds, or to grow wool for market. The business will, I think, soon be commenced, and be pursued with energy and profit. The pine region is a high, dry, open country, thickly coated with grass, herbage, and interspersed with spots and strips of shrubbery; it is very sparsely settled, and abundantly watered by springs, branches, and small rivers of the best water, perhaps, in the world; all that can be desired for wool-growing extensively. I know of no reason why this scope of country should not grow two millions of sheep, as well as one million and a half of cattle.

You will perceive that little improvement is made at the South in agricultural pursuits generally; some reasons for which I have referred to. A much greater variety of crops may be profitably produced than now is, as I have seen fair experiments made in rice, flax, tobacco, (Havana cigar,) indigo, &c. But cotton and sugar are the all-engrossing articles that supersede almost every thing else.

Supposing that it is as much the object of your inquiries to ascertain the prospective resources of the country to some extent, and the manner of culture and present production, I have written, on some points, at greater length than on others. I would here further remark, that there is a great want of facilities for markets to encourage the development of the resources and productions of this part of the country.

Very respectfully, your ob't serv't,

EBEN'R FORD.

HON. THOS. EWBANK,

Commissioner of Patents.

Edwards County, Mississippi, September 6th, 1850.

Sir:—In compliance with your request, I will endeavor to give you as faithful an account as lies in my power, of the agricultural interest of this State.

I will take your queries *seriatim;* and, passing by those to which I can give no satisfactory reply, will give the results of my own observation, or of my friends and correspondents. And I would here remark, that I may be thought to give preference to some things when not deserving, and to detract from others their just due. I confess myself liable to err; but, as I write for myself, I must freely give my own convictions.

Oats.—I have used the *ruffled, black,* and *Egyptian* varieties. The last I prefer, on account of being able to sow in the fall, and even without the land being ploughed. These oats give a good feed to hogs and milk-cows during the winter, without injury to the crop, if not stocked too close, nor stock permitted to feed during wet weather to cut up the land. If oats be cut high, so as to give but little straw, cut when barely turning, and then passed through the cutting-box, they make an excellent food for stock; but I am not so much pleased with them as formerly, thinking work-horses suffer from the distension of the stomach, thus encroaching upon capacity of chest. I have never used oats alone, nor are we, in this country, in the habit of noticing the yield. Not so much sown this year as usual.

Indian Corn.—I have planted many varieties; but prefer a kind between the flint and gourd-seed for feeding, and for yield of nutrition; for I think the same measure and, perhaps, even weight of gourd-seed possesses most of the covering of the grain, which is not nutritious. The shuck is better food for work-horses than the blade, weight for weight. This is merely conjecture, however, and I act upon it by cutting up my shucks with the blades. We are too negligent, in this country, to make accurate experiments about these matters. I prefer grinding and cooking grain for hogs when fattening, having practised it for years. I rate the saving at one-third.

The corn crop will be larger this year than last, yet there are portions where it will not be an average one. The scarcity of the crop of 1849 has caused 9 planters out of 10 in Middle Mississippi to go to the corn-fields in August. This will cause a demand for corn in 1851.

Hay.—The planters of Mississippi use the blades of corn, called in the South *corn-fodder*, in lieu of hay. There has been a larger quantity saved this year than usual. I have saved over 700 bundles per hand, with a good load of forage per hand, consisting of native grass, millet grass, and corn cut up when a little past the roasting ear. I save more provender than an average. Estimating my fodder at 1¼ pounds per bundle, which, when I have sold, I have found it to average, and a load of forage equal to a load of fodder, and I have saved nearly 2500 pounds per hand. This, say 1¼ tons per hand, would give to Mississippi, counting only negroes as laborers, at 100,000 field hands, 125,000 tons. In 1848, taxes were paid on 271,052 slaves. No returns have ever done justice to the *hay* crop of Mississippi.

Cotton.—This is our reliable crop: but, for several years, the seasons and the army and ball worms have become so unfavorable, that it has become very uncertain how to calculate. In 1846–48, and '49, my crops averaged about 6 bales, in 1847, 9 bales per hand—over a bale per acre. This year I do not expect over 1000 pounds per acre—about 6 bales per hand. I think the crop of Mississippi for 1850 will fall short of the last, and, instead of making 500 or 600 thousand bales, I cannot place the crop over 450 thousand, and it is very probable it will not exceed 350 to 400 thousand. Much of the crop looks well, and, to the inexperienced or the hopeful, there appears the prospect of a fair crop.

Last year, I expressed the opinion that the whole crop of the United States would be 2,000,000 of bales, not to exceed 2,200,000, nor to fall under 1,800,000. The result has well sustained that opinion. Again, I venture my opinion for 1850; yet saying the information is so contradictory between private letters and newspapers, that I am less sanguine than usual. Were I wholly ignorant of the peculiarities of the plant and of planters, I should incline to place this crop one with that of 1849. But I know of much cotton planted over in April, May, and even in June. I know the season was worse here than in 1849; I know there was more replanted (seed planted, where the stand was too good to plough up, and not a full stand either,) than I ever knew before; and I know, from my own fields, that replant cotton, and that in May and June, looks so well that it will deceive. And, besides, the very late fall last year gave a great advantage to the short crop of 1849: for there was no killing frost until 3d December; whereas I have known a severe frost 5th of October. Taking all these things into view, I place the crop of 1850 at 200,000 bales less than that of last year. The improved seed now planted will add materially to the grand total; and, owing to that, I may be mistaken in my estimate. For instance: I have about 40 acres planted with Mexican seed; if all my crop had been so planted, and all yield equal to this, I should not count over 800 pounds per acre, and really think 700 would be nearer the mark. My crop is always open to inspection; I procure the best seed of each variety, and am willing to send "for persons and papers," and submit the case to a jury of all the cotton-planters. Of the many who have seen my crops for 4 years, there is not one, I think, who doubts that upon best land my select seed yields 200 pounds more, and upon poor land nearly 300 pounds; and this year the difference is greater. I do not confine myself to any one variety, nor to that as it turns out from the field. I select yearly, so as to keep up purity, and, when a better seed is sold, I buy a few and try them: if good enough, I adopt.

This brings me to varieties:—1. I name *Sugar-loaf* as the best. I have tested it, grown upon rich and fresh land. Its good qualities are production, early ripening, and easiest of all others to gather. Seed sent to me by Mr. Farmer, Last Chance, Miss. I have grown five crops and selected seed from the field four years, and shall do so this year. I have always grown it upon rich land, and was so much pleased with the first year, that I resolved to improve on it, and, if it held its own, to adopt it as the main crop for this place. I think it has improved, as is shown by general resemblance.

2. The next in value for production is the *Banana*. Seed procured from David Gibson, Vicksburg, Mississippi. Maturing and picking qualities yet to be tested, as this is my first year.

3. The *Brown* stands next, and, upon rich and fresh land, it should stand second. This variety is the only one that has been placed equal, or superior to *Sugar-loaf*, by many of my friends living in the east part of Hinds County. I have tried the *Brown* cotton three years, and am sure any person would give it here, at this time, a good character, but not an equal or a superior to my pet, side by side, as it now stands.

The resemblance between Nos. 1 and 3 is close, but the *Sugar-loaf* has less leaf, smaller, rounder, and thinner-hulled bolls, and matures earlier.

4. *Vick's 100-seed.*—I have this variety 4 or 5 years, and up to this period it has stood next to No. 1, and give it richer land, a year or two more age, and it will equal it. This year, upon the same plat of land as the above three varieties, it has fallen back, making too much wood. This may be caused by all my seed being fresh from Deer Creek, where Colonel H. W. Vick, the spirited selecter of this variety, plants. I sold out all my own seed, with the view of getting a fresh stock, which was a damage to my general crop: fresh seed never has here given so good a crop.

I have the Hagner seed planted here; it has been selected two years. It was originally procured from W. H. Prout, of Tuscumbia, Alabama, who sells it under the name of *Cluster*. The *Cluster* procured by myself from Prout is nothing better, if as good as the above.

I have learned from Mr. Prout, that he procured his first seed from Georgia, Hancock County, I think, but this matters not; he has introduced seed extensively as Cluster. William Hagner, of Warren County, Mississippi, his brother-in-law, got his seed from W. H. Prout, of Tuscumbia, Alabama, and having quit planting it,—so his neighbor, Mr. Corwin tells me,—I will try and drop the name of *Hagner* cotton.

I now say that the *Cluster*, *Multiflora*, *Moneybush*, and *Royal Cluster*, were all originally from Prout. The *Banana*, I believe, is a better article, but not as above, as I know from his letters from the gentlemen in Georgia, where he had the first start; but yet it is the Cluster. The *Pomegranate*, General Mitchell avers to me, is not of the above, and that he has produced it by crossing. I say, after examining 50 acres or more, it is the same as the above, only improved very much by selection. I would prefer the character of a careful, patient planter, who improves, to that of the producer of new seed; but every man to his liking. The *Pomegranate* is more defined as a variety than the *Banana*, *Royal Cluster*, or *Multiflora* is here. How it would do on this soil, I know not, which is the only way to truly ascertain the difference; because General M.'s land, like most of Warren County, is peculiar to growing all cotton with short joints, much the reverse of this place, in the swamp of Big Black. The *Multiflora* is more free from the green seed than any I have yet ginned. The *Banana* is here for the first time.

I feel assured that your readers in the cotton region will not complain at the length of this, as I am known to be more devoted to experimenting with seed than almost any other person. I therefore make no apology.

Peas.—In my anxiety to get to cotton, I overlooked this article of Southern culture. Peas are mostly cultivated for stock-feed, and many think them equal to an ordinary crop of corn. They will fatten all stock as quickly as corn. I only use them as an improver of the soil, though I will fatten my *pork* hogs in my pea-field; no other stock will be allowed free access. The pea-vine, when well cured, makes a superior feed to fodder, but how much, pound for pound, I know not.

Peas seldom sell at less than $1 per bushel. Last year, they sold at that price, I think. We plant, most generally, the *Tory* pea. It being more hardy, and less liable to rot, it will lie on the earth all the year and vegetate. I am now trying a new variety, that is, new to me, the *Shinney* pea. Thus far I am pleased with it, as it is now bearing, whereas the *Tory* pea, though planted a month and a half earlier, and making double the vine, has scarcely bloomed. But with me the crop of peas is secondary, and I prefer the vine, if I only get enough peas to be able to gather seed without too much labor.

Root crops.—We only plant the many articles embraced under the head of root crops, for table use,—therefore in small quantities. The Irish and sweet potatoes being the only exceptions. The Irish potato was better and larger this year, generally, than I ever saw it before. The sweet potato, I think, is not as good as usual; in my own case, and in my neighborhood, it is a poor crop, though I have more planted than usual. We grow usually about 200 bushels per acre, though some planters claim 500 bushels. I have never seen an instance of 500 bushels being produced on an acre.

Our season for the year was one of extremes—very cool in April, so much so that I planted no cotton until the middle of that month. Then, heavy rains, with occasional very dry weather of short duration. June and July, very wet: rainy days, about 20 in each month. Thermometer ranging higher in August than I ever saw before. I have kept a thermometer over 20 years, standing where it now does 10 years, and I never saw it there above 93° until August last, when it rose as high as 98°, and was frequently above 94°.

In consequence of the unfavorable spring, the *fruit* crop was nearly a failure. I have not seen a grown peach on my trees, and I have over 2000. The apple crop is very light, many of them rotting before ripe.

Hoping that such items as I am able to give may prove acceptable to you and your readers, and that thus I may do some little service to the agricultural interest of the country,

I am, with respect, yours, &c.

M. W. PHILIPS.

Woodford County, Kentucky, November 1st, 1850.

Sir:—Viewing the production of sweet potatoes of great importance in the South and West, and believing that they can be produced in many of the Northern States, I have this subject at the head of my report, in order that public attention may be more immediately directed to it. I think that sweet potatoes can be grown wherever the late varieties of Indian corn have have time to mature; at any rate, the experiment is worth the trying on a small scale, and, if successful, they will be a valuable acquisition to Northern agriculturists.

We plant from the 15th May to 15th June, and harvest when the vines are killed by frost—about the middle of September—giving the potatoes from 3 to 4 months to mature in. I have planted the latter part of June with good results. When we commenced cultivating sweet potatoes, it was for some time a hopeless effort, they producing nothing but small, stringy roots, not worth the trouble of raising. At length, when slack-water navigation was opened on the Kentucky River, we received a small supply of *yams* from the South, a potato so far superior to any before seen here, that renewed and successful attempts were made with this variety. Our previous failures had been attributed to soil and climate, as uncongenial to the sweet potato; and it may have been so with the kinds tried before; but with the yam we have been eminently successful, and challenge to produce larger and better potatoes. As a specimen, I will take my crop the present year. I planted only one-fifth of an acre, which produced 28 bushels—at the rate of 140 bushels per acre. The yield would have been greater but for the drought in the spring, in consequence of which at least one-sixth of the plants perished. Six of the largest potatoes weighed 24½ pounds; six next in size, 23 pounds; six next, 21 pounds. The largest potato weighed 5 pounds; and the average, after taking out the seed-potatoes, was about 1½ pounds. There are several varieties of yams: the long red, the long white Spanish, the turnip-shaped, and the largest and best of all, which has a pale yellow skin, and a deep yellow color when cooked.

The soil for sweet potatoes should be light and rich, and the best system of culture, after the ground has been put in good order, is as follows:—In the first place, a broad deep furrow is made by twice running a large plough; the earth is then thrown back in the furrow, by running the plough first on one side and then on the other, until a ridge is formed, say 18 or 20 inches wide at the base; then, with the hoe, it is ridged up to edge. Another row is now commenced, in the same direction as the first. The rows should be 5 feet apart, measuring from the top of the ridges, which should be about 15 inches high. About the 1st of April, the seed-potatoes are put in the hot-bed to sprout. It is the general practice, when the sprouts are say 8 inches long, to draw them from the bed and plant out; but this practice I have abandoned, and adopted another far better, which is, to take the potatoes carefully from the hot-bed, breaking as few roots as possible; then with a knife cut out the sprout with a small piece of the potato attached to it—if it is no larger than a pea, it will be of great importance in keeping the plant from perishing, and will rapidly increase its growth. The sprouts, as they are taken from the parent stock, are carefully laid in a basket, and sprinkled with water, if the weather is warm and dry. In planting, make a hole with the hand on the top of the ridge, about 4 inches deep, insert the plant, and press the earth to the root. Never wait for a season; but plant when all things are ready, and, if the weather is dry, pour on each plant a pint of water, and repeat the same the next day, if necessary—that is, keep the roots moist until it rains. The common method is to plant 12 inches apart, but I find by experience that, at 18 inches, larger potatoes are produced. After taking off the sprouts that are ready to plant, the potatoes may be put back in the bed, and, if the weather is warm, the sprouts will soon be ready for another planting. As soon as the grass comes up on the ridges it should be scraped off with the hoe, and the loose dirt drawn up to the plants. Before weeding, a small plough should be run between the ridges, taking a part of the base of the ridge, say 3 inches on each side. Afterwards they will require another weeding and dressing, and the tillage is complete.

Irish Potatoes.—Every farmer is so wedded to his own manner of doing things, that it is difficult to divorce him from it. Hence it is that we have no regular system of culture; the principal object is to raise as many potatoes as will serve for family use, and the fertility of our soil always secures us an abundant supply, we having no rot to contend with. We put 6 or 8 bushels of potatoes in a heap, and cover them over, first with straw, and then with 10 or 12 inches of earth, for winter-keeping. On taking them up in the spring, we always find among them young potatoes, from the size of a bullet to that of grape-shot. Observing this led me to *deep planting*, which, during eight years practice, has been attended with success, the size being more uniform and larger than when planted in the ordinary way. Another important matter is, to avoid having too many sprouts in the hill; four sprouts are enough; if more come up, they should be thinned out. I cut my potatoes into small pieces, and, in planting, make furrows 8 or 9 inches and 4 feet apart, put 3 pieces of potato in a place, at 18 inches distance, and cover up deep. They make slow progress in coming up, owing to the exclusion of heat and the distance the sprouts have to grow before reaching the surface; yet they are germinating and forming new potatoes before they come to the light. Chip manure and rotted straw, put in the drills before planting, are the best manure I have yet tried for potatoes.

Cattle and Hogs.—For the want of a market, we are compelled to feed our grain to horses, mules, cattle, and hogs, and thus we realize about 20 cents per bushel for corn, which is a profit of about 100 per cent. on the cost. Our grasses and clover yield about the same profit in live-stock. I think the best method of feeding neat cattle, taking into account the saving in labor, is to feed on the ground with stock corn, that is, corn-fodder and husk, as it is cut and shocked in the field, allowing two hogs to each head of cattle, to feed on the waste, &c. In this way, the expense of houses and sheds, and time in husbanding and hauling manure, is saved. The hogs to be fattened are put in a field of corn, and when it is consumed, they are either put into a fresh field, or corn is husked and carted to them. The field, after the hogs are taken off, is ploughed, and the fertility of the soil by this mode of feeding very much increased. The cost of raising cattle until 3 years old is about $18 per head; the usual price at that age, $24. A good dairy-cow is worth from $24 to $30. A Durham will yield more meat from a given amount of food than the native animal.

Sixty bushels of corn will produce, on an average, 200 lbs. of beef, and 2 hogs (which are allowed to each bullock to feed on the waste) will give 200 lbs. of pork. Supposing 2 bushels of corn to weigh 100 lbs., then 100 lbs. of corn will produce $6\frac{2}{3}$ lbs. of beef, and $6\frac{2}{3}$ lbs. of pork; or, if 1 lb. of beef is equal to 2 lbs. of pork, 2 bushels of corn will produce 10 lbs. of beef, or 20 lbs. of pork.

The use of hay is so limited that but little attention is paid to meadows. Corn-fodder and oats are a general substitute for hay. Clover is a *sine qua non*; blue grass is next in importance. Without clover we could not raise hogs to advantage, it being as profitable a crop as corn, and, at the same time, fertilizing our exhausted lands so effectually, as in three years not only to double the product of grain, but to fit them for the production of hemp.

Corn.—The yield varies from 35 to 100 bushels per acre; the premium crop of 10 acres, awarded at the late Lexington fair, was 185 bushels per acre: 50 bushels is about the general average. The most esteemed variety is the *large white*, between gourd-seed and flint. The cost of production is estimated as follows:

Interest on 20 acres of land, $50 per acre...........................	$60
Cost of cultivation throughout..	80
	140
20 acres, at 50 bushels per acre, 1000 bushels at 14 cents........	$140

or 10 cents per bushel, allowing $2 per acre for stock fodder.

We have no regular system of rotation in crops, but usually cultivate hemp land 4 to 6 years, until it will no longer produce the article; then follows a crop of wheat, then clover, until the land is again fit for hemp. We endeavor to manage so as not to grow the same crop two years in succession on the same field.

Curing Bacon and Hams.—It is all-important that hams and shoulders be well pickled, otherwise the bacon cannot be made good by any process of curing. Before hanging, it should have a sufficient quantity of salt to preserve it, and no more; for if made too salt, all the juiciness, high flavor, and relish are destroyed. Salting in bulk does very well if the weather is favorable, neither too warm nor too cold. If very cold, it will take from 4 to 5 weeks to receive sufficient salt; if warm and damp, 2 to 3 weeks will be long enough. After remaining in bulk 1 or 2 weeks, the meat should be taken up, the old salt taken off, and resalted and bulked again. In thus changing the position, the salt is more uniformly diffused. An indication when the meat is sufficiently salt is, that it loses its rigidity, and will yield to a light pressure of the thumb, the hock becoming pliant and wrinkled. To corn hams in brine is the surest method, especially when the climate is very cold. The saltpetre may be put on before salting, or when it is hung up for smoking, using for each ham or shoulder about a tea-spoonful. If they are sugared, the molasses or sugar should be put on before salting. After the salting process is over, the bacon is hung up and suffered to drip 5 or 6 days before drying commences, which is done in the following manner:—Every morning a small fire is made in the middle of the smoke-house, using hickory wood, which is best, and, if the weather is freezing, the fire should be kept up all day, never suffering the meat to freeze. It should only be discontinued on damp, rainy days, when the bacon is dripping. In March the hams are taken down and put in good, thick cotton bags, then rehung and smoked as before, until the weather becomes warm and dry. It takes $\frac{3}{4}$ of a yard of cotton cloth, sewed up diagonally, to each ham, the hock end foremost, and tied closely at the gammon.

Another method is, after the hams have remained two weeks in salt, to take them out, resalt them, using equal parts of salt and hickory ashes. Sprinkle on the saltpetre, and again put them in bulk for two weeks more, when they are hung up and smoked, after covering the inside of the hams and shoulders with hickory ashes. In either of these methods, the meat should be well sprinkled with Cayenne pepper before salting.

Fruit Culture.—A Remedy for the Yellows on Peach-trees.—The culture of fruit in this section has been much neglected for several reasons—the high price of land, frequent changes in the ownership of landed property, orchards not enhancing the value of land, and, lastly, the spirit of emigration. But the spirit now manifested towards the production of fruits gives assurance that we shall, in a few years, be in the enjoyment of the most delicious fruits our soil and climate are capable of producing. Our farmers know very little about grafting or budding, and are entirely dependent on nurserymen for fruit and ornamental trees. I am indebted to my neighbor, Mr. Christian, for an effectual remedy for what is termed the *yellows* on peach-trees, having tried it for 8 years with complete success. This disease is caused by a grub-worm, about an inch long when full grown, largest at the head and tapering down. It is propagated by a long, slender, dark-colored fly, about the size of a *yellow-jacket*. The eggs are laid at the foot of the tree, in July and August, and, when hatched, the maggot descends and enters between the wood and bark of the roots, on which it feeds, until the leaves turn yellow, and the tree ultimately dies. The remedy or preventive is, to put stable-manure, closely packed, 3 or 4 inches about the trunk of the tree. This should be done in May or June, before the fly lays its eggs. It is a good plan to make small frames of plank, about 6 inches high, to put around the trees and hold the manure, thus keeping it in a compact body. Fresh manure should be applied every spring.

Very respectfully, &c.

BIRD SMITH.

Hon. T. Ewbank, *Commissioner, &c.*

FARMING IN WORCESTER, MASSACHUSETTS.

The Office is indebted to the Hon. John W. Lincoln, of Worcester, for having procured from an excellent practical farmer the following valuable essay:—

Wheat is but little cultivated in Worcester County, nor has it been for many years, as it is considered a very uncertain crop, owing to the blight, or rust, that strikes the straw before the grain has filled.

Many experiments were tried in 1837–8 and 9, to try to reproduce this necessary and useful crop, but I do not recollect of hardly an instance where the experiments succeeded.

Corn.—Indian corn is raised in this county in larger quantities than any other grain. This grain is produced more easily on our light land, and is considered by many to be a profitable crop. On most of this kind of land, from 20 to 50 loads of compost manure are spread on the acre broadcast, instead of being put in the hill, as in former time. The land usually ploughed twice before planting; corn planted in hills, 3 feet apart; seed planted

from the 1st of May to the 15th, and it should be worked out with a horse cultivator between the rows, and hoed each time, the last working to be done before the middle of July; the weeds all to be pulled in August. The average yield on this kind of land is 30 bushels per acre; cost of one-half of the manure taken by the crop, $15; paying carting, spreading manure, cultivating, and hoeing three times, $8; corn fodder against the harvesting, which will well pay. The corn crop, as it is usually cultivated on this kind of land, is not considered a profitable crop, though a remunerating one to a certain extent, as the corn produced in this way, and on this kind of land, will usually pay a reasonable charge for all labor and manure; and, as the manure is not all consumed by the crop of corn, the remainder assists in carrying out a crop of oats and one or two small crops of grass, and then leaves the land in the same low condition it was in before this process was commenced.

Corn is more usually produced in Worcester County, by the grass-growing farmers, for a different purpose than as above described on our more hilly and deeper soils. Corn is considered as one of the very best crops, as the first in a rotation of crops where our best English grasses are to be grown. Much of the land in the county will produce a good crop of hay for from five to eight years, without manure, after a crop of corn and oats, managed in the following manner. After the land has been cropped from six to eight years without manure, it is to be ploughed as soon after the hay harvest is over as may be, so that all the vegetable matter may have the autumn months to decompose in; this ploughing is the better for being shallow, say from three to four inches, as the grass stubble will more readily decompose than when turned under seven inches. In April following, from 40 to 50 loads, of 30 bushels per load, of whole or long manure should be taken from the barn-cellar, (and no farmer should be without one,) and spread evenly on each acre, and ploughed directly under, full seven inches deep. After lying a few days to the sun, this may be worked advantageously with a harrow, when it is in a condition to be planted as before described. Or the same quantity (more is to be preferred) of manure is frequently spread on the grass, about the 10th of May, and then ploughed under full seven inches, the furrows to be rolled with a heavy roller, and harrowed lengthwise of the furrows, and corn planted directly on top of the furrow. In this way, much green grass and stubble as well as manure is carried down to such a depth as will invite the roots of the corn down to where they should go, and the weeds are found much less troublesome than where the manure is near the surface. These furrows are not to be disturbed to their full depth by the plough or cultivator until the last time of hoeing, which is in July, and perhaps not at all, for the corn crop would be better. The majority of our deeply cultivated clay soils will give from 40 to 80 bushels per acre with the above treatment, but the average crop on this kind of land, with the cultivation it usually gets, will not exceed 45 bushels, but leaves the soil in good condition for oats and large grass for from six to nine years.

The most preferable way of feeding this valuable grain, is to grind with the cob, and mix 1 bushel of rye with 2 of corn, and to be used for swine with as many bushels of carrots or other roots, well boiled or steamed, and the meal well mashed in with the boiled roots, and then be permitted to stand 12 hours, with as much salt added as would be used for the like quantity of bread. This feed, in all cases in cold weather, should be fed while moderately warm. Four pounds of this meal, and 3 of roots, will probably make a pound of pork. The meal will cost one and one-fourth cents per pound, and the roots one-half cent per pound, and pork has averaged 6½ cents per pound for the last 5 years: any one of our more enterprising farmers would willingly feed swine in any numbers, and cook the food, for the manure. Corn, fed to cattle, is to be ground and fed raw, formerly from 4 to 6 ears twice a day, to a bullock of good size, that was intended for slaughter, for 3 months, on an average, before slaughtering, to be in good condition when put up from the pasture. This meal is used now with more economy on cut hay or straw, at least for milch-cows, horses, and working oxen, especially when the fodder is not of first rate-quality. It has been questioned by some whether it pays the labor for all kinds of stock.

Oats are cultivated on any of our soils that will produce corn, potatoes, or carrots; follow corn best, two bushels per acre on well-tilled land, and more on a poorer soil. Usual time of sowing is in April, or as soon as the land can be worked; later sowed oats will make more straw, but less grain, average crop is 35 bushels per acre. Oats are considered the best feed for road horses, and good for all other stock; they are not considered a great exhauster of the soil, and leave the land in fine condition for clover, which crop usually follows.

Barley has been considered a profitable crop, but for the last 4 or 5 years it has not done well, and has very much gone out of use; average crop in former years was 30 bushels per acre, fed principally to swine; usual time of sowing, from the 1st of May to the 15th of June: it has usually followed corn, and left the land in fine condition for grass.

Rye is cultivated but little, chiefly on worn-out pastures, or for one crop with grass seeds on newly cleaned land; it is considered a great exhauster of land; cultivated exclusively for home consumption, and is used principally as a mixed feed with corn, and is considered equal to corn for swine, when mixed in equal parts; average yield on old pasture land, 12 bushels, new land, 25 bushels per acre: average price in our market, 88 cents per bushel.

Peas and Beans are not cultivated to any extent in the county; field-beans are produced in moderate quantities, for table use, but not for market. Peas are seldom grown out of the kitchen garden.

Clover, timothy, and red-top are sown together, with oats or barley; 12 pounds of clover, one peck of timothy, and half bushel of red-top, per acre, on land of medium quality; more should be used if the land be poor, and less, if in a high condition, for this way clover predominates the first year, and averages from 2 to 3 tons per acre; clover is considered good hay for milch-cows, and young stock; average price, $9 per ton; timothy and red-top prevail the second year, and hold good during the time the field is to grass, which is usually from 6 to 9 years; average per acre, 3000 pounds. These are considered decidedly the best and most profitable grasses cultivated in the county. It is believed there is no crop that pays so well for the labor, and returns so much in way of manure. Average price is $12 per ton at the barn.

Dairy Husbandry.—Considerable attention is paid to this branch of business. Cows for the dairy have been much improved within the last 10 years; many cows may now be found that will produce from 10 to 15 pounds of butter per week, for two or three months, on grass alone; but no farmer has a whole herd of such cows: where we have one such cow, we have six that do not produce more than 9 pounds per week for the same time. One class of our farmers say in theory, that the Ayrshire or Durhams are the greatest producers; in practice, the other adopts the native, because he happens to have one of them, or a whole herd on his farm, or, more likely, because he has not thought on the subject at all. Our good cows are mostly cows of accident. These things ought not so to be. There are some honorable exceptions, however, among some of our most liberal and intelligent farmers. The Ayrshire stock, in a few instances, being introduced, and, it is believed, though experiments will be carried out, to prove very beneficial to the dairying farmers of the county. The Ayrshire seems well adapted to this part of the country, much more so than the Durhams, and they are destined, ere long, to take the place of any and all other breeds for the dairy.

The North Devons have recently been introduced here, and it is believed that no other cattle can excel them for the yoke, or early beef, but are not considered deep milkers. Great credit is due to the Massachusetts Society for Promoting Agriculture, for the introduction of the Ayrshire and North Devon, a bull and cow of each of these breeds having been presented to our county society from their importation, and there is no doubt but great good will result from their universality. Butter is manufactured in the north part of the county, and milk is produced in the south and east, for the Boston and Providence markets; milk at the farms here is worth, for these markets, 2 cents per quart for eight months, and 3 cents for the remaining four months. Average quantity per cow is 7 quarts per day for 10 months, or about $50 per year; and for butter, 8 quarts of milk for a pound of butter; average price of butter, 20 cents per pound: in either case our cows pay $50 per year; where butter is manufactured, the waste milk for swine or other purposes covers all cost of labor in its manufacture.

It is believed that to manufacture our milk into butter, instead of sending it to market at the above prices, would prove more profitable to the farmers of the county, first, because the waste milk goes far towards growing and fattening swine, and in all cases where suitable help can be obtained at fair prices, or, more fortunately, where the farmer's wife or daughters can personally attend to its manufacture, it is believed that the waste milk very much more than pays for all labor; besides, the economy of feeding swine with this milk causes the farmer to feed double the number of swine that his neighbor does that sends his milk to market; hence the difference in the manure heap. Good cows should be the first object for the dairy. The difference in cows for butter is not generally understood: good keep and cleanliness are indispensable when we want good cows. Milk should be strained in tin pans, and, with the exception of the extreme cold of winter and heat of summer, should be kept on the ground-floor of the house, in a room fitted up expressly for the purpose, well ventilated, and far removed from pig-sty or kitchen; the milk to stand from 24 to 40 hours, according to the weather, the cream taken off into stoneware vessels, and churned while fresh; the process should not be rapid, as the butter does not separate from the milk so well as when from 45 to 60 minutes are occupied in churning. When removed from the churn, the buttermilk should be worked out, and one ounce of the best pulverised rock-salt worked in—should stand 24 hours, and then all the buttermilk should be worked out, and lumped or packed in stone pots, where it may be kept for 8 or 12 months. Butter of this description is worth, on an average, 23 cents, while butter from the same cream, that is manufactured in a careless way, say where 2 oz. of salt are used, and 2 oz. of buttermilk are left in, will bring but 17 cents, and is worth but 14; hence the difference: the one that produces the good from the same materials, realizes from each cow his $60 per year, when his neighbor, that makes the poor, gets but $40; and all this difference in merely working and salting the article.

Neat Cattle.—Fifty per cent. of all our cattle are raised in the county, and the other half are driven in principally from Vermont, Maine, and New Hampshire. This foreign stock is purchased late in autumn, principally for the purpose of consuming the poorer sorts of fodder, and to be grazed in summer, and used to supply our markets with early beef. The best farmers select their best calves for raising: the usual way has been to take them from the cow at 3 days old, and teach them to drink milk; new milk is given until 4 weeks old, and skimmed milk continued until 10 or 12 weeks, when they are turned out to pasture, which practice is considered more judicious than to let them have a run with the cow, as it is considered injurious to the cow to be teased by them for so long a time, and not so well for the calf. Heifers are not permitted to come in until about 3 years old; steers are broken to the yoke at 2 and 3 years old; cost of keeping to this age is $25. Steers and heifers that are raised in this way are always in demand, and sell, for the yoke or dairy, 25 per cent. higher than foreign, or those from other States. Steers, well broken to the yoke at 3 years old, if well matched, sell for from $75 to $100. Heifers, at this age, with a calf at their side, sell for from $30 to $40, such as are raised at home, and those from other States for 25 per cent. less. Our Agricultural Society have offered large premiums for all kinds of stock raised in the county, which has stimulated our farmers to select the very best calves from the best cows for the dairy and the yoke. Much attention has been paid to the training of oxen for all purposes of agriculture, especially for the plough and cart, and it is believed that more well-matched and well-trained oxen are to be found in Worcester County than in any other section of the country.

The question is asked, which will yield the greatest amount of meat from a given amount of food—the Durham, Devon, or Hereford? The Durham is considered too large for profitable feeding; a cross with our native is preferred, as the animal matures one year earlier than the full-blood Durham. The beef of the half-blood is as well marbled at 4 years old as in the full-blood at 5, and it is considered more profitable with us to feed the grade than full-blood. Young cattle, from 2 to 4 years old, that are in good condition the first of May, are turned into our sweet pastures, and are fit for our markets in August, before the western and northern beef comes in, pay much better than larger and older cattle that depend on winter-stalling and consume much grain, which is quite too costly for this section, and the beef is worth but little more per pound than the grass-fed, which goes into market early. The North Devons have but recently been introduced into the county. Two animals of this breed, a male and female, were presented to the Worcester County Agricultural Society by the Massachusetts Society for the Promotion of Agriculture. These animals are of pure blood, from the importation of the Massachusetts society in 1846, and it may fairly be presumed that the experiment of a cross with our natives will greatly improve our stock, at least for the yoke and grazing. No pure-blood Herefords have as yet been brought into the county.

Sheep are not kept, to any extent, nor have they been for the last twenty years. Small flocks of the middle-wool sheep are kept, for producing early lambs for the June and July markets. Lambs fit for market at this season sell for from $2 to $3, and are considered profitable by those who have conveniences for keeping sheep.

Hogs.—25 per cent. less of hogs are now kept than ten years ago. Hogs are not considered profitable, as the grain raised on the farm is wanted for feeding to cows, to supply our markets with milk, and consequently we do not have the wash of the dairy, as in former times, which greatly aided in feeding our swine, and increasing our manure heaps.

The Suffolk, crossed with our best native, is considered the best for all purposes. Some inquiries are being made, to know if pork cannot be made without a loss on corn brought into our markets from the South and West, and which usually costs at our door $1\frac{3}{8}$ of a cent for good; strong shoats usually cost, the first of May, 5 cents per pound. Fresh pork is worth, on an average, $6\frac{1}{2}$ cents per pound the first of October; shoats bought the first of May, weighing 100 pounds, will consume 5 pounds of corn-meal per day for 5 months, and, if well cared for, will gain, on the above feed, $1\frac{1}{2}$ of a pound per day. From each hog, if properly managed, one cord of good manure can be made, which, in our market, is worth $4; this should go against all work for tending.

Best method of curing bacon and hams, put two quarts of butter-salt into an iron kettle, and place it over a slow fire, and stir it occasionally, so that it does not bake in the kettle; and while the salt is dissolving, the ham should be placed on a strong bench near the fire, and a common-sized tea-spoonful of saltpetre to be rubbed smoothly with the hand on the flesh-side of the ham; it will soon dissolve and disappear. The salt in the kettle is now hot; lay a table-spoonful on the ham, and rub it with the hand; continue to apply the salt to all parts of the ham until the ham *sweats*, which is an indication that the salt has penetrated through the ham. The above quantity of saltpetre is for a ham of 20 lbs.; a ham of this weight may be cured in 10 minutes; the ham may be thus treated before the animal heat is entirely out, and it is fit for the smoke-house, where it will be ready for use in 10 days, or it may remain with perfect safety for a year, or longer, before being used; the smoke-house is the safest place for keeping. Any lover of good ham, after trying this method, will be satisfied that it is the best method; certainly for family use, as it can be kept the year through.

Hemp is not cultivated, nor has it been for the last 25 years.

Root Crops.—Seventy-five per cent. more of turnips, carrots, and beets are now grown than 10 years ago.

Turnips.—The round flat for field culture have, in former years, been cultivated with our corn crop—1 pound of seed per acre is sown broadcast at the last dressing or hoeing of corn, which usually takes place the first part of July. No other attention or labor is required until harvest: from 100 to 200 bushels are gathered in this way. More recently, waste lands are broken up for the purpose of reseeding, and permitted to be summer-tilled without any other crop, until the last of June, and, at any time before the 1st of August, to be well manured, and seed as above sown and covered with a bush-harrow: from 300 to 500 bushels have been harvested in this way. This crop is not considered a great exhauster, and is worth, for stock to consume at home, $12\frac{1}{2}$ cents per bushel, fed principally to dry stock, while consuming the poor fodder. Seed should be imported from England or Scotland once in 3 years at least.

Carrots are grown in any kind of land that is favorable for corn—a deep, mellow loam is preferred. The land should have been used 1 year, at least, for corn or some other like crop, until the sod is completely rotted, and then manured liberally and ploughed to the depth of 10 or 12 inches; and if subsoiled, all the better: this should be done as early as the ground and weather will permit, generally as soon as the 1st of May. The ground should be deeply and thoroughly ploughed once or twice a week up to the time of sowing the seed; the land, as soon as in condition to take the seed, should be levelled with a bush-harrow, and 1 pound of seed to the acre is sown in drills with a common seed-sower, 15 inches apart. The wheel of this seed-sower shows the time on which the seed is dropped, and a light hoe should be passed between the rows before the young plant makes its appearance; by this process, the weeds are kept back and the land kept light; weeds in no case should be permitted to get the start of the plant. The hoeing and weeding should all be done while the sun shines. From 500 to 1000 bushels per acre have been produced, and this valuable crop is coming much into favor with our farmers. Ten dollars per ton is considered a fair price; feed principally to horses, milch-cows, and, more recently, to hogs. Carrots have been raised for several consecutive years on the same land, and apparently with better success than the first or second year.

The *mangold wurtzel* and *sugar-beet* have been cultivated for quite a number of years with considerable success: from 700 to 900 bushels to the acre have been raised; the land to be treated the same as for carrots. Worth from 17 to 20 cents; fed principally to milch-cows; 25 per cent. less of these roots have been raised for the last two years, on account of a blast that has struck the leaf before the root had matured.

Irish Potatoes.—Fifty per cent. less of this once valuable tuber was secured the present season; the vines looked remarkably well until about the 8th day of September, at which time we had a heavy fall of rain, and immediately after this, the vines had the same appearance that they usually do after a heavy frost; and, at harvest-time, the vines had nearly disappeared by decay, and nearly one-half of the potatoes were in a decayed state, and this decay has continued after housing, so that, at this time, 25 per cent. of what were saved at harvest-time are now lost.

Fruit culture is receiving increased attention in our county; young orchards of the most approved kind, principally winter fruit, are being planted out in large numbers, and much care and attention are now being paid to grafting all of the more hardy trees that have produced less valuable fruit. The Baldwin apple is receiving the most attention, and next the Rhode Island Greening; the Golden Russet and Roxbury Russet are considered the best varieties for market. High land, with a clay subsoil and a gradual descent to the east or north-west, is to be preferred; before setting out the trees the land should have been cultivated with corn or some other hoed crop, for at least one year. The young trees should be at least of 5 years' growth from the bud, straight and thrifty, and set not less than 35 feet distant in straight rows; the holes should be dug of a circular form, not less than from 6 to 8 feet in diameter, and 18 inches deep. Fine dry topsoil should be used to fill the hole; the roots of the tree to be nicely arranged and brought out in straight lines; from 1 to 2 bushels of bones may be used in filling the hole; whole ones are to be preferred, or at least they should

not be ground very fine, as the glutinous and limy qualities of the bone would be taken up too rapidly by the young tree; care should be taken that the tree should stand as near the surface as it can with safety; no staking or propping should be used; early in November earth should be placed about the trunk of the tree, which tends greatly to keep it in place during the winter months, and should be removed not before the 1st of May, which will prevent the buds from putting out too early.

The land to be kept in constant cultivation by some hoed crop for at least 12 years, or until the tree comes into full bearing. After this, no crop should be suffered to be taken from the land, except the product of the trees. The land must be kept light and free from weeds, either by the plough and cultivator, or by young pigs being confined in the lot during the summer and autumn months up to harvest-time. The latter practice is to be preferred, as all the apples that fall prematurely are taken up as fast as they drop by the pigs; and by this means all the worms, as they fall in the apple, are destroyed. All the worthless apples should be gathered up each day as they fall, to the 20th of September, or until harvest-time, so that no opportunity is left for slugs or worms to make deposits for future time. The unnecessary limbs should be removed several times in each year after the first, the process to commence the 1st of June, and no pruning after the middle of August: the young limbs to be removed, while small, with a sharp pocket-knife. Great care should be taken not to graze or loosen the bark. No one, on any account, should be permitted to step on or into the limbs while pruning or harvesting; care should be taken that not too much nor too little of the top or branches should be taken out at once: if too much, the sun strikes the trunk too hard; if not enough, the useless limbs take too much sap from the trunk. Great care should be taken that the tree does not limb out too low: the lower limbs should be at least high enough to permit a horse to pass under freely, without interfering with the limbs. If the limbs should incline down too much, one or two crops of corn may be grown on the land instead of roots, while the trees are yet young, which crop will cause the young shoots to go up, and by this process the top can and should be made very beautiful, and the better calculated to hold its fruit.

Winter fruit in this section is harvested from the 20th of September to the 10th of October, to be picked from the tree by hand and placed in flour-barrels, the barrels immediately headed up, and to be placed in a cool, dry situation for the first month, and then removed to the cellar or carried to market.

Average price for the Baldwin and other best kinds of winter fruit at our nearest market is $1.75 per barrel; fall apples, 33 cents per bushel. It is believed orchards cared for as above described pay a good interest, while trees scattered here and there in grass land, all over the farm, are worse than nothing. Some attention is being given to growing winter sweet apples. The Danvers Sweeting and Honey Greening keep well through the winter. The Lady Sweeting has but recently been introduced—is said to be a profitable apple.

Apples have not been used for feeding to cattle, but in a limited way. No experiments have been tried with milch-cows or other stock. It is believed that sweet apples will prove very valuable for milch-cows. They have been fed to some extent to hogs, both raw and cooked. Cider for drink has come into disuse, and refuse apples are used for swine, cooked and used with meal. Considerable attention is being paid to setting out peach orchards, and it is thought that peaches of quite as good flavour are produced here as further south. The early crop pays well, while the late crops are not worth cultivating. It is believed the market will be overdone with what trees are already set.

The pear has attracted some attention; orchards of this kind of fruit are now being set, and a countless number of varieties are being experimented on; with what success, after-time must show.

Our native grapes have been greatly improved within a few years, in quantity and quality, by being transplanted from their native forest to the garden and well-cultivated field. Many varieties of the foreign grapes are cultivated (mostly for home use) both in open fields and under glass; bones are considered the best substance that can be used as a manure.

Quinces flourish, perhaps, as well here as in any other section of the country, and have been considered profitable for the market; average price $1.50 per bushel.

Manure.—Fifty per cent. more manure is made and preserved for use now than 10 years ago. Barns are now built with cellars under them. The most convenient plan is to set the barn on a slope or side-hill—facing to the south is to be desired; the cellar to be walled on three sides and open on the other; 9 feet deep, if the land is dry on which the barn is to be set; the floor of the barn should run lengthwise, with stalls for cattle on one side and a deposit for hay on the other: in this way, the droppings of the stock are let down through scuttles into the cellar. In this way, the liquids as well as the solids are all preserved, and held fast until wanted for use. If the land is light and dry where the manure is to be applied, muck or swamp-mud if wet and heavy, loam or sand should be used, and all the waste hay and straw and other vegetable matter that can be collected should be deposited in this cellar, and the whole mass to be composted and worked over when the weather is too wet for out-door labor. The cattle to be kept in the stall all but a short time in the middle of the day in winter, and the cows to stand in over night the year round. Plaster should be sprinkled on the floor each day, and permitted to mingle with the manure below. The manure may be forked over as often as convenient during summer, and perhaps small quantities of lime may be used to advantage, to help decomposition. If the cellar does not get too much filled up, this whole mass should remain in the cellar until a convenient time for using—September is preferred. The cellar is then to be cleaned out and the manure to be ploughed immediately in, to prevent evaporation, where it may remain until the following spring. Hogs are frequently wintered on the compost, and, if properly cared for, will do well and thrive, besides doing much of the labor of mixing these several ingredients.

It is thought that from 37 to 50 per cent. is saved in this way in manure and labor, besides having much spare room for storing roots and housing farming-tools.

So much is thought of the above method of preserving manure from waste by evaporation and wet, that the most of our more thinking farmers are digging cellars under their old barns, rather than be without them.

Plaster is used 50 per cent. less than in former years.

Lime is used but in small quantities for agricultural purposes, as the cost in our markets is quite too high.

Guano has never been used in any great quantity, nor will it be until its market value is lower, and the different quantities are better understood by our common farmers. Guano may yet successfully compete with other manures; much every way may be done by our national government in securing and preserving the trade in this valuable article.

It is confidently hoped that the Agricultural Bureau, at Washington, will seasonably look to this matter.

Sutton, February 7th, 1851. HARVEY DODGE.

Hon. Thomas Ewbank,
Commissioner of Patents.

South Union, Kentucky, December 28th, 1850.

Sir:—Below you will find such answers to the inquiries from the Patent Office, on the sheep husbandry of this district, as our limited means for information will permit us to give. Answer 1st. The prevailing breed of sheep in this district is the common native, with the exception of some of the best flocks, which have crosses of the Merino, Saxon, Cotswold, and South-down breeds, with some thorough-bred.

2d. Two pounds per head of clean-scoured wool, ready for the manufacturer, are about the usual clip. The Cotswold and their crosses will yield from 4 to 10 pounds suitable for the comb.

3d. The sheep in this district of country are generally healthy and productive in young, the number of lambs being nearly or quite equal to the ewes, though, from the practice of unrestrained intercourse between the sexes and the want of shelter, from 25 to 50 per cent. of the lambs is usually lost during the months of January and February; but it is our practice to keep the bucks from the ewes until about the 20th of October, or 1st of November, so as to have the lambs come in the months of March and April, at which time the ewes can get something green to feed upon—consequently the lambs are more healthy.

4th. Hunger is to be far more dreaded among the native sheep of this region, than all the other diseases combined, excepting the devouring jaws of the dogs. Blooded sheep are not so healthy, the lambs being carried off during the months of August, September, and October, at the rate of from 10 to 50 per cent. by a lingering disease, known probably in the books by the name of pines.

5th. I cannot say the number of sheep is increasing in this district faster than the number of inhabitants—though they may be.

6th. Small farmers make no surplus wool—larger ones dispose of their surplus to the mechanical and non-producing class.

7th. From 50 to 60 cents per head, varying with the different range of neighborhoods, may perhaps be a fair estimate of the cost of keep in this district.

8th. The usual time of foddering is from the latter part of November until some time in March.

9th. The summer feed for sheep is in the wild range of the woods, consisting principally of grass and herbage, in great variety and abundance, of which some flocks get more or less the year round.

10th. Sheep are fed in this section during the winter on corn-fodder, hay, and sheaf-oats, with the addition in severe cold weather of Indian corn. Our flock of sheep, consisting of about 600, will average about 3 pounds of clean-scoured wool per head, about one-half of which is of the Saxon and Merino breeds; the other half, Cotswold, Bakewell, and Southdown crosses on select native sheep. The staple we consider good, and, if the sheep have proper treatment, it is, perhaps, equal to any in the United States. The Saxon and Merino fleece is worth about 30 cents per pound in the dirt, which loses about one-half in scouring. Other kinds vary in price according to grades, and will bring from 30 to 40 cents per pound when scoured.

Your friend,

URBAN E. JOHNS.

Hon. FINIS E. McLEAN,
Washington, D. C.

Great Crossings, Scott County, Kentucky, December 26th, 1850.

Sir:—I have just received your circular, and, as I highly prize the Patent Office Report, will attempt to give you some information upon the desired points, so far as I am able.

Wheat.—Several varieties are used in this neighborhood; the Missouri white, which is ten days earlier than any other, Illinois velvet-chaff, red-chaff, bearded, and Mediterranean. The Missouri white is moderately productive, and makes very fine flour. The Illinois velvet-chaff is a fine, heavy wheat, weighing, in good seasons, 65 pounds per bushel, yielding well, and makes a good article of flour. The Mediterranean is coming into general use; the flour is not so white as some other, and it is not so liable to rust; bears heavy grazing, and yields a fair crop. Average crop on our good lands, about 15 bushels per acre. Time of seeding, from 15th September to 15th October, and of harvest, from 20th June to 10th July. We sow from 4 to 5 pecks to the acre, and without any preparation of seed. Our wheat is generally sown after corn or clover, no regular rotation of crops having been adopted. We cut up and shock the corn, then plough the ground perhaps 3 inches deep, sow the wheat, then harrow, and the work is done. Some sow and plough it in, and do nothing more. Where wheat follows clover, the object is to enrich the land; hence the second crop of clover is allowed to grow, and is then turned under, thus affording a good coat of manure; the wheat is sown on the furrow, harrowed in, and left to grow. We have not been troubled with the Hessian-fly for a number of years, owing, I suppose, to late sowing, which was adopted when they were troublesome.

In order to avoid the white weevil, we get out our grain as soon after harvest as possible, and put it in rail-pens in the chaff, and cover well with straw, which is a certain remedy. Average price per bushel, about 60 cents.

Corn.—This is our great crop. Varieties, the Craig cone-gourd-seed, white flint, and yellow flint. The gourd-seed is supposed to shell the most, while the flint is thought to be the most nourishing. Average produce per acre, 40 to 50 bushels; cost of production, 17 to 20 cents. While the usual yield is as above, still, on highly manured land, an almost incredible yield has been obtained—150 to 175 bushels have been reported. Our lands have been so productive, and our farming operations of such a character, that no effort has been made to ascertain the best system of culture. But

a brighter day is dawning. Western farmers are becoming interested in so arranging their operations as to make the least number of acres yield the greatest number of bushels. Sufficient importance has never yet been attached to preparing the soil. We have generally ploughed our ground only two or three inches deep, then (if for corn) it was laid 4½ feet each way, and planted; but we now have better ploughs than formerly, and plough deeper, and plant our corn nearer, say 4 feet by 2, which is better than the old fashion. I now grind all my corn with the cob, that I feed. I intend to make some experiments with regard to feeding raw and cooked food, and, when I do, will forward you the result. For feeding corn to horses, mules, and cattle, I am fully satisfied that there would be a saving of at least 25 per cent. by grinding it.

Manures.—We rely mostly on small grain (wheat, rye, oats, and clover) for manures: we however occasionally haul the accumulated piles from the stables and barnyards, and scatter on the fields. The usual mode of resuscitating worn-out land, is to sow down with clover, about 6 pounds to the acre, and let it remain three or four years, pasturing it during the summer, and in winter feeding our cattle with the shocked corn or fodder; thus keeping the manure of the cattle, as well as that made by the waste cornstalks, on the ground. In this way, the produce of one field is removed to another, which keeps the land in good heart. I do not know a single farmer who shelters his manure heaps, or attempts to increase the quantity by adding muck, leaves, straw, or any thing else. That made in the usual course of farming, is on rainy days thrown out of the stables, there to remain till some convenient time arrives for drawing it away. All our level lands in Scott, Woodford, Jessamine, Fayette, and Bourbon counties, are capable of producing, when properly managed, 100 bushels of corn to the acre; and the time will come, in my opinion, (if the Union of these States is maintained,) when that will be the average.

Oats were formerly regarded as a very exhausting crop, and not much cultivated; but their excellence as an article of food for horses and mules was not understood. They now occupy a prominent place in every good farmer's rotation. Average yield per acre, 40 to 50 bushels; quantity sown, 1½ bushels per acre. *Barley.*—None raised in this county. Rye was extensively cultivated a few years since, and was highly esteemed as an article of food for horses; it was also esteemed for the fine pasturage it afforded for young stock in fall and spring, but it has become an uncertain crop, and is not much grown. Average yield per acre, 20 to 25 bushels; quantity sown per acre, 5 pecks. Beans and peans not cultivated here. Clover is seldom used in any other way than as a fertilizer, and, if not pastured, is left on the ground to act as a manure. Timothy is the meadow grass of this region. Mode of culture:—The soil is well prepared in August or September, and the seed sown by itself, when we wish to mow the next season. Sometimes it is sown with wheat and rye, or, in the spring, with oats, or on rye and wheat in February and March. Average crop, about 1½ tons per acre. Leached ashes is considered the best manure for timothy.

Butter and Cheese.—The price of butter is from 10 to 20 cents per pound, according to the season. No cheese is made, worth reporting.

Neat Cattle.—I suppose the cost of rearing until 3 years old, to be $15 to $17.50 per head, and the average price about $20 per head. Value of good dairy-cows in spring, from $30 to $50; and in fall, $20 to $30 each. I have no means of ascertaining how many pounds of beef 100 pounds of corn will produce. I believe the general calculation is to feed 50 bushels of corn to the steer during the winter, and that a fair gain is 150 pounds to the bullock. The short-horned Durhams are the favorites in this region; there is not a herd to be found which is not crossed with the Durhams. The Devons and Herefords have not been introduced here.

Sheep.—Some attention has been paid to them. Southdown, Bakewell, Merino, Saxon, and Cotswold, have, at different times, claimed attention. The Cotswold is now the favorite, the coarse wool being generally preferred for the manufacture of jeans and linseys. The Southdowns are the best for mutton, and a cross of the Cotswold upon the Southdown produces a fine carcass, good mutton, and a fair yield of wool. My own opinion is, that upon our lands, that cost from $50 to $60 per acre, wool-growing is not profitable. I think that 6 lbs. wool in the grease (worth 25 cents per lb.) is above the average per head for our flocks to yield, and that would pay only 10 cents per month for keeping. I suppose the number of lambs raised annually to be about ¾ that of the ewes.

Hogs.—The best breed, Woburn crossed with the common hog. They are long and deep, and fatten easily. I am clearly of the opinion that the cheapest way of making pork is to keep hogs always fat, which may be done with a little attention. I suppose 100 lbs. of corn, fed raw, would yield about 20 lbs. pork.

Hemp is next to corn in this part of Kentucky, as a crop; its culture is on the increase. It is a crop that requires good cultivation in order to obtain a good yield. The soil must be well pulverized by ploughing and harrowing before sowing the seed. Average yield, about 6 cwt. per acre. Cost of production, about 3½ cents per pound.

Root Crops.—None raised.

Potatoes.—Irish and sweet are all planted for home consumption. Owing to the peculiarity of the season past, there was almost a failure. Irish potatoes are worth $1 to $1.25 per bushel; the usual price at this season being about 40 cents.

The cultivation of fruit in this neighborhood has received but little attention. The old settlers planted a few seedlings, and turned their attention to farming, and, as the next generation came up, they were satisfied with what their fathers had done in this way; but a "better day is coming." A number of young orchards of good fruit are just coming into bearing. Some of the varieties are Pryor's Red, Jennett, June apple, Bell-flower, Holland Pippin, Newtown Pippin, Northern Spy, Roxbury Russet, Summer Pearmain, Minister, Emperor Alexander, &c. A large number of orchards have just been planted, and there are not trees enough here to supply the demand. Increased attention is paid to the character of the fruit, as well as to the quantity, and we hope to be able, in a few years, to show some good fruit. There is a decided interest, as well as improvement, in the smaller fruit, such as cherries, raspberries, strawberries, gooseberries, currants, &c. Pippins and other good-keeping apples are worth 16⅔ cents per bushel on the tree. Peaches are cultivated to a considerable extent, but the ravages of the worm at the root of the tree, causing early decay, almost discourage our efforts to raise them.

Permit me to say, in closing, that I am so fond of agricultural pursuits, that I introduced a resolution before the board of trustees of Georgetown College, for the appointment of a committee to inquire into the expediency of attaching an agricultural department to that institution. What are

termed the learned professions, are full, and the people begin at last to think that some learning is essential for a man to make of himself a successful agriculturist. I trust that in the wide-spread diffusion of useful knowledge, obtained through the agency of your office, an impulse will be given to the subject that will not be allayed till our fields shall be brought to the highest state of fertility, and until, in every county, associations of intelligent farmers are formed, for the better promotion of the science of agriculture.

Respectfully yours,

Y. R. PITTS.

Victor, Ontario County, N. Y., December 13, 1850.

Sir:—Among many other cultivators of the soil, I have received a circular from the Patent Office, soliciting information upon various points of agriculture, which I shall undertake to answer in the same order that they are found in that document.

Wheat.—Varieties in use, Soule, flint, and the Hutchinson; average, 25 bushels per acre; time of seeding, from the 10th to the 20th September; time of harvesting, from the 10th to the 30th July; preparation of seed—the only usual preparation, is to clear it of all foul seeds and sow it dry; we sow 1½ bushels to the acre; we plough three times, or once, and use the two-wheel cultivator; we plough from 7 to 10 inches deep; the yield per acre is increasing. Our most approved rotation is to sow wheat every third year, and seed with the large red clover each time; the intermediate seasons between the wheat crops, we mow the clover for hay, or use it for pasture. The best remedy for the Hessian-fly is to keep the land rich, and not exhaust it with spring crops, nor sow wheat oftener than once in three years; prepare the land first-rate, sow, in proper season, a moderate quantity of seed, and give it room to produce a large, rank, and vigorous stalk; upon such stalks of wheat the flies can do little or no injury; on the contrary, I have noticed that wheat sown too early in the season, or too late, or upon a poor, half-tilled, half-manured soil, and after spring crops, and where too much seed, by half, is used, would generally have a sickly appearance, a soft and tender leaf and stalk, most easily perforated, and altogether, it turned out to be just the wheat for the Hessian-fly to riot in. We have received about $1.13 this season per bushel.

Corn.—The most esteemed varieties are the Dutton, the eight-rowed yellow, and eight-rowed white. We get, on an average, 40 bushels per acre; cost of production, 8 cents per bushel, exclusive of land-rent. Best system of culture:—Plough the land early in May, harrow it fine; mark for rows, both ways, 3½ feet apart; plant from 5 to 7 grains in each hill; as soon as the corn is fairly up, plaster it with gypsum, ashes, and lime; in a week afterwards, go through with the shovel-plough or one-horse cultivator, two furrows in a row, each way; let a hand follow with a hoe, to uncover the hills that get covered with the plough. At this time it should be examined, and all over four stalks in a hill should be cut out. Corn should be ploughed at least three times, and well ploughed. If land is well broken up in the spring, and well harrowed, the rows run straight, the work of dressing corn can mostly be done with the plough. It is sometimes useful to grind corn for hogs; it would be useless to grind soft corn, but dry hard corn ought to be ground, and, under some circumstances, it is thought to pay well for cooking it; for instance, where animals have been fed a long time, and are pretty fat, then it will do to cook their meal. If the manure made from 20 bushels of corn be well applied, I think it will increase the yield at least 10 bushels.

Oats.—We sow 2 bushels to the acre, and get a yield of 40 bushels.

Barley.—We sow 2 bushels, and an average crop is 30 bushels per acre.

Peas.—I sow 3 bushels per acre, and get about 20.

Beans.—We sow beans in drills 2½ feet apart; 20 quarts is the usual quantity per acre; an average crop is 20 bushels.

Rye.—Those who sow this grain, sow 1½ bushels per acre; they get, on average, 15 bushels per acre. Peas are the least exhausting crop, and are not sown as a renovating crop.

Clover and Grasses.—1½ tons per acre is an average yield. The best fertilizers for meadows are plaster and stable manure. The grass seeds for meadows are red-top, timothy, and clover; we sow from 6 to 8 quarts per acre. The cost of growing, cutting, and stacking hay, including seed and plaster, is $2.50 per ton.

Dairy Husbandry.—In this vicinity, it is thought that cows will produce 150 lbs. of butter per year. It costs about twice as much to make butter as it does cheese. Milk, for butter, is treated something in this way:—It is strained into tin pans about 4 inches deep, and set in a place of the right temperature, where it stands until the cream rises, when it is immediately skimmed, not waiting for the milk to sour, for it is thought that the acidity of the milk destroys or neutralizes a portion of the cream. The cream is churned in the usual way, by agitating it in the churn, keeping it in a place of the right temperature. The point is not yet settled among good butter-makers, whether it is better to churn the milk with the cream, or the cream only; but one thing they all agree in—that is, that the pails, pans, and all articles used about milk should be kept entirely clean. Butter, after it is churned, should be thoroughly worked, to get out all the milk; if this part of the business is not well done, it soon becomes soft and rancid, and is unfit for market. Cows, for making butter, should be kept in good condition, with plenty of green food, be salted often, have plenty of water, and have shade in hot weather, and a good, warm stable in winter, with plenty of roots and other feed. All these things are requisite, both as regards the quality and quantity of butter. The average price of butter has been about 13 cents per pound; for the last season, cheese has brought 6¼ cents.

Neat Cattle.—It costs, at the usual rate charged, $30 to rear a heifer or a steer till three years old. The usual price at that age is $25 for a heifer, and $30 for a steer. The value of a good dairy-cow in the spring is $30, and $25 in the fall. A given amount of food will yield no more meat in a Durham, Devon, or Hereford, than in a native animal, if they are in every other respect equal.

Sheep and Wool.—The growing of wool is not profitable in a grain-growing country. It costs, at the usual rate charged for keeping sheep, 50 cents a pound to grow fine wool, and 45 cents a pound for coarse wool. A ton of hay is worth $7, and will winter 8 sheep, that will shear 28 pounds of wool. It costs 5 cents per pound more to grow fine Saxon or Merino, than it does coarse wool. The proportion of lambs reared is 8 to 10 ewes.

Hogs.—The best breeds are the Berkshire, Leicestershire, and Byfield. The cheapest way to produce pork is to keep just hogs enough to eat all the sour milk, small potatoes, and "bits o' bread," that may be produced upon the farm. Hogs, if allowed to run in the orchard, can be kept pretty cheap until they are 15 or 18 months old, when they will have usually got their growth, and will fatten easily upon corn, peas, or barley. One hundred pounds of corn, upon the closest calculation that I can make, will make 25 pounds of pork. Hogs should be killed in cool weather, and, after dressing, should hang till quite cold: otherwise the meat will have a strong, disagreeable taste. Pork for pickling should be cut in small pieces, the bloody parts well washed: the best rock or solar salt should be used. It should not be packed very tight, for the brine should flow through in liberal quantities: if not, the pork will have a greenish and bloody appearance. When it is packed down in large pieces, it is apt to taint before the brine strikes through. Casks that have ever contained sour brine should not be used again, for they are sure to "leaven the whole lump." Hams should be salted down a few weeks in brine made of common salt, saltpetre, and molasses: they should be smoked pretty thoroughly—when they are fit for market.

Cotton, sugar-cane, tobacco, and *rice* are not raised in this part of the country.

Carrots, Beets, and Turnips.—The cultivation of these roots is not on the increase. Land for these should be manured pretty heavily; it should be warm, sandy, or gravelly; it should be ploughed deep and subsoiled; it should be harrowed fine and laid into ridges two feet apart, and four or five inches high; they should be made true with an implement made for that purpose. Carrot-seed should be sown as early as the land can be prepared; it should be soaked till near sprouting before being sowed; it may be sown with a hand-drill running on the ridge; if they are carefully sown in straight rows upon ridges, the after-culture is greatly facilitated. I have a shovel-plough with a share made for the purpose, that cuts about 8 inches wide. By planting thus, I am enabled to plough with a gentle horse very close to the rows; the roots in the rows may stand two or three inches apart. This plan has some advantages over the old plan of doing all the labor with the hoe and the hands; it loosens the earth deeper, and enables the roots to send out their lateral fibres to a greater distance, which improves them very much, both in size and quantity per acre, and, more than all, it saves two-thirds the labor. Carrots yield, on an average, 600 or 700 bushels to the acre; beets, 350; and turnips, 250. For fattening animals, these roots should be boiled, but for milch-cows, or working cattle and horses, they are better in a raw state; but in all cases they should be washed clean before feeding.

Potatoes.—Average yield, 150 bushels per acre; cost of raising, 10 cents per bushel; the most prolific are the Rohan and Merinos; the most profitable are the early June, pink-eyes, and kidneys. The best system of planting, in order to escape the blight, is to select a piece of dry, sandy, or gravelly land; manure and plough it as early as possible; harrow it fine, and mark for rows 3 feet each way; plant the earliest varieties, put two potatoes of medium size in each hill; as soon as they are a few inches out of the ground, plough them both ways, two furrows in the row; hill them lightly with the hoe. Three times ploughing and hoeing are enough, if well performed.

The cultivation of fruit is receiving increased attention. From 500 to

800 bushels of apples can be produced on an acre; there have been large quantities shipped from this place this fall. Good winter fruit has been selling at from 75 cents to $2.50 per barrel of 2½ bushels, so that it is easy to estimate the product of an acre at from $100 to $200. The difference between apples and potatoes for feeding is about 30 per cent. in favor of potatoes. The best varieties for keeping, are the Northern Spy, Roxbury Russet, Spitzenburg, Greening, and Newtown Pippin. These are best also for exportation.

I think I know a preventive for the blight in pear and apple-trees. I have examined the subject carefully, and think I have traced the cause to the unsuitable nature of the soil upon which they are planted. I have examined pear-trees, with reference to this disease, in at least one hundred and fifty different localities, and have invariably found, that when they are planted on a rich, deep, loose soil, at the foot of a cultivated hill, they live to a great age, and bear heavy crops of fruit annually. On such soils they are healthy and free from blight. The soil for pear-trees should be at least 4 feet deep, as its roots are long, and almost fibreless. It is a rapid grower, and requires a great deal of nourishment, so that, upon a poor, thin soil, it soon becomes weak, like a straw-fed animal, and dies of the blight. The black ash, a native of low, rich soils, when removed to high, light soil, is subject to the same disease. I have never seen a pear-tree standing on the top of a dry, sandy hill, that was ten years old and free from blight, nor upon a thin soil of any kind.

It takes a long time to get them in bearing; so the land should be cultivated while the trees are young. Corn, potatoes, or other roots are preferable to grain. I have about two acres of apple orchard, and consider it the most profitable of any crop I raise. It will average fifty dollars per acre. My orchard is grafted with russets, which are the best for keeping, and will not injure by freezing so soon as other kinds. They are not so good on wet land as the Baldwin.

Currants are easily raised, and never fail; they make excellent wine, with very little labor. Moist land is the best for them.

Yours, most respectfully,

MOSES FRENCH.

Barbour County, Alabama, November 9th, 1850.

Dear Sir:—In making out a report in reply to your circular, I have endeavored to collect the most reliable information, derived from observation and other sources deserving confidence. I am happy to state that the general condition of the agricultural interest in this section of our widely extended country is very healthy and prosperous; more so than I have ever witnessed it before in a period of 13 years' residence. And, by the blessing of Providence, no people on the habitable globe are better prepared to live more comfortable and happy, would we but use the proper means to insure ourselves the rewards of industry, frugality, and enterprise. It is true that, in some things, we are far behind our colaborers in other sections, who have been blessed with advantages which we do not possess; but, at the same time, there is visible a spirit of improvement, which will gradually be infused among a people whose efforts are to advance in their respective callings; and we now see dawning upon us a general prosperity, the sure

reward of a people whose minds and energies are directed to an honorable pursuit.

With these preliminary remarks, I shall now proceed to answer the inquiries set forth in your circular.

Wheat.—My report for 1849 gives as fair an account of the condition of wheat culture in this section as could now be made out without repetition. In Columbus, Georgia, 45 miles north of this, extensive flouring mills have been established, which must, in time, encourage the growth of wheat. At present, much grain is imported from the West, to keep 3 mills in operation. The flour made is of very superior quality, equal to any of Northern manufacture.

Corn.—The most esteemed variety is the white corn; and, by proper management and cultivation, it will average from 25 to 35 bushels per acre. Of late years, much attention is bestowed to selecting the corn for seed, and it is better cultivated than heretofore, which results in a heavier yield per acre. From the protracted drought in May and June, the corn crop has been materially shortened; but sufficient has been harvested to meet the wants of the county.

There was introduced last spring, by Colonel Eli S. Shorter, a planter in this county, two new varieties of corn, the "Oothkalooga" and "Early Ohio Flint," which he pronounces to "have made the best corn he ever saw," yielding from 50 to 70 bushels per acre without manure. Some ears of the first-named variety were the largest I ever saw. I have handed Colonel Shorter one of your circulars, and requested him to make out a report for your department: in so doing, he will give a full account of this corn, its culture and production. The introduction of such seed among us will largely increase the production of corn, which, I think, can be made for 40 cents per bushel. My system of culture is to break the land deep at first, with large skooters, lay off the drills 5 feet apart, drop the seed 30 inches apart. In laying off furrow, manure at the same time with cotton-seed, and cover the corn and manure by running a light skooter-furrow on each side of it, and breaking the balk thoroughly out with shovels. This, however, is not the general system, as many still adhere to the old hill culture and covering with the hoe; and some in drill plant in a bed, covering with a board on the heel of the plough-stock. For my own part, I have found the first-named system most successful, and the after-culture easier. Three ploughings, and a hoeing after the first and last ploughings, is the culture given to corn, and the sweep-plough is becoming the one most in use for this purpose, as it performs the work rapidly, and, at the same time, stirs the land thoroughly. As regards feeding corn to stock, it is usually fed in the ear, as gathered, and the true economy of preparing by mills, or boiling, is lost sight of. I know of no experiments or calculations having been made in turning grain into manure by feeding stock of any kind.

Your next inquiries are in relation to *oats*, *barley*, *rye*, *peas*, &c. Oats, rye, and peas are extensively sown, but of barley and beans, none to my knowledge. Oats are sown down after corn, in October and November, and sometimes in February, from 3 pecks to a bushel per acre. I am partial to putting much seed in the ground, and have always done best when sown thick. Average yield, from 15 to 20 bushels per acre.

I deem this crop more exhausting to land than any other of the grains above named; it does best on low, wet lands, and we find it stands the winter's cold better on such lands than on high, dry, porous soils, where it is often winter-killed. When chopped and mixed with corn, oats make an excellent summer food for our mules and horses; as a renovator of land, I cannot speak of it as beneficial, further than its stubble prevents washing.

Rye is sown down for green pasturage more than for its grain, and serves as an excellent winter pasture for young stock to run upon; and I am only surprised that it is not more generally thus sown than it is, especially on broken lands, where it would prevent the washing of the soil during the winter rains, and, early in the spring, might be turned under to rot, in time for a late-sown crop. I have known instances where the overseer, in picking cotton in the fall months, scattered the seed ahead of the pickers, by whom it was trampled in, and in due time a good stand was had, with little or no trouble, furnishing a fine winter pasture, and, on undulating lands, preventing the alleys of the cotton-beds from gullying by the rains. The average yield is about 15 bushels per acre.

Peas.—These may be made one of the most valuable products of the South. Heretofore, and even now, a proper estimate is not set upon their beneficial qualities as a renovator. In this respect, they can be made to the South what clover is to the North and West. It is true that my experience with peas as a renovator is limited; but, so far as tried, very satisfactory, and I am now engaged in saving a large quantity for sowing broadcast on my corn lands next summer. I have never seen a piece of ground sown exclusively with peas for the purpose of turning them under as a fertilizer; but I have conversed with those who have tried it with very successful results. The manner in which have I tried them is in the last sweeping given to corn, sowing them broadcast before the ploughs, where they shade the ground completely from the penetrating heat of our summer's sun, protect the land, and keep the roots of the corn moist and cool, which, in a dry time, very much aids the corn in maturing well. In the fall, by early breaking up the ground for another crop, a vast amount of vine and litter is turned under to rot, which makes manure. By this system, but a partial benefit is derived from the peas as a renovator, although, considering the protection afforded to the corn from the influence of heat upon its roots, the preserving of the land from washing, and the keeping under of the noxious weeds and grass, this plan, involving but little labor and trouble, is well worthy the attention of planters.

Again, the vines, with the peas on, can be pulled up and cured so as to make an excellent winter forage for cows, mules, and sheep; in this way they readily fatten animals, very much increasing the milk of cows, if put away in a barn underneath which cattle can go and reach them through slat floors and racks. Or, they may be littered in lots, so as to make an abundance of manure. Thus a large amount of corn is saved, and stock can be wintered more economically than in any other method.

It is only with a certain class of planters, however, that this system will be adopted; for the putting in of the pea-seed is at a time when cotton-picking is most pressing, and where making large crops of cotton is the prime consideration of the planter, all other objects are lost sight of, embracing a general system of raising all things at home, which is the farmer's true policy and interest. Cotton is now bearing a high price, and the whole energies of the planters are bent on making all they can. The result will be, that they will find themselves dependent upon others for every thing they need, having neglected their provision crops, stock, &c. for cotton.

We are unable to answer your inquiries about *clover* and the *grasses*, they

not being cultivated in this section of country; also *dairy husbandry*, as nothing is done in this branch of rural industry, except for domestic wants.

Neat Cattle.—The cost of raising neat cattle to the age of 3 years may be set down as merely nominal; for, in summer, they are sustained by the range, and, in winter, the run of the fields with shucks is found sufficient. At 3 years old, in beef, they are worth from $7 to $9, and as stock cattle, from $4 to $5. The value of dairy-cows ranges from $12 to $25, according to their quality as milkers. As regards the amount of food required to fatten different breeds of cattle, we are unable to say, as with us blooded stock is scarce. Beef is used only in the summer months, where fattened by the range. Fall beeves, killed and cured for winter use, are generally fattened in the pea-fields.

Sheep and Wool.—We cannot answer the inquiries in your circular, for sheep have not been raised for the wool, except for domestic use. The breeds here are the most common kinds, and the average clip not more than 1½ pound per head. In Columbus, Georgia, 45 miles north, are several large woollen factories, lately established, and others now being erected, which will cause a demand for wool, and be the means of turning the attention of farmers to this important branch of business, now entirely neglected. I have been thinking, for some months past, of investing some capital in sheep, for the purpose of selling wool to the Columbus factories; and it strikes me that, with little trouble and good management, it can be done successfully and with profit; for we possess many advantages here in climate, woods-pasturage, and rye-fields, so that little expenditure is necessary in raising and sustaining them.

Again, our factories at present, and perhaps for years to come, will require but the coarser kinds of wool, as they manufacture coarse fabrics. This will enable us to begin with the common breeds, and, by importing blooded stock, to cross and improve the breeds gradually; thus ascertaining what breeds turn out the heaviest fleeces, and the quality most needed by manufacturers. No one can read the letter of Mr. Mark A. Cockrill, of Nashville, Tennessee, on the raising of sheep at the South, in the Patent Office Report for 1848, without feeling deeply interested on this subject. He has removed all doubts, done away with prejudices, and opened the way for all who may be disposed to make the trial, and who must succeed, with good management on his own part. With the farmers of the South, the starting of factories in our midst should be hailed with pleasure, and supported with zeal, for we have it in our power to supply the raw material, cotton and wool, and the food of their operatives. In short, an exchange of products is all that is necessary for us to be satisfied that we can, at last, live at home; and creating a diversity of products, and drawing our minds from the one object, cotton-planting, will add to the comfort of the farmers, and result beneficially to the country at large. Wool-growing I deem an advantage to the South, and no time should be lost in procuring the necessary stock and raising large flocks of sheep. The manufacturers now import from foreign countries 8,000,000 pounds of wool a year, to carry on their business. With this deficit in the supply, should we not be encouraged to furnish our own manufacturers, knowing that factories are on the increase, and being erected at our very doors?

Hogs.—The native or common stock we find to answer our purposes best, owing to its hardy habits, and being the most thrifty range-hog. There is no doubt, however, were proper attention paid to hogs, the improved breeds would be found most profitable; but among cotton-planters, and especially when prices range high, they raise only for their own supply, and import Western bacon for their negroes. What few hogs of improved breeds we had brought to the country did well so long as they were kept up, well fed, and attended to; but when turned on the range, they dwindled away to nothing. Pasturage is necessary for pork-raising, and, with the cotton-planter, none, comparatively speaking, is to be had; hence it is we are deficient in this branch of agricultural industry. Our climate, too, is so variable and uncertain, that it is a hard matter to save what pork is raised in the country. The drove-pork purchased is often much injured in saving, and the risk is so great, that the planters feel safer in purchasing their bacon from New Orleans, than in raising and curing. In putting up our meat, the worst enemy we have to contend with is the skipper-fly, which produces a bug that in summer destroys it. Many preventives against this enemy have been resorted to, but none, so far as I have heard, has proved entirely successful. Some have buried their meat in salt, some in fodder and shucks, and others in charcoal; still the ravages of this bug are manifested. So far as my experience goes, I have found it best, when the bacon is well dried, to take it down and brush it over carefully; have a large box in readiness, and pack it away in pulverized charcoal. It keeps better in this way than in any other that I have tried.

Cotton.—The season has been considered unfavorable, particularly to the upland crops, which are set down at 500 pounds per acre. It is allowed that it takes 1600 pounds in the seed to make a bale of 450 pounds clean cotton. The rotation of crops is governed by no regular system, for where corn and cotton are the only crops planted, cotton is generally run the longest, on lands best adapted to it, while the corn crop is kept up by manuring highly with cotton-seed. But, where the small grain crops are sown down, the rotation is corn after cotton, and cotton after small grain. So far, no preventives have been found against the rust and boll and army worms. Cotton can be made here at a cost of 5 cents per pound.

In relation to the remaining inquiries on your circular, most of the articles are not grown among us, while others are grown in such small quantities as to afford no important conclusions as regards production, culture, &c.

Very respectfully,

JNO. H. DENT.

Hon. Thomas Ewbank,
Commissioner of Patents.

Lake Swamp, Horry District, S. C., November 25, 1850.

Sir:—In reply to your inquiry relative to the culture of sugar-cane, and its premature decay from rattoons, &c., I can give you but little information, as I have never depended on rattoon crops. But so far as my experience goes, I think the cane does become inferior, shorter joints, and produces less juice than formerly. I have raised sugar-cane for four years, from the planting each year; and though I am 35 or 40 miles from the seaboard, and within nine miles of the North Carolina line, my cane does well, and I think it a profitable crop. I am of the opinion that cane can be raised in South Carolina or North Carolina, anywhere within 40 miles of the sea-

coast, to considerable advantage, and I do not think the time to be very distant when the sugar-cane will form a portion of the crop on every well-conducted farm; at least, enough for home consumption. Experience has taught me that this would be for the interest of every farmer.

I have had some experience in feeding apples to hogs, and can say that sweet apples will fatten them as fast as potatoes, but sour apples will not. I have a kind of apple, called Sweet James, which ripens in the month of June, and bears very full. I would as soon have a bushel of them for my hogs as a bushel of sweet potatoes; but when these were gone I fed on sour apples, and my hogs lost flesh, instead of gaining.

As to raising rice on high or upland, it is quite common. The gold rice or white-hull rice does well. There is a certain kind of soil, however, on which it prospers best, and that is a level, sandy soil, inclined to moisture. On such land, I have known the yield of rice to be three bushels to one of corn, from the same field.

Yours, with respect,

THOMAS A. BEATY.

Dry Goods Reporter.

Portland, January 16*th*, 1851.

Sir:—Some 8 or 10 weeks ago, I received a circular from the Patent Office, making inquiries concerning agriculture in this section, the which numerous pressing engagements have hindered me from considering until now.

Our farmers are by no means systematic or scientific in their agricultural operations; and, could they be induced to profit by the teachings of science, I am well satisfied that the result would be at least the doubling of their crops, with less labor than they now bestow on their farming operations. The experience of some two or three systematic and, to some extent, scientific farmers, with whom I am acquainted, bears me out in this opinion. I am happy to add, however, that there seems to be a growing interest in regard to the matter, induced, perhaps, by the operations of our county agricultural societies.

But to your inquiries:—

Wheat.—We raise comparatively little wheat in this (Cumberland) county, and, indeed, in the whole State—not *half* enough, I think, for home consumption. In 1850, 169,879 barrels of flour were imported into Portland alone, much of which went into the interior. However, since the failure of the potato crops, our farmers are turning their attention to the more extensive cultivation of wheat—the kinds most in use being the Kloss blue-joint and white-flint seeds. These varieties, so far as I have been able to learn, have not as yet been attacked by the weevil. The time of seeding is in all September; of harvesting, from the 1st to the 20th August. The average product cannot, I think, exceed 15 bushels per acre, owing to the unskilful manner with which it is cultivated. The seed is not prepared in any way—5 pecks of seed is about the usual quantity used per acre in planting; average price per bushel, $1.87½ cents. The ground is generally ploughed twice; depth, I think, not more than 6 inches. We have no system for rotation of crops; know of no remedies for flies or weevils. The yield per acre is increasing.

Corn.—The "Golden Field" variety is the only one planted; average product per acre, 45 bushels; cost of production per bushel, I should judge, might be set down at 55 cents. Most approved method of fertilizing is by spreading the manure broadcast. Our farmers generally plant in "hills," one hill to about every 12 square feet of ground, and hoe twice or three times. The best method of feeding it to hogs is, I think, decidedly, ground and cooked, or scalded. We raise more corn than wheat, but not enough for home consumption, 222,641 bushels having been imported into Portland last year. That corn can be raised in this section to advantage, I have abundant reason to believe. Last year, I knew an *amateur* farmer to raise 92½ bushels to the acre, and, as secretary of the Cumberland County Agricultural Society, in 1849, a written statement was put into my hands, *sworn to* before a justice of the peace, that the writer had raised, on one acre of ground, the almost incredible quantity of 123 bushels and 26 quarts of round yellow or golden-field corn!

With regard to the cultivation of oats, rye, and barley, there is a diversity of opinion here. I should judge the average yield per acre of oats was 20 bushels; of rye, 20 bushels; of barley, 25 bushels; average quantity of seed per acre, oats, 6 pecks; barley, 6 pecks; rye, 5 pecks. About enough of each of these grains is raised for home consumption. Peas, so far as I know or can ascertain, are not cultivated as a renovating crop. Beans are not much cultivated as a field crop, except among the hills of corn, one and sometimes two seeds being used to the hill. In this way, perhaps, an average of 8 bushels is raised to the acre. Separately and alone, I have heard of 35 bushels of beans being raised to the acre.

Clover and Grasses.—The grass crop of this (Cumberland) county is one of the chief dependences of the farmer, and generally, perhaps, his most certain and profitable crop, as things now stand. Much hay is annually exported from Portland to New Orleans and other Southern ports. I have known of 4 tons being cut to the acre on richly manured lands, but think the average quantity throughout the country cannot be more than 1¼ tons to the acre. The best fertiliser for mowing fields, where it can be had, is what is called "mussel-mud"—the mud and shells dug from salt-water flats or mussel-beds. Algæ, or sea-weed and kelp, thrown up on our sea-shores by storms, are also used, wherever they can be obtained, as fertilizers, and with much success. In the interior, ground plaster is used with most encouraging results, especially on heavy, clayey lands. Each of these manures is generally used as a top-dressing. Stable and barn-yard manures are also used. By "meadows," I presume you mean mowing lands generally. The seeds used in laying them down generally are herds-grass and clover—different lands requiring different proportions of the two seeds—but, on an average, I should estimate the proportion at ⅔ herds-grass, ⅓ clover. Red-top and foul-meadow are used in laying down boggy lands, or what are here called meadows. I do not think the average quantity of seed used in laying down grass lands is over half a bushel to the acre; but our farmers would find it to their advantage to use more. The average cost of growing hay per ton I shall set down at $5; average price from one year to another, $8 per ton. The Southern clover-seed does not work well here at all. I have known a skilful farmer enter upon a new farm, and, by the application of mussel-mud, plaster, and stable-manure, and the manure made by some half a dozen hogs, which he almost solely kept for the purpose, in the course of 7 or 8 years, increase the hay crops of his fields from 15 tons up to an average of 100 tons.

Hemp is not cultivated in this county, nor, so far as I am aware, in the State. It has been frequently tried; but without success.

The growing of carrots, turnips, and beets has been on the increase, as a field crop, since the commencement of the ravages of the potato disease, previous to which but little attention was paid to them as articles of agriculture: I have, therefore, but little experience on which to found an opinion as to the best mode of growing. I have an instance in mind where 900 bushels of carrots were raised to the acre; I should think the average yield of carrots and beets might be put down at 600 bushels per acre each. English turnips are not planted to any extent as a field crop. Ruta-bagas, however, are beginning to be planted extensively. Their yield will go above that of carrots and beets; but I am unable to give any definite information on the subject.

I cannot, from personal experience, afford any information as to dairy husbandry, neither have I been able to obtain satisfactory information on the subject.

Your interrogations in regard to neat cattle are likewise almost equally out of my line of experience. In Cumberland County, we have only here and there a single specimen of full-blooded *Durham;* and as to Devon or Hereford, I know of none in the country. Still, there may be some of each. The cost of rearing 3 years' old neat kine of our mixed breed is from $18 to $20 per head. The value of good dairy-cows in spring and fall averages about $25.

I am unable to give correct information in regard to sheep or wool-growing.

The best breeds of hogs, I believe, are the Berkshire, and a species called here the "Newbury White," and a cross of the two. The Newbury White fatten with a small amount of food, but do not grow very large. Most farmers, I believe, prefer the cross breed. The only method of putting up pork, is by packing in barrels, in salt pickle, excepting that a few hams are well smoked; but as to the manner of curing these latter, I am not able to give information.

Potatoes.—Prior to the advent of the disease, the average yield might have been put down at 200 bushels per acre, and they would pay for raising at 16 cents per bushel; but recently they cannot be considered a paying crop, generally, at four times that price. The varieties least subject to the *disease*, are the Churchill, (so called here,) the peach-bloom, and early blue. It was for some time thought that seeding the potato would prevent its decay, but this hope has proved fallacious, and I know of no preventive of the potato-rot or disease. I have tried experiments; have tried with the strongly recommended *peat-charcoal*, pulverized, for instance, but without satisfactory results. I shall, however, give it a further trial. Potatoes grown on *new* ground, without manure, suffer least. The method universally practised here, is planting in hills, about one hill to the square yard, and hoeing after the plants are 3 or 4 inches high. Some farmers hoe twice. As to manuring, some farmers spread manure on the land, before breaking up; some manure in the hills; no general system. We raise no *sweet* potatoes.

Fruit.—The culture of fruit is receiving increased attention in this county, and, I am inclined to believe, in the greater portion of the State. The apple crop, I think, *can be* made the most profitable one the farmer raises; and some of our farmers have, I believe, discovered this to be the case. The varieties here esteemed best for keeping, are the Baldwins, the Greenings, and Russets. Those who have had experience on the subject, say that in feeding hogs and cattle, if you can sell your apples at 37½ cents per bushel, and buy corn at 66 or 70 cents, you will be the gainer.

Manures.—The use of lime is little understood with us, and little used. Plaster (ground) is used successfully in the interior, on almost all kinds of crops. Mussel-mud works better on grass land than with other products. Guano has not worked so well here as on older cultivated lands, where the ammoniacal properties have been more nearly extinguished. Pulverized peat-charcoal, (a new article,) I am disposed to believe will be found to be a most excellent fertilizer; especially, composted with other manures. It is a *perfect* deodorizer, rendering human excreta and the most offensive offal, entirely scentless, as I have ascertained from frequent experiments. Hence its discovery will prove of great utility to the world, in a sanitary point of view, as well as for its fertilising qualities; and I am happy to add that a large manufactory of the article is just going into operation in our vicinity.

Meteorology.—The enclosed printed slip will afford all the information I can give on this head. I procured it for publication at the *Observatory*, a tall, octagonal building in our city, where inbound vessels are signalized in the offing.

With regard to the quantity of *rain*, I think it cannot average far from 35 inches per annum. Dr. William Wood, of this city, keeps a rain-gauge, and has promised to favor me with more specific information; but thus far I have not been able to find him sufficiently at leisure to fulfil his promise. Professor Cleaveland, of Bowdoin College, Brunswick, I believe keeps a rain-gauge.

Very respectfully yours,

S. B. BECKETT.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Thermometrical Table for December, 1850.

Augusta, Kennebec County, Maine, December 20, 1850.

Sir:—The following observations on a few of the topics embraced in your late Agricultural Circular are respectfully submitted for your consideration.

Wheat.—Previous to 1839, spring was pretty generally cultivated in this section of the State, but since the depredations of the wheat-midge (grain-worm, or weevil, as it is called here) have become so extended, the crop has been very precarious, and generally unprofitable, until, at the present time, comparatively little of it is sown. Within three or four years, the attention of farmers has been directed to the cultivation of winter wheat, and the success that has attended those who have given it a fair trial, is truly encouraging. Winter wheat, here, is seldom or never injured by the midge when it is sown in proper season. J. D. Lang, Esq., of Vassalboro', several years ago, introduced a variety of winter wheat from Poland, which has, thus far, stood our winters well, and yielded a very satisfactory return. The Kloss blue-stem has been extensively introduced, principally by the exertions of Rev. William A. Drew, of Augusta, who, six years ago, sowed in his garden a few kernels of this variety, which were sent from the Patent Office, from the produce of which, it has been estimated, that at least 5000 bushels were sown the past autumn in the valley of the Kennebec. Several other varieties have been cultivated. Nearly every bushel of the last crop of winter wheat raised in this State was used for seed, and it sold readily at an average price of more than $2 per bushel. Moses Taber, of Vassalboro', who cultivates the Poland variety, harvested, the present year, 50 bushels from 1½ acres. Other varieties have done as well as this. Mr. Taber, in a communication in the Maine Farmer, remarks, that where the proper method of cultivation has been pursued, the average yield, in this vicinity, for five years past, has been about 20 bushels from 1 bushel of sowing, and in no instance has there been a failure, or less that 14 bushels to the acre.

The method of cultivation adopted by many, is as follows:—The ground is ploughed in July, or early in August, and afterwards it is top-dressed with compost or well-rotted manure, which is thoroughly incorporated with the soil. The most favorable time for sowing is from the 20th to the last of August. The seed is covered with a small horse-plough, and the ground is rolled. The amount of seed recommended for the acre varies considerably. Mr. Taber sows from a bushel to a bushel and a peck, while others consider it best to sow from 2 to 3 bushels to the acre.

Indian Corn is very generally cultivated in this portion of the State, and it is regarded by many as the surest crop raised. An eight-rowed, yellow variety is the most common for field culture, although the twelve-rowed is raised to some extent. The usual planting-time is from the middle of May to the 5th of June, and the common varieties of corn planted during this period usually ripen well in the month of September, and before the frosts injure it. Corn is generally more highly manured than any other field crop, and its cultivation is seldom attempted without manure. Most farmers spread a portion of their manure, and apply the remainder, which must be well rotted, in the hill. The cultivator, plough, or harrow is used among the corn at each leafing, and the corn is usually hoed twice. The stalks and husks are used for fodder for neat stock. The expense of raising an acre of corn may be estimated at about $15, exclusive of manure; the fodder being worth the expense of harvesting. Beans or pumpkins are usually raised with the corn. Mr. Guild, of Sidney, raised 190 bushels of ears, or 95 bushels of shelled corn, to the acre. Mr. Wadsworth, of Kennebec, raised 72 bushels of shelled corn to the acre; and Mr. Snell, of Winthrop, raised 71 bushels, at an estimated cost of $17. These are among the best crops which were raised in this vicinity in 1849. The crop of the present year, I think, is full equal to that of the last. The average price has been not far from 80 cents per bushel. The average yield, per acre, I think, may be set as high as 30 bushels.

Potatoes.—Twelve years ago, it was estimated that more than $250,000 were paid for potatoes sent out of this State by way of the Kennebec river alone. Now, there are not enough, which are free from disease, to supply the wants of the inhabitants. Potatoes are now being sold in this market at 60 cents per bushel; but the disease is so prevalent that traders and con-

sumers are unwilling to purchase more than enough to supply their immediate wants. Last year, the potatoes in this vicinity were less diseased than they had been for several years previous; but this year, on some farms with which we are acquainted, they have rotted worse than ever. The summer of 1849 was unusually dry, while the spring and summer of 1850 have been wet. This difference in the seasons may have had something to do with the rot.

Turnips, and other Root Crops.—Turnips, and the root crops which are generally cultivated, may be successfully raised here, and they are, to some extent; but too little reliance is placed upon them for the support of stock. The hay crop is the most valuable one in Maine, and upon it nearly all our farmers are greatly dependent. For five years past, we have had a succession of good hay seasons, and the farmers have not considered it necessary to raise many roots for their stock. So far as I have observed, it appears to me that the root crops do not now receive more attention, perhaps not so much, as they did 10 years ago, among farmers in this vicinity. I can hardly account for this neglect, more especially since the failure of the potato crop. The root crops most cultivated here are ruta-baga, turnips, and carrots. In 1849, Mr. Watson, of Fayette, raised 425 bushels of ruta-bagas from half an acre, at an expense of $25. The same year, Mr. Taber, of Vassalboro', raised 395 bushels from half an acre, at an estimated cost of not more than 4 cents per bushel.

Fruit Culture.—An increasing attention is being paid to the culture of fruit. Many new orchards are being set out, and the old ones are being renovated and ingrafted. Our apples, for keeping qualities, are unsurpassed; and there is usually a ready market for all the good fruit that is raised, at remunerating prices. No branch of business, it is thought, will yield a better or surer return, in this part of the State, than orcharding, or fruit-raising, when properly conducted. A gentleman who has had considerable experience in these matters, calculates that an orchard of 12 acres, well cared for, will yield a clear annual profit of $800. Prime apples have averaged at least $1 per barrel in our markets; and when we take into consideration our facilities for sending them abroad, and their keeping qualities, it seems highly probable that they will continue to be in demand at fair prices. For three seasons past, we have not had a full crop of apples, although some orchards and some particular varieties of ingrafted fruit have done very well.

Meteorology.—The following, which is copied from the thermometrical record, as kept at the Insane Hospital in Augusta, will exhibit the mean temperature of the thirteen months previous to November last, together with the quantity of rain which fell, and the number of wholly fair and stormy days in each month.

Month.	6 A.M.	2 P.M.	9 P.M.	Range.	Inches rain.	No. wholly fair days.	No. rainy or snowy.

October..............	45.20	57.40	48.90	31 to 68	5.26	11	7

REMARKS.—The autumn of 1849 was unusually mild. The rains of early autumn, succeeding the severe drought of summer, seemed to infuse new life into vegetation. Roses and dandelions were frequently seen in blossom in October, and ripe raspberries and strawberries were gathered in the open fields during the same month. There was hardly frost enough to check vegetation until the 1st of December. The coldest weather for 12 years past was in February, 1850, the mercury, at one time during the month, remaining below zero for more than 36 hours in succession. The last spring was wet and backward. An unusual number of freshets have occurred during the season on the Kennebec and its tributaries, which were attended with considerable loss of property. The freshet of May 25th was greater at Augusta than any which has occurred since 1832. The navigation of the Kennebec was closed about the 5th of December, 1849, and the ice left the river April 1st, 1850.

AGRICULTURE OF AROOSTOOK COUNTY.

Before closing this communication, I wish to call attention to the wild land in the north-eastern part of Maine, and say a few words relative to the soil, products, and agricultural prospects of this new country. I have travelled, during the past autumn, some 200 miles in the county of Aroostook, visiting the principal settlements, and noticing, so far as I had opportunity, the success that had attended the hardy and industrious pioneers. There are many thousands of acres of very good land in this county, which, by industry and skill, may be converted into beautiful and productive farms. From what I there saw, I feel confident in the opinion that the valley of the Aroostook is the best grain-growing district in New England. Much of the land lies in beautiful ridges or swells, not too abrupt for cultivation; it is well wooded, there is a great abundance of noble cedars for fencing and other purposes, and the soil is deep and fertile, and generally free from stones. There is an abundance of lime in almost every township, and an inexhaustible supply of gypsum may be conveniently obtained from New Brunswick.

The crops of the past season were excellent. I have never seen any better wheat, oats, buckwheat, millet, and potatoes, than I noticed on this journey; and the average yield of all these crops is much greater than in the older settled portions of the country. With the single exception of

Indian corn, (and I saw some good and well-ripened corn there,) the field crops of Aroostook county will not suffer by comparison with those of the most favoured portions of our county. The potatoes are of very superior quality, and, in many neighbourhoods, they appeared to be entirely free from disease.

Mr. J. W. Haines, who resides in township letter D, informed us that, for the last 3 years, his wheat averaged 25 bushels to the acre for the first crop after a burn, and 20 bushels for the second. This crop, last year, averaged upwards of 30 bushels to the acre. His oats yield 60 bushels to the acre.

The following statement of the amount of crops raised the present year by Mr. John F. Goss, of Presque Isle plantation, was communicated to me by a trader of that place, whose name I do not now recollect. He assured me that reliance might be placed upon the correctness of the statement. The prices affixed were what he regarded as the fair market value of the articles in that township. Mr. Goss, in raising these crops, had only the assistance of his son, 17 years of age, and a hired man 4 months.

25	tons of	hay, $8 per ton..	$200

			$866

Hon. John Hodsdon, of Houlton, raised, in 1849, 54 bushels of spring wheat to the acre, and the present year his crop was at the rate of 45 bushels to the acre. These examples (and their number might be much enlarged from the materials before me) are very encouraging: they speak well for the agricultural resources of the county.

A gentleman, who has had much experience in draining new land in this part of the State, informs me that he hires the trees felled for 3 dollars per acre, and pays only 7 or 8 dollars an acre for draining. At this rate, the first crops not unfrequently yield a clear profit of $15 per acre, besides paying for draining the land.

It is true the county of Aroostook lies far to the north, being in latitude about 46°. The seasons are short, and there are probably some frosty locations; but we saw nothing while there to lead us to suppose that much of the land is so liable to frost as to render it unsafe for the principal crops in ordinary seasons. There was no frost to check vegetation until after the 25th of September. The snow generally falls early and covers the ground until spring. Besides the advantages of good sledding and sleighing, this prevents the ground from becoming much frozen; and, as soon as the snow melts away in the spring, farming operations may be commenced, and vegetation progresses rapidly. With their abundance of fuel and building materials, I am satisfied that the people of Aroostook suffer less from the cold than do those who live on the seaboard many degrees further south.

In accordance with an act passed at the last session of the Maine legislature, the land agent has caused to be surveyed 10 townships of the public lands. These are offered to citizens of the United States, for settlement, in lots not exceeding 200 acres for each individual, for 50 cents per acre, payable in 1, 2, and 3 years, in labor on the roads in the township where the lots purchased lie. No cash payments are required, and the labor is to be expended in opening highways for the benefit of the settlers. This very liberal arrangement offers an excellent opportunity for our industrious and enterprising fellow-citizens to procure for themselves tracts of land without money and almost without price, on which they may soon have comfortable homes, surrounded by smiling and fruitful fields, affording a support for all their reasonable wants. I have passed through 4 or 5 of the townships designated. The most of these have mills and schools already established; and I know of no better soil, or more pleasant natural scenery, than may be found in them.

Yours respectfully,

B. F. ROBBINS.

Windham, Connecticut, December, 1850.

Sir:—In compliance with a circular from your office, I submit a few remarks in relation to the interests of farming, and very briefly. The making and application of manure lies at the foundation of all agricultural operations. The best mode of making manure, as far as I can judge from experience, is, in summer, to yard your cattle on swamp muck, turf, or loam, in sufficient quantities to absorb all the urine, and composting the solid excrements every morning. Thus the loam absorbs the volatile portions of the manure, and retains it for the use of the farm. In winter, stables should be constructed large, admitting the animals to be turned in loose, and made without a plank floor, a quantity of straw put at the bottom, where the manure is allowed to accumulate until spring. Bed down your stock every day with a sufficient amount of straw to keep them clean. The solid excrements and litter will absorb and retain the urine; and, when the mass is removed in the spring, you may safely take the evidence of your sense of smell as an assurance that your manure is of the first quality. As this mass is removed, sprinkle it freely with gypsum, and plough under as soon as possible, and you will save the volatile portion from escaping. The hog-pen should be supplied with fresh loam every day, in quantities sufficient to neutralize and keep down all unpleasant odour. A hog weighing 300 lbs., where loam is added as above, will make 10 loads of excellent manure.

Potatoes.—This is an important crop in this part of the State, it being accessible to the large markets. The rot, during the past season, has been unprecedented: they have rotted on free sandy loams, where hitherto they have been exempt; but it may be remarked, that lots highly manured have suffered most. As far as my own experience goes, I have been most successful on new lands, or land which has not been manured with barn-yard manure, but which was of sufficient fertility to bring the crop to maturity. From this it would seem that a crop of clover, buckwheat, or some other grain crop, would be the best preparation (ploughed under) for a crop of potatoes. Fruit begins to attract the attention of the farming community in some degree, as it deserves, and, in particular, the different varieties of winter apples. The kind most esteemed here for its long keeping quality is the Roxbury Russet, which holds its flavor when other varieties become insipid. The Baldwin, Rhode Island Greening, Hubbartson, Nonesuch, Peck's Pleasant, &c. are among the leading varieties. The common error in regard to fruit trees is that they will grow anywhere and without culture. Having planted an orchard of 700 trees, within the last 4 years, I am satisfied that the growth of the trees depends mainly upon the culture given them. No orchard should be suffered to stand in a pasture or mowing lot, for the turf and grass will appropriate all the moisture in the shape of rain or dew, robbing the trees of all nourishment. The ground should be kept open, either by harrowing repeatedly or ploughing. If the latter, be very careful not to cut the roots, some of which are very near the surface. In planting, the trees should be set near the surface. The addition of a pail of water to the roots I consider to be useless, the soil, early in spring or late in fall, being sufficiently moist without such addition. I have set about 800 trees within the last 4 years, planting, both in the spring and fall, without using water, or losing any trees. I forbear to multiply topics of remark, but will take the liberty to add, in regard to the interest of the agricultural community, that what they want, to stimulate them to improvement, is a steady and reliable market for their produce. The farmer wants a home market, which can dispense with the jobber, the shipper, the wholesale dealer, &c., in order to enable him to make that improvement which the interest of our country demands.

Very respectfully,

WM. P. GATES.

Montgomery, Alabama, December 10th, 1850.

Sir:—The Agricultural Circular from the United States Patent Office, under date of 26th August, a copy of which has been sent to me, demands my attention, and I do not feel at liberty to withhold what knowledge I may possess on agricultural subjects from my fellow-citizens of a common country. Experience has taught me that it is good to stick close to old landmarks, and that nine-tenths of all experiments in our branch of industry better suits for periodicals and common talk than for profit. Improvements of real practical value are not of every-day occurrence, but are rare, and ought to be treasured up; and, if you find, in the remarks I shall make, any thing of value, I shall be glad to think I benefit my fellows. The kind of wheat best suited for this latitude is called "little white," and should be sown on the 1st of October. It does not produce largely to the acre, but makes fine flour if ground in June, so as to avoid the weevil. Rolling land, moderately rich, if a clay foundation, is best. Open prairie I do not find good for wheat. It is not a profitable crop here, on account of our frequent failures. A mixed kind of corn, of the flint and gourd-seed, is the best. We average about 30 bushels to the acre. Frequent ploughing is the best culture. The usual method of feeding corn is, unbroken and raw. I find boiling the best for hogs, and at least a fourth saving in it. The best method of manuring corn is to put the manure in the hill with the corn when you plant, and cover both together with the hoe or a good turning-plough.

We sow oats for pasture in the spring, commencing the first good weather in January. We cut some for summer feeding of horses, and the rest is fed off the land by the cattle and hogs, putting up barely enough for seeding. I have not yet seen any foreign grasses worth the culture. Indian corn, drilled thick, in rows about 3 or 4 feet apart, makes the best summer feed, or "soiling," of any thing I have ever seen.

Those who wish to raise stock on grass, better not come as low as latitude 32°, for cotton at 10 to 12½ cents per pound is much more profitable. All our planters who consult their best interests will attend to their dairies, neat cattle, sheep, hogs, and horses, for their own use, not for profit, but for saving. I am sure this section could produce sugar largely; but will not while cotton is our staple. From the tanyer, a tropical plant, to the salsify that flourishes at Green Bay, we can rear these and all intermediate sorts of vegetables: I may say as much of fruits. On the grape-culture and wine-making, I have about the same opinion that I have of grasses and cheese-making—they will not do for this country. The vicissitudes of our seasons are very great. I have known the mercury to fall 50° in 24 hours. The average of our winter weather is about 60° Fahrenheit—the range is 10° to 80°. In summer, the average is about 78°—the range from 10° to 100°. We are subject to long and heavy rains, lasting 6 weeks and more, and the same of dry weather. These great changes will account for the difficulty in raising exotic fruits or vegetables. And now let me make a closing remark. It is our best policy to improve our native plants and animals, and be less solicitous for the introduction of foreign ones; and, to succeed in this, we must be more industrious—directing and seeing to it ourselves, and not trusting to servants.

Very respectfully,

ELBERT A. HOLT.

Dennysville, Washington County, Maine, Dec. 16th, 1850.

Sir:—The following estimates, in answer to your agricultural circular, require an accompanying statement of the fact that they are given for the products of a district lying far north, the climate of which is less favorable to quantity than to quality of produce, and the soil not naturally fertile; that an average of the crops represent not so much the average productiveness of the soil as the quantity of manure and the labor and care in cultivation—the crops, except on new land, depending almost wholly on the manure; and that, as agriculture in this section of the country is, for the most part, made secondary in the pursuit to other employments, the crops are not so great, nor so economically obtained, as they would otherwise be. Therefore the estimates of actual cost here given are unduly large.

Corn.—The eight-rowed yellow Canada corn is preferred:—average produce per acre, about 35 bushels: is little raised, except in the interior, the cost being more nearly equal to its value than that of other crops raised.

Oats, Barley, Rye.—Average yield of oats, about 40 bushels per acre; of barley, 30 bushels; and of rye, 18 bushels. Quantity of seed used, 2½ bushels of oats or barley, or 1 of rye, per acre. Oats are least exhausting to the land, or, at least, they can be raised oftener on the same ground. The two-rowed barley is most in use.

Clover and Grasses.—Average quantity of hay, about 1 ton to the acre.

Red-clover, herds-grass, and brown-top are the kinds preferred. Quantity sown, 10 pounds of clover and ½ bushel of herds-grass, or herds-grass and brown-top to the acre, generally sown with grain. Meadows and pastures are usually renovated by ploughing up and manuring. Near the coast, sea-weed is used as a top-dressing with good effect. Hay can be grown for about $7 per ton.

Dairy Husbandry.—Average yearly yield of butter per cow is about 110 pounds. The climate being peculiarly favorable for butter-making, but little cheese is made—average price, 8 cents, and of butter, 20 cents per pound.

Neat Cattle.—The usual price at 3 years old is $20, and of good dairy-cows, in spring, $30; in fall, $16. Young cattle are housed for the first 3 years about 5 months in the year, and during the second and third winters, they are kept on the poorer hay. A given amount of food has been supposed to make less meat in a Durham or other large breed than in a native animal, they being smaller and hardier. Small cows are preferred as a general thing, and small oxen also, except where particular cases require heavy cattle. The native cattle will thrive where the Durhams will not—this opinion, I believe, is universally held. Whether native cattle will not gain proportionally to the amount of food consumed, when put upon the high keeping adapted to the Durham, has not been made a matter of accurate experiment to my knowledge.

Hogs are not generally raised but to consume the waste of the dairy and kitchen, and are fattened on potatoes and meal. It is thought by many that the Berkshire and some other celebrated breeds will grow faster than our native breeds, but make more lean meat—therefore are not much sought after.

Sheep and Wool.—Wool-growing for exportation is not considered profitable. The majority of small farmers keep about as many sheep as neat cattle, which goes to show that the relative profit of sheep and cows cannot be far from the proportionate expense of keeping; inasmuch as the cattle are not raised for beef, the oxen being kept only for their work. Small sheep are more profitable here than large ones. The finest Merinos are not raised here. The number of lambs annually reared will fully equal that of the ewes.

Root Crops.—Turnips, carrots, and beets. The cultivation of these as a field crop is increasing. Average crop of turnips (ruta baga) is about 700 bushels per acre.

Potatoes.—The Irish only are raised. Average crop, 250 bushels to the acre; cost to raise per bushel, 16 cents. The most prolific varieties raised here are the long red and the orange potato. The most profitable variety, and one which has nearly superseded all others, on account of the great price it bears in market, is the "white blue-nose." During the last 6 years, the potatoes have suffered so much from the rot, that their cultivation has lessened very much, and will soon be abandoned, unless a favorable change takes place.

Fruit Culture.—The culture of apples and plums is receiving increased attention.

Manures.—Lime has been tried at various times and in various places; but, so far as I can learn, without effect. Plaster is sometimes beneficial, though little used.

Very respectfully, your obedient servant,

THOMAS LINCOLN.

METEOROLOGY.

The subjoined notes have been taken from a register of the weather which has been kept for 35 years without interruption. This register has been kept at such a distance from the ocean as to be only slightly affected by it. The thermometer rises a little higher and falls a little lower in the interior than here. A record of two observations per day only has been kept; but it is believed to be essentially correct.

THOMAS LINCOLN.

Byberry, Philadelphia County, 12 *mo.* 3*d*, 1850.

Sir:—I proceed to give answers to some of the questions in your circular, sent me, calling for agricultural statistics for the year 1850. But as there is a large and efficient agricultural society in the county, (which appears to me to be the most reliable source of information,) my answers will be quite brief.

The wheat crop promised very fair while growing, but was very much injured by (what is here termed) the grain worm, a small insect which feeds upon the grain while in a soft or milky state. The varieties of wheat that have matured early have, as yet, escaped the new enemy, consequently the Mediterranean wheat is now almost universally sown. The quantity of seed sown is 2 bushels per acre, and the average yield is about 20 bushels per acre. The time of seeding is from the middle of September to the 1st of October, and of harvesting, the early part of July.

The average price this year has been $1.10 per bushel.

Corn.—This is an important staple, a good crop of which has been harvested say from 50 to 80 bushels per acre. The most esteemed varieties are a mixture of the gourd-seed and Cooper corn, and the gourd-seed, the former of which I think preferable. Corn is generally planted on timothy-sod, ploughed in the spring about 6 inches deep, and planted about the 1st of May, and worked principally with the cultivator and hoe.

Broom corn is extensively cultivated, and is generally planted after Indian corn. The average produce is 800 brooms and 30 bushels of seed per acre, worth, in the rough, $40. The brooms are principally manufactured by the cultivators of the corn, during the winter season. It is considered a profitable crop in this vicinity.

Oats are generally sown after corn,—about 3 bushels of seed, with an average yield of 40 bushels per acre. They are generally sown as soon as possible after the frost leaves the ground in the spring. The price this year has been higher than usual, being from 40 to 45 cents per bushel.

Clover and timothy are both sown with wheat. The quantity of hay is from 1 to 2½ tons per acre. The price this season has been about $18 per ton.

The dairy business is not very extensively carried on, although most farmers make some butter to sell. The average yearly produce of butter from one cow is about 200 lbs., worth about 20 cents per pound. It is generally taken to market while fresh, in lumps of one pound each. The usual price of a good dairy-cow, 3 years old, is about $30.

Very few sheep are kept for their wool, as it is impossible to compete with the great West in this particular. The Southdown breed is considered the most valuable. There are but few flocks of this kind in the county. Large numbers of common sheep are purchased from droves, in the fall, and are fed during the winter season.

Hogs.—The best breeds are the Berkshire and Chester county. They are much raised for market, but are principally kept to consume the offal about the farm. They usually weigh, at one year old, if well fatted, about 300 lbs.

Of the turnip kind, the ruta baga, or Swedish turnip, is by far the most valuable, though very little cultivated. Flat turnips are frequently sown among corn at its last dressing, or after early potatoes, and often yield from 200 to 400 bushels to the acre. The ruta bagas are planted upon ridges three feet distant about the first of July, and worked with plough and hoe. If properly cultivated, they frequently yield 600 to 800 bushels per acre. They are the best food for cattle of all the root kind.

Potatoes have become such an uncertain crop that many farmers have relinquished their cultivation. They have been more affected with the rot the past season than in any former one, and no remedy has yet been discovered. The most common variety is the Mercer. It also finds the most ready sale in the market.

Manure.—The main source of manure is the barn-yard, where the straw, cornstalks, and refuse of all kind are collected. Many farmers feed cattle during the winter, which helps to increase their stock of manure. Compost is often made of swamp-muck, loam, &c., mixed with lime, plaster, salt, &c. Lime is used in considerable quantities, and is generally applied on wheat stubble at the rate of 40 bushels to the acre. Plaster, or gypsum, is universally sown on clover fields in the spring, when the grass is about 4 inches high, at the rate of one bushel per acre, with most astonishing effect. It is a valuable agent in absorbing manures in the form of gases, and is used very profusely about manure-heaps, cattle-yard, and stables. Its action is just the reverse of lime, the one retaining the gases and the other assisting them to pass off. Guano has been used in small quantities, and with good effect, but the high price prevents its coming into general use.

JAMES THORNTON, Jr.

Richmond, Massachusetts, January 24, 1851.

Sir:—Your circular was duly received, and should have been replied to long ago, but unavoidable circumstances prevented my giving that attention to the subjects upon which it invited remarks, seasonably to address you before the present time.

As the seasons have much to do with the failure or success of agricultural labors, I remark first, that the months of December, 1849, and January, 1850, were of a mild and even temperature; so much so that the branches and buds of the peach and apricot looked nearly as well when they were past as when they commenced. During these months the ground was nearly free from frost, and during the greater part of the time was protected by several inches of snow. March was a cool, windy month, and although it thawed much nearly every day, it froze hard nearly every night. The consequence was that the branches of peach-trees soon began to exhibit at their extremities indications of shrivelling, which continued through the month, so that one-half or three-fourths of the previous year's growth in many situations were destroyed. It is not to be wondered at that many of the buds on the live part of the branches should be destroyed too, under these circumstances. April and May were cool. There were many cloudy days in both months, and much storm, so that the labors of spring were retarded, and many thought if it continued so it would not be much of a corn year. June, and until the middle of July, were warmer and drier, so that by the first of July vegetation had advanced to about its usual position at that time. From the 15th of July forward, there was much rain, and some sweeping winds, whose effects upon the grain were any thing but favorable to rapid harvesting. Thus much for the season.

Wheat.—Winter wheat is rarely sown in this region. Spring wheat has gradually been receiving more attention, but the last crop was an unfortunate one—not indeed half a crop. That was probably owing in some measure to the fact that the season of its filling was very wet. It suffered some from the fly, but the straw was unusually bright, and the empty heads stood erect. Spring wheat is usually raised after some hard crop, for which the land is well matured. It has usually but one ploughing at the time of sowing, which varies in depth according to the notions of farmers and the character of the soil. The importance of deep ploughing is now better understood than formerly, and farmers are practising accordingly. We are not troubled with the Hessian-fly. The best remedy for the weevil that I know of is to sow gypsum over the wheat while it is in blossom. This insect does its work while the berry is soft, and the plaster sown at this time operates as a stimulant to hasten its maturity and carry it beyond the insect's reach.

Corn.—Almost every farmer has his favorite variety. The early Dutton is probably as productive as any, though some prefer an eight-rowed variety with large kernels, growing more loosely on the cob, for its still earlier maturity. The crop of the last season was good, though many circumstances in its growth were unfavorable. The yield, of course, was as various as the soils on which it grew or the skill of the cultivator. Forty bushels to the acre were, perhaps, a fair average last season. The cost of producing a bushel of corn depends upon circumstances. An intelligent and successful farmer who never fails with his crop, and whose average produce is seventy bushels per acre, told me that it did not cost him over six cents a bushel to raise his corn. He estimated that the tops and shucks would pay for the labor, and that the increased productiveness of the land would pay for the manure. But all farmers have not his favorable soil. The process of cultivation varies with different persons. We think a very successful one to be to plough sward-land deep, and lay the furrow flat but a few days before planting. We say lay a flat furrow that the sod may not interfere with cultivation, and we would have the ploughing recent that the grass may not start up between the furrows, and for the reason that the later a clayey soil is ploughed in the spring the more friable it will be, and of course better adapted to the growth of roots. The ground is then thoroughly harrowed and struck out in rows for planting. Manuring in the hill is an almost universal practice, and from six to eight loads are applied to the acre. Farmers who can afford it use rotted manure of the previous year. Ashes and plaster are used as top-dressings.

Oats, Barley, Rye, Buckwheat, Peas, and Beans.—Oats and buckwheat are more generally raised than the other crops. The former because they are subject to but few accidents, and the latter because it will admit of a later sowing than other crops. Oats are an exhausting crop, but they command a ready market at an average of forty cents for thirty pounds. Buckwheat is a cleansing crop. From its rapid growth and shady habits it chokes weeds, which often overrun old fields, and one or two crops usually eradicate them. It is well adapted to low moist lands where other ploughed crops would fail, and its yield on such land is usually greater than on dry soils, like rye, of which but little is raised, and barley, which is not a very common crop it is good to stock after.

Potatoes.—The early part of the season being cool and wet, the expectation of farmers was that this crop would succeed well; consequently, larger quantities were planted than usual. The crop, however, has never been so near a total failure before. The rot commenced in July, earlier by some days than ever known before. Every variety, the earliest and most hardy, suffered more or less from its ravages. Peach-blows and some of the coarser varieties suffered least—and those more delicate, the most. A great proportion of the fields yielded no more than the seed, and in many instances the failure was so great that whole fields were left undug. Where they escaped the rot, the quality was poor and probably unhealthy. In consequence of the oft-repeated failure of the potato crop, other root crops, such as turnips, carrots, and beets, are receiving more general attention. In the culture of turnips, a piece of sward-land is turned over very flat in July, over which a dressing of well-rotted manure is applied, after which the ground is thoroughly harrowed. The seed is sown broadcast from the 10th to the 20th of July, and covered with a light harrow or bush. Soon after the plant appears, a dressing of ashes is applied, and the labor is done till the time of digging. The yield varies from 100 to 200 bushels per acre, and the uniform price of good turnips in the fall is 25 cents per bushel. A variety known as the cabbage turnip is coming into repute. In form it resembles the ruta baga, and in taste it has somewhat the flavor of a cabbage. Its productiveness is great, and its keeping qualities are beyond a question, it being, if possible, more tender in March and April than in November, and retaining its good qualities until June. They are easily raised, and are worthy of commendation to general cultivation. It endures the winter with only a slight protection, and will grow where other root crops will succeed.

Yours truly,

W. BACON.

Kalamazoo, Michigan, December, 1850.

Sir:—In answer to your circular of 26th August, 1850, I would say:—

Wheat.—Soule, Blue-stem, White-flint, Red-chaff, and Bald are varieties most in use, and preferred in the order I have placed them. A new variety called white-chaff blue-stem is said to have come from your office, and is much esteemed where it is known; average yield the past season, 20 bushels per acre in this county; time of seeding, from 1st to 20th September, and of harvesting, about the middle of July. Quantity of seed, one bushel and a peck per acre: plough twice, about six inches deep. The yield per acre is on the decrease. Our rotation of crops, is, wheat after wheat, every other year. The average price for the past season, 65 cents per bushel.

Corn.—Yellow-dent, two-thirds, and white-dent, one-third; product, 40 bushels per acre; cost of raising, 6 to 10 cents per bushel; tillage done by small plough and cultivator, once each. Corn is mostly used on the cob in feeding.

Oats.—White oats preferred; yield on prairie land, 50 bushels, and on oak openings, about 20 bushels per acre; price, this season, 20 cents per bushel.

Barley not much raised.

Rye, Peas, and *Beans.*—Seldom seen in cultivation.

Clover.—The medium size preferred; produces one and a half tons per acre, with the use of plaster. Other grasses are not much known.

Dairy Husbandry.—No surplus in the county.

Cattle.—Value: calves 8 months old, \$3; yearlings, \$5; two years old, \$8, and three years old, \$10 to \$14. Good cows, \$12 to \$20. Sheep are profitable and largely on the increase, but I am not able to reply to other inquiries.

Hogs.—We have a variety of crosses of all kinds, and the quantity of pork is on the decrease in this county, and I may say in this part of the State.

Tobacco does well, and matures before frost affects it, though now raised in small quantities. I think that a few years hence it will be next to wheat among our surplus crops.

Hemp.—Not raised.

Turnips, Carrots, and *Beets.*—Not cultivated in the field.

Potatoes.—Many varieties; cultivation much neglected; product, 100 bushels per acre; cost of raising, about 5 cents per bushel. Sweet potatoes do well; raised only in small quantities, on account of scarcity of seed, for we do not know how to keep them.

Fruit does well, and is of excellent quality; a great deal of attention is being paid to all kinds—also to grapes. This section of the State is of recent settlement, and it is only within a few years that a supply of trees could be procured at a reasonable cost, and the orchards are yet quite young; but a few years will give a large surplus of excellent grafted fruit.

Manures are almost wholly neglected, except plaster, which is used some on corn, and much on clover, at the rate of 60 pounds per acre, every spring soon after snow is gone. This section of the State is increasing in the culture of corn, and rather on the decrease in other grains, owing, I think, to the yield being less, arising from the soil being run hard, and neglect to manure; but more attention is being paid to a regular system of farming, and of applying the means to keep the soil in good heart.

The circulation of agricultural papers is producing much good, by stimulating the farmers to greater efforts, and in applying the recent improvements and labor-saving machines to carry out the work. One hundred copies of your Patent Office Report, in this county, would do much good, and I have made quite an effort to get a copy, but without success as yet, through Lewis Cass of the Senate, and William Sprague of the House.

Yours, respectfully,

WM. L. BOOTH.

URTICA WHITLOWI.—SUBSTITUTE FOR HEMP.

Townsend, Huron County, Ohio, January 30th, 1850.

Sir:—In looking over the Patent Office Report for 1847, I find, on page 163, under the article *Hemp*, an extract from Niles's Register, vol. 8, page 188, referring to the plant *Urtica Whitlowi*, discovered by Charles Whitlow, of New York. The plant alluded to underwent, at the time of its discovery, a very critical examination as to its merits and adaptation to the purposes of hemp and flax, by the persons or committees appointed for the purpose, and whose investigations were in accordance with the remarks contained in the Register.

Now, perhaps, some light may be thrown on this subject. I was well acquainted with Mr. Whitlow, and have seen the plant, together with a piece of the cloth manufactured from it, which was remarkable for its white and silk-like appearance, and also for its uncommon strength. Mr. Whitlow informed me, that General Macon, then a Representative in Congress, remarked that "the discovery was worth the whole contents of the Patent Office;" but this of course will go for just what it is worth.

The reason why no further experiments were made to test its utility was this:—Mr. Whitlow was making preparations to fallow for following it up on an extensive scale, but unfortunately death put an end to any attempt on his part to bring about the anticipated result. The fact that Mr. W. was a foreigner, (a Scotchman by birth,) and that he had but few friends in this country, and none who felt an interest in the speculation, will account for the abandonment of the enterprise.

But I think a knowledge of the plant may be reclaimed, if it has been lost, which seems to be intimated in the Report. I will attempt to give a description of it; but it is merely from recollection, and may be erroneous. The plants have radical stems, or rather they may be said to be all radical, as there are many springing directly from the root. Smooth or glabrous, or dark purplish red, or dark mahogany color, the leaf lanceolate, serrate, acuminate, sessile; but I am not certain, nor am I botanist enough to determine whether it is necessary that a plant should be pubescent or hirsute in order to constitute it a species of *urtica*. Be this as it may, I think I should recognise the plant if I should see it again. Mr. Whitlow informed me that he discovered it a few miles from the city of New York, on some of the moist grounds so common on the island. I have troubled you with these remarks more for the purpose of eliciting further research than with any other design. Should I visit New York the present year, I intend to make inquiries in order to discover what was thought to be of such immense value. Should I succeed, information will be duly communicated. I will add that if you should think it necessary to ask any questions relative to the above facts, or that will throw any more light upon the subject, as far as I am able, they will be given with the greatest pleasure.

Respectfully, your obedient servant,

BENJAMIN BENSON.

Hon. T. EWBANK,
Commissioner of Patents.

Remarks.—A space is given to the above as a matter of some interest to the public.

The family of plants to which the *Urtica Yucca* referred to belongs, flourishes principally in the Southern States, where it has attracted some attention from its textile properties. Its fibre, however, is not so strong as that of hemp.—ED.

Searsmont, Waldo County, Maine, January 6th, 1851.

Sir:—In answer to your circular, I submit the following:—

Wheat.—The variety used here is the Red Sea, so called here, and is preferred because it is less liable to be troubled by weevil, and matures about 15 days earlier than any other, and produces more grain; but the flour is not so good as that of another variety, called bald wheat. Average product, about 12 bushels per acre. We plough twice, about 5 inches deep, and harrow well, then roll or brush the ground. The yield was better the past year than for 4 or 5 previous years. Rotation in crops is almost universal. We know of no remedy for the weevil. If the Hessian-fly troubles our wheat, we do not know it. The average price is about \$1.50 per bushel. We have not sowed any other than spring wheat till within the two past years, when a few farmers have tried the white winter wheat and have succeeded well.

Corn.—The most esteemed varieties are the 8 and 12-rowed yellow, which will mature in about 3½ months from the time of planting. Average product, about 30 bushels per acre. Cost of production, say 65 cents per bushel. The most approved method is to plant upon ground that had been broken up the year before, plough twice, and spread on all the manure we have to spare for that purpose, say about 25 cart-loads to the acre; furrow it out about 5 feet apart, and manure in the furrows with well-rotted manure, and drop the seed in drills about 8 inches apart, and cover with the hoe. When the corn comes up, sow on unleached ashes and hoe it sufficiently to keep down all weeds, but not hill it up nor use a plough between the rows. The cultivator is the best, and not so liable to cut the roots as the plough. The seed, before planting, should be soaked in a solution of saltpetre or copperas, and stir in some warm tar, then dry with lime. We think this will prevent the worms, crows, and birds from eating it. We believe at least 25 per cent. is gained by grinding corn, and 15 per cent. more by boiling the meal. The next inquiry I cannot answer to my own satisfaction, never having known of an experiment of the kind, but am well satisfied that the value of the manure produced would be much more than is generally supposed. The average crop of oats is about 25 bushels per acre, and of barley, about 15 bushels; rye, 25 bushels; peas, 10 bushels; and beans, about 15 bushels per acre. The quantity of seed used is as follows, viz.

oats, 8 bushels; barley, 2 bushels; rye, 1 bushel; peas, 2 bushels; and beans, 1 bushel per acre. I think peas are the least exhausting to the land.

Clover and Grasses.—Average crop, about 18 cwt. to the acre. The grass seeds preferred for laying down meadows are red-top, tall meadow, and herdsgrass.

Dairy Husbandry.—The average annual product of butter and cheese per cow is about $20. The price of butter is about 15 cents per pound, and of cheese 10 cents per pound. The cost of rearing neat cattle in this State is all that they will sell for, which is about $25 per head. The price of good cows is about $25 each in the spring and $18 in the fall. The Durham, Devon, or Hereford are a decided improvement upon our native stock for every purpose.

Sheep and Wool.—We think the rearing of sheep more profitable than that of any other stock at this time. Large sheep are supposed to be the most profitable both for fleece and mutton. The proportion of lambs reared to the ewes is about four-fifths.

Hogs.—The most approved breed is a cross of the Newbury white and Tuscarora. The usual, and probably the cheapest, way of raising and fattening pork in this State is to feed with boiled potatoes, turnips, and pumpkins, mixed with meal and milk, and, a short time before slaughtering, to give them (the hogs) boiled meal either of corn, oats, peas, or barley, or of meal from corn ground in the ear, which last we have used as a substitute for potatoes for the last 2 or 3 years. Our method is to first crack the ears in what is called a corn-cracker, and then grind in a grist-mill. We learn, from experiments made, that the nutriment contained in 30 lbs. of corn-cobs is equal to 28 lbs. of oats, which weigh 30 lbs. to the bushel. This we believe from experience. The miller takes 3 quarts per bushel for cracking and grinding, instead of 2 quarts for grinding the corn alone. For this extra quart we get our corn shelled, (or, rather, are spared the trouble of shelling,) and save the nutriment of the cob. This meal makes excellent feed for horses and cattle. I do not think it profitable here to make pork by feeding on clear corn.

Root Crops.—We consider the cultivation of the ruta baga as one of our most profitable crops, and which is rapidly increasing. The cultivation of the largest crop within my knowledge was as follows, viz.:—The land was planted the year before with potatoes; the next year the ground was ploughed, and 40 loads of manure and 10 loads of leached ashes were spread to the acre; then a deep furrow was ploughed, and two furrows turned into that, which would leave the land in ridges. Drop the seed on the ridge and rake in, then roll with a horse-roller. When the plants appear, we thin them out, that they may stand 3 inches apart all over the ridge. This mode of planting will make the rows about 2½ feet apart. I have known the produce of an acre thus served to exceed a thousand bushels. The usual crop is, I suppose, about 700 bushels. Carrots and beets are not thought to be profitable crops.

Potatoes.—We do not raise any sweet potatoes, and comparatively few of any kind for the last four or five years. We, probably, cultivate 20 different varieties of Irish potatoes, and consider the long red to be the most prolific, though not so good for the table as the white and blue varieties. We plant on new land, preparatory to other crops. I think the best method is to manure the land and plant them in drills about 3 inches apart. The large ones should be cut. We usually hoe but once. Average crop, about 150 bushels to the acre; but before the disease affected them, our average was about 400 bushels per acre. Then we could make it profitable to raise them for 10 cents per bushel.

Fruit Culture.—The cultivation of fruit is increasing in this State; especially the apple. I think, if the apple should continue to flourish as it has for the last 10 years, it will be a very profitable crop. Thirty-four years ago, I planted 500 apple-trees. None of them, nor of the second crop, and only two of the third crop, are now alive, but I have continued to replace them as they have died, and I now have a very flourishing orchard, which I find to be profitable. The price of apples here is from 33 cents to $1.25 per bushel. We do not think it profitable to feed apples to hogs. It has not been profitable, in this part of the State, to rear apple-trees, until within the past few years. Russets are the best kinds to keep for winter.

Manures.—The best plan for making manure, we think, is to cart into our hog and barn-yards swamp-muck in the spring, and in the fall draw it into the field for use the next spring, and, before using, mix with lime. To preserve manure from waste is to cover it up as soon as applied to the land. The above are correct answers to a part of your questions, according to the best of my judgment.

Very respectfully, yours, &c.

HARRY HAZELTINE.

Scottsville, Monroe County, N. Y., January 14th, 1851.

Sir:—The circular issued by you from the U. S. Patent Office has been received by me, and the following are answers to the questions therein contained, so far as I am practically acquainted with the subjects upon which information is desired. The town of Wheatland lies on the Genesee River, in the very heart of the great wheat-growing region of Western New York, and possesses, in its soil and climate, in an eminent degree, those essential characteristics which have rendered Genesee wheat and flour so famous.

Wheat is the great staple article of produce both of this and all the adjoining towns, to which all other branches of farming are subservient. The varieties chiefly cultivated here are the white flint and Soule. The white flint was introduced here about 25 years ago, and quickly superseded all the kinds then in use, and still continues to be a favorite with most farmers. Its characteristics are, singular hardiness of constitution, which renders it less liable to damage while growing than any other variety now grown, and less liable to be destroyed by the various depredatory insects which infest this crop. It is also an excellent wheat for flouring purposes, making a large quantity, per bushel, of the richest and whitest flour. The Soule is of more recent introduction, not having come into any considerable degree of favor till within the last five or six years. This variety of wheat, as generally raised, consists of two kinds, a white and a red chaff, very similar in their habits of growth, and appearance after being threshed; so much so, that it is very difficult to distinguish them. It is a less hardy wheat than the white flint, the growth of straw is much less, and it is about a week earlier in ripening. The probability is, that it will not make so much flour per bushel as the flint, but it is of excellent quality. The Mediterranean variety has been introduced here from Maryland and Pennsylvania lately.

It is a coarse, hardy wheat, but not fit to be raised on the fine wheat-growing lands of Western New York. It will not make superfine Genesee flour, and its introduction here would destroy the high character that flour has hitherto sustained. The average product per acre for this town, according to the last State census, was 22 bushels, and was the highest in the State. The yield has undoubtedly increased since that time, and will now probably range as high as 25 bushels. Many farmers get better averages than that. Our seeding-time is from the 10th to the 25th of September, and our harvest from the 15th to the 25th of July. The general practice is to sow good clean seed, without any preparation, at the rate of from 5 pecks to 2 bushels per acre. Our usual manner of cultivation is to sow on summer fallow, ploughed two or three times; though it is becoming common to plough but once, the after-cultivation being done with the harrow and cultivator. The depth of ploughing varies from 5 to 10 inches. Our yield per acre has undoubtedly been increasing, ever since the settlement of the town. The most common rotation is to sow wheat every other year upon a clover lea, pasturing or mowing one year out of the three. As to remedies for the Hessian-fly and weevil, I know of none. The fly, of itself alone, in my opinion, is very rarely the cause of the destruction of a crop of wheat, but, when combined with other causes, it often finishes what they have begun. The average price of wheat at our mill in Scottsville, has been $1.03 per bushel.

Corn is cultivated here to a considerable extent, and its cultivation is on the increase. The most esteemed varieties are the Dutton, eight-rowed yellow, red blaze, and white flint. The average product per acre varies very much, some farmers getting 50 bushels, and others only 25 bushels per acre. It would be, however, not far from 30 bushels. The lowest cost to produce an acre is not less than $12, including interest of land and taxes, which, at an average of 30 bushels per acre, would be 40 cents per bushel. Thirty bushels of corn at 50 cents would be $15, stalks worth $3, which would leave a net profit of $6 per acre. My crop has averaged, for the last 8 years, 45 bushels per acre, including 1 year of almost total failure from severe drought. My practice is to raise corn on a clover lea manured with about 16 loads of good barnyard manure to the acre, ploughed in deep. I plant in hills, about 3 feet apart each way, about the 20th of May; the after culture is almost wholly done with the plough and cultivator. The whole expense would not exceed $14 per acre; so my net profit would be about $12 per acre. The best mode of feeding corn to hogs is, in estimation, to give it to them raw and unground, and for cattle raw, but ground. I do not think the increased value of the feed will pay for the labor and expense of grinding and cooking. As to the increased quantity of grain per acre that the manure of 10 bushels of corn consumed by hogs would make, I cannot say; but think it might be from 2 to 3 bushels.

Oats are only raised here in small quantities; many farmers not producing any. The average product per acre would not exceed 30 bushels.

Barley.—The cultivation of this grain is increasing. Average per acre, about 25 bushels.

Rye is not raised here at all.

Peas and *Beans* are raised only in small quantities; they do not average more than 20 bushels per acre.

Clover is chiefly cultivated in this town for pasturage and hay. Average per acre, about 2 tons. Gypsum is the only fertilizer used here for pasture and meadow. Clover and timothy are the only grasses used here for seeding meadows; quantity of seed sown per acre is from 6 to 8 lbs. of clover, and from 6 to 8 quarts of timothy. The cost of growing hay per ton will not exceed $3. The price it now brings is $12 per ton.

Dairy business is not pursued here as a means of profit; farmers generally producing merely enough of the dairy products for family use.

Neat Cattle are raised by most farmers to some extent, and are mostly fed on rough fodder, such as straw, corn-stalks, &c. The cost of raising till 3 years old in this way is but trifling, as they consume but little which would be valuable for other purposes; and the manure they make is worth quite a portion of the cost of their keeping. Average price at that age, from $25 to $30. A given amount of feed will produce more meat in a Durham or Devon than in a native animal. I am not acquainted with the Herefords.

Sheep husbandry is profitable here. The cost of growing coarse wool is greater than that of fine. Some of the coarse breeds were introduced here some years ago; but, after trial, they were universally abandoned. Many good flocks of fine-woolled sheep will average from 4 to 5 pounds per head. The cost of production is small; as, like cattle, they are fed on what would be otherwise wasted. The lambs, from a well-managed flock of sheep, will pay nearly all expenses. The Merino sheep are the most profitable, both for mutton and wool. The proportion of lambs annually reared to the ewes will not exceed one-half.

Hogs are raised by every farmer; but pork, as an article for market, will seldom pay. The best breeds are grade animals, produced by a cross of the China with some of our larger breeds, such as the Leicester and Byfield. One hundred pounds of corn fed to good hogs will produce 10 pounds of meat. We put down our pork in salt, using nothing else.

It is gratifying to be able to say that a better system of farming is taking the place of the old, careless, and slovenly method heretofore practised in Western New York. This is to be attributed chiefly to the liberal prices obtained for our produce for the last few years, thereby producing in the farmer a stimulus to exertion, which he does not often feel when prices are so low as barely to pay the cost of production. Give us a market and remunerating prices, and we can raise an amount of produce that will astonish the world.

I am, sir, yours very respectfully,

SAMUEL WOOD

THE TEASEL, AND ITS CULTIVATION.

Paris Hill, Oneida County, N. Y., December 26th, 1850.

THOMAS EWBANK, Esq.:

Dear Sir:—I had designed writing an extended communication, including a reply to several interrogatories contained in your Agricultural Circular, bearing date the 26th August last, a copy of which was forwarded to me: on reflection, however, I have concluded to confine my remarks to one subject, having reference to a branch of agriculture pursued to some extent in this State, as well as in a portion of New England, and which is not included in your list of inquiries. I refer now to the cultivation of *teasels*—an article of agricultural production of some importance, not embraced in the census returns, and of which, consequently, no reliable statistics can be obtained as to the quantity or value of the annual product. My present purpose is principally to call the attention of others to the subject, hoping some one more competent will be disposed hereafter to do it better justice.

The teasel is a biennial plant, found in the north temperate zone between the latitudes of 40° and 44° in the United States, and cultivated also in England, France, and Germany. The bulb or ball of the plant is the only part of it which is of any value, and that is highly useful, and, indeed, necessary in the manufacture of cloths and other woollen goods, being found far superior to any thing else for the purpose of raising and laying the nap, thereby enabling the manufacturer to give his goods a more perfect finish. In fact, although a great variety of experiments have been tried with other materials as substitutes, nothing has as yet been discovered that would answer the purpose equally as well; the flexible hooks of the teasel being admirably adapted to the purpose, and, with proper precaution, not injuring the texture of the goods upon which they are used.

There are several varieties of the teasel. Some of these grow spontaneously in the Northern States in old meadows, and by the roadside, and, in soils favorable to their growth, become sometimes difficult to eradicate, and are reckoned among the noxious plants. They attain a height of from 4 to 6 feet, and are in full bloom in this latitude in the latter part of August, bearing a purplish blossom. The head, being furnished with long, flexible, but perfectly straight prongs or spires, has never yet been found of value for any purpose. These varieties are therefore never cultivated.

The cultivated varieties, although distinct from each other, yet being similar in their general character, and requiring the same mode of cultivation, it is not necessary in this article to speak of them otherwise than generally. At what time the cultivation of the teasel commenced, or when and by whom it was introduced into the United States, I have not at hand the means of ascertaining. In the infancy of our woollen manufactures, however, it was cultivated only in gardens and small plantations, and that to a very limited extent. The cultivation, however, increased with the demand caused by the increase of our manufactures; but it was not until the year 1820 that it was known as an article of field culture among agriculturists. The supply being seldom equal to the demand, till within some 12 or 15 years, the deficiency was made up by importations from Europe: with the increase of the manufacture of woollen goods, however, there has been an increased cultivation of the teasel; and as the nature and wants of the plant have been more closely studied, and its cultivation better understood, there has been a corresponding decrease in the price, without materially diminishing the profits of the producer. The first grown in this country were sold, it is believed, as high as $10 per thousand; and as late as 1835, teasels were imported at a cost of from $4 to $5 per thousand. Since that time, there has been a gradual reduction of the price in market, until within the last 5 years, within which time it is believed they have reached their minimum price, being sold as low as 75 cents to $1 per thousand.

As no census has been taken of the quantity annually produced at the present time, no correct estimate can be made: any attempt at such an estimate must necessarily be only an approximation. It is to be hoped that hereafter teasels will be included with the other agricultural products in relation to which the various marshals and their assistants will be required to make inquiries, and report in their census returns, both as to the product and value. The benefits resulting from such a course can be properly appreciated by those who are fully aware of the importance of the article to the manufacturers, and as a substitute for which, no other production, either of nature or of the ingenuity of man, has yet been found *suitable*.

With these preliminary remarks, we will now proceed to give some directions (founded on experience) of the proper mode of cultivation of the teasel. And first, of the *soil*:—The teasel, being taprooted, requires a deep, rich soil. A strong, gravelly loam, if of sufficient depth, is found generally preferable—the teasels grown on such a soil being more durable in use, and the roots of the plant being less liable to be thrown out during the severe frosts of winter, which on many soils is frequently the cause of great loss. As a preventive of this evil, sward-land, ploughed deep, and well turned under, in April, is to be preferred. A subsoil plough will be found highly beneficial in giving a good depth, and preparing the soil in such manner as to enable the main root of the plant to penetrate freely, and to a sufficient depth to insure a vigorous growth. After ploughing, the surface should be thoroughly pulverized, and made as smooth and even as possible, by harrowing, or other suitable means. This will not only be of great benefit to the young plants, but will facilitate the after culture.

Planting.—This should be done in the month of April, or as nearly as possible in May; it being highly important that the plant should be well rooted before the coming on of the hot, dry season of midsummer. Another advantage in early planting is to enable the plant to attain sufficient maturity by the first season to insure its forming the stalk the second year, which small, late plants are likely to fail in doing, and, consequently, are a loss. The ground being properly marked out in rows, one way only, the seed may be sown in drills, by hand, or, more conveniently, with a drill-harrow adapted to the purpose, the drills being from 3 to 3½ feet apart. The latter distance is perhaps more suitable when the land can be afforded for the purpose, as giving a more convenient distance for working between the rows, especially in harvesting the crop. The seed should be but slightly covered. This may be done with a hand-rake, or more expeditiously with a light wooden drag, drawn by a horse, and following directly on the rows. Six quarts of seed, if properly distributed, is a sufficient quantity for an acre of ground.

Hoeing.—The seed being sown, no further attention is requisite till the plants are of sufficient size to admit of weeding, which will generally be between the 1st and middle of June, if the seed was put in early. As the plant in its earliest stages is a very slow grower, it will be necessary, unless the ground is quite clean, that the weeding should be done while the plants are yet quite small; otherwise there will be danger that the weeds will overtop them, and the after culture be likewise greatly increased. Usually, the hoe and the fingers are the only implements that can be used to advantage at this stage; the most important part of the work consisting in cutting or pulling up all the weeds in or adjacent to the row, and dressing down the plants into as narrow a row as is practicable, and thinning in the row to a distance of from 4 to 6 inches. Little or no earth should be thrown around the plants at the time of weeding.

The *hoeing* should principally be done about a month after the weeding—say from the 1st to the 10th of July. The plants by this time will have attained sufficient size to allow a cultivator to be used between the rows, and a portion of the earth may be drawn lightly around the plants with a hoe, thinning them at the same time, as they may require, to a distance of from 6 to 8 inches in the row. After this, if the work has been faithfully performed, but little further attention will be requisite the first season, other than to keep the ground mellow, by passing through between the rows occasionally with the horse-hoe or cultivator. The ground, however, should be kept perfectly clean and free from grass or weeds, and if this cannot be done without, another hoeing will be necessary, say in August.

As early in the spring of the second season as is convenient, or as soon as the ground is sufficiently dry to work properly, go through the piece again with the cultivator. Follow with the hoe, and give the plants another light dressing of earth. If the ground has been well tilled, as the plants will now commence forming the stalk, and will soon thoroughly shade the ground, but little further cultivation will be required. Should any weeds or thistles show themselves, remove them with a hoe or with the hand, but avoid working the ground to any depth, as, by disturbing the numerous fibrous roots now shooting out near the surface in every direction, the plants may be seriously injured.

Soon after vegetation has started freely in the spring, the stalk of the plant manifests itself, shooting upward, and attaining nearly its full height about the first of July, by which time the burs or balls of the earliest teasels will be visible. The plants attain to various heights, according as circumstances are more or less favorable to their growth, say from 4 to 8 or 9 feet, with several branches shooting out from the sides, and these again have their side branches, on the ends of all which, as well as on the rest of the main stock, the young teasels are formed.

These commence blossoming about the middle of July, and usually by the 1st of August the earliest are sufficiently ripe for cutting. This should be done as soon as the blossom is entirely off the bur or ball, and before the seed is fully matured; otherwise, the teasel becomes discolored and brittle, and materially diminishes in its value. As the teasels are formed at different stages, and ripen successively, at different times, they are, consequently, not all fit for cutting at the same time. It therefore usually becomes necessary to go through the field two or three times, to collect them all at the proper age, to prevent any being injured by remaining on the stem while others are being matured.

The process of cutting may be performed most conveniently with a large knife, held by the workman in one hand, while he seizes the teasel with the other, and, by a slight, quick, downward stroke with the knife, separates the stalk from 3 to 6 inches below the teasel, which is thrown into a basket ready to receive it. After a little experience, the workman will cut and retain 3 or 4 teasels in the hand before emptying it in the basket. In the height of the season, an experienced workman will cut from 20,000 to 25,000 in a day, if the crop is a good one.

The gathering of the teasels will generally be completed in the month of August. While in the green state, as taken from the field, they should be carefully spread, about 6 inches in depth, in some open, airy place, under cover, on open floors, permitting a free circulation of air. Should the weather be very fair or dry, but little attention will be necessary; otherwise, they should be frequently turned, to prevent heating and mouldiness. When sufficiently dried, which may be known by the seed separating freely

in moving, they may be stored away, or packed in boxes for market. As to the yield that may be obtained per acre, it is so various in different localities, and so likely to be affected by a great variety of circumstances, that no certain average can be named, it varying from 50,000 to 200,000 per acre, when the plants all come to maturity, and, in some instances, exceeding the latter quantity.

The common white grub is a great enemy to the teasel, feeding on the root of the young plant to such an extent, in some instances, as to destroy a whole crop that promised fair when the plants first made their appearance, and even for some weeks after. The winter also makes great destruction in some years, the plants being partially or entirely killed by an open winter, accompanied by severe frost. This may also occur in consequence of a sudden change from moderate to severe weather in the spring, after the plants have commenced growing, which they will do as soon as the frost is entirely out of the ground. The young and tender leaves becoming then expanded and open in the centre or crown of the plant, are far less able to withstand a severe frost than in mid-winter. In exposed situations, the effects of frosts may be guarded against, in some measure, by the erection of temporary cross-fences of rails, boards, or other convenient materials, which will serve to keep a covering of snow on the plants, and protect them, in some degree, from the bleak winds and severe frosts of winter and early spring, and prevent, perhaps, the loss of a valuable crop. These cross-fences should be removed as soon as spring fairly opens. A failure of the crop sometimes occurs after the teasel are fully formed, if at that time there is a long continuance of warm wet weather, which may cause a rust to strike them, which is very likely to injure materially, if it does not wholly destroy the crop. This was peculiarly the case, in some sections, during the last season, many pieces having been entirely ruined by the rust. Other evils sometimes befall the crop, and blast the expectations of the cultivator, but it is not necessary, at this time, to specify them.

I have thus, in the scattering fragments of time hastily snatched between the performance of other and more pressing duties, endeavored to give a brief outline of the most prominent and essential features in the mode of cultivation of the teasel. Although much more might be written, still, in this, as in all other matters appertaining to agriculture, very much that is essential can only be learned by experience.

Hoping that what I have thus hastily written will be acceptable to you, and also prove the means of calling the attention of others to the subject, I remain,

Very respectfully yours,

LORENZO ROUSE.

Union, Franklin County, Missouri, December 17th, 1850.

Sir:—Your circular, dated August 26th, 1850, has just come under my observation, printed in the "Valley Farmer," at St. Louis, Missouri, a journal devoted to agriculture.

Desiring to furnish information on the important subject of agriculture, and the products of the soil, that may be useful to the country, I have taken the familiar branch of raising Irish potatoes. The little time left me for investigation and inquiry (before the 1st of January) will compel me to give only my own experience, while I would have been pleased to add that of my neighbors also.

Irish Potatoes.—This is a good crop for the Western States, and, in first-rate ground, will yield 200 bushels per acre, and, in some instances, it has been known to exceed that amount. The best mode of raising them is to drill them in deep furrows, and cover them over first with rotten straw, and then throw on the dirt. The furrows should be 3 feet apart, so as to admit a plough, the use of which will be necessary once or twice to kill the weeds. In no case would I cut the potato before planting, and, instead of planting the small ones, (which are generally reserved for seed,) I would plant the largest size. Large potatoes yield large potatoes, while small potatoes, when planted, yield small potatoes. This is true, and let him who doubts it give a fair trial to the sizes, and the difference will be seen. The common white potato is the best for family use, but not so prolific as the large red-skin potato. This last quality is fine for fattening hogs and cattle, and, when boiled, will be eaten by them with an almost ravenous appetite. I consider potatoes the cheapest crop that can be raised, and, at the same time, one that repays the farmer better than almost any other.

Irish potatoes are now worth 75 cents a bushel in this county, and are never sold for less than 25 cents. So, you see that an acre, yielding 150 bushels of potatoes, brings the farmer $37.50, at 25 cents per bushel, the lowest price, and, at present rates, would bring $112.50—a nice little sum from one acre of ground, that did not require more than two days' tilling.

I will try and obtain statistics of different crops, the average yield, &c., for next Report, and also give such information on some of the various branches of agriculture as I may be able to collect.

Very respectfully, your ob't servant,

R. B. JEFFRESS.

Hickory Creek, Louisa County, Virginia.

Sir:—In reply to your circular addressed to me, I will state that it is not to be expected that one individual can profitably answer your numerous queries.

Passing by the previous questions, I will make some remarks on the tobacco crop. The average yield, in this part of the country, is, I think, about 1000 pounds per acre, on good land, though more can be made on very rich or highly manured lands. I have made on some land as much as 2000 pounds per acre. The cost of production varies according to circumstances: the cost does not exceed $30 per acre. It is highly important that the plants should be set out early, and, consequently, great care and attention should be paid in raising early plants. I am satisfied, from experiments made by myself and others, that the application of Peruvian guano will greatly facilitate the early and rapid growth of the young plants. I have applied it, both with and without burning the land, and its effects were very beneficial in both instances.

Being encouraged by its success in growing wheat and other crops, I applied it broadcast on tobacco land, not using over 200 pounds per acre, and, on a portion of the crop, not over 100 pounds per acre. The effect was decided and highly favorable. The tobacco grew faster, and ripened earlier than it did on better land adjoining, to which no guano had been applied, and the amount of the crop was unquestionably greatly increased.

I have pursued a plan in regard to topping tobacco, which I believe few planters in Virginia follow. I do not take off any of the bottom or ground leaves. I direct that the plant shall not be topped until it runs up high, nearly ready to blossom, then leaving the leaves on at the bottom for about four or five inches, the ordinary height of priming, I leave about eight leaves above, more or less, according to the fertility of the soil, the season, time of year, &c. The advantages of this plan are, that the tobacco is made of finer texture, that there are very few *suckers*, and that, after four or five priming leaves are stripped off for lugs, and curing what I have left, there is enough to make two small bundles of tobacco, instead of one, and that, too, almost entirely free of sand or *dirt*. From experiments I have made in priming and not priming, I am fully satisfied that I make *more* tobacco from the same land, and get a better price for it. A few of my neighbors have been convinced of it, and are now adopting the same course of priming.

The best crops to grow in rotation, to maintain the fertility of tobacco land, are wheat and clover, tobacco one year, wheat one year, and clover two years, then tobacco again.

Fruit culture is receiving increased attention. Apples, the most certain and durable kind of fruit, can be and are now by some raised with profit. Good apples are decidedly better food than potatoes for hogs and cattle.

The best variety for winter use known in this part of the country is called Milam; its color is brownish red, mellows early in the fall, is of delicious flavor, and, with ordinary care, will keep until June.

The Catawba and other grapes are extensively cultivated for the table, and but little attention is paid to wine-making in these temperance days, when more money can be made by other pursuits.

Being pressed for time, I have hastily sketched off the above crude remarks, which are at your service.

I am, very respectfully, yours,

WILLIAM A. GILLESPIE.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Tishomingo County, Mississippi, December 21*st*, 1850.

Sir:—The Agricultural Circular of the 26th August was handed to me a few days since for perusal, and I have concluded to write a few lines in answer to some of the questions therein propounded—not that I expect to add any thing of particular interest to the common stock, but, by writing something, I may probably receive the Patent Office Report, which will enable me to profit by the experience of more skilful planters embodied therein.

Wheat.—Varieties in use here are generally Orleans and red spring; I prefer the former; it is usually sown on corn or cotton land, after the crop is gathered; three-quarters to one bushel of seed per acre, put in with small ploughs, running two or three inches deep, and seldom harrowed or brushed—consequently the ground is very uneven, and a small crop the result, say from 5 to 7 bushels per acre. There is no preparation of seed, except being soaked in a strong solution of blue vitriol, for from 12 to 24 hours previous to sowing, to prevent smut, which is effectually done by this process. It is generally sown from the 20th October until the 15th November, and harvested between the 25th of May and 5th of June: it is sown thus late to prevent the ravages of the Hessian-fly; but I believe that wheat might be put in in August or September, and would furnish a good winter pasture for sheep or calves; by being grazed close in the winter, the fly is destroyed and the wheat not materially injured. I have tried this several times on a small scale, with very good success. For several years, I have sown wheat on oat-stubble, in the following manner:—Break the ground with a heavy, two-horse plough, running from 4 to 6 inches deep; (if this was followed by a sub-soil plough, the yield would be greatly increased;) I then run a heavy iron-toothed harrow lengthwise the furrow; I then put about one bushel of seed per acre, plough with a small plough the same way, and finish by harrowing or rolling; a light top-dressing of rotten straw long manure, or even leaves, will increase the yield considerably. Without this dressing I have usually made from 10 to 15 bushels per acre; the average price here per bushel the present year is $1. To prevent weevils, it is only necessary to get the wheat out as early as possible, have it well sun-dried and suffered to cool thoroughly, then put it in tight casks or boxes, in a cool place, (a good cellar is the best place,) and no weevil will be seen for 12 months.

After wheat, I plant corn, by first breaking and pulverizing the ground well; lay off rows 4½ feet apart, with a scooter or bull-tongue plough, throw two furrows to it with a turn plough, check off same distance, drop from 4 to 6 grains of large white corn to the hill, cover with a hoe, and then all the manure I can rake and scrape is put on the hill, at the rate of a shovel-full to each hill. The corn when half leg high is thinned to two stalks. I plough twice or three times, and finish the cultivation with a light harrow or cultivator. The second ploughing I plant the red-ripper or tory pea, in the step, from 10 to 20 in a place: they are a fine bearer, and a good renovator. I gather from 30 to 50 bushels of corn per acre, (but this is a poor common yield.) After the corn is gathered, I turn in my hogs, and very little corn will make them good pork. This crop is followed by oats, with a yield of from 15 to 25 bushels per acre, worth from 33 to 40 cents per bushel. I have followed this system of tillage for 10 years, and am confident my land has improved in fertility. One hundred pounds of corn, fed dry to hogs, will produce 20 to 25 pounds of pork; if boiled or soaked until soft, from 30 to 35 pounds; the manure from any given quantity of corn fed to hogs, if carefully saved, and skilfully applied to corn when planted, will increase the product from 30 to 40 per cent. of the amount thus fed away.

Sweet potatoes are a valuable crop for the table, for milch-cows, or hogs, fed either boiled or raw. The white or red yam are the kind generally cultivated here. These are generally bedded out, say from the 15th of March to the 1st of April, to secure a good and early crop of slips or plants. Dig a ditch 3 feet wide, 18 inches deep, and, for every bushel of seed, 3 feet long; fill this ditch to within 4 or 5 inches of the top, with fresh stable manure; then throw on sufficient of earth to raise it a little above the level of the surrounding ground, so as to prevent excess of water standing on the bed; on this, lay the potatoes so as not to touch each other; then cover with earth to the depth of 2 or 3 inches, as weeds and grass will first make their appearance, this depth will allow you to scrape off with a hoe or rake the first crop of weeds, leaving the covering 1½ to 2 inches thick; the ground intended to be planted should be well broken and pulverized; when the slips begin to come up, lay off rows 3 feet wide, and bed up with a good turn-plough, check the same distance the other way, and make hills, leaving the top flat, so as to catch the rain; when the slips are 3 or 4 inches high, they will do to plant. Should there not come a season to plant when the bed is well covered with plants, draw them in the evening, dip the roots in water, plant 1 in each hill, leaving 2 or 3 leaves above the ground, press the dirt close round them, pour on from ¼ to ½ pint of water to each plant, repeat next evening, and they will generally live. Four bushels of seed bedded out will be sufficient to plant one acre; in good time, after culture; as soon as the vines begin to run, scrape down with hoes; weed when they have reached 18 inches or 2 feet in length, (some will be longer, of course,) cut off the vines to within 6 or 8 inches of the root, plough both ways with a scooter-plough, running pretty deep into the hills, so as to loosen them up; hill up with a hoe, being careful to cover no part of the running vine. By cutting off the vines as above directed, new vines will start out and cover the ground much sooner than they would otherwise do; and should you be scarce of slips, the vines thus cut off answer every purpose planted in the same way; the yield is generally from 200 to 300 bushels per acre, and worth from 30 to 50 cents per bushel. On suitable fertile land, no manure is necessary: strong stable or barnyard manure injures both the flavour and smoothness of the potato: rotten straw, or leaves, are best applied broadcast. Those intended for table use may be kept in a cellar or house made for the purpose, or they may be kept in the following manner:—Raise a bank a little above the level of the surrounding ground, cover with dry straw, pile up the potatoes as high as you can lift dirt with a spade, cover with dry straw, then with earth to the depth of 10 or 12 inches, put a good coat of vines over this, and they are safe. I have not failed in upwards of 20 years to keep them through the winter in this way.

East Port, Miss.

I am, very respectfully,
Your most obedient servant,
JAMES WORD.

THOMAS EWBANK, Esq.,
Commissioner of Patents.

RICE CULTURE.

Matanza Plantation on Pee Dee, near Georgetown, S. C.
6th January, 1851.

Sir:—My time has been so much otherwise engrossed since the harvest, that it has not been in my power to communicate with you earlier, and now (if indeed it be not too late for your purpose) I must write briefly, and generally, in relation to the rice crop.

Our lands are improving under the grateful influence of the fallows and rotation practised by me, as that of a system, first in 1837–8, and they produce now rice of better quality than formerly. So much is this the fact, that there is a class of purchasers recognised in the Charleston market who will be content with nothing but the choicest samples, and for these they are willing to pay an extra price.

This system, extended as it is, and greatly improved, in the hands of my observant, skilful, and judicious neighbors of Waccamaw and Sandy Island, by manuring with rice-straw, chaff, and even flour, has been one among the chief means of producing the beautiful "long-grain" rice (cultivated now by the two most successful and experienced planters in this district, and by not more than two others, as far as I know) in the highest state of maturity.

Rice straw has long been valued as an excellent manure, when listed in and rotted, for upland corn and potatoes. It has latterly been used in the same way as a dressing for rice in the fallow swamp-land, on Sandy Island, and with favorable results.

Rice chaff, too, which formerly was discharged from the mill into the "race-way," in order to get rid of it, since its analysis by Prof. Shepard, for our Agricultural Society, is now used to some extent in renovating old lands. It is distributed over the surface, some three inches deep, and ploughed in, stimulating the production of the soil, and improving the quality of the grain.

Rice flour, notoriously of value as food for hogs, cattle, and poultry, and selling readily, when corn is scarce, at from 12 to 20 cents per bushel, has, within a very few years past, contributed its share towards improving in both quality and quantity a particular crop in Waccamaw.

The crop of last year, (1850–1,) affording, as it does, a good portion of very prime rice, where the salt-water did not affect it, will prove to be some 10 per cent. short, as estimated by us. This diminution is believed to be owing, chiefly, to the high winds which passed over the tide-lands about the middle of August last, when the greater half of the growing rice-plants were still in bloom.

Rice is essentially a "swamp-seed" here.

We do not cultivate any on the upland.

Every year, however, it is grown in small patches in the interior, and tended mostly with the plough.

The best kind of rice for this purpose is, I believe, the old-fashioned "white-seed," which was the only variety cultivated in the State until late in the last century, when was introduced among tide-swamp planters the "gold-seed rice," which is now universally approved. The "bearded rice," a variety of white rice, with a very long awn, was imported some years ago for this very purpose, (upland planting:) but, I believe, it is now nowhere seen but to be eradicated.

The "long-grain" seed alluded to above, some account of which is given in the proceedings of the State Agricultural Society of South Carolina, is the choicest variety now cultivated in this region. Like the ordinary seed, it requires particular care and attention throughout the process of culture, to have it produced of the primest quality. But, when thus produced, if it be carefully milled and skilfully prepared, the long-grain rice will command in the winter market from 50 cents to $1 per 100 lbs. more than the very best qualities of the ordinary small grain.

For example, during the month of December just past, the market in Charleston for small grain has ranged from $3 and $3.25 for prime, to $3.37½ and $3.50 per 100 lbs. for choice. Whereas the market for long grain has been influenced by fancy. Prices have been obtained for this kind of $4.25 per 100 lbs., $4.50 also, and even $5 for a small fancy lot.

These prices are never reported; but, having been informed that they were actually paid, I feel bound to mention the fact, when answering your inquiries as to improvements of the grain.

A specimen of this grain, with the entire plant, including the root, has been prepared, and will be sent to the Great Fair in London.

I have the honor to be, very respectfully,

R. F. W. ALLSTON.

Sir:—Your circular of August 26th, franked to me by the Hon. J. Smith, Senator from Connecticut, was received early in autumn, but got mislaid, and has just come to hand; and I would here remark, that I have turned my attention almost wholly to sheep and wool, but as yet I have not had experience enough to justify me in saying which is the most profitable branch of husbandry, stock or wool-growing. The prices I obtained for my wool, this year, I call remunerative—think it has paid me about 20 per cent. I have a flock of about 1000, mostly Saxons; I sheared from them, on an average, 2¾ pounds per head the last clip. I calculate to raise 80 lambs from 100 ewes; and I feed my sheep during the winter from 4 to 6 quarts of corn per day to 50 sheep, and what good hay they will eat; salt my hay when it is put up, 4 quarts to the ton. The sheep in this county are generally healthy, and there has been commendable zeal with the wool-growers in improving their flocks and wool for 2 or 3 years past.

Respectfully yours,

JULIUS S. PRICHARD.

Brunswick, Medina County, Ohio, Dec. 30th, 1850.

Cabarus County, N. C., December 31st, 1850.

Dear Sir:—I have been favored with a copy of your excellent Report for the year 1848. I have delayed my remarks to the latest hour of the present year. January, February, and March very cold and much rain, and even April very cold. The rains continued through the month of May, and up to the 3d of June. July very dry, and, up to the 24th of August, even as dry as the year 1845. Then great rain and wind from the north-west, that blew down the corn and overflowed the low grounds to a great extent. September showery; October favorable to cotton; November fine to the 17th, when there was a killing frost; and December fine for the gathering of crops till the 27th; but it went out pretty cold and wet.

Wheat not so good a crop as in 1849 by 20 per cent., although a greater quantity was sown than had been for many years. My residence, Cabarus county, Harrisburgh, School district No. 11, being 19 or 20 farmers in said district, but two besides myself raised over 100 bushels, it was so injured by the rust. Not a half crop was made. The time of sowing, from 25th of October to the 30th of November. The blue-stem white wheat much injured by the rust; the golden chaff also, with rust and big cheat, that infest our fields. The May wheat was all that was a good crop: weight, 64 lbs. to the bushel. Mediterranean is pretty good in our soil. Average crop on good land, 10 and 12 bushels to the acre. Price, from $1 to $1.25 per bushel. Indian corn is cultivated with good success in our county. The average yield, on good land, is 40 bushels per acre, and the average price is 50 cents per bushel; but this corn sold from the heap, in a very green state, at 75 cents. The drought in the months of July and August was so severe that there has been a very short crop; but I hope, with the surplus of old corn that is yet on hand, there will be a plenty to keep the price from going above 75 cents.

Cotton.—The season for this crop was, in the beginning, cold and backward and very wet. Rains continued to the 3d of June, which gave the crop a bad start; but the latter part of the cotton season was favorable both for working and gathering. No killing frost to 17th November. The time of opening so favorable, that I think there is an average crop. It will be larger than 1849; but how much, I can make no calculation.

Cotton is the important staple of this section of North Carolina. By it thousands of dollars are made, although the seasons are short and the spring cold, that make it difficult getting a start; but there is nothing the farmer can make so much by as cotton, the price being good this season, viz. from $12 to $18 per hundred in our near markets. The time of planting the crop is from the 15th of April to the 5th of May. The present crop is all gathered and in market. Negroes hire, this year, at $90 and $100 by the year.

With respect, your humble servant,
JOSHUA HARRIS.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Sir:—In answer to your circular, I will suggest the following method of cultivation, without confining myself to any form of questions or answers. Grass or hay is our most essential as well as our most sure and profitable crop, being less liable to accidents and producing a greater profit upon the labour expended than any other, and forms the basis upon which we build our beef, mutton, wool, butter, cheese, horses, hides, tallow, &c.; therefore low, wet land, not suitable for the plough, and intended for mowing, should never be grazed. In this way a good crop of hay may be had for many years, without the application of manure, which, when applied, should be directly after the crop is taken off. The quantity of manure that may be profitably put upon an acre of tillage land in producing corn, wheat, &c., should conform to the wants of the soil, to enable it to bear grass. One acre of worn-out mowing land ploughed in the fall, and put to oats in the spring, will usually produce 30 bushels without manure, and yield a small profit, as also will beans, peas, or potatoes; the latter doing better without manure, in consequence of the rot; either crop leaving the ground suitable for the cultivation of corn the succeeding year. Then, by spreading and immediately ploughing in 40 loads or 20 cords of manure in the fall, and applying 10 or 12 loads in the hill in the spring, and planting before the 1st of June, 3½ feet asunder each way, hoeing twice with the use of the horse and cultivator, and weeding the third time without it, we usually get from 50 to 65 bushels per acre, according to the value of the manure; that from the back-house and hog-yard being best, and that from barns, which has been sheltered from the rain and sunshine, being worth at least one-third more than such as has been exposed. This can be accomplished as easily and as cheap as the raising of but 30 bushels per acre, (which is about an average crop for Somerset county, Maine,) except the application of the extra manure, the cost of which should not be taken into the account, as it will produce 16 or more bushels of wheat the succeeding year, and fit the ground for grass. The third hoeing, besides forwarding the corn, will be more than balanced in the increase of bushels, and still more in the succeeding crops of wheat and grass. A greater crop of corn is often obtained, sometimes 100 bushels or more, but usually at the expense of many other acres. I never of late have applied green, long, or unfermented manures to the soil, being convinced by actual experiment that it is of less value to the present and succeeding crops; but invariably heap up all that lies flat upon the yard, and composed partly of straw, that it may undergo a process of fermentation, so that, when applied, it will easily incorporate with the soil; but if it is hauled to the field and left in long rows in the fall, as is practised by many, to be used in the spring, the wind and rain will destroy all its valuable properties, and, if it be put in the hill, will be worse than nothing. For manuring in the hill, I prefer a compost consisting of muck, lime, and ashes. The varieties of corn preferred are the 8-rowed orange-colored, producing more corn from a bushel of ears than the large kinds, and ripening earlier. Usually plant as early as the ground will admit, say the 15th of May, and often as late as the 10th of June. Average price, from 75 cents to $1 per bushel. Wheat, (spring,) red bearded or Georgia, stands the attacks of the rust and weevil better than other varieties; otherwise the bald would be rather preferable. Average per acre, about 16 bushels, succeeding a corn crop, which was well manured and kept free from weeds. Time of seeding, from the 18th to the 25th of May. Quantity of seed, from 1½ to 2 bushels per acre, according to the state of the land.

Ploughing.—In ploughing in manure for corn, usually go from 8 to 12 inches in depth, according to the quantity of manure, following, at the same depth, the succeeding year for wheat. Lands not exposed to the wash of uplands, and intended for wheat, should be ploughed in the fall and spring. The wheat crop had been increasing for several years prior to 1839, averaging in 1838 something over 20 bushels per acre, and in 1839 falling below 10, and continuing to decrease to 5; showing that it was not caused by a gradual draught upon the soil, but mainly attributable to the rust and weevil. But it has been increasing for the last three years. I have tried several preparations for seed-wheat, but consider them worthless. Average price, $1.33 per bushel. Winter wheat has been lately introduced into Maine, and so far has done well; and the quantity sowed this year is sufficient to test our ability to raise it.

Pork, if made wholly on corn, will cost 8 cents per pound; but, a part corn boiled, and mixed with other and cheaper feed, may be profitable. Milk is cheaper, and will make pork fatter. Maine can, and ought to make her own pork, and a superior article to Southern or Western, but it can never be done as cheap.

The best varieties of apples for barrelling are, Roxbury Russets and Baldwins, the cultivation of which promises a fair profit, as those raised in our latitude are hard and suitable for transportation. I have a number of trees that were grafted 85 years ago, and find that those that were grafted in the stump, near the ground, when not more than 1½ inch in diameter, are much shorter-lived than those grafted near the top and in the limbs. It is a ruinous practice to cut off the top of young apple-trees, as is often done, about 5 feet from the ground, in order to give them a widespreading top, thereby causing them to send out a number of sprouts near the wound, which, as they grow to form a top, crowd each other at the main stock, till the sap ceases to flow, and destroys the tree. The main trunk should not be touched, but serve as a conductor for the sap, and throw off limbs at a proper distance from each other. Many valuable hints may be gained by attentively viewing the trees of the forest, where the limbs of a tree rarely war against each other, from the fact that it is natural for them to grow right, without the dissecting knife to give them an artificial appearance.

Very respectfully yours,
WILLIAM D. HAYDEN,
Madison County, State of Maine, Dec. 23d, 1850.

THOMAS EWBANK, Esq.,
Commissioner of Patents.

North Kingstown, January 20th, 1851,
Western Congressional District, R. I.

Sir:—From my own observation, and the best information that could be obtained, I will endeavor to comply with the request contained in your circular, which required a statement of the agricultural products of this district, as compared with the preceding year.

The improved system of agriculture, noticed in my last, is annually progressing—the persevering industry and judicious management pursued by many of our farmers bids fair to restore to the soil that original fertility of which it has been deprived by a long course of cropping without manuring. Yet, we have some among us who are still wedded to their traditional custom of making no return to the land for its increase of products; but that class is diminishing, and their places being filled by their descendants, who are more susceptible of improvement.

The past season has been very favorable for most agricultural crops; the spring, however, was cold and backward, which retarded planting and sowing 8 or 10 days beyond the usual time. Twice the quantity of snow fell in March and April that we had in all winter. May was wet and cloudy, and not more than one week's sunshine during the month, but no frost. The summer was remarkable for its temperature; no extremes of heat and cold, and no lack of rain. The rains were frequent, and of short duration, and for the most part cleared off warm and pleasant. Notwithstanding an unusual quantity of rain fell during the summer, yet we had no destructive freshets, that visited some sections of our country, causing much damage to the crops. Autumn was very serene and pleasant, with much less rain than during summer, which gave a good season for ripening and securing crops. No killing frost till the last of October, and none to obstruct the plough before December. The crops the past season were more than an average for the last 10 years, and at least 25 per cent. better than the preceding year. On the last of May, vegetation was 10 days later than in ordinary seasons; but so rapid was its growth in June that, at the end of the month, it had received all that was lost by the backwardness of the spring.

Indian Corn was 30 per cent. better than last year, and of a superior quality. It ripened earlier, and there was much less of the soft, blighty kind. Rye gave about the same yield, but, more being sown, it is estimated that 10 per cent. more was raised. The price of corn and rye, the same, 80 cents per bushel. Other grain crops, such as wheat, barley, oats, and buckwheat, are not raised in sufficient quantities to require special notice.

Potatoes have suffered more by the disease, in this district, than in any one season since it made its appearance. An unusual quantity was planted last spring, and the prospect of a good harvest was held out till the first of September, when the blight struck them. At first it was not considered very alarming, as we had had a touch of it, in some particular localities, every year since its commencement, and it was thought that the failure would be greater than in former years. A considerable part of the early planting has succeeded in a sound state before the rot commenced; and the price opened lower than for several years preceding. Farmers offered their entire crops for 30 cents a bushel, but could find no buyers at that price. On digging the late kind, it was found that but very few yields had escaped the disease; and that the entire crop would be short full one third when the extent of the rot was known; and that it was more fatal in the neighboring States than in this. The price advanced to 50, and from that gradually to 80 cents a bushel. The crop is estimated 20 per cent. short of last year, and the price full 50 per cent. higher. The advance in the price being greater than the deficiency in the crop, the consumer has had to bear more than the whole loss, which has been the case in this district ever since the rot made its appearance. This may be accounted for by the disease being less fatal here than in the adjoining States. The producer, instead of being the sufferer by the malady, has actually been the gainer, as his product has sold for more than if there had been no failure in the crop.

Onions were 30 per cent. better, and more planted, which made the crop 40 per cent. above last year. Carrots and other roots, about the same as last year. One man in this town raised 1117 bushels of onions, and 1288 of carrots, aggregate 2405 bushels, on less than 3 acres.

Hay was above an average of the last 10 years, and 33 per cent. better than the preceding year. The weather was rather unfavorable for securing the crop. Rains were frequent during the season of haying; but of short duration, and generally succeeded by a clear sun. Hay that got wet one day, was, for the most part, dried the next, so that but a small part was put up in a damaged state; price, from $12 to $15 per ton.

Dairy—Owing to an excellent season for pasturage, was 25 or 30 per cent. better than last year.

Fruit.—Apples are the principal kind cultivated. This being the bearing year for orchards, the yield was 100 per cent. more than last year; the price at harvest was 25 cents per bushel, but at present they are worth 75. Peas, peaches, plums, grapes, &c. are not extensively cultivated—mostly for domestic use. Garden vegetables now very good—30 per cent. better than last year.

Yours respectfully,
J. G. CHADSEY.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Ann Arbor, Washtenaw County, Michigan, Nov. 25th, 1850.

Sir:—I give you below such facts as have come to my knowledge on the subject of agriculture in our region.

Wheat.—We use the white flint, Soules, the red-chaff, bald, and bearded, the Mediterranean, and blue-straw. The flint, Soules, and the red-chaff are the most approved, the Mediterranean yields well, and thus far is free from rust and insects—but the flour is dark, and consequently going out of use; the average product the past season is 20 bushels an acre; time of seeding, from the 1st of September to the 1st of October; the early sown is generally the best; usually sow 5 pecks per acre; plough always twice on fallow—better to be 3 times, and plough 6 to 8 inches deep; the yield per acre is rather increasing, owing to better tillage, and keeping sheep, &c. We have not been troubled with the Hessian-fly for 2 years past, and the weevil has not crossed the lake yet, that I am aware of, except in a bushel of wheat I received from an unknown friend from the East, and I gave them so good a portion of slacked lime and strong brine, that I have no fears of an increase from that source. The price at this place has averaged 70 cents per bushel this fall.

As regards *corn*, the eight-rowed yellow is rather the best with us; the average product being 50 bushels per acre, and cost about 20 cents to produce it, exclusive of use of land. The best method of raising is to plough in the fall, and again in the spring; plant about the 5th of May, in rows, 3 feet apart each way, 4 grains in a hill; cultivate or plough twice, and hoe twice. Best method of feeding is to grind and cook; but the most practised method is to feed raw in the ear. Most of our land is improved for corn by the application of plaster, and seeding to clover.

The average of oats and barley is 40 bushels, rye 30 bushels, beans 15: peas do not do well, being invariably buggy, and frequently an entire failure. The hay cut is 1½ ton to the acre on the average; we sow 8 to 12 lbs. clover-seed to the acre, and, when mixed with herds-grass, 6 to 8 lbs. of each; on wet sods red-top is used, and is very good for hay or feeding; it grows well on our natural meadows and marshes, of which we have a great many, where the grass is good for feeding and hay, some of blue-joint, wild oats, and a great many varieties which neat cattle are very fond of, and fat on remarkably well: such land, by ditching and then sowing with timothy and red-top, makes most excellent for mowing or pasture; but seldom makes good plough-land. There has been but little attention to dairies until the last 4 or 5 years, which has increased, and we have begun to ship to New York; but consume all our cheese. Butter is worth 12½ cents, and cheese 6 cents a pound.

The average cost of raising neat cattle to 3 years old is $12, which is about the usual price of heifers; and steers are worth about $35 the pair; good dairy-cows, new milch, worth about $16; the Durham are the easiest to fatten.

Wool-growing is very profitable this year, and, next to wheat-raising, is the chief business of our farmers. Coarse wool, common native, costs about 15 cents to grow it; finer, say Paulo Merino, about the same; Spanish Merino, 20 cents; Saxony, 33 cents; large sheep, Bakewell or Southdown, the best and most profitable for mutton; about middling kind, heavy-fleeced Merino most profitable for wool; about two-thirds as many lambs as ewes are raised annually.

Our hogs have rather degenerated in this county, within 5 years, owing to the fact that Berkshires were introduced, which have not proved to be an improvement. Leicestershire, Byfield, and grass-breed are the best, the first of which, with a cross of the second, is now being introduced.

Cotton, sugar-cane, rice, tobacco, hemp, and darkies do not thrive well in this climate.

Root crops are on the increase, such as turnips and ruta baga, carrots, and beets, and mangel wurzel being only experimented upon. Turnips do very well on new land, and all will flourish on a rich, sandy loam, with good hoeing, to keep clear of weeds.

Potatoes have done badly for the past four years, on account of the rot, but seem to be getting over it; the average yield is 200 bushels per acre. The Carolina sweet potato is beginning to be successfully cultivated by a few individuals, who have the right kind of warm, sandy soil.

A great deal of attention is being paid to raising and improving fruit, particularly apples, which are usually profitable; sweet apples, with pumpkins and meal, are better and cheaper than potatoes for fattening hogs and cattle; the best apples for winter keeping are the Russet, the Spitzenburg, and the Winter Greening. We have not been troubled with the blight as yet. Grapes will not be a profitable fruit on account of frosts in the spring.

Pears, apples, quinces, and *peaches* do well, and are as fine as in any country; plums do well in new gardens, but are destroyed by the curculio in a few years; we cannot yet discover any certain remedy, unless it be a daily and almost hourly shaking the tree in the spring, and pinching the rascals' heads. Our lands being new, do not need manure; so that but little attention has been paid to the subject, except to clear the barn-yards. You will have a report from one of the professors of our University on the subject of meteorology. And now, my dear sir, to sum it all up, I think there is no better country in the world, all things considered, for the farmer, than Washtenaw county, Michigan; our soil is good, land as easily tilled as it ought to be to prevent idleness; climate mild and healthy; sufficient quantity of wood, and good water; land rolling, but not hilly or mountainous; good mill-streams; plenty of small and beautiful lakes of pure water, abounding with fish; intelligent, industrious, well-educated inhabitants; good schools, and churches of all denominations. The rapidly increasing facilities for transportation giving us a market almost equal to a day's ride of Eastern cities.

Very respectfully, yours, &c.

WILLIAM S. MAYNARD.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Harwich, (Cape Cod,) Barnstable County, Massachusetts, December 20th, 1850.

Sir:—In reply to your circular of August 26th, I would state, that this town was originally covered with a growth of oak and pine wood, a large portion of which has been cut off, and the land cleared. The soil, which is naturally light and sandy, by the process of continual cropping, without restoring an equivalent, which has been carried on for generations, has become, to a great extent, exhausted. The average crop of corn or maize, which is the principal article produced, is not over 15 bushels to the acre; but it is found that these worn-out lands are very easily reclaimed. By applying pond-mud and muck, which are very abundant in this region, at the rate of 100 or 200 horse-loads to the acre, and sowing buckwheat, and turning it under, twice a year, when in blossom, or clover once a year, it has been well ascertained that, in one or two years, fields which were considered almost worthless are made to produce 40 to 50 bushels of corn to the acre. Seaweed, which abounds on our coast, makes a valuable manure when turned under, as taken from the shore; but its value is very much increased when carted into the barn-yard or hog-pen, with mud or muck in equal parts, and left to remain a few months. The most esteemed varieties of corn are the yellow Canada, and round, smutty white. The best system of culture we think, is to plough in the spring, plant the corn about the 10th of May, in hills 3½ to 4 feet apart, each way; thin out to 3 plants in a hill, hoeing four times during the season, each time running the plough or cultivator twice in a row one way, or, what is better, both ways. The harrow, which has been used from time immemorial, has been almost superseded by the plough and cultivator, which leave the ground in a better situation. No hilling is allowed around the corn, but the ground kept as level as possible. The corn is harvested by cutting near the ground, and is carted from the field in the husks, piled up in ridges, and then, during the pleasant evenings of *harvest-moon, husked out*, after the old New-England fashion, which is, by inviting one's neighbors and friends to *lend him a hand*. They sometimes assemble to the number of fifty or more, and in one evening husk a farmer's whole crop, which would have taken him, with his ordinary help, several weeks.

Rye has always been raised here in considerable quantities. It has been the practice to sow rye, (16 quarts per acre,) on the corn-field, at the last hoeing, about the middle of August, and an average crop has been 10 bushels per acre. But for the few last years, the crop has been very much less, and consequently less attention is paid to it. Its failure is owing, partly, to the exhausted state of the soil, and partly to the increased bleakness of the fields, in consequence of the ruthless inroads made upon the surrounding forests.

Potatoes are a valuable crop, especially since the rot has become so general, as those raised on the most sandy soil are less affected by that disease. It is also ascertained that potatoes raised on *new ground*, or land lately cleared, are less subject to disease, than on land under longer cultivation.

The *cranberry*, which is the spontaneous production of nearly all our peat-bogs, is improved remarkably by cultivation; and beach sand, or that which is most free from vegetable matter, is found to be the very best article for spreading upon the mud in which to set the vines. Considerable attention is being paid to their cultivation, and it promises to be a profitable business.

Fruit Trees thrive well in this soil with proper care and cultivation. There is much encouragement for the rearing of the apple-tree, from the absence of the canker-worm, which, although it nearly destroys orchards in the neighboring towns, has never appeared in Harwich. This is thought to be owing to the surrounding pine forests, which, in some way, prevent the migration of that insect.

Among the ornamental trees imported in considerable quantities, the silver abele flourishes remarkably in our soil.

The facility with which a growth of wood can be raised upon our worn-out lands is worthy of notice. Every neglected field, in a very few years, is covered by young pines, which spring up from the seed scattered by the winds, and grow rapidly; sometimes, also, a beautiful growth of pines is produced by sowing.

The *meteorology* of the cape is rather peculiar.

The weather is subject to very sudden changes, and is much cooler in summer and warmer in winter than in other parts of New England; the ocean, which nearly surrounds the cape, acting as a regulator of the temperature.

The subjoined tables will show the mean average temperature, as noted from the thermometer, morning, noon, and night, during the months of June, July, August, and September, for the years 1847 and 1848, and also the warmest and coldest days in those months.

	1847.				1848.

Very respectfully, your ob't serv't,

OBED BROOKS, Jr.

Harwich, Barnstable County, Mass.

Protumna, near Martinsburg, Berkely County, Virginia,
January 15th, 1851.

Sir:—In reply to your circular, I beg to present to you answers to some of the interrogatories.

Wheat.—In use, Zimmerman's, blue-stem, white, and Mediterranean; the latter is most in favor just now. We have two kinds of land in our county—limestone and slate. The average crop of the county in the finer land, for, say 10 consecutive years, is not over 11 bushels; on the latter, not over 8 bushels. One ploughing before harvest, except on very stiff clay land, is now the ordinary practice. We harrow well, sow Mediterranean wheat on stubble and corn ground, and other wheats on fallow—2 bushels of the former, and 1 and 3 pecks of the latter. The drill is getting into use, and is much approved of. Pennock's Pennsylvania drill is highly esteemed, and the wheat put in with this drill looks, generally, very well. I think the yield per acre is increasing, owing to more careful farming.

A neighbor of mine, the past year, raised, on 18 surveyed acres, 37 bushels and 1 peck of Mediterranean, on stubble ground; and 280 bushels were produced on 7 acres, within a few miles of me; and a miller, near Mill Creek, cut 104 bushels from 2 measured acres. I have raised 27½ bushels per acre on a small field. These are rare instances, but exhibit clearly the great yield land may be forced to by care. On strong land, some cultivate the half of the cleared land annually in corn and wheat—about one-fifth in corn annually. We sow clover, let it stand two years, pasture it, put it in wheat, stubble it; then corn it; and sow the corn ground down in the fall with wheat, and in the spring sow clover, a bushel to 8 acres: we thus get 3 crops of wheat, and 1 of corn. This is the general practice, though some let the corn ground lay till the following year, before sowing it down. We are not troubled with weevils; and Mediterranean is the only refuge we have from the Hessian-fly. Average price, 1850, $1.

Corn.—The dark yellow, between flint and gourd-seed, is the most approved seed; white gourd-seed is cultivated. The average product for 10 years, on limestone land, is not over 25 bushels; on slate, not over 12 bushels. I have raised 65 bushels per acre of measured shelled corn from one field, but it rarely happens; it was in a spirit of rivalry against some five or six neighbors, who cultivated 10 acres against mine.

Corn-and-cob meal is much approved of, and is getting into more general use. I, however, dislike giving 10 bushels of grain in one to have it ground, believing that the hogs get all that is not digested by the cattle.

Oats are cultivated without much success. I have raised 40 bushels to an acre, but it is usually a poor crop, yielding, on an average, not over 20 bushels. The cultivation of rye is almost abandoned; it rarely fills.

Clover and Grasses.—Quantity cut, from 1 to 4 tons per acre; generally about a ton; seeds preferred are timothy and red-top herdsgrass for low lands. I sow a bushel of timothy to 5 acres. Hay costs nothing to grow it but the land and cutting; we get it cut for about $1 per acre. Hay generally is worth, within 5 miles, $10 per ton.

Sheep.—This is a great market for sheep, for mutton. About 6000 are annually sent to Baltimore from this county, and they have a high reputation for flavor, but not for size; we think 70 pounds a large sheep. They are considered the most profitable animal we can pasture. We make but little on cattle.

Hogs.—The Chester and Berkshire cross are the best hogs we have. With the assistance of our stubbles and grass, 100 pounds of corn will produce 33 pounds of very fine pork. The best method of curing hams is, ½ of a bushel of fine salt, mixed with 4 pounds of brown sugar and 4 pounds of saltpetre, to 1000 pounds of hams; changing the position of the hams once or twice in six weeks; smoke them incessantly with hickory till late in the spring, and soak them before you boil them.

Your ob't serv't,

FRANCIS PETERS.

Hon. THOMAS EWBANK,
Commissioner of Patents.

East Montpelier, Washington County, Vt., January 10, 1851.

Sir:—Your circular of inquiries relating to the productions and other matters connected with the agricultural operations of this part of the country, I have received, and now proceed to answer some of the questions it contained.

Your first inquiry relates to the production of wheat. This was formerly one of the best countries in the world for the production of that most valuable kind of grain, but since the weevil appeared, their ravages have been such that many of us do not attempt its cultivation. It is those only whose farms are favorably situated that can make it a successful business: on elevated situations, with a fair western exposure, they seldom fail of a good crop. Sixteen bushels per acre is about an average yield. Land that was cultivated with corn the year previous is preferred. Plough once, in the spring, 6 inches deep. 1½ bushels of seed, well washed, is used per acre. If the seed is thoroughly mixed with lime or ashes 12 hours previous to sowing the crop, it is seldom, if ever, affected with smut. The varieties most esteemed here are Lea, Black Sea, and red bald. The hedge-row has been tried, and proved a failure.

I cannot say that we have any system of rotation in crops; the most common practice is, oats the first year, corn the next; then follow with oats or wheat, and stock down with grass-seed. The price of flour governs the price of wheat: $1 per bushel is the price of good wheat at the present time.

Corn is our most important crop of grain. The variety raised is the eight-rowed yellow, common to New England. There are other varieties cultivated, but not to any considerable extent. Average product per acre in this county, I think, does not exceed 35 bushels, while many of our best cultivators do not fall below 60 bushels. I was conversing, a few days since, with one of the best farmers of Orange county, who informed me that he planted, two years since, 4½ acres with corn, and the yield was 800 bushels, which he did not consider an uncommon crop. The cost of producing a bushel of corn varies but little from 50 cents. The most approved method of culture is to spread and plough in manure, and manure well in the hill; cover with the hoe; plant from the 10th to the 25th of May; use the cultivator and keep all weeds down, and there will be no failure of a crop in a common season. The most of the corn raised here is ground with the cob, and fed to cattle and horses without cooking: for hogs, I think the cob had better be dispensed with.

Oats are cultivated extensively: average yield, 45 bushels per acre. The quantity of seed used per acre is generally 4 bushels—some sow more and some sow less.

Barley is cultivated by very few. I think it an excellent kind of grain to mix with corn to feed to any animal. Land that will produce a good crop of oats will yield a good crop of barley.

Rye.—The cultivation of this grain is very limited. Brown bread cannot be made good without it.

Peas are raised to some extent, by mixing with oats, and sowed in that manner, for the purpose of raising provender to feed to hogs. Almost every man has his garden peas, and a little patch in the field for family use. There should be 4 bushels sowed to the acre, if not mixed. Peas are the least exhausting crop the farmer raises. Beans are cultivated but little, except for family use.

Hay is altogether the most important crop in this section: a failure in that is more sensibly felt than that of any other crop. The quantity cut per acre is about $1\frac{1}{2}$ tons; good, well-cultivated meadows, 2 tons. The best fertilizer for meadows is manure, which should be laid on unsparingly to every acre the farmer cultivates. I do not suppose this can be done every year, but as often as one ploughs a piece of meadow, it should be thoroughly manured before it is laid down. The effects of plaster are admirable on clay soil. I think, when applied to greensward oats, it will increase the crops four times its weight. Time of sowing is, when the oats are fairly out of the ground. The grass-seeds preferred are clover and timothy: 4 lbs. of clover and 8 qts. of timothy per acre are used. If the land is highly manured, the clover may be dispensed with. The growing of a ton of hay costs $5.

Dairy husbandry is a profitable branch of business: no man fails of success if he pursues it steadily, and is economical and industrious. Some three or four of my neighbors have given me the result of their past year's operations. One milked 24 cows; made butter only, average per cow, 181 lbs.; price obtained, 18 cts. per lb. Another milked 24 cows and heifers, and made cheese, average amount per cow, 408 lbs.; price in the city of Lowell, $7\frac{1}{2}$ cts. Another milked 18 cows, made cheese a part of the time, and butter the remainder; average amount of cheese — cow, 416 lbs.; average amount of butter per cow, 88 lbs.; net proceeds of butter and cheese, $650.73. I keep but 5 cows; the average of butter made from them the past year is a trifle over 200 lbs. Three calves had all the milk they would take, until six weeks old, and raised two; sold the butter we had to spare to people near us, for 16 cts. per lb. It is the invariable practice, as far as my knowledge extends, with those that make butter, to set the milk about 36 hours, which is long enough for the cream to rise, which is then taken off and churned. None, in this vicinity, churn the milk. Our practice is to churn in the morning. When the weather is warm, and the butter comes soft, we wash it in cold water till the buttermilk will not color the water; salt the butter, set in a cool place till the next morning, then work it over with the hand. Some make use of the butter-worker, but I think a woman's hand, if it is clean and expeditiously used, is the best butter-worker I have ever seen. The butter is then put in tubs, usually made of spruce or fir, holding from 30 to 60 lbs.; fill to within two inches of the top; fit a cotton or linen cloth, the size of the tub-cover, with good, strong brine; let the cover fit tight, so as to exclude all the air, if possible. The mode of churning is very uniform; the churn used is the float, or sometimes the barrel-churn, made by Ruggles, Nourse & Co., of Boston; but, where the business is small, the old dash is preferable. I use one of Stone's, (I do not mean that the dash is of stone;) they are very easy to keep clean and sweet, and much better in warm weather. Fifteen pounds is enough to churn at once. The best butter and cheese commands the prices before stated, and there are none in this vicinity that are willing to be beat by another in producing a good article.

Neat cattle are reared extensively, and, in addition to the beef that is made, large numbers of young cattle are driven to Connecticut, Massachusetts, and Rhode Island. The cost of rearing, in the ordinary way, until 3 years old, is not far from $25. The price is so fluctuating for store cattle, that it is difficult to determine their average value. The price of good dairy-cows in the spring is $30, in the fall, $18 to $20. There has been little done here in foreign stock. Vermont has long been celebrated for raising good cattle, and we cannot see much improvement in the foreign breeds. I have seen beautiful animals produced by crossing with the important breeds; and if it were my object to make a large animal, I would select a Durham; if to make a given amount of money, the native breed would be preferred.

Sheep and *wool-growing* are profitable. Our flocks are very much reduced at the present time, owing to the failure of the hay crop of 1849, which was occasioned by the extreme drought of that season. There is but little comparative difference in growing a pound of coarse or fine wool; either will cost at least 34 cents. There is a very great difference in the amount produced from different flocks; it ranges from 4 to 5 lbs. per sheep. One flock in this vicinity, numbering 300, averaged 5 lbs. each, and was sold for 39 cents per lb. 100 sheep will consume 15 tons of hay during the winter. The pasturing will cost from $25 to $34. The large coarse-wooled breeds are much the most profitable for mutton, and less so for their fleeces: 2 lambs to 3 ewes are generally reared.

Hogs.—We used to make a large amount of pork for market, and it was a profitable business; but it has dwindled down to little more than enough for domestic purposes. The native breeds are the most esteemed. The Berkshires had a pretty extensive run here, but they proved to be of but little value, except for their foreign origin. There are some few of the Suffolk breed brought here from Massachusetts; their meat is said to possess a peculiarly excellent flavor. If it does not, I see no reason why they should be an improvement upon the native breed; they are quite small, but very handsome animals. The price of pork flesh is 5 cents per lb.

Root crops are but little attended to, except for family use; they are not cultivated as a field crop; but when their value is better understood, I think they will be extensively cultivated, especially if the *potato* malady continues. The potato crop is still an important one, notwithstanding the ill success we meet with. Before the appearance of the rot, the yield was from 200 to 400 bushels per acre; it is now uncertain: light, open soils are best to raise potatoes upon; manure light, plant deep, and the crop will be light, but generally sound. Land that has been least cultivated has proved to be the best. The most prolific and profitable varieties are the English white, and Long John, known in New York as the Mercer, I believe.

Fruit culture has been sadly neglected in this region; the old orchards have disappeared, and little or no pains is taken to supply their place with young trees. The effect is beginning to be *sensibly* felt upon the *purse*, and that always awakens the energies of a New Englander. One man told me that he set over 6000 scions last spring; the method of engrafting most common, is to split the stock, the scion is made in form of a wedge, and inserted in the split, and the wounded parts covered with wax: but few die set in this manner. Sweet apples are of nearly as much value for the purpose of feeding to cattle and hogs as potatoes; whether they could be profitably cultivated in this climate for that purpose is problematical; I think they could not. We have few varieties here; some Baldwins, Greenings, Pumpkin, Sweet Pearmain, Spitzenberg, Pippin, Russet, Seeknofurther, and perhaps some few others are the varieties most cultivated. Our latitude is too high for the general cultivation of most kinds of stone-fruit.

Manures are not attended to as their value and importance demand; much has been said and written about the manner of applying it to land, while the great question in relation to increasing the *size of the heap* has been neglected; in that lies nearly all the sweet of good husbandry. There was a young man passing this way, some three or four years since, selling Bommer's patent for making manure, and several of our farmers purchased the right at $4 for a single farm, if I am not mistaken; but they do not think much of the speculation, I presume, for I am not aware of their practising upon the principle they purchased, in a single instance. The barn and hog yards are the principal sources to look for manure. There are various ways to increase the quantity and quality. The hog is a working animal, if not too highly fed; keep his yard well supplied with muck, straw, leaves from the forest, and, by all means, the weeds that grow in such profusion about our barns and dwellings, and he will convert the whole into good rich manure, and grow fat in the mean time; besides, the only effectual method of preserving it from waste, is to keep it under cover: permanent sheds for that purpose may be maintained with economy: rain and sunshine are admirably calculated to extract the fertilizing qualities of manure.

I have thus endeavored, in my own homely way, and in as brief a manner as I could, to answer some of the interrogations contained in your circular. I hope the time is not distant, when we shall be able to give a better account of our agricultural pursuits; there seems to be a spirit of emulation among the producing classes, that must lead to good results; and nothing, in my opinion, has done more to produce this feeling and action than the interesting and valuable Reports sent out from the Patent Office.

I am, sir, very respectfully, yours,

ISRAEL GOODWIN.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Farmington, Connecticut, January 16th, 1851.

Sir:—Yours is received, requesting information on the various branches of agriculture, to some of which I will reply, according to the best of my ability. The section of country in which I reside, in the valley of the Farmington river, is admirably adapted to produce grass and corn, which are our staple productions. Our meadows are annually overflowed, whereby we are enabled to obtain large crops of grass without the aid of stable or foreign manures.

In regard to your first inquiry, the raising of wheat, I would say that but very little has been raised in this neighborhood, until, within a few years past, some attempts have been made, and very successfully, by the aid of lime, by which we are enabled to raise very fair crops—in one instance, upwards of 40 bushels to the acre. My first attempts at raising wheat on a small scale was made last year, on 3 acres of potato ground. The land was alluvial, a sandy loam, and good soil, on which I raised by measure upwards of 75 bushels. Planted potatoes in 1849; after digging the potatoes, I ploughed the land 7 inches deep with one of Ruggles's ploughs, which is the only kind I use upon my farm, and sowed it at the rate of two bushels to the acre of the yellow bearded variety, and at the time of sowing I also spread and harrowed in with the wheat about 6 bushels of air-slaked Thomaston lime to the acre; and on the 3 acres I obtained upwards of 75 bushels of excellent wheat, most of which I sold for $1.50, for seed, to the neighboring farmers. The land on which this crop was raised had lain in grass for several years, and was manured with unfermented manure spread upon the land previous to ploughing for the potato crop, at the rate of about 20 cartloads (30 bushels) to the acre, and a mixture of lime, ashes, and plaster put in the hills—to the application of which I attribute the soundness and large yield of the crop.

My wheat was sowed about the 20th September, after soaking in a strong brine 12 hours, and then applying lime; at the time of harvesting, the straw was slightly rusted, but the berry was plump and sound. I have now 10 acres in wheat, which promises well; and I trust that the time may come when our farmers may, by the aid of lime and other manures, be enabled to raise wheat, at least for their own consumption.

The corn crop being our principal grain crop, and a most important one, and there being such a diversity of opinion in regard to the different varieties, the method of preparing the ground, manures, and whether most benefit will be derived by applying it in a fermented or unfermented state, I will only state my own experience in the matter; and seeing good results from the plan I have adopted, I have determined to pursue it in future, which is as follows:—I take 5 or 10 acres of my grass ground, meadows on which the grass begins to run out, and apply from 20 to 25 loads of unfermented manure to the acre, and plough it in as deep as I can make the plough run, say 7 inches, taking care to plough in the manure as fast as applied to the land, and, at the time of planting, put half a shovel full of rotten manure into the hill—in the absence of which I use ashes and plaster, a gill to a hill. I cultivate in the ordinary way, using the cultivator three times during the season, and hoeing as many times, leaving the ground as level as possible, and have never failed to raise, on an average, 60 bushels of corn to the acre. On six acres prepared in this way in 1849, one acre through the middle of the piece was measured, and it contained 204 bushels of ears; the whole piece was estimated to yield upwards of 75 bushels of sound corn to the acre. In regard to using unfermented manures, I differ from many good farmers, I am aware; but my own experience leads me to believe that, by applying it in an unfermented state, the strength of the manure reaches the crop at a time when it is most needed, that is, to fill out the grain, and make it produce well; whereas, by applying only rotten manures at the time of planting, the strength of the manure becomes exhausted before the grain comes to maturity, and in consequence the crop fails to produce well. It is, I think, necessary to apply a small quantity of manure, or ashes, &c., to the hill at the time of planting, in order to give the crop a start, after which it will receive its principal aid from the long manures ploughed under and the decaying sod. The variety most in use, and which is most highly esteemed, is the yellow eight-rowed variety. A greater portion of the crop is used for fattening cattle among us, which is considered preferable to selling off the grains.

Oats are raised usually after corn, and produce from 50 to 60 bushels to the acre; average price, 45 cents per bushel. With this crop our lands are usually seeded to grass as follows:—Half bushel timothy seed, and 4 quarts clover, and on low and moist land the clover is omitted, and red-top is applied, at the rate of half bushel to the acre, with the timothy. The lands are then kept in grass from 5 to 8 years, or as long as they continue to produce from a half ton to two tons to the acre, after which they are again put in corn, as before. Many of our uplands, or "home lots," so called, are made to produce from 3 to 4 tons to the acre, at two cuttings, after which they are grazed closely until winter sets in.

Very little attention is paid to dairy husbandry in this neighborhood, farther than to supply our own immediate wants; considerable attention has, however, been given of late to improving our stock, several very fine animals of the Durham, Devon, and Ayrshire breeds having been introduced among us, and it has evidently improved our stock, though many farmers among us are unwilling to acknowledge that any improvement can be made by introducing foreign stock; but it is rather amusing to see these same farmers, who decry foreign stock, endeavoring to become possessed of the grade animals, at an advanced price. Whether they are, or are not superior to the native stock of the country, I shall leave with them to decide. I have, myself, a fine head of Devons, and am highly pleased with them. The grade animals are very superior, making excellent working cattle, and also good for the dairy and for beef. No attempts have been made by crossing the Devon and Durham with us, but I think, by crossing the two breeds, a great improvement might be effected, particularly if wanted for the dairy or for beef; but for working, should prefer the unmixed Devon. I have extended my remarks farther than I intended, but have omitted sundry articles of products, such as root crops, fruit culture, &c. Should the above statements be of any benefit to you, you are at liberty to make such use of them as you think proper.

I am, very respectfully, your obedient servant,

WM. L. COWLES.

Halifax County, Virginia, January 1st, 1851.

Sir:—The county of Halifax is one of the extreme southern counties of Virginia, on the North Carolina border, and is characterized by the same features as the adjacent counties of Pittsylvania and Mecklenburg. The staple agricultural productions are tobacco, wheat, corn, and oats.

Wheat.—The varieties most commonly sown are the early red May, the bearded golden-chaff, the white bearded, Mediterranean, and, in some few instances, the early purple-straw. The usual time of sowing is between the 25th of September and the 5th of November. Could I sow my whole crop in a single day, I would select the 10th of October. I have no hesitation in preferring the early red May to any other variety that I have tried. Of one thing I am sure—that the late varieties do not suit our meridian. The rust is our great enemy. I have never had my wheat winter-killed, nor have I ever had any thing like a general destruction of crop from the ravages of fly; but I have seen whole fields destroyed by rust. I have for some years soaked my wheat in strong brine, or steeped it in a solution of blue-stone, at the rate of an ounce to the bushel. The brine is found, after repeated trials, not to be a cure for smut, and the use will be abandoned. The blue-stone is a preventive of this disease; and if the wheat, after being steeped in it 5 or 6 hours, is rolled in recently slaked lime, the cure is rendered certain. In this climate, where the frost does not destroy the wheat, a bushel of seed to the acre, in average land, is deemed sufficient. But there is nothing in which agriculturists differ so much as about the proper quantity of seed to the acre. Soil and culture determine the yield far more certainly than the quantity of seed—nature, in this instance, kindly repairs the mistakes of the husbandman.

Those among us who grow wheat after clover, plough the land with 2 or 3 horses, between the 10th of July and the 1st of September, as time and seasons will allow. I think the best cultivation is to break the land in the month of July, or early in August, to the depth of 6 or 8 inches, and then, with a small dagon with a single horse, to turn again just before sowing to the depth of 3 or 4 inches; then sow, and cover with a harrow drawn by 2 or 3 horses. In the county of Albemarle there are some respectable farmers who advocate and practise the single ploughing; but now the practice has disappointed me, and I have no hesitation in saying that the second ploughing will more than remunerate the additional labor.

My greatest yield of wheat was 33 bushels to the acre, from 11 acres. This was cut off from a field of 60 acres, on account of its being free from smut, while the remainder of the field was tainted with the disease. Probably the whole field would have averaged between 25 and 30 bushels to the acre. It is difficult, in such a climate as ours, to make the soil yield more than 35 bushels. If you fertilize the land to the degree necessary to produce this crop, such is the tendency of a warm climate to make woody matter and straw, that it is very apt to fall and smother the grain, or mildew it. That wheat, then, should be selected by us, which yields least straw. It will bear the most stimulus from the manure-pile, and the greatest yield may be expected from it. The red May is a wheat of this character, and it is the wheat from which I have received the heaviest returns on highly enriched land. The only objection to it, that I know of, is its liability to the frosts of spring. This may, however, be generally counteracted by grazing it down, when there is an early luxuriance. In 15 years I have sustained but one heavy loss from this cause, and I have used no precaution, save the one of not sowing till after the 10th of October. To state the average yield for the county is impossible; but I will hazard a guess. Perhaps 10 bushels to the acre, in average years, would be near the mark. Remember, however, that there is not a very large breadth of wheat, and the land is generally manured in which the wheat grows. The tendency now is to increase this breadth, by taking for wheat more corn land, and, while the quantity of wheat grown is evidently increasing, the average product per acre is evidently diminishing.

Corn.—The varieties in use are endless. I think that there is but little difference in the yield of acclimated varieties. The early kinds, which are importations from a northern climate, are more easily parched by drought.

The average yield might be stated at 33 bushels for our river and creek flats, and 17 for the uplands. Manure applied to corn in the spring, with us, often burns up the crop. It had better be applied as a top-dressing to the clover, and the clover turned in for corn, the fall succeeding the application: unless farm-yard manure be well rotted, it will, 3 years in 4, injure the corn to which it is thus crudely applied. In a cold, moist climate, like Western New York, the warmth derived from the manure while in a state of decomposition may greatly aid in forcing forward the corn; but it will not answer here.

We grow no barley, and but little rye: once we sowed a good deal of rye; but it is now a neglected crop. Beans are not a field crop with us. Peas are cultivated by some as an improver; but it is not much used in this way. On sandy soil, where clover will not take, it is doubtless an improver; but in all clay soils, clover is incomparably the better and the cheaper. Oats are generally and extensively cultivated. The crop is thought an exhausting one; but no good reason has been given for the opinion; and in South Carolina, I hear that it is looked upon as an ameliorating crop. Very little attention is here paid to the meadow grasses. Oats and the offal of corn are our chief resources for feeding our work-animals. Some clover is cut for hay; but not a great deal. Herds-grass, or the red-top, is our best and hardiest grass. The timothy does not flourish in our climate. Planters make milk, butter, and beef enough for family consumption; but none, or next to none, for market. We have not yet made our first cheese. Our cattle are, in the main, unrelieved by imported crosses, and no great account can be given of them. The same may be said of our sheep. Our hogs are pretty fair. We have tried the Berkshire breed; but, when weighed in the balance, they were found wanting. The Irish grazier, crossed in the old Virginia hog, has the largest amount of testimony in his favor. Our pork is raised at a high cost—100 pounds of corn producing about 25 of pork. But this corn is derived from the inferior part of the crop—the short and the imperfectly matured ears.

The leading crop of this county is tobacco: more is grown here than in any other county of the State. There is no new process of culture known to me. The present mode of cultivation, in the main, was in vogue before the American Revolution. That is, the new land, which is the land best suited to the crop, is prepared now and cultivated now as it was 70 years ago. We have sometimes deviated a little, but we are always compelled to try back. In curing the ripe plant, 10 years ago, we flattered ourselves that we had made some improvements; but even here we had to fall back on first principles, or rather primitive methods. It is true that we have better implements; plough and manure better; and have introduced clover as a rotation crop.

I have known 1100 lbs. to the acre made, in a crop of 50 acres; but the average would fall, if fairly stated, to 600 lbs. for the whole county.

No root crop is cultivated in fields; we have turnip-patches, but no turnip-fields. Our climate, particularly in the month of September, is too dry for the turnip. When the land is powerfully stimulated by manure, we sometimes make a great crop, but ordinary lands yield too discouragingly to justify its extensive cultivation. Besides, an idea prevails among us that it is a poor thing at last.

We have two varieties of the Irish potato—and but two—the watery and

the waxy. The sweet potato grows well, and often abundantly, yet for the last year or two we have failed, on account of our late, cold spring.

Guano is rather a stranger yet among us, but we are well acquainted with the magical effects of plaster—especially on clover. Lime is but little used, as we have no beds of it in this county. I tried it in three different kinds of soil, some years ago, at the rates of 20, 30, and 50 bushels to the acre. I saw no effect in the corn or the wheat, nor in the clover which followed them. The late Mr. Randolph Harrison, of Elkhill, gave me the same account of an experiment which he made with lime. I believe Mr. Sampson, of Goochland, made experiments with like results. That lime does act well in some soils, there can be no doubt; it is the veriest scepticism to deny it—but that it does not act well on all soils is equally undeniable. I believe, however, that the latter opinion now is, that the most important effects of lime are mechanical—rendering clays more friable, and sandy soils more tenacious. To produce this effect, it should be used very liberally, much more so than is indicated by my experiments, or the experiments of either Mr. Harrison or Mr. Sampson.

Fruit culture, though still greatly neglected, is receiving more attention than formerly. In the absence of a blighting frost in spring, we produce, in tolerable abundance, apples, peaches, cherries, strawberries, raspberries, and melons. We export no fruit of any kind. Our pride revolts against these petty sales and petty savings, while our necessities urge very strongly the duty of submission. What will be the end of the struggle, I know not.

Pears do not grow well with us, and the grape, from bad varieties, bad management, or unpropitious climate, yields a poor return. They rot, generally, before maturing.

Meteorology.—For three years, commencing with the 1st day of May, 1838, I caused a memorandum of the temperature each day, at 3 o'clock, P. M., to be entered in a book. This book is now in my hand. The thermometer used was Fahrenheit's; the position of it, a cool passage in my house, six miles south of our court-house. The result may be confided in as accurate, as the observations and the records were made with great regularity. I regret that there was but one observation for each day, and that they do not come down to the present year.

Here is the table:—

MONTHS.	AVERAGE, 1838.	AVERAGE, 1839.	AVERAGE, 1840.	AVERAGE, 1841.	AVERAGE, for 3 years.
May	67°15′	71°09′	69°07′	....	69°10′
June	79 24	77 02	76 06	....	77 52
July	85 37	78 42	78 38	....	81 37
August	80 40	77 27	77 09	....	78 25
September	70 48	73 15	69 48	....	71 17
October	60 04	67 00	64 07	....	63 44
November	51 00	48 08	51 42	....	50 17
December	42 12	42 42	43 30	....	42 48
January	....	43 27	39 00	44°00′	42 09
February	....	48 24	55 07	43 51	49 07
March	....	56 20	58 42	54 39	56 33
April	....	65 24	66 30	57 02	62 58

From this table we have the average temperature for three years, at 3 o'clock, P. M., a fraction over 62°.09.

I conclude with the expression of my hearty regret in being able to add so little to the value or the interest of your forthcoming report.

Very respectfully,

JAMES C. BRUCE.

Hamilton, Butler County, Ohio.

Sir:—In answer to your request, I submit the following remarks:—

Wheat.—The Mediterranean is the best that we have in Butler. I raise from 40 to 50 acres per year; the average crop is about 30 bushels. I seed about the last of September. I sow about one and a half bushels to the acre. I let my field grow late for wheat in the spring, when it gets a good crop of weeds, and then plough it under and let it lie till seeding-time, and then harrow it, and sow and plough it in, and harrow it. I believe that the average price is about 80 cents.

The best plan for raising corn that I know, is, after harvest, when the weeds grow up, to plough them under, and let them lie till spring, about the 15th of April, and plough it and cross it out 3 feet each way, and put 3 grains in a hill. I have raised 105 bushels to the acre. Our average crop is about 60 bushels per acre.

Oats yield about 40 bushels per acre—barley about 50 bushels. Barley does not injure the land, but it will enrich the land.

Grass-seed.—Timothy is the only grass that I sow, and it yields me about 2 tons per acre. It is the best to fertilize the land. I sow one gallon per acre. The average price, $10.

The cost of raising cattle till 3 years old would be about $10, and they would bring about $25.

Sheep.—Wool-growing is a poor business. The land is better calculated for cultivation, and we don't raise many sheep. It wants poor, hilly land, to make it profitable to raise sheep. I should say the large sheep was the most profit.

Hogs.—The best breed that I know of is the grazier and Poland mixed. About 30 bushels of corn will make 350 lbs. of pork; the average $3, and corn weighs 60 lbs. per bushel.

Irish potatoes.—Average yield per acre, 100 bushels. I plant them about the first of May. The orange is the best that I know of. I plant them in new ground, or manure them well in the hill with stable manure, or plant them in straw.

Very respectfully yours, &c.

JOHN CARR.

Hon. Thomas Ewbank,
Commissioner of Patents.

Locustwood, Taylor's Island, Dorchester County, Md., Nov. 1850.

Sir:—Your "Agricultural Circular" was received some months since, but, from a multiplicity of professional and other engagements, I have failed to attempt a compliance with your request until the present time.

I must premise what I shall hereafter say with the remark, that I can-

not possibly follow, *ad seriatim*, in reply to your interrogations, from the fact, that much information could not be obtained in this county, as no agricultural societies, or clubs, are now in organization, and farmers not caring to take the trouble to ascertain accurate results, by or from experiment, in manuring and cropping. This county is one of the Eastern Shore counties of Maryland; and, from its easy access by water, and its contiguity with the flourishing city of Baltimore, and the consequent large demand for lumber and fuel, this demand has, for the last century, engrossed the attention of the people, to the almost entire neglect of agricultural pursuits, and to the manifest impoverishment of the county, from the inevitable result, in exhausting all the timber, and failing to add any thing to the virgin soil, admirably adapted to manuring, but naturally thin in soil.

But the last ten years, I am most pleased to say, has been marked by a decided reformation in the farming operations of the county. Ten years ago, the most *primitive* agricultural implements were used. The common, and now universally used "drag-harrow," was then almost a curiosity among our people. Manuring was looked upon as an idle loss of time, and loss of outlay of money.

But now, how changed! Every farmer is striving, with commendable spirit, to outstrip his neighbor in the largest yield of crops, and, of course, in manuring, and in all the improvements in farming utensils, machinery, and all that pertains to good farming; and the beautiful result is—

"The desert buds and blossoms like the rose!"

As an instance of the improvement and the result, I will but mention that of the farm of Samuel K. Travers, Esq., of this county. This farm contains about 100 acres in cultivation; the average yield of the wheat crop for the 50 years next preceding 1840 was about 150 bushels; since 1840, that gentleman has been a pioneer in manuring and improvement in farming; and the present, in last harvest, (1850,) the same farm has yielded 850 bushels of superior wheat—indeed, of such an excellent quality, that some 800 bushels were sold for seed, for all parts of our county. Many others are pushing on the race of improvement, with a like most cheering prospect; and really *we* cannot help but think, that failure in the *pine wood crop* has eventuated beneficially to the farmer, especially the lazy one, as it has driven him to better things.

And now of the WHEAT crop for 1850. The prospect in May and the early part of June was never equalled before in this country; the winter had been quite open, with unusual quantity of rain, and the wheat plant came out of the winter strong and flourishing: the spring was very favorable to the growth of wheat, and, like the winter, much rain fell: hence, the cheering prospect to the farmer. But, alas! like many human things, the hour of blight came. About the latter part of June, that one of the most malignant of all diseases to the wheat crop, *rust*, began to make its appearance, and, in a few days, thousands of acres were rendered almost a total failure, very few fields being entirely exempt from the blight. That which escaped most generally was, I believe, the "Wicker wheat," (a new species in this country, of which I will say something more,) and the "German," owing chiefly, I am of the opinion, to maturing some week or ten days before most other species. It is also worthy of remark, that fields open to the wind blowing off or from bodies of salt-water, (sea-water,) were much less injured; and the same fields, the farther they receded from the waters, the more baneful the effects of the rust. The result of our harvest has been a very large yield of straw, and a poor yield of indifferent, light grain. Of course, there are exceptions to this. And again, there are cases in which the crop was not cut, but left to the cattle. The price of wheat in Baltimore, our general market, has ranged for "family flour wheat," from $1.12 to $1.35 "per bushel," and inferior from 75 cts. to $1.12 per bushel, of 60 lbs. weight: the range of the Baltimore wheat market has been more uniform for 1850 than for many years preceding.

I regret to say, many adhere to the old and much-to-be-condemned rotation of seeding corn ground as the whole or principal crop: in this mode, wheat is badly put in; in ground already exhausted by the corn crop, the wheat, by this custom, is put in by sowing the wheat upon the ground, without previous fallowing, many times among weeds 2 and 3 feet high, and then an attempt made to plough, or, properly speaking, to scratch it in. This is generally done in October, the quantity sown about 1½ bushel per acre. The more improved way has been considerably brought into practice, and is increasing, of fallowing in August, and seeding in September, and with decided increase in yield; in many instances double. Our harvest commences sometimes as early as the middle of June. Upon the whole, I can congratulate our farmers on the decided and rapid improvement they have made. The wheat most common in use was known here by the name of "Lawler," a small but heavy white wheat, yielding but poorly; the "Taliaferro" has also been extensively sown. The "Thimble" is also quite popular with some. "Crate," another species, is celebrated for its large yield; but that now most sought after for seed is a species introduced by myself in this neighborhood, and now through the county, which I have named the "Wicker wheat;" it came originally from Virginia—the James River country, I believe—and is justly esteemed one of the best species ever known in this region. It is very large "grained," a plump, heavy, *and a rich white*, rated by wheat merchants in Baltimore, when thoroughly cleaned, and free from impurities, as "A. I. No. 1 family flour wheat;" it also has the great advantage of ripening early as any of the early species; and in the last crop, was decidedly more exempt from rust than any species, perhaps except the "German." I believe, in a few years, from present indications, it will supersede all other species in this county. I would but remark, it is beardless, and the chaff of a *red-brown* cast, and when machined, entirely clean of "white caps," a *desideratum*.

Corn is extensively grown, and, until the last ten years, the great staple with the farmers here, the mode of cultivation being decidedly better than for wheat, and the yield better per acre in comparison. Some idea of the importance of the corn crop may be formed, when it is a fact that it is the main article, and in many instances the only article, for subsistence, for master, slave, horse, cow, oxen, hogs-feed, poultry. Some portions of our county will not produce wheat. Then it must be the "staple." The provender is, in nine cases out of ten, the only dry food on which our horses or cattle are fed. Meadows we have none; and few, I believe, have yet cut clover for hay. I know, for myself, I have frequently been compelled to purchase hay in Baltimore for my horses and cattle, when my stock of corn-fodder was exhausted in the spring. By the way, I believe there is nothing superior for horses to well-cured corn "blades." We have the most improvident custom of feeding our corn. In nine cases out of ten, it is fed to horses and cattle whole, and on the ear; hogs are fed and fattened

in the same wasteful manner; the provender is fed in the same way, without any preparation, just as it comes from the field. The varieties planted are so mixed, that I know of no distinction but "white" and "yellow," except in a few cases of experiment, by *amateur* farmers. The mode of feeding corn in this region calls loudly for a change and economy; some day will demonstrate to our farmers this fact.

Oats in small quantities are sown, and appear to yield well; but most farmers have a prejudice that they are very exhausting to the ground. Yield, some 30 to 40 bushels per acre.

Clover is sown to some extent; and, where the ground has been limed, grows luxuriantly: producing most excellent pasture, and improving the crops, when *turned in green*. I believe there are few instances where it is cut for hay.

Dairy husbandry is at a low ebb; and nothing can prove this more conclusively, and not much to the praise of our farmers, than the fact that a large proportion of the butter for farmers' families is brought from Baltimore. This should not be in any farming district.

Neat Cattle.—The great objection to a large proportion of our cattle is, they are *too neat*, especially in March. This is a branch of husbandry that is shamefully neglected: arising mostly from the farmer attempting to keep too many, and in being then exposed in all weathers in the winter, with a short allowance of food.

Orchards and *fruits* of all kinds have been greatly neglected; very few persons or farmers producing even the common apple later in the season than Christmas—those used after that date being procured from Baltimore, the growth mostly of the Eastern States. There is, however, more interest felt on this subject, and of late years many have purchased from distant nurseries choice fruit-trees.

Manuring.—The most valuable article for improving our lands is of the *calcareous* kinds. Stone-lime is very largely employed of late years, and with the most satisfactory results. Oyster-shell lime is also in high favor, and by some yet preferred, when the shell can be procured large and thick. Beyond a cavil, this species of manure must be the basis of permanent improvement in our lands; then followed with the *high-pressure* manures, as guano, ammoniacal salts, and the results are truly wonderful. The mode of applying lime here is, to spread it broadcast, immediately after the corn is planted, averaging from 50 to 100 bushels per acre. This plan has the advantage of incorporating the lime thoroughly with the soil, in the cultivation of the corn crop. The first year after the application, very little can be realized in the crops. Another mode is to spread the lime broadcast upon the earth, at least one year before ploughing or cultivating, and thus permitting the lime to act upon what vegetable matter may be on the surface. Those who have tried this plan speak highly of its efficacy, and prefer it to the former mode.

Guano.—I have been using for several years this article on my wheat land, and, I think, with more profit in the yield than any other. I am of the opinion, Peruvian guano, at $40, or even $45 per ton, is the cheapest manure for our lands. In the autumn of 1849, I applied one thousand pounds of Peruvian guano upon four acres of ground, (previously in corn,) upon which I sowed four bushels of Wicker wheat. From this I harvested *one hundred* bushels *pure heavy wheat*. The last time previous, the same ground, when seeded in *wheat*, yielded some 5 bushels per acre by average. No other manure had been used between the crops of wheat and a crop of corn taken off. Here is a striking experiment that it will pay. Compare the results, and I am fully of the belief that my ground is at *this time* more benefited from the dressing of the guano than the original cost of the article. Just so far as the guano extended, so far a heavy coat of clover is now flourishing luxuriantly.

I must conclude these hasty, disjointed statements, with the remark, that I regret some more competent writer had not undertaken the task. They have been thrown together at various times, and are but a bare *statement of facts*—an attempt at nothing more. I hate apologies, but in looking over what I have written, I am compelled to say thus much.

Respectfully,

WASHINGTON A. SMITH, M.D.

Virginia, Buckingham County, December 10th, 1850.

Sir:—I now proceed to reply to your circular, and fear my limited information will not be satisfactory to the department, as it is not even to myself.

Wheat is seeded upon fallow land from 15th to 20th September, with about 5 pecks to the acre. At that time corn is safe to cut and put up in stooks, or hauled off upon the stalk to the granary, which is much the best management. Where the teams are adequate to harrow in, (which ought to be double,) plough and haul the corn. Our corn land is flushed with the barshares, seeded with one bushel to the acre, and double harrowed. Seeding our tobacco land is often delayed by a late crop of tobacco; as soon as that is off, the ground is ploughed with barshares, and seeded with six pecks to the acre; for the reason that the land is more fertile, and being later in the season; besides, we expect a better reward, as any and every crop grows well after tobacco. For several preceding years, tobacco brought a very low price. Pending that season, a much broader surface was laid down in wheat, but will be much curtailed by the advanced price of tobacco. This is the most general rust year perhaps ever known, and seems to silence a long entertained opinion that rust is produced by frequent showers alternating with a hot sun. We had no showers, and believe the drought was very general previous to and at harvest; therefore, the showers seem not a necessary element, and that it is fairly ascribable to a hot sun. The general weight is from 25 lbs. to 57 lbs. the bushel. The average crop of Middle Virginia has been given for several preceding years. It is now more uncertain, and would seem unfair to give an average of this very important crop. We are experimenting largely with Peruvian guano, ploughing it under 7 or 8 inches, seeding and harrowing in the wheat. This depth is thought necessary, for the rains and snows to reduce its caustic property before the roots of the wheat reached it. I applied, the last year, under wheat and oats, 100, 150, and 200 lbs. to the acre, and have decided in favor of the latter quantity, and applied that quantity the present year to my wheat, and will next spring apply that quantity to my oat crop, and two pennyweights under a hill of tobacco, which I tried last year with success. Under corn, it did not equal my expectation. Upon oats its action was better than wheat. Its durability in aiding a subsequent crop, I believe, is yet to be ascertained, other than a clover crop. It may give that a stand, which would not take upon exhausted land. At present prices, we cannot afford to buy and apply it to good land. A portion of the guano is carbonated, and requires pounding down; indeed, the finer particles, from dampness, has become clotted, and require rushing during the process of pounding and riddling; for there are small stones in it. I have seen them that would weigh 3 oz. The ammonia, a principal element of its fertility, is constantly escaping: also, when strewn before the plough, cover it in. To prevent this waste, I add plaster, measure for measure, when I pound it. Liebig informs us that plaster acts by combination. I also add top-soil, which damps the mass; but frequently sprinkle it with water, to prevent its dusting off when throwing it before the ploughs. This process of preparing and applying guano I deem important, as it prevents great waste. As to edible roots, their cultivation is limited to family supply. Our great reliance for bread, and food for stock, is corn, (maize,) which in good seasons yields from 15 to 40 bushels; say an average of 20 bushels the acre. We plant the first of April, upon lands well ploughed and well harrowed; planting deep, and covering about two inches—pressing the broken land above the planting, rather than under it. Corn is a hard drinker, and should be ploughed deep to get moisture in drought, and stands up in storms much better. When fairly up, we pass a single coulter each side of the corn, rather bearing the point under the corn. When 6 to 8 inches high, run a barshare, with the bar next to the corn, throwing the earth from it. When it begins to joint, plough well with the barshare, returning the earth to the corn, having previously thinned it, then weeding, pulling a small hill to the corn, as a large hill is no benefit to it, and very injurious in seeding wheat; after which, upon the appearance of a young crop of grass, run over with the cultivator, which will destroy the grass, leave a close level surface, retentive of moisture, and favorable to seeding wheat, preventing wash and a deleterious action from the sun. If these operations are well done, and at the right time, it is as much cultivation as corn requires. It is a question with many, whether suckers should be permitted to grow or be jerked off. I am in favor of the former. They will yield fodder, and, occasionally, a nubbin on the tassel. When taken off, the roots of the mother-stalk are often ruptured, and the wounds bleed much sap, until they heal up. A redundancy of nutrition produces suckers; to prevent them, plant your corn close.

In this section of Middle Virginia, tobacco is the primary crop, and we are rather to be estimated as planters than farmers, although we lay in largely for wheat, which rewards us well when exempt from all disasters. I estimate the tobacco crop at 800 pounds net to the acre of 4000 plants; the bottom leaves, and others imperfect, are called lugs, and worked up by the manufactories at about half-price. It is the most laborious crop in the whole vegetable kingdom, and, if its cultivation depended upon white labor, but little would be cultivated, and yet our slaves are fond of working in it; owning the labor, we find it the most profitable crop. The price depends much upon its quality, and that depends much upon capricious whim and fashion, to suit the various European markets. Sun-curing had its day, and commanded very high price, by the manufacturers being exempt from smoke, which was deemed offensive to the stomach of those with dyspepsia, now the prevailing disease of the country, from over-eating, late sleeping, and spending the balance of the day in idleness. That mode is now pursued by but few: curing by steam is entirely abandoned. I believe that a good rich tobacco cannot be made but by the direct application of fire under it, applying, at the right time, a proper degree of heat. Upon this process of curing tobacco it may be thought that I am too tedious, but believing that some information will be given to my brother planters in this and other tobacco-growing States, is my apology. First, be sure that your tobacco is ripe: to ascertain that, view the top leaf on the north side of the plant; if the yellow (the oil) is down to the point, it is ripe; cut sticks and scaffold, 8 large and 10 smaller plants to a stick; scaffold close and strong; sun will cure it green before it yellows; yellowing is a separation of the water and oil; the sun has opened the mouths of the leaf vessels; when the water weeps out imperceptibly, and the oil retained in large yellow spots, generally 5 to 6 days, (dependent upon a warm sun and a damp atmosphere,) it is ready for the house; give 8 inches space between your sticks; let it hang a day or a night before you apply fire; 3 fires are enough to a house 20 feet square—half-seasoned wood the best; tie a thermometer to the lower tier-pole, in the centre of the house—the heat draws to the centre; tie a thread at 85°; a negro can see when the mercury is up: the house being cool and damp, will bear that degree of heat if raised very gradually; in 24 hours, the tails will curl about 4 inches, when the heat may be forced a little, say 2 degrees, and kept up regular 3 days and nights. The leaf ought to be cured—be sure of that, by examining above joist—before you raise the heat to cure the stem; above joists (it does not cure as soon as below) the leaf must be thoroughly cured, before you raise your heat to 120°, to cure the stems: the water is evaporated, the oil retained, the the mouths of the vessels sealed up; there is no danger but by a blaze communicating with the bottom tier; you cannot burn a dry bundle of tobacco, enveloped in sparks of fire. If heat is rightly applied, the bottom tiers will be the best, because cured by a dry heat; as the heat ascends through the different tiers, it becomes vapor, warm enough to force out water, and not hot enough to dry it off, when it drips down on each side of the stem, scalds and kills the tobacco, and is what the planters call house-burn. And estimating the worth of the labor, from the seed-bed to the press of the tobacco, I put it at $20 per acre.

I received, from the Patent Office, 3 half-pints of wheat, called Chinese, Polish, and red-straw; the latter is a very early wheat; the Chinese, bearded, very lofty, with a fine large grain; the Polish, smooth head, white large grain. I hope to acclimate the latter. The next crop I will give you a more detailed result. I have about one bushel now flourishing under drill culture; also I raised some seed of the Osage orange, but none vegetated; supposed they were not of the preceding year, as I learn old seed will not come up.

Barley is not cultivated at all; having no breweries, there is no market for it. *Rye* is preferred, as giving the best yield; like all new and novel things, sold at $4 the bushel; now at $1, or even 75 cents.

Our fathers were careless as to good fruit. The old seedlings have died out, been cut down, and replaced with the best kinds of grafted apples, peaches, plums, pears, cherries, &c. This is a good climate for native grapes; some of the foreign kinds succeed tolerably well in good seasons. I have a little vineyard of one acre, containing 600 vines; have made some wine, which was esteemed good. I have been manuring with the vines from pruning, which is slow in decomposing; I am now applying guano in solu-

tion, from the wash of my guano bags. I am constrained to remark the neglect of our people in not raising the vine, the fine fruit of which adds greatly to the comfort and enjoyment of a family. I find it very uncertain propagating vines by cuttings, and wish to know whether two prunings, fall and spring, are best. I will thank any vine-trimmer for the information upon the two subjects.

We find mixed grasses succeed best in our meadows; timothy, herds, and red clover are most approved. The yield in hay, well saved, 1½ ton to the acre is about an average. The best top-dressing, applied in February, I think, is plaster and ashes, a bushel of each to the acre. Many of our farmers are experimenting with peas, mostly in our maritime counties, where the pea flourishes in a very sandy soil; they are sown broadcast in the corn-field, and harrowed in, 5 pecks to the acre, after the corn is laid by, and fallowed in in October as a green fallow, and wheat seeded; I learn it succeeds well: I have a little trial on hand, when I can speak more correctly, after the next wheat harvest. Peas, at 75 cents, and 5 pecks to the acre, are 90 cents. Clover, at $5.50, will sow 8 acres, say 68 cents the acre; a little the cheapest, and well-established as the great auxiliary to made manures, it must maintain its ground, and pea-fallow will be consigned to the tomb of the Capulets everywhere, except where clover cannot make a stand on sandy soil, which is where peas succeed best.

Your inquiries of raising neat cattle to 3 years old; the price, at that age; value of good dairy-cows, spring and fall; how many pounds of beef will 100 pounds of corn produce; will a given amount of food yield more meat in a Durham, Devon, a Hereford, than in a native animal?—Feeling an interest in these inquiries from their great importance, I will hazard opinions, with the view of eliciting information from others, better informed, and hope to see them in your next Report. First, to rear a calf till 3 years old, I estimate to cost $8, and, at that age, it would be worth $15. A good dairy-cow, with her calf, in the spring, is worth $25; in the fall, I would reduce her value to $17. The 100 pounds of corn, reduced to meal, with the like weight of provender, and that cooked, and fed to a grown animal, might give an increased weight of 5 pounds, say ⅘ of an ounce to a pound of the grain.* Lastly, I believe all the improved breeds take on fat more readily than our natives, and that the Durhams more kindly than either the Devons or Herefords, but they require more food.

Wool-growing has but recently commenced. We have two or three sheep-walks, to the extent of 4000 or 5000 head. Our climate and fine mountain-range are admirably adapted to the rearing of sheep. We farmers prefer the largest breeds, on account of mutton and wool, estimating quantity in preference to quality, it being manufactured into negro clothing. The price in our mart, Richmond, is about 30 cents.

To make good bacon, make your hogs really fat; the best food is corn-meal, cooked to the consistency of dough; if more liquid, and might be called swill, it would be better; but the waste is great; they are always fighting whilst eating, when the swill pours out at each side of their mouth. Make the dough up with red pepper-water twice a week—it is a fine condiment, especially after a gorge from over-eating, and they are very fond of it. After slaughter, let the animals cool, cut out, and salt; ground alum much the best to red pepper, pound it well in a mortar and mix with the

* Note.—Our correspondent should get 20 pounds of meat from 100 of corn or meal.—Ed.

salt; then rub it in well upon the skin side of the joints, when you will be astounded to see the quantity of salt and pepper that enters in through the pores; it requires hard rubbing, with the hog's ear in the hand—friction and heat open the pores. Pork derives but little benefit from salt on the flesh side; saltpetre makes the hams dry and hard, the pepper makes it red to the bone, sweet, and juicy; let it lie in a bulk to take salt, 4, 5, or 6 weeks, according to the weather, then shake off all the loose salt, clarify that by boiling and skimming—it will answer for stock; plaster well with ashes from seasoned hickory-wood—ashes made wet to stick; hang up, shank downwards; smoke with any sound wood except pine; reduce 100 lbs. of pork to 75 lbs. will be good bacon. If you smoke in wet weather, as is usual, it will give a black skin; in dry clear weather it will be a fine yellow skin. I never take down and pack away in corn, bran, and other things, as many do; my bacon hangs till I cut down the last piece to cook; and I have had it to hang 4 years, as sound as a roach, when you could chip it off and eat like dried venison—but much richer. To guard against the skipper-fly, I make a smoke 3 times a week either of red pepper or trash tobacco, which is offensive to them, through May to middle of June, which seems to be past their egging season. See that your door fits tight; if not, tack list around; they are not fond to enter dark places; when you open the door to give out for dinner, close the door after you. Now for cooking a ham: it requires soap to wash off the ashes; place the ham in cold water in the pot, to remain 30 minutes; when put over a slow fire, to commence boiling gradually with small blubbers; lid upon the pot to retain heat; force no more by increased fire—you have got the boiling-point, and can make the water no hotter; but a violent agitation from increased heat to make the pot boil over will drive the juice out and make the ham hard and dry; skim the pot often, and keep on the lid. Now for the time of boiling a ham: for every pound it weighs, boil it for so many 15 minutes.

I am glad to hear that Congress has directed 130,000 copies of your Report to be published—regarding it the most valuable document published by Congress—which is all they do in favor of the great agricultural interest, which is the base of every avocation in this life, and is more neglected and disregarded than any other avocation in the whole civilized world. This is not as it should be. All which is very respectfully submitted, and, from its great length, may require you to curtail it.

Very respectfully yours,

CHARLES YANCEY.

Spottsylvania County, Virginia, December 31st, 1850.

Dear Sir:—Your circular, dated August last, came duly to hand.

1st. In regard to the wheat crop, I will say that the soil through this region of country, about the head of tide-water, has been considered not well adapted to the growth of wheat; consequently our farmers have not turned their attention so much to the production of it until within a few years past. The quantity seeded has been gradually on the increase, and, from manuring and improved culture, the product per acre has gained from year to year, nearly to double that of former years; the last harvest particularly, and, in some instances, where guano was used at the rate of about 200 lbs. to the acre, the product trebled that from the same land raised in any year previous for the last 20.

The average product from improved land without the aid of guano was about 12 bushels per acre, and upon guanoed land the highest average per acre, through the field that I have heard of, was $17\frac{1}{2}$ bushels, and the lowest 13 bushels. I will add, that much the larger portion of the guanoed land seeded to wheat could not have produced much more than the quantity sown upon it without the aid of the guano; and again, the quality of the grain was so much superior that the merchants and millers of Fredericksburg have said that the wheat raised in this and one or two of the lower adjoining countries, principally from improved and guanoed land, was less injured by the rust, and of better quality in all respects, than any offered in their markets this year. Clover seeded upon guanoed land stands well, and presents a good appearance.

The usual mode of applying guano to the wheat crop with us is to sow it upon the land without mixing with any thing else, turn it under with a double plough from 4 to 6 inches deep, sow the grain immediately, harrow in well with a heavy harrow in the same manner as wheat put in without the guano, when it follows the corn crop; the cornstalk and all being removed from the field before the plough: this is done in all the month of October.

Fallow ground is ploughed generally in the month of August, and seeded about the last of September, and the average quantity sown in either case is about $1\frac{1}{4}$ bushel to the acre. The semi-bearded wheat is the principal favorite with our farmers. The Poland has been introduced, and was harvested in our last crop; it yields finely, probably exceeds any other variety we have had, but, from its exceedingly rank growth of stalk and blade, I think it will be very apt to take the rust, and consequently will not suit this lower country so well. Harvesting commenced with us this year about the 25th of June—this is rather later than usual. The best remedy against the weevil is to thrash as early after harvest as possible, and put your wheat up in the chaff. Pens made of rails, with the floor raised from the ground, so as to keep out the dampness and let the air pass underneath, and well lined at the bottom and sides with straw, are used for this purpose by some of the farmers; and, if covered so as to keep out the weather, will keep wheat in the chaff for months without the slightest injury.

The average price obtained for wheat at our nearest markets, this year, has been about $1.07 cents per bushel.

We are almost surrounded by railroads and water improvements; our own roads, are, however, naturally fine, and we have an easy access to markets.

Corn.—This is our best established crop—not so, however, from its great average yield or profit, but owing to the peculiarity of our soil. Its preparation for this crop is easy, and the culture simple; so far as experience teaches, deep ploughing, as well in the preparation of the land as in the cultivation of this crop, is in all respects the best.

The ordinary preparation for the corn crop, as practised by most of our farmers, of throwing their lands into narrow beds, I think injudicious; especially so, when it is to be followed, as is usually the case here, by a crop of small grain: it never produces as much, and the corn, although it grows off and makes a little better show in the early part of the season, when planted in this way, it is more liable to suffer from droughts, and never ears out so well. My last crop of corn was made upon land prepared by a fallow, from

6 to 8 inches deep, (without bedding, except the wet spots,) and at planting-time, a large harrow was run over it, to break the clods and close the furrow-seam, to keep the grass from coming up. The ground was then furrowed off horizontally, and about 4 inches deep; the corn was planted, and as soon as it was well up, I commenced culturing about 8 inches deep, running on either side, and as near the corn as practicable. This was followed by the hoe, brushing away the clods from the corn, and adding a little fine dust when necessary. Through with this operation, say about the 10th of June, the corn was large enough to thin, and receive the dirt which was thrown to it, and completed its cultivation.

The yield was about double that produced from the same field 4 years since, when the cultivation was about the same, but the land was prepared by throwing it into narrow beds, as spoken of above.

The small grain crop usually follows the corn crop immediately after, sowing oats upon the most indifferent parts. The land is then permitted to lie idle, or, as the common phrase is, turned out, for 2 or 3 years, when it is again brought into cultivation, and the same routine followed up. It may be well to observe that much land in this section of country has been "turned out" and abandoned as being worthless, rendered so by bad and often repeated cultivation, a good portion of which has grown up in broom-sedge and pine, and some of it is still being cultivated, or rather *teased to death*, to procure a subsistence from it, but the product is so small as not to be worthy of notice. The pine upon it, however, is an inexhaustible source for fuel, and is profitable as such when contiguous to market.

The average yield of corn per acre on good land with us is about 20 bushels, and some of the farmers bordering on watercourses, particularly those in the valley of the Rappahannock, produce a yearly average yield of 50 bushels to the acre. A white corn, known with us as the twin-corn, a species of the Baden, is mostly cultivated. I have known, from good land, when the season suited, as many as six good ears gathered from one stalk of this corn. Another kind, somewhat similar to the old-fashioned gourd-seed, is now being introduced; it yields extremely well. The cob of this corn is small, and the grain very long and deep, and some of the ears produced in this vicinity, the last crop, counted upwards of 1200 grains to the ear.

I know of no experiment made, by which I could give the quantity of corn produced from application of a given quantity of manure, over and above the ordinary yield from the same land without it. The average price of corn in our markets is about 60 cents per bushel.

Oats are also produced for horse-food; they usually command, when sold, about 30 cents per bushel.

Tobacco is also raised with us, and our soil is pretty well adapted to the production of the finer kinds; the Orinoco is mostly planted, and yields about from 1000 to 1200 pounds per acre.

Peas and *beans* are only produced for family use; occasionally a few bushels for market.

Our farmers grow neither flax nor hemp, but almost every one produces cotton in quantities sufficient for all the family purposes, and it is for the most part manufactured at home, during the inclement seasons, by the female servants, or else it is carried to the factory, after being seeded at the gin, and exchanged for the manufactured article. The cotton-patch is continued in the same place from year to year, and manured principally with ashes

in the hill before planting. About the 1st of May is the time for planting; and one of my old and experienced neighbors informs me that he has known as much as 250 pounds produced from an acre of clean-seeded cotton.

Wool-growing is only extended to the supply necessary for family use. Our sheep are of the native stock, and subsist through the winter (unless a great fall of snow) in good order, with but very little foddering. After supplying the table plentifully, we generally have muttons and some lambs for sale every year. This is not a grazing or a cattle-growing region, except for the necessary supply of the farm; some of our cows, though small, are fine milkers, and butter is produced for sale to some extent, by almost every family, and a good article usually commands about 20 cents per pound, the year round.

Pork is raised also for family use only, and the best hogs that I have seen have been produced by a cross of the Parkinson with Berkshire.

Orchards are not as well attended to now as formerly, when they were more profitable in the article of brandy distilled from the fruit. All kinds of apples, except the winter pippin, however, grow well here, and obtain a fine size and exquisite flavor. Very few are marketed, but merely fed to the stock, dried, and made into vinegar. I think the crab-apple would be profitable made into cider; our best article of crab-cider usually sells for 20 cents per gallon by the barrel, but I do not know that a large quantity could be sold at that price.

Yours, respectfully,

JAMES M. NALLE.

P. S.—I have usually kept a memorandum of the advance of the planting season, noting its forwardness or lateness, one year with another, and other matters connected with farming in that way, but have not time to add it now.

Yours, J. M. N.

Fort Madison, Lee County, Iowa, December 17th, 1850.

Sir:—I have received your Agricultural Circular, and herewith furnish some information in reply to the questions annexed to it.

Wheat.—Varieties in use for fall sowing are red-chaff, bearded, and smooth, red and white-chaff, velvet, and Siberian. Red-chaff bearded is best. Wheat is always a sure crop on sod. Average produce per acre is about 18 bushels. Time of seeding is from 1st September to 1st October, and time of harvest from 27th June to 15th July. A few farmers prepare their wheat for sowing by steeping it in strong brine, and then rolling it in lime. It is thought that wheat thus prepared is not so liable to be injured by the fly, and that the preparation acts as manure. Quantity of seed used per acre is 1 to 1½ bushel. Plough once on sod ground, and twice on stubble, 6 inches deep. No perceptible diminution of crops. There is generally no rotation of crops, but farmers endeavour to put in corn after small grain. They are beginning to use clover for the purpose of manure. No weevil in wheat here. Average price per bushel for 1850, about 63 cents. Yellow corn most esteemed, ripens soonest. White corn yields more, but ripens later. Yield of yellow, about 45 bushels; yield of white, 55 bushels per acre. Cost of corn, from the seeding to the crib, is about 7 cents per bushel. Best mode of cultivation is to plough well and deep. Best mode of feeding is to have the ear (corn and cob) crushed and fed raw. Average price here for 1850, about 25 cents per bushel. Oats yield about 40 bushels per acre. Quantity of seed per acre, 2 bushels. Barley yields about 15 bushels per acre. Quantity of seed, 2 bushels per acre. Rye, average yield, 25 bushels per acre. Seed sown, one bushel per acre. Barley is least exhausting to the soil. Beans and peas cultivated only as garden vegetables. There may be a few exceptions.

Clover and Grasses.—Quantity of hay per acre, about 3 tons. Some plaster used. Stable manure the only kind in general use. Kinds of grass used are timothy and clover. Quantity of seed per acre, about a peck of timothy and clover seed, (chaff.) Hay is the most profitable crop that a farmer living near the Mississippi can raise.

Dairy Husbandry.—Annual average produce of a good cow is about 200 lbs. cheese and about 200 lbs. butter. Average price of butter for 1850 is 10 cents per pound, and that of cheese, 7 cents. Old-fashioned churns generally used. Neat cattle cost but little till 3 years old; feed about barn and stack-yards. Usual price of native animal, 3 years old, $15 to $20; good milch-cows, from $12 to $24. Very few Durhams here, but the number is increasing. They will yield much more meat with same amount of food than the native animal.

Sheep and Wool.—Wool-growing is profitable; large sheep more profitable for fleeces and mutton than small ones. Costs but little more to grow Merino wool than native. The proportion of lambs annually raised to the number of ewes is about 1 to 5.

Hogs.—Best breed is the China and common, crossed. Berkshire not so highly esteemed as formerly. Only method of raising hogs here is by feeding them corn in pens and small fields.

Cotton, sugar-cane, rice, hemp, none raised. Tobacco, a little raised in gardens. Root-crops are on the increase. Potatoes, a few sweet raised, and do well, especially red ones. Of Irish potatoes, the Neshanic is the best kind for table and market. The red potatoes are most prolific. Average yield, 200 to 400 bushels per acre. Cost of production, not more than 10 cents per bushel. Best system of planting is in hills. Plough twice and hoe twice; about 10 bushels seed per acre. Rotted straw manure improves them. Not much used. Fruit culture is receiving great attention. Not enough apples grown at present for home consumption. A few grapes, grown in gardens, do well, and rapidly increasing.

Manures.—Lime and plaster but little used. Soil here new and rich. Guano not used. Wherever manure is applied, it increases the crop, especially grass.

Meteorology.—See accompanying abstract, prepared by Daniel McCready, Esq., to whom I am indebted for much of the information contained in the foregoing answers.

Very respectfully yours, &c.

EDWARD JOHNSTONE.

Abstract of Meteorological Observations, made near Fort Madison, Lee County, Iowa, for the Year ending November 30, 1850.

Yearly mean....	50.75			Depth of rain and snow,			46.42	22.20		

The thermometer has a northern exposure, out of the direct rays of the sun. *Mean Temperature.*—This is the temperature as deduced from the daily observations during the year, at sunrise, noon, and sunset. The rain-gauge was a vessel of equal width at top and bottom, usually set upon the ground. N. B.—The thermometer is elevated about 6 feet from the ground. February 5th was the coldest day during the year; thermometer 12° below zero, and was not above zero all day. The greatest heat was on the 9th of July, from 12 till 2 o'clock; thermometer 100°. The 5th of July was the warmest day; thermometer, at sunrise 74°, at noon 94°, and at sunset 84°, being a mean of 84°.

DANIEL McCREADY.

Fruit Farm, Peoria County, Illinois, November 2[illegible]th, 1850.

Sir:—The postmaster at Peoria has handed me your circular of the 26th August, with a request that I would reply to the queries in regard to fruit culture.

1st. "Is the culture of fruit receiving increased attention?" Although this is a new district, settled principally within the last 12 years, yet the culture of good fruit, particularly of apples, peaches, and pears, is receiving very decided attention. The number of grafted trees, planted in orchards in this county, must be more than 75,000. A considerable share of these have commenced bearing, and the result, thus far, has been entirely satisfactory.

The demand for young fruit trees is rapidly increasing, and the time is close at hand when there is likely to be more good fruit in this and the adjoining counties than is now to be found in any district of equal extent in the United States. The supply of young trees in the nurseries has heretofore been nearly equal to the demand; and there are now on hand and for sale, at least 150,000 in the county of Peoria alone. I can, therefore, answer your first query in the affirmative.

2d. "Cannot apples enough be grown upon an acre to render the crop a very profitable one to the farmer?"

The disposition to plant orchards, so universal in this district, indicates a general belief, that they will become profitable. In no part of the world do trees grow better than on the table lands of Northern Illinois; and wherever they have attained sufficient age, they are very productive, and the fruit of most excellent quality. The specimens of apples and pears raised in this vicinity, and exhibited at the great fair at Syracuse, N. Y., in 1849, were at once pronounced to be the best and the most beautiful of the season; and the same remark will hold good in regard to those exhibited at the State Fair, held in Cincinnati, Ohio, in October last. The table lands of the region, comprising, as they do, more than three-fourths of the whole country, are entirely free from the visitation of untimely frosts; and this probably accounts for the great productiveness of our trees. This happy exemption may be attributed to the absence of every obstruction calculated to impede the full sweep of the winds, which come in immediate contact with the ground, and thereby retard vegetation in the spring until the whole atmosphere becomes warm. There is about ten days difference between the starting of vegetation on the table lands of the prairie and the timbered district in the same latitude east of us; hence, we often escape the effects of a late spring frost, which often makes sad havoc in the timbered districts. For the above reasons, the apple and pear crops are about as certain with us as any other crop, and so it has been ever since the first trees of the early settlers came into bearing, (now about 15 years.) Another consideration in favor of the extensive culture of the apple in this district, is the fact that good winter apples, fit for exportation to a warm climate, cannot be raised successfully south of latitude 39° or 40°. Whenever a surplus beyond the home demand shall be produced, we have the great Southern market as an outlet; and, by having the best article, we can always control that market. Our cultivators, instead of being influenced by a narrow, monopolizing spirit, are anxious to see their neighbors go into the business, being confident that the more good fruit there is to sell, the more profitable the cultivation of fruit will become. It is very difficult to make even an approximate estimate of the profits of an acre of orchard. The oldest plantation of apple-trees in this vicinity is now 22 years old from the seed. The best bearing varieties in it have averaged about 15 bushels per tree, or 600 bushels per acre, for the last 5 years. It is probable that for the next 10 years they will average 20 bushels per tree, or 800 bushels per acre. The present standard price for winter fruit is 50 cents per bushel at the orchard when gathered. With so large a market to the southward, where the apple never can be grown, we do not anticipate any material decrease in the price for a long series of years.

3d. We have no data upon which to make an estimate of the "comparative value of apples and potatoes, for feeding hogs and cattle." Indian corn is the universal article for feeding and fattening in this country, and where it can be produced so cheap, and in such profusion, nothing else is likely to supersede it for this purpose.

4th. "What varieties best to keep for winter use, and for exportation?" Being in the infancy of the apple culture in the West, the above are of necessity quite unsettled questions. There are some 200 varieties of late fall and winter apples now in the course of trial among us, many of which will be totally rejected, while a few only will meet the general approbation of cultivators. Among those which have been pretty fairly tried, and found well adapted to our soil and climate as winter apples, are the American Golden Russet, English Golden Russet, Flushing, Spitzenberg, Esopus Spitzenberg, Michael, Henry, Pippin, Milam, White Bellflower, White Winter Pearmain, Red Winter Pearmain, Wine-sap, and Fulton. Of such as are adapted to the spring market, the following have been well proved, viz. Green Newtown Pippin, Rowle's Jennet, Limber Twig, and Red Romanite, (Carthouse.) The celebrated Northern Spy has not yet fruited with us; the tree, however, grows well, and is hardy. The Fulton, above named, is a new variety, and is believed by many to be the best apple now cultivated in the West.

5th. "Do you know any preventive or remedy for the blight on pear and apple trees, or the yellows on peach-trees?"

The yellows has never made its appearance among our peach-trees, and of the blight we have had only two visitations since the settlement of the country. The first, in the summer of 1842; and the last, in 1850. In both cases, the disease commenced after a severe chill in the atmosphere, which had been preceded by very great heat and moisture. Its attacks were confined, in a great measure, if not entirely, to trees the branches of which were stimulated to the utmost, either by severe pruning, or high cultivation on a rich soil. Where the affected branches were removed soon after the attack, the disease did not spread over the tree; but, where they were suffered to remain, it spread from branch to branch, often doing great injury. Whatever may be the cause of the disease, it is certain that it will spread by infection unless the diseased parts be removed. I am confident that most of the injury done by the blight, in the years above named, was caused by a too free use of the pruning-knife before the malady commenced, and a too limited use of it afterwards.

6th. The transplanting of trees is an operation so simple, so easily performed, so free from mystery, it would seem that all the world might understand it. Yet, many who attempt it either fail in toto or in part. For the benefit of the inexperienced, we will venture to state some of the causes of failure: 1st. In taking up a tree. If it is small, it is often pulled up; this strains and lacerates the roots. A tree should always be dug up, not pulled up. 2d. The work is often done with a dull instrument, and the few roots which remain are often bruised and broken. 3d. There is often an unnecessary exposure of the roots to the atmosphere. If properly handled, the most tender tree may be taken up, transported a thousand miles, and reset with safety; when a few hours, and, in some cases, a few minutes of needless exposure will destroy it. By dipping the roots in diluted clay immediately after being taken up, then wrapping them in moss or some other substance which will not ferment, and will retain moisture, they may be kept out of the ground long enough to be carried any desirable distance. This work should be done in the spring or fall, when the temperature is above freezing and below the vegetating point. 4th. Another very common error in planting trees is a neglect to pare off all bruised and diseased roots at the time of transplanting. 5th. And last, though not least, the bungling manner in which the earth is placed about the roots, sometimes being shovelled in upon them, and then trodden down. No man can be a successful planter of trees if he is too proud or too lazy to get upon his knees and carefully pack the earth among the roots with his hands.

7th. *Budding.*—This operation we perform as early in July as it is practicable to obtain mature buds. The stocks should be cut off (above the bud) in seven or eight days after the insertion of the buds. In this way, if the stocks are thrifty, we are sure to obtain shoots from 10 to 30 inches long the first season. The best stocks for budding are seedlings, transplanted at one year old, and budded the second summer after.

Grafting.—Most of the grafting done here is what is called root-grafting. This is done in a warm room, in the winter season, upon the roots of one year's growth, taken up in the fall, and secured from the frost. The stock of the seedling should be cut off, leaving with the roots about 3 inches, upon which scions of the same size should be attached, and firmly tied with a moistened corn-husk. They should then be packed in earth, in boxes 8 inches deep, with the points of the scions left exposed about an inch above the earth. In this condition they should remain in the cellar until warm weather in the spring, when they should be exposed to the light and heat. After they begin to expand their leaves, and to throw out roots, they should be taken from the boxes and transferred to nursery rows, where they push up a shoot 3 or 4 feet high the first season. It is a very good practice to take up root grafts the next fall after planting, and bury them securely during the winter, as they are tender when the growth is very great, and often suffer during a severe winter. This, however, is seldom done.

Grapes.—The experience thus far acquired in grape culture in this newly-settled country is of course very limited, yet we are not without hope of a good time coming, when pure wine will supersede the poisonous beverages now too much in use. The Catawba grows well, is hardy and productive, so far as tried. I have a vine on my premises, said to have been brought from the Rhine, which has produced a full crop of delicious grapes every season for the last ten years. This variety has been spread considerably over the country, and will soon be tried for making wine. The Isabella has proved to be a failure with us, except when trained upon walls. We have, in this vicinity, some seedling grapes from the valley of the Connecticut, which bear prodigious crops, the quality not first-rate. From the experience

thus far had, we have good reason to believe that the bluffs of the Illinois are as well adapted to grape culture as the hills in the vicinity of Cincinnati, where so much wine is made.

Yours, &c.

EDSON HARKNESS.

IRRIGATION.

No country has greater natural advantages for irrigating all improved land than the United States; and the time approaches when these advantages will be turned to a useful account. To encourage improvements by the aid of running water, which is always charged with both the organic and inorganic food of plants, in a greater or less degree, we give an instructive and suggestive article, translated from *L'Echo Agricole* of a recent date:—

Drainage and irrigation are measures of the highest utility in agriculture. Indeed, it may be said that all our agricultural energies should be devoted to this object. But works of drainage and of irrigation are not within the easy reach of everybody. They require a pretty considerable outlay, and special information; without which the result would be almost always uncertain. A company, offering every necessary guarantee, and devoted especially to undertaking works of drainage and irrigation, would be of signal service to the interests of agriculture. We have frequently been the medium of recording the desires of the agricultural body, in their appeals for the formation of a company of this description. The Central Society of Agriculture, after hearing an excellent report by M. Batailler, on the irrigation effected by him on his estate of Portail, near Montargis, expressed, in 1849, the same opinion and desire.

Such a company is now established. For a long time past, several gentlemen, appreciating the excellence of M. Batailler's system of irrigation, and carefully weighing the advantages afforded by drainage, have been engaged in the formation of such a company. We are now in a position to announce its definitive establishment, and publish its programme and regulations.

The director of this great undertaking, M. de Liron d'Airolles, chevalier de la Legion d'Honneur, and formerly a practical agriculturist, has just favored us with all the documents and necessary information for the purpose of replying, through the medium of the *Echo Agricole*, to the numerous questions which have been addressed to him on this subject. We will now place these documents before our readers.

"The object of the company is to carry out, in France, works of irrigation, on the plan of those so much admired in the plains of Lombardy and in Piedmont, and which, wherever they have been skilfully carried, have secured large profits to the proprietor of the soil, and comfort and prosperity to the people. The company will extend its operations, limiting them, however, within the extent of its capital, to all districts which offer the most profitable investment; and advantageous proposals have been addressed to it from all sides. The Committee of Management feel convinced that whatever may be the amount of capital at disposal, it will, for very many years, be inadequate for the works which can be beneficially executed."

"*Data on the probable results of the operations.*—In many localities, the value of the soil has been increased tenfold by irrigation. But the company will ground its calculations on works executed under more ordinary circumstances, and under a climate which does not join the advantages of a high temperature to those of irrigation. Such an example presents itself in the works executed by M. Batailler, a landed proprietor, and formerly a pupil of the Polytechnic School, on his estate of Portail, near Montargis, where, by an expenditure of 600 francs the hectare,* (about £10 an acre,) he has transformed an arid and almost useless soil into rich meadow land.

"These results have been confirmed by numerous reports from the Inspector of Agriculture, and from commissions appointed by the agricultural committees, and by the administration of the department of Loiret.

"'The land on which M. Batailler has been operating,' say MM. de Sainville and de Montferrand, delegates from the Agricultural Society of Montargis, in their report of the 1st of September, 1847, 'was of very indifferent quality, and let at 10 francs the arpent metrique, or 20 francs the hectare,' (about seven shillings the acre.)

"This rental represents a capital of 700 francs; and it is notorious that these meadows, producing 1600 boottes† of hay, of the first quality, in two crops, are worth more than 4000 francs the hectare: being an increase of more than 3300 francs, a sum from five to six times greater than the capital expended.

"'To resume,' continue MM. de Sainville and de Montferrand, 'we think that the works executed by M. Batailler are well conceived and executed; and that the application of his system would be exceedingly advantageous in all situations where a sufficient supply of water and a suitable adaptation of the land are to be found. We do not, therefore, hesitate to propose that the gold medal offered for the best system of irrigation be awarded to M. Batailler.'

"The correctness of this example is further confirmed by the precisely similar results obtained, under a colder climate, in La Campine, the Sologne of Belgium, which have been published in a valuable work, by M. Mangen, engineer of bridges. 'The government works, and those of the Irrigation Society,' says M. Mangen, 'have already increased the value of some thousands of hectares of land, six or seven fold. There are also uncultivated downs in La Campine, which have been transformed into meadow land of the first quality, at an expenditure of 600 francs the hectare.' 'These are,' adds M. Mangen, 'remarkable instances of industrial companies engaging in agriculture. It is highly desirable that a large amount of capital should be employed in the same way in France.' We entertain no doubt of the success of this sort of undertaking, judiciously and honorably conducted.

"The above results are independent of those obtained by the aid of M. Batailler's system of liquid manure.

"MM. Dumas and Paine had long drawn the attention of cultivators to the advantages attending the application of copious irrigation with water, charged with some thousandth parts only of organic matter, as a means of

* The "hectare" is 11,960¼ square yards.
† The "bootte," weighs about 11 pounds English.

accelerating the progress of vegetation in an extraordinary manner. M. Batailler has responded to this appeal, and has succeeded in rendering these principles more thoroughly applicable than could have been possibly anticipated; for he not only makes practical use of all the fertilizing principles of *Flemish manure,* but he applies it to the land in irrigating streams in the exactly suitable proportions, without the expense of spreading; and, consequently, experiences no loss of gas and no offensive smell. This new process in irrigation has been unanimously approved by both practical and scientific men.

"1st. The Agricultural Committee of Montargis, which has inquired into M. Batailler's plan of irrigation on the estate of Portail, has awarded him a gold medal.

"2d. The Central Society of Agriculture, in its sitting of the 7th of February, 1849, recognised the special advantages secured by this method, and declared it deserving of serious attention. A member, M. Payen, cited the example of a similar system of irrigation, carried on in the plain of Issy, which produces four or five crops of hay, where, previously, only one was gathered.

"3d. The Society of Encouragement, in its second sitting of February, 1849, voted the publication of M. Batailler's paper, after a public and highly complimentary approval, pronounced by its president, M. Dumas.

"4th. The Jury of the Exposition has awarded two medals to M. Batailler; one from the report of the Commission on Chemical Arts, and the other on the proposition of the Agricultural Committee.

"5th, and lastly. The Council of Public Health, in its sitting of the 8th of March, 1850, impressed with the importance of the results obtained, recommended a grant to M. Batailler of the 30,000 metres of nightsoil reserved for such purposes by the city of Paris.

"The company, therefore, seconded by the most talented engineers and distinguished agriculturists, appeals confidently for the raising of its capital to the friends of agriculture, and to those who wish to employ their money in a manner most safe, the most beneficial to the country, the most productive of moral good, and its substantial advantages. M. Batailler has granted to the company the sole use of his system.

"We cannot do better here than to quote some extracts from modern writers who have treated on the subject of irrigation.

"*M. Mathieu de Dombastes.*—'Of all the improvements in the means by which the products of the soil may be permanently increased, there is, perhaps, none more important than irrigation; and yet the practice of this system has been, hitherto, confined to but a small number of the departments of France. It affords, in fact, a most striking instance of the slow progress made in agricultural arts of the most evident utility.'

"*M. Jaubert de Passa.*—'Who could venture to form a calculation of what the future has in store for France, if irrigation obtains a footing there, under the protection of the laws; if new and peaceful channels of labor be opened up for the poorer class; if a more perfect and diversified culture of the land, and an application of irrigating streams for improving waste lands, retain in their villages these numerous labourers, now congregated in populous towns, through want, neglect, and many other causes; if more extensive meadows and superior pasturage conduce to the improvement in the breed of cattle and horses; and if the food of the people become more wholesome and abundant?'

"*M. Hericart de Thury.*—'The law of Angeville is but the first instalment of a more complete legislation on this high and important question of irrigation. There is not perhaps, in other districts, a sufficient knowledge of all the advantage that can be rendered by irrigation and the influential part it may perform in the destinies of the people.'

"*M. Auguste de Gasparin.*—'At Orange, the fifth part of the land is submitted to irrigation. Meadows as beautiful as those of Milan are mowed three or four times a year, and are let as high as 450 francs the hectare. One-third of this sum is expended in the management of the land. These returns equal from three to ten times the revenue of identically similar soils under ordinary cultivation. At Avignon, the water triples the value of the excellent land which surrounds the town. At Vaison, and at Malancene, irrigation raises the value of the naturally inferior soils to 12,000 and 14,000 francs the hectare. At Cavaillon, the waters of the Durance have, in some places, increased the value of the soil tenfold. Lands, which hardly fetched 500 francs the hectare, are valued at 5000. At Sorgues, a sterile country, which was repulsive to the eye of the traveller, has improved a hundred-told through irrigation. The desert has been here changed, as it were, into the smiling plains of Lombardy.

"M. Taluyers, of Saint Laurent, (Rhêne,) has, with an outlay of only 20,000 francs, formed a meadow of 33 hectares, producing an income of 10,000 francs. The land brought in previously no more than 1200 francs. It is, moreover, with very small outlay that the riches of the soil have been thus opened up. At Cavaillon, close to the banks of the Durance, occurs almost the only instance in which the system has acquired a remarkable development. Everywhere else the operations have been mere experiments. An example is hereby, however, bequeathed to posterity, demonstrative of the course they ought to adopt, as well as of its practicability.'

"*M. Nadault de Buffon.*—'France alone requires the formation of at least 5,000,000 hectares of meadow land, to give it the proportion of one to two with land cultivated by the plough. An increase of riches would then ensue to the amount of more than 6000 millions, (£240,000,000,) equivalent to a revenue of more than 300 millions, (£12,000,000.) Thus, notwithstanding the expense incurred, irrigation is one of the most certain elements of wealth to the countries which employ it: a fact easily confirmed by the more outward aspect of general comfort among the population in irrigated countries, by the cleanliness and convenience of the rural habitations, and by the facility with which the various liabilities are discharged.'

"*M. de Maunay de Mornay*, in his 'Studies on the Irrigation of Upper Italy,' has given a description of the magnificent works executed in that country, with information as to the manner of their construction, and the changes requisite in French legislation necessary to get rid of the obstacles, now frequently invincible, which are opposed to the use of running waters. 'In the present state of things,' says M. de Mornay, 'the streams pursue their course to the sea without affording one-twentieth part of the advantages which might be secured from them.'

"It would be superfluous to enlarge here on the considerations of public interest which are now more strongly than ever connected with the subject of agricultural labor. Those who are anxious for the future prosperity of the country are bound to second the government in realizing the idea expressed by the Minister of Agriculture and Commerce, in his circular of the 3d March, 1850:—'The government wishes the lot of the agricultural laborers to be so enviable as to counteract the temptation to exchange it for a town-life. On the other hand, it is desirable that the artisan in town be induced to remove to the midst of the fields, where he will find health and prosperity for himself and his family.'

"All these motives amply prove that the moment has arrived for carrying into execution the long-meditated project of forming a company which shall raise the funds necessary for those great works of irrigation which do honor to some neighboring countries, and of which France has been hitherto deprived. It is with this object that the company whose title, constitution, powers, and regulations are given below, has just been definitively constituted. The company is entitled, 'The General Agricultural, Irrigation, and Drainage Company, with or without the use of Liquid Manure.'"

December 1st, 1850.

House of Representatives, Washington, December 13th, 1850.

Sir:—I have the honor to reply to your interrogatories of the 12th inst. on the subject of sheep husbandry in the South.

1st. In my congressional district, we have the Southdown, Bakewell, Merino, and other *blooded* sheep; but by far the greater quantity are mixed-blooded; and these last are the more healthy, and are consequently the favourite sheep.

2d. The clip of wool varies, of course, according to the quality of the sheep. Two pounds per head for the ordinary stock of the country is about an average. Flocks of the improved breed yield much better.

3d. They are remarkably healthy and very prolific in young, more so, perhaps, than in any country where they are so little cared for by their owners.

4th. *Sheep-rot* is the only disease to which they are very subject, and does not happen so often as in other countries.

5th. I do not think it an object with our planters to increase their flocks to a greater extent than to supply their family wants. The sheep is valued with us more for his flesh than his fleece. The mutton, we think, is quite equal to any *in the world*.

6th. We market our wool as we do our cotton, and ordinarily sell it to the same persons and in the same way. A good deal is worked up into cloth in the country.

7th. The cost of raising and keeping sheep is so near nothing, that I have never heard it computed. Our farmers sometimes have waste grounds, on which they pasture their sheep; but generally they run in the open woods; and here, I think, they do best. They have a little salt thrown them once a week, and besides this no attention is ordinarily given them.

8th. We do not ordinarily feed them at all. They generally subsist themselves in the woods or in the fields.

9th. We have no grasses or other esculents for the feed of sheep in summer. The ordinary grasses of the country, such as are indigenous to the soil, we find quite sufficient.

10th. We have neither grain nor dry food for them in the winter. If we have occasion to feed them, which seldom happens, we give them the blades of the Indian corn, which we call "fodder." Sometimes a little corn is given them, but I doubt if it does not more harm than good.

Our winters are mild, and it seldom happens that a sheep is not able to subsist himself without aid. If we find him lingering in January or February, we give him some assistance; but he gets along very well on the old grass until late in the winter; and by the 1st of March he can nip the new crop.

On the whole, I know of no country where the sheep prospers more than in South Mississippi. The fleece may not be so fine or so heavy as in more northern latitudes; but he yields it free of cost, and throws his flesh into the bargain. The flocks multiply with singular rapidity, and, as I have said before, the mutton is equal to any in the world.

Very truly, your obedient servant,

A. G. BROWN.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Lisbon Post Office, Union County, Arkansas, January 6th, 1851.

Sir:—The Patent Office Circular of 1850 having been placed in my hands by Colonel John R. Hampton, to whom it was sent for reply, I submit, after due reflection, the following observations, which are designed to have reference more especially to the southern upland counties of this state.

Wheat.—This crop is not generally cultivated in this region, the soil and climate not being well adapted to it. However, of a favourable season, the yield is, say 15 bushels per acre, and of very superior quality, weighing from 65 lbs. to 70 lbs. per bushel.

Corn is planted generally for home consumption, and as yet there has been seldom more made than the wants of the country called for, owing to its recent settlement and constant and rapidly increasing population. Kind most successful, large white. Average product, say 20 bushels per acre.

Oats, so far as tried, do well here. The large white, or Egyptian, for fall, and the little black for spring sowing. Our lands are, as yet, too fresh to enable us to judge with any degree of accuracy as to what extent this crop is an exhauster. This crop is much more generally cultivated than wheat, our light sandy lands being better adapted to it.

Sweet potatoes are largely cultivated and constitute our most valuable root crop. Product per acre, 200 to 400 bushels. Kind most cultivated, yellow yams.

Irish potatoes succeed well, and are generally planted for spring and early summer use. Time of planting, middle of January to middle of February for early crop. Average per acre, 30 to 40 bushels.

Cotton.—This is our staple crop; time of planting, middle of March to the middle of April—though fair crops are occasionally made, with a favorable season, planted as late as the middle of May; average product per acre, with fair cultivation, 200 pounds ginned cotton. We value cotton-seed very highly as a fertilizer either for corn or cotton; and, as a general thing, but little attention is given to any other kind of manure. A few of our planters, however, are now turning their attention to that subject, as well

as hill-side ditching and horizontal cultivation, which I feel assured will result in a great benefit both to themselves and the community.

With sentiments of the highest regard and respect,

I am very sincerely yours,

E. W. WRIGHT.

THOMAS EWBANK, Esq.
Commissioner of Patents.

Sir:—Through the kindness of Thos. C. Fletcher, Esq., of this place, I have been favored with a copy of your agricultural circular, and requested to reply to its inquiries so far as the productions of Jefferson county extend.

Wheat.—The varieties mostly cultivated are the red-chaff, bald, and May wheat; average product per acre, 8 bushels; time of seeding is from the 15th of September to the 15th of November; and the time of harvesting from the 20th of May to the last of June. It is usually sown without previous preparation of seed: one bushel per acre is the quantity usually sown. It is usually sown among corn or on oat stubble, and ploughed under. The yield per acre is not increasing. There is no system of crops practised; the ground is usually cultivated in corn till it will not produce a full crop, and then sown with wheat or oats "to rest it." Wheat was worth from 75 cents to $1.20 in St. Louis, in 1850.

Corn.—Common white and yellow are varieties sown; the average yield per acre is 30 bushels; the cost of production, about 15 cents per bushel. The manner of cultivation is to break up the ground in the spring; check off about 4 feet apart each way, having from 2 to 4 stalks in a hill; plough 3 or 4 times with shovel or Carey-plough, and by this time the weather is generally very warm. "Get up on the fence and lay it by." It is usually fed whole. Manure is not much used.

Oats.—We sow 2 bushels per acre, giving a yield of about 20 bushels per acre. In the opinion of your correspondent, oats are the most exhausting crop grown on our farms, (weeds excepted.)

Barley, rye, peas, and *beans* are not cultivated.

There are but few good meadows, notwithstanding much of our soil is well adapted to the growth of grass. The yield per acre is about one ton without manure.

Butter is worth 10 cents per pound. We have no pastures for our cattle. They live in the "range" in summer, and in the stalk-fields in winter. A good cow is worth from $10 to $12. We have no imported cattle; never stall feed, but allow our beef to fatten in the range. Flocks of sheep usually diminish in numbers on account of the depredations of wolves.

Wool-growing would be profitable with proper attention.

Our best *hogs* are a mixture of the Berkshire and the common breeds. They run at large; and get just corn enough to keep them alive until it is time to fatten them, when they are turned into a lot and fed on corn in the ear from 2 to 6 weeks.

Potatoes and *turnips* are grown only in small quantities for family use.

Fruit.—There are a few good orchards in the county. Fruit, especially apples, is one of the most profitable crops we raise. The large yield 50 bushels per acre; expense, from 20 to 30 cents per bushel, which sells from 62½ to 70 cents.

John Shoener raised, in the neighborhood of Orwigsburg, 270 bushels on 3 acres of land, of the red-gourd corn. On ordinary land, his mode of planting is by dropping a single grain in the drill 12 or 15 inches apart; distance between the drills 3 feet.

Rye and *oats* are raised here, of which rye is the least exhausting and the most profitable crop.

Buckwheat is an excellent and profitable article, if it succeeds; but it is a very precarious crop. It is used extensively in this county for fattening hogs and cattle. Lime, as a top-dressing, is an excellent manure for this grain. Land that will produce no other crop will bring buckwheat. Clover seed may be sown with buckwheat, and a good crop expected, if the land is previously limed.

A large crop of the common turnip and potato is raised in this county; and they generally find a good market. There is no particular mode practised in raising these crops. This county depends upon the north and northwestern parts of Pennsylvania for its supply of beef and mutton. The farmer has so good a market for his grain and hay, that he finds the raising of cattle a poor business. The great facility of procuring ready-burned lime from Berks County, via of Schuylkill canal, enables us to improve our lands rapidly and with reasonable expense. Lime is delivered on the canal at 9 cents per bushel; and 50 bushels to an acre are considered sufficient to produce a good crop of hay. Let the general government protect our coal trade, and enable our miners to pay us for our produce, is all the farmers of Schuylkill county ask. They want no foreign market. If we are to depend upon that, we shall soon be obliged to stop raising crops; but if the coal business flourishes, then we have an excellent market for all we can raise.

Respectfully yours,

JAC. HAMMER.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Statesville, Aredell County, N. C., December 28th, 1850.

Sir:—Your circular, soliciting information on the various branches of agriculture, was placed in my hands. I feel extreme reluctance in undertaking to answer any part of it. We have no systematic farming, except what may be done by a few isolated individuals; nor have we any agricultural society here. You will therefore perceive how difficult it is to collect information nearly approximating to the truth, of the kind you desire, as well as how important such returns must be. I have concluded, however, to answer, as well as I am able, with the means at my command, a few of the questions presented in your circular; and you can make what disposition of this you think proper.

Wheat.—We have the spring wheat, the red bearded, fly-proof, blue-straw, May, and Mediterranean: a number of other varieties have been tried within the last few years, and discarded. The two first named proved the best last season; and, in consequence, more than usual of both kinds have been seeded down this fall. Seeding of all the varieties, except May, usually in October. Early seeding would be greatly preferable, if it were not from danger of the fly, which is certain to attack the young wheat, in case of drought immediately succeeding sowing. The May wheat, to avoid the spring frost, to which we are subject, cannot be safely sown until November or December. The latter kind is harvested about the last of May, or first of June; the other varieties, from the 15th to 25th of June. One bushel of seed is sown per acre; and usually dispatched, whether on stalk or fallow land, with one ploughing. Wheat, owing to the Hessian-fly, late frost, and, I may add, to our indifferent farming, is here an uncertain crop. No remedy is known here for the Hessian-fly. Threshing as soon as the wheat is dry is an effectual remedy for the weevil.

Corn.—The white is most esteemed for bread, and on account of its deep and extended roots; in other words, standing a drought better than the yellow. The yellow, on account of its being a softer variety, is preferred for stock, and is supposed to yield better than the white on bottom land. The average yield, I think, must be about 15, or farthest, 20 bushels per acre. A bushel of corn cannot be grown here with profit, for less than 40 cents. Farmers seldom get that much for it; more frequently, 20 and 25 cents per bushel.

Oats are extensively grown in this county; 15 bushels is about the average yield per acre; 1 or 2 bushels, according to the land, sown per acre.

Peas are beginning to be extensively cultivated here; not, however, as a renovator of the soil; though, from experiments I have seen made, I have no doubt of their being a very renovating crop, and the most economical fertilizer of the soil of any crop we can grow upon it; for the beneficial effects of this are observed, whether turned under ground or left to decay on the surface. The pea is mostly planted here for hogs, and they easily repay for the labor bestowed upon their cultivation for that purpose. From experiments made in this county with clover, I am inclined to think it will not do to rely upon it as a renovator of the soil, as it requires a rich soil to produce it; yet, it is an excellent renovator, but liable to be cut short by early drought. Abundance of hay is made in this county on our swamps or wet bottoms, though not so much as formerly, as vast quantities of our swamps have been redeemed within the last few years, and converted into clover land. No attention is paid in this county to the growing of wool, except for domestic purposes; neither would it be worth while, on account of the dogs. The extermination of the whole canine race, I have no doubt, would result to the advantage of the people of this county; as there can be no doubt of the susceptibility of our soil and climate for the purposes of wool-growing. Our whole system of farming is gradually tending towards a change for the better. Increased attention is being paid to the subject of making manure; though we labor under great disadvantages in this respect. We have neither lime nor plaster in this county, but abundance of every other material, which, as experiments have proved, and are proving, can, with little cost, be converted into excellent manure; and even the small deposit of those matured upon the soil and turned regularly. When the plants are of a sufficient size, they should be thinned, so as to be 10 or 12 inches apart; and, by chopping over twice, and ploughing once, you may expect an abundant crop. I consider turnips are more profitable for a farmer than any other crop he could plant or sow on the same piece of ground. The kind of seed most sown or preferred in this section is the English white, which grows mostly out of the ground, and, for this reason, the turnips need hilling up before much cold weather comes on them. I cannot do the subject justice—so I will close.

Very respectfully, yours,
R. H. BENNET.

T. EWBANK.

Vermilion, Erie County, Ohio, December 10th, 1850.

Sir:—Your Agricultural Circular came to me in due season, and, although I cannot flatter myself with being able materially to add to the value of your report, still, as this report from the Patent Office is becoming more and more the means of extensive good to our wide-extended country, I cannot refuse my feeble efforts to increase its usefulness. My field of observation is confined chiefly to the eastern parts of Erie and Huron, and the west part of Lorain counties. This territory is on the extreme southern bend of Lake Erie, and comprises almost every variety of soil, and so intermingled that it is difficult finding 100 acres which do not embrace several varieties. The western parts of the above-named counties are upon the limestone formation; the eastern parts, and Lorain, on sandstone and clay. The drift forming the *superstrata* appears to have come from the west and northwest, so that considerable quantities of lime are intermingled with the soil of the eastern parts of the field of my observations. The climate is somewhat severe and open in winter, very little snow falling, which often winter-kills wheat, especially on clayey and wet soils. The spring is always cold, chilly, and backward, for this latitude, owing to the large quantities of ice and cold water in the lake. Summer is warm and pleasant, and the autumn very serene, mild, and pleasant, owing to the proximity of a large, shallow body of water, by the powerful rays of the summer sun. Hence we feel almost sure of sound corn, if planted by the 10th of June. It is a good fruit country, for the chills of spring keep back the buds, and, although disagreeable to the senses, are still above the freezing point, and prevent injury from late frosts. Apples scarcely ever fail; and peaches, along the lake, and 3 or 4 miles back, only fail once in 3 or 4 years.

These preliminary observations on our geographical and geological situations and meteorological peculiarities will enable the intelligent reader to comprehend the advantages and disadvantages of our location.

Wheat is our most important crop. In its cultivation, we often run on Charybdis in attempting to avoid Scylla; that is, by sowing late to avoid the fly, (for the Hessian-fly seldom injures wheat sown after the 24th of September,) we expose the too tender plants to the severe frosts and frequent thaws of winter, thus losing by winter-killing; or else the rust is liable to take it just before it ripens, on all but the warmest soils. The most successful way to avoid all these evils is to keep the land in high tilth; sow late, to avoid the fly; plough deep; and thoroughly drain, either by ditching or by throwing into narrow beds, to prevent heaving, and drowning out; and cultivate the earliest varieties, to avoid the rust. The Soules, bluestem, white, improved flint, and Hutchinson are all in good repute for this purpose: and those who practise the above seeds seldom fail of a good crop of wheat. There is no regular system of rotation which has obtained among us. Such is the diversity of soils, and so much do our farmers accommodate their operations to what they call their convenience or necessities, that few practise alike, or pursue any fixed plan. Fronting on the lake is a soil remarkably adapted to wheat culture. Here a system (if it may be called a system) of stubbling prevails—wheat succeeding wheat for a series of years, and without any material diminution of the yield. This year, 30 or 40 bushels per acre have been produced from lands from 3 to 6 years in wheat, without rest or any intervening crop—merely burning off or turning under the stubble. Generally, back from the lake, naked summer-fallows secure the best crops. Deep ploughing is found beneficial, as the subsoil is generally composed of all the materials for promoting the growth of vegetation, and only needs exposing to the action of the elements to fit it for that purpose.

Two ploughings are given in summer-fallowing, and generally one for stubbling, or when wheat succeeds corn or oats. From the 20th to the last of September is the best time to seed, though, the Hessian-fly out of the way, the first part of September would be much better. One and a half bushel per acre is about the average amount of seed used. This was a heavy-timbered country; and, as the stumps get out of the way, we can plough deeper and cleaner, and in every way manage it better than formerly. So that the crop is increased by the greater quantity in cultivation, and the larger yield per acre. I am satisfied the average yield is not far from 18 bushels per acre, for a series of years previous to this year, while, this year, the average is not less than 25 bushels—probably over. Taking all the wheat raised for 5 years, I estimate the average cost of production at 67 cents; and the average price during that time has been about 85 cents—this year, 75 cents.

Corn.—We cultivate several varieties of what is here called gourd-seed. They are all nearly a hybrid between the rough gourd-seed of the South and the flints of the North. Experiments have proved that the gourd-seed of the South, in a few years, accommodates itself to our climate, by becoming more flinty; while the flint corn of New England approximates towards the gourd by becoming dented, and increasing in size of ears and number of rows. Fifty bushels per acre are about the average product, and the cost of production not far from 25 cents per bushel. The best crops are raised with least labor (and those two words, *best* and *least*, are much in favor) by manuring from the stock-yard a clover sod, or an old meadow, thoroughly breaking it up just before planting; and, having rolled or bushed it, drag with a sharp harrow till it is mellow, then plant, and use a corn-cultivator and plough, particularly in keeping down the weeds. The best time for planting is the last of May, except on dry, sandy soils.

Clover and Grasses.—In good seasons, 2 tons per acre are the average. This year it was less, by half. The average for a series of years is about 1½ ton. Timothy and red-top for permanent meadows, and clover and timothy on arable lands, are preferred. From 4 to 8 quarts of seed per acre are usually sown; and in seeding marshy and wet lands, which produce weeds very abundantly, from one-half to one bushel of seed, sown in September, has proved very successful. The cost of production is about $3 per ton, and it is generally worth from $4 to $5.

Sheep and Wool.—We consider wool-growing profitable, when common or medium quality brings 25 cents per pound. I compute the cost as follows:

Dr.

To 100 sheep	$100.00	
" 30 acres, $15 per acre	450.00	
	$550.00	capital.
Interest for 1 year	$33.00	
Saving 5 tons of hay	10.00	
Salt, attention, shearing, &c.	50.00	
	$93.00	outlay.

Cr.

By 96 fleeces, (deducting 4 for casualties,) each of $3\frac{1}{2}$ lbs. in weight, at 25 cents per pound, would equal	$84.00	
By 60 lambs, more than keeping old stock good	30.00	
	$114.00	income.
	93.00	outlay.
	$21.00	profit.

This estimate is made upon good common sheep. The advocates for the coarse-woolled, and their opponents, for the fine, *figure much larger profits.* I doubt whether there is much difference in the amount of food necessary to produce a pound of either quality, or whether there is much difference in the profits. The superior bodies, for market, of the coarse-woolled, their hardiness, and superior nursing qualities, fully, if not more than balancing the higher priced fleeces of the fine-woolled. We need both kinds; and it is presumable that those who will give the *necessary attention* to raising a fine-woolled flock, will find it equally as profitable as those will who prefer to devote less attention to a coarser one. Our lands are rather wet, and the grass rank, which seems to indicate them as better suited to the coarser woolled sheep. Some few amateur breeders will, of course, command the market, and make much ado about the *enormous* profits and wonderful fleeces of their respective flocks; but, in general, we must content ourselves with ordinary fleeces, common prices, and moderate profits—not, however, neglecting any opportunity for improvement.

Hogs.—We consider the Berkshire, and crosses between that and the grass, the best breeds. The southern part of this State, Kentucky, Indiana, and Illinois can raise corn and, consequently, pork, so much cheaper than we can, that they have nearly driven us out of the market; and especially since corn has brought an advanced price at our lake markets, in consequence of its increased exportation to Europe. *Our* corn is worth more than the pork it will make. Very little is made for export. The cheapest way we can make pork is to fatten mostly on apples. They will increase in weight nearly or quite as fast on good ripe apples as they will on corn, and the pork is nearly as good, if fed on corn a few weeks before killing. A little grain should be given with the apples. Meal is much better than dry corn, and, if cooked, all the better; but grinding and cooking is very little practised.

Fruit Culture.—There is increased attention to the cultivation of good

fruit. I have no doubt but land put out to apple-trees, providing suitable pains is taken in selecting the best varieties, is as profitable to the farmer as almost any other crop. I am satisfied, from feeding them to various kinds of stock, that good sweet apples are worth nearly as much as potatoes. I tried them on a colt we were weaning this fall, and which had fallen away considerably, and he improved faster than I ever had one on oats. Probably, cooked potatoes are more nutritious than apples, but, taking the trouble and expense of cooking into account, we hardly doubt that apples are worth within from 50 to 75 per cent. as much as potatoes, for all kinds of stock.

Peaches, too, may be made profitable, to the extent of the demand, green and dried. Peaches, peeled and dried, bring from $3 to $3½ per bushel; unpealed, half price. It is said, by those pretending to know, that our climate and soil will not produce as fine peaches as New Jersey. I can see no good reason for this opinion, except that there has not been pains taken to cultivate them here. We have a better soil, and as good warm weather in summer and fall as they, and as much of it. What, then, is there to hinder? I have a small pioneer orchard growing, and just wish to notify our New Jersey friends that, if they can send peaches to our lake *now*, to look out for competition from this quarter, even as far as New York and Boston, before this generation has passed away.

Grapes.—I would suggest that those who wish to have a supply of delicious grapes for the table, fair and bright, will be much more likely to have their desires gratified by letting their vines climb some good-sized tree, instead of keeping them confined to a stake, near the ground. My Isabellas never fail of being fair and bright, and ripen a week or two earlier up in a tree-top; while, near the ground, on the arbor and trellis, they mildew and rot, nearly half the time. Very good wine is made here from the Isabella, by boiling the unfermented juice—about three barrels to one.

The year 1850 has been very remarkable on several accounts. By referring to my diary, I find January was cold up to the 7th, then warm, with some rain.

BENJAMIN SOMMERS.

Centreville, Wayne County, Indiana, December 24th, 1850.

Sir:—In answer to the interrogatories contained in your Agricultural Circular, a copy of which I have received, I will endeavour to give the information required, so far as my limited means will permit. As the nature and quality of the soil is connected with agriculture, I will merely state that a tenacious clay soil prevails in our county, with a subsoil of the same, except our creek bottoms, which are a black loam. A large proportion of the timber is beech and sugar-maple, with hickory, oak, ash, poplar, walnut, and cherry. In agriculture, we are in what might be termed a transition state: done making farms, and beginning to farm. Much interest is manifested by some in receiving and imparting knowledge on the subject and in procuring improved implements of husbandry. The result of this wholesome condition in the farming community was the organization of the Wayne County Agricultural Society.

Wheat.—The white and red-chaff bearded are the kinds generally cultivated. The velvet and Mediterranean are sown, but not extensively. The velvet is much esteemed, and more of it will be sown than formerly. The

Mediterranean yields more per acre and is the least liable to casualties; but it has a soft straw, which renders it liable to lodge. Probable average yield per acre, 19 bushels. Time of seeding, from the last of August to the 10th of October: from the 5th to the 15th September is preferred. Harvesting, the last week of June and first week of July. Quantity sown per acre, 1¼ to 1½ bushel, the latter quantity to be preferred on strong land. One ploughing, from 4 to 5 inches deep, is all the land usually gets. By means of a better method of farming, and our lands having been longer in cultivation, the quantity of straw is diminished and that of grain increased, while the number of acres sown has increased threefold in consequence of the improvements in roads and the building of mills, which afford a ready cash market. We have no established system of rotation in crops, but are governed by circumstances or the nature of the soil. The practice of sowing wheat on the same field one, two, and three years in succession is finding favour with some. Many sow after corn; but we do not get so good a crop as on fallow ground or stubble. The difficulties that the wheat-grower here has to contend with are the Hessian-fly, freezing out, and rust. Manure is considered a good remedy against all of them. Sowing on sward is the best preventive against freezing out. Average price for 1850, 60 cents per bushel.

Corn.—This great staple of the farmer is a crop of the first importance with us, and, whatever mishaps befall other crops, this always comes forward and takes us through. It is planted from the 24th of April to the 1st of June. From the 1st to the 10th of May is best, 4 quarts of seed to the acre. We have a white gourd-seed corn, with a red cob, much esteemed, and a large white variety that yields well; also the yellow gourd-seed, much in favour with some for feeding stock. Probable average product per acre, 40 bushels. It is difficult to make an accurate estimate of the cost per bushel for raising corn, for the difference in the quality of the soil would make a difference of 10 per cent. in raising. The following is an estimate for a medium quality of land:—For ploughing, 75 cents per acre; harrowing, 85 cents; marking, planting, and seed, 60 cents; one harrowing and three plantings, $1.50; interest for the land, $1.20; total cost for one acre, $4.40, or 11 cents per bushel. The great art of raising corn consists in keeping the ground free from weeds, and well pulverized about the roots while it is young, and stirring the soil deep.

Clover and Grasses.—Our meadows will average one ton per acre. Timothy is best, though, on land somewhat worn, equal parts of clover and timothy are sown, say from 4 to 6 quarts to the acre. Cost of growing hay, $2.60 per ton.

Dairy husbandry is not followed here as a business. Our surplus butter is sold in our towns at an average of 10 cents per pound.

Neat Cattle.—Some attempts have been made to introduce the Durhams among us, and, judging from the results produced by crossing them with our native stock, I feel assured that great good would result from having a full-blooded Durham bull in every neighbourhood. As regards the cost of rearing until 3 years old, the best answer I can give is, that it is not worth the price they would sell for at that age, which is from $16 to $18 per head. Pasturage is worth 50 cents per month, and wintering on corn fodder and straw, about the same. Good cows sell from $14 to $16 each the year round.

Sheep and Wool.—In a country like ours, where the land is nearly all adapted to agricultural purposes, the growing of wool cannot be profitable at present prices. The number of lambs annually raised is about two-thirds that of the ewes. Sheep do well here; and, if farmers would so arrange it as to have the lambs come in spring, there would be very few lost.

Hogs.—What the best breeds? This question reminds me of the farmer who was noted for his good-looking porkers, and, on being asked of what breed they were, answered by pointing to his corn-crib. Notwithstanding the old farmer's opinion of the potency of a large and well-filled corn-crib in making a good breed of hogs, there are some varieties that show fuller and more palpable evidence of the benefits of said crib than others. The Irish graziers are most esteemed here. While corn is so cheap and so easily raised as at present, feeding it to hogs in the ear is thought to be the best plan; but I have no doubt that cooking potatoes, pumpkins, and apples together, and adding corn meal, is a method worthy the attention of farmers. Root crops are only raised for family use.

Fruit culture is receiving increased attention, but it is not much used as food for stock.

Potatoes are considered preferable for that purpose. Orchards have suffered far more from the "fire-blight" during the past than in any previous year, which has been attributed to an exceedingly dry season. Those on dry localities have suffered most. All attempts to raise peach-trees have proved unavailing for the last eight or ten years, in consequence of the "yellows."

Manure.—When it accumulates about our barns and stables, so as to be in the way, we generally remove the nuisance to our fields, instead of pulling down our buildings. I am under obligations to you for a package of lucerne, or French clover seed. It came up, and grew well, but after it had attained 4 to 6 inches in height, it was mostly destroyed by an insect at the root. The Germans say it will grow there. Oats not sown as much as formerly; it is thought to be an exhausting crop. Average yield per acre, 25 bushels. Barley not much raised; is not so hard on the soil as oats; average per acre, 20 bushels. Rye, hardly any sown. Peas and beans raised only for family use.

Yours respectfully,

A. HOOVER.

Bethmont P. O., Orange Co., N. C., December 21st, 1850.

Sir:—I have this day received your Agricultural Circular, and proceed to answer, as well as I can, such of your questions as apply to this vicinity.

Wheat.—Varieties in use, golden chaff, Black Sea, white bearded, Mediterranean, occasionally red and early purple straw, and Pennsylvania blue-stem. Time of seeding, May, October, November, and December. October is best. Harvest about the 20th June. No preparation of seed generally, except to clear it from cockle and cheat. It is generally sown on corn land, and put in in a slovenly manner. Some do better, sowing on fallow ground broken up late in summer, or early in autumn, and ploughed or harrowed in. I think the yield per acre has been diminishing for many years, and hope, after falling to an average of 5 bushels per acre, it has reached its minimum, and is beginning to rise, by a gradually improved system of farming. A few of us have bought up old exhausted broom-straw fields to yield 8 to 10 bushels per acre. The rotation has too generally been corn, wheat, pasturing after harvest, for 8 or 10 years, till the ground refuses to bring wheat. Then, corn and oats alternately, till the poor returns compel the unthrifty farmer to turn out his fields to broom-straw, and clear more land to be destroyed by a similar process, or move to the West. The average price of wheat may be set down at 80 cents. I have introduced the early purple-straw, a red wheat, ripening June 10th, therefore not subject to rust, which is the greatest enemy to wheat in this section, but not attacking earlier than the 10th of June. I secure it from smut, the great enemy to early wheat, by soaking it in a solution of salt, from 12 to 48 hours, and drying in lime or ashes, so as to scatter. This I have found a perfect protection. I sold my crop this year for seed, at $1.25 per bushel. I have sowed this fall samples of Troy, Iturean, white Genesee, and Zimmerman's, besides the early purple-straw, and hope to report another year.

Corn.—Common gourd-seed and Collins's corn: I think the average per acre is 15 to 20 bushels. Some do much better. Others worse. Mostly cultivated with the plough—little hoeing done. Oats generally sown on the worst land, having been planted with corn the previous year: regarded an exhausting crop. Seed per acre, 4 to 5 pecks. Product in good ground, 30 to 40 bushels; common average, about 10 bushels. Barley and rye not cultivated. Beans and peas not much cultivated, except for the table. Clover found valuable by the few who have adopted it. Timothy mostly sown in meadows, though most meadows are not sown at all, but grow up to the coarse native grasses. I am experimenting with orchard grass, lucerne, Guinea grass, perennial rye grass, and herds grass, and may, hereafter, be able to report useful results. Neat cattle receive little attention here, cost little, and are worth little. What are called dairy-cows sell at from $10 to $14 each. A few Durhams were introduced a few years since, without profit. The Devons will probably succeed well. Sheep very little attended to, and sadly annoyed and destroyed by dogs.

Hogs.—The Berkshire, or rather half Berkshire, seems to be the favorite. A cross of the Berkshire with the long-sided Kentucky sow has proved a valuable hog. Tobacco, very little cultivated. Potatoes, Irish and sweet, cultivated for domestic use only.

Indications of the Thermometer, observed at sunrise only.

Average for JANUARY, 1850	39°34′
Coldest day, Tuesday, 1st	18
Warmest, Saturday, 26th	64
(Much rain, little or no snow.)	
FEBRUARY, average	35.34
Coldest day, Tuesday, 5th	14
Warmest, Saturday, 9th	54
12 days as low as 32°, a little snow once.	
11 days of rain.	
MARCH, average	42.86
Coldest day, Friday, 29th	27
Warmest, 1st	62.30
Falling weather, 15 days; snow, 27th and 28th.	
APRIL, average	50.14
Coldest day, Thursday, 18th	32
Warmest, Tuesday, 23d	66
Rain 12 days.	
MAY, average	59½
Coldest day, Sunday, 12th	42
Warmest, 5th	70
One good rain, and several light showers.	
JUNE, average	66⅔
Coldest day, Monday, 12th	49
Warmest, Thursday, 27th	74
Very little rain this month.	
JULY, average	71⅔
Coldest day, Friday 12th	67
Warmest, 31st	76½
Temperature uniform, much cloudy or foggy weather, little or no rain.	
AUGUST, average	71½
Coldest day, Wednesday, 28th	68
Warmest, Thursday, 1st	76¾
Uniformly warm, 5 slight showers, and 1 good rain, Wednesday, 14th.	

SEPTEMBER, average	65°
Coldest days, 18th and 30th	52
Warmest, 2d	74
First half cloudy; last half clear; rather dry on the whole.	
OCTOBER, average	49½
Coldest day, 21st	36
Warmest, 18th	67
Slight frost 7th and 8th, ther.	42
One rain, the 26th.	
NOVEMBER, average	48¼
Coldest day, 18th	26
Warmest, 28th and 29th	67
Rather a dry month.	
DECEMBER, average to the 23d	42⅔
Coldest day, 14th	20
Warmest, 4th	64
A dry month.	
From JANUARY to MAY, unusually wet.	
From MAY to DEC. unusually dry.	

I send the above hasty sketch, and hope to do better another time.

Very respectfully,

W. J. BINGHAM.

P. S.—The wheat crop much injured by rust, and in some cases ruined. Oat and corn crops cut short by drought.

W. J. B.

Litchfield, Connecticut, December, 1850.

Sir:—Having seen the notice of a circular from you, requesting information on various subjects relating to agriculture, I give such information as I have been able to collect.

Wheat.—Very little, if any, raised in this State; none in this part of it.

Corn.—Yellow eight-rowed most common; some other varieties cultivated; 40 to 45 bushels per acre a fair yield; sometimes 60 bushels, and even 100 bushels have been raised; cost of production not generally estimated; system of culture, the plough, cultivator, and hoe in general use. It is generally fed raw, and often without grinding.

Barley.—Very little raised in this part of the State.

Beans.—Not extensively cultivated. *Peas*, ditto.

Rye.—Average yield per acre, 20 to 25 bushels; quantity of seed sown, 1½ bushel per acre, and often much benefited by harrowing in the spring, when the ground is sufficiently dry.

Clover and Grasses.—Average quantity of hay per acre about 1 ton. Fertilizers, barn-yard manure, ashes, gypsum. Clover and timothy generally preferred for seeding down.

Dairy Husbandry.—I have had no opportunity to ascertain, except the prices of articles. Butter, in summer, 12½ to 14 cents; in winter, 18 to 20 cents per pound; cheese, 6 to 8 cents per pound.

Neat Cattle.—Cost of good cows, $25 to $45 each; working oxen sell from $80 to $100 per pair.

Cotton, sugar-cane, rice, and *tobacco* not cultivated.

Potatoes.—Irish formerly much raised: product 300 to 400 bushels per acre; this year nearly all rotted—a few favored pieces on sandy loam without manure, were the only exceptions. "Waterbury reds" the best—yield generally good—this year, hardly 100 bushels per acre.

Turnips are on the increase since the failure of potatoes; price per bushel, 15 to 20 cents.

Beets, Carrots, &c.—Few raised except for table use. Hemp not cultivated here. No extra attention is paid to fruit culture in this part of the

State. The subject of manures has scarcely begun to excite attention here; very little used except barn-yard and ashes.

I have thus given you a brief and very imperfect sketch of agricultural matters in this part of our State. Should the same be desired another year, I may, perhaps, be able to send you something more valuable.

Meteorological Table for 1850.

Months.	Mean.	Highest.	Day of month.	Lowest.	Day of month.	Range.	Remarks.
	° ′	°		°		°	
January	28.20	52	25	8	30	44	Wild month—sleighing good.
February	26.08	50	26	5	6	55	" " road dusty.
March	29.25	59	14	7	4	52	Great storm, night of Feb. 28th.
April	37.51	70	28	18	18	52	Cold, unpleasant month.
May	47.79	76	28	29	2	47	" " wet "
June	63.88	90	20	41	1	49	Warm, growing month.
July	69.	90	30	50	12 27	40	" " "
August	64.48	88	13	40	19	48	Distinguished for great rains.
September	57.71	80	6	31	30	49	Mild, pleasant month.
October	48.45	73	17	22	30	51	" " Indian summer.
November	39.87	63	4	19	23 4	44	" " month.
December	23.88	47	1	2	24	49	Mean of year, 44° 38′; range, 95°.

I am sorry to feel obliged to say that the agricultural resources of this part of the State are but feebly developed, owing to the stereotyped notions of the people, and there is but little prospect of immediate improvement. The agricultural society, however, is doing something, and may in time make an important change.

Respectfully yours,

J. L. HENDRICK.

Hoodlands, Perrysville P. O., Cecil County, Maryland,
December 25th, 1850.

Sir:—In reply to your circular, I would say that the varieties of wheat most esteemed by me, and in use in our neighborhood, lying on the navigable waters of the Susquehanna and Principio Creek, are the white and red blue-stem; the time of sowing with us ranges from the 15th of September to the 10th of October, and our harvest usually commences about the first of July. I have latterly used Pearson's improved wheat drill with good effect: as at present gauged, it sows about 1½ bushel to the acre. Where the ground is properly prepared, it is a neat and expeditious method of putting in wheat. One hand with two horses will drill in 8 acres in a day. I have been accustomed to immerse my seed-wheat in brine, principally for the purpose of cleansing it, stirring in, when partially dry, as much plaster as would adhere to it; but have ceased the practice since using the drill, as it interferes with the proper distribution of the grain in the drill-boxes. The best fertilizers I have tried are leached ashes and lime; the former is

used as a top-dressing, preceding the operation of the drill upon land cultivated the previous year in corn, at the rate of 100 bushels to the acre; the latter, after being slaked, is spread upon the land, after the ground is flushed and made ready for the crop, at the rate of 60 bushels per acre. Our method of cultivating green clover fallow for wheat has scarcely ever failed of success, even in the most disastrous seasons. We commence ploughing in the latter part of May, soon after the clover begins to blossom, using Davis's three-horse plough, set to run about 8 inches deep; it does its work very handsomely, turning the clover well under, if the stock has not been permitted to tangle it; this operation is followed by the harrow, which closes up the interstices, and in the month of August we stir the ground with small ploughs, which throws the decomposed vegetable matter near the surface, and, after a dressing with the harrow, the field is ready for the drill; but when the seed is to be sown broadcast, the harrowing should be omitted till after it is sown. Where the ground is well set in clover, a cultivation of this kind, without the aid of manure, is good for 20 bushels of wheat to the acre. It is usual with us to turn the clover in the second year, mowing the field in the mean time, and sowing it once with plaster, at the rate of 3 pecks to the acre. The price of wheat at our landings, for the last five years, has averaged about $1.10 per bushel. I do not cultivate oats as a crop, but merely for the use of the stock. I have found by experience that the kind known as the white brier corn (so called from the roughness of the ear to the touch) is the most prolific on our soil. We endeavour to break up the sod as deep as 9 inches, and plant the corn at a distance of 18 inches, in rows 4½ feet apart: for its cultivation we rely principally upon the plough, using the harrow only occasionally. The average product is about 10 barrels, or 50 bushels per acre. I am, very respectfully,

Your obedient servant,

JOSEPH COUDON.

South Hadley Falls, Hampshire County, Mass.,
December 22d, 1850.

Sir:—It is with pleasure I comply with your request to furnish some information in relation to a few of the questions proposed in your circular. The season past has been more than usually productive for grass. Other crops a fair average, except apples and potatoes, the latter of which have suffered more from the disease than ever before. The best variety here is the peach-blow or sand-lake, being productive, good for the table, and having thus far withstood the blight better than any other kind. The tobacco crop is becoming one of our staple commodities. The amount grown on the banks of the Connecticut the past season, say, from the vicinity of Hartford, Conn., to about 40 miles up the river, is about 800 tons, and has all been sold at prices ranging from 10 to 18 cents per pound, averaging about 12½ cents. The variety raised is known by the name of Connecticut Seed Leaf. It is used for segar-wrappers, being a large thin leaf, a single one often measuring more than 3 feet in length by 14 to 16 inches in width. A fair average, on good ground, is 1600 pounds to the acre, though much more is often produced. I raised, on 1¾ acre, the past season, 2662 pounds, and sold it at my door for 14 cents per pound, amounting to $368.90. The ground must be made rich, and much care is required while growing to keep it free from weeds and worms. When ripe, it is cut and hung in sheds (made for that purpose) to cure: it should hang till perfectly dry, which will take from 8 to 10 weeks; it is then taken down in a damp or rainy time, that the leaves may not be broken and stripped from the stalk, tied into bands of about half a pound each, and then it is ready for sale. It is bought up by dealers, who press it into boxes of about 400 lbs. each, and sent to market. They have received large profits on the last year's purchases. I consider that 10 cords of stable manure (worth $3 per cord) are sufficient for an acre, to produce a good crop. A fair compensation for carting manure and cultivating 1 acre would be $50; deduct one-half the cost of manure ($15) which remains in the ground, and the whole cost would be $65.

Neat Stock.—In reply to your inquiry, whether a given amount of food will produce more meat in a Durham, Devon, or Hereford, than in a native animal, I can best express my opinion and experience by quoting from the "American Herd Book," published by L. F. Allen, Esq. "Were the short-horns generally introduced into our great cattle districts upon the strong soils, and crossed upon our native stock, up to three-fourths and seven-eighths blood, there can be no question but 1 to 2 years in maturing would be gained, with increased weight of carcass; and, to say the least, an equal quantity of beef, with a diminished consumption of food. The market value of the flesh, too, would be enhanced; that is, a greater weight of mess beef can be cut from a short-horn than a native animal. The brisket, crop, plate, loin, and rump, in the one, being much heavier, relatively, than in the other. The peculiar mellow handling of the short-horn is also indicative of a superior quality in the flesh, adding to its selling price on foot, and rendering it easier of support, on a less quantity of food. So, too, with the milking qualities of the cow. The milk of the short-horn is proverbially rich; the quantity is also increased; and we have no hesitation in asserting that an average herd of high grade short-horns will yield, with a proportionate weight of carcass to the animal, and an equal consumption of food in the aggregate, at least 10 per cent. more butter and cheese, than a like herd of common cows. Many accurate judges estimate it higher; but we are content with this low scale of superiority, sufficient, at all events, to induce a reform in the entire dairy system of our country. With many, it may be considered a minor question; but the profitable disposition of the cow, after her dairy qualities shall have been exhausted, should not be disregarded. It is important that she be turned to good account always; and, having performed her whole duty at the pail, she should finally yield her full quota of profit in a valuable carcass. All this can be effected with the short-horn in a superior degree, as those powers of secretion which make her unrivalled at the pail, will, when turned in an opposite direction, equally prove her excellence in the shambles.

We do hope, that the day is not far distant, when our farmers themselves will, in their flocks and their herds, pay such attention to their breeding, and their quality, as shall make them objects of high interest, not only to themselves, but to their families; and to that degree, that such interest shall not abate, but increase, with age and experience. We indulge the anticipation, not altogether that our noble race of short-horns are to become the *universal* cattle of America, but that some of the improved races of neat cattle shall everywhere predominate, circumstances permitting; and this pleasing and important branch of agriculture shall receive the consideration to which it is so strongly entitled. So far as climate is concerned, they have flourished equally well in all the Northern, Middle, and upper Southern States. A good and productive soil, yielding an abundance of pasturage in summer, with a fair quantity of winter forage, will content them. True, short-horns are moderate consumers, compared with their capacity to yield both milk and flesh."

Yours, respectfully,

PAOLI LATHROP.

Lockington, Shelby County, Ohio, December 21st, 1850.

Sir:—A friend sent me, last winter, a work emanating from the Patent Office. I almost immediately lent it to a friend who has gone West, and wished to learn how to raise the Osage orange. I am anxious to obtain a copy of your next volume, and, though the statistics of our common country will soon be laid before you, (imperfect to some extent, of course,) yet there is much we must learn aside from them. 1st. Why do we not more frequently change our own acclimated wheat, say from Canada and New York or New England best varieties to our Ohio and Western soils? We lose every other crop, in some vicinities, by rust, fly, or wireworm; even this season, half of our fields here were ruined by a worm. 'Tis true, the grasshopper eat off the early sown: but that sown from 20th September to 10th October, was greatly injured by the worm. On pulling up stalks, a small worm was found, ½ to ¾ inch long, in the heart of the young shoot, striated, brown and yellow, having the general characteristics of the common wireworm, unknown before in wheat here. A good variety of spring wheat is much needed in N. W. Ohio. Can any one tell how to change a Southern winter into a Northern spring wheat? Two or three of us have tried and failed: but one variety exists in nature; climate and cultivation do the rest. Wheat is an annual in growth,—but seeding the ground after maturity, and, of course, can be brought back to its original state. There is no such thing in nature as spring wheat whose seed would perish if sown in the fall.

Information with regard to the cultivation of the Osage Orange.—Four times out of five, we fail here; some of our best farmers in the Miami valley have tried on all kinds of earth common to this country, and have failed. I tried in one year on heavy upland clay, side-hill gravel, and deep, sandy loam, in bottoms, and failed, while a few of the *same* seeds were taken to Rochester, New York, and did well, sowed dry in a garden. We sow, after laying out in the frost, dry, soaked in cold water, tepid, and boiling water; yet if any one succeeds, it is only with a few plants—an exception to the rule, *fail.* Fancy-gardeners may do better. We need the orange here, and in the Sciota valley, nearly as much as in Illinois. I hope the able correspondent of your office, Dr. ———, of Jacksonville, Illinois, will inform the public of his successful mode of cultivation, and whether the orange, like the Morus Nigri, Acacia, the Ailanthus, and Catalpa, will not send out new scions, if the plough comes near the roots; if so, your hedge will soon be a forest. Will not all these varieties bear grafting on each other? I think so; all but the orange, I know will. Any information relative to the above, would be of great value to our agriculturists, as this is the season when we prepare for spring labor. I trust the President's suggestion, with regard to a Bureau of Agriculture, may meet with favor. Science will do much, but practical knowledge is what our farmers want: they are not educated for fancy farming, or gardening, but are tillers of the *earth*—I wish I could, with propriety, say *soil*. You will pardon my troubling you; I trust and hope by another year to be able to give you some information in return.

Respectfully, your obedient servant,

JAMES COOK.

FRUIT CULTURE IN MICHIGAN.

Detroit, January 2d, 1851.

Sir:—In Oakland county, where I have resided for 11 years, the culture of fruit has received increased attention. Good apples have brought from \$1.25 to \$3.00 per barrel of 2½ bushels. At 50 cents per bushel, the lowest price for apples of the first quality, there has been realised more net profit per acre, from the land in orchards, than from any other crop our farmers have raised. A farmer living near me, who has only about 1½ acre in orchard of cultivated fruit, has sold, some years, over \$400 worth of apples. Unfortunately, the orchards first planted here were mostly of natural fruit; these have, in many instances, been grafted by persons who go from farm to farm every spring for that purpose, and the result has been that the fruit of a large portion of the trees thus grafted proves of little value for market. Some improvement, however, has been made in the fruit, but the trees have been very much disfigured, owing to the incompetency of those performing the operation, and an inconvenient mixing of fruit, by grafting several kinds of apples upon the same tree. A tree grafted or inoculated when small, is far preferable to one altered over when grown large, for several reasons, one of which is its increased length of limb, and another is, it cannot be so well shaped as while young, for then the head may be so formed as to produce more fruit and of better quality than trees of the same age and size altered over; and besides, what is of some importance, they will have symmetry, instead of being unsightly objects. Farmers have made a great mistake in grafting large varieties, without regard to quality. Apples of large size are invariably coarse and inferior for the table, and are liable to be blown from the tree, and the result is that three-fourths of them fall prematurely. This is a decided objection, as far as profit is concerned, even if they were of good quality. I have a decided objection to a great number of varieties. Suppose a farmer has 100 apple-trees, and 50 varieties of fruit: now, he cannot well have more than 3 or 4 trees of any one kind; and in 50 varieties he will of course have early, summer, fall, and winter fruit, and the result will be, he will have to keep running to market all summer and fall, and many times with half a load. Would it not be better to have, say, 80 trees of good winter apples, and 20 trees of other varieties, merely for family use; then the apples for market could be all gathered at one time, and marketed after the most important business of the farm is over. Let these 80 trees be of the best varieties, and those that bear well. The Rhode Island Greening, Swaar, Spitzenburg, Westfield, Seek-no-further, and Roxbury Russet, are good varieties, and bear well in this climate. If only two varieties were to be selected, I would prefer the Greening and Spitzenberg, as producing the most fruit and of the best quality. A farmer of my acquaintance put up last fall 120 barrels of apples from 20 trees, and they were worth in Detroit \$1.50 per barrel. I know of no farming products that would net as much, or any thing like it. An apple that originated at Kingston, New York, and introduced by Judge Buel, called the Jonathan, I find to be a very valuable variety. Out of 70 or 80 varieties I have fruited within the last 6 years, I think this is one of the best. It is a great annual bearer. This fruit is ripe in November, and keeps well till May. It is of medium size, good flavor, and invariably fair, and withal a very handsome apple. Skin thin and smooth, the ground clear light yellow, nearly covered by lively red stripes; stalk three-fourths of an inch long, and rather slender, and inserted in a deep, regular cavity; calyx set in a deep, broad basin; flesh, white, tender, and juicy. Much has been said and written upon the importance of picking fruit carefully, and of packing it properly. Full directions have been given at various times, in nearly all the agricultural journals. It is absolutely necessary that fruit, in order to have it keep well, should be picked by hand, and after being carefully picked, it should be placed in the barrels by hand, and when the barrel is full it should be shaken gently, that the fruit may settle together, so as not to move in the barrel by carriage. The barrel should be full, that the head may press firmly upon the fruit. The barrels should never be placed upon the head after they are filled, but should be carefully packed away upon the bilge, in a shed or other out-building, and kept dry till the weather becomes cool enough for the mercury to fall below 30°, when they may be placed in a cool, dry cellar. Apples will not injure at a temperature 2 or 3 degrees below freezing; but if they could be kept at freezing point, they would remain perfectly sound for almost any length of time, if kept dry.

I submit a few remarks upon grafting apple-trees. It is the usual practice to graft the extremities of the limbs, or to cut them where they are not more than 2 inches in diameter. Now, I consider it important to cut the limb near the main stock; no matter if it is 5 inches in diameter; it will do better, and make a more perfect tree, and produce more fruit. To graft small trees, cut them off below the surface of the ground, and graft in the usual way of cleft-grafting; then replace the earth around the stem, and the work is done. For grafting above-ground, a composition, made of three parts rosin, two parts beeswax, and one part tallow, melted together, and applied with a brush while warm, (it should not be hot,) is a good composition. Split the stock to be grafted in the centre with a knife and mallet, drive in a wooden wedge to open and hold till the scions are inserted. The scion should be of the last year's growth, and wedge-shaped at the end to be inserted; put one upon each side of the stock, so that the inner bark of both the limb and scion may come in contact; then take out the wedge, and the scions will be held firmly: now, to finish the operation, apply the composition as above directed. If both scions should live, let them grow till the next spring, when it would be well to cut out one of them. In preparing the ground for an orchard, it is important to have a deep rich soil. For manure, a compost is generally recommended, which, no doubt, would be preferable; but I am satisfied that almost any kind of manure will answer, if it is buried deep in the soil. I would recommend that as much manure should be spread upon the ground as can be turned under with a large plough; then have two good teams, and let the latter plough be set off so as to follow in the furrow of the first, that the subsoil may be brought up and turned upon the sod. I have had land ploughed 12 inches deep in this way, with a pair of horses, by changing the set of the plough every time of coming round. I am satisfied that this is a good operation. By having two teams of sufficient power, the ground may be broken to the depth of 16 inches. If the land be thus treated, the trees may be set without further preparation, and will succeed better than they will by merely digging large holes, as is often recommended. The usual distance is about 2 rods each way. Where peaches do well, and it is profitable to raise them, they can be planted between the rows of apple-trees, as they will die out before the space will be required for the apple-trees. It will require 40 trees to the acre, at the above distance.

Very respectfully, your ob't servant,

A. C. HUBBARD.

P. S.—The above remarks are respectfully submitted, which you are at liberty to use as you see fit. They have been written in haste, and without having been reviewed. A. C. H.

Washington, Macomb County, Michigan, December 16th, 1850.

Sir :—In reply to your circular of August 26, 1850, I would give you some hints for the benefit of professional men and mechanics, who never, or seldom keep but one cow and one hog. This practice is generally considered a matter of economy, is to keep one hog, as the milk of the cow, over and above what is used in a small family, together with other rejected morsels from the table, will keep the hog very well, without much extra expense.

Now, the idea I wish to suggest is, to dispense with the hog entirely, and feed to the cow all that is usually given to the hog. There is no difficulty in learning the cow to eat all the milk, &c. I will give you the result of the experience of a neighbor, a physician by profession and practice, as well as a rigid economist. My immediate neighbor, Dr. D. Cooley, has, for several years, pursued the above plan, and I will give you a brief sketch of the result.

In the year 1849, Mrs. C. kept an account of the butter made in 3 months, June, July, and August, as follows:

In June	$52\frac{4}{16}$	pounds.
July	$44\frac{13}{16}$	"
August	$46\frac{1}{16}$	"
	$143\frac{4}{16}$	"

In the summer of 1850, the same lady kept an account for six months, with the same treatment of the cow, beginning with May, and ending with October. The following is the result for 1850:

May	$34\frac{1}{16}$	pounds.
June	$38\frac{4}{16}$	"
July	$36\frac{4}{16}$	"
August	$35\frac{2}{16}$	"
September	$26\frac{8}{16}$	"
October	$36\frac{11}{16}$	"
Aggregate	$211\frac{5}{16}$	"

This cow was 6 years old in the spring of 1849, of good size, though not above the medium size. She grazed in a common pasture of timothy and clover, and was fed the slops of the house, as above stated.

The family consisted of three adult persons, and one child 10 years old. All the milk and cream was used that was wanted in the family, and the balance set for butter, which produced the above amount. You will see that the months of June, July, and August produced about 33 pounds more than the corresponding months in 1850. The deficiency in 1850 is readily accounted for, from the fact that the first season had been very dry and the pasture very poor.

I believe it is not generally expected of one cow to supply a family with butter, but only milk and cream for ordinary use. Now, this cow has done all that, and produced over 200 pounds of butter in 6 months, with only the extra feed that is ordinarily given to a hog. Butter is worth, on an average, 12½ cents per pound. Pork is worth from 3 to 37½ cents per pound. *Quere*—Would the slops of the house fed to a hog, instead of a cow, have produced $25 worth of pork in 6 months?

If the above hints are worth correcting and revising for use, you are at liberty to do so, and make such use of them as you please.

Very respectfully, your ob't,

G. W. KNAPP.

ROOT CROPS.

Having been engaged, for the past eighteen years, as one of the firm of E. Risley & Co., in horticultural pursuits, I have given considerable attention to the growing of roots, being forced to raise large quantities every year, that we might have good selections for the raising of seed, which has been the principal object. We have had many to feed, yearly, to our horses and cattle.

For feeding, we give carrots (the long orange) the preference over all roots. Beets, for cows giving milk, are rich, sweet food, and preferable to turnips; but for working oxen and horses, no food, for winter and spring feed, in my opinion, equals carrots. To feed them in the winter, a cellar, attached to the stable, is indispensable.

One and a half bushels of carrots about equals, in substance, one bushel oats. Horses, that have been stiffened by hard work and high feed on grain, can be much renovated by a change to carrots for a few weeks, and it is the next thing to a run in forest grass.

Having obtained the premium every year from the New York State Agricultural Society since its organization, perhaps it would not be amiss to give the statement of crops and expense of raising.

On one acre of land, in 1846, we raised 1590½ bushels of carrots, 56 lbs. to the bushel, at the following expense:

25 loads of manure, 62½ cents	$15.62
1½ days ploughing, $1.25	1.88
20 " raking and sowing, 62½ cents	12.50
30 " weeding and thinning, first time, 62½ cents	18.75
20 " " " second time, 62½ cents	12.50
12 " hoeing " third time, 62½ cents	7·50

36 days harvesting, 62½ cents	\$22.50
Improvement on land	10.50
6 lbs. seed, 50 cents	3.00
	\$104.75

Or a little more than 6½ cents per bushel. In 1847, on half acre, 498 bushels, on green-sward, turned over and harrowed after rolling down, at an expense of \$25.76, or a little over 5 cents per bushel. Same year, on ¾ acre of land, on which carrots had been raised the two preceding years, 826¼ bushels, at an expense of \$42.69, or a little less than 5 cents per bushel.

In 1848, on one acre, 966 bushels, at an expense of \$50.10, or a little over 5 cents per bushel.

In 1849, on 1¼ acres, 2318½ bushels, at an expense of \$54.37, only about 2½ cents per bushel.

In 1850, on 1 acre, 951½ bushels, at an expense of \$46.63, or a little less than 5 cents per bushel.

The aforesaid crops were all raised on land of about the same quality, and, on the same land, some for 3, and some for 4 years in succession. Rich green sward, turned over and sowed, produces good crops, and at less expense than land kept under the plough and hoe for years, as weeds are much less troublesome, which are the farmer's dread, and discourage many from trying a second crop; yet, but few crops pay better for a little pains and patience.

Sow in drills from 12 to 14 inches apart, and, as soon as they can be seen, hoe them through with a common hoe, to stir the ground between the rows, which prevents weeds from starting. As soon they are fairly up, hoe again, and then thin out to from 2 to 4 inches in the row. I have never known the crop injured by insect or worm. By soaking the seed before sowing, will forward the crop, and keep it ahead of weeds, and much labor will be saved. I raise sweet potatoes in this latitude, 42½°, by starting them in a hot-bed, for my family's use. Seed should be procured from farther south every season, to prevent degeneration. I raised, this season, over 20 bushels on 50 feet square.

I, last fall, fed two pigs, and as I think it is more healthy for a hog to grunt than squeal, I gave them all they would eat, and found that 4 quarts of meal, wet with cold water, was no more than they would eat at one time. I also found that 16 quarts would thicken 8 pails of boiling water to a pudding, which they would not eat at 6 times.

In this place, the warmest day in 1850 was July 16th; 11 o'clock, A. M. 94½°; average, 85¾°. Coldest day, December 31; 7 o'clock, A. M., 6 below zero; average, 17½° above.

The mean temperature for each month:

January	$34\frac{1}{31}$°	May	$56\frac{11}{31}$°	September	$66\frac{11}{30}$°
February	$31\frac{1}{4}$	June	$74\frac{1}{30}$	October	$55\frac{11}{31}$
March	$39\frac{1}{4}$	July	$77\frac{11}{31}$	November	$49\frac{1}{30}$
April	$48\frac{11}{30}$	August	$75\frac{4}{31}$	December	$29\frac{11}{31}$

Mean temperature for 1850, 53½°.

LEVI RISLEY.

Fredonia, Chautauque County, New York, December, 1850.

North Harpersfield, January 1*st*, 1851.

Sir:—The number of acres in this vicinity under the plough has been on the decrease for some number of seasons, perhaps towards twenty; and this for two reasons: one was, (and that might have been sufficient,) that the returns of ploughing, sowing, and harvesting, was generally a meagre pittance: another was, that the cheapness and fertility of Western land, with their easy means of transporting to market, rendering competition from this vicinity entirely abortive. It therefore requires no sophistry to prove that a wrong course has been pursued in the managing of farms; and, indeed, excessive ploughing has been followed by (almost equally ruinous) excessive feeding, or pasturing, and mowing; even meadows are allowed but a short season of rest, from the earth-treading hoof; grass lands are left in late autumn, without any covering to shield them from the severity of the wintry blast.

Now, I would propose the keeping of less stock: the stock would present a healthier appearance, would arrive at maturity much quicker, (which is an important item,) and, no doubt, would be more profitable. Another reason, and stronger still, is, the land would improve; the grass left on in the fall would keep the land warm in winter, and would hasten vegetation in the spring, by its decay. By these means, land would improve; but it is evident, it can be improved much faster by a judicious system of ploughing and manuring. There is but little manure made, saved, and applied, to what might be; as evidence of this, I can point to those who manufacture two loads for every acre they possess; and to others, who do not apply as much as one for every two acres; and this, too, of an inferior quality, being bleached and drenched by sun and rain. Of the different and scientific ways of obtaining fertilizers, I shall not speak—only of their application. To improve a piece of land which has been too much worn by the plough, and has lain in grass some time, I would prefer corn for the first crop: it will depend on the nature of the soil, and its locality, whether it should be broken up in the fall, which may be done to advantage where the soil is not light, sandy, or exposed to severe wind. After the land is ploughed, which should be done very nice, it may remain, with the exception of a slight harrowing occasionally, until near the time for planting, which is the middle of May. It should then be allowed a coat of coarse manure, which should, by harrowing and ploughing, be well mixed with the surface soil; then, if you would have a good growth of fodder, with ears of corn well filled, and ripe before the frost, furrow the ground, and manure in the hill, with a compost from the hog-pen and hen-house, with a mixture of ashes or plaster, or both; 12 or 15 good cart-loads to the acre will work wonders. The rows should be 3½ feet apart, running north and south, the hills 2½ feet in the row. Special pains must be taken in planting; 5 or 6 kernels to the hill should be allowed, which should be covered an inch and a half deep, the hill being left no higher than a level with the surrounding surface. If possible, each hill should have a small handful of ashes or plaster before the plants appear above the ground. The after-culture should be thorough, stirring the soil with the plough and hoe as often as possible, the more the better, not hilling the plants until the appearing of the tassle. No weeds or grass should be allowed to start, which they cannot do, if the ground is worked half as often as it should be. When about one-half of the corn on the ear is ripe and hard, and the other half well glazed, the corn should be cut from the ground, and stood up, in as small bundles as may be and have them stand up good. As soon as the stalks are thoroughly dried, the corn should be husked off, and the stalks put in a barn. They make good fodder.

By the opperation above described, if thoroughly performed, from 25 to 50 bushels of corn, and an amount of fodder equal in substance to at least a ton of good hay, may be obtained from an acre, while the land will be improved in quality, and in a condition easily prepared for another crop, which may be winter wheat or rye, if the ground does not heave too much by frosts; if sown with either of these, it should be done as soon as the corn can be taken from the ground. Wheat or rye should be sown at the rate of 1½ bushel per acre after the ground has been made mellow by ploughing, or smooth by harrowing. If the land is intended for meadow, it should have 6 or 8 quarts of timothy seed per acre, sown when the grain is with from 4 to 6 quarts of clover seed sown early in the spring. If spring grain is preferred to winter grain, wheat, barley, or oats are good crops, and good to seed, or stock down with; if these are sown, the ground should be ploughed as early in spring as possible, the land being free from frost, and not too wet; it should be cross-ploughed and harrowed smooth before sown, and well harrowed afterwards. Wheat should be sown 1½, and barley and oats 3 bushels to the acre; timothy and clover with 6 quarts of the former, and 4 of the latter; the acre should be sown on previous to the last harrowing.

Grain of all kinds, it is allowed, should be cut before it is what is called fully ripe, as the grain will make more and better flour, and the stalk will be more palatable and nourishing for animal food, which is very important in this latitude. The sooner any green fodder, calculated for animal food, is thoroughly hayed or dried, and put in the barn, the better, as it is very injurious to have it bleached by sun and rain, or dew. Immediately after the crop is taken off, it is a very common practice to allow the young grass and clover to be eaten off, or trodden down by stock, which should in no instance be allowed. If the land is intended for meadow, the less it is fed off the better; no hoof should be allowed to range over it until it has lain in grass one summer, when it will do to feed it off some. If it is wanted for pasturage, it should lie without being fed until the next June, when the grass will have acquired a good hold of the soil; and then it must not be eaten off close, leaving the ground naked.

If, by this manner, one field is improved, it may remain from 2 to 8 years, (but never until the grass runs out,) while another, or several fields in succession, may undergo the like, or a similar process, varying the manure, the manner of culture, the seed, &c., as circumstances seem to require or judgment dictate.

With regard to different breeds of cattle, I would remark, that a species of stock, suitable for a warm climate, a level (or not mountainous) country, and very rich grazing lands, might be poorly calculated for this region. For this rough, uneven part of the country, perhaps Devon cattle are the most suitable, as they combine the most of the qualities required in a species of stock. Considering the market value of land, the price of labor, the distance from market, together with the great length of winter, and shortness of summer, it is no easy matter to sell a hundred dollars' worth from a farm. Yet, with all these hindrances, a farmer, by thorough and judicious management, may realize a handsome profit from his expenditures.

As a general thing, taking one year with another, a calf can be raised or afforded at 6 months old for $3; a yearling, in the fall, at $7; a two-year old, in the fall, at $15; a good cow, in the fall of the year, for $18—in the spring, for from $25 to $30; 100 pounds of butter for $14; 100 pounds of pork for $5, made mostly from the proceeds of the dairy.

There are very few farmers who can afford to raise grain to sell; if they do, they must be governed by New York market prices.

Wool-growing, together with the rearing of lambs for market, will, perhaps, (counting all expenditures,) return the greatest profit. I have a flock of Merino sheep which average over 5 pounds of well-washed wool per head per annum, which wool costs me, one year with another, from 25 to 30 cts. per pound. Mine is as fine as any Merino wool that I am acquainted with. One more item, and I am done. There is but little irrigation practised in this country, and that little is generally in an imperfect manner; hence, I would urge those having experience in this branch of business to write upon the subject, publishing an account of their way and its effects.

With these remarks, I am yours,

N. M. DART.

New Harmony, Indiana, July 15th, 1850.

Dear Sir:—The object of the present communication is to relate the strange phenomenon which has occurred along our river—the cane Arundinaria Gigantea (*Michaux*) going to seed this year.

Michaux, in his description, states that it goes to seed once in from 20 to 25 years. I have been a resident of the Wabash upwards of 30 years, and it never having occurred before, has caused me to make some inquiries of those whose residence was many years in advance of me, and they state that it never has happened on this river before.

If my memory is correct, in the year 1830 or '31, in descending the Mississippi, I noticed a similar circumstance. The planters collected and used the seed for feeding to their stock. It must possess much nourishment, as I was informed that the stock on the Mississippi were that year remarkably fat. My son Charles informs me that the squirrels he killed a few days ago, in the cane, were literally covered with fat. Trusting that the seed herewith enclosed may add to the collection of the Patent Office, I subscribe myself

Yours very respectfully,

WM. AUG. TWIGG, P. M.

Hon. Commissioner of Patents, Washington.

Ashland, Ashland County, Ohio, January, 1850.

Sir:—The varieties of wheat in this portion of country are Asbridge, white blue-stem, Mediterranean, stubble, mountain sprout, valley, white flint, red-chaff bearded, three varieties of club wheat, and many others. Our soil and climate being congenial to the production of this important staple, our farmers have spared no pains in introducing the best varieties. The two first named have precedence over all others with which I am acquainted, either from experience or from inquiry. They exhibit a plump white berry, with thin bran and bald head, which last renders them far more pleasant to handle than bearded wheat. Under favorable culture and suffering no calamity, they will yield 30 bushels per acre. The Mediterranean is extensively sown on account of its enduring the winter better and being fly-proof, and thus escaping two great injuries. The objections to it by some are its reddish brown color, its light yield, and its liability to fall from slight winds. All the other kinds possess each some peculiarities which render them estimable or objectionable with the farmer. The club wheat has two high recommendations: 1st. That of enduring a storm that would prostrate all other varieties; 2d. It grows erect, and yields well on rich bottom lands. The Asbridge, white blue-stem, and white flint are the most highly esteemed. The Asbridge possesses the greatest number of important peculiarities. The average product per acre is 15 bushels. Time of seeding from the middle of September to the 1st of October; but more good crops are obtained by sowing as near the 20th of September as possible. If we sow before that time, we give license to the fly, because there is usually much warm weather about that time, and, if we sow much later, it is frequently winter-killed. The time of harvesting is from the 4th to the 10th of July. The quantity sown per acre is from 1¼ to 1½ bushel, without any preparation, with the exception, in a few instances, of having it clean. A vast quantity of wheat is sown upon inverted oat-stubble previously manured. The depth to which we usually plough is 9 inches. We plough fallows about the 1st of June, about 6 inches deep—manure just before sowing, then plough 10 inches deep. The yield has been increasing for the last 5 years, because there has been an improvement in the system of culture; the cause of which, in a great measure, must be credited to the influence of a good agricultural paper (The Ohio Cultivator) which circulates among us. If it would not be foreign to the object of this Report, I would here speak in high terms of that excellent paper.

The system of rotation upon uplands is first oats or corn, then wheat, then seed to clover or timothy. Those who cultivate only 50 or 60 acres, usually raise two crops of wheat upon the same field successively before seeding down. This will answer well, provided the soil is sufficiently fertile. The bottom lands are sometimes cultivated in corn for several years in succession, without any apparent exhaustion of the soil, provided the corn is husked upon the standing stalks, and fed in that way.

The best remedy for the Hessian-fly is to sow as near the 20th September as possible, for its depredations cease about the 23d, and the wheat becomes sufficiently rooted to withstand the winter. From special observation upon this matter, I can safely say that, by observing the above remedy, the wheat crop in the aggregate would be increased one-fifth. The weevil was destructive to the wheat crop of 1848, just before harvest, and for which I know of no remedy. The average price at our nearest market is 70 cents per bushel.

Corn.—The varieties are numerous. The most esteemed of which are the large yellow, white flint, and small yellow. The large yellow grows very tall, has long ears, ripens tolerably early, and is much esteemed by many. The white flint, so called because its grain is very hard, has a short thick ear, is hard to husk and hard to shell. It moulds in the husk easily in a wet time. It weighs 60 lbs. to the bushel, and makes excellent white meal. The small yellow possesses the greatest number of advantages: 1st. Its early maturity; 2d. Its small growth, which renders it susceptible of close planting; 3d. It is therefore more easily cultivated, easy to husk, not liable to damage by wet at husking-time, and yields more corn with less labor than any other with which I am acquainted. The average product of this variety upon good bottom land and with good culture is 100 bushels of shelled corn per acre. The average yield of corn in general is 50 bushels per acre. Cost of production is 8 cents per bushel. The best system of culture is to check, and plant corn of short growth 2 feet 10 inches apart, and pass once each way between the rows, at each time of hoeing, with a shovel-plough, and that will throw fresh ground against both rows. This method saves two-thirds of the expense of ploughing, and produces nearly double the quantity generally raised. Corn of tall growth must of necessity be planted about 4 feet apart, and it requires ploughing 3 or 4 times between the rows. Corn is in the best condition for feeding when ground. The difference in favor of cooking is not sufficient to warrant the expense. Corn meal, fed in the form of thick swill, is the most advantageous. The manure of 20 bushels of corn consumed by hogs, if carefully saved and well applied, will add about 2 bushels per acre.*

Oats.—The average yield is 30 bushels per acre. The quantity of seed sown per acre is two bushels. This crop is very exhausting to the soil.

Rye.—The average yield per acre is 20 bushels.

Peas are not cultivated to any extent as a field crop, either for profit or for renovating the land.

Clover and Grasses.—The quantity of hay cut per acre is one ton of clover and one and a half of timothy. The best fertilizers for meadows, so far as my experience goes, is to scatter the droppings of cattle and horses, which is done most easily by knocking them about with a 4-foot stick, shaped like a sled-runner, in the spring of the year, just before the vegetation starts. This kind of manure pulverizes very fine, if scattered in that way. I know by experience that if the soil is pretty well represented with droppings, and thus treated, the yield will be at least one-third more than if they were not scattered. Timothy is preferred for seeding down meadows. The quantity of seed sown is 4 quarts per acre. The cost of raising hay per ton is $1.50.

Dairy Husbandry.—The average yield of butter per week, for each cow, is 4 lbs., and of cheese 8 lbs. One of the best methods for treating milk for butter is to skim before the milk is sour, and churn immediately. This mode brings good butter in a short time, if the cream is at the right temperature, say 55 degrees. The modes of churning are various, but we generally use the barrel churn and dasher churn. A good improved churn, upon the atmospheric principle, would meet with general approbation here. The mode of putting down butter for exportation is to pack it in kegs containing about 180 lbs. The average price of butter is 9 cents, and that of cheese 5½ cents per lb.

Neat Cattle.—The cost of raising till 3 years old is about $15, which is about what they sell for at that age. So there is comparatively little attention paid to this department. They are only raised as a means of converting our pastures into cash, with little or no profit. The value of good dairy-cows in the spring is about $14, and in the fall about $12, at which time they usually go dry. They are generally wintered on good straw,

* Our correspondent is mistaken if he supposes that land in his county is generally so fertile that the manure made from 20 bushels of corn, all saved and properly applied, would add only 2 bushels per acre to the crop. Let the experiment be fairly made on a soil of medium quality, and we venture to predict that the gain will be at least 10 bushels.—Ed.

which is better than hay for them. The number of pounds of beef that 100 lbs. of corn will produce is about 20.

I can say nothing definite respecting the relative fattening qualities of the Durhams, Devons, or Herefords. The two latter are not raised as distinct breeds to any extent in this part of the State. The Durhams are mostly noted for their neat appearance, exhibiting a prominent disposition to fatten easily. The native breeds are distinguished for their good milking qualities. This county possesses some of the very best milkers.

Sheep and Wool.—Wool-growing is profitable. The cost of growing coarse wool here is 15 cents per lb., and for fine wool 12 cents. A ton of good hay, judiciously fed, will produce 35 lbs. of wool. Small or ordinary sized sheep, of fine wool, lengthy staple, are now generally acknowledged to be the most profitable, such as a cross of the French and Spanish Merino. I rejoice that this great and long-sought object has finally been attained—lengthy staple with fine wool. There are a great many native sheep in this county, which are improved in fineness by a cross with Merinos. They are hardy, grow large, and sell readily to the butcher. The proportion of lambs annually raised to the number of ewes, under good management, will be 5 lambs to 4 ewes, among the natives.

Hogs.—The best breeds, from what I have learned from experience and inquiry, are a cross of the Berkshire and China breeds, or of the Berkshire and grass breed. I would prefer the first named, as a hog the most docile and profitable. Of this kind I killed 4 pigs, at five months old, which dressed 89 lbs. each, without any other effort at feeding. They are very highly esteemed, because they fatten so easily, and at any age, with but little expense. If they are pigged in March, they may be butchered in November, and will weigh 200 lbs. If 100 lbs. of corn be fed to a pig of good quality, it will make 25 lbs. of pork. My method of putting up and curing pork for home consumption is, first to salt slightly in open casks, and let it stand one week, then pour off the brine, for it is generally bloody, and would taint the meat; then pour on strong fresh brine, and put on weight enough to keep every particle of meat perfectly submerged. Let it stand 4 or 6 weeks, according to the size of the pork, then hang it up and smoke with green hickory or sugar wood, until it shows a rich yellow color, then pack down in clean oats.

Hemp.—This article receives so little attention in this county, that I know nothing definite concerning it.

Potatoes.—The usual average yield is 40 bushels per acre. The cost of production is 10 cents per bushel. The most prolific varieties are the long red cudgels, pink-eyes, and peach-blow. The varieties for table use are the pink-eyes, and old, pure, blue Neshannocks. The best mode of culture is to plant on a loose, gravelly loam, ploughed 8 inches deep, and check for hills, 2 feet 10 inches apart, and 3 inches deep. This would leave a loose subsoil of 5 inches, which is highly necessary, that all superabundant water can readily filtrate. Lime alone is the best manure for potatoes. Lime and ashes have been used to prevent the rot, but without any effect.

Root Crops.—There is but little attention paid to these crops, except the turnip, which is mostly raised for table use. I do not believe this department will receive much attention, for it exhausts the soil incomparably faster than any other product. For example, I can raise but two root crops on rich bottom land, the first a good one, and the next a meagre one, which after that would yield a meagre crop of corn: whereas the same soil would

have produced 60 bushels of corn per acre, for 10 years in succession, without manure, which, of course, would be more profitable.

Fruit Culture.—Some farmers are paying quite a spirited attention to fruit, by way of grafting their seedlings. There can be enough raised on an acre to make it profitable. Mealy apples, having but little acidity, will compare well with potatoes for fattening pork. There is not enough attention paid to the culture of winter apples even for home consumption. Some of the best here are the Red Seek-no-further, Yellow Pippin, Vandevere, and Rambeau. The two last are extensively cultivated; the Rambeau for cider, and the latter for winter sauce and pies. No doubt a great variety of good winter fruit will be developed upon the great number of grafts which have been recently set upon the old seedlings.

Grapes.—I think the culture of the Isabella and Catawba could be made profitable here, for they both thrive and yield well.

Manure.—The plan regarded as the best for making and preserving manure from waste, is to keep all the stock enclosed in the barn-yard as much as possible, and all the feeding should be done in the yard. If there is a quantity of straw remaining in the spring, designed for manure in the fall, on wheat land, let it be thrown into the yard, and a half-bushel of lime to the ton of straw be scattered upon it. This, with the moisture of the yard, will decompose it in a short time. Neither lime nor plaster are used to any great extent. Lime is obtained at too great a distance from this for us to make a very extensive use of it, and plaster is only used occasionally on corn, but with signal benefit. Barnyard manure seems to answer all purposes for field crops. Lime is sometimes applied to potatoes, with good results. Guano has not yet been introduced here. This species of manure should be submitted to a chemical analysis to ascertain its properties, for it must possess the best combination of elements of any manure that has yet been tested. The time has come when the farmers of this portion of the State are beginning to feel the dignity of their station, and the independence of their position. Many an inconsiderate, repining farmer, with small income, if thrown upon other resources for a livelihood, it would cause him to reflect with pain upon his once exalted position.

HENRY MILLER, Jun.

At home, near Milledgeville, Georgia, December 1st, 1850.

Sir:—In reply to your circular of inquiries, I send you the following, which you may dispose of as you think best.

Wheat.—The varieties raised in this section are the big and little white, the red, and two or three kinds of bearded wheat. The little white has formerly had the preference over all others, until a few years since, when the fly began to be so troublesome, that farmers were compelled to seek for that variety which ripened earliest. The bearded wheat has been raised very extensively for the last year or two, on account of its early maturity, while the yield is thought to be greater than that of the little white. The big white is an excellent kind, but so uncertain that very few raise it. The average yield of wheat per acre is from 3 to 5 bushels; the time of seeding is from the middle of October to the last of November. Time of harvesting, the last of May or first of June. It is usually sown without any preparation, except sifting through a cockle sieve, to take out the cockle and the imperfect grains of wheat. If the wheat is inclined to blast, it is soaked 12 hours in a solution of blue-stone, which is a certain preventive against that disease. Wheat is generally sown on corn land, and put in very roughly, the land being ploughed but once, though I am satisfied it would pay well to break up the land good before sowing, and to harrow the seed well in. I am inclined to think the yield per acre of this crop is increasing, from the fact that farmers pay more attention to it than formerly. We have no remedy for the fly but late sowing. The best remedy for the weevil is to get out the wheat as early as possible, and spread it out in the sun, say 5 or 10 bushels at a time, and let it remain till it gets very hot, then take it up and put it immediately into boxes or barrels, and cover tight until it cools. In a short time after it is put up, it will be hot enough to kill every weevil or worm in it, though it will not injure the grain. I believe, if wheat thus served was put into clean, tight casks, it would keep several years. The average price of wheat this year has been $1.25 per bushel, and that of flour, from $8 to $9 per barrel.

Corn.—We have but two distinct varieties of corn, the white and the yellow, though there are different kinds of white, possessing different qualities. The yellow corn is thought to grow better on thin land than the white, and is generally believed to contain more nutriment. The average yield per acre is 5 bushels on poor land, and 15 to 20 on good land. The land should be well cleared and broke up before the corn is planted; then lay off the rows with a bull-tongue plough; drop the corn, and cover with the same kind of plough, making a ridge on the corn; and, before it comes up, scrape off the top of the ridge with a board attached to the foot of the plough-stock. If the season is favorable, the corn will be out of the ground in a few days, and in a week or ten days it will be high enough to admit the plough, when it is hoed out and replanted. In about three weeks, it is ploughed out with a shovel or turning-plough, the hoes following; and, three weeks after this, it is ploughed out with a sweep, and laid by with the hoes. The price of corn is $1 per bushel, and that of fodder $1 per 100 pounds.

Oats.—This crop was better than an average the past year, which may generally be put down at 15 to 20 bushels per acre, though 60 or 70 bushels are sometimes obtained. The quantity of seed varies from 3 pecks to a bushel per acre: price, 75 cents per bushel when cleaned, or the same price per hundred in the sheaf. Oats are generally considered to be an exhausting crop. Time of seeding, from the first of January to the last of February.

Barley is but little cultivated here, except in small lots, for feeding to stock while green, for which it excels every other grain. I believe that one acre of good land, sown in barley, would be worth $50 to any farmer; but it is useless to sow it on any other than rich land. The average yield of grain per acre is about 20 bushels. The quantity of seed per acre varies from 3 pecks to 3 bushels. Price, $1 per bushel.

Rye receives but little attention, as it yields but a small quantity of grain, though it will produce more straw, and exhaust land less, than any other grain we have. The quantity of seed used is 1 peck to the acre; the price per bushel is $1.

Peas are raised mostly between the corn, few fields being planted with them entire, though they improve the land very rapidly, when thus planted in the spring, and followed with rye in the fall.

Clover and Grasses.—Little or no attention paid to them.

Dairy Husbandry.—But little attention is paid to making butter and cheese for market. Every farmer tries to have as much milk and butter as he needs for his family; and as for cheese, there is none made in the county, to my knowledge.

Neat Cattle.—We have very few cattle, of any improved breed, among us. The usual price of beef is from 3 to 4 cents per pound. The price of milch-cows is about $10.

Sheep and Wool.—Wool-growing is a profitable business, but, owing to the depredations of dogs, no one seems willing to go into it on a large scale. Most farmers raise wool enough for their own use. The average yield of wool per head is 4 lbs., though perhaps large sheep might yield a little more, but of coarser quality. Wool is worth 25 cents per lb. in the fleece, or 50 cents when carded into rolls.

Cotton.—This crop has been rather below an average the past year. The storm in August injured it very much. The average yield of cotton in the seed is about 500 lbs. per acre. The crops which grow best with cotton are corn and wheat, or other small grain. The best preventive against rust and worms is lime, sowed in the drill at the time of planting, at the rate of one barrel to the acre. Cotton has commanded a higher price this winter than it has for several years, which has enabled a great many of our farmers to pay their debts, and get in a way to live; but others have gone in debt, and, should the price of cotton fall, they will be seriously injured.

Rice.—None raised, except in small patches, for home consumption, though it might be raised with profit, if the necessary attention was paid to it.

Root Crops.—The turnip crop was not so good the past year as formerly. Many farmers did not sow at all, but those who did, and succeeded in getting a stand, made good crops. The seed is usually sown broadcast, and raked or harrowed in, and the weeds and grass are pulled out by hand. Some, however, prefer to sow in ridges, about 18 inches apart, and work them. They can be chopped out to a stand, like cotton, which plan I prefer.

Potatoes have turned out rather sorry, owing to the dry weather in August and September, the principal months in which they grow.

Every farmer should, by all means, have his patch of fall cabbages. None but those who have tasted them can imagine how delicious they are. They are altogether different from those raised in spring. They are more tender to cook, and stand the freezes of winter when spring cabbages are all killed. They are much more easily raised, and should be sown the first of July; then the weeds will not grow much before the frost comes, but the cabbages will continue to grow every warm spell until Christmas.

Very respectfully yours,

WILLIAM C. DICKSON.

Springfield, Ohio, December 28th, 1850.

Sir:—The information called for by your circular of the 26th of August last is herewith submitted. I hope it will reach you in time for the purpose for which it is designed. Owing to a daily press of my official duties, I must necessarily be very succinct in my answers to the inquiries proposed. I have been compelled to rely mainly upon the practical experience of other gentlemen, who are more familiar with the walks of agriculture than myself.

The little I may say, however, I hope will contribute something to the great interests which you are now engaged in promoting.

Kinds of Wheat.—White and red chaff, bearded white, bald, Wabash, red-chaff, white Mediterranean, blue-stem, and several other varieties now on trial. Average yield per acre, 22 bushels; sown during the first weeks of September; harvested about the first in July. Fallow should be twice ploughed; ploughing should be from 5 to 8 inches deep. Yield increasing, as well as the mode of culture improving. Rotation in crops. Best remedy for the fly, good manure. Pasture fallow close, and sow after a sharp frost. Very little danger from weevil. Average price per bushel, 75 cents. Quantity raised in the county the past season, 600,000 bushels.

Corn.—Varieties obtained by mixing the large Southern corn with that of the North; and from the seed thus selected the yield is 85 bushels per acre. Cost of production, 15 cents per bushel. Best mode of culture: winter-ploughing, good manure, often stirring the soil, after planting, with cultivator and plough. It is fed both ground and whole. Too little attention is paid to manuring. Quantity raised in this county the past year, 700,000 to 800,000 bushels.

Oats, Barley, and *Rye* are largely cultivated. Yield per acre—oats, 80 bushels; barley, 30 bushels; rye, 25 bushels. Peas and beans are raised only for domestic use. Oats and spring barley are hard upon the soil; rye and fall barley least exhausting.

Clover and Grasses.—Season dry; average yield, 1 ton per acre. Best fertilizers, a light coat of stable manure, with a little lime or plaster. The mowing-land should not be pastured too short. Kinds used—clover and timothy on all lands dry enough to plough, and herdsgrass on wetter lands. Quantity of seed sown, 1 bushel to 8 or 10 acres.

Dairies.—Not carried on largely, as a business. Average quantity of butter per week, for each cow, is 4 pounds: cost, 10 cents per pound. Milk is generally placed in cellars, or spring-houses, and skimmed while sweet—churned once or twice a week, in the dash or barrel churn. The butter should be set where it is not too dry to mould, nor too damp for the salt to evaporate and settle upon the surface. Average price of butter, 12 to 15 cents per lb., and that of cheese, 5 to 7 cents per lb.

Neat Cattle.—Cost of rearing till 3 years old, $10 to $15 per head. Average price, $12 to $35. Price of good dairy-cows, in the fall, $10 to $15, and in spring, $15 to $20. Price of cows for the blood or stock, $80 to $300. Twenty-five bushels of corn will produce 150 lbs. of beef. The largest quantity of beef will be produced from the least amount of food when fed to pure short-horned Durhams.

Wool-growing.—Profitable. Cost of growing per lb., 18 cents for coarse, and 28 cents for fine wool. One ton of hay for half the year, and the cost for pasturing the other half is equal to another ton, which will produce 20 lbs. of wool. With care, large sheep are best for mutton, and small sheep are more profitable for wool. Two-thirds of the ewes raise lambs, if well cared for.

Hogs.—The Irish grazier, Russia and English white crossed, China and small Berkshire, best for quick maturity. The cheapest method for producing pork is by feeding the hogs with ground grains in slop. With clover pasturage in summer, and apples in the fall, 10 bushels of corn will produce 100 to 130 lbs. of pork. Sugar-curing, with a little saltpetre; and when cured and smoked, take ground pepper and mix with good molasses, and rub in well upon the soft or fleshy parts; then enclose in a canvas bag, and hang in a dry place.

Cotton, Sugar-cane, Rice, Hemp, Tobacco, and Roots.—Some of these are not raised at all—others very little. Turnips, carrots, and the French sugar-beet: a few experiments have been made with good success. Only for the scarcity of labor, and its high rate, experiments would oftener have been made. Potatoes grow well. They were cut short the past season by severe drought. Not more than 50 or 60 bushels to the acre were raised of either variety.

Fruit culture is attracting considerable attention, and is very much on the increase. The varieties are numerous, and of superior quality. Apples are better for hogs than for cattle. They contain too much acid for the latter. Potatoes, when boiled, and mixed with other food, are better for hogs than apples.

I am, very respectfully, your obedient servant,

J. HENDERSHOTT, P. M.

Urbana, Champaigne County, Ohio,
Black Creek Farm, December 26th, 1850.

Sir:—I will undertake to reply to a few of the questions contained in your Agricultural Circular, which I received some time since.

Wheat.—The most approved varieties of wheat are the Etrurian, reed-straw, and Kentucky smooth wheat, and the Mediterranean and old red-chaff, both bearded. There are also various other varieties grown. The average product of last harvest, I think, is about 20 bushels per acre. We prefer to plough but once for wheat, and then from 7 to 9 inches deep. We sow about the middle of September. I think the yield per acre is increasing. The last year's crop, I suppose, will average about 65 cents per bushel.

Corn.—The kind most extensively grown in this county is a large, yellow corn. The average product upon good land, well cultivated, I think, is about 50 bushels per acre.

Good meadows will yield about 2 tons of hay per acre. Timothy is the kind preferred.

Neat Cattle.—The cost of rearing till 3 years old, I think, is not less than $20 per head, and they are worth, at that age, about $25 each, if they are of good quality. The Durham cattle are preferred in this section of country.

Hogs.—The best breeds with which I am acquainted are the Byfield, Berkshire, Irish grazier, and the Calcutta; and I have learned, from actual experiment, that either of these breeds may be improved by crossing with another. I believe the cheapest method of raising pork is upon clover and corn; and I think that 100 lbs. of corn, fed to a thrifty hog, will make 25 lbs. of pork.

Among all the recent improvements in farming implements, I believe that the reaping and mowing machines will save the most labor. I have used, for the last 2 years, a mowing machine of Huzzy's patent, with some improvement by the manufacturers, (Messrs. Minturn and Allen,) with success and entire satisfaction.

Very respectfully yours,

SMITH MINTURN.

Greenwich, Cumberland County, New Jersey, 1850.

Sir:—In compliance with a request contained in your Agricultural Circular, I forward you some practical hints on the different crops which I cultivate.

Wheat.—Varieties sown, Mediterranean, and white, or blue-stem. My average crop is from 20 to 30 bushels per acre. I sow from the 10th of September to the middle of October. Quantity of seed per acre, 2 bushels. I plough 5 inches deep. The best preparation for a crop is a clover lea; second crop ploughed in by the middle of August, and the wheat should be well harrowed in, together with 200 pounds guano per acre, at the time of sowing the wheat. The best remedy for the fly is to pasture pretty close, early in the spring, with sheep. Average price, $1.10 per bushel.

Clover and Grasses.—Quantity per acre, 1½ tons. The best fertilizer is guano. Cost of growing, $5 per acre. Price in market is $10 per ton.

Hogs.—The best breed is the Berkshire. The best mode of raising is on clover pasture in summer, and corn-feeding in the fall. Ten bushels of corn, or 560 pounds, will make 100 pounds of pork.

Potatoes.—The best variety of Irish potatoes, for market, is the Mercer. Average yield, 150 bushels per acre. I plant in drills about 10 inches apart, with 2½ feet between the rows. I cut my seed, and plant in May. The best manure is barnyard manure, with 100 bushels oyster-shell lime per acre. Average price in our market, is 50 cents per bushel.

Manures.—That best adapted to our soil is vegetable manure and lime, which we consider the cheapest fertilizers we use. I have used guano very successfully, particularly on the wheat crop. The quantity I use is 200 pounds per acre, which will produce a good crop of wheat and grass before it is exhausted.

Yours, truly,

SAMUEL C. FITHIAN.

Fort Jessup, Louisiana, December 11th, 1850.

Sir:—I have recently had the honor and pleasure to receive your Agricultural Circular, and would now attempt a reply.

Corn.—The Spanish, or St. Antoine corn, I esteem far superior, in this climate, to any other. I have tried several different kinds, and, after eight years' experience with the St. Antoine, consider it the best. It grows much larger than any other variety, and is about two weeks longer in maturing than the gourd-seed varieties. It stands the severe droughts to which we are subject in this country much the best, and produces, on the same kind of soil, and with the same labor, from 25 per cent. to 33 per cent. more. The height to which it attains is from 16 to 18 feet. I send you a sample of it. It is what may be called a native of this country.

Cotton.—There has been so much said by men of high attainments and great experience upon this subject, that I fear to advance an opinion. I would say, however, with regard to bedding the land, which should be done the last of February, or first of March, I use a large shovel plough for opening the first furrow in the middle, then, with an old-fashioned coulter, run 2 or 3 furrows 8 or 10 inches deep in that before made, and fill up with

stalks of every kind which may be upon the ground; then, with turning-plough, finish the bed. Under this mode of treatment, the tap-root descends below the reach of drought, and the leaves will be green and the cotton growing when that on a hard foundation will turn yellow and drop its leaves. The quantity per acre we seldom estimate. I have raised the Sea Island cotton on our highest lands, where it produces nearly as well as the Petty Gulf, and of fine quality. I send you a sample both of the black and green seed. We have the prolific cluster variety, which is far superior to any other as to quantity per acre, and also for its picking qualities.

Sugar Cane.—We raise it here both on high and bottom land (provided it is rich) for our domestic use, but find it exhausts the soil more than any other crop. Our cultivation of it is limited.

Tobacco grows well here on any dry land. I have seen it growing and in blossom at Christmas. It is not raised here as a crop, though it might be to good advantage, if we were acquainted with the treatment of it.

Root Crops.—All kinds do well here.

Peas.—The cow pea is used for renovating the land, by turning under while green, and is considered the best variety. All kinds do well.

Cotton-seed, rotted, is the best manure we can use for our crops.

Meteorology.—I herewith send a sketch of a table from 1st June to the 10th of December.

Sheep and Wool.—The different breeds here are Merino, Saxon, and native. They are raised here without feed, either in winter or summer, except what they get in the pine woods. Their wool is very fine.

Respectfully,

G. W. THOMPSON.

Please accept this table as above, and find in this box a sample of the Spanish or St. Antoine corn. Also, of the black and green seed varieties of the Sea Island cotton. Also, a sample of the bolls of the prolific cluster cotton.

Respectfully,

G. W. THOMPSON.

Dunlapsville, South Carolina, November 10th, 1850.

Sir:—In reply to your circular of the 26th of August, I will proceed to answer such points as come within my particular knowledge, in the order in which they are stated.

Wheat.—We have tried a great many varieties, but the kinds most generally in use are the big white, late, and the red spring wheat, early. The time of sowing big white, first of November; red spring wheat, all November. We sow late to avoid the Hessian-fly. But for the fly, either would do better sown early, say in September, for the late, and October for the early variety. Our late wheat is often damaged by the rust, for which we know no remedy, except early sowing. Preparation:—We soak in bluestone, 1 pound dissolved in water, for 5 or 6 bushels of wheat, to prevent smut, which it does effectually. Sow from 3 pecks to a bushel to the acre, after corn or cotton. We generally plough but once, about 3 inches deep; two ploughings are said to do better. Yield per acre, about 8 bushels; when manured with compost or cotton-seed, it is increased to 15 or 20 bushels. A day's sunning in hot weather is our remedy for the weevil. Average price about \$1 per bushel. Owing to the cheapness of land here, the small quantity of seed sown, and the little cost of labor in our mode of putting in, we can grow wheat as cheaply, perhaps, as in any part of the United States. But cotton engrosses our attention, and but little more than will supply our inland towns is sold. Our time of harvest is from the 1st to 15th of June.

Corn.—The most esteemed varieties are the gourd-seed, or between that and flint; the Oregon succeeds well. We have all the shades of white, yellow, red, speckled, &c. The small Northern varieties do not answer so well here; they come in two or three weeks earlier than the Southern corn. Average product per acre, on upland, is 15 or 20 bushels, and on bottoms or lowlands it is 40 or 50 bushels.

By high manuring and good culture, these products can be greatly exceeded. Cost of production per bushel varies under different circumstances, say 33 cents. The best system of culture:—Planters have different methods: I prefer the following. Plant on wheat or oat stubble; break up deep and thoroughly, early in the winter, the earlier the better. About the middle of March lay off furrows with a shovel plough, about 5 feet apart, taking care to run them as nearly straight as may be, throughout the whole field. In these furrows drop 2 or 3 grains every 3 feet, to be thinned to one stalk, when secure from birds, &c. If manure or cotton seed is to go in, drop it on one or both sides, close to these grains; cover lightly with one shovel or two small scooter furrows, or with a harrow. When it is fairly up, run round with a scooter or small cultivator, and follow with the hoe a few days after, taking care to kill all the weeds and grass on the ridge, and earth the corn lightly. This operation should be finished by the first of May, when the cotton will call for our attention. Some 15 days afterwards give the corn a deep, close ploughing, and at intervals of about 20 days two more ploughings, both of which should be more shallow, especially the last. It is now supposed to be "laid by," unless the ridges are foul, in which case they must be cleaned with the hoe. This is our principal cereal crop, forming two-thirds or three-fourths of the bread eaten by our people, and the principal food of our horses, mules, and hogs. Enough is generally

raised for the home supply, and little or none is sent to a distant market. For feeding to our stock, it is rarely ground or cooked, except in years of scarcity. The common opinion is, that it will go farther when ground or cooked.

Oats are more extensively cultivated than any other small grain. Average yield per acre, 10 to 20 bushels.

Barley and *Rye* are but little sown, except for grazing-lots and pasture.

Beans are only raised for the table.

Peas are cultivated for the double purpose of pasturing our stock in the fall and early part of winter, and for renovating our lands. For this last purpose they are estimated by many very highly; so much so, that they have been called the clover of the South. Whether they are more valuable than the same amount of other vegetable matter, I have never been able to determine: true, the authority in favor of the opinion is very respectable. They are generally drilled in between the corn rows at the second or last ploughing.

Clover and *grasses* receive too little attention. Our summers, I think, are too dry and hot for them. With high manuring and seasonable rains, I have seen fine lots of clover. We depend upon the native grasses.

Neat cattle are raised for the home supply of beef, milk, and butter; but little is sent to a distant market. The smaller breeds are thought to suit our short pastures best.

Sheep and Wool.—Almost every farmer has a small flock of sheep, to supply wool for winter clothing. For any other purpose they are not raised, but the opinion begins to prevail that wool-growing might be as profitably conducted here as anywhere else.

Hogs.—The best breed is a mixture of the Berkshire and our native stock. The best method of raising:—Feed with corn except when they have the run of the harvest and pea-fields. One hundred pounds of corn will yield about 25 pounds of meat; if cooked, perhaps more.

Cotton.—This is the great crop of the region. Upon it the planter mainly depends for his moneyed profits. It gives character to, or marks with its impress, every system of culture adopted here. No other crop can be permanently introduced, that intrudes upon or displaces this. It throws every other into the background. No other attains to that perfection among us which it otherwise might do. As now generally managed, it is unfavorable to any system for improving our lands. Indeed, many of our farmers aim at nothing else than to crop with cotton until they run down their land, and then throw it out. Such a practice is becoming less and less common, and must soon cease from necessity. There is no doubt that a rotation might be adopted which would preserve and even improve our lands. There is no more cleansing crop than cotton, nor none after which other crops succeed so well; none, therefore, can better be made the basis of a good rotation. I have adopted the following, with great benefit to the soil, viz. 1st, cotton, manured with compost in the drills; 2d, cotton; 3d, oats or wheat; then cotton, manured as before, &c.; resting once in 8 or 10 years. But no doubt a better system, when the fields lie sufficiently near the stables and cattle-yard, is that of Dr. Cloud, of Alabama. His course is, 1st, cotton; 2d, corn; 3d, small grain, and so on continuously. He manures every cotton crop with compost, both broadcast and in the hill. The product, he reports, almost exceeds belief. (For a full account, see the back volumes of the Albany Cultivator; also, I believe, the Southern Cultivator.) It is evident, then, that an improving rotation can be adopted, but further experiments must decide what it shall be. Perhaps no one course will suit every locality and every condition. Average yield of clear cotton per acre, 290 pounds, and of ginned cotton-extremes, 100 to 600 pounds. (I should have said before, that my remarks are intended to apply only to the granitic region of South Carolina.) Cost of production, per pound, 6 to 8 cents: it varies greatly. Best preventives against rust, army and boll worms:—Except in newly cleared lands, the rust does not often appear, and the army and boll worms rarely visit us. The cotton-louse is more troublesome than either. I know of no certain remedy. The best, I presume, is not to repeat cotton too often, successively, on the same land; thus starving out these insects for want of proper food. Owing to our comparative exemption from these plagues, notwithstanding our soils and climate do not suit cotton as well as in the South-west, our crops are more uniform and certain. Cold springs, too much wet, and drought are the evils we most dread.

"Your experience with cotton-seed as a fertilizer."—It is excellent for every crop to which I have seen it applied, as we would infer from their analysis. They are as valuable in the garden as in the field. I know of no exception. The greater part of mine are scattered over the wheat and oat crop, at the rate of 20 or 30 bushels to the acre, but sometimes they are applied to the corn and cotton also; but I have found it difficult to get a stand of the last, owing to its dying out. For potatoes and beets, nothing can excel them.

Potatoes.—Irish potatoes highly manured and planted early, say in February, if the spring is wet or seasonable, succeed very well—coming in for table use often in May. If planted later, they are more uncertain. I have never heard of the potato disease in this region. Sweet potatoes, on sandy soils, succeed admirably. We are too far from market to raise them for any other than home use.

Manures.—A greatly increased attention is beginning to be bestowed upon the making and applying compost manures. We are too far from the seaboard to import fertilizers. Lime is to be had only in two or three localities. I know of no instance of its having been extensively spread over the land. Whether it would do good on our soil remains an open question. I have thus touched imperfectly on some of the points in your Agricultural Circular. As I have been able to communicate nothing new, I fear I have been tedious. If any part of this communication will serve your purpose, it is freely submitted to your disposal.

Very respectfully yours,

JOHN H. DAVIS.

Magnolia, Putnam County, Illinois, December 10th, 1850.

Sir:—Your circular of the 26th of August was duly received, in answer to which are subjoined the following impressions upon certain agricultural branches in this portion of our State. Having had very little practical experience in these matters, should I depart from practical observers in some of my estimates, it will be only a matter of conscientious opinion, not presumed to be entirely correct, and therefore will not alter the fact.

Our State occupies a space between 37° and 42½° north latitude, and here, near the 41st, we have a beautiful prairie country, subject to all the

varieties and changes of season peculiar to the same latitude in States lying east of this, and with a fertility of soil unsurpassed by any other State in the Union. Perhaps not more than one-tenth part of our land in its native condition is found covered with wood, and this generally borders on the rivers and small streams. From this circumstance, you will readily perceive that the first settlement of such a country will take place at or near the junction of prairie and timber, thence generally extending into the prairies, the central portions of which, in our State, will, at no very distant period, be teeming with the rich productions of a wealthy agricultural community. The abundance of mineral coal found to be so generally diffused will supply the place of fuel. Then, again, the practicability of growing different kinds of wood in a few years, to supply the natural deficiency, and likewise a reference to that branch of agricultural interest which so naturally suggests itself in the interior of an extensive prairie—the production of hedges, which later enterprise, under the investigations of Professor Turner, of Jacksonville, Illinois, seems very flattering, even beyond our former most favorable anticipations in making a living fence. The kind which he prefers, and in which he has every confidence, is the Osage orange, and if its permanence or ability to endure the severity of our latitude, becomes established beyond a doubt, all difficulties in fencing will disappear, as I have been informed that a good hedge of this material can be grown at an expense of 25 cents per rod. However, should this article fail to sustain the reputation which it has already obtained, we have several varieties of the common thorn, of spontaneous production, some of which, I have no doubt, may be converted profitably to hedging purposes. The above advantages being so confidently available, seems to justify the opinion that it will be but a few years when the prairies in Illinois will be densely settled.

The cultivated proportion of our country is yet relatively but fractional, and the fertility of the soil has enabled the farmer to procure abundant crops by a very easy mode of farming. Many early settlers have cultivated the lands for the last 20 years, and still obtain very good crops, without ever having manured them—say from 50 to 80 bushels of corn to the acre. The largest amount above specified is procured from bottom land, and the least from the table or prairie land, at a cost of about 15 cents per bushel, and has been selling at from 25 to 45 cents per bushel during the past season.

The production of wheat on new land as a first crop, after breaking up the prairie in May or June, then sowing in August, 1½ bushel per acre, is the most common rule adopted by farmers; and in this way they generally succeed in getting good crops of from 20 to 30 bushels to the acre. The above I refer to as being the most successful mode, although very good crops are frequently obtained from old lands with but quite indifferent cultivation. I have no doubt our old lands will yield most abundant crops of wheat with a good system of agricultural preparation—as much, perhaps, to the acre as when first broken. Very little exertion has yet been made to increase the natural fertility of our prairie lands—seeming rather to question the propriety of urging the old dame, already so profuse.

Those machines of modern invention, constructed for cutting grass and grain by horse-power, are regarded as truly labor-saving inventions, and will enable our farmers to engage more extensively in the grass and grain-growing business. From actual observation, I should speak in high commendation of their utility. Two hands and 4 horses can cut, in a very neat and saving manner, from 12 to 20 acres a day with one of these machines, and with them, under their present degree of perfection, we are enabled to cut and save one-third more than under former modes of harvesting. And yet I apprehend that the genius of invention will still simplify, improve, and render them even more desirable.

The cultivation of fruit is receiving increased attention, with no risk of overrating its true importance. This is not saying too much, when from one who believes that half the value of life is lost in the absence of the finer varieties of fruit, so far, at least, as luxurious eating constitutes the value of life. Our nursery-men seem to be striving to excel in the production of thrifty, healthy trees, with the accomplishment of which they express themselves most highly gratified.

The wool-growing business, under existing circumstances of our country, is regarded as not particularly profitable, other investments of industrial capital producing better compensation. Those gentlemen who have entertained a favorable opinion, and who are engaged in this business, have generally driven in good flocks from the East; but have had the misfortune to lose largely of their numbers during the first and second years, either by injury sustained from driving, or otherwise by acclimation. It is, however, proper to say that those raised here are healthy and large, even above the size of those generally raised in other portions of our country, with like care and attention. I am not able to determine the expense of rearing cattle until they are 3 years old. I am well assured that a succession of mild winters will produce very essential differences in the true expense of rearing. Some winters are so mild that cattle have wintered very well without foddering, by having their range in corn ground and timothy meadows. Other seasons, much more unfavorable, require a period of foddering of from 3 to 5 months. A very common price for wintering 2 and 3 years old cattle is from $2 to $2½ per head, and, under the present condition of the settlement of the country, the summer range costs but very little, except the expense of salting and keeping them within a range of observation, just to prevent their straying; and, with access to this wide range, extremely fine beef is produced, better than I have ever seen grown upon pastures of tame grass.

I have the honor to remain, very respectfully yours, &c.,

J. B. ASHLEY, M. D.

Hamptonburgh, Orange County, N. Y., December 26th, 1850.

Sir:—In reply to your circular of the 26th of August, I will briefly mention a few things pertaining to agriculture, of which I have some practical knowledge; and first of *Wheat*. This most valuable product is with us a rather uncertain crop. There are several varieties in use, but the one known as the Mediterranean is most esteemed. If sown early, say from the 1st to the 15th September, it generally escapes the attacks of the fly and weevil, or worm, in the head. We usually sow wheat after oats, and many of our best farmers prefer once ploughing to more. Our rotation of crops is corn on sward land, well manured, succeeded by oats, and then wheat or rye. The average yield of wheat in this county may be set down at 12, or possibly 15 bushels per acre, occasionally going as high as 35 bushels. The average price of wheat for the last five years has been about $1.20 per bushel.

Corn.—This with us is a much more important and certain crop than wheat. The kinds usually planted are the 8 and 12-rowed white and yellow, which ripen early. We usually plant from the 10th of May to the 1st of June, and generally harvest or cut up at the root as early as the 10th September, and place it in shocks, and let it remain till we husk it in October. The average yield per acre is about 50 bushels, though some of our premium crops have exceeded 100 bushels. The cost of culture I am unable to state, but on rich soil the stalks will nearly pay the expense. They make a most valuable food for milch-cows; the milk and butter being of the richest kind and of the finest flavor. Corn is mostly fed whole, but I think it would be much more profitable if ground and cooked for hogs. We usually grind the ear for cattle, and feed raw. Price from 50 to 63 cents per bushel.

Oats we consider a good crop, and sow mostly after corn. Yield per acre, from 30 to 70 bushels. Seed sown, 2 to 2½ bushels. Price, 30 to 45 cents per bushel of 32 lbs.

Rye is sown after oats, from 1st September to 10th October. Seed sown, 1½ bushels per acre. Average yield, 15 bushels per acre. Price, 60 cents.

Clover and Grasses.—In this section, the two most esteemed grasses are clover and timothy; the latter sown in the fall, with wheat or rye, at the rate of 4 to 8 quarts per acre, and the clover is sown in the spring, about 6 lbs. per acre. Yield from 1½ to 2½ tons per acre.

Dairy Husbandry.—Since the construction of the New York and Erie Railroad through this county, large quantities of milk are sent to New York, though those only who live near the line of the road can avail themselves of this source of profit; so butter is the main dependence of the dairyman. The annual yield per cow is from 150 to 200 lbs. I know of one or two small dairies, of 10 or 12 cows, where the average is 240 lbs. The average price of butter with us is from 18 to 21 cents per lb. In this county we churn the milk, using large churns, which hold one or two barrels. We use horse, sheep, or dog-power, and water-power where we can. In large dairies the horse is preferred, but in very many a sheep will perform all the labor, and fatten, while churning the milk of 15 or 20 cows. Being convenient to the New York market, our butter is sent off weekly, as a general thing, in tubs of from 13 to 50 lbs., though many pack down in large firkins, and keep till fall. A very important item in the profits of the dairy is the pork made on the buttermilk, averaging, say $4 the cow; also the calves, which are sold, at four weeks old, at $3.50 to $5 each. Some of our most successful farmers will make their cows pay, from all sources, from $40 to $52 per head.

Neat Cattle.—Very few are raised in this county. Good dairy-cows are worth, in the fall, from $18 to $25, and, in spring, from $25 to $35.

Sheep and Wool.—Our lands bear too high a price to make the growing of wool a principal business: still there are many sheep kept. The coarse-woolled are generally preferred for mutton and lambs. As a general thing, the lambs will equal the number of ewes annually. I could name a farmer who last year kept 50 ewes, which cost $1.75 each, and raised 71 lambs, which sold at $2.25 each per head. The ewes averaged 3 lbs. wool, worth 28 cents per lb., and they were worth this fall, $2.50 each.

Hogs.—The cheapest, and of course the most profitable method of producing pork is on the buttermilk of the dairy, and corn-meal cooked, upon which they thrive rapidly, and make the best kind of pork.

Potatoes.—This crop proved almost an entire failure the past season, scarcely enough having been saved for family use. The average yield formerly was 200 to 300 bushels per acre.

Very respectfully yours,

W. W. JACKSON.

Wheeler, Steuben County, New York, December, 1850.

Sir:—Your Agricultural Circular has been received, and, in reply, I will transmit such information as I have been able to obtain. This county contains about 1600 square miles, situated in lat. 42° 36′ N. Its principal products are, wheat, corn, oats, barley, wool, &c. The land is well adapted to all kinds of farming common in this part of the State, and our agricultural interests are receiving increased attention.

Wheat.—Our wheat crops are generally good on the high lands, and in lower situations it is subject to rust. We are somewhat troubled with the Hessian-fly, but not with weevil so far as my knowledge extends. The best means of avoiding the ravages of the former is to sow late. In some sections of the county, wheat has been much injured by the wireworm, which can generally be exterminated by cultivating the land for several years. Varieties of wheat, Hutchinson, Soules, white flint, blue-stem, and the red-chaff. The Hutchinson variety is not so highly esteemed as formerly, on account of its liability to shell so soon as ripe. The Soule variety is liable to the same objection. Both are early, and should be cut before fully ripe. The white flint is an excellent variety, for the reason that it will not shell if it stands several days after it is fit to cut. The Ohio flint is much esteemed by some, because it will admit of being sown later than any other variety that I am acquainted with. Our crop, last season, was probably an average one, though the quality is not so good, owing to the wet weather at the time of harvest, which caused much wheat to grow in the straw. Average yield, 12 to 18 bushels per acre. Time of seeding, from 1st September to 1st October. Harvest, about 20th July. Quantity of seed per acre, from 1 to 2 bushels, though, according to my experience, 1½ bushel is enough. After sowing, we sometimes use the cultivator to cover the grain, which, by the way, is one of the best modes of putting in wheat. I consider the cultivator next to the plough in point of utility. The yield per acre is generally on the increase. Preparation of seed:—Some soak in brine, and others in vitriol-water, and dry with lime; though, perhaps, the majority sow without any preparation. One of the best preventives against smut is to soak the seed in lime-water from 24 to 36 hours, and dry with fine lime in order to sow. Wheat prepared in this way always looks strong and healthy when it comes up, and, I think, pays well for the trouble. Two seed-drills were last fall introduced into this county, and were used only to a small extent. I used one of them to put in about 20 acres of wheat, and think that, where the land is not rough, these machines will prove very valuable to the farmer. By using them there is quite a saving of seed. Price of wheat, last fall, $1 per bushel. Spring wheat is grown here to some extent, though not much where we can raise good winter wheat.

Corn.—This important crop proved to be unusually good the past season, notwithstanding the cold and wet weather at the time of planting. Varieties, the large and small 8-rowed yellow, the 8-rowed white, also 10 and 12-rowed yellow. Each variety has its patrons. After an experience of 40

years in growing corn, I consider the 8-rowed white to be the best variety I have ever tried, though it may not look quite so rich. Average yield per acre, about 40 bushels. The cost of production depends much upon location and soil; for some land can be cultivated much cheaper than other. The average, however, may be set down at 31 cents per bushel, exclusive of interest on land. My method of cultivating corn is to spread upon sward land a good coat of manure, and plough in as deep as the strength of the team will admit of; harrow thoroughly, and mark off the rows 3½ feet distant each way. I use the cultivator to work among my corn, running it both ways at each time of hoeing. I think it pays well to grind all grain the farmer may wish to feed out to his stock. As to cooking, I do not know, but presume it would be a good plan.

Oats are extensively cultivated in some parts of this county, where wheat is liable to be winter-killed. Average yield, about 40 or 50 bushels per acre; price per bushel, 37 to 40 cents. It is thought to be a more exhausting crop than any other. Quantity sown per acre, about 3 bushels.

Barley.—More sown the past season than usual. The 2-rowed variety is now preferred on many accounts. It weighs more, has less beard, consequently pleasanter to handle; also a longer and stronger straw, so that we can cradle it and bind it in bundles. Price, the past season, about 70 cents per bushel. Seed, per acre, from 2 to 3 bushels.

Rye not much raised. Beans raised only in small quantities. Peas are grown somewhat extensively in sections where corn does not succeed well. The value of peas for making pork is nearly equal to that of corn. Average yield per acre, about 30 bushels. I have no knowledge of their being sown as a renovating crop. Quantity sown per acre, 3 to 4 bushels. Buckwheat is grown to some extent. Yield per acre, about 20 bushels. Quantity of seed, ½ to ¾ bushel. I am inclined to believe that barley, peas, and buckwheat are the least exhausting crops.

Clover and Grasses.—The hay crop is a good one with us. Average yield per acre, 1½ to 2 tons. Plaster is the best fertilizer for meadows. I sow about 4 quarts each of clover and timothy for meadows, and, for pasture, rather more clover. The cost of growing hay depends so much upon circumstances, that I am not able to estimate it.

Dairy Husbandry.—There is considerable attention paid to this branch of industry, though I am unable to enter into particulars on the subject. The price of butter is from 12 to 15 cents; and that of cheese, 6½. Those who have large dairies use horse-power for churning, and the smaller ones, dog-power.

Neat Cattle.—The cost of rearing till 3 years old is more than they will sell for; usual price at that age, from $16 to $24. Good dairy-cows are worth from $20 to $30 in spring, and in fall from $15 to $20. The only advantage to farmers generally in rearing neat cattle is, that they can use their coarse fodder in this way that would otherwise be lost. More attention is paid to improving the breed of cattle than formerly, though not so much as in the neighboring counties.

Sheep and Wool.—Most wool-growers do not think it a profitable business at the present prices; but as they have arranged matters expressly for that purpose, they continue it, hoping for better prices. I have conversed with a number of those engaged in the business of wool-growing, relative to its cost per pound; and all agree that it cost 40 cents. We are of the opinion also, that it costs as much to grow coarse wool as fine, though, if we had a good market for mutton, it might be preferable to grow coarse wool, as these varieties have larger carcasses. Nine-tenths of all the wool grown in this county is what may be termed fine wool, and, according to the testimony of wool-buyers, is of superior quality. Average yield per head, about 3 lbs. The average consumption of hay per head, during the winter, is about 300 lbs. The proportion of lambs annually reared to that of ewes, is as 7 to 10.

Hogs.—The Berkshire were formerly much esteemed; but we have another breed, which I cannot designate by any particular name, more popular than any other. They are of a red or sandy colour; no bristles, but fine hair, and small bones, and will fatten at any age. The pigs, (if pure blood,) when about two weeks old, will shed their tails. Cannot say how much meat 100 pounds of corn will make.

Sugar.—There are considerable quantities of maple-sugar made in this county.

Root culture is on the increase. Carrots are excellent to feed to horses and cattle, and grow best on light, sandy soil.

Potatoes have, during the past season, suffered much from rot. Many pieces were not worth digging. I planted 18 different kinds, all of which (except the "Mountain Junes") were more or less affected with rot: these were not. They are very early, and are fine for the table, and yield very well. Know of no remedy for the potato disease.

Fruit culture is receiving increased attention. We have many excellent varieties of apples, pears, peaches, plums, cherries, and grapes. Peaches do not flourish well but in a few localities. Apples are thought to be worth as much for feeding to hogs and cattle as potatoes.

Manures.—There is not as much attention paid to this subject as there should be. Some farmers heap up their manure in spring and let it remain till fall. I have no knowledge of plaster or lime having been used with manure as a compost. No guano used here to my knowledge.

Respectfully yours, &c.

O. F. MARSHALL.

Hancock, N. H., December 20th, 1850.

Sir:—It is believed that a very considerable portion of the agricultural statistics contained in former reports from the Patent Office, may be far beyond the common average products. This may be accounted for on the ground that none but the most favorable are furnished. Concerning the products of the dairy, there are but few accounts that may not be considered as very extraordinary. Having kept an accurate account with our small dairy the past season, we have thought that it might not be amiss to forward to you the result. On a farm of about 100 acres, divided as usual into mowing, tillage, pasture, and woodland, we have kept 4 cows of the native breed, from which 4 calves have been reared, principally on skimmed milk, and 268 lbs. of butter have been made, from May to November inclusive. This is but 67 lbs. to each cow, and is probably not far short of the ordinary quantity made from cows generally in this section.

Respectfully, yours,

REED CUMMINGS.

Keene, Cheshire County, New Hampshire, January 13th, 1851.

Sir:—Please receive what follows as an answer to your circular of the 26th August, 1850.

Wheat.—None raised in this town, and but little in the county.

Corn.—There are two varieties much used here, though, perhaps, not extensively known—one of which, if not both, originated in Canada. The kind referred to has short ears, eight rows, and is very compact on the cob. It grows larger from year to year, and may, in time, become less valuable. It is thought to be the best variety for flat land. It has yielded, with good culture, 75 bushels to the acre. The other variety has 12 rows; the kernel long and slim, the yield good, and is best adapted to hills which are not exposed to early and late frosts. I do not know how it is at the South, but here the varieties of corn are numerous and evanescent. In my opinion, they originate in the peculiarities of soil, cultivation, and locality, and disappear when not fostered under these peculiarities. Average product, in Keene, 40 bushels; in the county, 30 bushels. Time of seeding, about the 20th of May; and harvesting takes place in October. An intelligent, aged, and successful farmer has given me the following account of his mode of raising corn, its cost, product, &c. He ploughs his land (always sward) in the spring, about 7 inches deep, turning it well over, then harrows and furrows it. He then puts on 20 cart-loads of dung to the acre, all into the hills. The dung used, say in 1850, was made in the winter of 1848–49, remained in the yard during the summer of 1849, was hauled into the field in the fall, placed in large heaps, and shovelled over once or twice during the next spring. He uses great care in covering the corn and dung; hoes the corn twice, and harvests in October. He is never troubled with the wireworm, and attributes his exemption to planting on sward land.

The cost he estimates as follows:

Ploughing, per acre			$2.00
Harrowing "			75
Furrowing "			25
Twenty loads of dung			20.00
Putting dung in hills			2.00
Planting corn			1.00
Hoeing corn twice			4.00
Cutting up corn			1.00
Husking corn			4.00
Harvesting corn			1.00
Total			$36.00
Corn fodder	$10.00		
Manure left in soil	10.00		20.00 deduct.
Net cost			$16.00
Product, 75 bushels, at 70 cents			52.50
Income per acre			$36.50

The above product was unusual, but was obtained in the year he had in view. The next spring, he spread upon one acre 15 loads of dung, and sowed oats and grass-seed, and the product was more than 90 bushels of oats. He sowed 10 qts. of timothy, and 5 or 6 lbs. of clover-seed. This is his usual quantity. He keeps his land in tillage two years, and in grass from four to six; and on the whole of his grass land (about 70 acres) he averages one ton, or more, of hay per acre.

Dairy.—The above-mentioned farmer keeps 6 cows, and has kept the same cows for 12 years past. For the last 10 years, he has made 100 lbs. of butter and 100 lbs. cheese, annually, to each cow. He has generally reared 10 calves each year.

Neat Cattle.—The extreme prices, at 3 years old, are $15 and $30; the average price for the county, $23.

Hogs.—The Suffolk breed is considered the best. An intelligent farmer, who speaks from his account-book, says that a bushel of corn will make 15 pounds of pork, and that his pork costs 5½ cents per pound. The most approved practice of feeding hogs here is to feed with potatoes and cornmeal, boiling the potatoes, and, while hot, mix in the meal. Such food, whether for hogs or cattle, is much more valuable for being cooked. To bake bread for horses would not be without precedent.

Respectfully yours,

S. HALE.

Hudson, Lenawee County, Michigan, January 6th, 1851.

Sir:—I have taken considerable pains to inform myself, both by observation and inquiry, on the subject of agriculture, and I think you may put implicit confidence in my statements, as I have not only advanced my own opinions, formed from experience and observation, but have compared them with the concurring judgment of the best farmers in this part of the country. This county is blessed with every description of soil, and all of the most fertile character; so that our remotest backwoods can boast of as fine farms as any part of the West. Agriculture is yet in its infancy, comparatively, but much interest is taken in its improvement; also in an annual fair. The prospect of an agricultural work, of real merit, is hailed with unfeigned pleasure.

Our staple product is wheat, of which too much is grown for the good of the soil and the best economy of the farmer—a fact which many begin to appreciate. The most common varieties are white, as they do as well as any other, and bring a higher price. Soules, Hutchinson, and white-flint are the most esteemed. Some of the red-chaff bald is raised, and some Mediterranean. In Monroe, the red varieties only are raised, on account of the ill success of the white. The average product, this year, is about 20 bushels per acre. The yield appears to be rather on the increase, owing, probably, to the improvements in culture. Time of seeding, from the 1st to the 20th of September. The most of it is done during the first and second weeks. Harvest commences about the 1st of July. There seems to be but little necessity for any preparation of seed, as we are almost entirely free from smut, weevil, and fly. Our best system of farming is winter fallowing, with some early spring crop as a renovator; though, perhaps, the most common is the summer fallow, with two or three ploughings of about 6 inches deep. One and a half bushel of seed is generally used to the acre. The average price is 75 cents per bushel.

Our next most important crop is corn, of which the large, eight-rowed yellow, the red-cob, and dent are the most esteemed varieties. The average product is 40 bushels per acre. Cost of production, taken from several

careful estimates, by different men, is 17 cents per bushel. The best method of feeding is, certainly, in the form of meal, cooked and mixed with something less hearty, such as apples and potatoes. Time of planting, from the 1st to the 20th of May.

Oats are much cultivated here. Yield per acre, about 35 bushels; quantity of seed sown, from 2½ to 4 bushels per acre.

Rye, Peas, and Barley.—But little raised.

Beans are grown to some extent, and are thought to be a profitable crop. Average product, not known. These latter crops are sometimes planted to good advantage as renovators.

Grasses.—The small red clover, timothy, and red-top are the varieties raised here. Average product, about 1 to 1½ ton per acre. Timothy and red-top are used on the low lands, and clover on the high lands. The large red clover is used as a fertilizer.

Dairy Husbandry.—This is a profitable branch of farming. The product of 4 cows, during the past 10 months, has been the rearing of 4 fine calves, nearly 600 pounds of butter, and 200 pounds of cheese, which may be taken as about the average. Butter is worth 10 cents, and cheese 6 cents per pound.

Neat Cattle.—Some of the foreign breeds seem better adapted to the climate than the native.

Wool-growing is becoming better understood than formerly, and meets with better success. The coarse-woolled sheep are gradually going out of use, and the fine-woolled are supplying their place, as it costs no more to raise them.

The rearing of hogs has received some attention, but I have had no opportunity, as yet, to ascertain which are the best breeds. I believe Byfield and Leicester to be among them.

The only root crop raised, to any extent, is potatoes. Product, about 200 bushels per acre.

Fruit culture is rapidly increasing, and no doubt is entertained as regards the comparative value of this crop above all others. All our fruits thrive well, and none of the diseases mentioned are known.

I have had neither time nor opportunity to observe the indications of the thermometer, but shall keep an accurate account of its range during the coming year; also of other meteorological observations which may be convenient.

If these remarks meet with your approbation, I hope, in future, to be able to communicate something of more value.

GEORGE W. BOWLSBY.

P. S.—Please forward your Patent Office Reports to this place. Any seeds which may be for distribution I shall receive with extreme pleasure. I shall send a new variety of wheat, which seems about to supersede all others in this section, as soon as I can obtain a pure article.

G. W. B.

Union Mills, Carroll County, Maryland, December 23d, 1850.

Sir:—Your circular has been duly received, and I have hesitated whether I should reply or not, because of my limited information upon the subject, and want of practical knowledge in farming operations. I have concluded, however, to state what has come within my observation, and you are at liberty to make what use of it you may think proper.

The section of the county in which I reside has mostly a thin and barren soil, and in many parts gone to waste from neglect and a want of means to renovate it, though in many other instances (and such cases are increasing) farms of the same nature of soil present quite a different appearance, owing chiefly to the use of lime and careful tillage, which have so changed the nature and productiveness of the soil as to show plainly that some powerful agent has been used. You will find then, upon those farms which are in a more flourishing condition, that lime has been used with more or less advantage, according to the care and skill of the farmer. There are many farms in this section that, fifteen or twenty years ago, might have been bought at from five to ten dollars per acre, which would now readily command thirty to forty dollars per acre, and some even higher than this. This difference arises in a great degree from the improvements that have been made upon them, and will without doubt be still further improved, when they may with propriety be classed with some of the better limestone lands as to value; for it is generally admitted that the grain produced upon this soil is of the best quality, and superior to that which is raised upon limestone land, which is naturally of a better quality. Farming in our section has not been reduced to any thing like system. Industry and close application, with the use of lime, have effected more than science: how far this may aid is yet to be tested. No doubt *it* will also much advance the interest of the husbandman when properly directed. It is, therefore, for the want of proper care, that lime has been and still is used without any definite quantity per acre, or particular time for application. In fact, it is not considered of so much importance as it once was. The quantity varies from 40 to 100 bushels per acre. Mostly applied in the spring to corn ground. It is supposed to continue its virtue according to the quantity used, which may be set down at from five to ten years. The cost is from 10 to 15 cents per bushel on the ground: this difference of cost arises from the difference in the distance of transportation. The first cost may be set down at 8 cents per bushel. It is carried, at most, some eight to ten miles. One gentleman in our neighborhood, who occupies as thin land as any in the county, has been in the habit for some years past of housing his stable and other manure. I have not heard his opinion as to whether he derives essential benefit from this practice or not; but the appearance of his farm and his success in raising crops would seem to indicate and justify an impression in favor of this mode of preserving manure.

I have thus made a few general remarks relative to our section of the county. I may probably be able at another time to give some more satisfactory information; but as it is my impression that none should be given unless it can be relied upon, I forbear saying any thing more at this time, as any thing short of this is calculated to defeat the great object of your Report.

I am, very respectfully, &c.

A. K. SHRIVER.

Franklin, Warren County, Ohio, December 21st, 1850.

Sir:—In attempting to answer some of your agricultural queries applicable to this region, where the soil of almost every farm differs from the neighboring one, consequently requiring different modes of culture, I can only give approximate answers. The variety of wheat principally sown for some years past is the Mediterranean, a red wheat of inferior quality, but ripening earlier than most other varieties, and not so liable to rust—therefore a surer crop. I procured seed of the improved white flint from Ira Cook, of Byron, New York, some years ago, and have sown of it each year since, as have some of my neighbors. Though a very excellent variety, yet, in consequence of its late ripening, it is liable to fail from rust. The only preparation we give our seed is to free it from chess and cockle. A large majority of our farmers plough but once; the usual depth is four to eight inches. We sow from one and a half to two bushels per acre, and harrow in, though a few cover their seed with a small plough; the result is about the same either way, if well put in. The time of sowing is from the last of August to the first of October, though the greater part is sown between the 5th and 15th of September. Our harvest commences the last week in June, or the first of July. The yield varies according to the season and culture, from 5 to 35 bushels per acre. The usual average is about 18 bushels, and has been for the last fifteen years. Not often troubled with fly or weevil. Average price for the year, 87 cents.

The varieties of corn are as numerous as those of the soil we cultivate, but generally known by sectional names, as Honey Creek, Keever, bullskin, &c. Average crop for upland, 40, and for bottom lands, 60 bushels per acre. I can raise the best crop by ploughing deep (say ten inches) and thoroughly before planting, plant in squares, four feet each way, and work with the harrow and cultivator till the corn is knee high; then plough to the rows once with a small plough, and lay by with the cultivator. So long as the price for farm hands is so high, ($220 a year each,) the difference in product will not justify grinding or cooking grain for feeding stock, without an increase in the price of grain and meat. Broom-corn is becoming a crop of considerable importance in this vicinity, large quantities being raised annually for shipment, and still more that is worked into brooms at home. The usual method of growing it is to plant in drills three feet apart, and cultivate the same as Indian corn. Product from 600 to 800 lbs. of clean brush per acre, worth from $90 to $100 per ton; besides from 20 to 40 bushels of seed, which makes a good feed for hogs. I cannot state the increase of grain by feeding hogs on the ground, but I know many fields which have been planted in corn for twenty years successively, without any diminution of crop by turning on hogs to feed off the crop in the fall. The cost of raising Indian corn is about 9 cents per bushel, exclusive of land rent. Average price, the last year, 31 cents.

Oats turn out about 40 bushels per acre, average price 28 cents.

Timothy meadows yield from one and a half to two tons per acre. Grass-seed sown on wheat land immediately after the harrow, use some 10 lbs. of timothy, and 6 of clover. I save about a pound of seed per acre, by sowing it with a machine of my own construction, with which I can sow eighteen acres a day, perfectly even on the ground.

But little attention is paid to the dairy or the raising of cattle. Average price at 3 years old, $10 per head. Our county has been celebrated as producing the best hogs in the State; and I know of no better stock than the old Warren county breed, which was produced by crossing the Russia and China breeds; they have good size, fine bone, feed well, and will fatten at any age. As to how many pounds of pork 100 pounds of corn will make, I can say, from my own experience, that after hogs have been put up to fatten, every 100 pounds of corn fed to a fair lot of hogs will increase their weight 10 pounds. Tobacco culture is on the increase; yield per acre, 1500 to 1800 pounds. Potatoes are the most uncertain of all our crops, their product varying from 50 to 500 bushels per acre, according to the season; this year it was less than 50 bushels per acre, owing to excessive drought, which has lessened our corn and oat crop fully one-third. Of fruits, if we may be allowed to judge from the exhibition at the horticultural fair, held at Cincinnati in October last, our county bids fair to rival any other part of the Union, both as regards variety, quality, and quantity. In our own county, almost every farm has an orchard, generally of select apples, with a few pear and peach trees. The latter is an uncertain crop, liable to be winter-killed. We know of no effectual remedy for the blight in pear-trees; and, as a consequence, are losing our trees. Apple-trees are not seriously affected by blight, though, for some years past, the bitter rot has rendered some of our best varieties worthless. I have found a palliation of this evil by digging off the top soil down to the roots, and manuring well with chip-manure, or with rotten wood and leaves. Some of the Newtown pippin trees, which I treated in this way last year, bore sound fruit this year, while that on trees of the same kind in an adjoining row was all rotten. We use what manure our barnyards afford, putting it upon the thinnest part of our fields, either for corn or wheat, doing no more than what has been done in this vicinity within the present generation, viz. to pull down our barns to get them out of the manure which had accumulated around them.

Respectfully, yours,

J. P. SCHENCK.

West Springfield, Mass., December 24th, 1850.

Sir:—The following table will show the quantity of rain which fell at Springfield during the year ending October 31st, 1850, as indicated by the rain-gauge in the care of Mr. Lucius Allen, at the United States Armory.

Nov. 1849	2.56 in.	March, 1850	2.94 in.	July, 1850	5.28 in.
Dec. "	2.04 "	April "	4.29 "	Aug. "	5.94 "
Jan. 1850	4.18 "	May "	8.21 "	Sept. "	5.78 "
Feb. "	3.67 "	June "	8.55 "	Oct. "	4.03 "

Coldest day, February 6th, 5° below zero.
Warmest day, June 19th, 90° above zero.
Thermometer hanging on the north side of a tree.

The census returns will probably give you all the necessary information relative to crops, &c. There is little change from last year worthy of note, except that more broom-corn and tobacco has been raised than usual. Tobacco has been a profitable crop, yielding 1800 or 2000 pounds per acre, and selling at 12¼ cents per pound. Potatoes have yielded a light crop, and have rotted worse than ever before. The cultivation of fruit is receiving increased attention; and the best varieties of apples for winter use are the Baldwin, Rhode Island Greening, and Roxbury Russet. I usually transplant my apple-trees in the fall; I dig a hole large enough to accommodate the roots, and about a foot deep, then fill it with rich earth.

Cellars under barns and stables are coming into use, and are undoubtedly good for preserving manure from waste. Lime is used but little as a fertilizer. Plaster is sown on grass land at the rate of 1 to 2 bushels per acre, and put upon corn and potatoes with good effect, generally about a spoonful to each hill.

Respectfully yours,

AARON BAGG.

Floral Retreat, near Columbia, Lancaster County, Pa.

Sir:—Having been favored with a copy of your circular, soliciting information relative to agriculture, crops, modes of farming, &c. &c., I cheerfully comply, so far as my limited experience may enable to aid in imparting the desired information. I shall reply in the order designated in the circular.

Wheat.—This grain is the staple of Lancaster county. The varieties cultivated generally are Mediterranean, red blue-stem, white blue-stem, red-chaff, smooth and bearded, Hershey's white, Oregon, white flint, besides others designated by local names. The Mediterranean seems to take precedence of all others as a *sure* crop. It does not produce the finest quality of flour, nor perhaps quite so large a yield as some others; on a medium quality of ground, it will yield from 20 to 30—and we have known it to reach 42 bushels per acre; is far less subject to casualties, such as fly, mildew, rust, &c. It is not fly-proof, as was supposed, but *recovers* after being attacked by fly, much better than any other variety. Rich, strong soils do not suit it so well, as it is then likely to lodge, and is generally sown on wheat stubble as a second wheat crop, instead of rye. The average product of wheat of all kinds, I should judge to be about 20 bushels per acre, say for the last 10 years.

Our system of farming, or rotation of crops, is generally in the following order: 1st. We commence on a clover lay or sod that has been in grass for 2, 3, or 4 years, having during this time produced annually from 2 to 3 tons of hay per acre, or been pastured a part of this time: this is well ploughed in the fall, say 8 inches deep, (subsoiling will soon be introduced,) and sometimes limed at the rate of 80 bushels per acre, and well mixed with the soil by harrowing; the next spring it is well pulverized by going over with the harrow or cultivator, or both, and is then furrowed out 3 to 4 feet apart, and planted in corn, about the first week in May, sooner or later, according to the season. Some plant in hills, 3 or 4 grains in each, and work with the cultivator both ways—others plant the grains single, 10 to 12 inches apart. The crop is then well worked during its growth with the cultivator, and, when the corn is from 8 to 12 inches high, the double mould-board plough is drawn between the rows by a span of horses, throwing up a light furrow on each side. The cornfield is then left without further attention (except pulling off the suckers, if any appear) until the corn is nearly ripe, when it is cut off at the roots, put in small shocks till perfectly dry; it is then husked, and the fodder stacked and fed out to stock during the winter.

The varieties generally cultivated are the different kinds of gourd-seed; and the average product per acre I suppose to be about 50 bushels, though 80 and even 100 are not uncommon. The cost of production per bushel I am not able to give accurately, as the difference in cost of raising 100 bushels per acre is very little over that of raising 20. The ploughing, planting, tending, &c. is nearly the same for a small crop as for a large one. Ten dollars per acre I believe to be near the cost of labor for a crop of corn; consequently, if we raise 20 bushels to the acre, the cost of production will be 50 cents per bushel; or, if the yield should be 100 bushels per acre, the cost may be a little over 10 cents per bushel. The true answer will be intermediate, according to the quantity produced.

The best method of feeding:—The corn is ground into meal: sometimes the corn and cob are ground together, and those who have fed in that way say they do not believe the cob to contain much nutriment, nevertheless think there is a great saving of corn. To explain the *rationale* would, however, extend this paper to too great length. Steaming or cooking would be preferable; but whether more economical, I am not prepared to say.

Oats, Barley, Rye, Peas, and Beans.—Average yield of oats I should suppose to be about 50 bushels per acre; 2 or 3 bushels of seed sown to the acre. This crop is a great exhauster of the soil, yet it is almost universally sown after corn; the ground is well manured with stable-dung, partially decomposed, as soon as the oats are removed, preparatory to sowing the ground in wheat. Barley is not so much cultivated, owing to a limited demand; the crop is uncertain, and the price fluctuating. This grain is much less exhausting than oats; 2½ to 3 bushels is the quantity sown per acre. Peas and beans are not cultivated in Lancaster county, to my knowledge, as a field crop. After the oat crop is removed, stable-manure is spread on the ground, and ploughed under as soon as convenient; about the middle of September, the ground is again ploughed and sown with wheat, generally with the drill, of late. After this crop of wheat is removed, the ground is ploughed once more, and Mediterranean wheat or rye sown with grass-seed, to remain in grass 3 or 4 years, when the same rotation is again commenced—1st, corn; 2d, oats; 3d, wheat; 4th, wheat.

Clover and Grasses.—The quantity of hay cut per acre varies from 1 to 4 tons, and the quantity of seed sown per acre from 3 to 6 quarts. For laying down pastures or mowing-lands, red clover and timothy are the only grasses used; sometimes a lot is sown with orchard grass, but is not much approved. Lucerne, saintfoin, Italian rye-grass, tall meadow-oat, Gama grass, and others have been tried, but are not likely to displace clover and timothy. There are no permanent meadows, properly so called, except such as can command a stream of water; these seldom receive any fertilizers but what is contained in the water used in overflowing them: with a sufficiency of this element to irrigate them at proper times, 3 or 4 tons of excellent hay may be taken from each acre at two mowings, besides the aftermath fed on the ground in the fall by stock. Such meadows are a valuable appendage to a farm.

Dairy Husbandry.—I have no data from which to give any thing like a correct estimate of the average yearly produce of butter or cheese per cow. Farmers here keep from 4 to 12 cows each; milk twice a day, and keep the milk in a cool spring-house in summer, and, during cold weather, in a heated room; the cream is taken off as soon as it becomes sour, and kept in large crocks from 3 to 6 days; it is then churned, and the butter washed in cold water till the buttermilk is all out; it is then lightly salted for immediate use, or more salt is used if intended for preservation. The farmers' wives usually take it to market or exchange it for groceries as soon as made, and the country storekeepers resalt and pack it in small firkins, to send to other markets. Lancaster county butter "can't be beat."

The cost of rearing neat cattle till 3 years old is quite as much as they are worth; consequently few are reared except for cows, and occasionally a bull-calf. All the stock fattened in this section is brought from the Western States—it is cheaper to buy than to raise it. The cost of a 3 year old is from $15 to $30, according to size.

Sheep and Wool.—The keeping of sheep is not much attended to here, owing mainly, I think, to the risk of losing them by vicious dogs. Some farmers keep a few long-woolled sheep for their own wants. Were it not for this danger of loss from dogs, the raising of sheep might be made a very lucrative business.

Hogs.—The Chester county breed is considered more valuable than any other, from their large size, early maturity, easy keep, and peculiar aptitude to take on fat. The only objection that can be brought against them is, they are poor breeders; a mixture with our common hog is by many considered desirable: they become more prolific, and, though smaller, are equally valuable. Hogs are here allowed to range over the pasture fields, orchards, &c., during the summer, and, with the spare milk and refuse from the kitchen and garden, they thrive well. In the fall they are confined in pens, and fed on corn for a few weeks, till killing time. The pork is cured with ground alum and salt, and smoked with green hickory wood, or, what is preferred by many, corncobs.

Cotton, rice, and *sugar-cane,* not cultivated.

It is only a few years since that *tobacco* began to be cultivated in this vicinity. It is now largely on the increase, and, should the present high price continue, it will soon take a place in our regular rotation of crops. The price is now from $10 to $16 per 100 pounds. At these prices, it is the most profitable crop that can be raised in this section of country. The average product per acre may be near 1000 pounds; still, twice this quantity is not uncommon on strong land, with a favorable season and good attendance. Yet it is thought to be very exhausting to the soil, requiring much manure to produce a large crop. I entertain the belief that it is not more exhausting than wheat or oats, provided it is not grown upon the same ground year after year, but changed from one field to another, the same as grain and grass, giving the soil an interval of six or seven years before it is again raised on the same ground, taking a regular course in the rotation. Tobacco is a good feeder, and all kinds of manure seem acceptable and beneficial; coarse stable-manure, lime, ashes, plaster, even anthracite coal-ashes have been used with manifest advantage. Guano, bone-dust, poudrette, or any kind of artificial compost would undoubtedly fully compensate for its application in the increase of the crop. The variety termed *seed-leaf* is the most esteemed here. Lancaster county tobacco is considered a very superior article.

Hemp.—Twenty years since, almost every farmer had his hemp patch, of one-fourth or one-half an acre; now there is none cultivated. The low price of cotton fabrics has superseded this article.

Root Crops.—Turnips, carrots, beets, &c. These are not cultivated as field crops.

Potatoes.—The common potato has of late become a very uncertain crop; sometimes the rot destroys them, and generally the plant seems to have lost that vigor and health it formerly had: the best success seems to attend early planting, and on moderately dry soil.

The cultivation of fruit does not receive that attention which its importance demands. As a matter of course, every farm has its apple orchard, producing a full crop every second year, unless cut off by frost, or some other casualty. There are many causes operating to produce this state of things, among which is the want of a market. When the trees produce a full crop, the price of fruit will not compensate the fruit-grower for his trouble in picking and hauling to market. Another is the depredations committed by lawless bipeds, who prowl about the country and appropriate to their own use the best fruit. The pear is so generally destroyed by the blight, that very few trees are to be found. We know of no remedy when the trees are once affected. In a soil that is not disturbed by the plough, of a tenacious nature, and deep, with a sod of grass over the roots, and not too dry, the trees will then grow more slow, become hardier, and much less subject to blight than in a rich and cultivated soil, but the fruit will not be so fine. Peaches succeed admirably on elevated ground, where they are less subject to late spring frosts. The worms are easily prevented from doing damage, by protecting the stems of the trees about one foot from the ground. A few shovels full of leached ashes, heaped around the trunks early in the spring, and left there during the summer, are as good a preventive against the fly as any thing else. The yellows are now well known to be contagious, and during the time of inflorescence, the wind, bees, and other insects, in search of honey, convey the diseased pollen from tree to tree—thus in a short time infecting a large number of trees. The only remedy for this disease is *to lay the axe to the root*, and remove it without loss of time.

Plums, apricots, and *nectarines* are annually destroyed by the curculio—consequently not much cultivated. There is, however, a much stronger interest felt towards cultivating good fruit than formerly, and we trust that ere long horticulture will be more generally appreciated.

With great respect, I remain, &c.

J. B. GARBER.

Sir:—Your circular of August last having been received, desiring information from all practical men having had experience in the various matters therein set forth, I take the liberty of making a few suggestions on the raising and management of neat cattle. First, you wish to know the expense of raising till 3 years old, usual price at that age, value of good dairy-cows in spring and fall. In reply to these inquiries, I would say it depends very much on the animal, its kind. The Devon is undoubtedly raised and kept till that age at the least expense, being a small animal, and of gentle disposition. The Durham, being larger, will cost more. The grade, being a mixture of Devon or Durham and native, &c., will probably equal the expense of the Durham; and the native, being of such variety, it would depend much upon its kind to determine its cost. The Holderness will probably equal the cost of the Durham. The Hereford not having been raised much in this section, I am not prepared to decide upon its merits, or the expense of raising, or value of the animal. To have cattle valuable, at any age, much depends upon their keeping. The better they are kept, the more profitable the return. Calves should never want suitable food until they are at least one year old. Being kept well and in first-rate condition at that age, they will then provide for themselves, good pasture and water being accessible to them. The expense of raising is, in Western New York, $15 per head, and their average value $20; although I have raised some that cost more, and their value at that age much more. To make the greatest profit, I should prefer the grade. Good dairy-cows are worth, and have been for years past, in the fall, $15; in the spring, $22 per head; and some extras, above this price. A volume might be written on the raising and management of neat cattle; but experience will teach more. Sheep, like cattle, when well cared for, are very profitable: perhaps, at the present time, more so than cattle. Much, however, depends upon their management and the attention paid them.

Yours respectfully,

AARON RILEY.

To THOMAS EWBANK, Esq.,
Commissioner of Patents, &c.

East Aurora, Erie County, New York, December 18th, 1850.

Woodland, North Manheim Township, Schuylkill County, Pa.
October 23d, 1850.

Dear Sir:—In responding to the circular from the Patent Office, dated Washington, August 26th, 1850, I have prepared a few remarks on the agricultural productions of this county.

The neighborhood was early settled by the Germans, who took up lands to cultivate, the greater part of which being mountainous and rough, a small portion only fit to cultivate, was worked so hard by the sturdy farmer, that long since they have been in some measure abandoned for richer soils in the West. But, since the discovery and working of the anthracite as a fuel, it has brought thousands of hardy, working miners to this region, thus erecting a good market for all productions of the farm, and giving a stimulus to the farmer to manure and lime his worn-out land. Aided by a rotation of crops and better tillage, they have brought those worn-out fields to a high state of cultivation, producing good crops of wheat, rye, barley, buckwheat, Indian corn, potatoes, turnips, and all the hardy vegetables and fruits of our northern climate.

The meadow land produces the finest crops of timothy, say from one and a half to two and a half tons of hay to the acre. I am in the habit of sowing from six to eight pounds of seed to the acre.

Indian corn grows most luxuriantly, and produces large ears and grains. I have cultivated the common yellow, white flint, gourd-seed, Black Hawk, Tuscarora, and sweet or sugar corn, besides other varieties. The sample of white corn received last spring from your office, through the politeness of the Hon. C. W. Pitman, came so late in the season that it did not come to perfection before the frost overtook it.

The general yield, on good land, is about 40 bushels to the acre.

Wheat.—The blue-stem, red-top, bearded, and the Mediterranean are mostly grown in this neighborhood. The product is about 30 bushels to the acre. We sow the first week in October, and harvest from the 8th to the 10th of July, and plough twice.

Oats grow well. I have raised the common, but give the preference to the black oat. The average yield is 40 to 50 bushels to the acre. Two bushels of seed are sown to the acre.

Rye grows well and tall, yielding 20 bushels to the acre. Sow 1½ bushel to the acre.

Potatoes.—Red, white, and pink-eye are generally preferred, as the most profitable, yielding 200 bushels to the acre in sod. In low and wet places, the rot has shortened the crops for the last few years. The variety of hogs mostly esteemed are the Berkshire and Chester county. A cross of the two produces a good variety, and easily fatted.

Very respectfully yours, &c.

RUBENS PEALE.

Hon. THOMAS EWBANK,
Commissioner of Patents.

New Steubenville, Brooke County, Virginia,
December 15th, 1850.

Wheat.—Varieties in use are red-chaff bearded, club, white and red smooth, blue-stem, and Mediterranean; the last is not much in favor, it being about the poorest yield of any. Average product, about 20 bushels per acre. Best yield on limestone land. Seeding generally done about the last of September and first of October. Harvesting done first of July. No preparation of seed other than having it clean. Quantity sown per acre, from a bushel and a peck to a bushel and a half. Hard land is sometimes ploughed twice, but generally but one good ploughing of from eight to ten inches deep. The ground should be ploughed several weeks before sowing, and well pulverized before sowing. Never sow too wet; better to sow in the dust than too wet. The yield is rather on the increase. The practice here is to sow wheat one season, and then let the field lie in grass one season, and also to plant corn, and the next spring to sow the same ground in oats; then sow the oats stubble in wheat, which answers very well. There is very little difference in the yield on one or two ploughings, provided it is well done. I know of no remedy for either the Hessian-fly or weevil. The average price so far, in Steubenville, has been about 72 cents per bushel.

Corn.—The best variety for this section of country is the common yellow corn, not too deep in the grain. The product per acre will average somewhere between 50 and 75 bushels. Cost of production, about seven or eight cents per bushel. Plough your ground deep, and never when wet; harrow well before planting. It is a very good plan to harrow the ground over several days after planting, taking care to straddle each row. This helps to pulverize the ground, and also to keep back the weeds until the corn is up. After the corn is up, my plan is to take a one-horse barshare plough, and go through my corn and throw the dirt from the corn; the next week, to go through with a one-horse harrow, once or twice in a row, according as it may seem to require; next, with a double shovel plough, or cultivator, as may seem best; and so on, until harvest time, keeping the ground well stirred, each time following with hoes, more or less, as the case may require, taking good care not to work the ground too wet. Some of the questions you ask are too hard for me. I must, therefore, leave them for more scientific heads to cipher out.

Oats and Barley.—Not very extensively raised.

Fruit culture is receiving increased attention in this part of the country; particularly apples. Great care is taken to plant none but the best grafted fruit. A good orchard here will average about $50 per acre. Our principal market for apples is the river. I never have found apples of any consequence as food for stock. Some of the best for keeping are, the Newtown pippins, Russets, Romanites, Lopsides, and Spitzenburg. The Gates are among the best fall apples we have.

The peach-trees have mostly died here, although, I think, they might be preserved, with care and attention to apply hot soapsuds to the roots about the months of May and June. The "yellows" I believe to be produced by the worms at the root; destroy them, and the tree becomes healthy. To bind refuse tobacco about the body, near the ground, the first of June, is also a preventive of the worm. I might write more, but suppose you will receive a great number of communications from persons better calculated to give information than I am.

I remain yours, &c.

LEWIS BROWNING, JR.

Mr. THOMAS EWBANK.

Somerset, Hillsdale County, Michigan.

Sir:—In reply to your Agricultural Circular of August 26th, I shall make but a few limited remarks.

1st. WHEAT.—There are a great many varieties grown in this section. The best varieties are the Siberian, Soules, Indiana, and white-flint; the first is commonly called the choicest kind. At present, however, the Indiana and flint are both extensively grown, with good success. It is too generally the case here that *any thing* is sown for seed, instead of procuring a choice article. The difference in our markets between superior and inferior wheat is so trifling that the farmer is but poorly paid for his trouble in procuring a good article for seed. My opinion is, that if all wheat-growers here would adopt the plan of sowing none but the choicest varieties for two years, the result would be, at the end of that time, an advance of 10 per cent. on Michigan flour in the New York market. The average product per acre is about 15 bushels; the present year, a great many fields have averaged 20, 30, and even as high as 40 bushels per acre.

Time of Seeding.—The month of September, from 10th to 15th, is the best time.

Harvesting.—From 10th to 25th of July. Seed per acre, from one to one and a half bushels. If ground is well prepared, and sown early, one bushel is sufficient, but one and a half bushel is generally used.

Ploughing.—Plough twice, about seven inches deep. The yield per acre is not diminishing; on the contrary, if the crop is threshed on the field, and the straw ploughed in the next year, and a flock of sheep kept on the ground, to prevent the weeds from seeding, the crop will *increase.*

Average price, at our nearest markets, 65 cts.; last year, 80 to 85 cts.

2d. CORN.—The most esteemed varieties are the yellow and white dent. Average product per acre, 35 to 40 bushels; in some instances, the yield reaches as high as 80 per acre. Cost per bushel, 20 to 25 cents. Best method of *feeding* is to have it ground, and, for swine, to have it cooked.

3d. OATS.—Average yield per acre, 33 bushels; quantity of seed per acre, 2 bushels.

4th. SHEEP AND WOOL.—Wool-growing is profitable. Fine wool at 30 to 33 cents per pound, coarse and medium at 25 to 27 cents per pound, are considered fair market prices here. Fine, long Merino wool can be produced, at the above rates, with more profit than coarse wool, at the corresponding rates.

5th. FRUIT.—The culture of fruit is receiving a marked attention, although the country is yet in its infancy in regard to that important item. Apples have been sent from this State to Europe, at a good profit to the grower.

With due respect, yours, etc.

CHESTER HUNT.

Jonesborough, Washington County, Maine, December 18th, 1850.

Sir:—I acknowledge the receipt of your "Agricultural Circular" of inquiries relating to the farming interest, particularly confining myself to this vicinity. I proceed to answer such of your queries as have fallen under my observation and experience.

Maine is not an agricultural State: her people, relying on different resources for a subsistence, turn their attention to the development and improvement of these resources, leaving the cultivation of mother Earth, as though of insufficient importance and utility to expend their industry upon. The manufacture of lumber has so deeply engaged our people, it may be considered as constituting the principal branch of labor; in fact, it forms a striking characteristic of the inhabitants of the eastern and newly-settled counties of Maine. Our grandfathers and fathers were lumbermen, and we seem strongly inclined to follow in their footsteps. Hence, the boy of twelve thinks as much of cutting and drawing his "timber stick" or his "saw-log" from the forest as the man of forty; and the first start of the young man, when he sets up for himself in life, drifts naturally towards some branch of this great "State advantage." Now, it is easily perceived why so little attention is given to agricultural labor, it heretofore having been neglected; and the people seem quite unwilling to quit old pursuits, and engage in what they consider uncertain and unprofitable. But this unfavorable impression begins to slacken its hold upon the public mind; and as causes multiply to lessen the productiveness of lumber manufacture, the same causes produce a more favorable inclination towards agriculture. It may be said, and in truth, that our climate is not such as to encourage the farmer in the attempt to effect the productions of milder and more southern latitudes; yet, it is well adapted to the cultivation of oats, barley, peas, beans, potatoes, root-crops, the grasses; and, in the older settled and western counties, corn and wheat are raised with no inconsiderable success. Many of the farmers in the Kennebec valley are turning their attention to raising stock: their lands being well adapted to grazing, renders it profitable in furnishing beef cattle for the Western markets, and working-oxen for lumbermen in our own State.

The past season has been rather unfavorable to farmers, from a variety of causes. Snow lay on late in the spring, there being a fall of two feet on the level, 16th April, and disappeared only through the agency of the sun: cold and heavy rains succeeded, rendering May, our month of seed-time, cold and unpleasant. June gave beautiful weather, while July and August were extremely dry, vegetation suffering much. 25th August, frost in low land, scorching pumpkins, beans, &c., stopping their growth for the season. 1st September, heavy rain; 10th, the potato-tops showed signs of the plague, universally complained of as killing the stalks, and in most cases affecting the tubes. Our hottest weather was in July, when the thermometer ranged above 90° in the shade. It may be proper here to remark, that the past winter was unusually mild and open. The 10th of February, we had a warm rain, and the weather, for three weeks in succession, was spring-like, even inducing the robins to quit their winter quarters, and appear in flocks in the open land!

Wheat.—A field of wheat is now seldom seen in our vicinity. Its cultivation has been very nearly abandoned within the last five years, and unless something now unanticipated should occur to encourage its restoration, and give it the productiveness of former days, it will be lost entirely, and quite forgotten. The rust and mildew have been the great enemies of wheat, so much so, that that once staple crop of our county has been completely subjugated and driven from the soil.

Corn.—Heretofore, this article has not been much cultivated; but since the failure of wheat, our farmers feel disposed to plant a little corn: not enough, however, is raised at present to justify an attempt to enumerate cost of raising, or quantity procured from the acre. It is encouraging to know that the impression obtains very generally among farmers, that it might be raised to advantage; and there is but little doubt, if seasons continue favorable, considerable quantities will be raised in Washington county. Of the varieties used, the Canadian (eight-rowed) is preferable, better suited to soil and climate, yields more, and of superior quality to other kinds now used. When used as feed for cattle or hogs, should be ground and scalded; so agree all who are practical experimenters in the matter. When fed to poultry, is better "round."

Barley.—This grain is raised quite extensively in this county—is found profitable feed for hogs and poultry, always commanding a price equal to corn, varying from 80 cents to $1 per bushel. Loamy soil is preferable for barley: pasture-lands, or old cultivated grass-lands, with a fall ploughing, will yield a good crop. 20 bushels is considered about an average crop per acre; it is considered less draining to soil than wheat or oats. Quantity sown per acre, 2 bushels; time of sowing, from 20th May till 10th of June.

Oats.—All our farmers raise more or less of this grain. It is peculiarly adapted to our soil and climate, commands a good price as feed for horses, cattle, hogs, and poultry; and then the straw (which is better for cattle than the coarse grasses of the meadow) pays for all expense of cultivation. Three bushels to an acre is light seed enough, taking seasons together; dry weather is injurious; hence, if thick sown, will stand it better, thereby retaining the dews and moisture of the soil. 25 bushels per acre probably an average crop, though some would place it higher. Without extra labor, 40, sometimes 50 bushels are obtained from the acre. Time of sowing, the first week in May. Earlier sown, earlier ripe, and fuller and heavier grain. In the fall and winter are worth 50 cents per bushel; in spring, 60 and 75 cents. Previous to the failure of wheat and potatoes, oats were not much cultivated, the opinion generally prevailing that they were exhausting to the soil, but now a very different impression prevails, and are often used in stocking lands.

Peas are not raised in large quantities, though nearly all our farmers raise enough for home consumption. They constitute a valuable dish when green, and during winter months a healthy soup is ofttimes served up from them. Are considered renovating to soil: when mixed and ground with oats and barley, are a valuable feed for hogs and cattle. One and a half bushel to an acre for seed. Average crop, 20 bushels; generally worth $1 per bushel. Haulms of little use, except to strew in the hog-yard, where they are readily converted into dressing, again to be spread upon the fields.

Beans.—Nearly every farm has its patch of beans. I have known them raised for 10 years in succession, giving a fair crop on the same piece of ground. Our farmers are beginning to learn that it is cheaper to raise their beans than to buy them; hence an increased attention is very manifest in their culture. Time of ploughing, 15th to 20th May; price, $2 per bushel. Some plant corn, beans, and pumpkins in the same hill; but this is injurious, and prevents the growth of all; beans in particular should be planted by themselves.

Hay.—The last two years have been unfavorable for raising hay. An increase, however, of 25 per cent. for the crop of 1850 over 1849 may safely be allowed, and then not have more than 75 per cent. of what we formerly obtained. Quantity per acre this season, including highlands and intervales, (what some would term meadows, being the low lands on the banks of rivers,) 1¼ ton. Intervale mowing lands need no fertilizers other than what the flow of the rivers in spring and fall spread upon them. By the agency of the water in its coursing over them, they become as smooth as if wrought upon by man. After once cleared, they require no other attention than a day of labor, (on a patch of 3 acres,) in the spring, removing the drift stuff carried on by the freshets. These lands seldom fail of producing two tons to the acre, principally "brown-top," which commands a price in the market little inferior to best highland hay. *No fertilizer* is better for English grass fields than stable manure, either ploughed in previous to stocking, or spread on the sward of old fields in the fall, say October: the latter mode is much practised, and is thought as profitable as the former. Average price of hay $12 per ton, some seasons as high as $18. I think the cost of growing hay is about $3 per ton. This may seem low at first, but, by correct estimation, I think it an average cost.

Cattle.—Good dairy-cows, in spring, are worth $30; in fall, about $18. To the question, "Cost of raising cattle till 3 years old?" I find various opinions are entertained. All seem to think that they cost more than they are worth in the market; but their reckoning is this wise: allowing 3 tons of hay (little enough) to each animal till 3 years old, and that hay worth no more than $10 per ton, we have $30 as cost of raising, while the average price of the animal is only $15! Another method of reckoning, and in my opinion the correct one, is to put the hay at actual cost of raising, (which is about $3 per ton,) allowing the manure to pay for pasturing and care bestowed through winters, and we have fair profits in raising the animal. Were all our stock raised attendant with the cost estimate of the former method, it would cost triple its value at any age, or in any condition.

Many are induced thus to consider the matter; but when we take into consideration that we could raise but little hay without stock, that stock on the farm is what *makes the farm*, we shall be inclined to more liberal calculations. Upwards of 14,000 cattle were received at Cambridge market, (Massachusetts,) from the western and central counties of Maine, during the year ending November 1st, 1850. This business has sprung up very recently, and, by the great increase of last year over former years, it is inferred that the farmers of these counties find it profitable in furnishing beef cattle for that and other western markets. Working oxen vary in price from $50 to $100.

Sheep.—There are no animals kept on the farm more profitable than sheep. In summer they provide for themselves, and the expense of keeping through winter is more than doubly exceeded by the income. In the first place, the lamb raised by the old sheep at six months old is worth $1.50, and then the fleece, say 4 pounds, (which is an average,) at 25 cents, $1, leaving still the carcass of the old one, worth $2, which amply pays all expense of keeping. About 17,000 sheep have been driven from Maine to Cambridge, (Massachusetts,) where a good market is always found, within the present year. Our flocks are mostly a mixture of Saxony and Merinos, and we find that the larger the sheep, the more and better wool, and the same with regard to increase. The proportion of lambs raised to ewes is about 80 per cent.

Root Crops.—Not extensively cultivated as a field crop, yet nearly every homestead has its garden; average worth, about 12 cents per bushel.

Potatoes.—Our farmers have become almost discouraged in the attempt to raise potatoes, by the return of the "plague," the past season, more destructive than ever before. Potatoes generally, were planted in May, came up and grew well till 1st of September, when, after a smart rain, the cry commenced at the same time all round, "The plague's come," and, sure enough, it had. Nowhere, in a day's travel, could you see a field without the darkish hue upon it. Some dug and put them in their cellars before the tubers were affected, and were wise in so doing, while others concluded to let them rot it out, and they did so pretty effectually. The only means practised successfully to avoid the rot is early planting and digging. Some individual had notions of *experimenting*, which they boasted of as being sure preventives, but, the present season, it showed no respect of persons, performing its mission trustworthily and well. Crop of 1850 about half of 1849. Price, 50 to 75 cents per bushel.

Orcharding, like many other branches of the agricultural interest, is gaining increased attention in this county. It is not deemed of sufficient interest to give it a minute description in this Report. Price of apples, seldom less than 50 cents.

It is found exceedingly difficult to collect accurate and satisfactory information, as answers to many of the questions in your circular. Farming here is generally carried on without any particular system, each annually pursuing such a course as seems best calculated to insure success; hence a variety of systems are practised. Our farmers universally give more attention to growing hay than any other crop, and seldom yet has the supply equalled the demand. No other crop pays so well as this, and few are better adapted to soil and climate. Prices, too, are such as would seem inviting enough to hay-growers, to produce enough for home consumption. It is a cash article generally, and times are hard indeed when it cannot be exchanged for flour, corn, &c. So long as lumbering is prosecuted to the extent that it now is, hay will always be in good demand, whether produced in our own county or imported from abroad.

If the above will be of any service in making up your Annual Report to Congress, you are at liberty to arrange it to your convenience. The package of seed forwarded me last spring, I sowed and cultivated on choice grounds, many of which produced well. In future, if my services will be of any utility, I shall be pleased to render all due assistance. I think your labors are deserving of the highest success, comprising, as your Reports do, a volume of agricultural information, not surpassed by any other, and, when once known only, will be appreciated and admired.

Yours, with high respect,

GEORGE W. DRISKO.

Hon. THOMAS EWBANK,
Commissioner of Patents.

New Lebanon, New York, December 11th, 1850.

Friend:—I received your circular in due season, and now attempt a reply.

Wheat.—Very little is grown in our township, because of its tendency to winter-kill. Our soil being generally what might be termed an argillaceous mould, resting upon a firm hard pan, which renders it so retentive of a superabundance of moisture, that winter grains, unless a slight coating of litter be thrown over them, are very apt to be thrown out by frosts in early spring. Some wheat, however, is grown; average per acre, about 15 bushels. It is badly injured by the fly. Late sown, best—effete lime, sown upon it while wet with dew, is beneficial to prevent the fly.

Corn.—The kinds mostly cultivated in our neighborhood are early Canada, ninety days, and eight-rowed yellow. Dutton has been grown some—is not admired. Best method of culture with us is to put green manure upon the sward early in the spring; turn carefully under, and pretty flat; roll down; harrow up a tilth, also harrow in a few loads per acre of well-rotted manure, with about 4 bushels of salt; as soon as corn is large enough to weed, dress it with a hoe, and add to each hill a handful of unleached ashes and plaster. Average product per acre, 50 to 75 bushels. We never feed whole corn; think it enough better when ground to quadruple the cost of grinding. We greatly prefer cooked feed.

Oats.—Largely cultivated; average yield per acre, 25 to 60 bushels; about 3 bushels seed to the acre; sown on green sward, inverted and harrowed.

Barley always succeeds well in a rotation after a hoed crop; for seeding down, is preferred before any other grain, because it is of quick growth, thus furnishing shade for the germinating grasses, and comes off early, thus giving them a chance to grow when started. It is extensively used with oats and corn for feeding. Average per acre, 40 to 60 bushels.

Peas are but little cultivated as a field crop; neither are *beans.*

Rye is extensively raised on certain locations, being generally a sure crop. Average per acre, about 15 bushels. Barley, with us, is considered the least exhausting to the soil.

About an average quantity of English hay per acre, on newly-seeded land—2 to 3 tons; old meadow, about 1 ton. We prefer herds-grass or timothy, with Southern red clover for meadows; about 8 quarts of timothy and 4 of clover is generally sown to the acre. Best fertilizers for our meadows and pastures generally are plaster and ashes, about 25 bushels per acre. Cost of hay per ton, say $9 to $12.

About an average yield of butter and cheese per cow, in our neighborhood, is 120 pounds butter, 100 pounds cheese. Our method of treating the milk for butter is to strain immediately from the cow and put into tin pans about 8 inches deep, filling about 2 inches deep, and set upon shelves exposed in warm weather to a free circulation of air, in such way as not to ruffle the cream. In very warm weather we set our milk in refrigerating sinks, made of stone or cement, exposed to a spring or passing current of cold water. In very cold weather, fire is made in our dairies, so as to keep the temperature about 60 degrees. We endeavor, by the means of refrigeration in warm weather and warmth in very cold weather, to keep the cream at nearly a uniform temperature. If the cream is cold, warm it to about 60 degrees, and if very warm, cool it with ice before putting into the churn. Modes of churning are various; both dasher and revolving churns are used. All churning by hand is done with the revolving churns; some of these will frequently churn 30 pounds of butter in 15 minutes, in the fall and spring. We do not perceive so much difference in the mode of churning as in the state of the cream, as to the time it takes. Mode of putting down butter for market is, in substance, as follows:—Clean oaken firkins, or earthen pots, are prepared by scalding in brine and wheat-bran water, or by soaking in it 12 hours previous to using, then wipe dry. A layer of fine rock salt, washed before being ground, is then spread upon the bottom, and between each layer till the vessel is full; the layers about 3 inches thick. The butter is thoroughly worked with a butter-ladle, or a fluted concentric butter-roller, until all the buttermilk is extracted, and then about 12 ounces of clean rock salt, 4 ounces saltpetre, and 4 ounces sugar are worked into 16 pounds butter: it is then packed down, and has been pronounced, by the best judges, to be new butter at nearly a year old, and has been sold in New York at 20 cents per pound, when the common price was 16 to 18 cents. Made in one dairy of 20 cows, the past year, 2000 pounds butter, 1200 pounds cheese; besides furnishing new milk for about 75 persons to use at table as drink, and about 4 times per week as food. In another dairy, of 40 cows, about 5200 pounds of butter and 3044 pounds cheese have been made; in another, of 40 cows, 4000 pounds butter, and 3000 pounds cheese; and, in a fourth, of 18 cows, 2410 pounds butter, and 2040 pounds cheese—in 1850. Thus making an

Average to each cow in dairy	No. 1,	of 100 lbs.	butter and	60 lbs.	cheese,
"	"	"	No. 2,	130	"	76	"
"	"	"	No. 3,	100	"	75	"
"	"	"	No. 4,	134	"	113	"

It should be observed, that each of these dairies has furnished milk for food and drink for about the same number of persons, in proportion, as dairy No. 1. The manner in which cheese is made by the society of Shakers is simply as follows:—The milk at night is set in a large tub, the morning milking is put in with it, and then warmed to 60 or 65 degrees; add about 1 gill of rennet to 12 gallons of milk; it is then allowed to set until curded, say 2 hours, and then gently cut through and through in the tub with a long wooden knife, to let out the whey; after a few minutes it is carefully broken with the hands and the whey dipped off; this operation is repeated at short intervals, until sufficiently drained to put into a strainer, and, after remaining half an hour, it is cut into slices and put in a cloth, with a little weight upon it; this operation is 8 times repeated, at intervals of half an hour, increasing the weight each time; it is then cut in pieces of about half an inch square, and put in a cloth, and thence into the curb and press; after pressing until thoroughly drained, it is taken out, cut up a little finer than before, and scalded about 5 minutes in sweet whey and water; then dripped, and about half a pound of clean fine rock-salt is added to the curd of 12 gallons of milk, and again put into the hoop for a final pressing. Our cheese has sometimes sold for 20 cents per pound; but we do not manufacture for sale. An average price would be 8 cents per pound for new cheese, and 16 to 18 cents for that a year old.

Neat Cattle.—Very few young cattle are raised for sale in our neighborhood. Average price of milch-cows, in fall, $30 to $50 each, and in spring, $40 to $60. It is generally believed, among us, that a given amount of food will produce more meat in a Durham than in either Devon, Hereford, or native; but we prefer a cross of the Holderness and native, both for beef, working-cattle, and milch-cows, though some prefer the Ayrshire for milk.

Sheep and *wool-growing* are considered profitable on mountainous locations. Cost of growing fine wool is about 42 cents per pound; cost of coarse wool, about 30 cents: large sheep are considered more profitable, both for mutton and fleece, but some wool-growers of our town give the preference to the small Merino. We have had very fine-woolled sheep that sheared from 6 to 7 lbs. each—I mean yearlings. The comparative cost of Merino and common coarse wool, is about one-third more for Merino. The number of lambs annually reared very nearly equals the number of ewes. Merinoes fall short about one-third.

The culture of roots as a field crop is extensively increasing, especially the carrot; and in our seed-markets we probably sell a hundred pounds of carrot-seed where we formerly sold one. Our report on roots must be much the same as last year. We generally raise our roots on an old tilth, as one of a rotation of crops; the land is subsoiled, heavily manured, say 45 to 50 loads well-rotted manure to the acre. Potatoes have almost entirely failed us, under all circumstances, on various soils, and under every variety of treatment.

Manures.—Our yards are constantly kept littered with straw, swamp-muck, or other refuse. Beyond all doubt, the most economical plan, and one extensively adopted for manufacturing manure, is to compost the droppings of the yard and cleanings of the stable with muck, leached ashes, or, better, unleached ashes, (as our soils, and old soils generally, are deficient in alkali,) adding plaster to fix the ammonia; but never use lime in compost with animal manures, as it sets free the ammonia, which is the life of manures —*this*, plaster fixes: to this salt should be added, the soapsuds from the wash-house, and chamber-lie from every quarter.

It is the general opinion in this section that apples are fully equal to potatoes for stock, especially for milch-cows, and we are in the habit of feeding all our apple-parings, windfalls, and most of our cider apples, to our cows, reserving only enough to make our vinegar.

The foregoing is, as near as we can come at it, a cursory statement of the statistical condition of our agricultural interests. The minutiæ of detail in the management of various crops must necessarily be much abridged in a

report of this nature. Crude as it is, we submit it to you, desiring a charitable overlooking of blunders and incongruities.

GILES B. AVERY.

Shaker Village, Columbia County, New York.

Hatfield, Hampshire County, Mass., December 18th, 1850.

Sir:—Having received one of your Agricultural Circulars, I shall endeavor to give what information I can upon the cultivation of winter wheat.

Winter wheat is cultivated only to a limited extent in New England, and especially in Massachusetts.

I believe it can be cultivated with profit on the "alluvial bottoms" of the Connecticut and other large rivers. In this town, 20 bushels per acre are considered an ordinary crop—25 and 30 quite common—and, in favorable seasons, we sometimes have 40 and 50 bushels per acre, which, being in the market, readily commands $1.25 per bushel.

Our mode of cultivation is as follows:—

After land has been cultivated for a number of years, it is frequently seeded down to clover, for the purpose of renovating it. After lying thus for one or two years, the second growth is ploughed under, generally in the month of September, and is immediately sown. It is also sown to a considerable extent after broom-corn. The broom is cut as early as possible in autumn, and the stalks, making a great quantity of vegetable matter, are buried in the soil with a plough adapted for the purpose; then, previous to sowing, the ground is rolled and harrowed, in order to make the soil as finely pulverised and compact as possible.

Seed wheat is prepared by soaking 1 or 2 days in strong solution of saltpetre, then the water is drained off, and the seed is rolled and dried with lime. This is a very effectual remedy against smut.

S. G. HUBBARD.

East Salisbury, Essex County, Mass., December, 1850.

Sir:—Agreeably to your request, by circular from the U. S. Patent Office, of 26th August, 1850, I shall try to contribute my mite.

One of our most profitable crops is hay, which, on our best fields, yields 2 tons per acre. Timothy, with a little clover, is preferred for seeding, and not more than half a bushel per acre. The cost of raising, with interest or rent of land, is $8 per ton.

Good cows are worth $30 each in the spring, and from $15 to $18 in the fall.

We consider our best breed of hogs to be the Suffolk and McKay.

Fruit culture is receiving increased attention here. Many have been planting orchards. My plan is to have plenty of roots to the trees; then dig a large hole, and, if on clayey land, fill in with sandy loam, or, if sandy, fill with well-pulverized clay-loam. I believe it is generally admitted that every tree is naturally suited to a particular soil, and in new countries we can tell what the soil is by the timber. We all know the soil of the bur-oak, the pitch-pine, beech and maple and hickory, the cedar and spruce, chestnut, hemlock, &c.; but we plant pear and apple trees wherever we like, and, if they show any symptoms of dislike to the soil, instead of applying a remedy to the roots, we begin to doctor the branches, bark, and sap. All these, in turn, have been the subjects of treatment, but without effect. Now, let cultivators give their trees half the choice of soil that nature does her forest-trees, and the pear-blight and peach-yellows will be among the diseases of the past.

Transplanting.—Land to be set with fruit-trees should be ploughed in the fall, or very early in the spring; it should be ploughed very deep or subsoiled. When the ground is quite ready, get your trees, and set them the same day, if you can: never buy trees that have been dug over winter, and "lain by the heel;" nor plant so late in the season, as when the leaves have started: trees of this kind may live, but you lose the growth of them the first season, whereas, by the right kind of management, transplanting will hardly put them back at all. I have often planted trees which grew 4 feet the first year. Holes should be dug of sufficient width and depth to extend the roots to their original capacity. When the trees are placed in the holes, spread out the lower roots and cover them with fine earth, as also all the rest in like manner: get the roots into the earth so that they will stand interspersed, in regular system, with the soil, as the roots of a growing tree always do. The practice of thrusting the roots of a tree all in a heap, then piling on hard earth, manure, &c., and stamping it down hard, is sometimes successful, but no scientific cultivator would recommend it. After trees are set, the ground should be stirred around them while the heat of the season lasts, as often as once in 2 or 3 weeks; and if great drought should prevail, they should be occasionally watered; this should be done by making holes with a stick among the roots, and then pour on a pail of water.

Budding.—Apple-trees, and all others except plums and cherries, should be budded in September, and these should be budded in the latter part of July or the first of August; they should be put in so late that they will not grow the same season. The plan of operation is to select a shoot of the present season, with good buds, and cut off each leaf within half an inch of the leaf-stalk; then hold the shoot in the left hand, and the knife in the right, the lower part of the blade is placed on the shoot about half an inch above the bud—the thumb of the right hand rests on the shoot at the lower extremity of the bark to be removed with the bud; the knife is then drawn towards you, parallel with the shoot, smooth and level, so that the bark and a portion of the wood will be taken off. The stock to be budded should be of the present year's growth—a T should be made in the bark with the knife, and the bark raised with some convenient instrument: the bud is then inserted, and the bark is brought back and tied down over the bud, letting the leaf-stalk project out of the seam in the bark. Grafting is performed in the spring. The last of March is the proper time for plums and cherries, and April for all others. In grafting, thrifty young stocks should be preferred. The operation is simple, and consists in cutting off the stock at the point where we wish to insert the scion, and splitting the stock down the centre: the scion is cut at its lower end, in the form of a wedge, and inserted in the split in the stock: the outside bark of the scion should fit nicely the bark on the stalk. A salve made of 1 pound beeswax, 6 of rosin, melted with 1 pint linseed-oil, is then used to cover the seams made in the operation, so as to render the whole air-tight: the salve should be looked to occasionally, and kept smooth and tight on the seams, for it sometimes gets open and lets in the air, which will destroy the scion. Scions should be of the last

year's growth, and have upon each two or three buds. The cultivation of the grape is increasing here; we think that hardy native grapes might be extensively grown: I have seen 4 bushels of Isabella grapes upon a single vine; from 1000 to 1200 bushels of that variety might be produced upon an acre. There are several varieties of native grapes cultivated here, among which are the Isabella, Catawba, Sweet-water, Spanish-gray, Raisin, and Clinton. The Isabellas are considered the best. To bring the grape to perfection, into beauty, size, and flavor, the ground upon which they are set should be prepared by digging a trench 3 feet deep, and the same in width; fill it with all kinds of earth, such as sand, clay, gravel, loam, muck, and all sorts of manure, such as stable, ashes, lime, bones, forest-mould, and a little fine salt; set your vines in the trench, 8 feet apart; build a trellis 8 feet high and 8 feet long for each vine; beyond such limits they should not be allowed to extend. The vines should be well pruned, so as to allow every cluster to have the direct rays of the sun: grapes grown in the shade are generally small, watery, tasteless, and often mildewed. Vines are propagated by layers, which is done by bending down a branch of the last year's growth, and inserting the knife below a joint; the stalk is cut half off—the knife is drawn, splitting the stalk to the next joint; it is then pegged into the ground, with a hooked wooden peg, to keep it in its place, and to keep the cut open; it is then covered with earth, placing the stalk in an upright position: in 2 or 3 months it will be rooted, ready for transplanting.

Manures.—I would observe that a great saving can be effected by judiciously locating buildings, around which manure is to be made; such buildings should be so situated that all the manure that washes from them might be carried over land that requires manuring annually: a garden or yard for raising roots or fruit would be greatly beautified by receiving the drainings from the manure-yard; but the locating of buildings is only one thing in the arrangement for making and saving manure, and not to be trusted to entirely. Yards for stock should be small, and, if possible, upon hard, dry land; they should be covered, to the depth of 4 or 6 inches, with straw or muck, lime, or whatever else you can procure that will absorb the urine of stock, and hold it until spring: the same should be kept under stables for the same purpose. The manure made in fattening hogs should be collected into heaps, and be covered with bog-earth or muck. In the spring, all the yards should be cleared of all straw and other manure, which should be drawn into the fields, to be planted or sown with spring grain; it should be left in heaps till you are ready to plough; then spread the straw and unrotted manure upon the wettest land; dry straw helps such land wonderfully; it is far better than fine manure—it absorbs a great deal of water, and keeps the land loose and porous, so that an excess of water will soon dry off or run through it. Manure that is well rotted should be spread upon the driest ground, and thoroughly mixed with the soil: it should be ploughed under to a moderate depth, and then harrowed fine. If stables, barns, hog-houses, &c. are well located, and plenty of straw and muck be kept under the stables, and a plenty of that material is constantly thrown into the yards, and all cleared away early in the spring, there will be but little manure wasted. This system is far more simple, and less expensive, than to set buildings by the roadside, or upon the bank of a stream, and then go to work making drains, tanks, and pumps, to carry away the urine of the stock in a liquid state: the very thought of such reservoirs in barn-yards is disgusting. All the straw that is made on a farm should be well stacked after threshing in the fall, and thrown into the yard a little at a time during the season of foddering; then, after soaking under the manure of your stock a few weeks, it is in a first-rate condition to plough under in the spring. Swamp-muck is a powerful manure upon old wornout ridges, or on light dry land of any kind; it is nearly as good as stable-manure. Lime is indispensable for wheat lands, if it does not abound in the soil. It should be sown annually, at the rate of 4 or 5 bushels per acre. Gypsum should be sown yearly upon all dry soils, at the rate of 2 bushels per acre. Guano is not used in this part of the country. The plan of fencing with wire is beginning to receive some attention, and bids fair to supersede the use of crooked rail-fence; it has one advantage over hedges, for we need not wait 4 or 5 years for it to grow. Wire for fencing can be bought for 7 cents per pound; the posts may be set from 4 to 6 rods apart; the whole cost of materials for making a substantial wire-fence will not exceed 60 cents to the rod. It is thought that galvanized wire will last a long time.

I must submit my production to your discretion, and you can use the whole or a part, as will best comport with your ideas of the public interest.

I am, sir, yours truly,

GERSHOM WIBORN.

P. S.—I am entitled to a Patent Office Report for last year; please send me one. I would thankfully receive any rare specimens of grain for trial that you may have for distribution. I would give them a trial, and report my success.

G. W.

Portland, Chautauque County, New York, November 7th, 1850.

Sir:—In reply to your circular requesting information on the various branches of agriculture, I submit the following, which it seems necessary to premise by stating, that the soil and climate of this county are very diversified. The northern part, extending from lake Erie to the dividing ridge, which separates the waters which flow into the lake from those which flow into the Alleghany River, embracing a section three or four miles wide, has a soil and climate very different from that part of the county extending south of the dividing ridge to the State of Pennsylvania. The high lands are rolling, the hillsides of gentle slope, and well watered by numerous springs and small streams, and the soil well adapted to grazing.

The northern part of the county is adapted to the raising of grain, and all the varieties of fruit which are cultivated in any part of the State. The climate is much milder than in the more southern and higher sections; generally but little snow or extremely cold weather, and early and late frosts seldom injure vegetation.

Agricultural Improvements.—There has been for many years a very perceptible change for the better in all branches of agricultural pursuits; while a better system of tillage is practised by those who raise grain, and much labor saved by the use of ploughs, harrows, cultivators, reapers, and other improved farming utensils. Thus the land is better worked, and at less expense than formerly. Those engaged in the dairy business have generally obtained the best apparatus therefor, by which means the labor

is performed with greater facility, and a better article produced than was formerly the case.

A county agricultural society was organized in 1836, and the annual fairs are usually very interesting. The exhibition of stock this year was equal, if not superior to that of any preceding year.

Winter wheat is one of the principal crops in the northern part of the county; and most of the lands in that section produce it well. It is also raised to some extent in the southern part of the county, near Chautauque Lake and its outlet. The quality of the wheat raised is equal to that grown in any other part of the State; the product per acre depends upon the culture and soil. Crops of from 40 to 50 bushels to the acre have been raised, but much of the best wheat land has been, and now is, cropped for many years in succession with wheat or wheat and corn, without manure, until the fertility of the land is greatly impaired. I think the average product will not exceed 18 or 20 bushels. Very little land is prepared for wheat by summer-fallowing. It is generally sown after a crop of oats, barley, spring wheat, or corn, the land being ploughed but once after the preceding crop.

The practice of ploughing pasture and meadow in the fall, and sowing wheat with but one ploughing, has succeeded well. From the 1st to the 20th September is considered the best time for sowing wheat; but as much is sown after a crop of corn is taken off, it is necessarily sown later, even until the ground freezes.

Of varieties, the white flint, Soules, Mediterranean, red-chaff, and blue-stem white wheat are all raised more or less. The white flint and Soules have generally succeeded well. The product of the Mediterranean is small, and not so much is raised now as formerly. The blue-stem white wheat is the product of a small parcel sent here from the Patent Office, in the autumn of 1843, and has thus far succeeded better than any other variety. The quality of the grain is very fine, and in most cases, when sown by the side of other varieties, with soil and culture equal, it has exceeded them in product, and not been injured by the rust or fly when the other varieties have. The product of that small parcel has been sown in Vermont, Canada, Wisconsin, and many counties in this State, this fall. That sown last year in this State and Canada succeeded well, so far as I have heard, and should the product of that now sown be as good as that of former years, it will soon be the most common variety raised. When sown broadcast, from 1½ to 2 bushels is the quantity usually sown per acre. This fall, considerable has been sown with drills, at the rate of 1 or 1½ bushel per acre, and another season will decide which is the best method of sowing.

Spring wheat is sown to considerable extent in all parts of this county. The product, however, is not so great as of winter wheat; but is better in the southern than in the northern part. The tea, Italian, red-chaff, and Black Sea are the varieties grown. Of these, the last named is usually considered the best, and is less liable to rust and fly than the other varieties. Average product, 12 to 14 bushels per acre; although sometimes crops of 25 or 30 bushels have been raised. The product is diminished greatly by the rust, fly, and very warm weather at a certain stage of its growth, which renders it a more uncertain crop than winter wheat. Both winter and spring wheat are limed before sowing, which, when thoroughly done, prevents smut. Blue vitriol is also considered a preventive.

Hessian-fly.—I have heard of no remedy for the Hessian-fly that could be generally practised; but late sowing is considered safest as respects injury from them in the fall. I think that the hard straw of some varieties makes them less liable to injury than others of common straw.

Corn is raised in all sections of this county, and the crop is generally good; but in the southern part it is sometimes injured by frost: for the last few years, however, the crop in that section has been good. The northern part of our county is considered equal, if not superior, to any other section of the State for corn. It grows well on any land that can be ploughed. The usual mode of cultivation is to plough sward or stubble once, and harrow it well before planting; the usual time of which is from 1st to 20th of May. The steel-teeth cultivator is used by many in dressing and weeding it, and very few hill the corn, as formerly. Early planted corn is usually hoed or dressed twice; but most of the late planted (and some of the early, where the land is clean) is hoed but once.

There are many varieties raised, and all produce well. Some prefer one kind, and some another. On good, fertile land, without manure, 50 to 60 bushels per acre are not an uncommon yield; and 110 bushels have been raised on an acre. The probable average, in the northern part, is 40 bushels per acre. When fed to cattle, it is generally ground with the cob, and considered thus better feed for them than if ground without it. Very few grind corn for hogs, but feed it in the ear. I have no doubt that a less quantity, when ground and boiled, is required to fatten hogs; but I am aware of no experiments to show which is the cheapest, taking into consideration the price of corn and the expense of grinding and preparing it. The corn is cut up when ripe enough, and the stalks and shucks saved for fodder.

Broom corn is raised to considerable extent, and the culture of it is increasing. From 500 to 600 pounds of the brush, and from 40 to 60 bushels of seed have been raised on an acre, and are not considered an uncommon crop. It is manufactured into brooms by those who raise it.

Oats, in the southern part of the county, are considered a profitable crop, and are grown to considerable extent; averaging 40 bushels per acre. In the northern part they are not much raised, the climate being too warm and dry for them, the average product not exceeding 25 bushels per acre.

Barley and *rye* but little raised.

Peas were formerly grown as a field crop; but the bugs injured them so much that few are now sown, except in gardens.

Manures.—Barn-yard and stable manures are principally used; but plaster, lime, and ashes, leached and unleached, are used by many with much success. Plaster and ashes would be used more if the expense was not so great. The stone for both plaster and lime is brought from Canada. Buckwheat and clover are sometimes ploughed in to manure the land. Coarse, unrotted manure is applied in spring, and ploughed under. When applied to wheat, it is spread before sowing, and harrowed in with the wheat. Lime, plaster, and ashes are very beneficial; but lands that have been exhausted by constant cultivation without manure, can be restored to their former productiveness by a thorough application of barn-yard manure, and by deep ploughing. Gravelly and loamy soils are ploughed deeper than formerly; subsoil ploughing has not been tested sufficiently to ascertain its results.

Clover and Grass.—Clover is generally sown on grain, and on lands seeded for permanent meadow or pasture. It is usually mixed with timothy, which is the principal meadow-grass, but, on moist lands, the red-top grows apparently spontaneously, after the land has been seeded a year or two with timothy. Hay is worth from $5 to $6 a ton, when the crop is fair. The

quantity cut per acre varies from 1 to 2 tons. The expense of cutting and making hay is much less now than formerly. Where the meadows are smooth, revolving horse-rakes are used, and a more efficient labor-saving machine for farmers never was invented.

Dairy Husbandry.—The high lands of this county are considered equal to any section of the State for dairying. This is the best business pursued by farmers, and has increased very much within a few years past. The income varies, according to the quality of the cows and the skill employed. While the product of some amounts to $35 per cow, others fall far short of this, and the average will not, probably, exceed $25 per cow. The butter and cheese made in this county stand, deservedly, high in the market.

As the dairy business has increased, the raising of stock has diminished. The Durhams and Devonshires, or a cross of these with native, are the most common. Much interest has been manifested in raising the best of stock, and many of our enterprising farmers have imported the most valuable pure-blooded animals to be found in the Eastern States.

Sheep husbandry was, a few years since, a very extensive branch of farming in this section, but, from the low price of wool and the dairy business being more profitable, wool-growing has decreased, so that comparatively little attention is now paid to the business. There are, however, some very superior flocks of Merinoes, and most of the sheep of the county are of a fine grade.

Fruit Culture.—The cultivation of fruit has received much attention for many years. Apples are raised in all sections of the county, and most orchards have a good assortment of the best varieties of early and late or winter apples. That portion of our county near Lake Erie is well adapted to the cultivation of almost all varieties of fruit. Apples, pears, peaches, quinces, plums, cherries, apricots, and grapes, are cultivated, and of these we have most of the varieties considered the best. Pears have been much injured by the blight for some years past, but the early and late varieties do not appear to be as much affected by it as the others. The Isabella and Catawba grapes produce well, and with but little attention. Those which are trained into the tops of fruit-trees and extend a great distance, flourish and bear well, with but little pruning. Buffalo is the only market for grapes, where they are sold, in large quantities, at 4 to 6 cents per pound, and the culture of them is increasing. Our market for apples is poor, there being so many raised in the county; and the cost of transportation to Buffalo is so great that the price here is usually low. This fall, the best of winter apples were sold, at the orchard, for 12½ cents per bushel. They are considered good feed for hogs, and great quantities are thus consumed. Previous to the potato-rot, many farmers practised boiling potatoes and apples together for hogs; but since the rot has so diminished the crop of potatoes that not enough are raised to feed to hogs, it has been ascertained that hogs thrive as well on mellow apples as on any other feed, except corn, which is considered the best when well advanced in fattening. Sweet apples are better for hogs than sour; and many are of opinion that an orchard of sweet apples would be very profitable for fattening hogs.

I would here remark, in regard to the crops the present year, that the wheat crop was not more than an average one; the dry weather in May injured it considerably, but it was very promising up to that time. The corn crop is good—fully equal to last year. Hay was injured by the dry weather, and will not, probably, average more than two-thirds the crop of last year; but corn-fodder and straw are well saved, in good condition, which will, in a great measure, supply the deficiency; and the feed being good this fall, with uncommon warm weather, foddering will not commence as early as usual.

Yours, respectfully,

TIMOTHY JUDSON.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Doylestown, Bucks County, Pennsylvania, November, 1850.

Sir:—I received your circular some time since; and it gives me pleasure to answer, so far as I am able, the inquiries therein proposed. I do not flatter myself, however, that I can add much to your knowledge on the subjects referred to; but if the information I send will enable you to select a single grain of wheat from the chaff, I shall feel well repaid for my labor.

Permit me to say that the Patent Office Reports are yearly exciting increased attention among our farmers, and are much sought after, and perused with an interest which gives strong evidence of their intrinsic value.

Wheat.—The varieties of wheat that have been cultivated in Bucks and the adjoining counties, for several years past, are very numerous, and the success various, depending somewhat upon the seasons; but, from the experience of the last harvest, public opinion has settled down very decidedly in favor of that known as the Mediterranean, the product being larger and the quality superior to any other variety grown the past season. The average produce at the last harvest would, I think, fully reach 20 bushels per acre; time of sowing this variety, from 5th to 25th September; of harvesting, from 1st to 10th July, in ordinary seasons; the seed generally sown without steeping, or any other preparation; quantity of seed, 1½ bushel per acre—rather less when drilled in. As a general rule, the ground is ploughed 3 times for wheat; the first and second ploughings tolerably deep, say from 4 to 6 inches; and the last ploughing not so deep, forming a ridge furrow, by which the grain is thrown into rows, and has the appearance when grown of having been drilled in. The use of the drill is yearly becoming more common, and, I think, with advantage.

In this section of the country, the quantity, not only of wheat, but of other grains and grasses, is rapidly increasing, and has no doubt been doubled in the last 15 or 20 years, and is, at this time, increasing faster than at any former period. The common rotation of crops, commencing with a grass sward, is, first corn, then oats or barley, (seldom the latter,) and the same summer, after the oat crop, the land is prepared with lime and stable-manure for wheat; it is then sown with grass-seeds, generally in March or April following. The timothy-seed is frequently sown immediately after the wheat, with the best chance of success; but the wheat is sometimes injured at harvest, by the strong growth of the timothy, particularly on low and moist lands.

The Hessian-fly is the greatest scourge we have to contend with, and no specific remedy has as yet been discovered. Strong manuring is the best we know; but much depends upon the weather during the month of April and the early part of May: if that season is cold and wet, little injury is

done; if, on the other hand, it is warm and dry, the crop is not only injured but in a measure destroyed by that pernicious insect. The Mediterranean and other early varieties were very little injured by the weevil at harvest; but whether they will injure it in the sheaf, previous to threshing, we have yet to ascertain. The price, since the beginning of 1850, will average about $1.20 per bushel, and seems to be declining since harvest, from the abundance of the crop and the fulness of the supply in Europe.

Corn.—It is somewhat difficult to describe the different varieties of corn, and fix precise values on each—one rule is applicable to the North, and another to the South, depending mainly upon the length of season. The small flint corn would be comparatively unproductive at the South; and the large-eared and grained Southern corn would be equally so at the North, as it would not attain perfection before a frost. The most esteemed variety with us, and in the Middle States generally, is that with the largest grain that will come to full maturity in our climate; and this a medium between the large Southern and the small Northern flint corn, having a large, heavy, smooth grain, without indentation. The average yield, in a series of years, would probably range from 40 to 50 bushels; but 60 or 70 bushels are sometimes reached by our best farmers, in good seasons. In estimating the cost of production, I could hardly expect to approximate the truth. I think it is, however, for the labor bestowed on its production, as profitable as any other grain, and its aggregate value in the whole Union, very nearly, if not quite, equal to all other grains cultivated.

The system of culture varies much in different sections of the country, and possibly with advantage in each. With us in Eastern Pennsylvania, it comes in rotation after the ground has been laid down in grass for 2 or 3 years, and used for mowing or pasturage. The sod is turned down as early in the spring as practicable, and, at the proper season, repeatedly harrowed, until the surface is made quite smooth and mellow. It is then cross-furrowed on the surface, without disturbing the sward underneath, so as to form hills at equal distances, and usually planted from 1st to 20th May. In many instances, it is manured in the hill previous to planting, either with unleached ashes or rich earth, combined and prepared for that purpose, and deposited in the hill before planting the corn, and the farmer is well repaid for the additional labor and toil. A week or 10 days after it appears above the ground, plaster is sprinkled over the hills, in moist weather, and after that time the cultivator is mainly used in keeping the ground loose and free from grass and weeds. It is generally fed to hogs whole, the refuse or soft grain being first used, and answers the purpose of fattening well. For stall-feeding cattle through the winter, it is almost invariably ground, and not unfrequently the corn and cob are ground together, without shelling. The quantity of manure made by hogs is small, the quality, however, is rich: our hogs are seldom confined to the pen, except during the fattening season, and then but for a few weeks. In regard to the amount of manure made by hogs fed upon a given quantity of corn, no definite answer can be given. I can only express the opinion that, if mixed with rich earth, and a small portion put into each hill before planting, it would greatly increase the crop and amply repay the farmer for the extra labor required.

Clover and Grass.—Our principal grass crop is raised upon upland, and the seeds of clover, timothy, and herdsgrass are sown upon wheat and rye, following the regular rotation of these crops with mowing ground or pasturage for 2 or 3 years in succession. We have also our natural meadows, which are but seldom ploughed, and which, by irrigation and occasional top-dressing, with short manure, are made very productive not only for hay, but, in autumn, for the best pasturage. By top-dressing, our meadows are made to produce a fine sward of natural grass, which is equal, if not superior to any other, both for hay and pasture, in producing milk and butter.

The average of hay per acre on upland, in favorable seasons, is about 2 tons. When meadows are ploughed, (which is seldom,) they are generally laid down with timothy and herdsgrass: the quantity of seed to the acre I can hardly specify; but there is little danger of getting too much. Of clover and timothy, 1 bushel of each for every 6 or 8 acres of upland, is about the quantity required.

Dairy Husbandry.—Much attention has been paid to this branch of industry in the vicinity of Philadelphia, and the yearly increase of the product of butter is an evidence that it is profitable to those engaged in it. I believe I am safe in saying, and the fact will be conceded by every one who has visited the different portions of this country, or even of Europe, that Philadelphia butter stands unrivalled at all seasons of the year for its excellence. This market is chiefly supplied from Bucks, Montgomery, Chester, and Delaware counties; all in the immediate vicinity of Philadelphia. But little cheese is made in these counties, and the cost per pound I cannot give of either. The price of butter varies considerably in the Philadelphia market at different seasons, but a fair average for the whole year, would be from 20 to 25 cents per pound; and a large proportion of all made in the aforesaid counties is sold in pound lumps from market-wagons and stalls.

Neat Cattle.—There are comparatively few cattle raised in Bucks county, the calves being generally sold for veal when from 4 to 6 weeks old, and their places supplied by purchase of stock 3 or 4 years old from New York, New Jersey, Ohio, and the western part of Pennsylvania.

The raising of *sheep* is not much attended to, and the wool grown is principally for domestic use of farmers in their own families.

But few *hogs* are raised and fattened more than are required for our own tables. The curing of hams and bacon has undergone a great change within a few years, by combining a portion of sugar and saltpetre with the salt, and putting them down with what we term *sweet pickle*, a valuable discovery, which gives a fine flavor to the hams.

Root Crops.—The Irish potato only is cultivated to any extent: the exact expense of raising, per bushel, is difficult to ascertain. The yield varies with the season; 200 bushels have been raised, under the most favorable circumstances, on an acre; but the average is less than half that quantity. The white Mercer is considered the best variety. They are planted in rows, about 3 feet apart, being deposited at intervals of 10 or 12 inches on the manure, which has been placed in the furrows. The free use of lime and plaster will much increase the crop: but the main secret of producing large crops is the plentiful use of short manure on a tolerably dry soil, and cultivating frequently early in the season. No additional earth should be placed around the stalk after the blossom appears, or a new set of tubers will be thrown out, which may increase the number, but will diminish the size of the potatoes. Large quantities have, the present year, been destroyed by rot, and no effectual remedy has been discovered.

Fruit Culture.—More attention is now paid to the cultivation of fruit and the selection of the best varieties than formerly. Apples are wholesome, and convenient for family use, but could not be made a source of much profit in this section. The early droppings of the orchard are valuable food for hogs, as they serve to put them in a healthy and thriving condition before the season for fattening commences. The same remark will apply to the use of potatoes and pumpkins. The blight seldom attacks our apple or pear trees. For the "yellows" in peach-trees, I know of no remedy but setting out trees every year, and thus keeping up a succession of crops. I prefer budding to grafting for choice fruit; in transplanting, they always succeed when done at the ordinary season in spring. Grapes are raised in great perfection for the use of the table. Most of the foreign varieties succeed, and are a luscious and delightful fruit in their season. They are principally cultivated in gardens, and answer well for arbors in the vicinity of dwellings, both for fruit and shade.

Manures.—There is scarcely any subject that more engages the attention of farmers than that of manures, and none on which there is a greater variety of crude opinions, without any precise facts or experiments to sustain them. When we shall have discovered the *pabulum*, or appropriate food of plants, in their various stages of growth, we shall have the foundation on which to erect theories, and verify them by direct experiments. The merest *tyro* in farming knows that the application of many substances stimulates the growth and perfection of plants; but, if asked by what means, and through what agency these substances are conveyed to the growing plant, he, in common with myself, would be unable to answer. We all know that heat, air, light, and moisture are necessary to the proper growth and perfection of all cultivated plants, and that the absence of any one of these is fatal to their natural and full development; but what the action of any, or the combined action of all these, is upon the healthy growth of a plant, we do not as yet understand. That the principal sustenance and increasing growth depend upon the absorption by the roots and transmission through the stalk or stem to the extremities of the branches and leaves, is undoubtedly true, but we question whether this is the only channel whence nourishment is derived.

The beautiful theory, at one time generally admitted, that a wise and bountiful Providence has provided the vegetable kingdom as the great absorbent of the deleterious portions of our atmosphere—it giving out only such as are favorable to health and comfort, thus at the same time nourishing the vegetable kingdom and purifying the air we breathe—though probably true, as a general theory, requires to be received with some limitations. The limits of a reply to your inquiries on the subject of manures will scarcely allow me to go into detail, or extend my remarks further on this subject.

Very respectfully, yours, &c.

WILLIAM CARR.

Hon. Thomas Ewbank,
Commissioner of Patents.

Arkport, Steuben County, N. Y., December 20th, 1850.

HON. THOMAS EWBANK, *Commissioner of Patents.*

Dear Sir:—Your circular, requesting agricultural information, was duly received, through the politeness of Hon. D. Rumsey, Jr. I regret, exceedingly, that I am not able to give you a more detailed account of the interests of agriculture in Steuben county. We labor under the disadvantage of having no county agricultural society. I believe there was one established in this county several years ago, but, from some cause, (to me unknown,) it has long since "gone to that bourne whence no traveller returns."

Wheat.—The crop of wheat harvested this season was much more than an average one, and the quality would have been remarkably good had it not been for the heavy rains to which it was exposed in the process of harvesting—which commenced here about the 20th of July; and what was got in previous to the 25th (about one-tenth of the whole) was in fine order. It then rained for 15 days in succession, and consequently the greater part of the wheat crop was more or less grown—some fields almost worthless. The "Hutchinson" wheat has been preferred to all other kinds; but, for the past two or three years, it has found a successful competitor in a variety known here as the "Soules" wheat. It is the general opinion, among our best wheat-growers, that the latter will yield, on an average, 5 bushels more per acre than any other variety known. Average product, about 20 bushels per acre. We seed from the 25th of August to the 20th of September; soak the seed in strong brine for 12 hours, and then add half a bushel of unslaked lime to 10 bushels of wheat—mix thoroughly—let it lie over night and sow in the morning, from 1½ to 2 bushels per acre; the latter quantity preferable. The land is generally summer fallowed in June, turning under a good coat of clover. Plough about 6 inches deep, and cross just before seeding; sow on the furrow, and harrow thoroughly. Drills are not much in use about here. The yield per acre is increasing. We are not troubled with the "Hessian-fly" or "weevil." Average price, at our nearest market, (Dansville, Livingston Co.,) for the year 1850, is 94 cents per bushel; although, by getting it floured, and disposing of it to the workmen on the New York and Erie Railroad, at our own doors, we get something over that—$5 per barrel.

Corn.—This most important farm crop, and one that has been too much overlooked by the most of our farmers, is receiving the attention of many who have heretofore entirely under-estimated its value and its importance as a farm crop. The different varieties are, the early gourd, and the 8, 10, and 12-rowed yellow Dutton corn; the latter will yield from 5 to 10 bushels more per acre, and, when the season is favorable for ripening, is much preferred. Average product per acre, about 50 bushels. We harvested this fall, from one field of 9 acres, which was so badly injured by the worms that in June we thought it hardly worth hoeing, 1200 bushels of ears, which would make about 500 of shelled corn. The method we most approve is to plant on sward ground, ploughing it but once, and turning under all the manure we make during the winter; then harrowing, lengthwise of the furrow, until a good tilth is produced. Mark it, 3½ feet each way, and plant about the 10th of May. As soon as the corn is up, (say 5 or 6 inches,) start the cultivator, and have a boy follow, to see that there is none covered. Immediately after, put half a handful of unleached ashes on each hill. In about two or three weeks, we again go through with the cultivator, twice in a row each way, and follow with a hoe, giving a thorough dressing, throwing a little fresh dirt round the plants—but no hilling. This is all that is required until the kernel is sufficiently glazed to cut up. We then put 25 hills together, binding firmly round the top with stalks—husk in October. Cost of production, as follows:—

Interest on land, per acre	$5.00
Ploughing, once	2.00
Harrowing	1.00
Seed, marking, and planting	1.00
Ashes, and putting on the hill	50
Cultivating	2.00
Hoeing, once	1.00
Cutting up	75
Husking and threshing	3.00
Seeming stalks	50
	$16.75

Average yield, 50 bushels; cost of production, 33 cents. In this estimate I have made no account of the manure, because the stalks are worth (well-housed) $5 per acre, to feed stock; besides adding materially to the next year's supply of manure for another crop. The home, with us, is much better than the foreign market. We generally sell at our barns, in the spring, for 62½ cents per bushel.

Oats.—This crop generally follows corn; sow about 3 bushels per acre. We consider it the most exhausting to the soil of any crop we raise. Still it is cultivated very extensively. Average yield, about 60 bushels per acre; worth from 30 to 50 cents per bushel.

Barley.—But little sown; does not do well on our soils; very liable to rust; worth from 60 to 75 cents per bushel. Peas and beans are cultivated only for our own use.

Clover and Grasses.—The quantity of hay cut per acre, in good seasons, will average about 2 tons. We generally seed after oats or wheat, about 5 quarts of clover, (the small kinds,) and 2 of timothy; sow plaster annually on meadows, half bushel to the acre. Hay is worth at the present time, $10 per ton.

Neat Cattle.—Our young cattle, after the first year, are usually wintered on coarse feed—straw, cornstalks, &c., with hay in the spring, till they are 3 years old; they are then worth from $15 to $20. Good dairy cows are worth from $25 to $30 in the spring, and, in the fall, from $12 to $18.

Sheep and Wool.—Wool-growing is not considered very profitable; the average weight of fleece is thought, by good judges, to be about 3 pounds; the price has ranged from 30 to 44 cents, according to fineness of fleece: average, say 36 cents; mutton is worth 2 and 3 cents per pound. Pelts, from 75 cents to $1.

Potatoes.—The potato crop has proved a very light yield, and the disease has prevailed to a very alarming extent; the best remedy yet discovered by us for the rot is to plant healthy tubers on well-prepared dry, but not gravelly soil, as early as the season will admit; harvest early, and keep them dry, but not warm.

I have thus hastily glanced at a few of the topics suggested in your circular, with which I am familiar.

I feel a deep interest in the Reports from your office, and think they are the means of furnishing much useful information, especially to the agricultural part of the community, and shall be highly gratified, should the above be of any service to the Commissioner of Patents, in making out his annual report.

Respectfully yours,

JOHN HURLBUT.

Cumberland County, Virginia, September 17*th*, 1850.

Sir:—Agriculture in this region is in a state of transition. By injudicious modes of cultivation, our lands are much deteriorated, and large quantities nearly ruined. We are generally convinced that they must be improved or abandoned. We find our *patient* in a desperate condition, and conclude that something must be done, and are ready to resort to any experiment, however wild. As necessity stimulates invention, we may in this way occasionally discover something valuable, and eventually adopt a systematic course well adapted to our circumstances. Much useless expenditure has been incurred by sowing clover-seed and plaster on lands utterly incapable of producing clover without an application of nutritious manures. Much loss has been sustained by laboriously cultivating lands too wet to produce any valuable crop without thorough draining. Our manures are often rendered nearly inert by exposure to rains, which wash out the soluble portions, and produce chemical decomposition so rapidly as to evaporate their most valuable elements previous to their application. Many of our animals die, too, from want of proper protection from bad weather. These, and many other obstacles to successful agriculture, must be carefully guarded against, before we can emerge from the difficulties that surround us, and place our fine country in that rank of improvement and value of which it is so highly capable. I have often heard despondent remarks regarding the capabilities of the soil in this region for improvement, at least until the far West shall be fully peopled. From these lugubrious croakings I most deeply, and almost indignantly, dissent. I can personally bear witness to many instances of profitable improvement, rising annually before my eyes. A kind Providence has adapted each portion of our great country to fill its place in a grand and glorious Union, if each portion will but be content to strive to remove *its own* evils, and patiently await, however slow, the unerring progress of national improvement. This is progression for which all should labor.

Wheat stands deservedly at the head of your agricultural inquiries. There are so many who appear to sow wheat simply to make straw—often failing even in that—on poor corn land, that it is very difficult to form even a surmise as to the average crop. Our climate being so variable, forms another difficulty in estimating the average quantity produced, even by those who sow on lands capable of yielding wheat. Leaving the *straw-makers* out of the account, I suppose that 10 bushels per acre might be set down as our average product; for though our best lands, rich tobacco-lots and fallow-grounds, in our best wheat years, go up to 30 bushels, and, in some rare instances, to 40; yet, in unfavorable seasons, the average often falls below 10. And besides, much of our land, which may be called rich, is deficient in those elements necessary to produce good wheat, while they yield largely in tobacco and some other crops.

And now the question arises, how shall we increase the average products of our lands in wheat? Space is denied for a full discussion; but a few remarks in reply may be allowed. We must plough deep, and thoroughly pulverize the soil. Those elements necessary for the formation of wheat which are wanting in the soil, must be supplied. We are denied the free use of lime; but we may use it to a limited extent. Three or four bushels of lime put on with rich stable manure, in which the volatile gases have been fixed by means of gypsum and common salt, must do good by combining with the phosphoric and other acids in the manure. It is admitted that lime, applied to manure, not previously guarded by a suitable acid or salt, will cause a disengagement of ammonia; but if the sulphuric acid in gypsum will absorb the ammonia, I should hardly think a further addition of lime would cause a separation. Some of the chemical salts manufactured in our cities are believed to be worthy of trial. Kettlewell and Davidson's renovator, made in Baltimore, is becoming popular, and I expect to sow wheat this fall, on lands where 70 barrels of this fertilizer have been applied. Several of my neighbors will also try it—one of them largely. Guano certainly, in some instances, increases the quantity of grain and straw; but that the money expended on its purchase invariably affords a profitable return, is, I think, yet to be proved. I have seen failures after the careful use of what was doubtless the genuine article. Whatever manure may be applied, it is important that the utmost care be taken in draining off the redundant water. This should be done to guard against *rust*, which I consider the greatest drawback on our production of wheat. We had, this year, during the last half of May and until late in June, very dry and hot weather, which seemed to parch up instead of ripening our wheat crop. Notwithstanding this severe drought, we suffered more from rust than for many years before. I ascribe this to the excessive rains which fell before the drought, leaving stagnant water upon the land, which, by its putrefaction, poisoned the crop, and caused the rust. For the last 10 days, we have had, perhaps, the coolest weather ever known, for the season, with the ground tolerably dry; yet the tobacco is fearfully firing. This, I think, arises from the same cause as rust in wheat, for we had, some time ago, the heaviest falls of rain that I have ever witnessed. Firing in tobacco and rust in wheat seldom appear until these crops approach maturity.

The time of sowing should depend much upon the variety of seed. Late kinds should be sown about the 20th September. The seeding of earlier varieties may be deferred a month later. I made several experiments of sowing in August; but lost much of the crop from the fly. Many of our best farmers think from 10th to 20th October the best time to sow, to escape the fly. When smut was common, we soaked our seed wheat in a solution of salt, skimming off light grains, spelt, and other seeds of noxious plants, and rolled our seed in lime before sowing. I have heard nothing of smut for many years, and very few now make any further preparation of seed than to clean it. From 1 to 1½ bushel is the quantity usually sown per acre.

Land that has been cultivated the preceding summer in tobacco or any other hoed crop, need be ploughed but once for wheat. It is better, in order to destroy noxious weeds, to plough under a clover or grass-fallow before their seeds ripen in early summer, and to refallow in the fall, before sowing wheat. But most of those who operate on such fallows plough but once, and then get in their seed with what we call a big rake—a large kind of harrow, with 20 or more straight teeth. I prefer the harrow or cultivator, with 7 long and broad-pointed teeth, as, in using the rake too large, a portion of the grain is left uncovered. I like to cover seed wheat at least 2 inches deep. We plough much deeper and use better implements than we formerly did. In place of a little, scratching, 1-horse trowel hoe, we now use 2 and 3-horse ploughs, of various models, cutting from 6 to 10 inches deep. There was, at first, a great outcry against deep ploughing, as burying the soil too deep for return; but it is found to make soil of the whole tilth, and the benefits are too manifest to all who will look, and believe their eyes, to admit of question.

It is difficult to say whether the yield per acre is increasing or diminishing. While the country abounded in forest, the system of culture and, consequently, the product, was more uniform than now. Then all cut down their woods, cultivated their land a few years, and, as soon as it began to fail in fertility, turned it out as old fields, and cut down more woodland. Those who had no more woods to cut down, began to save and apply manure to tobacco lots. The average of other crops began to lessen, until necessity drove many to new countries, others to struggling in ignorance against their hard fate, and some few to earnest endeavors to improve our condition. We have cut nearly all the forest that we dare cut, and are now divided into various classes. Some make less wheat and less straw every year, giving all their manure to standing tobacco lots. Others move their lots every year, to "extend the area" of fertility, and reserve a part of their manure for other crops besides tobacco, sowing clover and plaster, and resorting to every practicable means to improve their lands. Many of these are greatly increasing their crops, and serve as examples and teachers of the rest, who, it must be confessed, are slow to learn. Those who cultivate no tobacco, and are directing all their energies to the general improvement of their land, are too few in number to form a class. In this category, for the present, stands the writer, quite confident that this is the most speedy way of renovating the face of the country;, but sadly doubting whether the individuals who adopt it may not be lost in the mazes of an intricate and untried way, without the guidance of common custom around them to enlighten their path.

We have no uniform system of rotation in crops. Individuals are striving to strike out new plans of their own, adapted to their peculiar circumstances. So far as there is any established system, I think the four-shift rotation of the late John Taylor, of Caroline, the most common. The following is my own plan:—I cultivate corn only upon low grounds; the surface to be smoothed at the last working, for sowing clover-seed, and the clover to be fallowed the next fall, for seeding wheat. I prefer that corn should grow after wheat than after clover, to avoid the clover worm; and I think wheat grows better after clover than after corn. My high land is alternated in clover or peas, and small grain; wheat being sown on the richer and oats on the poor land. Should the price of wheat keep up to a dollar per bushel, and my faith not fail in the efficacy of manure for increasing the average yield, I may be able to get along in this way. I had to begin, however, with most of the high land in a state of great sterility. I do not think our high lands can bear so exhausting a crop as corn oftener than once in 6 or 8 years, and the land should be heavily manured even then, and much less of it tended.

I know no remedy, not already published, against the Hessian-fly. Early threshing and bulking will, doubtless, prevent the egg of the moth weevil from hatching in the wheat; and fumigating the granary thoroughly with burning sulphur is said to expel the black weevil.

Corn.—There are many esteemed varieties of this noble grain, among which, perhaps, the old Tuscarora and Dearing stand foremost for this region. Hardly two persons can be found who would agree as to the average product per acre. There are extensive tracts of land so extremely poor as not to produce a single ear, unless favored with a genial season. It is difficult to divine why such land should be cultivated at all. A man, judicious in other matters, will sometimes cultivate 100 acres in corn, 25 or 30 of which will produce all the crop he makes. Those whom we consider good farmers obtain from 4 to 6 barrels of corn per acre.

The system of culture depends upon the season. I always wish to avoid breaking the corn roots, but, when the grass has grown rapidly during a rainy season, it cannot be killed by the cultivator, and a turning-plough must be used, especially in stiff land. The earth should be completely turned up and pulverized before planting. After this, if the land be light, the big horse-rake, with its front teeth drawn out, may be dragged over the young corn, which should immediately be dressed with hand-rakes, with large spike-nails for teeth. In stiff lands, hoes should be used for dressing the young plants, followed by a mould-board plough, turning the earth first from, and then directly towards the corn. The after culture of the crop may then be trusted to the hoe and cultivator. The chief labor on the corn crop should be applied on its preparation. If the land be rich, it should not be planted until the first half of May. The ground is then much better prepared, the young corn not being in the way. Many good managers plant in March and early in April; but, in that case, the young plants are stunted and discolored by much chilly weather in early spring, and I think never fully recover. If not planted until the ground begins to be warm in May, their growth is vigorous, and they derive the full benefit of hot weather, as well as being in a better state to receive the late rains which often succeed a drought. Poor and low lands require earlier planting.

The *cow-pea* is attracting considerable attention. It has, however, so recently been introduced, that there is need of some caution in its praises. From four years' experience, I am greatly pleased with it as a green crop. It renders an early summer ploughing necessary, which, if early enough, turns under the young spelt, wild carrot, ribwort, wild onion, and other noxious weeds, before their seeds mature; and if there remain a few, they are much smothered by the rank luxuriance of the pea-vines. These vegetable pests are more successfully opposed by a smothering crop than by any other means which I have observed. I have never known the wild onion yield so much to any treatment as to turning it under early in June, when it is in blossom.

Enough has been said of the pea as an antidote against vegetable pests; its value as a cleansing crop cannot be doubted. It remains to speak of it as a fertilizer. I am old enough to have learned, from those long since dead, much about the first settlement of this part of Virginia. Some of them told me that the forests were so thickly covered with wild pea-vines, running up the trees and bushes, that a man on horseback could not be seen in many places at ten feet distance. That on some of our ridges, now esteemed the poorest sort of land, then chosen as the most productive, the decayed vegetable matter laid in such a stratum, all over the woods, that a man could run his foot into it knee-deep, with facility. That cattle could be transported in droves from the Carolinas and Georgia to Philadelphia and Baltimore, without feeding, except on the wild pea-vines, until they approached the thick settlements—and fattened all the way. The traveller or hunter reposed on a couch of Nature's spreading, while his horse, tethered by a short cord, luxuriated on more pea-vines within his reach, than he could destroy. I know not what kind of wild peas were then most abundant. In my boyhood, there were many varieties not to be found now. The most luxuriant grew on the trees, to the height of 25 or 30 feet, but they were very scarce. They had perennial tuberose roots, resembling sweet potatoes, and bore, near their tops, enormous clusters of pods, containing very pretty peas, of medium size. I have seen none of these for many years. There are still many smaller varieties, one of which climbs 8 or 10 feet on weeds and bushes, in rich lands. The custom of allowing stock to roam at large has, however, nearly exterminated them. Their decay formerly, in the opinion of our forefathers, caused that generous fertility which so much distinguished our lands in those days. But that fertility has departed since the wild pea has been exterminated, and it may well be questioned whether there be not a peculiar adaptation of the pea as a fertilizer to the soil of this region, and whether the use of it might not be one of the best means of renovation. The Indian pea has been declared by chemists to contain much of the peculiar nutriment constituting the substance of wheat, and it is known to afford a larger mass of vegetable matter than almost any other plant will produce in one summer. It grows better in dry weather than any other vegetable we have. It has been an almost universal custom for every family to cultivate a patch of peas for domestic use. A Middle or lower Virginian, having wandered to colder climes, could hardly think of his native home without remembering the cornfield pea. These pea patches have always been remarkable as yielding better wheat than the adjoining land. The knowledge of this fact has doubtless led to their more extensive field culture; and all who have tried the pea fallow, I believe, rank peas before any other green crop. There are many ways of cultivating them. Some drill them in: some sow them broadcast, immediately after ploughing in clover or grass, and cover them by running the big rake or drag in the same or exactly contrary direction to that in which the plough went. Some sow them broadcast with oats, and I have heard that the plan answers well. Others sow them in cornfields, and get them in with the last working of the corn. I have been told that on low grounds, cultivated in this way, the product has annually increased, yielding but 3 barrels the first year, and 8 barrels on the eighth. Peas are cultivated further south for the sake of the haulm as provender for stock. I know of no vegetable which in this climate would produce, on rich soil, a greater supply of fine food for animals. They have but recently been introduced in this section, and we cultivate them entirely as a fallow crop for wheat, and some gather the seed for sale.

The chief objections to pea culture on a large scale, arise from the time of sowing being a very busy one, and the great difficulty of breaking up land at that season, if drought occur. This latter objection may be obviated by a previous fallow in winter.

Hogs, Curing Bacon, &c.—The excellence of Virginia bacon is known far and near. We prefer dry and very cool, but not bitterly cold weather, for killing hogs. After killing, and nicely cleaning our hogs, we hang them in an airy place by their gambrels, from 12 to 24 hours, that the animal heat may escape, the blood may drip, and the superficial moisture may evaporate. They are then taken down and cut up, each piece being taken from the butcher, by other hands, to a table, where it is thoroughly rubbed, inside and out, with good Liverpool salt, having, according to size, from one to three tea-spoonfuls of pulverised saltpetre, sprinkled over it, and squeezed around the bones that project. The saltpetre is chiefly put on the hams, sometimes on the shoulders, never on the middlings, which are nearly all fat. I have often eaten excellent bacon on which no saltpetre had been used. The pieces are then packed in "powdering tubs," made of half-hogsheads, or piled upon broad planks. This is preferred when the weather is rather warm: if the weather afterwards be very cold, the meat is permitted to lie in this condition for six weeks. In soft, mild weather, it will "take salt" in three or four weeks. The salt should be piled between the layers thickly enough to prevent the pieces coming in contact, as this causes mouldness. When it is known to have "taken salt," the pieces should be hung in the roof of the smoke-house, on poles, across beams fixed for the purpose, at such intervals as will prevent their touching each other. Moderate fires, made of green hickory or red-oak billets, or the green chips of such wood, are then to be carefully kept up, and especially attended to during damp or rainy weather, until the meat appears to be dry enough, and smoked enough, which must be judged of by the appearance and color. If very closely attended to, it will be converted into good bacon in three weeks. If some remissness be indulged, it may require six. As the fires are intended to dry and smoke the meat, not to heat it, they should, of course, be moderate; and if the house cannot be made perfectly dark, red pepper, bits of old leather, or slow-matches of brimstone should be burned in it, in warm weather, to keep off blowing-flies. After the bacon is cured, it should be packed in the "powdering tubs," with dry ashes or common salt. I prefer the salt, because it looks neater, more effectually excludes rats, is commonly cheaper in spring than fall, and will answer just as well as new salt for the next year's supply.

There are other ways of curing bacon, which do well. It is enough if it be well salted, smoked, and dried. I believe, however, that we are as much indebted to the dryness of our atmosphere for the excellence of our bacon, as to our skill in curing.

Tobacco.—The culture of tobacco is so well understood in Virginia that I cannot hope to benefit the planters of it by descanting lengthily on the subject; and those living elsewhere would take no interest in such remarks. The amount made per acre ranges from 400 to 1800 pounds. I judge the average product, in this immediate vicinity, may amount to 600 or 700 pounds. In districts where shipping tobacco is not aimed at, but light sun-cured tobacco is made for manufacturing, and less manure is used, the average may fall as low as 300 or 400 pounds per acre. It is harder to estimate the average cost of production per cwt. If we compute only the simple cost to the individual grower in labor and expense, it might be put down at from $4 to $5 per hundred; and even less than $4, were he to make arrangements to become exclusively a tobacco-planter. This crop may be managed so as to be made without the expense of teams, the grubbing-hoe being substituted for the plough. But the expense of production is incalculable, when we consider its influence on the wealth of the community, by detracting all the manure from other crops, and a large share of the labor, while the attention of the proprietor must be withdrawn from those objects calculated to adorn and enrich his estate.

I cannot describe very definitely any new mode of curing tobacco. I have heard of a gentleman, in Nelson county, who has cured tobacco by packing the green plants in common salt, and permitting them to remain in that condition until such fermentation has occurred as prepares the leaves readily to cure on exposure to the atmosphere. The article thus managed is said to be fine. I know too little about it to detail the process.

What guano will do for tobacco planters, is yet to be tested. It certainly works wonders in some instances. There is now in my immediate neighborhood a field of good tobacco, just coming to maturity, on which no manure except guano was used. The land was so poor as to be utterly incapable of producing tobacco without aid. I believe it is generally thought that to cultivate tobacco alternately with wheat and clover is the best rotation to maintain the fertility of tobacco land.

Fruit Culture.—From my boyhood, I have been an enthusiast in fruit culture. I am glad to be able to say, that this branch of rural industry is receiving increased attention. I have been told that, 70 or 80 years ago, the orchards rarely failed. In modern times, there is seldom a general fruit crop, and often an almost entire failure. We often, in January and February, have weather warm enough for May, and sometimes we have hard weather in March and April. Low, sheltered places were formerly selected for orchards. In such situations, the ground becomes so warm as to swell the bloom-buds too early in the spring. Experience has taught that fruit-trees are most likely to succeed on our high, bleak ridges. This may be owing to the more profound torpidity, or *hibernation*, so to speak, into which the trees and roots have been thrown by the previous cold weather. I would recommend that the planting of permanent orchards be deferred until one can learn by experiment what part of his farm is best adapted to fruit-trees. This can easily be ascertained by setting out early-bearing trees in different localities. There are few years in which fruit would not escape, to some extent, in the best situations. It is, moreover, worthy of inquiry, whether trees procured from the North are not more easily stimulated to early vegetation by sudden changes from cold to warm, than our native trees. Northern trees, however fine their fruit in their appropriate climate, seldom yield good fruit here. I have 12 or 13 acres in fruit-trees, and, while I do not believe I have lost one native tree by the weather, several of Northern origin die annually. Most of them die from the freezing of the sap, bursting the bark from the wood, which happens in hard weather, after one of the warm spells in winter. It has been but a few years since I first saw an apple-tree affected with blight. I have lost no native trees with that disease, but some of those imported are liable to it, and those budded or grafted from them as much so as the parent. My trees are permitted to branch out near the ground, that their bodies may be shaded and the wind operate against the shortest lever. One main stem only is preserved to the top, from which side branches shoot. Large bifurcations cause splitting.

I have long attended to grapes, and have learned the following rules:—The cuttings should be well planted in November: the vines should be transplanted the second year, as large ones become wormy and die. They should be trained on high scaffolds with flat tops, that the grapes may hang beneath

and get air. Too little trimming is better than too much. Trim closely to the eaves of the scaffold, and a little on its top. Dig in manure from the hen-house, well plastered, and sprinkle freely slaked lime on the surface. Vines are more affected than any other fruit-bearers by peculiarities of soil, in their healthfulness and the flavor of their fruit. But few foreign vines do well here. Out of about 60 varieties, sent me by a friend and relative in Bordeaux, none bore well but a few of the *Chasselas* family. The *Pyrenean Chasselas* yielded a most delicious fruit, but they all died in a few years, in spite of my utmost care. I have rarely succeeded in budding or grafting vines, except between the 20th May and 10th June, and I cut off the part above the bud, as soon as I find it has adhered, that it may grow off at once. On the whole, I am fully convinced that the vine may be successfully cultivated here.

Manures.—This is an important subject to the farmer. I regard as the best plan for making and preserving manures from waste, to have a close reservoir for the urine, well filled with charcoal, sawdust, or any other light absorbent, plentifully intermingled with salt and plaster, where the excrement is kept until wanted for use, as dry as the guano in the South-sea Islands. A little ingenuity will suggest contrivances the most convenient to each individual, for effecting these purposes. My sheep and cattle are furnished with houses made by covering extensive frames of timber with straw, piled up in the shape of a "rick." Spacious as these are, I hope, during the winter, to make them so full of pine-leaves, and other absorbing litters, that there will hardly be room for the stock. It is needless to write long dissertations on making manures. We all know well enough how to make, and apply them, too, were we not so anxious to make money on poor land without them. Lime has been used as a manure in some few instances which have come to my knowledge—in some cases with no perceptible effect, which can only be accounted for after an analysis of the soil. It has sometimes yielded no benefit the first year, but much afterwards. Guano is looked to by many as the sovereign panacea for all the ills that earth is heir to. I have known signal successes and signal failures from its use. Much is yet to be learned about it. From 100 to 250 pounds are applied per acre; and I have seen striking effects from only 50. The use of plaster and its benefits are both increasing.

With sincere wishes for your personal and official welfare, I am, sir,

Your obedient servant,

W. S. MORTON.

CHINESE FRUITS, &c.

Washington, August 28d, 1850.

Sir:—It gives me great pleasure to lay before you the enclosed communication from Mr. S. Wells Williams, of China. This paper was handed to me by Mr. W., on the eve of my departure from Canton, with a request that I would bring it to your notice. It contains many valuable suggestions upon the subject of introducing into this country certain vegetable productions indigenous only to China. The well-known reputation of Mr. Williams, in both literature and botany, will, I am sure, bespeak for his letter your careful consideration.

Very respectfully, your ob't servant,

JOHN W. DAVIS.

To the Hon. Commissioner of Patents.

Canton, (China,) May 21st, 1850.

Hon. J. W. Davis:

My Dear Sir:—Having noticed, in late papers, that the project is mentioned of establishing, at the city of Washington, a department for Agriculture, I have thought that you would be willing to bring to the notice of this bureau, (supposing that the recommendation of the President will be acted upon,) the desirableness of introducing into the United States some of the valuable and important productions of China, and encouraging their growth in such parts of the country as are fitted for their culture. Among the plants which are worthy of the attention of this bureau, are the *lichi, whampe,* and *loquat,* among fruit-trees, and the *cassia, camphor, varnish,* and *tallow* trees, among useful trees.

All of these trees occur in the southern provinces of this empire, and would thrive equally well in the Southern States: all of them are indigenous to this country, and, except the *lichi,* none of them have, to my knowledge, been naturalized in any other country. The *lichi* is now grown in Bengal.

The *lichi* (*Dimocarpus lichi*) belongs to the family of the Sapindaceæ, of which only a few plants are natives of America, and they of no great value. The Chinese have 15 or 20 varieties, but there are only 2 or 3 which are distinctly marked, the others being the growth of different districts, and bearing the name of the places which produce them. It has been cultivated for ages in this country, and furnishes a large amount of food to the people, the produce of a single healthy tree often amounting to 4 bushels.

The *whampe,* (*Cookia punctata,*) or "yellow skin," as the name means, grows in clusters, like the lichi, but belongs to the same family as the orange, though, in shape and size, the fruit resembles the cherry. The wood is hard and close-grained, and would serve for various purposes in the arts. The fruit is pleasantly acid, and might be improved in flavor and size by grafting, for it is now, as seen in these markets, often sour, and harsh in taste, and not fully developed. The produce of the tree is not far from the average of 2 bushels, and, under some of the clusters, bearing 50 or more berries.

The *loquat* (*Eriobotnya Japonica*) resembles the medlar of England more than any other fruit, and has been introduced into hot-houses there. It belongs to the family Rassacea, and the subdivision of Pomacea, or apples,

pears, &c. The loquat ripens early in April, in this country, and is more hardy than the lichi or whampe: it is a more acid fruit than the apple, and serves for cooking rather than as a table fruit. Its size and flavor could both be increased, I have no doubt, by cultivation, and the fruit rendered a valuable addition to our list of early spring fruits, which are not numerous. The loquat grows as far north as Fuhchan, but does not produce as good fruit as in Canton.

You are well acquainted with the taste and qualities of these fruits, and are able to judge, too, whether they would repay the labor and expense of naturalising in our own country. I think they would all become favorite fruits, before many years, and, from a comparison of climate, soil, and position of the two countries, I should infer that the shores of the Gulf of Mexico would be as favorable to their development as those of the China Sea. None of them are properly tropical fruits, for even a fall of snow here, in 1835, (Feb. 7th,) did not injure the loquat trees then in flower, nor cut off the crop of the lichis.

The other trees mentioned are valuable for their timber or products. The camphor and cassia both belong to the Laurinæ, or laurel family—the same as the cinnamon, sassafras, alligator-pear, and red bay. The camphor-tree (*Laurus camphora*) grows in Formosa, and the adjacent provinces of Fuhhien and Kwang-tung, where it forms forests, furnishing wood for timber, and camphor-gum for exportation; the latter is obtained from the leaves, twigs, and rootlets, by distillation, and the former from the trunk. Some of the boards brought to Canton are 18 and 22 inches in diameter, indicating a tree of large size. The tree does not grow near Canton city, but occurs most abundantly on the hills in the departments farther from the coast, and living plants could be most easily obtained at Fuhchan and Amoy, where large quantities of the timber are sold.

The cassia (*Laurus cassia*) grows west of Canton, in the provinces of Kwángsí and Kweichau, whence all the cassia fistula exported from this port is obtained. The cassia is not used for timber, nor does it grow to the consideration of a tree, the object being to increase the twigs, and produce as much bark and oil as possible. The manner of obtaining the cassia would be to send a native to Kweilin, in Kwángsí, and let him bring numbers of the plant, in all stages.

The varnish-tree is less known than either of the preceding, but is quite as valuable. It is allied to the sumach and poison-oak of America, and grows about 25 feet high, and the cultivators trim the branches to increase the size of the trunk. The varnish-tree is found across the mountains in Kwángsí, up and down the valley of the river Kan, whence the inspissated juice is brought to Canton in small cakes, for the use of the lackered-ware manufacturers. It has a much wider range, however, than this valley, and is cultivated over most parts of Central China, and in Japan, furnishing the material from which the well-known lackered-ware is manufactured, by mixing it with lampblack, cinnabar, and other substances, to give it a color. There can hardly be a doubt that the varnish-tree would grow in the United States, as far north as Philadelphia; and our manufacturers would soon be able to produce lackered-ware rivaling that of the Chinese: the processes of this art can all be learned in Canton.

The tallow-tree (*Stillingia sebifera*) is cultivated to a great extent at Ningho, Chusan, and the eastern provinces, for the white tallow which surrounds the seed, which is used for and possesses most of the properties of beef-tallow, furnishing candles, cerate, plasters, &c., for housekeepers and doctors: it is not used for cooking so much as some other vegetable oils by the Chinese. Besides being serviceable for economical uses, the tallow-tree is one of the most beautiful shade-trees known in China, and, with a little care, can be made to take a symmetrical shape. The leaves resemble the aspen in shape and color; and even if the tallow should not be thought valuable for its own uses, the tree would form a valuable addition to the ornamental trees of our country. The tallow is produced in considerable quantities, for it is sold at a few cents per pound at Chusan; and, when mixed with wax, forms a good material for candles. Both the living plants and the seeds can be obtained at Ningho, and all the details of manufacture learned there. It is found about Canton, but is neither cultivated for its tallow nor its shade, as the heat here causes it to run to leaf.

There are many other vegetable productions to be obtained in this country, some of them of considerable use, in the arts. Among these may be mentioned, the *swan-chi*, or Chinese ebony, a tree whose wood furnishes a solid and excellent material for furniture, and is much employed in the carved work so skilfully done by the Chinese. It grows in the western provinces, and would require some trouble to procure available plants for exporting to another country. The *sheh-liáng*, a plant extensively grown in this part of China, for dying cottons and silk brown, is worthy of notice, as presenting a new sort of vegetable pigment; it not only dyes the cloth, but almost tans it, as it is very astringent. Many other pigments are known among the Chinese. The native indigo, cultivated in Cheh-kiang, being one of the most common, and probably inferior to the true indigo.

In respect to the best means of obtaining these plants, and forwarding them to America, I can hardly give any definite information. The three fruit-trees can be sent from this port and Amoy, but all the others must be sought elsewhere. The varnish and cassia trees can only be obtained by trusting their procurement to natives, whose time and travelling expenses must be risked in sending them to the districts where the plants grow, and something trusted to their knowledge of what is wanted. Margin, too, must be left for the expense of unsuccessful attempts, and the death of plants on the passage. The three fruit-trees have all been grown in English hot-houses, and, perhaps, specimens can be obtained there also. I should think the object worthy of an attempt; and, if a few hundred dollars would obtain it, the introduction of so many valuable plants would amply repay it. An appropriation of a thousand dollars, to be expended under the direction of the consuls, might be made, and the experiment attempted, if it comes within the duties of this Bureau of Agriculture to apply their funds to such objects. It would perhaps hardly repay the expense to send out a person for such an object, but the man who undertakes to collect them should be encouraged by the assurance of remuneration, if his attempts be successful. The cassia and camphor trees furnish valuable articles of commerce. The exportation of the gum, the bark, wood, and oil, obtained from them, amounting to fully $200,000 annually. The consumption of camphor-wood in China is enormous; and if it grew among the forests or preserves of our own country, would, I am sure, be equally prized: its bulk quite prevents its being carried to America as timber. The manufacture of cassia-oil would, I think, repay the expense of introducing the cassia-tree, and enlarge the consumption of an article of which the supply here is seldom equal to the demand, and

whose manufacture is attended with considerable trouble and expense from the immense amount of fuel required to distil it.

Attempts to enlarge the sources of national wealth, by the introduction of the productions of other countries, belong to a government, and unsuccessful attempts fall easily on a government, though disastrous to an individual. The attempts now making to introduce the cultivation and manufacture of tea into Carolina will certainly disappoint, for the tastes of our people are formed from the Chinese manufacture, and this has never been successfully imitated abroad; and besides, none could compete with the Chinese in the labor of preparing tea for market.

Such would not be the case with the trees I have recommended, for it is their natural fruit and produce which are wanted.

Commending the subject to your consideration, and hoping you will bring it to the favorable notice of the department at Washington, which is referred to above as about to be established,

I am, my dear sir, most respectfully yours,

S. WELLS WILLIAMS.

Oakland Farm, near Springfield, Clarke County, Ohio, November, 1849.

Dear Sir:—It is with much diffidence that I attempt to answer the queries contained in your circular; but so far as my experience goes, you shall have it freely.

Wheat is first in importance, and first on your circular. We have here 10 or 12 varieties, of which only 3 or 4 are under names known out of the neighborhood. That in most general favor, from its productiveness and early maturity, is the "Mediterranean." This has a large berry, with a thick dark bran, and weighs from 60 to 66 pounds to the bushel. It has improved in quality of late years, and, with care in grinding, makes a very fine quality of flour. The old *red-chaff bearded* is fast getting out of favor, from its failure within five years. Though never considered very productive, yet it withstood the fly, frost, and rust better than other varieties. The *Wabash* is a bald wheat, with a very thin white bran, stands up well in low and rich ground, but is not much raised, from its lateness in ripening, and not more than one crop in three is first-rate: weight from 56 to 60 pounds per bushel. A variety has lately been introduced from a neighboring county, under the name of *Shot wheat*, which, I suppose, is a local name, but denoting well its peculiar plump character. It ripens about the time of the Mediterranean; has a bearded and stiff straw, a fine, round, red berry, and will yield nearly equal to the above: the usual weight is 60 to 62 pounds. Other varieties are raised in different sections, where they are favorites. The only serious enemy the wheat crop has to contend with is the Hessian-fly; and that has not troubled us much for the past two years. The weevil has been very troublesome in some parts of the State; but I have not yet seen any signs of it here. The *rust* is its most serious disease, and is, indeed, a severe check to the cultivation of this grain. This year, from the estimates made, there will not be one-third the usual average crop in this State. In regard to change in character, I find a marked difference in quality when raised on different soils; and experienced millers say they can make from 1 to 2 pounds more flour per bushel, from wheat raised in uplands than from the same variety grown on black bottom soil. We consider the medium between the high and low lands, or what is termed here, "second bottom," the best soil for this crop. Not one acre in ten of wheat has any manure applied. A summer fallow, or corn ground after that crop is taken off, is the usual custom. But sometimes two or even three crops in succession are taken off the same land. The common mode is to put the manure on the fallow ground, and plough it in when the grain is sown. The straw is very little valued, and often burned in the field, and is seldom taken into account as food for stock. The average crop of this and the adjoining counties cannot exceed 14 bushels per acre; and this, I think, is about the average of the State.

Oats.—These are considered a secondary crop in this section. The varieties cultivated are the *common dwarf*, the *side oats*, and the *Tartarean*. The first is not so productive as the other two, but stands up best through our summer storms. The second is most productive, but grows tall, and is very liable to fall. The third is a new variety, introduced within a few years, and is liked so far as known, from its stiff straw and large-sized berry. The straw, from its softness, is used as food for stock. This grain is generally considered of about three-fourths the value of corn for feeding to stock, but is preferred to corn for horses. Standard weight, 33 pounds.

Rye.—There are two varieties in use, known as the *white* and *black* rye. It is principally sown on low, rich soil, which will not produce good wheat, and is quite a certain crop, yielding 20 to 25 bushels per acre. But, from the low price it bears, compared with wheat, it is not much raised. It is nearly all consumed in distilling; and but a small portion is ground for bread. Near towns, the straw is expected to pay the expense of threshing by hand.

Corn.—We have many varieties of this grain, mostly crosses between the gourd-seed and small flint. Our seasons are not long enough for the first, but a larger and later variety than the latter is preferred for this climate. We find by experiment, that this grain soon becomes acclimated; but, in so doing, it loses its peculiar characteristics, and becomes larger or smaller, as the case may be. With good cultivation, our medium lands will produce from 50 to 75 bushels; but the average of this county will not exceed 40 bushels. It is generally ripe enough to cut up on the 15th or 20th September. Our uplands produce the heaviest grain, but the bottoms yield larger stalks and ears. I have never tried any experiments to test the comparative value of the husk and blades; but have observed that sheep, if they have plenty of both, will often refuse the husk entirely; while cattle will eat the husk first, and then the blades. We find that ground corn well repays the extra expense; and the profit of cooking is illustrated every day at our distilleries, where, after the process of distilling, the refuse is found to be equal to the grain in a raw state.

Hay.—We generally consider clover best for cattle, and timothy for horses; but most of our hay is composed of these mixed. Clover is chiefly raised for pasture, or as a fertilizer, and timothy is only raised alone when intended for market. Herdsgrass and timothy is the common mixture for our natural meadows, where the first forms a solid turf, and eradicates the natural grasses. The average produce of pure timothy per acre, I should say, does not exceed 25 to 30 cwt.

Root crops.—Irish potatoes have always succeeded well here until within 2 or 3 years, since which time they have suffered much from the rot. The average yield in field culture does not much exceed 100 bushels per acre. The sweet potato requires a warmer soil and climate than we have here to succeed well. Turnips are rendered very uncertain by the fly, and warm, dry weather at the time of sowing. Beets, carrots, mangel-wurzel, and artichokes are raised to but a limited extent, as food for stock; and, from experience, I think their culture is not profitable, when labor is so high and other fodder so plenty.

Horses and Mules.—Of the number in the State, I have no data upon which to base an estimate. The average value of working-horses here is about $50, and of mules over 3 years old, $60 to $65. Very few of the latter are used, though they are undoubtedly cheaper than horses.

Cattle.—At 3 years old, if of common stock, their price ranges from $15 to $20 per head; if of improved blood, from $30 to $40. Our cattle are driven to the eastern part of Pennsylvania and New York. Six dollars per annum is the usual estimate of the cost of feeding stock from 1 to 3 years old. The Durhams seem to be the favorites, of which we have some very fine specimens, chiefly descended from the Sciota importations.

Sheep.—Wool-growing is quite an extensive branch of industry in this part of the State. Ninety thousand pounds of wool have been bought in our county town the present season; and the aggregate clip of the county is from 75,000 to 80,000 pounds. Nearly all our flocks show the crosses of the Merino and Saxony with the common sheep of the country. From 3 to 3¼ pounds is the average clip. The cost of keeping through the year is about 50 cents per head.

As my experience in farming has not been of many years' standing, it must be my apology for any errors that may exist in the above report. Such as it is, however, it is most respectfully submitted.

Yours truly,

J. MORRISON WARDER.

Hon. Thomas Ewbank,
Commissioner of Patents.

TRANSPLANTING FOREST-TREES.

Report of the Committee of the Rockingham Farmers' Club, "On Transplanting Forest Trees."—Submitted April 4th, 1849.

The kind of Trees.—Above all others, for the street, the elm is preferred. For beauty, gracefulness, *grandeur* even, it has no equal in New England. Besides, it is hardy, long-lived, easily procured, and free from the attacks of insects and disease.

The rock maple comes next—a beautiful and stately tree, though somewhat precise and rigid in its outline, and of much slower growth than the elm. It is hardy, bears transplanting well, affords an impenetrable shade, and, alternating in rows with the elm, by the wayside, or mingling in groups, where there is room for them, it affords a beautiful and desirable variety. Neither the red maple nor the white maple can be compared with the rock maple. They are smaller, shorter lived, less hardy, and altogether inferior to it in grace and beauty, and are recommended only where there is room for variety.

The white ash is a tree which seems not to be appreciated, and is one of our finest trees; and, for size, durability, and beauty, entitled to the third place in our list.

Then we have the bass, or American linden, not surpassed by any tree in the richness and beauty of its foliage. A tree not sufficiently hardy, perhaps, for the street, but "beautiful exceedingly" in a lawn or private grounds.

The beech is a tree deserving its classic fame, but too full of local attachments and home feelings to survive removal without great care—and the walnut is liable to the same objections.

Where space allows, as in public squares and lawns, avoid rows and circles, and mathematics in general, in tree-planting. Avoid sameness in kind, and size, and shape, and endeavor to imitate the cunning hand of Nature in tasteful irregularity of grouping.

Time of transplanting.—All deciduous forest-trees may be removed at any time after the fall of the leaf in autumn, and before the bursting of the buds in spring. If removed in the bright, warm days of spring, their roots should be carefully shaded from the sun, and, in fall and winter, they must not be exposed naked to severe cold.

Preparation for setting.—For trees upon the streets, dig the holes 6 feet in diameter and 18 inches deep, *before the trees are procured;* replace the subsoil with good soil, and procure enough more and deposit near, to fill up level with the earth, so as not to use the sand or gravel from the bottom; and have ready two pieces of joist or plank 4 inches wide, with proper strips of board for protection of the trees. Do all this at your leisure, before the trees are dug. It is the largest half of the whole operation, and should never be left to the hour when, returning late, weary, and heavy laden from your labor of procuring them, you will have neither time nor strength to perform it carefully and speedily, and when your poor trees, like so many fish out of water, are panting and suffering for a return to their native element.

Selection of Trees and digging up.—Procure trees from open land rather than from thick woods, if possible, and those of thick and low growth rather than tall and slender trees, and be sure they are young and growing. It is generally advised to take them from land similar to that where they are to be set; but this is not essential. Elms from swamps and bogs, transplanted on dry lands and pine plains, are now growing all about us in Exeter. It is of more importance to take them from such soil as will allow their removal with least injury to the roots, and, therefore not from land filled with stones or large roots.

Some writers insist that the trees be marked before removal, that they may be set in the same position as to the points of compass as before; and the *theory* is reasonable, though the practice, however it may promote their growth and comfort, is not essential to their life. They soon "get the hang" of their new position, if the theory is disregarded; while Sam Weller's reason for a father's whipping his boy, "It can't do any hurt, if it don't do any good," may be given in support of the practice.

Having selected a tree of about three inches in diameter, with a sharp spade, an axe, and a bog-hoe, dig a trench about two and a half feet from it, completely round it, deep enough to cut off every root; then dig under it till it is loosened, using no crowbar or lever to gall and split the roots, and carefully preserving all the small roots and fibres. Load the trees,

when dug, upon a long wagon, putting pine boughs under them to prevent rubbing, and cover the roots from the sun. About a dozen such will make a load for one horse, and three or four smart men can dig and get them home in half a day.

Trimming and setting out.—With a fine saw and a knife, cut off smoothly all the broken roots. *Next, cut away one-half, at least, of the top*, either by shortening the limbs, or cutting part of them away entirely, as the shape of the tree may require. We are aware that this is disputed territory, and take the responsibility of holding it. We suppose that the sap is supplied through the roots, that in hot, dry weather evaporation goes on rapidly from the leaves, and, if that evaporation exceeds the supply of sap, the leaves wither and the tree dies. But there are other reasons for lessening the top. The tree has grown in a sheltered position, protected from the rude "winds of heaven"—perchance in society, resting its long arms on the shoulders of its friends and kindred—supported in the loving embrace of its companions. It has had no discipline or preparation for the cold, and lonely, and trying exposure of a public position. But now you have cut away its old supporters—literally *root and branch.* With its full top exposed to the tempest, the small, newly-formed roots, which should attach it to its new position, are constantly broken off, and it cannot live. This is the cause of the failure of many attempts at transplanting. Plant the tree no deeper than it grew before. Nature, which has attended to growing trees some six thousand years, understands well how they should be set, and cannot be improved upon. Drive your stakes before the roots are covered, that you may not injure them. Then, having carefully placed the roots in their natural position, fill up with finely pulverized soil, and see that no space is left beneath them. When the roots are fully covered, place about half a bundle of straw, or as much hay over the whole surface of the hole, and cover it with soil, leaving in spring a little hollow about the tree. If you plant in the fall, make a little heap of earth about the tree to turn off the water, and remove it the next spring. The straw will prevent the evaporation of the moisture about the roots and keep the soil around the tree light for several years: it tends to prevent the growth of weeds and grass, and admits the free passage of rain, or water artificially applied. Do not omit this precaution; it is almost essential on sandy land.

Care after planting.—If you plant trees in a public street, do not consider the work complete until they are protected from animals, as well as from motion by the winds, by securing them with stakes, as before suggested. A strip of board on each of the two sides of a tree, or a strip of leather put round it and attached by a wire to each stake, will protect it sufficiently against the racking of the winds, and against roving cattle, which take delight to find a new tree to rub against. But we may still utter the prayer, "Save us from our *friends*," for many of them seem to think that trees are principally useful as a means of *securing horses.* Trees then, near your dwellings, should be boxed up about seven feet high, if you do not intend to lose both your friend and your tree. He will tie his horse to your tree, and the horse, of course, will amuse himself with gnawing the bark. You will be exceeding vexed, and possibly rude, and will be *consoled* by the assurance that he never knew his horse to do so before; and you will part, your friend grieved at the accident, and you wishing him and his horse at the end of their journey.

If a drought comes in midsummer, such as those forgetful people, the "oldest inhabitants," do not recollect to have seen—and such seasons are nothing unusual—if then, once a week, you give the trees a copious watering, it will be an act of generosity which they will not forget; but, if planted according to the foregoing directions, in ordinary situations, nineteen of every twenty of them will live with only the water from the clouds to moisten them. We believe it to be not only unnecessary, but a positive injury to trees to water them daily.

Transplanting Evergreens.—There are no trees more beautiful than the hemlock, the white pine, the spruce and the fir-trees of our own hill-sides, and yet comparatively few of them are seen about our dwellings. The reason is to be found, partly in the want of a just appreciation of what is so common, and partly in the idea that this class of trees cannot be successfully transplanted. This idea is entirely erroneous. In the month of April, 1847, 140 white pine trees from 5 to 8 feet high were transplanted in Exeter, only one of which has died in consequence of the removal.

In the moist climate of England, the summer is said to be the best season for transplanting evergreens; but a variety of experiments have satisfied us, beyond doubt, that this is not the case here. The method to be pursued is this:—Select trees on the open plain, and, with a spade, cut down around them, leaving a circle of turf, two feet or more in diameter, about each tree—and then lift the tree and set it upright in the wagon, with the ball of earth unbroken.

At the place of planting, a hole is to be made, corresponding with the ball of earth, the soil at the bottom made light, and the tree set in, and with a little earth thrown on and pressed down, and the work is done.

Care must be taken to load the roots with stones, or by driving a short stake by each tree, and confining it, that the wind does not upset it. Evergreens should not be much pruned.

Their foliage is covered with a gummy substance, so that evaporation does not go on so rapidly from them as from deciduous trees, and they do not rapidly recover their beauty of form, if mutilated.

Evergreens should be planted in groups, both for beauty and that they may be partially shaded and sheltered. Plant the evergreens of our own forest. In no way can bare walks be so readily screened or the stark and blank landscape so beautifully variegated and adorned, as by setting, here and there, little *vases* of the white pine and hemlock.

Transplanting in winter with balls of earth.—The best of all methods of moving trees of any kind is that suggested in the above title. The process may be described in a few words:—Late in autumn, dig a trench completely round the tree, at a distance proportioned to its size, cutting off all the roots, and digging under the tree, but not so as to loosen it: then dig away the earth on one side of the hole, so that a shed, or drag, may be backed down under it: place some straw or leaves in the bottom of the trench, or cover it with boards, that the bottom may not freeze too hard. Leave it until the ball of earth is frozen hard, and, when there is a little snow, remove it. It will, of course, be necessary either to dig the hole for receiving it, before the ground is frozen, or to cover the place intended for it with straw, that the hole may be made in winter. In the former case, a few loads of soil, with which to fill up, may kept in a barn-cellar, or otherwise protected from frost. Great care should be taken to fill compactly every crevice about the ball in setting, and it is well to confine the tree to an upright position, by braces from the ground against its lower limbs, or by other

means, that it may not lean when the frost comes out of the ground in spring. By this process, we have known elm-trees of 12 and 18 inches in diameter, and hemlocks 25 feet in height, removed with perfect success.

Indeed, if the work is done with skill and care, the tree, on *awaking* in spring, will scarcely know that it has changed its place, and will soon become entirely reconciled to its new position. In this mode, little pruning is necessary, and most of the top may be saved, as the greater part of the roots may be preserved.

The weight of an elm-tree a foot in diameter, with a ball of earth 6 feet across and 18 inches in thickness, would be, probably, 5 or 6 tons; and, in order to execute the work properly, a set of ropes and pulleys would be found convenient. Trees of 6 inches in diameter may be readily moved with a yoke of oxen and the implements commonly at hand.

In conclusion, we would say to all, *plant trees;* let every *young* man plant trees, that he may have something ever near to bring back pleasing recollections of his youth—something, when he is an old man, that will seem of his own age, and sympathise with him, and look on him with a familiar face, that he may not feel quite alone among a new generation. Let the *old* man plant trees. They will, perhaps, be beautiful in his own time, and entice him to remain longer where there is still something left to interest him, and where he may still be useful; and, at least, they will keep alive in the minds of men the memory of one who lived not for himself alone.

For the Committee,

H. F. FRENCH, *Chairman.*

Exeter, N. H., April 4th, 1849.

Talladega County, Talladega P. O., Ala., December, 1850.

Sir:—Having received your circular, I feel disposed to respond, although a small and inconsiderable farmer. The information sought after is of so great importance to the agricultural interests of our common country, that I feel regret that my means of imparting information on the subjects of inquiry presented in the circular are so exceedingly limited, being restricted to the narrow limits of Talladega county, in which few of the subjects of inquiry are cultivated, and even those with more labor than skill; for, as yet, the Talladegians have not turned their attention to scientific agriculture.

The county of Talladega, in this State, (Alabama,) possesses as many advantages as any part of the country I have seen. The valley is chocolate-colored soil, of limestone and stiff clay foundation, and, therefore, well adapted to the cultivation of wheat, oats, Indian corn, tobacco; and the red valley lands of Talladega county resemble, in every point, the red lands of Morocco, in Africa; the climate is precisely the same. John Gray Jackson, who resided at Mogadore, as consul-general, for 12 years, says "that a crop of wheat would feed the entire people for seven years. But the government of Morocco does not admit exportation, except as a special favor, and thousands of acres are left unreaped on the fields." Were it not for that great Southern staple, cotton, (the pest of the age,) Talladega county can compete with any grain-growing part of the United States. When the price of cotton is a little enhanced in value in market, all improvements are dropped, and the whole people rush into the cultivation of that article. No attention is paid to manure.

Bordering on our valleys, we have pine land resembling the pine lands of Georgia and Carolina, affording valuable timber, and the best kind of land for grazing; and when we consult the histories of the pine-clad hills of Sweden and Norway, that have done more for those countries than the rich lands bordering on the Danube and the Vistula, we are compelled to consider them the most valuable land we have. These fine hills abound in iron ore; copper veins have been discovered; gold, marble, and lead are found on those hill lands of pine and oak. With all these advantages around us, we will direct your attention to our agriculture.

We have an agricultural society, called the Talladega Agricultural and Mechanical Association, that has existed some five years. The late Colonel Taul was president at the time of his death, last June. The duties of secretary devolve on myself. This society awakened the attention of the people for some time, and a spirit of improvement was aroused among farmers generally. Very flattering reports of the productiveness of our county were handed in and read.

We have a great variety of wheat; the most successful is called the Orleans wheat. It may be sown as late as December, and succeed well. The usual time of sowing is from the 20th October to 20th of November. This variety of wheat may be sown so late that it escapes the ravages of the fly, and it comes on and ripens so early, it generally escapes the rust, while other varieties are more or less injured by both. The best manner of preparing land for a wheat crop, if upon stalk land, is to break the land deep, subsoil it, level the surface, by drawing a harrow or large brush over it; then seed down the land, I would say, from 1 to 2 bushels per acre, according to the strength of the land, and plough it in deep with a very small plough. In March, upon pine-hill land, 20 bushels of lime per acre should be spread on the field; and, in the last of April or middle of May, about 50 bushels of charcoal per acre will secure the crop against rust, and increase the product of the wheat crop. Wheat cultivated in this way is always secured against the grub, wireworm, and fly, as well as the rust; and the thinnest land will average 25 bushels per acre, where its usual product is not more than an average of from 8 to 10. The quantity of wheat per acre will diminish if sown, and continued to be sown, upon old lands, in the usual way. The price of wheat in Talladega is $1.50 per bushel. As a rotation crop, wheat succeeds better after cotton than any other crop.

We have a great many varieties of corn, some highly spoken of; other varieties preferred by different people, according to fancy. The yellow-flint stands, in my estimation, the highest, though not approved of, for its color, by others. It grows off freely, ripens earlier, stands drought better in our Southern country than any variety I know, and yields more on the field, from the fact that it can be planted much closer than other varieties. I have made an experiment by blending the yellow flint with the red-blaze variety, and I have succeeded beyond my expectation—a sample of which I will forward to the office. The *rationale* of the experiment is this: the yellow flint was considered too small, although it possessed more oil and saccharine juices than the other varieties, that contain so much starch and gluten, with woody fibre, and are affected severely by drought, grow late, and exhaust the soil considerably more than the yellow flint. Now, blend the varieties, and you have the very corn desired; one that grows well upon thin land,

may be planted very thick in the row, bears drought, matures early, possesses more saccharine matter than the other varieties, and makes a larger corn than the yellow flint, possessing all its desirable qualities. The manner of cultivation is, simply to subsoil the field well in breaking; lay off the rows 4 feet wide, and subsoil the furrow for planting, by running a deep furrow in the bottom of the one intended for planting; give 2 feet between the stalks in the row, and cover lightly, not more than an inch deep. I prefer the drill planting to hill planting; it is the most convenient way, and easier cultivated, with a considerably greater production from the same field, as well as a less exhausting manner of cultivation. When the corn is up, just take a side-harrow, or cultivator, and run by the side of the plants, filling nearly up the furrow made in planting. Two harrowings and one ploughing are sufficient to insure 80 bushels of this variety of corn to an acre, on even tolerable land, with a favorable season. No hilling or hoeing is necessary, if the harrowing and ploughing have been done properly.

The best method of feeding corn to stock is by grinding and cooking. Hogs particularly will fatten on half the corn ground and cooked, that they would require fed to them whole; that experiment has and will succeed in every country, and has been long established by even common sense. The manure formed by feeding 20 bushels of corn to hogs, carefully saved and skilfully applied, will make 40 bushels of corn to the acre, where 25 would grow before.

My experience about rye, peas, and beans is that they are fertilizers or renovating crops; they, however, are not attended to in Talladega. No crop equals the pea crop as a renovator; it takes its own nourishment from the atmosphere principally, while its vine protects the land from the exhaustion of exposure to the sun.

Cotton, our great staple, has experienced a great falling off this year, owing to the unfavorable season. The average yield of cotton is 1000 lbs. of seed-cotton to an acre; though the valley will yield considerably more to the acre. The chocolate lands produce cotton finely. The cost per pound is something like 3 cents. All crops do well in rotation after cotton; various experiments have been tried to prevent the rust, army and boll-worm; but none have given general satisfaction, so as to command confidence. The most approved method of cultivating cotton is to plough deep, subsoil the whole field, and then ridge, plant shallow, and cultivate lightly. Cotton land can be improved without resting, by manuring deep, subsoiling, and imbedding the stalks, limbs, &c. in a deep furrow, or subsoil in the middle of the old rows, make the new ridges on the subsoiled furrow, containing the old stalks and limbs, with a little scrapings from the barn-yard and lots, or even scraped up in the woods, where leaves and litter are rotting, will not only keep a cotton field up, but will enrich it every year, though constantly cultivated. Cotton-seed is a great fertilizer, equal to any thing known, when properly applied to either wheat, oats, or corn: it makes splendid food for sheep, cows, and hogs, if boiled with meal.

Rice I have tried upon stiff red-clay upland, and I found the production to surpass my expectation. My experiment was on a small scale, but sufficient to show me what could be done by the cultivation of rice upon upland. I planted a piece of ground in rice, 60 feet by 20, that produced 12 bushels of rice without any extra cultivation, beyond drawing a furrow, and dropping the seed, and keeping down the weeds. Rice is one of the most productive grains in all the Southern country, and will be cultivated to considerable extent, if a market can be found for it, or if cotton should cease to be a staple. Clover and herdsgrass are beginning to receive attention in this county, and promise to do well; nearly as much so as what is grown in more northern latitudes. Thus, you see, that seeds and plants meet in Talladega county, as extremes of latitude from north to south, and flourish side by side. I have seen an account of a clover-seed in the Patent Office, from Brazil, I think, that was furnished by our consul, residing at Valparaiso, termed southern clover, which succeeds well in Florida with Governor Brown. If any remains in the office, please forward the seed to me for the benefit of our Agricultural and Mechanical Association.

Yours, respectfully,

J. A. BROWN.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Williamsport, Warren County, Indiana.

Sir:—A reply to the Agricultural Circular received by the subscriber, may very properly be commenced with some mention of the season, of the products of which it asks information. The winter, which, for six weeks in January and February, had been unusually mild, resumed its accustomed severity in the latter half of the latter month, and continued without abatement till the middle of April. Pasture to sustain cattle did not occur till the 1st of May. The planting of corn was unusually delayed, owing to the backwardness of the season. Much corn never came up, and the stand generally, in this section, was very poor. Then succeeded a period of drought, stunting the meadows, and dwarfing the corn, varied by but a single shower, sufficient to wet the ground to the depth of 4 inches, until about the 4th of July; from that period till the latter part of the fall, the rains were more seasonable, but never such as to swell the streams, or replenish the wells. Our river (the Wabash) was never lower within the memory of the residents of this section. While the heat of summer was uniform, and continued, it was never extreme.

Wheat thrived and yielded well; oats were a short crop.

The settlement of this county cannot be said to have commenced till 1827. Its agriculture, so far, may be characterized as diffuse, improvident, and exhausting. It is only within a very few years that the necessity of a more economical mode of farming has at all been felt. Within the last three years, clover has been used to manure, and as a preparation for wheat, by a few persons. Tradition says that, in the early settlement of the country, no difficulty was felt in raising wheat, either in timber barrens (oak openings) or prairie, the crop being certain, and the yield large: now, raising wheat on the prairie is more uncertain than the yield of a lottery ticket, or the result of an election bet.

The varieties of wheat most in use in this county are the Columbian or Mediterranean, the golden chaff, the China, which is a yellow chaff and heavily bearded, and the bearded red-chaff. The popular names by which they are known in the neighborhood are given, the subscriber and his informants being alike ignorant of their botanical appellatives. The first is the favorite variety, being earlier to the harvest by a week; both it and the golden chaff have less blade and fur, and are believed to be less liable to

rust for that reason. Wheat is sowed, in this region, from the last of August till the middle of October, with no preparation beyond a ploughing from 2½ to 3 inches deep. Much wheat is put in on corn ground with a shovel-plough, the corn being afterwards cut up and shocked. Harvest-time seldom extends beyond a week, and varies from the last week in June to the first week in July, according to the season. Wheat yields as low as 10 and high as 25 bushels, and may be said to average at 12 bushels per acre. It is sown in amount from a bushel to a bushel and a peck to the acre, though an additional bushel of seed not unfrequently adds 5 or 6 bushels to the yield. The product per acre falls much short of the earlier returns, but has advanced on that of more recent culture. It succeeds best on fallow or sod. No remedy for the fly is known or attempted. Weevil is not here. Those among us who know it in Ohio, believe that wheat is best secured against its depredations by threshing, and putting up in the chaff. The average price hereabout may be stated at 65 cents.

The undersigned once believed the gourd-seed corn to be the preferred variety; but further inquiry has shaken that opinion, without establishing any other as a preference. With some, the smooth white is most esteemed. It has a stiffer stalk, and is less liable to break in high winds than other varieties—a quality not without value in a prairie country. The yellow corn, being some 3 cents above white in the market, being as easily raised, yielding better in the opinion of some, on account of its smaller cob, and being easier husked, because a smooth grain, than the white, will always enlist the preference of some; and, of that kind, a long variety, with no special designation, but having an ear from 10 to 13 inches in length, is much affected by some who have strong land. It has a large cob, which makes it measure well in the wagon or barrel, and would be much more cultivated for sale, were it not that, taking the entire season to make itself, it is liable to be nipped by early frosts. Forty bushels of corn are claimed here to be the average product per acre, and it is, perhaps, not far from the truth. A hand, at $12 per month, for 3 months, in cultivating, and 2 in gathering a crop; a team worth $120, which will pay its expenses during the balance of the year, and is therefore only chargeable with half the interest on cost and half the annual depreciation, amounting together to $10; implements, the wear and tear of which will not exceed $10 per annum; and the board of a hand for 22 weeks at $1.50 per week,—form the elements for estimating the cost of cultivating 20 acres, which will yield 800 bushels, worth, at market, 30 cents per bushel, chargeable, of course, with the expense of marketing, and to be credited with the value of the stalks, or fifty cents per acre.

A shallow plant, in close rows, say 3 feet apart, which lays the grain liable to the germinating influence of slighter showers, and shades the ground at an earlier period of the season; a harrowing as soon as the corn is up; a ploughing and cross-ploughing, first with one and next with two furrows in the row, making in all four ploughings with the shovel-plough,—is the course pursued by the best corn-raisers. There is no point in the culture of corn about which men are more generally agreed, in this section, than the propriety of constantly stirring the ground in dry seasons. It was abundantly demonstrated in the past summer. On the 4th of July, corn, on an average, was only knee high, owing to the drought described in the early part of this communication. But, though stunted, it was, owing to the constant stirring of the ground, free from weeds and of a good color. That week there fell a plentiful shower, and the corn, which had grown below while unable to grow above ground, sprang up as if by magic, and, in a week's time, a man and team could not be seen while tending it.

Corn, hereabouts, is only fed whole. When fed to cattle, followed by hogs, this course is far less wasteful than it would seem, the hogs consuming the corn which passes undigested through the cattle. When this is done, it is customary to have two enclosures, in which the cattle are fed alternately—the hogs occupying that which the cattle had been fed in on the previous day. This, however, is said by some to be unnecessary, as the hogs, after the first few days, give preference to the swollen and partially digested grain that has passed through the system of the cattle.

There are four varieties of oats cultivated hereabouts:—the black, the white, the barley, and the side oats, each of which has its advocates. The average products are 35 bushels per acre. It is less exhausting to ground than corn, and, if followed by the latter, the crop of corn will be better than that which preceded it, other things being equal.

The average yield of hay is believed to be 1¼ ton to the acre: timothy, clover, and herds-grass are all used in laying down meadows: the cost of hay per ton is from 60 cents to $1.08 per acre, not reckoning the cost of land.

A good calf costs $4 at weaning, the expense of rearing which may be averaged at $3 per year, till 3 years old, when, at an average, a steer will be worth $16.

Wool-growing is not profitable in our section: the number of lambs saved is not over one-half.

As to hogs, a cross of the China and Russia hog is believed by some to be the best, having sufficient size, and a kindly tendency to fat. Twenty-five bushels of corn will make a hog weighing 220 pounds, with range of field and woods.

Owing to the circular being mislaid after the information was collected, this communication is delayed till this time. A more prompt attention will be given to it another time, if it is deemed desirable.

Very respectfully yours, &c.,

C. R. BOYER.

THOMAS EWBANK, Esq.
Commissioner of Patents.

Palmyra, Wayne County, N. Y.

Sir:—In compliance with your circular of August last, I will cheerfully contribute my mite. I am a mechanic, a tailor by trade, and continually occupied: therefore, but little need be expected; but, so far as I have farmed it, I have been a close observer of results. In the fall of 1836, I purchased 16 acres of meadow and pasture land, situated half a mile out of our village, north of and adjoining the Erie Canal, which leaches more or less and wets the land on the surface some considerable distance. The soil, black mould and clay bottom on the low land, and gravelly loam and clay bottom on the high land: the land was in a bad state, cold and wet, stony and full of scrub-bushes, elders, &c., and very uneven surface. I paid $35 an acre for it: there was not a rod of good fence on it. I commenced work in the spring of 1837, and have made more or less improvements every year since, until it has become like a house-floor on the surface, and has averaged two and a half tons per acre of good timothy and clover hay yearly, for the last ten years. I divided the land in three lots the first season, and made all my outside fences with swamp-oak posts and hemlock boards, costing $1 a rod; the best and cheapest fence that a farmer can make in this section of the country: swamp-oak posts will last from 20 to 30 years, if sawed from live timber; the same with hemlock boards. I have paid out in improvements, during the time, say $65 an acre, all told, in *fencing, grubbing, taking out stone and making blind ditches with them, seeding, &c. &c.*, making a cost of $100 an acre, exclusive of all manuring. As I said above, it has averaged two and a half tons of hay an acre, of the best quality, at an average price of $5.50 a ton, delivered in this village, from the meadow, when cut, or $2 for fall feed, at 37½ cents a week for horned cattle, making an income of $15.75 an acre. I have, until the last two years, hired it cut and delivered for $3 an acre; but I find I can please myself and customers better to hire it done by the day, at a cost of $4 or more, superintending it myself. The usual price of labor is $1 a day of ten hours, for a man and board himself, and $2 for a man with horses and wagon, excepting in haying and harvest, when they work more hours and higher wages, 25 per cent. or more. The land now clears me about 12 per cent. on $100 an acre. *I have uniformly kept Dr. and Cr., and charged $1 a day for my own services, and interest on the investment,* striking a balance on the first of January in every year, and *adding one year's interest on the balance until it has ceased to be a debt.* On the first day of January, 1850, fourteen years after my purchase, there was a surplus of $40, giving me 7 per cent. interest on all costs and charges from beginning. *The land and $40 in cash as costing nothing.* This land has been brought to its present state by many blind ditches leading into a large open ditch running through the field. The blind ditches are laid with common stone, of the smaller size, taken out of the land, laid so as to leave a narrow trench from 4 to 6 or 8 inches, capped with suitable stones, and well chinked in with the smallest stones and covered with straw, and the earth round up over it, and seeded. The wettest part of it, next the canal, has been well covered with chips and dirt from wood-yards and leached ashes at the rate of fifty good wagon-loads on an acre. Twice during the time, (fourteen years,) I have covered the whole with a good dressing of horse-manure, put on mostly in September, at the rate of fifty large wagon-loads on an acre, at an average cost of 50 cents a load when spread. Good stable-manure, from horses fed mostly with grain, is decidedly the best; and I prefer to put it on as soon after the hay is cut as I can, thereby keeping the ground moist, so the roots will not dry out during the hot season, and keeping them warm and in a growing state through the winter. It does well to put on coarse manure in swales and low places, in the spring, if it can be done without cutting up the land too much in getting it on the spot wanting it.

From all this, I learn that quite wet, cold land can be made dry by blind ditching, the sourness taken out with leached ashes, and made warm with dirt and horse-manure, making an abundant crop of good timothy and clover hay, where naught but short, sour grasses and noxious plants grew before. I seed with timothy only, sowing twelve quarts on an acre: clover comes in of itself, more or less, in a few years after seeding. The poorest acre there was of this land next to the canal, now rolls out a windrow of a swath, mostly clover: it has never been ploughed. I have sowed timothy, and dragged it in and covered it at the same time with horse-manure: this is the land that had the chips and ashes on it, as well as manure. It pays well to cover all newly seeded land with a light dressing of horse-manure the first fall after seeding: it takes much better. Red-top hay is good for horned cattle, and does better than timothy on all low, moist land, or that which is often wet through swales, &c.; but timothy is most decidedly best for horses.

One word in regard to the manner of securing a crop of grass or making hay. Timothy should not be cut until it will shell a little by the process of making it hay. All that is mowed in the forenoon, *in case the sun shines*, should be spread before going to dinner—the thickest of it turned over by all hands immediately after dinner. Then, let some rake round the field with a hand-rake, and pitch it in from the fences, and others mow: from 2 to 3 o'clock, P. M., put the horse-rake in motion, and men enough to cock it up after them. Hay makes in that way better than in any other that I have tried. Put up in the hot sun, in moderate sized cocks: the next day, as soon as the dew is off, it is fit to deliver. In pitching it on and off, it dries out the sweat and makes a perfect cure. This cannot be done, however, if cut too green, neither will clover or red-top cure in this manner sufficiently, without opening the cocks to the sun before delivering. I have 3¼ acres of similar land, that I have managed in a manner similar to the former: for the past three years, I have more than doubled the crop of hay and improved the quality: this year, I delivered 12 tons 98lbs. of hay from it; that is, nearly 4 tons an acre: it was well cured. I find, by several experiments in weighing hay newly made, and weighing it over in the fall or winter, that it does not shrink or fall short in weight over 8 or 10 per cent., if properly cured. It is far more profitable to put land in a high state of cultivation and keep it so, than to work it in a cheap and slovenly manner, getting but half a crop, and that of a poor quality.

I have three acres of corn ground, joining this last piece of meadow, clay and sandy or gravelly loam: it had been pastured many years. I had it broken up in the month of November, in 1846; it froze hard in a few days after: that killed the wireworm, which so often spoils a field of corn the first and, sometimes, the second season. After breaking up, it was planted on shares two years: the soil rich and mellow. They raised less than 100 bushels of ears on an acre. I took it in hand myself, put on 150 wagon-loads of manure in the spring of 1849; spread it evenly over the whole field; ploughed it once; marked it with a horse, and a piece of scantling with four pins in it, at a suitable distance for the rows apart; planted on the surface, all but half an acre of swale that was soaked from the canal, which I ridged up while wet, and planted on top as soon as sufficiently dry. That gave me the best corn on the field, where none of consequence had grown before: my rows were 40 inches apart, running east and west, and the hills only 20 inches in the row. The philosophy of that is, that it takes the morning and evening sun more, and, at noonday, less. I pulled out at second hoeing all but two stalks: it grew tall and rank, and stood the drought of that season much better than any other corn about: it did not ripen as well as thinner pieces. I planted the 12-rowed Dutton: had 125 bushels of ears an acre; but few pieces went over 100. The labor of planting and hoeing in this close manner is more than the gain. I planted it again this season, selecting the best ears of last year's crop; broke off the small ends before shelling; ploughed once, and planted the 4th of June; rows 3½ feet each way: it ripened well, and gave me 144 bushels of ears to an acre, although planted two weeks later than my neighbors, pulled out to four stalks at second hoeing: had 21 loads of pumpkins each year, at $1 each, and 25 cents a bushel for corn in the ear delivered.

Respectfully,

BURR BUTLER.

Hon. THOMAS EWBANK,
Commissioner of Patents.

Hunter, Green County, N. Y., December 20*th*, 1850.

Sir:—I owe you an apology for my delay in reporting my potato crop, which escaped in a good measure the rot, while my neighbors lost nearly their whole planting. I wished to see how they would keep in the cellar, before communicating further with you. I planted the most of my seed on sandy bottom land, oat stubble, dressed before ploughing with a good coat of fresh stable-manure, early in May. They were hoed twice, and, after each hoeing, I had a boy, 12 years old, pass along the rows, and scatter a handful of plaster over the stalks. The hoeing was easy, and my laborers covered the hills too deep, as I thought. This piece ripened in September; the yield was light, and about 30 per cent. of them were more or less affected by the dry rot, generally lightly, next the skin. The other was a small piece, planted on upland, naturally wet in the spring, which had been turned from the sod in 1849, and had a dressing of manure as above, and planted with potatoes. We had no rot in 1849. It was late before I could plant this piece, and having used all my manure on the other, I was unable to prepare a new field; so I ventured a second crop, contrary to my usual practice. It was hoed but once, and lightly covered. It was plastered like the other, ripened in October, and yielded a good average crop. From 3 to 5 per cent. only were affected by the rot. My neighbors, who did not use plaster, have, without exception, so far as I have heard, lost from 50 to 90 per cent. of their crops. My Irish laborers used no plaster on their patches, upon which they depended for their winter's supply, and scarcely got their seed. I feel warranted, therefore, to attribute my success to the use of plaster, (the common ground Nova Scotia,) and recommend a handful being cast upon the seed before covering, and another on the vines after hoeing. I am also confident that late planting is better than early, for winter supplies. Experience has taught me, that in all lands not subject to early frost, the growth, after the drought of harvest, is far greater in size and number than when the vines mature at or before that period. In the late planting, the tubers grow until the vines are killed by the frost. I am equally certain, that upland is better than lowland, for this esculent. I prefer a slope, where the water will not remain long on the surface. I feel well assured, that potatoes may be raised on such lands, far to the South, if planted in July or August; (I have known fair crops to be raised here, from planting the 4th of July;) and wherever public improvements are in progress, planters there will find it greatly to their interest to cultivate them. I passed rapidly through the State of Virginia, from Guyandotte to Charlotte, about the first of September, and rarely saw a potato on the table; and when I did, they were very small. In the few fields which I saw between Stanton and the Blue Ridge, the stalks looked dry and dead. And I saw a farmer selling potatoes to the Irish laborers at the tunnel, so small as would be certainly rejected at the North. I saw one small field, on Paint Creek, which had been late planted, and never hoed: the vines were green and rank as the weeds which wellnigh smothered them. I urged the owner to attend to them, as a substitute for his short corn crop; but his hands were all boat-building, and I doubt if any thing came of it. I hope some public-spirited men will be found, who will try late planting next season south of the Potomac, and give you the result.

I am yours, respectfully,

WM. W. EDWARDS.

REMARKS.—Our correspondent should know that nothing is more common at the South than to plant Irish potatoes every month, from August to April: even north of the Potomac, in Maryland, they were grown out in the open air, in the winter of 1849 and 1850, and ready to dig, for cooking, in March and April. They need *cool weather*, and not only plaster, but wood-ashes, and either leaf, straw, or sod mould to feed the plants. Give potatoes the right temperature and moisture, and proper food, and they will do well, provided the seed is sound.—ED.

Scottsville P. O., Town of Wheatland, Monroe County, N. Y.
December 30*th*, 1850.

Sir:—In consequence of sickness for the last month, I have found it impracticable to answer your circular at an earlier period; consequently, the time employed on it has been so limited, that I find it so imperfect, and of so little interest, I very much doubt the propriety of troubling you with it. Although I have farmed it in this town for the last 30 years, I have never found time or inclination to go into minute calculation or investigation as to the exact cost or profit of particular modes of cultivation, and still less to experiment on different processes of fattening animals, or the exact result of such processes. My remarks will, therefore, be principally limited to a general view of the method of farming, as it actually exists in this vicinity. I also find that I have extended my remarks to too many subjects, and have, consequently, not been sufficiently particular about any to make them useful; but, such as they are, they are placed at your disposal.

The town of Wheatland is located on the Genesee River, 12 miles south of Rochester, where the Onondaga salt group of rocks crosses the river, and contains several plaster-beds; and it has been found from experience that the cultivation of wheat, clover, and corn are most suitable and profitable, and to them the attention of farmers is principally directed. Although oats, barley, peas, and root crops are necessarily cultivated to a limited extent, for home consumption, they are never depended on for market or exportation to any considerable amount. Their cultivation may be considered incidental, and limited to particular pieces of land, that happen, from the nature of the soil and previous cultivation, to be particularly adapted to an occasional crop. The land in this town consists almost wholly of what is called oak-openings, and was originally considered poor and barren, which, in fact, was the case, until the use of clover and plaster was resorted to, and which took place from 1815 to 1820, at which time the capability and fertility of the soil were fully developed, and the crops of clover, wheat, and corn were not unfrequently doubled, furnishing food for sheep and

cattle, which also increased in the same proportion, and the means of improving and renovating the soil both by pasturage and barnyard manure.

Manure.—In 1815, the price of lands, partially improved or cleared, was from $10 to $20; from that time until the present, the price has gradually advanced, selling at this time at from $50 to $70, as to quality and improvements. When the plaster first came into use, the soil was wonderfully sensitive to its effects, and the results on the clover fields truly astonishing. Such strips as happened to be missed in sowing were so small and dwarfish that they could not be mowed with the scythe; in fact, the same strips were almost equally perceptible in the succeeding wheat or corn crop. The effect did not appear to depend so much on the quantity used as upon the evenness of sowing; and when 100 pounds could be spread even, it seemed to have the same effect as double the amount; indeed, any given amount exceeding 150 pounds did not appear to improve the crops in the least.

From 1820 to 1825, the crops arrived at their maximum, and from that period to 1840 the average product did not appear to vary much, although, towards the close of that period, the average began to diminish sensibly, and the plaster to lose its effects. The land generally, and especially that portion of it well adapted to the cultivation of wheat, being summer fallowed and sown every other year, and although the clover crop was frequently ploughed in the rotation, proved too exhausting, there being little other manure used. The land appeared to tire of this continued drill of the same crops.

Since 1840, many of the farmers have adopted the three year rotation, pasturing the land the year succeeding the wheat crop, and either summer fallowing the second year, or manuring the sward in the spring, and planting with corn, which is cut up about the middle of September, and sowed with wheat, seeded to clover the next spring, to go through the same rotation. Where the three year system has been adopted for any length of time, the crops improve, and the average product increases gradually to about the old standard. I would not be understood that the above changes were confined to the mentioned dates, or that the above results would correspond to the experience of every farmer. The lands being brought successively into cultivation, and the use of clover and pasture commenced at different periods, the crops of one farmer might be increasing, while those of his neighbor might be diminishing, all depending upon the period at which the process, as described, commenced. But it is believed that the land went through something like the above process, in periods corresponding to the above dates.

The average yield of wheat, per acre, at different periods, is supposed to be about as follows:—Being in 1815, 15 bushels; in 1820, 20 bushels; from 1820 to 1830, 25 bushels, and, under favorable circumstances, as high as 35 and 40 bushels, per acre, which last was by no means uncommon. At this time, I suppose the average product to be about 22½ bushels.

The red-chaff bald, with white berry, was the variety universally used originally, and succeeded well while the land was new and fresh: it was, however, particularly obnoxious to the Hessian-fly, whenever they abounded; but as the ground became stiff and old, it gradually began to be liable to rust and winter-kill, until, from 1825 to 1830, it became quite uncertain, and was succeeded by the white flint, which proved a much hardier variety, and less liable to injury from the fly, from the peculiar solidity and hardness of the straw, and was less liable to rust. Several other varieties were introduced, and cultivated to some extent, the most prominent of which were the Hutchinson, a bearded wheat, and the Indiana white, beardless: both did better than the original bald, but could not compete with the white flint. Within the last six years, the Soules wheat, a white variety, has been cultivated to some extent, and, when the tillage is good, and the land in good heart, it not unfrequently outyields the flint from 5 to 10 bushels per acre. In many localities it is fast coming into favor, and superseding the flint. It is about a week earlier, rendering it less liable to rust: it shells readily: if not harvested in season, it does not withstand wet so well, the berry being but slightly covered with chaff. The white flint, on the contrary, is but little liable to sprout in consequence of exposure, nor does it shell readily. The last two are the varieties principally in use. For the past two years, the Mediterranean has been tried to a limited extent: it is the earliest variety known here, and is said to escape injury from the weevil; but it being a red wheat, and thick hulled, our millers object to it on account of the inferior quality of the flour; and as the weevil has not made its appearance, or not to any extent, west of Seneca county, the wheat in question will not find much favor until that event takes place. It will be unnecessary to enter more into details in relation to the particular qualities of the different varieties, Professor Emmons having done it in the last volume of the Natural History of this State. The time of seeding commences, with the stiffest soils, about the 1st of September, and, on low clay lands, even as early as the last 10 days of August; but for our best upland wheat soils, from the 10th to the 15th of September is preferred. As to the preparation of the seed, we find but little necessary, the soil being so natural to, and so well adapted to the cultivation of wheat: it has hitherto been liable to but few diseases: whenever any smut occasionally makes its appearance, the application of brine, and drying in lime or plaster, is found to be a sure remedy. The quantity sowed, per acre, we find necessary to increase gradually as the land grows older; we commenced with 1 bushel per acre, of the old red-chaff, and, when the white flint was first introduced, 3 pecks were found to be sufficient under favourable circumstances: the quantity has been gradually increasing, and has arrived at 5 pecks on the most favorable localities, up to 6 and 8 pecks on stiff and lumpy clays, where much of the seed does not vegetate.

The time of harvest never varies but a few days from the 15th of July, and any pieces whose ripening is protracted, from any cause, such as late sowing, or cold, wet soil, much beyond the 20th, hardly ever escape more or less injury from rust.

Until within the last six or eight years, the usual preparation of the soil for wheat was to plough two or three times: now, the practice of turning over clover in June, and following with the harrow and cultivator, to keep the land in good tilth, and subdue any grass that may spring up until sowing time, has been fast growing into favor, and now appears to be the most approved method of preparation: if, however, in the spring, the wheat appears to be so grassy that there is little or no prospect of clover succeeding well, the stubble is generally fallowed the succeeding season, and ploughed two, or, if necessary, three times, to eradicate the grass thoroughly, and then seeded with clover to remain two years.

When the oak openings were first broken up, it was not found advisable to plough very deep, or not more so than was necessary to get under the roots of grass and brush, which was about four inches; but as the land

become exhausted at the surface, from continued cultivation, it has been found necessary to deepen the furrow gradually to 7 or 8 inches, and even to 10 inches; and as the lime and salts become exhausted on the surface, a supply is sought in the subsoil for the wants of the crops.

It may be well to mention in this connection, that the New York system of lime-rocks extends from east to west, and that we consider, and, in fact, find from experience, that the Onondaga Salt Group, and its immediate vicinity, are the best calculated for the cultivation of wheat; and that as we recede from it, either north or south, the capability and fitness of the soil for wheat decrease, until at certain distances, varying in different localities, the cultivation of wheat is nearly abandoned. As far as the debris of this rock extends, and is mixed with the soil to any great depth, it only requires exposure to the atmosphere, and a certain admixture of vegetable matter to develop its peculiar adaptation to wheat culture; and hence, the extensive fame of Genesee wheat, and the high price of its flour in the markets of the world.

There has been no remedy found for the Hessian-fly, except late sowing; and this has, of late, been but little attended to, it being found that to protract sowing much beyond the usual and approved time, exposed the crop to a more serious injury, viz. rust and shrinkage, and liability to winter-kill, the roots not being sufficiently strong and well established to withstand the continued freezing and thawing of March and April. It has also been found, that in seasons when the fly prevails, they frequently attack late sown wheat, and even barley, in the spring, and injure it far more than the early sown. It is, however, a subject of congratulation to the wheat farmer, that the ravages of the fly are steadily upon the decrease, and that at present little apprehension is felt from them, and comparatively little damage sustained. No weevil has hitherto appeared in this vicinity, or nearer than Seneca; but, as they appear to be on the march to the west gradually, we may reasonably expect to make their acquaintance in time. The average price, during 1850, at the mills, in this town, will not vary much from $1.19 or $1.22.

Estimated expense of cultivating 5 acres of wheat:

5 days ploughing, using 8 horses and 1 man, at $2.25 per day...	$13.25
Wear of plough and points...	1.00
1 day harrowing, 1 team and boy, and use of harrow...	2.00
2 days cultivating " " " cultivator...	4.00
1 day drilling in wheat, " " drill...	2.25
Seed wheat, 5 pecks per acre being sufficient, drilled, at $1.19 per bushel...	7.45
Harvesting and drawing to barn per acre, $2...	10.00
Use of land one year, allowing pasturage, spring and fall, for its use the seasons that the wheat is sowed and harvested, $4. per acre...	20.00
	$59.95
Estimated yield, 22½ bushels per acre, at $1.19 per bushel...	$133.87
Deduct expense...	59.95
Profits on 5 acres...	73.92

Or, on one acre, nearly $14.75. Or, if the whole is done well, or in good season, we may safely calculate on 25 bushels per acre, which would increase the profits nearly $8 per acre, or $17.75 per acre, admitting the straw and chaff will pay for threshing and carting to mill.

The cultivation of corn is supposed to be increasing, and taking the place of root crops to a great extent: it is considered secondary to wheat, principally used for home consumption, and seldom for exportation: there are several varieties in use; but the early 8 and 10-rowed yellow and white, are preferred on wheat soils. Corn is usually cut up by the ground, and followed by wheat, as already mentioned. The yield per acre is exceedingly various, depending upon the adaptation of the soil to the crop, and the amount and quality of the manure used; indeed, the land can hardly be too rich: under ordinary or rather unfavorable circumstances, the yield may be 30 to 40 bushels; and under favorable circumstances, depending on season and cultivation, it will go as high as 60 to 70 and even 80 bushels per acre.

It is difficult to arrive at correct estimates of the cost of raising, although such estimates are frequently made, so much depending upon the natural qualities of the soil, as well as upon previous cultivation and manuring.

The mode of cultivation most approved here is to apply the manure of the previous winter on clover sward: if the land is dry and loamy, plough once from the 1st to 15th of May; roll, harrow, and cultivate, and plant as soon thereafter as possible; or, if a stiff soil, inclining to clay, manure and plough in the fall, pulverize from the 15th to 20th of May, planting as soon after as possible. At one time, it was not unusual to plant about the 1st of May: it is now discontinued, it being found that it increased the labor of after cultivation, and gave time for the growth of grass and weeds before the first hoeing, and the corn being very liable to injury from late frosts. Corn is usually fed to hogs in the ear; for cattle, it is always ground.

Oats are considered an exhausting crop, and are also cultivated mostly for home use; the stubble is seldom used to follow with wheat, and very rarely succeeds when tried. Average yield, under ordinary circumstances, 30 bushels; but when the season is favorable, or we have seasonable rains, they will yield 40 to 50 bushels: the land for oats is hardly ever ploughed but once: average price, 30 or 34 cents.

Barley is but little cultivated on our best wheat soils, and is confined principally to loamy soils, containing a good supply of vegetable matter, or on well manured corn or potato ground: it does not succeed on poor or grassy land: under favorable circumstances it may yield 40 bushels per acre, but more frequently less: it is almost wholly sold to brewers, and seldom fed out on the farm. It is not considered an exhausting crop, and is generally followed by wheat. The price per bushel generally 50 to 60 cents: this season it has sold at 75 in Rochester.

Rye not cultivated.

Peas are raised to some extent on loamy and moist localities, and frequently do well there, yielding about 30 bushels per acre; but seldom succeed on dry, light soils: they are generally followed by wheat, which generally succeeds well after them. When the pea crop does well, it is useful in subduing grass, leaving the land light and in good condition, and is therefore considered an ameliorating rather than an exhausting crop. The green crop is never ploughed in for manure. When cultivated extensively for a few years in succession, they become so infested with bugs that farmers are compelled to abandon their use for a time: they are fed to hogs either in the straw, or soaked, or boiled, and are considered equivalent to corn: they

are seldom sold off the farm, except in the spring, for seed, and frequently sell at $1 per bushel.

Beans have been tried to a limited extent as a fallow crop, but did not appear to succeed, probably on account of the expense involved, their cultivation being now mostly limited to family use.

Clover and *timothy* are the only grasses used for cultivation; and meadows of said grasses, except in cases of unseasonable droughts, will yield 2 tons per acre. The principal and almost only fertilizer used is plaster, either sown with the seeds in the spring, or the following spring, early in May: the seeds are mixed, when sown in the spring, 6 or 7 pounds of clover to from 2 to 4 quarts of timothy to the acre. Of late years, the practice of sowing the timothy in the fall, and immediately after the wheat, has been adopted, the clover in the spring, from the 1st of March to 1st of April, and is considered an improvement, as timothy sowed in the spring frequently failed in consequence of drought. The expense per acre would be about as follows, viz.:—

Cost of seeds	$0.80		
150 lbs. of plaster, and sowing plaster and seeds	0.70		
Mowing 2 tons per acre	1.50		
Raking and drawing, &c.	2.50		
Interest on land	4.00	expense	$9.51
Cr.			
By 2 tons hay	at $7.50		15.00
Profit per acre			$5.49
Or $2.75 per ton.			

Wool-growing, at present prices, disconnected with wheat-raising, and at the present price of land, would not pay; but a certain amount of sheep may be kept on wheat farms to advantage, to consume the clover, and consequently enriching the land, and also to reduce wheat straw by feeding on it, trampling it fine, and mixing with their manure. Sheep may be wintered on straw and chaff, with a small daily additional allowance of ½ a gill of corn, or its equivalent in other grain, successfully, and averaging 3½ pounds fine wool per head: in lieu of the grain, 1½ pound of good hay may be substituted; indeed this is a very common practice with all except lambs, which require plenty of good hay. Having no experience in coarse-woolled sheep, I cannot judge of the comparative profits of each.

Farmers here do not keep many more neat cattle than are required for the use of the farm, and none follow dairying as a principal business. Cattle, after the first winter, are principally kept on straw and chaff: the straw being stacked near the barn, they are allowed to run about it, and a sufficient quantity being daily cut off the stack and spread about the yard and sheds during the winter, to be converted into manure; a certain amount of cattle or sheep, or both, being necessary for that purpose, and as the straw is of but little or no value here for any other purpose; we do not estimate the expense of wintering the number requisite for that purpose as costing us any thing, but being rather an advantage. Calves, milch-cows, and working-cattle are either stabled or have separate yards, and are fed, in addition to the above, with hay or cornstalks. The cost of rearing a calf the first summer will be about $5, the first winter $5, the two succeeding summers, say 60 weeks pasturage, 18 cents per week, $10.80, making $20.80. Steers, in fall, at 2½ years old from the pasture, ordinarily sell at about the amount, and, if kept through the winter until 3 years old, (if kept as above described,) would still sell for about the same amount, not being in so good condition. Cows may be valued in the fall, at from $16 to $18; in the spring, from $22 to $25. Durhams and Devons, and their crosses, are the cattle usually raised, and of the two breeds, pure, the Devons are generally preferred, both on account of their beauty and their being the most hardy and easiest kept. Having but little experience in the fattening and management of cattle, I am not competent to give you reliable information. Of late years, the facility of sending fresh beef and pork to Eastern markets by railroad, has considerably enhanced their price. I have seen good beef sold in Rochester at $2.50 per cwt.: it now sells at $4 and $4.50.

As to *hogs*, new varieties are so frequently introduced, and are so quickly mixed up, it is difficult to determine the best breeds; farmers vary much in opinion: I have been the best pleased with what has been called the Mocha, and their crosses. The cheapest method of fattening, and the one generally adopted here, is to commence as early as a supply of potatoes and apples can be got, boiling them together in such proportions as our supplies of each will admit, adding some meal or middlings after boiling; the more the proportion of apples, the greater the quantity of meal required: pumpkins may be added as soon as they come to maturity, but they are inferior to either of the former: this course is followed until with a few weeks (2 to 4) of killing time, when corn in the ear or meal is used to harden the pork. The Onondaga coarse or evaporated salt is used for packing pork, little or no bacon being made.

Root crops of all kinds, except potatoes, are now but little cultivated. From 5 to 10 years ago, the cultivation of ruta baga, beets, and carrots was pretty extensively tried by our most enterprising farmers; but, owing to the expense of cultivation, and the uncertainty of the crop, arising, principally, from the prevalence of unseasonable drought, they have gradually been disused, it being found that when large breadths had been planted, and stock provided specially for their consumption, the crop so frequently failed that it subjected the farmer to much loss and inconvenience, and the corn crop has almost uniformly taken their place, as being more reliable. Still, with proper preparation of the soil, and the present improved demand for meat, their culture may be revived with more success.

Irish potatoes are cultivated to a considerable extent. The most approved method of preparation and tillage is the same as corn, except that the manure ought to be finer and better rotted; they do best planted in hills, not less than 2½ feet apart each way; a handful of plaster and ashes, half of each, applied to each hill, either before or after covering, is frequently used to advantage. The most prolific variety in use is the Merino; they are not considered as nutritious as the other varieties, and are used principally for feeding out. Some years ago, the Rohan potatoes excited much attention; but, when tested, were disapproved of and discontinued. The flesh-coloured (Plate II. of Professor Emmons) is much in use, and is more firm and better for the table than Merino, but second as a bearer. Next best in yield is the long and round pink-eye; then follows the Mercer as a yielder. The Carter potato is now being introduced; it is a late variety, superior to any other for table use; its yielding qualities are not sufficiently tested as yet to form correct conclusions. I have raised it, to a limited extent, the last two seasons; it has suffered less from the rot than

any of the above varieties, which were planted in the same field. The quality of the above varieties for table use improves from the first to the last mentioned, and from the last to the first as bearers.

The raising of potatoes has been curtailed, on account of the prevalence of the rot, for the last 5 years, and they have suffered from it the last season probably more than ever before. The average crop is estimated from 160 to 170 bushels per acre. Cost of production, 18 cents per bushel; usual price at the time of digging, 25 cents; profit per acre, taking the average at 170 bushels, would be $29.

Having paid but little attention to orcharding, and my communication being spun out to such a length, I will forbear saying any thing on the subject, and here conclude.

It will be observed that the above estimates fall far short of the results published in the reports of our agricultural societies, which, since writing the above, I have partially examined: mine have been made without reference to any other, and from my own observation and experience, if any thing, they may be too low; but it is confidently believed that they will not vary materially from the general results as they actually exist. When a farmer contends for a premium, he selects his land in reference to the intended crop, cultivates with extra care, and, perhaps, is assisted by adventitious circumstances, such as a seasonable and, perhaps, limited shower of rain, that does not extend to many of his neighbors; and, if successful, he naturally endeavors to make the most of it, in order to exhibit his skill and the superiority of his soil over that of his neighbor.

Very respectfully yours,
DAVID McVEAN.

Hon. Thomas Ewbank,
Commissioner of Patents.

Allenton, Washington Co., Rhode Island, Dec. 23d, 1850.

Sir:—Having been kindly furnished with a circular from the Patent Office, requesting information upon various subjects connected with agriculture and rural economy, I proceed to reply (though incompetent) as far as the questions have a local application, and shall confine myself to some of the most important farm products and operations. There are but few kinds of business which require a closer personal attention and more skill in order to succeed than that of farming. The purchasing of a large portion of his cattle, sheep, and swine; the feeding and preparing them for the butcher; the rearing of calves, lambs, pigs, poultry, and eggs; the making of butter and cheese; selling milk; raising vegetables and fruits of various kinds for market, with some of the more staple products—constitute, in part, the occupation and resources of the farmer.

The land is generally uneven, both in surface and quality, and presents many varieties of soil even within the same field. No uniform rule of practice can well be applied. Each one must determine for himself the best mode of operations. The great secret of success consists in the judicious preparation and liberal distribution of manures. It is the foundation upon which every farmer must rely for a profitable return for his labor and capital employed. By the liberal use of manure and thorough cultivation, the crops are, comparatively speaking, placed beyond the influence of unfavorable seasons and other vicissitudes to which they are so subject.

Indian corn forms one of our most valuable crops, regarded both as forage for stock of all kinds, and as food for the support of man. It must be admitted to hold a rank far above any other plant known in husbandry. The soil best adapted for raising this crop is the sandy loam; although it thrives well on all soils, if well manured, excepting the cold and wet clay soils. The varieties most esteemed here are the large and small white-cap corn. The former for strong and rich, and the latter for poor and light soils. They always accommodate themselves, in a remarkable degree, to the soil and the seasons, always maturing and yielding, according to land and cultivation, from 10 to 60 bushels per acre. Cost of production, from 20 to 75 cents per bushel, not including the cost of manure, which will be more than balanced by the additional quantity of fodder obtained during the several years which the manure continues to exert an influence. The largest yield costs the least per bushel. One of the best methods for raising this crop is to allow the grass to grow upon sward land till about the 25th of May, then spread 20 ox-cart loads of good, unfermented stable manure to the acre, and plough the whole under to the depth of eight inches; roll it well, mark out with the plough 3½ feet apart, and intersect the furrows at right angles with a chain, the same distance apart for the hills, put a small quantity of fine compost in each, then drop in four grains and cover deep. The whole work should be quickly performed. As soon as the corn can be well seen, pass a fine-tooth harrow between the rows, each way, and follow with the hoe to clear away, leaving no hill. Soon after this, let the cultivator pass in like manner; also follow with the hoe, leaving but small hills. The third hoeing should take place before it tassels out, avoiding large hills, as before. As soon as the corn is well glazed, cut it up close to the ground, and put up in small shocks. If the land could be made smooth, it would be a great saving of labour to plant with a machine. Tarring the corn, before planting, is a sure preventive against the depredations of birds. The past has been a favorable season for corn.

Rye is well adapted to our light, poor soil, and, with a little manuring, will yield from 12 to 30 bushels per acre: cost per bushel, from 20 to 50 cents, not including manure, which will be paid for by the straw, it being worth from $6 to $7 per ton.

Oats and *barley* are cultivated only to a small extent, and are considered very exhausting.

Beans do well on light soil. Yield, about 12 bushels per acre. Cost of raising, $1 per bushel.

Hay is an excellent and profitable crop on moist land, if supplied occasionally with suitable manure. Fish, spread on the land after the crop has been taken off, at the rate of 50 barrels to the acre, will produce astonishing effects, frequently quadrupling the next year's crop. Stable manure will do well also. Moist land should always be selected for this crop, when practicable, and the dry lands for tillage. The past year has been very favorable for grass—at least 25 per cent. over that of the year before. The quantity per acre varies from ½ ton to 2½ tons, and it is worth about $3 per ton to cut and secure it in good order.

Potatoes.—This is the most valuable of our root-crops, and its qualities are beginning to be better appreciated as the difficulty and uncertainty of raising become more apparent. The past season has proved to be the most

fatal to this crop. It has also been remarkable for the unusual quantity of rain. These circumstances may not be without their benefit in assisting to determine the cause of the disease, and thereby settle the question that has given rise to so many unprofitable and speculative theories. It may not be out of place here to suggest what has appeared to me evidently to be the cause; and that is, an excess of heat and moisture, combined with ammonia, a highly fertilizing salt, well known to exist in all rich soils and manures. The rot has always been found to be excessive on highly manured and wet land, and in a season of high atmospheric temperature; while in poor, dry soils, it rarely, if ever, makes its appearance. Notwithstanding its liability to decay, it continues to be extensively cultivated, and proving to be, in many instances, where it is only partially destroyed, the most profitable crop raised by our farmers. Yield, from 50 to 250 bushels per acre. Price per bushel, 50 to 80 cents. To those near a market, or on the waters of the Narragansett Bay, the Mercer or Chenango is the best variety, more especially on light soils. The ground should be well ploughed twice before planting. A little plaster on the seed in the hill is a good manure for the potato; also, a little manure is good with the plaster, on light soils. Wet land should be avoided for the Mercer variety, and, perhaps, for most others.

Onions and *carrots* are raised on the same ground, in alternate rows, producing full crops of each. The onions come to maturity early, and are gathered, thus leaving the carrots in full possession until they mature. This is considered a beneficial occupation of the land. Roots, of various kinds, are beginning to be cultivated for the use of stock in winter.

Stock-breeding has been much neglected in this county. It is to be hoped, however, that some of our enterprising farmers will make the experiment, for, I have no doubt, it would be a profitable undertaking, if well conducted. They should avoid the imported stock, which, by extreme care in crossing, together with high keeping, have been brought to the highest degree of perfection, and which would, without this same care and high keeping, probably degenerate, as they have done in other cases. But, by careful and judicious crossing with some of our best native cattle, there might, no doubt, be a breed produced that would be valuable both for work, the dairy, and the shambles, and which would be better suited to our climate, and better prepared to endure the careless treatment common among us. Feeding stock for beef is practised to some extent by some of our best farmers. In selecting animals for this purpose, care should be taken to procure those that will fatten readily; and when the business of feeding has commenced, it should be attended to faithfully, for the sooner it is done the more profitable it will be.

Sheep have decreased in number very much, of late. They are now kept, not so much for wool, as for the rearing of lambs, which are sold to the butchers at about three months old, and bring about $2 per head. The coarse-woolled, native breeds are the best for this purpose.

Hogs cannot be raised and fattened at the present price of pork, with any degree of profit, beyond what are required to consume the offal of the farm, dairy, and kitchen. Breeding-sows are kept for raising pigs, and produce two litters a year, which are sold, at about 8 weeks old, for $3 each.

Poultry.—Washington county has become quite celebrated throughout the country for its fine-flavored poultry. The quantity annually produced is large, the greater portion of which is sent to Boston. All our farmers are engaged more or less extensively in this business. Some devote almost their whole attention to this branch of industry.

Manures.—The collecting and composting of manure should be attended to by all means, whenever it is practicable. Peat taken from the swamp and composted with stable manure, in the proportion of one of manure to four of peat, and allowed to remain until a slight fermentation takes place, makes an excellent manure for all light soils, and for almost all crops. Leached ashes mixed with peat, in proportion of one to two, makes a good manure also. Stable manure is the best for top-dressing on grass lands and for corn, to be ploughed under in an unfermented state. Fish manure is very active, and, whenever it can be procured at a reasonable rate, will pay well for the expenditure. The stable is our main dependence for manure, and should be kept well littered with straw, eel-grass, lowland hay, and peat, kept dry for that purpose.

Dairy.—Narragansett was formerly one of the most celebrated dairy districts in New England. The business is now pursued to some extent, and, where the land is suitable, is, perhaps, one of the most profitable branches of husbandry. The annual amount realized from each cow, including the calf, is about $35. Ice is used in all good dairies for cooling the cream, and preserving the butter till marketed. Price per pound, 22 to 25 cents. Cheeses of inferior quality are for the most part made, and sell for about 5 cents per pound.

Fruits of all kinds are receiving increased attention, and are beginning to be extensively cultivated, not only as a source of profit, but also for the decoration of the homestead. They are also highly esteemed as a healthy and delicious food. Many of the old orchards of common fruit are fast going to decay, and others are being planted to supply their places, great care being had to procure esteemed varieties. The best variety of apples, for this district, is the Rhode Island Greening. It is unsurpassed for all purposes, is an early and constant bearer, and the trees are long lived; some of which are now in a bearing condition, being 100 years old. It is much finer flavored, the flesh is firmer, is of a deeper green color, and keeps longer when produced in this vicinity, than when produced west of the Connecticut River. In cultivating an orchard of apples, pears, or peaches, care should be had to keep the ground loose, and deeply ploughed and under tillage, till the trees are well grown and nearly shade the ground. It should be lightly manured every year with good compost manure. No grass, rye, oats, or barley should ever be allowed to grow in an orchard. Some root crop, alternating with Indian corn, will be best. June is, perhaps, the best month for pruning an orchard, though it may be done at any season of the year. The heads should be cut out and formed while the trees are growing, and little care will be necessary in after years.

Very respectfully yours,

CHARLES ALLEN.

Benton, Elkhart County, Ia., Dec. 24th, 1850.

Sir:—In answer to certain questions contained in your Agricultural Circular of the 26th of August, 1850, I proceed according to the best of my abilities.

Wheat.—The Mediterranean has been sown, of necessity, for a few years past, on account of the ravages of the Hessian-fly, for other kinds are destroyed, while this escapes. It is not a very productive wheat. Its average product is estimated at 15 bushels per acre. The kinds in use, and most esteemed, when not disturbed by the fly, are the Wabash, Hutchinson, red, and white chaff bearded. The average product is 20 bushels per acre. The time of seeding is from the 1st to the 20th September, and of harvesting, from the 4th to the 15th of July. No preparation of seed. We usually plough twice and harrow in the seed. It is better to plough deep the first time, (say 8 inches,) and the next time not so deep. The best fallow land is that on which corn grew the previous year. If the land receives good culture, we consider our yield increasing. We know of no remedy for the Hessian-fly but to sow the Mediterranean wheat. We have no weevils. Average price per bushel, 56 cents.

Corn.—The variety most esteemed here is white with a red cob, though a yellow corn, lately introduced here from South Carolina, is the most productive; but it is sometimes injured by frosts. It is, however, becoming better adapted to our climate, and, I think, it will soon be the most profitable kind to raise. Our old varieties averaged 45 bushels, and the last-named, 65 bushels per acre. The best system of culture is, to plough the ground deep in the spring, furrow and cross it about 3½ feet apart, plant 3 or 4 grains in a hill, harrow, and then plough 3 times, and hoe at least twice. Average price per bushel 20 cents.

Oats.—A fair crop is about 30 bushels to the acre. One bushel and a peck are sown. Average price, 18¾ cents.

Neat Cattle.—Owing to our dry, sandy soil, grasses are not productive, consequently, we raise but few cattle. Three years' old steers are worth from 10 to 12 dollars. Good milch-cows, with their calves, in the spring, average $12, and in the fall, $10. Native stock suits our climate best.

Sheep.—The raising of sheep has attracted some attention of late, owing to there being a demand for wool from abroad. Coarse wool sells for 31 cents per pound. The finer kinds are not much grown here. Sheep do well.

Hogs.—Not much more pork is raised here than is necessary for home consumption. Average price, $2.75 per cwt. Our method for putting down pork is to salt it well, and, after it has taken the salt, hang it up and smoke it, and when well smoked, prepare a mixture of ground black-pepper and salt, and rub it well all over, which prevents the bugs from disturbing it.

Potatoes are raised only for home consumption. Varieties, the Meshannock and Mackinaw, which yield well. Mode of culture, manure the land, plough and harrow it, then furrow and plant four potatoes in a hill, about 3 feet apart; afterwards harrow and plough two or three times, and hill well with the hoe.

Fruit.—Great attention is paid to the culture of fruit. We frequently have apples which weigh from 16 to 22 ounces, though our orchards are young. The "never-fail" and bellflower are the best kinds for keeping.

The best time for transplanting and grafting is in the month of April. My information upon the other subjects of inquiry contained in your circular is so limited, that I think it unnecessary for me to attempt to answer further.

I am yours respectfully,

JOHN JACKSON.

Mount Pleasant, Clockville, Madison county, N. Y. Dec. 17, 1850.

Sir:—Your Agricultural Circular was duly received. I shall be able to reply to but few of the questions it contains.

Dairy Husbandry.—The average yearly produce of butter, per cow, in this section, taking altogether, would not much exceed 100 lbs.; of cheese, 200 lbs. There are extra dairies, however, which will give over 200 lbs. of butter per cow. One pound of butter is generally considered equal to two of cheese; yet, I think, two pounds of cheese can be made from less milk, and with less expense, than one of butter. The average price of butter, the past season, has been 13 cents per lb., and cheese, 5½ cents.

Neat Cattle.—The cost of rearing, until three years old, is about $10, for the first year, and $8 for the second, and $10 for the third, making in all $28. The usual price, at that age, is $30 for a steer, and $20 for a heifer, in the spring. The value of good dairy-cows in the spring is $25; in the fall, $16. Extra cows are worth more, while many are worth less. As to whether a given amount of food will make more meat in a Durham, Devon, or Hereford animal, than in a native, I am fully convinced, so far as the Durhams are concerned, it will; but cannot say with regard to the others, having had no experience with them. There has been, for years past, too little regard paid by farmers in general to neat cattle. When it is considered that the expense of rearing an inferior, common, or superior animal is nearly the same, it is astonishing that we have not more superior animals. In the estimate above, I have given as the price of a three-year old heifer, $20. A good grade heifer, say half Durham, (or a cross on any other of the improved breeds,) at two years old, would bring as much or more, and a saving, by the owner, of one year's keeping. A thorough-bred animal, at two years old, would bring from $100 to $300, and could be reared at about the same expense as a native animal. It is, however, the first cost that stands so much in the way of improvement; yet, when it is considered with what ease, and comparatively small expense, grade animals can be obtained in most sections of this country, and this grade be again improved by the introduction of more pure blood, the farmer who neglects to improve his stock has no excuse. It has now been little over half a century since the first Durham cattle were brought to this country; yet they were not imported to any great extent until some sixteen years since. The rapidity with which they have since found their way into almost every section of our country, and the universal satisfaction they have given, in almost every instance, when fairly tried, proves their superiority over the native cattle. In 1846, E. P. Prentice, Esq., of Albany, New York, slaughtered a Durham ox, five years old. His live weight was 2546 lbs.; dead weight, four quarters, 1688 lbs.; loose tallow, 260 lbs.; hide, 126 lbs.; making the whole net weight 2074 lbs., or a shrinkage of only 472 lbs. in an animal weighing over 2500 lbs. The shrinkage in our native cattle is allowed to be one-third; that is, a native animal, weighing 1200 lbs. alive, is expected to weigh 800 lbs. when dressed. They are as superior, in many instances, for the dairy, as for the shambles. In 1844 the New York State Agricultural Society awarded the first premium to George Vail, Esq., of Troy, New York, for the largest quantity of butter made from six cows, in thirty successive days. The quantity made was 265 lbs. 10 oz. These cows were all thorough-bred Durhams, and had no feed, during the trial, but grass pasture. In the Patent Office Report for 1848, page 397, mention is made of one of my short-horned heifers. I have given this cow, during the past season, a very thorough trial, as regards milk and butter. She gave, on grass feed, in 71 days, 3484 lbs. of milk. In favorable weather, 19 lbs. of her milk would give one pound of butter. She made, during ten days in June last, (very unfavorable weather,) 20 lbs. 4 oz. of butter; during ten days in August, 19 lbs. 14 oz.; her feed being grass only.

I might give many other examples, showing their great value, both for the dairy and the shambles, but fear it would occupy too much space in your Report.

I would not be understood, by the foregoing, that the Durhams should be introduced exclusively into all parts of our country; but I do contend that some of our improved breeds should be much more generally adopted. Let farmers also pay greater regard to selecting, secure the best animals within their reach, give them proper care and attention, and millions of dollars will be added to the real wealth of our country.

I am, sir, yours truly,

S. P. CHAPMAN.

Sir:—As to the inquiries in your circular, respecting agriculture, I shall be very brief, knowing, as I do, that there are so many who are extensively engaged in that business, and who possess so many more advantages than myself, that I think it would be unwise for me to say much on that subject; but will give you my views on a few points, which, if worth noticing, well—if not, as well.

Wheat.—Very little is grown in the easterly part of Connecticut: I do not know of one bushel having been raised in this town last season. The easy transportation from the West, by railroad, for flour, reducing the price so low, and the high price of labor, have put a stop to growing it almost entirely.

Corn is a staple article with us, our common brown bread being made from a mixture of corn and rye meal. As to varieties, the yellow is preferred. In Rhode Island, the white is mostly used, especially for johnny-cakes, &c. The average product, per acre, is 35 to 40 bushels. The expense of raising the same would be, for labor, $7, and for manure $10, which is spread broadcast. For feeding, we grind with the cob, and cook it. Twenty bushels of corn, consumed by hogs, will produce 10 loads of manure, which, spread on an acre, will add to the crop from 25 to 30 per cent. I think a great addition may be made to the manure of hogs, both in quality and quantity, (when it can be done,) by letting the refuse matter of the kitchen and sink run into the hog-yard, and by throwing in wash weeds, &c., and let the hogs muzzle it. Perhaps not more than one-third of our clover crop is used for fodder; it is worth $5 per ton. The remaining two-thirds are saved for seed, which Windham county is somewhat noted for, as Wethersfield is for onions. We get from 140 to 180 pounds of seed to the acre: the price is from 10 to 15 cents per pound: the miller has 10 per cent. for getting it out: the straw is worth but little, except for manure. I have received for the seed, per acre, more than $33 net profit. The cultivation of apples has received uncommon attention for a few years past, more as to quality, than quantity, for very few are planted out without being budded, or grafted, which is *vice versa* from what it was 40 years ago. Double the quantity of apples has been sent to market the present year than in any previous year; and more within five than ever before. Good apples have sold, the past fall, for 40 to 60 cents per bushel. I think an acre of good land, with good cultivation, would yield from 200 to 300 bushels. The Roxbury Russet, which is an annual bearer, I consider fully equal to any other variety for winter use; and for fall use, the Royal Pound apple, a native of Connecticut, also a good bearer.

I send you a set of meteorological tables, as requested in your circular, only, perhaps, more extensive than your request, which I thought required only one year; but, as far as my knowledge extends, I do not recollect seeing a single table or page on the subject from Connecticut. I thought I would give the result of my observations for several years past. I think they are correct, and do not extend too far back to give the general information of the heat, cold, wind, rain, and snow. It would be very agreeable to have the tables published entire; but they are at your disposal: please arrange them in such order as you think best. The tables are so plain as to need no explanation.

Yours respectfully,

JONATHAN CLARK.

P. S. I have no rain-gauge.

Meteorological Tables for the Village of Goshen, in Hampton, Windham County, Connecticut; N. latitude 41° 47′ 49″; *longitude* 72° 7′; *elevation above tide-water,* 561 *feet; and* 19 *miles north of tide-water. By* JONATHAN CLARK, *County Surveyor.*

Last snow in spring, April 11th.
Last frost in spring, May 31st, so severe as to kill corn and vines.

First frost in autumn, September 14th.
First snow in autumn, November 10th.

July 14th, at 2 o'clock, P. M., a severe thunder storm commenced, with high wind and rain; hail-stones fell as large as ounce balls. Just as it began to rain, the Rev. Nathaniel Rawson, of this town, who was raking hay in an open field, was instantly killed by lightning: a small hole was made in his hat, and his rake split in pieces; while a Mr. Lincoln, who was within three or four rods, received little injury. Much damage was done by the lightning and storm.

REMARKS.—You will see that 1830 was the warmest, and 1836 was the coldest year in the above table; and that July, 1838, was the warmest, and February, 1838, the coldest month in said years; and that the 24th of August, 1838, was the warmest day at noon, mercury 96°; and that the 16th day of December was the coldest, mercury 7° below zero at sunrise and at noon, and at 9 P. M. 13° below. The 3d of January, 1829, it was 12½°, below zero, and at noon ½° below.

This table contains all the days on which the thermometer stood at and above 90°, at sunrise and at noon of same day, for 22 years, beginning with the year 1829, and ending with 1850.

This table shows when July was the warmest and when August was the warmest, for 22 years: also, when January was the coldest, and when February was the coldest, for the same period:—

Years.	January.	February.	July.	August.
1829		Coldest.		Warmest.
1830	Coldest.		Warmest.	
1831		Coldest.		Warmest.
1832		Coldest.		Warmest.
1833		Coldest.	Warmest.	
1834	Coldest.		Warmest.	
1835		Coldest.	Warmest.	
1836		Coldest.	Warmest.	
1837	Coldest.		Warmest.	
1838		Coldest.	Warmest.	
1839	Coldest.		Warmest.	
1840	Coldest.		Warmest.	
1841		Coldest.		Warmest.
1842	Coldest.		Warmest.	
1843		Coldest.		Warmest.
1844	Coldest.			Warmest.
1845		Coldest.		Warmest.
1846		Coldest.	Warmest.	
1847	Coldest.		Warmest.	
1848		Coldest.		Warmest.
1849		Coldest.	Warmest.	
1850	Coldest.		Warmest.	

Temperature of water in 4 wells and 5 springs, taken in August, at and near my residence:—

Wells: 1 at	53¾°	Springs: 2 at	54°
1 at	53	1 at	53
1 at	52	1 at	52
1 at	51	1 at	51

As cold-water establishments have of late become quite popular in curing diseases, I have made this note.

The author of the foregoing tables, Mr. Jonathan Clark, is one of the most careful and laborious observers and recorders of meteorological facts, of my acquaintance, in our State. I hope they will be carefully transferred to the pages of the Patent Office Report.

C. F. CLEAVELAND, M. C.

Burlington, January 8, 1851.

Sir:—About the first of this month, your circular of August 26, 1850, was put into my hands, with a request that I would furnish you with something in relation to our meteorology. I have kept a meteorological journal here, most of the time, for the last 20 years, and for the last 13 years it has been uninterrupted. The enclosed paper contains some abstracts from it. In addition to this, my journal contains daily records of the clearness of the sky, course of the winds, range of barometer, closing and opening of the lake, &c. &c. Those could be furnished, if desired, if I could find time to copy them; but perhaps I now send you more than you will think best to use.

Respectfully, your ob't servant,

ZADOCK THOMPSON.

THOMAS EWBANK, Esq.
Commissioner of Patents, Washington, D. C.

Abstracts of Meteorological Observations made at Burlington, Vermont, by Zadock Thompson.

Burlington is on the east side of Lake Champlain, where the lake is 10 miles wide. The place of observation is one mile from the lake shore, and 256 feet above the mean level of the lake, and in lat. 44° 29′ N. and 73° 11′ W. from Greenwich. The mean level of Lake Champlain is 90 feet above that of the ocean.

The mean temperatures are deduced from *three daily observations*, made at sunrise, 1 P. M., and 9 P. M.

Monthly and Annual Temperature of 13 Years.

Meteorological Table for 1850.—*Climate of Newark.*

Barometer, one of Troughton's, well-regulated: Thermometer, self-registering, hanging about nine feet from the ground, with a northern exposure, protected from rain and reflection. The monthly means are deduced from those of each day. The surface of the rain-gauge, four feet from the ground. The number of fair days, derived from the addition of half-days, the general character of each A. M. and P. M. being recorded. Days of rain, those on which it fell in appreciable quantities. Days of snow, those on which it fell, without regard to quantity.

The mean range of the Thermometer is represented in the three first columns.

The rain-gauge is graduated to the hundredth part of an inch. All days in which rain fell are marked rainy days. Days, the greater part of which were cloudy, are registered cloudy days. When thunder and lightning occurred, they are marked one to the day under their appropriate column.

D. C. ROSS.

Report of the Temperature for 15 *Years, from* 1836 *to* 1850.

Hillsborough, Highland County, Ohio.

Latitude about 39° 15′ North; longitude about 6° 45′ West from Washington. Elevation nearly 700 feet above low water at Cincinnati.

The thermometer hangs outside of the house, on the north side. It has been examined at sunrise in the morning, and about 2 o'clock, P. M., each day. The highest and lowest points during each month, are put down in the 1st and 2d column for each year, and, in the 3d column, the average of the month. The average for the whole year is given at the bottom, except three years, during which I was from home part of the time. The lowest point to which the mercury has sunk, in the 15 years, is 22 below zero: the highest to which it has risen, 92 above. The coldest year was 1836; the warmest, 1846. The coldest winter was that of 1840 and 1841; the warmest, 1844 and 1845.

JOS. McD. MATHEWS.

OF THE INORGANIC CONSTITUENTS OF FOOD.

From the Journal of the Royal Agricultural Society of England.

We discover in the bodies of animals the several mineral substances the existence of which are ascertained in vegetables. The bones, as we have seen, contain a large quantity of phosphate of lime; it is requisite, therefore, that the elements of this salt, phosphoric acid and lime, should form part of the ration or diet-roll: this is a point upon which all physiologists are agreed; but the point upon which there is nothing like uniformity yet attained, has reference to the precise quantity of mineral matter which must enter into the constitution of the food.

The analyses of ashes which I have given show that, if vegetable aliments all contain nearly the same inorganic principles, they still contain them in very different proportions: thus, potatoes, wheat, oats, and beans contain much less lime than clover, straw, and peas. The phosphoric and sulphuric acids and the alkalies do not vary less: so that we are led to ask, whether a ration compounded of such and such an article, or of such and such articles, will furnish the animals to which it is supplied with the necessary dose of inorganic principles which must be assimilated daily, and are quite indispensable to maintain them in health and vigor.

It is easy to arrive at the knowledge of the mineral principles which are necessary as elements of the diet, by ascertaining their quantity in the ration, which long experience has shown to be sufficient; yet, as there is reason to believe that, in many cases, mineral substances are present in excess, I have thought that it might be useful to determine by means of analysis the nature and the proportion of the inorganic elements which are actually assimilated by an individual, in order to have a minimum which might serve as a basis for any reasonings or inferences on the subject. My experiments were performed in two opposite circumstances, in which I regard assimilation as most rapid and most complete; videlicit, a calf in full growth, and a milch-cow in calf.

The calf was six months old, and weighed 369 lbs. Some days before being made the subject of experiment, it was fed with hay. During the two days, when it had this fodder ad libitum, it ate 19 lbs.

In the course of the 1st day, the calf passed......	21.49	lbs. of excrement,
2d day..............................	20.39	
	41.88	

which, dried, was reduced to 7.41 lbs.

In the course of the two days, 5.584 lbs. of urine were collected, which, evaporated, yielded 2933.2 grains of extract: the animal having, in the same interval, drunk 45.7 pints of water.

Analysis discovered in 100:

Of the hay, azote...............	1.6.........	Ashes.........	7.6
Of the dry excrements.........	2.1...........................		12.7
Of the urinous extract.........	4.0...........................		40.0

Now, if we inquire from these data, in regard to the quantity of azote, and of mineral matters which were consumed with the food, in the course of two days, we have,

In the food, discarding fractions, azote....	69.	Mineral substances,	328
In the excrements..........................	50.5		214
In the urine..................................	3.8		38
Together......................................	54.3		252

Therefore azote fixed or exhausted in 24 days.......... 14.7 half-drachms.
Mineral substances fixed in two days..................... 76 "

The composition of the ashes obtained from the hay and from the excrements shows us approximately both the quantity and the nature of the several inorganic substances which had been assimilated.

The composition of these ashes is as follows:—

	Of the hay.	Of the excrements.	Of the urine.
Acids, Carbonic...........	9.0	2.0	17.3
Acids, Phosphoric........	5.3	5.1	9.2
Acids, Sulphuric..........	2.4	2.3	7.0
Chlorine......................	2.3	1.9	9.9
Lime...........................	20.4	16.0	0.9
Magnesia.....................	6.0	6.5	6.0
Potash and soda............	17.3	12.5	57.3
Oxide of iron, alumina......	1.5	1.0	...
Silica..........................	33.7	51.0	1.2
Loss...........................	2.1	1.7	...
	100.0	100.0	100.0

If the hay consumed contained 328 half-drachms of ash, or mineral matter, the excrements and urine 252 half-drachms of the same matter, the difference between the two sums, 76 half-drachms,* is the quantity of mineral matter fixed in the course of two days, of which 200.6 grains were phosphoric acid, and 494.0 grains were lime.

This quantity of lime, however, is more than four times as much as is necessary to constitute a subphosphate of lime—such as exists in the bones. It is true, indeed, that there is always a quantity of carbonate of lime associated with the subphosphate in bones; 10 of carbonate, for 38 of phosphate, according to Fourcroy and Vauquelin, in those of the ox. Still, the quantity of lime assimilated was vastly more than it ought to have been, had it only gone to assist in the formation of bone. If there was no error in the observations, it is probable that the base in question enters into the constitution of the salts with organic acids, which are encountered in all parts of the animal body.

By a series of weighings, I ascertained that my calf, fed simply upon hay, increased, every day, by a quantity equal to 9725.9 grains troy, in

* The exact quantity is 2392.8 grains troy.

which were included 858.35 grains of mineral substances. The calcareous phosphate and carbonate of the bones, in this quantity, being represented by 262.4 grains, or nearly 3 per cent. of the entire weight acquired in the course of twenty-four hours.

In the experiment with the milch-cow in calf, I limited my inquiries to the phosphoric acid, and the lime taken in and given out. The animal, four years old, was two and a half months gone with calf, and weighed 1452.6 lbs. She had the same allowance, during the experiment, as she had had for several days before, and which, for twenty-four hours, consisted of

Hay	16.6 lbs.
Cut wheat straw	9.9 "
Beet	59.4 "

The experiment was continued for four days, during which the excrements, the urine, and the milk were carefully collected and weighed, and the ashes, both of the food consumed and of the products rendered, were determined by chemical analysis. Suffice it to say, that, representing the quantity of mineral matters assumed into the body, in the course of the experiment, by 849.9 half-drachms, the quantity voided amounted to no more than 5.56 half-drachms. In the quantity assumed, there were 100.2 half-drachms of phosphoric acid, and 203.8 half-drachms of lime. In the quantity voided, there were but 68.2 half-drachms of phosphoric acid, and 116.8 half drachms of lime. This is at the rate of about 8 half-drachms of phosphoric acid, and 22 half-drachms of lime assimilated in the course of twenty-four hours. Here, as in the case of the calf, the quantity of lime assimilated is greatly superior to what it ought to be, in order, by combining with the phosphoric acid, to constitute the phosphate of lime of the bones.

From these inquiries into the nutrition of the calf, and of a cow in calf, it follows that there is a portion of the mineral substance taken in with the food, which remains definitively fixed to concur in the growth, or in the evolution of the individual. In an adult animal, it is to be presumed that no such definitive fixation of inorganic principles takes place, or that it is much less considerable, that in the dejections and several secretions ought to be found the whole of the phosphoric acid, of the lime, &c. taken in with the food; and this presumption is confirmed by experience, for, on instituting an inquiry into the matter upon a horse, it was found that the mineral matters assumed were almost exactly balanced by those discharged. Nevertheless, and granting this to be quite true, which it is, it would be a grave mistake to suppose that an adult animal could go on, for even a very short period of time, upon food that contained no mineral matter. Precisely as in the case of organic matter, it appears that a portion of inorganic matter is also fixed in the living frame, where, for a time, it forms an integral element in the wonderful structure, and a supply of the latter kind is, undoubtedly, no less necessary than is the supply of the former description recognised by all the world.

Were there an inadequate quantity of phosphoric acid, of lime, &c. in the food, there is no question but that the body would speedily feel the effects of the deficiency, and that disease and death would by-and-by put an end to life. So much, indeed, seems demonstrated by the very interesting experiments of M. Chossat, in which he kept graminivorous animals upon a diet rich in azotized principles and in starch, but deficient in lime. From some previous inquiries, M. Chossat had observed that pigeons even

require to add a certain proportion of lime to their ordinary food, the quantity naturally contained in which does not suffice them. Wheat, as we have seen, though it contains a large proportion of phosphate of magnesia, contains very little phosphate of lime, and pigeons, put on this grain, though they do perfectly well at first, and even get fat, begin by-and-by to fall off. In from 2 or 3 months, the birds appeared to suffer from constant thirst; they drank frequently; the fæces became soft and liquid, and the flesh wasted; and, in from 8 to 10 months, the creatures died under the effects of a diarrhœa, which M. Chossat attributed to *deficiency of the calcareous aliment* in the food: and it is neither uninteresting nor unimportant to observe that the same thing occasionally occurs in the human subject, during the period when the process of ossification is usually most active. But one of the most remarkable features of M. Chossat's experiments was observed in the state of the bones of the pigeons; they became so thin and weak that they broke, during the life of the birds, with the slightest force.* The conclusion from this fact is obvious—supplies of all the elements of all the parts of the body are indispensable to the maintenance of health, to the continuance of life.

A pigeon will eat about 468.140 grains of wheat per diem, containing 9.725 grains of ash, in which analysis discovers 4.569 grains of phosphoric acid, and 0.277 of a grain of lime. But this small quantity of lime is incompetent to maintain the bones in their standard condition. I have thought it of moment to insist upon these facts, because I see that they may sometimes come into play in practical rural economy. No breeder or feeder ought to be ignorant of the influence of mineral substances on nutrition.

It is not only indispensable that the allowance of an animal in full growth be sufficient to support and even to add to the soft textures; it must further contain the elements requisite for the nutrition of the osseous system; and it is not impossible but that in managing the feeding of young cattle or young horses in such a way as to reduce to a minimum or to give in excess certain of the inorganic elements of the food, we may succeed in impressing one character or another upon a race. It is even possible that the empirical rules which are acted upon with a view to increase or diminish the quantity of bone, the weight of flesh or of fat, &c., are all connected with various proportions of phosphoric acid, of lime, magnesia, &c. in the food. It will probably be discovered some day, that Bakewell's art is to be explained through the composition of the ashes of the food.

Wheat is not the only alimentary matter that contains an insufficient quantity of lime: maize or Indian corn contains still less; and if that which is grown in the tropics contains as little as that which is produced in Europe, it would be difficult to explain how the grain should answer so well, as it unquestionably does, for food.†

It is true that it is seldom or never consumed alone and without addition; and in South America, where the animals have it largely, I have observed that they frequently eat earth. The habit which certain tribes of the natives have of eating earth, too, which has been particularly remarked upon by travellers and missionaries as an instance of depravation of taste, presents itself to me in quite another light, since I became acquainted with the com-

* Chossat, in Comptes Rendus, t. xiv. p. 455.

† An ash of maize, analyzed in my laboratory by M. Letellier, contained but 1.8 per cent. of lime to 50.1 of phosphoric acid, and 17.0 of magnesia.

position of the ashes of the ordinary article of diet in the countries where it occurs.*

The calcareous and other salts necessary to nutrition, however, are not derived from the food exclusively; the water that is generally consumed contains a quantity which is by no means to be neglected. A horse or a cow, for instance, which drinks from 15 to 45 quarts of water per diem, will, even if the water be as pure as that of the artesian well of Grenoble, take in from 35 to 108 grains of saline matter, in which carbonate of lime predominates. Water that is less free from saline impregnation would, of course, introduce a much larger proportion; some waters, in the quantities above specified, will contain from 188 to upwards of 400 grains of saline matter, one-half of which may be carbonate of lime. And I am here speaking of clear or filtered water; that which is muddy or turbid contains a still larger quantity of earthy matter in suspension than in solution. In an experiment made for the purpose of getting at the amount of earthy matter taken by a milch-cow from the watering-trough in the course of the day, I found that it amounted to about 770 grains troy.

Notwithstanding these facts, it is still doubtful whether the lime contained in ordinary well-water would prove sufficient to supply a growing animal with the material requisite to the formation of its bones; in adults, indeed, changes in the elements of the bones appear to proceed so slowly, that a very small quantity of calcareous matter, probably, suffices to repair losses; but it is otherwise with young and growing animals. I have shown that a calf, six months old, receives with its forage a quantity of phosphoric acid which corresponds to 555.7 grains of phosphate of lime. A calf, a few weeks old, when it has 17 or 18 pints of milk per diem, receives 802.7 grains of mineral substance, into which subphosphate of lime, or bone-earth, enters in the proportion of 370.5 grains. It would be interesting to ascertain what quantities of these substances were assimilated by so young an animal, and at a period when the growth is so rapid that the increase, from day to day, sometimes exceeds two pounds.

The importance of the inorganic principles of the food once recognised, it concerns us to take note of their nature and quantity in the ratio we allow to our domestic animals. It is, in fact, this consideration which has led me to determine the quantities of phosphoric acid and lime contained in the various articles of food the ashes of which have been analyzed. With these data the proportion of bone-earth contained in a given ratio is forthwith perceived.

One thousand parts of the forage, gathered by Bechelbron, in its ordinary state, contained—

* I several times saw children chastised in Indian villages, who had been caught eating earth.

Forage.	Mineral Substances.	Azote.	Phosphoric Acid.	Lime.	Bone-earth.
Hay	66.88	11.50	8.37	10.04	6.96
Potatoes	9.64	8.70	1.09	0.17	0.38
Beet	7.70	2.10	0.46	0.54	0.95
Turnip	5.70	1.80	0.85	0.62	0.72
Jerusalem Potato	12.47	8.75	1.85	0.29	0.56
Wheat	20.51	20.50	9.64	0.60	1.16
Maize	11.00	16.40	5.51	0.14	0.27
Oats	81.74	17.87	4.78	1.17	2.27
Wheat straw	51.90	8.00	1.61	4.41	8.82
Oat straw	85.70	8.00	1.07	2.97	2.21
Clover hay	78.50	21.00	4.68	18.06	9.85
Peas	80.00	88.40	9.03	8.08	5.88
Haricots	85.00	48.80	9.88	2.02	5.94
Beans	80.00	51.10	10.26	1.58	9.27

We seem here to observe a certain relation between the proportion of azote and that of the phosphoric acid contained in the food. The most highly azotized are also those that generally contain the largest quantity of the acid—a circumstance which seems to indicate that in the vegetable kingdom the phosphates are connected more especially with the azotized principles, and that they accompany them in passing into the textures of animals. With the assistance of the above table, it is easy to ascertain the quantity of phosphate of lime which enters into a given ration. Let us take that given to the horses in experiment 3d, in which the half of the hay was replaced by potatoes, one of the articles that contains the smallest proportion of lime, and to find in the

26.6 lbs. of hay, 632.9 grs. phosphoric acid and 1869.9 grs. of lime,
30.8 lbs. of potatoes, 387.7 grs. " 37.9 "

numbers which correspond with 1798.5 grains of bone-earth, and 978.7 grains of uncombined lime.

In his usual allowance, a work-horse at Bechelbron receives,

Hay, 22 lbs. containing 524.8 grs. of phosphoric acid, and 1543.8 grs. of lime,
Straw, 5.5 " 60.7
Oats, 7.2 " 230.2

81.57

In other words, 1735 grains of bone-earth, and 864 grains of free lime.

I have found that very young foals, growing rapidly, and weighing about 374 lbs., consume per diem,

Hay.... 19.8 lbs. containing of phosphoric acid 463 grs., lime 389 grs.
Oats.... 7.2 " " 231 " 58.6

which represents 95 of bone or subphosphate of lime. As a consequence of the relation which appears to exist between the azote and phosphoric acid of an article of sustenance, it comes to pass that like nutritive equivalents also indicate like proportions of phosphoric acid; so that, by introducing a suitable quantity of hay or clover, articles that abound in lime, into the ration, we are always certain of having food favorable to the development of the osseous system, whatever the nature and quality of the other articles that enter into the constitution of the allowance.

The relation of the phosphoric acid to the azote approaches the ratio of 8 to 10 in the more ordinary articles of forage; but the same relation is no longer apparent in the cereals and leguminous vegetables: in grain, and peas, and beans, the phosphoric acid amounts to about a fourth of the azote contained. Thus we have,

	Theoretical equivalent.	Phosphoric acid in the equivalent.
Hay	100	0.34
Potatoes	320	0.35
Beet	548	0.28
Turnip	885	0.31
Jerusalems	273	0.34
Wheat straw	235	0.87
Oat straw	380	0.40
Oats	68	0.32
Maize	70	0.38
Wheat	43	0.41
Haricots	27	0.25
Beans	23	0.24

THE COTTON TRADE, FROM 1825 TO 1850.

BY PROFESSOR M'KAY, UNIVERSITY OF GEORGIA.

Instead of our annual review of the cotton trade, for a single year, we propose to extend our examinations back to a longer period. For this purpose, we have collected, in our statistical tables, the production, consumption, stocks, and prices of cotton for each year from 1840 to 1850; and, for the more important particulars of the trade, we have gone back as far as 1825. This period of 25 years we have divided into intervals of 5 years, and given the average for each, noting the rate of increase or decrease for each country separately. By taking average results, we get clear of the fluctuations arising from short crops, and other disturbing causes, and are able to observe the general progress, free from those temporary variations which prevent our judging accurately the real changes that are taking place. In this review, we shall see a very prominent place assigned to our country. The United States is now, not only the largest producer, but the largest consumer of cotton: our production has advanced with such rapid strides, that we have distanced all competitors: the cotton goods worn by our people exceed now the amount used by Great Britain and all her dependencies in the four quarters of the globe; and the demands of our manufactories have increased with much greater rapidity than those of any other country in the world. In the table of supplies, (Table I., at the end of this article,) we may observe, that, while other countries have been nearly stationary, our production has advanced with great rapidity. In 20 years, our average crop has increased from 848,000 bales to 2,351,000, or nearly three hundred per cent. If the period of 25 years, from 1825 to 1850, be divided into five equal intervals, the increase for each will be found to be 27, 37, 38, and 15 per cent. In the same time, the production of all other countries has only

risen from 383,000 to 440,000 bales, having absolutely declined, in the last five years, over 16 per cent. In the first period of five years, the crop of the United States constituted 68 per cent. of the whole; in the second, 74; in the third, 77; in the fourth, 80; and, in the fifth, 84 per cent. of the whole. As our bags have increased very much in weight, and are now much larger than those of other countries, our advance has been still greater, and our rank still higher than these figures indicate. If the table of consumption (Table II.) be examined, it will appear that our progress is none the less rapid, in comparison with other countries. In the same 20 years, the deliveries to our manufactories have advanced 325 per cent., viz. from 127,000 bales to 539,000; while, in the same time, the advance of Great Britain has been only 125 per cent., viz. from 653,000 bales to 1,472,000. In each one of these periods, our rate of progress has been more than twice as rapid as hers; and though the absolute amount of our consumption is yet far below that consumed by the English manufacturers, yet, in the last five years, our increase has been 176,000 bales, while theirs has been only 180,000. At present, our consumption is 37 per cent. of the English, while twenty years ago it was only 19 per cent.

France, during all this period, has remained nearly stationary. Twenty years ago, her consumption was 257,000 bales; now, it is only 368,000. In the last five years, she has gone backward, the decline having amounted to 58,000 bales. From 1825 to 1830, the deliveries to her manufactories were double those of the United States; now, they are 33 per cent. less than ours. Her rank, compared with Great Britain, and with nearly every other country in Europe, has also declined. In Spain, Belgium, Germany, Holland, and Russia, the increase has been nearly as rapid as in the United States. In the last five years, their advance (Table III.) has been 46 per cent.; ours, 49 per cent. Their rank in the cotton-consuming countries is yet low, but their rapid progress will soon bring them to a more important position. At present, their consumption is 34 per cent. of that of Great Britain, and the time is not far distant when, taken together, will equal her. Twenty years ago, the comparative rank of the United States, Great Britain, France, and the rest of the continent, was in proportion to the numbers 11, 55, 22, and 12; in the last five years, the percentage of each has been 19, 51, 13, and 17. If France be left out of the comparison, the rank of each, twenty years ago, was as 13, 70, and 17; now, it is as 21, 59, and 20. Although Great Britain requires for her manufactories more than half of all the cotton worked up in Europe and America, the amount actually used by her people, including all that is exported to India, British America, Australia, and all the colonial dependencies of Great Britain, is less than the amount used in the United States. This has been shown to be true for the last four years; and the present year, although it exhibits an apparent decline in our home consumption, forms no exception to this result. The enlarged imports of cotton goods imported into our seaports, compensate, in part, for the falling off of the wants of our factories. If we compare the progress in the demand and supply, it will be seen that, during the last five years, the consumption has increased much faster than the production—the one having advanced 19 per cent. and the other only 9. This might be inferred from the decline in the stocks, but it will be more satisfactory to consider the average production and consumption of the last ten years. The average amount taken by the manufacturers, from 1840 to 1845, was 2,414,000 bales, and, from 1845 to 1850, 2,869,000 bales, showing an increase of 465,000 bales; while the supply advanced from 2,561,000 bales to 2,791,000, with an increase of only 230,000 bales. When it is remembered that the last period embraces the year 1847, when, from the revolutions in Europe, the consumption declined over 600,000 bales, and the years 1845 and 1849, when the American crop so far exceeded its usual average, this result will be more striking and important. The table of stocks (Table IV.) confirms and establishes this same result. At the end of 1844, the cotton on hand in Europe was 1,101,000 bales; at the end of 1849, it was only 646,000 bales.

It may be further observed that the increase in the supply, during the last five years, has been slower than the natural increase of laborers. The advance in the one has been only 9 per cent., and in the other 12 or 13. As many new hands have been brought to the Southern States during this period, the rate of increase in the working force of the cotton-growing States has been still greater than 12 or 13 per cent. This excess has occurred at no former period. From 1825 to 1850, the increments for each period of five years have been 18, 32, 33, and 9 per cent.; always above the increments of population, except in the last interval. It follows, from this, that labor and capital have found other modes of employment more attractive and profitable than the raising of cotton. It is well known that this has been to some extent true in the United States, but it has been more evident and striking in India and Brazil. In these countries, the crop has declined 16 per cent. in the last five years. From Brazil, it has declined regularly for the last twenty years, and the recent advance in coffee will tend still more to divert labor from the production of cotton. The abolition of the discriminating duty in favor of East India cotton, by Sir Robert Peel, and the very low prices which have recently prevailed, have not only stopped any increase in the imports of Surat and Madras, but turned the current in the opposite direction. The advance in the fifteen years before 1845 was 10, 80, and 60 per cent., in each interval of five years; but, from 1845 to 1850, the decline has been 24 per cent. It may fairly be deduced, from this, that the prices of the last five years have not afforded sufficient encouragement to production, and that the planters may now look for a permanent improvement in prices. The table of prices (Table V.) shows that for the last five years the average price at the seaports of the United States has been seven cents and three mills; and it may be expected, with confidence, that they will not rule so low hereafter—that the average rates will not merely experience a temporary rise, as if caused by the short crop and the small stocks of the present year, but a permanent and continued advance.

The table of stocks (Table IV.) represents the amounts on hand in the seaports of Europe continually increasing from 1840 to 1850, while during the four years ending 1849, they have been nearly stationary. Comparing them with the wants of the manufacturers, as is done in the column which contains the number of weeks that the stocks would supply the consumption of the factories, the supply was a trifle lower at the close of 1849, after the receipt of the largest crop ever brought to market, than it had been during the last ten years. The number of bales was a little greater than at the close of 1848; but the time this stock would supply the wants of the manufacturers was a little less. After this review of the history of the trade in cotton for the last ten years, if we remember that the production of 1850 has been much below the average of the last five years, and that the prospects of the next year's crop are but a little better, it is evident that the present advance in cotton is founded upon no speculative basis, but on the unchangeable laws of supply and demand. Two short crops are succeeding each other, while the stocks on hand are very much reduced. To this, it may be added, that every thing is favorable to a large consumption. Peace everywhere prevails, except in the unimportant Duchies of Schleswig Holstein. Money is abundant, and the currency everywhere undisturbed. Food is very cheap. The present harvest of Europe, as well as the last, is much above an average. Thus, while stocks are low, and the supply small, the demand is large. Prices, therefore must maintain a high level, unless commotions in France, or some unforeseen event of commanding importance, interferes with the regular operation of commerce. In considering the supply and demand of the coming year, we must, therefore, base all our estimates on high prices. The receipts from India and Brazil, and the consumption in Europe and America, will all be affected by this fact. If the advance were slight, it would not experience any sensible check; but when the price has risen to its present rate, (13½ cents for middling fair, Savannah, October 23d,) an advance of 85 per cent. over the average of the last five years, the amount purchased even in our country may be expected to decline. The supply for 1851 will probably exceed that of 1850, not only from the United States, but from India and Brazil.

The past season here has been unfavorable for the growth of cotton; but its disasters, especially in the West, have not been as severe as in the preceding year. In South Carolina and Georgia, there will be a decided decline. The late cold spring, and the long drought in June and July, left the plants small, and the bolls few and scattering. The severe storm on the 24th of August blew out on the ground much open cotton, and prostrated and twisted the stalks so much that there has been no late crop of forms to mature in October. September was a beautiful season for gathering, and so was much of October. There are some plantations where the crop is very fine. The hot summer favored a rapid growth, and repaired, in part, the injury done by a late spring. The general drought was, at some places, relieved by local showers, which brought out some superior crops. The amount of land planted was greater than ever. The receipts at Charleston and Savannah will also be increased by the extension of the Georgia Railroad to the Tennessee River. Were it not for this last cause, a falling off of 100,000 bales might be anticipated. With this, the deficiency will not probably exceed 70,000 or 80,000; and the receipts of these two ports may be expected to reach 650,000 bales. From Alabama, the reports have not been so disastrous. The spring was late, and the stand poor; but the dry summer prevented the ravages of the worm, which had done so much damage the preceding year. The river floods had also done harm the last season; and these they have escaped. The prairie lands have not suffered so much with rust as before. On the Tombigbee, and also on the Black Warrior, the prospects of the planters are very much above those of last year. On the Alabama, the promise is about the same as last year. Still, the disasters have been severe, and the crop will be below an average. An increase of 90,000 or 100,000 bales in the receipts at Mobile, including the Montgomery shipments to New Orleans, may, with confidence, be anticipated. From Florida, a slight increase may be looked for. The amount of land planted has been considerably enlarged, and the drought has not been as general as in the eastern part of the cotton region. At New Orleans and in Texas a gain may be looked for. The failure, last year, was so great, that it is almost impossible to expect a like deficiency again. From Louisiana, Arkansas, and the greater part of Mississippi, the reports have been better than last year. The early frost of October 6th injured not a little of the cotton as far north as Memphis; but in general, even in Tennessee, the plant remained green and flourishing, till the general frost at the close of the month. The production of Tennessee and North Alabama will fall below that of last year, and a portion of this will not reach New Orleans. The crop was everywhere backward, but the hot, dry summer helped to repair this damage, and by keeping off the caterpillar and bollworm, permitted the forms to mature. The severe storms, that did so much harm in Florida and the Atlantic States, did not extend so far to the west. The season for gathering has been very fine, and the time of frost late enough to mature nearly every boll that could make cotton. The average receipts at New Orleans, for four years past, have been 943,000 bales; and this period includes two short and two full crops. For the present year, I would estimate them at 850,000 bales. Combining these estimates, the whole supply from the United States will amount to 2,200,000 bales, (see Table VI.) which is about 100,000 in advance of the last five years. The receipts from India have increased very much during the present year, under the stimulus of high prices, and they are destined to advance still more for the coming season.

The purchases now making in Bombay for the English market are reported to be large; and when the new crop begins to arrive at the seaports, the current will turn still more strongly towards England. Not only is their production enlarged by high prices in Europe, but a larger portion of the crop is diverted from China, and from domestic use, for the Western markets.

The average imports into Great Britain for the last 3 years have been 211,000 bales; but for the first 9 months of the present year, they have reached 128,000 bales for Liverpool alone; and for the whole year, for all the ports, they will probably reach 300,000 bales. For 1851 not less than 325,000 bales may be anticipated. This is higher, much higher than any former year. The year 1841 was the largest before 1850, and then the amount was 275,000 bales. The high prices that are now prevailing, and that are likely to prevail for the present season, authorize us to expect an increase even over the present year. (Table VII.)

From Brazil, Egypt, and other places, an advance over the usual average may also be looked for. The average imports into England from 1845 to 1849 were 175,000 bales; but for the present year, the amount will exceed 260,000 bales, and for 1851 will be still larger. (Table VIII.) If we estimate them at 275,000, the whole supply from all these sources (Table IX.) will reach 2,800,000 bales. In reference to the consumption, we may remark that the purchases for our home manufactories have declined during the present year over 30,000 bales. The high price of the raw material, the low duties on foreign goods, and the immense imports of cotton fabrics from England, have caused this retrograde movement. In 1849, there was a falling off of 14,000 bales, so that our consumption is now 44,000 bales below that of 1848. Doubtless the stocks in the hands of the manufacturers are very small, and a slight advance in goods would set all the mills at work again. The universal prosperity of the country forbids us to expect the extension, or even the continuance of this depression. For 1851, I would estimate the demand at 500,000 bales, which is 11,000 above the consumption of the present year, (Table X.) and 18,000 below the average of the last year. In Great Britain, the falling off in the purchases of the manufacturers have been very slight, (Table XI.) and as the reported purchases last year were 80,000 or 90,000 bales above the actual deliveries to the manufacturers, the real deficiency is less than the apparent. For the present year, the consumption in Great Britain will not be below 1,500,000 bales, against 1,588,000 in 1846, and 1,491,000 in 1848. Every thing has been favorable to a large consumption, except the price of the raw material. Money has been abundant—food of all kinds cheap—and labor well rewarded. These elements of prosperity have not been confined to Great Britain, and therefore her exports of cotton goods have been unprecedentedly large. The home and foreign demand being both good, the factories have run full time, in spite of the high price of cotton. This never occurred before, and cannot be expected again with any considerable confidence. At every former period, an advance in the raw material has checked the demands of the factories, and lessened the purchases of the consumers. For the coming year, every thing is fully as favorable as the last; and, if these favorable tendencies have counteracted the tendency of high prices in the raw material, it will be proper to expect the same for 1851 as for 1850. We may, therefore, set down 1,500,000 bales as the probable English consumption for the next year.

In France, there has been a decided decline (Table XII.) in the deliveries to the manufacturers. Our exports have fallen from 368,000 bales to 290,000, and the stocks on hand the 1st of October were almost exactly the same as last year. The purchases at Havre for the first 9 months of the present year have been 249,000 bales, against 290,000 in 1849. From these figures, we cannot estimate the consumption of American cotton for the present year higher than 300,000 bales, against 351,000 for 1849. No advance on this can be expected for the next year, nor is there any reason to anticipate any appreciable decline. For the rest of Europe, we have the exports from the United States for the present year, 194,000 bales, and the exports from Liverpool up to October 11th, 198,000 bales. The whole English exports of 1849 were 254,000 bales, and as their amount on October 12th was 21,000 more this year than last, the whole exports for the year from all the ports will probably reach 275,000 bales, making the total supply from these two countries of 469,000 bales. As the stocks on hand on the continent last year were very low, it is impossible to reduce them much lower. They are now, however, at several ports, lower than last year, so that the consumption will probably exceed 469,000 bales. As this is a decline of over 100,000 bales from 1849, it is not to be expected that so low a limit can be reached for the year 1851. Heretofore, their progress has been forward and rapid, and, were it not for high prices, this would continue. If we estimate their wants for 1851 at 500,000 bales, we have the total consumption (Table XIII.) of 2,800,000 bales—the same as the supply. As the stocks are now much lower than last year, (Table XIV.) and as they were then very low, they will bear no further reduction without a material advance in prices. On the contrary, any decline in price would immediately permit the consumption to expand, not only in France and the rest of the continent, but even in England. We may expect, therefore, that the present high range of prices will be maintained.

The review that has been taken of the supply and the demand shows that the present advance in cotton is the result of no speculative movement, but that it is based on the immutable laws of trade. The long prevalence of low prices has stimulated consumption and diminished production, until the stocks on hand have fallen to an extremely low limit. Exactly at this point, an unfavorable season has lessened the crop, and an abundant harvest and every other element of general prosperity have encouraged the demand. We congratulate the planters on the handsome returns they are receiving for their crops, and we may extend our congratulation to the whole country, for what benefits them is a benefit to all.

THE POTATO-ROT.

WE find the following article in the Boston Journal:—

"From all quarters of the State, we hear of the prevalence of the potato-rot. It seems to be more virulent in its operation and injurious in its effects than in former years; for now, in large fields, scarcely a potato can be found that is sound. One man, in Newton, lately offered a field of three acres for $5, and could not find a purchaser. In several towns in Middlesex county, there is not a field where the potatoes are untainted. We have already mentioned that in Essex county, and in the western part of the State generally, the potato is found to be very generally rotten; so much so as to threaten its almost entire destruction, unless the disease is soon arrested."

In Plymouth county, also, the blight has appeared, it is said, in nearly every farm in the upper part of the county. The Plymouth Memorial says:—

"It is confined principally to one or two varieties: the Chenangoes and the pink-eyes, or calicoes, are nearly all which have yet, to our knowledge, been affected. The former has, ever since the first appearance of the rot, some years since, been the most affected, and we should think it advisable to relinquish its culture, at least, for the present."

In Barnstable county, likewise, this mysterious rot has made its appearance. The Sandwich Observer says:—

"The potato rot has reappeared in this town, and is thought to be doing greater injury than it has done in any preceding year. The potatoes, in some fields, will hardly pay for the digging. When they come out of the ground, many of them look fair and sound, but an inside inspection shows their rottenness."

We have, also, accounts of the prevalence of the disease in New Hampshire:—

"In Rockingham county, N. H., the rot has suddenly taken hold of the potatoes, and the crop is very seriously injured, if not totally cut off. One patch of eight acres, which was calculated to produce 2000 bushels, is wholly lost. In Greenland, some potato fields are being ploughed up. In Rye and Newington, the disease is felt to the same extent."

The Portsmouth (N. H.) Journal says:—

"The loss of potatoes, in towns adjoining this city, cannot be much short of $100,000, should the crop utterly fail, as the present prospect seems to indicate."

From Rhode Island, we have a similar report. The Providence Journal says:—

"We regret to learn that this disease has suddenly appeared in this quarter. A few days ago, the potatoes looked finely. But now, we hear of their decay in all directions, and many fields, which promised a large yield, will not be worth digging."

SUGAR-CLEANSING MACHINE.

The New Orleans "Crescent" thus describes the operation of "Hurd's Patent Centrifugal Machine," which is represented to be an important invention to sugar-planters, both in the saving of time and sugar, as well as improving its quality.

The machinery is propelled by steam. The process is as follows:—The dark mixture of sugar and syrup, just as it is taken from the sugar-house coolers, is placed in a cylindrical tub, made of iron, the bottom of which is tight; but the sides or circumference is pierced full of small holes, which are covered over by fine wire-gauze. The cylinder is so arranged that it can be made to revolve on a stationary axle with great rapidity, making from 1000 to 1500 revolutions in a minute—or a speed of 2 or 3 miles per minute. The sugar, as soon as the machine begins to revolve, gradually leaves the bottom of the cylinder and attaches itself to the circumference. The motion continues; and if the wire-gauze were not strong enough, the sugar would break it and escape. The crystals, however, are retained by the fine network of the wire, but the molasses or syrup is driven by centrifugal force through the wire, and is projected with power and rapidity into an outside case, arranged to retain and collect it. In the course of a short time, varying from 5 to 10 minutes, the molasses has been thrown off, and the sugar is drained and fit for shipping, being much drier than when usually put on board. The syrup is now ready to be boiled a second time, before the air or heat has had any influence upon it, and another crop of crystals can be obtained, which can be subjected to the action of the machine; and the syrup coming from this second operation can be treated a third time, until its strength is exhausted.

ANALYSIS OF THE APPLE.

BY J. H. SALISBURY, M. D.

This examination was entered into with the view of throwing some light upon the composition of the apple. To determine whether or not it contained a sufficient percentage of nutritious matter to render it profitable as food for stock. That it has been used with a good degree of success in many instances, for several years, is well known; but it is by no means generally conceded that the apple is so nutritious as it actually is. Those who have had some experience in feeding good varieties, will find in the following analysis the reason of their favorable opinion of this valuable product of the farmer—valuable, because, if properly managed, the crop is sure, large, rich, and attended with less labor and expense than almost any other.

It was the intention to have analyzed several varieties of sweet apples; but, owing to the lateness of the season before the examination was commenced, and the scarcity of these varieties, I was unable to obtain any except the Tolman Sweeting.

Percentage of Water, Dry Matter, and Ash.

	Pulp of the Swaar.	Skin or Epidermis of the Swaar.
Percentage of Water	84.75	61.20
" Dry matter	15.25	38.80
" Ash	0.26	0.72
" Ash calcined on dry matter	1.705	1.856

Percentage of Water and Dry Matter.

	Tolman Sweeting.	Roxbury Russet.	Kilham Hill.	English Russet.	R. Island Greening.
Percentage of Water	81.52	81.35	86.31	79.21	82.85
" Dry matter	18.48	18.65	13.69	20.79	17.15

*The above results were obtained the 1st of March. The per centage of water in the six varieties examined, ranges from 79.21 to 86.31 per cent. The Kilham Hill contains the most; the Swaar stands next; the Greening third; and the English Russet has the least. The percentage mean from the six results is 82.664.

The percentage of inorganic matter in the apple is small, not much exceeding that of the richer grains. Like the ash of wheat and corn, it is obtained free from coal with some difficulty, on account of its fusing at a low red-heat.

Organic matter thrown down by nitrate of silver	4.30	5.021	4.64	5.187	6.11	7.508
	99.75	100.000	99.59	100.000	99.46	100.000

The analyses are inserted both with and without the carbonic acid. They were calculated without it, in order to show the real composition of the inorganic matter of the fruit. The carbonic acid is formed during the combustion of the inorganic matter, and hence cannot be regarded as a constituent part of the apple, except in very minute quantity.

In silica the apple is by no means rich, containing, in the varieties examined, from about 1 to 2.3 per cent. The mean percentage of the five results is 1.637. The phosphate of iron ranges from about 1 to 2.2 per cent.; the phosphoric acid, from 11 to 15 per cent.; the lime, from about 3 to 5 per cent.; the magnesia, from about 1 to 2.2 per cent.; the potash, from about 35 to 42 per cent.; the soda, from 19.3 to 30.4 per cent.; the chlorine from 1.85 to 2.33 per cent.; and the sulphuric acid, from 6.66 to 8.02 per cent.

The percentage of ash in the apple is small, yet rich in phosphoric and sulphuric acids, potash, and soda. 100 pounds of apple-ashes, deprived of carbonic acid, contain, according to the mean of the foregoing results, about 13 lbs. of phosphoric acid, 7 lbs. of sulphuric acid, 38 lbs. of potash, and 25 lbs. of soda. In other words, these four bodies make up about 83 per cent. of the whole ash.

1000 lbs. of fresh apple contain about 827 lbs. of water, 170.4 lbs. of organic matter, destroyed by heat, and 2.6 lbs. of inorganic matter or ash. 1000 lbs. of dry apple contain between 17 and 18 lbs. of ash.

Mean of the five foregoing Analyses.

Besides the above-mentioned bodies, the apple contains a small quantity of tannic and gallic acids. Of the varieties examined, they were found in larger proportion in the Russets than in either of the others. To these acids this fruit owes that peculiar astringency, so strikingly developed in some varieties, and easily detected in all, by the taste and by the black color struck through them when cut with a knife, or any instrument made of iron.

Liebig states that starch is found in the unripe apple. I have not been able to detect it in the ripe fruit, except in the Tolman Sweeting, which give a very faint blue with iodine.

A small quantity of white wax is found, which is derived mainly from the epidermis, over which it is spread, imparting to it, in many varieties, a smooth, greasy feel. A little fatty matter is also present, together with a respectable percentage of gluten. The glutinous matter differs from that of the grains, in being less adhesive when moist, and more granular when dry.

The foregoing analyses were made during the months of March and April. The Tolman Sweeting was somewhat shrivelled, and rather past its season: the other varieties were fresh and in good eating order. The Tolman Sweeting, English Russet, and Kilham Hill, were furnished by E. P. Prentice, Esq., of Mount Hope.

Mean of the Six foregoing Analyses.

	1000.00	....

The ripe apple is rich in sugar, and a body analogous to gum, called *dextrine*, which has the same composition as starch, but differs from it in being soluble in cold water, and not colored blue with iodine. It derives its name from the action of its solution on polarized light, it causing the plane of polarization to deviate to the right; hence its name, *dextrine*.

Dextrine and gum should not be confounded with each other. They differ very materially in many respects. The former possesses the property of being converted into grape sugar, by sulphuric acid, and by diastase, while the latter does not. Dextrine belongs to the class of bodies which are susceptible of nourishing the animal body. All the starch taken as food is converted into dextrine before it is assimilated by the system. The acid of the stomach possesses the property of converting starch into this body.

In the fresh apple, 100 lbs. contain about 3.2 lbs. of fibre; 0.2 of a lb. of gluten, fat, and wax; 3.1 lbs. of dextrine; 8.3 lbs. of sugar and extract; 0.8 of a lb. of malic acid; 1.4 lb. of albumen; 0.16 of a lb. of casein, and 82.66 lbs. of water.

In the dry apple, 100 lbs. contain about 19 lbs. of fibre; 1.1 lb. of gluten, fat and wax; 18.7 lbs. of dextrine; 49.8 lbs. of sugar and extract; 2 lbs. of malic acid; 8.4 lbs. of albumen, and 1 lb. of casein.

In the fresh potato, 100 lbs. contain about 9.7 lbs. of starch; 5.8 lbs. of fibre; 0.8 of a lb. of gluten; 0.08 of a lb. of fatty matter; ¼ of a lb. of albumen; 0.45 of a lb. of casein; 1.27 lb. of dextrine; 2.64 lbs. of sugar and extract; and 79.7 lbs. of water.

In the dry potato, 100 lbs. contain about 48.5 lbs. of starch; 29 lbs. of fibre; 1 lb. of gluten; 0.4 of a lb. of fatty matter; 1.25 lb. of albumen; 2.25 lbs. of casein; 6.32 lbs. of dextrine; and 13.2 lbs. of sugar and extract.

By comparing the composition of the apple with that of the potato, it will be noticed; first, that the former contains, according to the above analyses, about three per cent. more of water than the latter. Second, that dextrine and sugar, in the apple, take the place of starch, dextrine, and sugar, in the potato. Of the former, 100 lbs. of good fruit contain of dextrine, sugar, and extract, 11.4 lbs.; the latter has, in the same amount of fresh tubers, 13.61 lbs. of starch, dextrine, sugar, and extract. In the dry fruit, 100 lbs. contain of dextrine, sugar, and extract, 68.5 lbs.; in the same quantity of dry potato, there is, of starch, dextrine, sugar, and extract, 68.02 lbs. The above proximate principles are the main bodies in the apple and potato which go to form fat. In the aggregate amount of fat-producing products, it will be seen that the apple and the potato do not materially differ. It would be natural, however, to infer that 50 lbs. of dextrine and sugar would, if taken into the system, be more likely to make a greater quantity of fat, in a given time, or, at least, to make the same amount in a shorter period, than an equal weight of starch; for this reason, that the two former bodies, although nearly the same in composition with the latter, yet are physically further advanced in organization, and hence probably approximate nearer the constitution of fat. If this view be taken, then the apple, if of good quality, may be regarded equally, if not more rich, in fat-producing products, than the potato. Thirdly, that the apple is richer in nitrogen compounds than the potato. 100 lbs. of fresh apple contain of albumen 1.38 lb; the same amount of fresh potato has ¼ of a lb.; 100 lbs. of dry apple contain 8.37 lbs. of albumen, and an equal weight of dry tubers has 1¼ lb. 100 lbs. of fresh fruit contain of casein 0.16 of a lb.; and an equal weight of fresh tubers, 0.35 of a lb. 100 lbs. of dry apple have 1 lb. of casein; and the same amount of dry potato contains 2¼ lbs. Hence it will be observed that 100 lbs. of fresh apple contain of albumen and casein 1.54 lb.; and the same quantity of fresh potato, 0.7 of a lb. 100 lbs. of dry fruit have of albumen and casein 9.37 lbs.; and an equal amount of dry tubers, 3.50 lbs.

From the above, it will readily be seen that, in albumen, the apple is richer than the potato, while in casein the reverse is the case. That the aggregate amount of albumen, casein, and gluten, in good varieties of the apple, is more than double that of the same bodies in the potato; hence the former may be regarded richer than the latter, in those bodies which strictly go to nourish the system, or, in other words, to form muscle, brain, nerve, and, in short, assist in building up and sustaining the organic part of all the animal body.

The juice of the apple forms what was regarded, not long ago, a favorite and almost necessary appendage to the farmer's stock of winter luxuries. It is now, however, looked upon by him with comparative indifference as a beverage, he having found a far better and more profitable use for his apples, that of converting them into fat, instead of alcohol. The juice of the apple, after being fermented, is called cider, and contains much of the nutritive matter of the fruit. Cider contains alcohol, sugar, gum or dextrine, malic acid, and the phosphates and sulphates of the alkalies, with a little tannic and gallic acids. The juice, before being fermented, has, in addition to the above ingredients, albumen and casein.

For the purpose of comparing the composition of the apple with that of several other kinds of fruit, it may not be uninteresting to introduce their proximate organic analyses here, in connection with those of the apple. M. Berard has examined the unripe and ripe cherry, the unripe and ripe peach, the ripe pear, and the unripe and ripe gooseberry, and arrived at the following results:—

	Peach.		Pear.		Cherry.		Gooseberry.	
	Unripe.	Ripe.	Ripe and Fresh.	Kept for some time.	Unripe.	Ripe.	Unripe.	Ripe.

ANALYSIS OF RHUBARB.

BY J. H. SALISBURY, M. D.

General Remarks.—Of rhubarb, the following are the principal species and varieties in cultivation. The *Rheum rhaponticum*, (common pie-plant,) a native of Asia, introduced into Europe in 1575; *Rheum undulatum*, a native of China, introduced in 1734; Elford rhubarb, or scarlet variety; *Rheum hybridum*, a native of Asia, cultivated in 1778; Giant rhubarb, a variety of the *rhaponticum*; *Rheum palmatum*, or Turkey rhubarb; *Rheum compactum*, and *Rheum australe*.

Besides the above, there are several varieties cultivated in this country, principally derived from the *rhaponticum*. The first five kinds are cultivated entirely for their petioles. Several attempts have been made in the western part of Europe, and in this country, to cultivate the root of the first and last three mentioned sorts, for medicinal purposes; but without any degree of success. I do not see, however, if the composition of the root and the rest of the plant were well known, together with its habits, mode of culture, time of gathering, &c., why success might not attend its cultivation in the United States as well as in China and Turkey. The root of good Turkey rhubarb commands now in market from $3 to $4 the pound. If it could be successfully cultivated here, it would constitute one of our most valuable and lucrative articles of trade.

Uses.—The large succulent petioles are highly esteemed for making tarts, pies, jelly, preserves, wine, &c., which resemble much those made of apple and gooseberries. The root of several species is highly esteemed in medicine as a cathartic, possessing mild tonic and astringent properties. Among the species used in medicine are the *Rheum rhaponticum*, *R. palmatum*, *R. compactum*, and *R. australe*. The *R. rhaponticum* and several varieties derived from it, are mostly cultivated in this country for their very fine flavored petioles. The root grown in the western part of Europe and the United States is less firm, and acquires much less medicinal value than the root of the same species grown in China, Turkey, and Russia. The reason of this difference is not well known, but is probably owing to soil, climate, time of gathering, and mode of culture.

Composition of the several parts of the plant.—In this country, the several species of rhubarb are cultivated mostly for the petioles, or leaf-stalks. The texture and flavor of these vary greatly with the soil, mode of culture, and climate.

We should naturally infer that the soil in which rhubarb thrives (from its size and rapid growth) must be richly supplied with those materials, in a soluble form, which are found in the various organs and tissues of the plant. It is necessary to know, then, the composition of the plant, before we can positively decide what kind of soil is best fitted to its growth. The following analyses were made with the view of throwing some light upon this subject.

The Giant rhubarb, a very fine variety of the rhaponticum, cut June 1st. Plant in flower. Stout growth. The roots were very compact, and remarkably large. Furnished by Mr. C. N. Bement, of Albany.

Percentage of Water, Dry Matter, and Ash, in the several parts of the plant.

	Root.	Stalk.	Petioles.	Leaf-blades.	Flowers and pedicels.
Percentage of Water	82.000	89.500	93.465	88.00	86.900
" Dry matter	18.000	10.500	6.535	12.00	13.100
" Ash	0.925	1.130	0.940	1.52	1.320
" Ash calcined on dry matter	5.194	10.762	14.384	12.75	10.076

The percentage of water in all parts of the plant is large, amounting to from 82 to 93 per cent. The dry matter of the several parts is richly supplied with ash. The petioles contain the greatest proportion, and the root the least.

Inorganic Analysis of the several parts of the plant.

* In the essay on Indian corn will be found the method followed in obtaining the organic matter from the ashes of plants. This organic matter, in the paper referred to, is set down as organic acids. This was done from the fact that it seems to be combined with the inorganic bases of the ashes, after the manner of acids. It does not discolor the ashes in the least, and is so firmly united with them, that it is quite impossible to expel it entirely, unless they (the ashes) are kept for some time at a temperature above their point of fusion.

As there has been some objection raised to the name used in the paper referred to above, we will—till it has undergone a more thorough examination—call it organic matter thrown down by nitrate of silver. It may not be improper to state here that some chemists have doubted the presence of this matter in the ashes of plants. We do not blame them—for several reasons—for doing so; but would kindly ask them, before they make their opinions more public, (for their own sakes as well as ours,) to give the subject at least a cursory examination. We seek only for truth, and when it is clearly shown that there is no organic matter in the ashes of plants, which can be determined by the method described in the aforesaid paper, then we will be most willing to acknowledge frankly that we have heedlessly fallen into the ditch of error, our friends kindly endeavoring to keep us out notwithstanding.

The analyses have been calculated without the carbonic acid, (this is not a constituent of the plant, but is formed during the combustion,) to show the real composition of the inorganic matter which actually exists in the plant and is necessary to its constitution. The stalk and petioles contain but a small percentage of silicic acid, while the leaves, flowers, pedicels, and root contain a respectable quantity. All portions of the plant are rich in phosphates, ranging from 19 to 34 per cent. in the several parts. The root contains the most; the flowers and pedicels stand next in order; the petioles next; the leaves fourth; and the stalk contains the least. The lime ranges, in the several parts, from 1½ to 6.7 per cent.; the magnesia from one-tenth of 1 per cent. to 3.3 per cent.; the potash from 5.8 to 10.8 per cent.; the soda from 26.5 to 38.75 per cent.; and the sulphuric acid from 5 to 12 per cent.

The analyses show that the ash of this plant is in a great measure made up of the phosphates and sulphates of the alkalies; these making up from 69 to 79 per cent. of the entire inorganic matter of the plant.

It will be seen from the above, that a soil well suited to nourish and sustain vigorously the rhubarb plant, must be peculiarly rich in the phosphates and sulphates of the alkalies. Bone-dust, plaster, salt, and ashes afford the inorganic bodies required by this plant. Besides these, decomposing animal and vegetable manures are also needed to warm and loosen the soil, and facilitate the decomposition, and consequently the solubility of the inorganic materials.

Proximate organic analysis of the petioles.—Petioles, or leaf-stalks, taken from the plant the first of September: very large and succulent: 1½ inches in diameter, and 2½ feet long. A variety of the rhaponticum, furnished by Mr. Y. Rathbone, of Kenwood.

Percentage of Water, Dry Matter, and Ash.

Percentage of water	87.79
" dry matter	12.23
" ash	2.27
" ash, calculated on dry matter	18.56

Proximate Organic Analysis.

	With water.	Without water.
Fibre, with a little starch and chlorophyl	1.265	9.894
Malic acid and extract, with a little tartaric and oxalic acids	5.710	44.622
Dextrine	0.550	4.302
Fibre	3.235	25.303
Matter separated from fibre by a weak solution of potash, gives the characteristic color of albumen with sulphuric acid	1.605	12.554
Albumen	0.270	2.112
Casein	0.150	1.173
Water	87.770	......
	100.555	100.000

The above specimen is larger and firmer than the one examined the 1st of June, and contains less water and a greater percentage of inorganic matter. The leaves contain a little oxalic and malic acids. The oxalic acid is probably in the form of binoxalate of potash and soda. The petioles or leaf stalks have a mild, pleasant acid taste. They contain a large quantity of malic acid, with considerable oxalic, and a little tartaric acid. These acids are most likely in the form of acid salts of the alkalies.

The well-known and highly valued medicine called *rhubarb* is the root of several species of Rheum. It has been analyzed by Schrarder, Brande, Hornemann, M. Ossian Henry, Schlossberger, and Dopping. (*Pereira's Materia Medica, Liebig's Annalen, Thompson's Vegetable Chemistry, U. S. Dispensatory, &c.*)

It contains *Rhein*, (Syn. Rhabarbaric acid, Rhubarb Yellow, Rheumin.) This is a yellow granular crystalline body, somewhat analogous to chrysophanic acid. It is extracted nearly pure from the root by hot sulphuric ether. On carefully evaporating the solution, it is obtained in small crystals, which are quite tasteless, and insoluble in cold water. It imparts to concentrated sulphuric acid a beautiful carmine color: to solutions of ammonia and potash, a fine red; and to soda and lime, a light red hue. It is soluble in ether, alcohol, and acetic acid, to all of which it imparts a deep yellow color: it is less soluble in cold nitric acid, and but slightly soluble in hydrochloric and oxalic acids, all of which it colors yellow. On boiling these latter acids, more is taken up, but is again precipitated on cooling. It is thrown down from an alkaline solution by sulphuric acid in the form of a deep yellow powder, which is nearly or quite insoluble in water. It is precipitated by the acetate of lead on standing for some time. The neutral salt throws it down in the form of light yellow flocs, leaving a clear solution slightly tinged with yellow. The basic salt throws it down in the form of a red flocculent precipitate, leaving a slightly turbid light-red solution.

Aporetin.—A resinous body of a black color, brittle, decomposed at a temperature below its point of fusion.

Erythroretin.—$C_{20}H_9O_7$. A light yellow crystalline, resinous body, soluble in ether and alcohol, and volatilized partially by heat without decomposition. It affords a dull red solution with concentrated sulphuric acid, from which it is thrown down in the form of a flocculent precipitate by water.

Phæoretin.—$C_{16}H_8O_9$. A yellowish brown powder, quite insoluble in ether and water, but readily soluble in alcohol. With the alkalies, it forms a deep red solution, from which it is precipitated by the mineral acids.

Rhaponticin.—A yellow, tasteless, crystallizable body, insoluble in ether, but soluble in a large excess of dilute alcohol. Besides the above, the root also contains chrysophanic acid, a trace of oil or fatty matter, starch, gum, mucilage, sugar, woody fibre, pectin, tannic, gallic, oxalic, sulphuric, and phosphoric acids, together with chlorine, lime, magnesia, silica, iron, potash, and soda.

VIII. STATISTICAL INFORMATION.

LAKE TRADE OF THE UNITED STATES.

The following table, derived from an official source, affords a pretty good idea of the magnitude of a portion of the internal trade of the United States. The aggregate valuation of our lake trade, for the year 1850, (imports and exports,) amounts, it will be seen, to the large sum of $186,484,905; or more, by $40,000,000, than the whole foreign export trade of the country. The aggregate tonnage employed on the lakes of the United States is equal to 203,041 tons, of which 167,137 tons is American, and 35,904 tons British.

Total Value of Exports and Imports.

The commerce of Lakes Erie, Huron, Michigan, Ontario, Champlain, and St. Clair, is as follows:—

Erie	$115,785,048	Ontario	$28,141,000
Huron	848,152	Champlain	16,750,700
Michigan	24,820,481	St. Clair	639,524

Showing a total value of $186,484,905, as above stated. To this must be added the passenger trade of the lakes, valued at $1,000,000.

The aggregate value of the tonnage of Lake Erie is	$5,808,085
" " " Lake Huron	75,000
" " " Lake Michigan	564,435

EXPORTS OF ICE FROM BOSTON, IN 1850.

The following table exhibits the total amount of ice, in tons, exported to the under-mentioned ports, during the year ending December 31st, 1850, and the total amount for the five previous years:

East Indies	8,897	Demarara	1,077
Port Louis, Mauritius	616	Matanzas	548
Liverpool	505	St. Johns, Port Royal	365
Havana	5,521	South America	50
Kingston, Jamaica	2,525	Vera Cruz	259
Rio Janeiro	915	Sisal	179
St. Thomas	1,177	Nassau	100
Pernambuco	240	Bermuda	80
Barbadoes	709	Martinique	36
St. Vincents	205	San Francisco	1,299
St. Jago	450	Sacramento City	260
Trinidad	282	Southern ports	43,579
Neuvitas	406	Total	69,623

1845......48,422 | 1846......57,293 | 1847......54,625 | 1848......57,507 | 1849......66,808

EXPORTS OF BOOTS AND SHOES FROM BOSTON.

This branch of Massachusetts manufactures appears to have been unusually active and prosperous during the year 1850, as will be seen by the subjoined table, in the increase of exports over previous years. This increase is attributed, for the most part, to the large shipments to California, either direct from Boston, or via New York, Philadelphia, and Baltimore. The clearances at the custom-house have been as follows :—

	Cases.		Cases.		Cases.
1845	90,782	1847	72,424	1849	101,371
1846	67,887	1848	79,118	1850	147,769

VALUE OF BREADSTUFFS, ETC., EXPORTED FROM THE UNITED STATES.

Statement, exhibiting the aggregate value of Breadstuffs and Provisions, exported annually, from 1821 to 1850, inclusive.

Years.	Value.	Years.	Value.	Years.	Value.
1821	$12,341,901	1831	$17,538,227	1841	$17,196,102
1822	13,886,856	1832	12,424,703	1842	16,902,876
1823	13,767,847	1833	14,209,128	1843*	11,204,123
1824	15,059,484	1834	11,524,024	1844	17,970,135
1825	11,634,449	1835	12,009,399	1845	16,743,421
1826	11,303,496	1836	10,614,130	1846	27,701,121
1827	11,685,556	1837	9,588,359	1847	68,701,921
1828	11,461,144	1838	9,636,659	1848	37,472,751
1829	13,131,858	1839	14,147,779	1849	38,155,507
1830	12,075,030	1840	19,067,535	1850	26,051,373
		Total			$535,207,285

COMMERCE OF CONNECTICUT.

During the year ending June 30, 1850, there were built, in Connecticut, 3 ships, 7 brigs, 27 schooners, 9 sloops and canal-boats, 1 steamer; total 47; tonnage, 4,820.

The tonnage of the several districts in Connecticut is as follows :—

	Registered.	Enrolled.	Total.
Middletown	96.55	12,033.72	12,129.82
New London	23,364.23	17,120.62	40,484.85
Stonington	13,188.47	6,724.03	18,912.50
New Haven	4,994.65	10,736.70	15,981.40
Fairfield	868.35	13,960.27	14,828.62
Total			103,336.69

FOREIGN COMMERCE OF CHARLESTON, SOUTH CAROLINA.

The exports of Charleston, to foreign countries, during the year 1850, amounted to $12,394,497; being an increase of nearly $1,500,000 over the exports of 1849, and of $4,500,000 on those of 1848. It is gratifying, also, that this increase of exports has been attended with a corresponding increase of imports, as will be seen by the following comparative statement of the duties collected on foreign imports during the years specified :—

* For nine months ending June 30th, 1843.

Duties for the year 1851	$533,706.95
" " 1849	421,774.68
" " 1848	327,898.42
Increase of year 1850 over 1849	$111,932.27
" " 1840	205,818.53

If the goods in the public warehouse had been taken into consumption, the aggregate amount for the past year would have been considerably over $600,000, as the quantity of goods similarly situated at the close of last year was comparatively trifling.

DEPOSITES AND COINAGE AT THE UNITED STATES MINT, PHILADELPHIA.

The coinage at the United States Mint, at Philadelphia, for the year 1850, as stated by E. C. Dale, Esq., Assistant Treasurer, has been as follows :

Gold Coinage.

	Pieces.	Value.
Double Eagles	1,170,261	$23,405,220.00
Eagles	291,451	2,914,510.00
Half Eagles	64,491	322,455.00
Quarter Eagles	252,923	632,307.50
Dollars	481,953	481,953.00
Total	2,261,079	$27,756,445.50

Silver Coinage.

	Pieces.	Value.
Dollars	7,500	$7,500.00
Half Dollars	227,000	113,500.00
Quarter Dollars	190,800	47,700.00
Dimes	1,931,500	193,150.00
Half Dimes	955,000	47,750.00
Total	3,311,800	$409,600.00

Copper Coinage.

	Pieces.	Value.
Cents	4,022,644	$40,226.44
Half Cents	39,812	199.06
Total	4,062,456	$40,525.50
Whole amount coined	9,635,335	$28,206,471.00

Deposites for the Year 1850.

Total gold deposites		$33,150,000
Of which, from California	$31,500,000	
Other sources	1,651,000	
		$33,150,000
Total silver deposites		$428,000
The deposites for the month of December, from California, are about		$4,500,000

The number of gold and silver pieces, and the value of the same, coined at the United States Mint, Philadelphia, for the month of December, 1850, was as follows :—

Gold Coinage.

	Pieces.	Value.
Double Eagles	189,821	$3,796,420.00
Quarter Eagles	45,000	112,500.00
Dollars	78,098	78,098.00
Total	312,919	$3,987,018.00

Silver Coinage.

	Pieces.	Value.
Quarter Dollars	66,800	$16,700.00
Dimes	115,000	11,500.00
Half Dimes	290,090	14,500.00
Total	471,800	$42,700.00

Copper Coinage.

	Pieces.	Value.
Cents	794,847	$7,948.47
Whole amount coined	1,579,566	$4,087,666.47

The bales of cotton taken for consumption are reported in the annual returns of the New York Shipping List, as follow. These we have converted into yards, and averaged them on the population:

Years.	Cotton Consumed.	Equal to Yards.	United States Population.	Yards per head.	Increase per cent.
1830, bales	126,512	151,814,400	12,966,020	11½	....
1840 "	295,193	354,221,600	17,067,453	21	9½
1850 "	595,269	684,322,800	21,000,000	32½	11½

Three times the cotton cloth, per head, is made now, in the United States, that was produced 20 years since, and the production has been very steady in its increase. It was 9½ yards per head in the 10 years ending with 1840, and 11½ yards in the last 10 years, assuming the current estimate for the population. Now, the consumption of cotton by the people of Great Britain, as given in Du Fay's circular, was 136,420,765 lbs. in 1849, which averages 4½ lbs. per head. The consumption, in the United States, is 11 lbs. per head. Thus, in the United States, the inhabitants consume, per head, nearly three times as much as the inhabitants of Great Britain. We may now make another comparison, which is this, viz. to take a year when Great Britain consumed as much cotton as the United States took in 1850, and compare the exports:

	Great Britain.		United States.	
	Cotton Consumed. Pounds.	Value of Cotton Exports.	Cotton Consumed. Pounds.	Value of Cotton Exports.
1827	249,804,896	$85,000,000	59,806,400	$1,259,457
1849	626,710,160	180,000,000	288,107,600	4,784,424

Now, then, two important truths are manifest here; namely, in 1827, the United States consumed a quarter as much cotton as Great Britain. In 1849, we consumed three-eighths as much; thus, we have gained 50 per cent. upon England. Again, we manufactured, last year, as much as did England in 1827, but we exported only $4,784,424, or $80,000,000 worth per annum less. England sold all she made; the United States consume all they make: deducting the cost of material, which, in 1827, was 7*d*., or, in the aggregate, $35,000,000, she sold $50,000,000 of her labor for articles other than cotton. Her cotton, last year, cost $60,000,000, and she sold $70,000,000 of her labor. Now, if the people of the United States, instead of consuming two yards each more than the English consume, should

sell that for other things, our external cotton trade would be as large as that of England was in 1827; but our manufacturers have exclusively a home trade—what the English manufacturers never have had. The larger consumption of cotton in the United States keeps the prices higher, and, by so doing, absorbs all the home make, and the quantities imported also. This home market has been overdone. It is glutted, and the prices were naturally depressed. The annual returns of the Secretary contain the values of dry goods imported. These, as compared with previous years, are as follow:—

Imports of Dry Goods into the United States.—Fiscal Years.

	1848.	1849.	1850.
Woollens.			
Cloths and Cassimeres	$6,846,145	$4,995,957	$6,184,190
Merino Shawls	1,857,129	1,196,876	934,848
Blankets	1,146,587	1,161,429	1,244,875

Hosiery	731,009	718,794	718,185
Other Woollens	1,140,410	1,068,807	1,880,526
Total Wool	$14,597,696	$18,211,548	$15,965,824
Cottons.			
Prints and Colored	$12,490,501	$10,286,894	$18,640,291
White	2,487,256	1,488,635	1,773,802
Tamboured	495,576	702,631	1,267,286
Hosiery	1,888,871	1,815,788	1,558,178
Yarn and Thread	727,422	770,509	799,156
Other Cotton	836,963	1,240,889	858,422
Total Cotton	$18,421,589	$15,754,841	$19,896,680
Silks.			
Piece Goods	$10,762,801	$7,588,822	$14,450,560
Hosiery	427,708	468,393	616,217
Tamboured	1,026,235	1,045,216	1,131,462
Other Silk	2,671,868	4,873,336	872,380
Silk and Worsted	2,456,652	2,452,289	1,658,809
Total Silk	$17,845,259	$16,428,056	$18,724,428
Linen	$6,012,197	$5,156,924	$7,063,184
Other Flax	611,451	750,318	1,031,638
Grand total	$56,988,192	$51,501,667	$62,681,704

The classification is not so extended as would have been desirable, but the general heads indicate the nature of the transactions. The aggregate increase is, as compared with 1848, $5,836,781, of which each description partakes in nearly equal proportions. The increase in silk piece-goods seems to have been greater than any other single article, but some different classification has, no doubt, varied the figures. It would seem to be the case, that the quantities of dry goods increase far less than the internal increase of trade.

BALTIMORE.—ARRIVALS IN 1850.

The annexed table presents a complete view of the foreign commerce of the port of Baltimore, during the year 1850. It comprises monthly statements of the arrivals, clearances, aggregate tonnage, and value of cargoes.

	Foreign Arrivals.	Foreign Clearances.
Ships	60	95
Barques	85	91
Brigs	208	206
Schooners	105	119
Total	467	511

The vessels cleared during the year were destined to the following countries, viz. to England and Ireland, 33; Holland, 18; Bremen, 29; France, 6; Peru, 4; Mexico, 3; Russia, 2; Africa, 4; Spain, 4; Brazil, 45; Venezuela, 5; New Grenada, 3; Spanish Main, 4; Buenos Ayres, 2; Austria, 1; Portugal, 1; Quebec, 1; Chili, 2; to the various West India Islands and British Provinces, 269; and to California, 51.

	Aggregate Tonnage.	No. of Men employed.
January	11,962	459
February	10,948	442
March	9,827	417
April	10,162	449
May	12,540	511
June	13,727	447
July	12,065	490
August	12,053	470
September	7,658	333
October	11,527	482
November	7,885	222
December	10,238	480
Total	130,587	5,202

FOREIGN EXPORTS.

	Total Value of Foreign Exports.	Value of Exports to California.
January	$677,319.00	$250,000.00
February	707,402.71	234,962.00
March	752,656.28	226,002.65
April	665,532.23	128,171.29
May	653,989.05	86,950.93
June	743,681.74	75,198.10
July	617,691.59	105,724.72
August	601,240.25	86,964.24
September	588,849.94	134,504.55
October	765,697.93	256,309.80
November	776,497.21	262,987.69
December	647,840.57	230,215.54
Total	$8,278,418.45	$2,027,986.54

The receipts from "duties" at the custom-house, from the 1st January to 31st December, 1850, amounted to $1,008,633.28, being larger than for any previous year. The total receipts into the depository at Baltimore, during the year, were $1,026,340.97, and the disbursements, during the same period, $1,029,965.51; the latter exceeding the former by $3,624.54, and leaving on hand, 1st inst., $16,681.70, against a balance, 1st January, 1850, of $20,286.24.

It is impossible to ascertain the precise value of the imports during the year, for the reason that a large portion of them are non-duty-paying articles. In this latter class, we note nearly 200,000 bags coffee.

The value of merchandise exported, during the year 1850, to foreign countries, including California, was $8,278,418.45. Of this amount, exports to the value of $2,027,986.54 were sent to California.

Vessels built in 1850.

	No.	Tons.
Ships	9	5,641.05
Barques	5	1,465.17
Brigs	2	340.78
Steamboats	2	231.16

1848	786,441	333	60,225	1,322	7,578
1849	764,519	428	51,772	2,051	8,011
1850	896,592	272	42,403	3,369	5,430

Tobacco.—Inspections, &c. in 1850.

The stock on hand, in 5 warehouses, 1st January, 1850, was	19,628	hhds.
Amount inspected in 1850	41,833	"
Total	61,461	"
Exported and consumed in 1850	50,844	"
Leaving on hand, 31st December, 1850	10,617	"

The kinds inspected were as follow:—

Maryland	27,086 hhds.
Ohio	13,965 "
Kentucky	756 "
Virginia	15 "
Pennsylvania	12 "
Total	41,883 "

From the above it will be seen that the stock, 1st January, 1850, was 10,617 hhds; same period of 1850, 19,628 hhds.; and of 1849, 32,690 hhds.

The stock on hand on the 1st January, for 20 years past, has averaged	13,927 hhds.
For 10 years past	17,881 "
For 5 years past	25,510 "

The crops to come to market in the year 1851, are estimated as follows:—

Virginia, about	30,000 hhds.
Kentucky, Tennessee, and Missouri, about	50,000 "
Maryland, about	22,000 "
Ohio, about	14,000 "

Whiskey.

The amount inspected during 1850, was 1,067 hhds. and 31,323 bbls., of which 665 hhds. and 7,837 bbls. were received by the Tidewater Canal, and 928 bbls. from New Orleans.—*Baltimore American.*

Total	169,879	222,641

Above are the receipts of flour and corn at this place for the past three years, made as correct as circumstances will permit, but presumed to be rather less than more in quantity.—*Argus.*

Imports of Molasses and Sugar.

The following is the amount of molasses imported into this port:—

	Hhds.	Tcs.	Bbls.	Gallons.
In 1850	34,997	1,579	774	3,824,143
In 1849				2,864,511
Excess in 1850				959,632
Sugar, in 1850				1,039,759
" 1849				27,130
Excess in 1850				1,012,629

Arrivals and Clearances—Coastwise.

The number of arrivals, coastwise, at this port, for the quarter ending December 31st, 1850, is 53; tonnage, 8691[illegible]; men employed, 337.

The number of clearances, coastwise, during the same time, is 86; tonnage, 18,518[illegible]; men employed, 598; boys, 10.—*Advertiser.*

RESOURCES OF OHIO.

In a late number of the Cincinnati Gazette, we find some statistical information in regard to the resources of Ohio, from which we glean a few items:—

It is well known, that two or three counties in this State have produced upwards of a million of bushels each of wheat, and that others, not deemed first-rate wheat counties, have produced half a million each. Now there are in Ohio 87 counties, and we shall be within bounds to say they have produced thirty millions of bushels in 1850. This crop does not appear in the census returns, but it is nevertheless a reality. Now there are, in round numbers, two millions of people; and six bushels each is an abundant allowance for consumption. We have, then, this result:—

Wheat crop of 1850	30,000,000 bush.
" " consumed	12,000,000 "
Surplus for export	18,000,000 "

At 75 cents per bushel, the surplus is worth $13,500,000.

This is the money value; but look at it in another view, as a food-supplying State, for people who cannot supply themselves. Then the problem runs thus:—

30,000,000 bushels feed	5,000,000 people.
12,000,000 " "	2,000,000 at home.
18,000,000 surplus, feed	3,000,000 abroad.

Thus, we find Ohio giving fine wheat flour to three millions of people out of her own domain!

No grain is as much the agricultural glory of our country as Indian corn. Its value as an article of commerce is hardly greater than its beauty as a plant. We are speaking of bread. We happen to have the return of Indian corn (in 1850) for two counties—one (Pickaway) a first-class county for corn, and the other (Greene) only a second-class one. The comparison of these, with the return of the same counties in 1840, may serve to give an idea of progress in corn.

	1840.	1850.
Pickaway county	1,323,809	3,323,000 bush.
Greene county	659,296	1,161,082 "
Total	1,963,180	4,484,082 "
Increase		125 per cent.
Amount for each person		100 bushels.

This increase and result seem almost incredible, and yet there can be no doubt of its truth. Let us suppose, however, that the increase for the entire State is but three-fourths the increase for these counties, viz. 93 per cent., and look at the result. In 1840, the States producing the most Indian corn, in order, were—Tennessee, 44,986,184; Kentucky, 39,847,120; and Ohio, 33,668,144. If Ohio, as the returns indicate, has increased the corn production 90 per cent., then the crop of 1850 is sixty-four millions of bushels.

Looking to the consumption of this vast crop, the surplus is chiefly used in fattening cattle and hogs for exportation, and no export of corn and meal. Both these we know very nearly, and the result is:—

Corn crop	64,000,000 bush.
Consumed for stock	42,000,000 "
Exported in fat animals	20,000,000 "
Exported in bulk	2,000,000 "

The last two items give an exported surplus of twenty-two millions of bushels. If we add to the value of this corn the labour of packing, cooperage, commissions, &c., on the export of animal products, we have at least ten millions of dollars for this surplus. Thus, we find, that the surplus food of Ohio, in two leading articles, will come to twenty-five millions of dollars—and, in raw material, is enough to feed another population equal to her own.

PORK TRADE OF THE WEST.

We give below returns from the West, as far as received, including those previously published—keeping each State separate. In giving the number packed at Terre Haute this season, in our last number, we understated it by 10,000 head. This error we correct below.

There are yet a great many points in Missouri, Illinois, and Iowa, to hear from.—*Cincinnati Price Current, Jan.* 29, 1851.

ANALYSIS OF THE ASHES OF THE HOP.*

The 2 lbs. of hops, when dried at a steam-heat, lost 3 oz. of moisture, and left 1 lb. 13 oz. of dry hops. The dry hops were burned to ashes in a large earthen crucible, and furnished 1282 grs. of ashes, being at the rate of $\frac{3}{10}$ per cent.

These ashes were analyzed in the usual manner, and every hundred parts contained as follows:—

1. *Ashes of the Hop.*

Silica (or pure sand)	20.95
Chloride of Sodium (common salt)	7.05
Chloride of potassium	1.63
Potash	24.50
Lime	15.56
Magnesia	5.63
Sulphuric acid (oil of vitriol)	5.27
Phosphoric acid	9.54
Phosphate of iron	7.26
Carbonic acid	2.61
	100.00

2. *Analysis of the Ashes of the Leaves of the Hop Plant.*

The $9\frac{3}{8}$ oz. of leaves, dried at a steam-heat, lost $1\frac{1}{8}$ oz. of moisture, and left $8\frac{1}{4}$ oz. of dried leaves. The dried leaves, burned to ashes as before, gave 572 grs., being at the rate of $16\frac{1}{3}$ per cent.

The ashes were of the following composition in the hundred parts:—

* In the following tables, the loss is previously deducted.

Ashes of the Leaves of the Hop Plant.

Silica	10.14
Chloride of sodium, (common salt)	7.92
Soda	0.82
Potash	12.48
Lime	41.46
Magnesia	1.90
Sulphuric acid	4.20
Phospharic acid	2.02
Phosphate of iron	2.98
Carbonic acid	16.54
	100.00

3. *Analysis of the Ashes of the Hop Bind or Stalk.*—The 1 lb. 2½ oz. of the bind, dried at a steam-heat, lost 1⅞ oz. of moisture, and left 1 lb. .0⅝ of dry bind. The dry bind, burned, gave 353 grs. of ashes, being at the rate of nearly 5 per cent.

The ashes gave the following results in the 100 parts :—

Ashes of the Bind of the Hop.

Silica	4.64
Chloride of sodium, (common salt)	4.95
Chloride of potassium	7.38
Potash	18.62
Lime	29.59
Magnesia	8.15
Sulphuric acid	2.63
Phosphoric acid	5.22
Phosphate of iron	0.81
Carbonic acid	23.51
	100.00

4. *Composition and percentage of the Ashes separated from the Carbonic Acid.*—The carbonic acid, combined with the lime, &c. in the ashes, was produced, during the burning of the plant, by the oxidation of the carbon of the vegetable matter. It is, therefore, not a mineral ingredient of the soil; and, in order to arrive at the real percentage of inorganic matter, it is necessary to withdraw the carbonic acid from the foregoing tables.

This has been done in the following tables :—

TABLE 1.—*Quantity per cent. of Mineral Ingredients in the Hop, Leaves of Hop, and Bind, dried at the temperature of Boiling Water.*

	Hop.	Leaves.	Bind.
Percentage	9.87	13.6	3.74

TABLE 2.—*Composition in 100 parts of the Inorganic Matter.*

	Hop.	Leaves.	Bind.
Silica	21.50	12.14	6.07
Chloride of sodium, (common salt)	7.24	9.49	6.47
Chloride of potassium	1.67	......	9.64
Soda	......	0.89	......
Potash	25.18	14.95	24.35
Lime	15.98	49.67	38.73
Magnesia	5.77	2.89	4.10
Sulphuric acid	5.41	5.04	3.44
Phosphoric acid	9.80	2.42	6.80
Phosphate of iron	7.45	3.51	0.40
	100.00	100.00	100.00

5. *Quantity of Inorganic Matter taken from the Land by 4 hills of Farnham Hops.*—In order to obtain practical benefit from the foregoing analysis, it will be necessary, in the next place, to ascertain the whole amount of inorganic matter removed by the 4 hills of hops; and, likewise, the amounts of the separate ingredients.

The following table gives us the actual weight, in grains troy, of the various ingredients removed from the soil by 4 hills of hops :—

Actual Weight of Mineral Ingredients removed from the Soil by 4 hills of Hops.

	Hops.	Leaves.	Bind.
Silica	268.11	54.24	16.68
Chloride of sodium	90.28	46.31	17.78
Chloride of potassium	20.82	......	26.41
Soda	......	1.90	......
Potash	314.00	72.96	66.72
Lime	199.27	242.89	106.12
Magnesia	71.95	11.66	11.23
Sulphuric acid	67.46	24.60	9.43
Phosphoric acid	122.121	11.81	18.68
Phosphate of iron	92.90	17.18	1.10
Total weight	1247.00	488.00	274.00

6. *Amount of Mineral Ingredients removed from the Soil by an Acre of Hops.*—The number of hills of hops to an acre varies in different localities. In some places 1000, in others 1260, in others 1440 hills go to the acre.

In the present instance, I believe about 1000 to be the number of hills contained in an acre.

Therefore, by multiplying the numbers in the preceding table by 250, we shall have the actual weight of the various inorganic ingredients of the soil removed from an acre of land by the hop.

For the convenience of agriculturists, I give, in the following table, these weights in pounds and ounces avoirdupois :—

Amount of various Mineral Ingredients removed from an Acre of Land by the Farnham Hop.

	300 lbs. of Hops.		143⅜ lbs. of Leaves.		229 lbs. of Bind.		Total in Hops, Leaves, & Bind.

TRADE OF ST. LOUIS.

The St. Louis Republican of the 1st January contains an elaborate statement of the trade of that city for the year 1850, from which we make the following extracts:

Tobacco.

The article is classed among the most important agricultural productions of our State, and, since 1838, has attracted considerable attention for export. While the receipts for 1850 fall short 609 hhds., compared with the receipts for the previous year, they still slightly exceed the receipts of 1848.

Total receipts in 1850	9,055
Receipts of 1849	9,664
Decrease in 1850	609

	Prices in 1849.*		Prices in 1850.*
March	$1.50 to $7.00	March	$3.00 to $12.00
April	1.50 to 7.50	April	4.45 to 7.75
May	1.20 to 8.00	May	3.00 to 12.00
June	2.50 to 9.00	June	4.15 to 13.20
July	2.50 to 9.50	July	4.45 to 8.45
August	2.50 to 8.00	August	5.50 to 10.50
September	1.50 to 7.00	September	5.00 to 13.50
October	1.25 to 6.50	October	5.45 to 9.35
November	1.25 to 6.50	November	6.00 to 15.00
December	1.25 to 6.50	December	4.75 to 8.30

* January and February, no sales.

Hemp.

Receipts of hemp during the past year greatly exceed those of any year since 1847, when they reached over 72,222 bales; a circumstance, however, measurably owing to the non-reception during the preceding year of the crop due, the receipts of 1846 having been less than 34,000 bales. The market throughout 1849 was marked by more firmness than during the past year, and the rates were higher, having ranged between $1.20 and $1.26, varying a little from January to December. At the close of 1849, the stock in store was 893 bales. The stock in store and on sale at the close of 1850 is about 2,000 bales. The market during January was inactive at the figures of the previous year, and declined in February to $90 to $105 per ton. The ruling rates for the balance of the year were $80 to $95.

Total	60,862
Receipts of 1849	46,290
Increase of 1850 over 1849	14,572

Lead.

The production of this article has been gradually declining since 1845; receipts, per rivers, since that time, having fallen off from 750,877 pigs to

873,502. In the mean time, the demand for home consumption has materially increased, and very little has been exported. In consequence of this decline in production, prices have gone up, and, during the last two years, have ranged much higher than for many years previous. For the greater part of the past year, the price of upper-mines lead has been over $4.25, and the market closes firm at $4.37½ to $4.40 per 100 pounds.

Monthly Receipts per Rivers, Upper and Lower Mines inclusive.

Wheat.

Receipts of this article, during the year just closed, have slightly exceeded those of last year, but fall short of those of 1846, 1847, and 1848. The last year has, doubtless, been a better wheat year than 1849, but owing to a generally entertained opinion that the article must advance, farmers and shippers held back, until threatened by closing navigation. This will account for the heavy receipts during November, compared with other months in the year.

Castor Beans.

Under light receipts, prices have been highly remunerative. The season opened at the high price of $2.20, but in April prices ranged to $2.60 to $2.65 per bushel. From this, the article gradually declined to the close of the year, and we now quote at $1.25, and few arriving.

January	$2.20 @	2.37½	July	$1.70 @	1.75
February	2.26	2.50	August	1.60	1.70
March	2.50	2.60	September	1.45	1.50
April	2.60	2.65	October	1.35	1.40
May	2.55	2.60	November	1.25	1.30
June	1.75	1.80	December	1.30	1.35

Flaxseed.

The demand has been active throughout the year, and prices have been proportionably high. The following have been the monthly rates, per bushel:—

January	$1.45 @	1.50	July	$1.30 @	1.35
February	1.40	1.50	August	1.25	1.30
March	1.50	1.55	September	1.10	1.20
April	1.55	1.60	October	1.25	1.30
May	1.50	1.55	November	1.45	1.50
June	1.30	1.35	December	1.60	1.65

Pork.

The receipts of the last year vary but little from those of 1849; but our monthly table will show that the bulk of the sum total was the product of 1849, very little having been received since the present packing-season commenced. The high price of corn induced growers to send forward that staple, rather than to apply it to fattening, and hence few hogs have been prepared for slaughtering. Up to the present date of the last packing-season, the number of hogs slaughtered in this city alone was nearly 115,000; and at points above, and throughout the West, the number was also large. So far as we are informed, with regard to the present season, only 55,000 hogs have been killed in this city, and a corresponding falling off is observed throughout the country. This deficiency must advance the price of pork, but whether sufficient to remunerate dealers for the high prices paid for hogs, is doubtful. The hog market opened timidly, at figures approximating to $3, but, since the commencement, has steadily advanced, until within a few days, since which it has been less firm; and few sales are now effected beyond $4, for hogs weighing 220 lbs., though drovers are contending for $4.15 to $4.20.

	Tcs.	Bbls.
Total receipts, 1850	1878	101,562
	1745	111,164

The following have been the monthly prices for mess pork, per bbl., during 1850, prime and clear mess having the usual average differences, below and above:—

January	$8.87½ @	8.50	July	$10.00 @	10.50
February	8.87½	8.50	August	10.50	11.00
March	8.25	8.87½	September	nominal.

Tonnage.

The number of steamboats arrived during the year was as follows:—

	1849.	1850.
From New Orleans	813	303
Ohio River	401	498
Illinois River	686	788
Upper Mississippi	806	635
Missouri River	855	890
Cairo	122	75
Other points	217	215
Total	2,900	2,599

It appears that 246 different boats arrived at the port during the year.

WHALE FISHERY.

ANNUAL REPORT.

Review of the Whale Fishery for 1850.

We present to our readers a full and reliable review of the whale fishery for the last year, as compared with previous years. By this, it will be seen at a glance, that the past has been a year of great prosperity in the trade. The number of ships returning with full cargoes has been large, while prices have risen to an unprecedented height. Nevertheless, the importation of oil in 1850 will be found to fall short of that of 1849 about 7000 bbls. sperm, and 48,000 bbls. whale, and the number of arrivals is less by 6 sperm and 19 right whalers, yet the stock on hand is about the same as on the 1st January, 1850. This discrepancy, as regards whale oil, is undoubtedly owing to a diminished consumption, arising from the very high figure at which oil has been held, which has forced many substitutes into the market, and seriously impaired exportations.

The number of vessels employed in the fishery is about the same as that of last year. Of the fleet, 145 have cruised in the Russian and Arctic seas, during the last season, with great success; indeed, the average quantity of oil taken is larger than in any previous year.

We regret to say, that accounts from the sperm whalers in the Pacific are not at all encouraging. The old cruising grounds are pretty well exhausted for the present, and very light catchings are to be expected. If we are to judge by present indications, importations of sperm oil, for the coming year, will hardly exceed 75,000 bbls., while that of whale oil will not, probably, fall short of 275,000 bbls.

Perhaps no better evidence can be offered of the confidence felt by business men, than the fact that no less than 14 first-class vessels are in process of construction, or are under contract, all intended for the business, from this district alone, while 5 or 6 will be added to the New London fleet.

Importations of Sperm and Whale Oil, and Whalebone, into the United States, in 1850.

Missouri	......	......	......	8	11	19	2,886.51
Illinois	1	8	9	......	......	18	2,210.84
Ohio	......	2	9	8	44	63	12,816.92
Michigan	......	......	15	2	8	25	5,148.66
Texas	......	......	......	......	......	......	....
Oregon	......	......	......	......	......	......	....
Total	198	148	623	370	208	1547	256,577.47

It is seen that, in point of amount of tonnage, Maine is highest; New York, second; Pennsylvania, third; Massachusetts, fourth; Maryland, fifth; Ohio, sixth; Kentucky, seventh; New Jersey, eighth.

Of the inland States, Ohio has built the largest amount.

The amount built in the several States was as follows:—

	Tons.
Ohio	12,816
Kentucky	8,428
Michigan	5,148
Missouri	2,886
Illinois	2,210
Tennessee	242
Total	31,726

In addition, there were built, at Pittsburgh, Pennsylvania, about 60 steamers. We have no means at hand of ascertaining the proportion of the New York tonnage built on the lakes.

The tonnage of the principal ports of the United States was as follows:—

Ports.	Tons. 95ths.	Ports.	Tons. 95ths.
New York	776,491.79	Norfolk, Va.	23,016.26
Boston	296,890.04	Mobile	25,067.79
New Bedford	123,911.57	Buffalo	40,667.34
Bath	88,820.84	Pittsburgh	35,770.68
Portland	84,568.80	Detroit	38,466.94
Philadelphia	188,057.21	St. Louis	32,225.06
Baltimore	134,025.66	Cuyahoga	30,047.11
New Orleans	240,206.24	Oswego	22,151.68
Charleston, S. C.	29,285.48	Chicago	17,832.48
Wilmington, N. C.	10,641.87	Cincinnati	16,897.74

From this it is seen that the registered tonnage of twelve sea-port cities, including New Orleans, is 2,049,477 tons, against 228,585 tons at eight inland cities. Of the latter, 84,922 tons belong to Cincinnati, Pittsburgh, and St. Louis.

The value of some of the principal articles of agriculture and manufactures exported, we compare with the exports of 1849:

Articles.	Values.	
	1848.	1849.
Beef, tallow, hides, and horned cattle	2,474,208	2,058,858
Butter and cheese	1,068,087	1,654,157
Pork, (pickled,) bacon, lard, and live hogs	8,888,884	9,245,885
Wheat	1,681,975	1,756,848
Flour	11,668,669	11,282,582
Indian corn	1,186,668	7,966,869
Indian meal	945,081	1,169,625
Tobacco	8,478,270	5,804,207
Hemp	....	8,458
Soap, and tallow candles	680,041	627,280
Snuff, and tobacco	695,914	613,084
Iron, pig, bar, and nails	122,225	149,358
Cotton, printed, and colored	380,549	466,574
" white	1,978,031	8,955,117
" nankeen	818,189	3,206
" twist, yarn, and thread	81,318	92,555
All manufactures of cotton	255,799	415,680

The greatest increase, in any article of agriculture, was in the product of the hog. In the exports of cotton goods, the figures show a most satisfactory increase.

In order to show the comparative extent of our commerce with the several nations, we give the total value of the exports to some of the principal countries.

Russia	$987,557	British West Indies	3,985,884
Prussia	84,760	Canada	2,820,828
Sweden and Norway	725,281	France, on the Atlantic	11,646,612
Danish West Indies	727,197	" Mediterranean	877,147
Hanse Towns	2,710,248	Spain	1,619,428
Holland	2,155,828	Cuba	4,641,145
Belgium	2,448,064	Mexico	1,047,999
England	60,161,992	Brazil	2,888,889
Scotland	3,549,960	Chili	1,722,457
Ireland	8,916,842	China	1,460,945

The value of the exports to England, Ireland, and Scotland exceed, by $20,891,529, the exports to all other countries.

PHILADELPHIA.

The following statement, showing the capital invested in manufacturing, the value of the raw material consumed, the number of hands employed, the wages paid, and the value of the annual product of this branch of industry, in the city and county of Philadelphia, during the year ending June 30th, 1850, is taken from the census returns furnished to A. E. Roberts, Marshal of the Eastern District of Pennsylvania.

Name of Ward or District producing Articles to the Annual Value of $500.	Capital invested in Real and Personal Estate.	Value Raw Material used, including Fuel.	Average number of Hands employed.		Wages.		Value of Annual Product.

* Excess of exports over imports this year.
† Prior to 1821, the amounts are not given on which duties accrued.

HOG STATISTICS.

[From the Louisville Courier.]

We subjoin the following statistics in regard to the product of the hog, which have been accurately and carefully compiled from authentic sources, and will prove serviceable to the mercantile community. It gives the exact number of hogs slaughtered, around Louisville, for the last two years; also, the actual weight of hogs, the weight of lard, and the quantities of pork made, together with the deficiencies and gains, here and elsewhere. The list embraces full returns from Kentucky, Tennessee, and the hogs driven South, and shows a total deficiency of 131,800 hogs, this season.

This table will be valuable for future reference.

	Hogs slaughtered.	Hogs packed.	Average Weight per Hog.	Aggregate Weight, (lbs.)	Aggregate Weight of Lard.	Number of Barrels Pork.
1849-50.						
Adams & Co. (Allen's house)	41,545	41,524	218$\frac{15}{100}$	8,852,898	1,782,210	19,755

Collector's Office, New York,
December 24th, 1850.

Absalom Bull, *Collector.*

Lumber Trade.—An English writer, in speaking of the various lumber marts in the world, sets down Albany as one of the most important, if not the largest, on the globe. Of the truth of this remark, we have no means at hand to substantiate the assertion; but, that a very large business has been done here, in lumber, every year since 1836, no one, who is conversant with the trade, will deny. A considerable amount of the lumber sold here has been brought down the Champlain Canal, and entered the Hudson River at West Troy, from whence it is brought down the river in canal-boats, by means of small steam-tugs, which ply between this city and Troy during the season of canal navigation. Nor is lumber the only article which reaches us in that way. Several of the Oswego and Buffalo lines of canal-boats, which have run directly from here to those cities, have ascended and descended the canal at West Troy, so that in no way can an accurate statement be made of the business of this place, except by a resort to the books of the shipping and receiving houses in this city.

The six mill tolls, besides other expenses in the way of towing, is no small item to forwarders, who are compelled, by ruinous competition, to take property frequently at about, or only a fraction over canal tolls.

The best and most costly lumber sold in this market is from the neighborhood of the Genesee Valley and Chemung Canals.

We have prepared the subjoined tables, giving the receipts at tide-water of boards and scantling, timber, shingles, and staves, and their estimated value for the year named. In submitting these tables, we do not pretend to assert that this amount of property has been sold here. We are willing to yield a suitable proportion to our friends up the river; but to give them all that a writer in Hunt's Magazine claimed for them, viz. all that entered the Hudson at West Troy, is more than any forwarding merchant would venture to claim. What we do maintain belongs justly to Albany is the entire receipts of lumber at this place, and at least a third, if not a half, of that coming into the Hudson at West Troy. The figures for the year just closed, show that more than one-half the entire receipts of boards, &c. at tide-water, came to this city by the Erie, while the exhibit of staves show that three-fourths the entire receipts were taken in at this place.

Years.	Boards and Scantling, (ft.)	Value.	Timber, (Cubic ft.)	Value.
1836	189,116,847	$3,782,336	1,445,408	$289,181
1837	133,385,757	1,867,400	624,188	81,144
1838	151,114,100	2,191,154	695,600	90,428
1839	141,494,033	2,384,671	301,420	124,311
1840	124,173,383	1,985,774	784,310	156,862
1841	177,720,349	3,021,245	1,028,576	216,000
1842	150,657,900	1,958,552	361,589	65,086
1843	177,402,600	2,749,741	586,013	125,993
1844	140,891,000	2,395,147	917,295	159,873
1845	237,924,666	4,044,720	2,492,668	498,584
1846	260,335,271	4,422,936	1,798,198	251,096
1847	299,078,633	5,078,564	1,613,943	169,160
1848	262,279,116	3,981,277	1,510,777	212,598
1849	297,481,140	4,459,157	1,497,627	119,598
1850	425,095,436	6,365,728	3,080,588	440,490

In glancing over the foregoing figures, which exhibit the trade for the past 15 years, we find that the smallest receipts of boards, &c. was in 1840, and the largest in 1850; and that, compared with the former dates, the business has increased more than threefold. The receipts of timber were the lightest in 1842, and heaviest in 1850.

Years.	Shingles, (M.)	Value.	Staves, (lbs.)	Value.
1836	30,792	$ 92,376	41,063,060	$328,264
1837	59,052	175,182	66,887,990	531,108
1838	47,327	165,644	75,133,400	525,933
1839	46,087	196,651	69,646,284	417,877
1840	55,084	220,136	48,996,000	293,976
1841	46,385	185,540	110,542,859	552,714
1842	36,765	119,466	55,268,500	193,439
1843	62,387	210,244	56,768,700	227,074
1844	77,763	233,289	96,356,100	381,424
1845	72,120	234,390	189,754,800	628,896
1846	69,822	244,378	106,152,500	1,518,532
1847	101,527	405,548	95,104,000	1,289,677
1848	104,270	338,861	114,246,000	514,109
1849	51,258	156,774	154,159,339	693,701
1850	57,906	262,668	262,224,450	908,613

The largest receipt of shingles was in 1848, and the smallest in 1836. The receipts of staves were the smallest in 1836, and the largest in 1850. Since 1847, there is, apparently, a great falling off in their estimated valuation; for, notwithstanding the receipts of the following year were much larger than that named, their estimated value is set down at a sum less by more than one-half the valuation of 1847. It appears, however, that, with the exception of 1846 and 1847, their valuation has been pretty uniform; and probably this apparent discrepancy can be easily explained by those who were then engaged in the trade.—*Albany Evening Journal.*

SURFACES OF STATES AND TERRITORIES.

Table, showing the Estimate Surface of Territories of the United States North and West of the regularly organised States of the Union, and the portions of territory thereof situated North and South of the parallel of 36 deg. 30 min. north latitude.

Territories.	Sq. miles north of the parallel of 36° 30′.	Sq. miles south of the parallel of 36° 30′.	Total sq. miles.
Oregon Territory, bounded on the north by the parallel of 49° north latitude, south by the parallel of 42° north latitude, east by the Rocky Mountains, and west by the Pacific Ocean	341,463	....	341,463
Territory north and west of the Mississippi River, bounded on the north by the parallel of 49° north latitude, east by the Mississippi River, south by the State of Iowa and the Platte River, and west by the Rocky Mountains	723,248	....	723,248
Wisconsin Territory, bounded east by the Mississippi River, and north by the State of Wisconsin,—being the balance remaining of the old North-west Territory	22,336	....	22,336
Indian Territory, situated west of the States of Missouri and Arkansas, and south of the Platte or Nebraska River; held and apportioned, in part, for Indian purposes	190,505	58,346	248,851
Territory in Upper California and New Mexico,* situated west of the Rio Grande, to its source, and of a meridian line thence to the parallel of 42° north latitude. Ceded to United States by the treaty with Mexico, of 1848	321,695	204,383	526,078
Total	1,599,247	262,729	1,861,976
* This estimate excludes all that part of Texas which lies outside of its limits, as designated by the yellow shaded lines on Disturnell's Map of Mexico. The part of Texas which lies east of the Rio Grande and west of the Nueces River, from the mouth of the former river up to a line drawn from a point a short distance north of Paso, to the source of the Ensenada River, is estimated at	....	52,018	52,018
And the part which lies north of Paso and the Ensenada River, up to latitude of 42° north	43,537	81,396	124,933
†Making together	43,537	133,414	176,951

† This estimate, as will be seen, limits our acquisitione of territory from Mexico, by the late treaty, exclusively to those portions of country lying west of the Rio Grande.

Texas in Three Divisions.

		Sq. miles.
1st.	Between the Sabine and Nueces Rivers, south of Ensenada River, (Texas proper)	148,569
2d.	Between the Nueces and Rio Grande, south of Ensenada River	52,018
3d.	North of Paso and the Ensenada River, (Santa Fe county)	124,933
	Total	325,520

1st.	Number of miles of coast acquired by the annexation of Texas, from the mouth of the Sabine to the Rio Grande	400
2d.	Number of miles of coast on the Pacific, including Oregon and California. In California, 970; Oregon, 500; Straits of Juan de Fuca, 150	1,620
	Total, including Texas	2,020

NEW MEXICO.

The ages of the free inhabitants of New Mexico, as ascertained by the census, having been classified, we give below a table, showing the number in each county over 80 years of age. These facts prove the health of this Territory to be as good, if not better, than that of any other country in the world; and are interesting, as showing the extraordinary longevity to which many of the inhabitants have attained.

In Valencia county, Candelario Agular, a farmer, was 130 years old when the census was taken; Jose Ortado was 110; Rosa Billejos, 110; Rose Montallo, 106; Maria J. Pacheco, 103. The males seem to attain a greater age than the females, in proportion to their number.

Counties.	Persons over 80 years of age.			Persons over 90 years of age.			Persons over 100 years of age.		
	Males.	Females.	Total.	Males.	Females.	Total.	Males.	Females.	Total.

All which is respectfully submitted.

THOMAS EWBANK,
Commissioner of Patents.

APPENDIX.

Westfield, Chatauque County, N. Y., August 20th, 1851.

Hon. Thomas Ewbank:

Dear Sir:—In compliance with your request, I send you, herewith, a description of my recently imported sheep.

They are pure Merinos, were bred in France, and were selected from the best flocks by John A. Taintor, Esq., of Hartford, Connecticut, a gentleman widely known for his enterprise, liberality, and public spirit, in introducing into this country the choicest specimens of imported stock.

These sheep are of unusual size, and possess, to a remarkable degree, all the qualities to be desired in sheep, for mutton as well as for wool-growing purposes. From the nose to their feet, they are completely covered with a long, thick, and fine staple of wool, and they yield enormous fleeces, the ewes usually shearing from 15 to 20 pounds each of clear, unwashed wool; and I have known them to shear as high as 25 pounds each. The rams shear proportionably larger fleeces. Many of these sheep are encircled with large folds of loose skin around their necks and shoulders, giving them greater surface for the growth of wool. They have strong and hardy constitutions, are very prolific, and, as the ewes are excellent nurses, there is no difficulty in raising their lambs. I have never failed of raising more lambs than I have had ewes.

The sheep represented in the accompanying engraving were taken from life by R. H. Pease, Esq., of Albany, and are very correct likenesses of the animals.

Respectfully yours,
JOHN D. PATTERSON.

Clatsop Plains, mouth Columbia River, Oregon Territory, December 16th, 1850.

Dear Sir:—Having resided on these Plains for upwards of four years, and a cultivator of the land for my occupation, I can speak with a knowledge of the products of this section of the world, as far as my observations have extended. In reference to the dairy business, the average yearly product of butter per cow is estimated at 96 pounds. Cheese, double that amount. Comparative cost per pound for making, 6 cents. Mode of churning, with the common churn. Average price of butter per pound, \$1; cheese, 75 cents.

Neat Cattle.—Cost of rearing till 3 years old, is what they gather from the range themselves; scarcely fed any in winter; usual price at 3 years old, if sold for beef, is from 16 to 25 cents per pound. Value of good dairy-cows, $75 at any season of the year; we have but a few of the most approved breed of cattle.

Turnips.—Are raised here to great perfection. This year's crop, in manured ground, 300 bushels per acre of the common flat turnip, larger, in general, than any I ever saw raised in the States. The common weight of a turnip is from 10 to 15 pounds, some larger and some smaller.

Carrots and Beets.—The cultivation of these roots as a field crop is on the increase. The yield is usually good.

Irish Potatoes.—Average yield per acre, (manured ground,) 400 bushels. Cost of production per bushel, 10 cents. Most prolific and profitable, the kidney and common blue. Average price per bushel, (wholesale,) $2.75.

The cultivation of fruit-trees is receiving increasing attention.

The above prices may seem to be high, but owing to our section of country being so nigh the mining country, every thing that can be raised is in ready demand, and at a high rate.

Very respectfully, yours, &c.

O. C. MOTLEY.

Hon. Thomas Ewbank, *Commissioner.*

THE MOUNT AIRY AGRICULTURAL INSTITUTE.

BY JOHN WILKINSON, PRINCIPAL.

December, 1850.

This institution has now been in operation about 6 years, and its patronage has been gradually increasing, the students now numbering 32. The object of it is to combine science with judicious practice in agriculture, and to instruct its pupils in all the mysteries thereof. There are connected with the Institute about 70 acres of land, quite various in its natural characteristics, which is well adapted to the purposes of an agricultural seminary.

It is accessible several times a day from Philadelphia, by stage and railroad.

The tuition year is divided into two terms, of five months each; the summer term commencing on the first Thursday of April; the winter term on the first Thursday of October.

The charge per term is $100, payable in advance half-yearly.

The *practical course* consists of instruction in the practice and principles of agriculture, and the rotation of crops; the best modern modes of tillage; rearing, selecting, and feeding live stock; breaking and training horses and oxen; slaughtering and curing meats; horticulture, forestry, and floriculture; fencing, road-making, levelling, grading, seeding, and laying out ornamental grounds; the application of steam and other motive power; the construction and use of farm machinery, implements, &c. &c. A portion of every day is spent in the practical operations of the farm; the balance in the literary department, which consists of the following collateral branches, viz:—The natural sciences, as applied to agriculture; the classics, and modern

languages. Each student is required to lecture upon the science he is pursuing, to make surveys, with plots of the same, and also to keep a replete journal or diary of all experiments and farm operations. Two evenings of the week are spent in the discussion of practical subjects, on which full notes are preserved for reference. I now feel that I am no longer conducting an experiment, founded on the quicksands of contingency, but, stimulated by the happy results that have thus far attended my efforts, I proceed with promptitude and confidence towards the goal.

I anxiously look forward to the day when a thorough course of instruction in scientific and practical agriculture shall be considered an indispensable collateral branch of the classical course, preparatory to any of the learned professions.

My experience has proved to me that the addition of this branch to the common collegiate course will, while it adds but little to the time requisite to complete the diplomatic course, add very much to the health and happiness of the student, and greatly facilitate his progress, by insuring a vigorous, well-disciplined mind, which is the natural and happy result of proper moral and physical culture.

Besides this very desirable consequence of combining the agricultural with the literary course, are many others, no less important, among which is the advantage of a knowledge of this standard pursuit, to which the unfortunate or unsuccessful in other professions may resort to as a reliable support. So far from detracting from or interfering with the progress of the student in his literary pursuits, it, on the contrary, greatly facilitates his progress, by alternating the confining, feverish monotony of the class-room with the delightful and invigorating exercises of the field, garden, stable, and workshop, from which he returns with clearness and accuracy to master the most difficult mathematical solutions, or investigate and follow out the deep, complicated, and mysterious principles of science.

JOHN WILKINSON.

THE END.

OF

THE COMMISSIONER OF PATENTS,

IN RELATION

To Arts and Manufactures for the year 1851

May 3, 1852.—Laid upon the table and ordered to be printed.
August 30, 1852.—Ordered that 50,000 extra copies be printed.
August 31, 1852.—Ordered that 10,000 extra copies be printed for the use of the Patent Office.

United States Patent Office,
March 13, 1852.

Sir: I have the honor of transmitting to you, with the view of its being laid before Congress, that portion of the Report of this Office for the year 1851 which relates to Arts and Manufactures. Its presentation has been delayed for the completion of a report on the World's Exposition, by Mr. Riddle, commissioner from the United States, which it was desirable to include.

The second or Agricultural section of the Report will shortly be submitted.

Very respectfully, your obedient servant,

THOMAS EWBANK.

Hon. Linn Boyd,
Speaker of the House of Representatives.

REPORT

OF THE

COMMISSIONER OF PATENTS.

I.

UNITED STATES PATENT OFFICE, *January*, 1852.

SIR: Before introducing the usual financial and statistical sections of the Report, I beg to submit some remarks and suggestions in relation to

THE PATENT OFFICE, ITS ADMINISTRATION, ETC.

1. *On the Supervision exercised by the Secretary of the Interior.*—There is in the business of the Patent Office nothing congenial with or allied to that which is transacted in the departments, while its very nature is such as to render exterior control often embarrassing. Whatever may have been expedient in the infancy of its organization, when it was little else than a clerkship under the Secretary of State, its position and requirements are very different now. To vest a controlling power over its administration in heads of departments who have no time to devote to it, and who, from education, habits, profession, and feelings, can have little or no active sympathies with interests represented in it, or with the class of citizens with whom it has most to do, can hardly prove otherwise than prejudicial. Hence there is an increasing desire among inventors and patentees, mechanics, manufacturers and others, whose feelings no less than their interests centre in the Patent Office, that its dependency on the department should cease.

On this subject I beg to quote from a communication addressed by me to the Secretary of the Interior on the 30th of January last:

"There is probably no question bearing more on the future usefulness and efficient administration of the Patent Office than the extent to which Congress designs it to be subject to any other department. Exclusively devoted to the progress of science and art, to the development of new elements of civilization, it should be protected in the prosecution of its mission, wholly freed from political influences; and it is believed that no administration can more readily command the approbation of reflecting citizens, of all parties, than by securing to it this immunity. It was designed, as generally understood, by the law of 1836, to be an independent bureau, with a very limited check vested in the department. Such was the avowed intention of those who drew up the law, and such, as has been always understood in the office, was the intention of Congress, as manifested in instructing the Commissioner to report his proceedings directly to both Houses; in special legislation for his guidance; and, contrary to the practice in any other department or bureau, requiring from him bonds for the faithful performance of his duties, and for the disbursement of moneys from the Patent fund.

"A difference of views between the office and the department elicited the opinion of the Attorney General, that, 'The general supervision and direction over the Patent Office, which is vested in you, (the Secretary of the Interior,) comprehends the appointment of such temporary clerks in that office as are authorized by law; and also the payment of their salary or compensation out of any money appropriated for the purpose. And, of course, that the Commissioner of the Patent Office, in the employment or appointment of clerks, and in the disbursement of money appropriated for their compensation, acts under the superintendency and subject to the control of the Secretary of the Interior; and that it makes no difference in the case whether the money so to be disbursed is appropriated out of the agricultural fund, the Patent Office fees, or out of any other fund.'

"Since this opinion was communicated to me, it has been invariably respected; but as long as it is enforced, this bureau can never fully accomplish the objects for which it was organized. Whatever may be the practice in other bureaus, it will be impossible for any Commissioner to carry on, with credit to the country and satisfaction to inventors and patentees, the peculiar, important and multitudinous affairs, and to reconcile the often conflicting interests committed to his charge, if he be not permitted to judge of the merits and qualifications of his assistants, or to remove such as are incompetent, or in other respects unfit: that is, if he is made responsible for the acts of those over whom he has no control. And again: if the department has the control of the disbursements, it is but reasonable that the Secretary should file the required sureties, and not the Commissioner.

"On subjects deemed vital to the integrity and usefulness of the Patent Office, there should be left no room for doubt; hence, I respectfully recall these to your consideration, and propose to submit them to Congress, with a view of having the powers and responsibilities of the office distinctly defined."

The arts and sciences have no affinities with, and should not be linked to, temporary politics. To suppose the business of this office can be carried on, if its desks are occupied, as in some departments, by persons even of general qualifications, instead of special fitness, is a great mistake. Mechanical inventions and discoveries, for which patents are issued, are based upon the great physical laws of nature, and are illustrations of them; hence it is in conformity with those laws that the decisions of the office must be made. But this requires close and undivided attention, and, above all, freedom from extraneous interruptions and influences. These are, and ever must be, detrimental in the highest degree. They not only embarrass the proper and harmonious working

of the institution, but are subversive of the great objects contemplated in its organization.

The duties of the Commissioner and examiners are of too purely scientific a nature for them to be subjected, with advantage, to heads and sometimes chief clerks of departments, who cannot be expected to enter into the peculiar business of the Patent Office, or appreciate the very serious evils of interference. If the Commissioner and chief officers are not competent to perform, or are not faithful in the discharge of their onerous tasks, they should be removed; but if they are able and honest, they ought not to be harassed with calls to answer complaints preferred to the Department of the Interior, and often to the President, by disappointed applicants and their friends; by parties stimulated with promises of large sums, made payable on the issue of a patent; and by agents and speculators, smarting under the loss of such contingent fees. Nor is there the slightest ground or reason for such attempts at coercion; since, if the office improperly refuse a patent, the law has provided a court of appeal, in which its decisions can be revised and reversed.

Dissatisfaction on the part of applicants is unavoidable, because of the number of old devices presented for patents; nor can this ever be prevented, unless by the publication of such an Index of Inventions as has been in previous reports, and again in this, recommended to the favorable attention of Congress. There is no disposition in the office to refuse patents; the feeling is the very reverse. Rejections are made only in performance of a duty imposed by law. This duty is an unpleasant and arduous one, often blighting the fond anticipations of ingenious and worthy men, and often necessitating a more or less elaborate defence of the grounds of action in the case; whereas, in granting a patent the office is relieved from these and other difficulties. Hence it is absurd to suppose that refusals are wantonly made, there being no possible motive to refuse a patent, but every inducement to grant one. When doubts exist, the benefit is always given to the applicant.

If systematic endeavors to overawe and overrule the Commissioner be not frowned down, they will, in time, affect the integrity of the Patent Office, and will make it a source of injustice to the public and of grievous wrongs to real inventors. Its judicial character requires that it be cordially sustained, and jealously protected from improper influences. It should be surrounded with the same safeguards that defend the independence of every United States court. What would be the condition of judges of the Supreme and of other courts, if they were constantly called upon to reopen carefully adjudicated cases, and answer complaints of defeated litigants, accompanied with insinuations and often direct charges of ignorance, imbecility, partiality, corruption, and kindred attributes? Few high minded men would accept and fewer would remain in office. In this bureau, everything is matter of record. No decision is made without communicating the reasons, in writing, to the parties concerned; they are placed on file, and become part of the public archives of the office. This, together with a court of appeal, secures the rights of applicants, and is an ample guarantee against unjust and arbitrary decisions.

It would, in my opinion, have been a dereliction of duty to have refrained from thus soliciting the attention of Congress to a subject so essentially affecting the character and usefulness of the Patent Office;

so deep are my convictions of the positively injurious effects of departmental control, unaccompanied, as it is, by one single compensating advantage to the office, the administration, or the public.

2. *Additional room required.*—I respectfully but earnestly urge an early provision of additional room for the clerical business of the office, as well as for a proper exhibition of the models. The continued occupancy of the largest and best part of the building as a museum, and the delay in finishing the new wing, have resulted in embarrassments that are daily becoming more and more serious. Indeed, if the evil be not soon corrected, it will prove a positive interruption to the business of the office. The few rooms at its command have become so crowded, that the mails have, for the last twelve months, been made up in the open passage, where the correspondence and daily cash remittances are unavoidably exposed.

Such an exhibition of the models as was contemplated and directed by the law of 1836 is not only impossible, but it is scarcely practicable to protect them from serious injury, if, indeed, the more delicate among them can be secured from positive destruction. Their condition is a great injustice to their authors, and to inventors and patentees generally; since the rooms and cases, prepared expressly for them at the expense of the Patent fund, have now been withheld from the office for a period of ten years. As Congress alone has the power, I would respectfully suggest that immediate action be taken to provide room necessary for the classification, arrangement, and proper display of the models.

In relation to the details of the subject, I beg to introduce the following correspondence, elicited by a resolution of the Senate, of January 28, 1851:

PATENT OFFICE, *January* 30, 1851.

SIR: Having been desired by you to express our opinion on the wants of this office, as far as room is concerned, we have the honor to report:

First. That the patented models now in the office are so much crowded that the provision of the law with respect to the exhibition of them cannot be complied with; that the rejected models are in a similar, but worse condition.

Second. That the draughtsman's room, library, and record-room, are at present crowded to an extent which renders it extremely difficult to perform the duties that are required to be done in those departments; at least three times the space is wanted for the library, and double for the draughtsman's room.

Third. It is a matter of almost absolute necessity that the recording clerks should be in the vicinity of the record-room.

Fourth. That the copying-clerk for letters and the clerk who has charge of assignments are at present crowded into apartments of other officers, whose rooms are too full without them.

Fifth. That it has become a matter of necessity for the examiners to have rooms in which they may converse with applicants, without the latter having an opportunity to examine, or even glance at, the models of pending applications.

Sixth. Rooms are required for workshops, caveat models, and pending models.

Seventh. That an ante-room has become indispensably necessary.

Eighth. That it is a matter well understood that the force of this office must be yearly increasing, and that the foregoing considerations are based upon the present force and the expected increase of records, but not upon an increased number of clerks.

We therefore believe that the whole of the basement of the present building and the wing are necessary for a proper distribution of the rejected models and for workshops; that the whole of the upper halls, both of the building and wing, are at present required for patented models, and will probably be filled to overflowing in the course of three years. And we also believe that the whole of the first floor of the present building and the wing will not more than suffice for the wants of the Commissioner, examiners, machinist, draughtsman, and clerks, when it is considered that the library and draughtman's room are daily narrowing in effective space, and that it would be useless to move them into apartments which, in the course of less than three years, would be quite as contracted as those which are now daily hindering the effective action of this office.

If a different arrangement from that herein intimated be adopted, it will merely vary the distribution of offices, models, and records, but will not alter, in the least, the absolute amount of space that is needed.

All of which is respectfully submitted:

CHAS. G. PAGE,
N. P. N. FITZGERALD,
HENRY B. RENWICK,
L. D. GALE,
Principal Examiners.
J. H. LANE,
SAML. COOPER,
T. R. PEALE,
THOS. J. EVERETT,
Assistant Examiners.
R. S. CHILTON, *Librarian.*
A. L. McINTIRE, *Draughtsman.*
SAML. P. BELL, *Machinist.*
S. T. SHUGERT, *Accounting Clerk.*
A. B. LITTLE, *Assignment Clerk.*

Hon. THOS. EWBANK,
Commissioner of Patents.

—

UNITED STATES PATENT OFFICE, *February* 4, 1851.

In reply to your letter of January 31st, I have the honor to state that, with a view of ascertaining the sentiments of the principal officers of this bureau respecting the information called for by the resolution of the Senate of the 28th ultimo, viz: "What additional room, if any, is required for the proper accommodation of the Patent Office," &c., &c., I asked for their opinions, and thought it the safest course to submit them for your consideration in place of my own.

My personal opinion, now required, was, after an examination, expressed in the Report of 1849, page 512. Though the business of the office has increased since the date of that report, I still think that, were the upper floor and its cases restored to the office for the reception of its models, and the space now occupied by the models converted into rooms, there would be sufficient for the immediate wants of the office.

If the museum is to remain where it is, then, certainly, the whole of the upper floor of the new wing will be required for the models now in the office; but that would be an inconvenient arrangement, since by it the models would be far distant from the rooms of the officers requiring them. It would be better to assign the new wing entirely to this office, or remove the museum into it. Under any circumstances the models, if they are to be properly disposed of and arranged for exhibition, as the law requires they should be, must be placed on the upper floor on account of light. When the west wing is completed, it is doubtful if there would be sufficient light to examine the objects in the cases were they to remain on the present or first floor. They are partially obscured now, and would then be much more so.

In conclusion, I have no hesitation in saying that, in view of the rapidly increasing business of the office, the present building will, in my opinion, be found wholly insufficient for the purposes of this bureau in three or four years, if not sooner. The papers accompanying your letter are herewith returned.

I have the honor to be, very respectfully, your obedient servant,

THOS. EWBANK.

Hon. ALEX. H. H. STUART,
Secretary of the Interior.

The number of models at present in the office is nearly 20,000. The yearly accumulation exceeds 2,000; so that in ten years, the number cannot be estimated at less than 50,000, since the annual increase for the last four years has been between two and three hundred.

If the largest and best portion of the original building is still to be occupied with the collection of the Exploring Expedition, and if a moiety only of the new wing be accorded to this office, I submit that the $211,000 withdrawn from the Patent fund, and expended on the wing, be returned; since, after the payment of that sum, the office will have no more room than what is admitted belonged to it before.

Were the Patent fund held sacred for the direct encouragement of science and art, and the interest expended in premiums for inventions and discoveries of national importance, (as suggested in the report of 1849,) it would be a fruitful and enduring source of honor and of benefits to the Union. I believe it of more importance to the country to preserve that fund intact, and to expend the interest as suggested, than to have a stately structure in which to transact the business of the office.

3. *Increase of clerical force.*—With the exception of two, authorized by the act of 1848, there have been no permanent clerks added to this office since its reorganization in 1836; while the duties of those employed have increased more than three fold during that period. They are, consequently, over-tasked, and inadequately paid. I would, therefore, respectfully and most earnestly ask Congress to authorize the employment of *four* additional permanent clerks, at salaries of $1,200, to be assigned to such service as may be deemed necessary by the Commissioner for the despatch of the public business. Some of the duties for which these clerks are designed are now performed by persons employed

under the act of 1837. They are not qualified officers, but necessarily admitted to the secret archives, and other business requiring care and responsibility. These places, it is believed, should be filled by permanent clerks, sworn and qualified as such.

As examples of the necessity of permanent aid and increased compensation to certain branches of business, the duties of some of the officers whose desks are over-tasked are here referred to, by extracts taken from a report made by the Commissioner to the Secretary of the Interior, in September last, in obedience to a resolution of the Senate of the 7th of March, 1851, in relation to the classification of clerks, and "apportioning their salaries according to their services," with slight alterations, in which he recommended—

First. That the salary of the CHIEF CLERK of this bureau be increased to two thousand dollars per annum. This increase would only place the chief clerk of the Patent Office on an equality with those of other bureaus who receive a reasonable compensation, and who are exempt from the necessity of giving bonds, with surety, for faithful performance of duty, required by the chief clerk of this office.

Besides his heavy clerical and administrative duties, the entire business of the office passes through his hands, receiving its appropriate direction to the different branches. The duties thus devolving and accumulating upon him, rendered the services of an assistant necessary. This aid, supplied under the act of 1837, authorizing the employment of temporary clerks, is intended, also, to relieve other desks, and the clerkship should be made permanent.

Second. That the salary of the DRAUGHTSMAN, which is now twelve hundred, be raised to fifteen hundred dollars.

He has charge of the secret archives of the office; the drawings patented and rejected; pending files and evidence in cases of interference; receives applications from the chief clerk, entering them in books kept for that purpose, before they are distributed to the examiners; examines all drawings attached to patents before they go out of the office, and all copies of drawings made for courts or other purposes, besides attending to a large amount of miscellaneous business. It was found impossible, before the increase of the examining corps, for this officer to give his personal attention to these multifarious duties. Accordingly, an assistant was assigned to him under the act of 1837, whom I recommend to be made a permanent clerk.

Third. The MACHINIST. The duty of the machinist is to receive, classify, and arrange the models, to exhibit to inventors such classes as may be in the line of their discoveries; furnish the examiners with such as may be required in their examinations; keep records of those patented, suspended and rejected, and to conduct the correspondence relating to models, generally. The number of these interesting proofs of the inventive genius of the country has doubled within a few years, and now amounts to about 20,000. It has long been impossible for one person to meet the demands of this department. An assistant was necessarily appointed some years ago, and paid out of the contingent fund; and as the duties of the assistant are equally responsible with those of the machinist—he having a knowledge of models of pending applications and others belonging to the secret archives—he ought to be a sworn officer, and his place a permanent clerkship.

Fourth. That the salary of the ACCOUNTING OF DISBURSING CLERK be increased to $1,500 per annum, and he be required to give bonds.

He has charge of the records of the office—the patented and withdrawn files; and is required to give information in relation thereto whenever called upon. He is also the accounting and disbursing clerk, and conducts the correspondence in relation to withdrawals; the discharge of which duties involves a heavy responsibility, and requires a person of not only reputable talents, but also of rigid integrity. Seventy or eighty thousand dollars passes through his hands annually, and yet for a salary of $1,200 he assumes all the responsibility of such a trust.

Fifth. That the salary of the ASSIGNMENT CLERK, who now receives $1,000, be increased to $1,200. When this salary was authorized, the amount was, in a measure, commensurate with the duties performed; but, owing to several changes in the business and *personnel* of the office, many very important matters have been transferred from other desks to his, making it a very responsible and laborious position. He is charged with the preparation of all certificates for copies of records, files, &c., conducts the correspondence respecting copies, transfers of patent rights, and miscellaneous inquiries, and receives and accounts for the fees paid for copies and for recording deeds. In miscellaneous correspondence, which pertains to his desk, questions often arise involving preliminary legal points, requiring a competent knowledge of the patent law, as well as a thorough acquaintance with the practice of the office.

4. *Librarian.*—The library is an indispensable element in transacting the business of the office; and it is essential that it keep pace with the advancement of science and the arts, abroad as well as at home. As its importance and contents daily increase, it is desirable that a salary be attached to the librarianship commensurate with the services required; one sufficient to engage a person whose habits, education, and tastes, fit him for the position. Besides cataloguing, collating, and indexing the books, he might keep a digest of patents as they are issued, and post up materials for and aid the Commissioner in the preparation of the annual report. He should understand the German and French languages. I would recommend that the salary be made permanent, and not less than $1,200.

5. *Patent laws.*—It is believed that a registry law might be beneficially substituted for the law relating to designs. It would be more comprehensive, and better calculated to secure the objects sought, than the law at present in force.

I would recommend that in all cases where a patent is granted, upon proof that the applicant invented it prior to the issue of a patent granted before the application, or prior to a publication of the same invention made before said application, or prior to the use of the same by others before the filing of said application, said patent shall take the date of the earliest patent, the earliest publication, or the earliest use of said invention.

I would also recommend that, for the purpose of diminishing litigation, a system of cumulative damages and cumulative costs be authorized, depending upon the number of times a patent has been affirmed or invalidated before a court of competent jurisdiction. It is believed that such a system will, to a great extent, prevent calling the validity of patents in question for mere purposes of vexation, and will also check

the bringing of suits upon invalid patents for the purpose of procuring unjust tribute through fear of litigation. No plan has occurred to me which I consider so well calculated to check unnecessary and vexatious litigation under patents.

6. *Judge of appeals.*—The infirm health of the venerable chief justice of the District of Columbia, renders it necessary for Congress to make early provision for giving appellate jurisdiction over the decisions of the office.

In submitting the following letter from the chief justice, I feel it my duty again to call the attention of Congress to the total inadequacy of the compensation allowed by the act of 1837 for the services therein prescribed.

My immediate predecessor, in the report of 1847, uses the following language in reference to this officer: "From that time (March 3, 1837) down to the present, many appeals have been taken from the decisions of the Commissioner and decided by the chief justice, who has sustained his decisions by able and elaborate opinions, involving important principles of patent law." These opinions were published by Congress; they constitute the most valuable body of decisions on our present patent laws; are respected as authority in all our courts; and evince the high integrity, profound learning, and great industry of their author.

For these labors his only pecuniary compensation was $100 per annum; whereas single cases have occurred wherein a larger sum would have been inadequate. I respectfully suggest that an additional sum be allowed Judge Cranch out of the patent fund, as an acknowledgment of the important services he has rendered to this office.

Letter of Judge Cranch.

WASHINGTON, D. C., *December* 15, 1851.

DEAR SIR: I am unable, by reason of great age, sickness, and infirmity, to discharge the duties imposed upon me by the patent laws of the United States.

I have, therefore, petitioned Congress to repeal such parts of those laws as require me to hear and determine appeals from the decisions of the Commissioner of Patents.

My memorial is, I believe, referred by the Senate to the Committee on the Judiciary.

I suppose some substitute will be required for the provisions which may be repealed.

With great respect, I am, dear sir, your obedient servant,

W. CRANCH.

Hon. THOMAS EWBANK,
Commissioner of Patents.

7. *Analytical and descriptive Index of Inventions.*—Respecting this great desideratum, I beg to refer to my Report for 1849, page 516; to repeat the recommendations and to urge the appropriation therein named, for the commencement of such a compilation. Its importance, utility and necessity are becoming more and more apparent. No state paper and no mere human volume can ever surpass it in immediate and endur-

ing value. A greater boon to inventors, to science, and to the world at large, could hardly be named. It would be consulted as long as the arts are cherished, and would rather increase than diminish in interest as time rolls on.

If the cost of printing it be deemed an objection, a fair manuscript copy would be of great value to the examiners, and above all price to inventors and others, who should have access to it in person, or through their agents.

8. *Chemical apparatus for the use of the office.*—In the chemical branch of the examining department the furniture of a small laboratory is much needed, to enable the examiner to verify or disprove alleged ingredients and results of applicants for patents for materials, processes and compounds. Section sixth of the act of 1836 provides that every applicant for a chemical patent shall accompany his application "with specimens of ingredients and of the composition of matter, sufficient in quantity *for the purpose of experiment.*" Hitherto no means of testing such specimens have been provided, although obviously within the meaning of the law. The increasing number of applications belonging to this class and their alleged importance render it highly desirable, and indeed indispensable, that the examiner should have at hand the means of arriving at correct and definite decisions. It is therefore proposed to have a room fitted up as a laboratory, and that the Commissioner be authorized to procure the requisite apparatus, at an expense not exceeding $800.

9. *Reports of the office illustrated.*—It is very desirable that these documents should be rendered more practically useful to inventors, and to others interested in the progress of the arts. They are essentially defective in descriptions of devices patented, such descriptions being confined to the claims, the full meaning of which can seldom be understood for want of details and drawings. To publish the specifications in *extenso* would swell the annual exposition into several large volumes; but if simple and neat engraved illustrations were introduced along with the claims, a moderate addition only would be made to the volume now devoted to inventions. Let a small but clear outline engraving be given of each patented invention—that is, of the peculiar portion covered by the claim—and every person consulting the reports would understand the precise nature of the inventions at once, and consequently be prevented from repeating them. As long, therefore, as the specifications and drawings are not published in full, it would be a decided improvement, and in a majority of cases all that is wanted to convey a correct idea of the devices patented, to accompany each "claim" with a neat and lucid wood-cut illustration. Nearly every inventor would be glad to supply one, and few would object to a provision made by law, requiring one, or an electrotype cast of one, to be furnished by each patentee. They might be, and in general ought to be, confined to the features patented, so that seldom more than half a page would be taken up, while in a majority of cases one-third of a page, or even less, would suffice.

The insertion of such illustrations would make the reports much more popular and useful. They would impart greatly increased and more definite information and would save many an inventor an inconvenient outlay of time and money in travelling to Washington to examine the models in the Patent Office. The reports would be more care-

fully preserved, both in public and private libraries, and more frequently consulted by inventors and others.

As regards the style or workmanship in which the office reports are got up, I beg to suggest that a much smaller number than what is usually printed would be preferable, in nearly every point of view, provided they were issued in respectable and enduring volumes. As permanent records, *ten thousand* copies, got up in a style creditable to the office and to the country, would be more valuable and do more service than ten times the number of the usual character. Instead of being rapidly consumed as waste-paper, they would be preserved in both private and public libraries. A complete set is not now to be had; and it is doubtful if a dozen sets are in existence; (there are none in the office of a date prior to 1845) This is believed to be chiefly, if not wholly, due to the inferior quality of the paper and printing—to the unattractive and unsubstantial dress in which they have been sent forth.

If inventions are fraught with consequences of the highest import to the well-being of society and honorable to the people that originate them, descriptions of them are worthy of preservation; and the more so since every new application of science and every addition to art has a lasting value. Tomes of the early printers are extant, and their pages appear fresh as when struck off, promising to outlive most of modern works. Few, if any, of our Patent Office reports will be found on book-shelves four centuries hence—their materials will have perished;* while there is no room to doubt that thousands of volumes printed in the fifteenth century will be consulted in the twenty-fifth. The annual reports of a bureau so intimately allied with mechanical progress as this is, ought, in some degree, to correspond with the present state of the arts connected with book making. Our ministers abroad have often felt ashamed when comparing some of our documents with those of foreign governments. Of the 500 copies of the Report of 1849, Part 1, which the Senate authorized the undersigned to have printed, at a cost not exceeding fifty-five cents each, some were forwarded to American embassies abroad. The secretary of the legation at London, in acknowledging the receipt of a parcel, expressed his gratification at being furnished with a national document which he could exhibit without blushing.

It is the practice in nearly every public library to have its volumes bound in one uniform style; but with bound Patent Office reports this could not be done without cutting away the text, in consequence of the small portion of margin left by official binders; hence unbound are often preferred to bound copies. As the public binding is not calculated to be durable, it would be a decided improvement if the margin left by the binders were required to be not less than five-eighths or three-quarters of an inch in width.

10. *International exchanges.*—It is proper, in this place, to acknowledge the obligations of the office to M. Alexandre Vattemare, the well known founder of the system of international exchanges, for valuable contributions to its library, and for collections of foreign seeds.

The "*Annales des Ponts et Chaussées,*" a journal containing the transactions of the corps of topographical engineers in France, and

* A large edition of an English classic disappeared in thirty years, from the corroding action of chlorine used in bleaching the paper.

"*Annales des Mines*," a journal devoted to mining and metallurgic operations, have been received from him entire; also, the continuation, for several years past, of the "*Brevets d'Invention*," containing descriptions of patents granted in France, together with various works upon agriculture, chemistry, &c., received, through his agency, from individuals and scientific societies in France.

A series of specimens of Algerian soils and products, prepared by order of the Secretary of War of France, together with a collection of the agricultural productions of France, prepared by Mons. A. Vilmorin at the request of the Central Agricultural Society, have been received through Mons. Vattemare; but as it was understood that they were intended for the Department of the Interior, they have been handed over to the Secretary of that department, who has made mention of them in his late report accompanying the message of the President to Congress.

11. *Examiners' reports.*—These have been omitted, partly on account of the pressure of business on the examiners' desks, but principally because complaints have been made of partiality in the selections of inventions noticed. To avoid this, all must be mentioned or none. These reports necessarily made invidious distinctions in regard to the relative importance and merits of devices patented. Such distinctions doubtless exist, but the duty of pointing them out does not attach to this office. They have been a fruitful source of complaint, of charges of partiality, and even of corruption; and although such charges are to be expected under any circumstances, it is inexpedient for the office to travel out of its path to invite them.

II.

FINANCIAL AND STATISTICAL.

The number of applications for patents received during the year ending December 31, 1851, is two thousand two hundred and fifty-eight; the number of caveats filed during the same period is seven hundred and sixty; being an increase of applications over last year of sixty-five, and of caveats one hundred and fifty-eight.

The number of patents issued during the year 1851 is eight hundred and sixty-nine, including twenty five re-issues, three additional improvements, and ninety designs. Three disclaimers were entered during the year.

Within the year 1851, four hundred and thirty-eight patents have expired, a list of which is annexed, marked H. There were fifteen applications made during the year to extend patents, the terms of which were about to expire; which, with five pending applications at the close of last year, made twenty cases to be considered. Of these, nine were granted and eleven rejected. None have been extended by Congress during the year.

The receipts of the office for the year 1851, on account of applications for patents, caveats, additional improvements, re issues, extensions, recording assignments, powers of attorney, &c., and for copies, amount to $95,738 61, as per statement marked A; being an increase over the receipts of last year of $8,811 56.

The expenses of the office for the year 1851 are as follows, viz: For salaries, $33,719 73; contingent expenses, $11,533 81; books for the library, $1,183 32; temporary clerks, $14,391 12; agricultural statistics, $4,937 84; refunding money paid by mistake, $186 77; compensation of librarian, $250; chief justice of the District of Columbia sitting on appeals from Commissioner of Patents, $100; on applications withdrawn, $20,614 31, as per statement marked B; leaving a balance to be carried to the credit of the Patent fund of $8,821 68, as per statement marked C.

On the 1st day of January, 1851, the amount of money in the treasury to the credit of the Patent fund was $15,331 27; to which add the excess of receipts over expenditures for the year, $8,821 68, leaves a balance in the treasury to the credit of the Patent fund, on the 1st day of January, 1852, of $24,152 95, as per statement D.

There were one hundred and sixty nine cases on the examiners' desks on the 1st of January, 1851; the number of applications received during the year, two thousand two hundred and fifty-eight; making the whole number of applications before the office during the year two thousand four hundred and twenty-seven. Of this number, one hundred and fifty-five remained unexamined on the 1st day of January, 1852.

The business of the office for the past year shows the examination of two thousand two hundred and seventy-two applications, resulting in the issue of eight hundred and sixty-nine patents and one thousand four hundred and three rejections and suspensions, as exhibited per statement E.

A statement is also appended, showing the amount of fees received, applications and caveats filed, during each month of the year, marked F.

A.

Statement of receipts for patents, caveats, additional improvements, recording assignments, &c., and for copies.

Amount received for patents, caveats, re-issues, and additional improvements	$89,022 00
Amount received for recording assignments, &c., and for copies	6,716 61
Total	95,738 61

—

B.

Statement of expenditures and payments made from the Patent Fund by the Commissioner of Patents, from January 1, 1851, to January 1, 1852, under the acts of Congress making provision for the expenses of the Patent Office, viz:

For salaries		$33,719 73
For contingent expenses		11,533 81
For books for library		1,183 32
For temporary clerks		14,391 12
For refunding money paid by mistake		186 77
For withdrawals		20,614 34
For compensation of librarian		250 00
For compensation of district judge		100 00
For collecting agricultural statistics, viz:		
Salary paid agricultural clerk ($500 due for 1850)	$2,500 00	
Salary paid assistant, Mr. Fogg	222 15	
Amount paid for copying report	501 69	
Amount paid for seeds, stationery, &c	1,714 01	
		4,937 85
		86,916 94

In the above sum of $86,916 94, which shows an increased expenditure for the year 1851 over that of 1850 and former years, is embraced—

The salaries of two principal and two assistant examiners, authorized at the last session of Congress, at the rate of $8,000 per annum for nine months	$6,0 0 00
The excess of expenditure for the agricultural desk over last year	1,078 49

Besides these extraordinary expenditures, the withdrawals of applications have been unusually large, exceeding the amount of those of last year—which was greater than any preceding year—the sum of	$2,601 01
	9,679 50

This sum of $9,679 50 deducted from the whole expenditure, $86,916 93, and the ordinary expenses of the office for the year 1851 is shown to be only $77,237 43—$2,863 52 less as compared with the expenses of last year.

—

C.

Statement of receipts and expenditures of the Patent Office for the year 1851.

Amount received from all sources	$95,738 61
Amount of expenditures of all kinds	86,916 93
Amount carried to credit of Patent fund for 1851	8,821 68

—

D.

Patent Fund, January 1, 1851.

Amount of fund January 1, 1851	$15,331 27
Amount carried to Patent fund for 1851	8,221 68
Amount remaining in the treasury to the credit of the Patent fund January 1, 1852	24,152 95

—

E.

Statement of applications on hand January 1, 1851, and number received during the year and acted upon.

Number of cases on examiners' desks January 1, 1851		169
Number of applications received in 1851		2,258
Number of cases before the office during the year		2,427
Number of patents issued during the year	869	
Number of applications remaining unexamined	155	
Number of rejections and suspensions	1,403	
		2,427

F.

Statement showing amount of fees received and number of applications and caveats filed during each month of the year 1851.

Months.	Cash received.	Certificates receiv'd.	Small fees received.	Total received.	Applications filed.	Caveats filed.
January	$2,860 00	$3,845 00	$477 97	$7,182 97	183	78
February	4,095 00	5,340 00	549 96	9,984 96	211	93
March	3,650 00	5,150 00	982 45	9,782 45	237	72
April	3,195 00	4,021 00	531 92	7,747 92	184	73
May	3,669 00	4,865 00	419 78	8,953 78	218	52
June	3,487 00	5,475 00	635 59	9,579 59	187	50
July	3,319 00	2,725 00	524 44	6,559 44	178	61
August	2,745 00	2,810 00	358 37	5,913 37	141	52
September	4,400 00	3,110 00	669 15	8,179 15	229	55
October	4,225 00	2,955 00	401 30	7,581 30	150	64
November	4,465 00	2,855 00	428 73	7,748 73	171	49
December	2,725 00	3,045 00	737 85	6,507 85	169	61
Total	42,826 00	46,196 00	6,716 61	95,738 61	2,258	760

Table exhibiting the business of the office for the last eleven years, and the necessity of an increase of permanent clerical force.

Years.	Applications filed.	Caveats filed.	Patents issued.	Amount of cash received.	Amount of cash expended.
1841	847	312	495	$40,413 01	$23,065 87
1842	761	291	517	36,505 68	31,241 49
1843	819	315	531	35,315 81	30,776 96
1844	1,045	389	502	42,509 26	36,344 73
1845	1,246	452	502	51,076 14	39,395 65
1846	1,272	448	619	50,264 16	46,158 71
1847	1,531	533	572	63,111 19	41,878 35
1848	1,628	607	660	67,576 69	58,905 84
1849	1,955	595	1,076	80,752 78	77,716 44
1850	2,193	602	995	86,927 05	80,100 95
1851	2,258	760	869	95,738 61	86,916 93

The foregoing statistics exhibit a very large increase of business in this office for the last eleven years; and by reference to the table it will be seen that the increase for 1851 is in full proportion with former years. This accumulation of business has been provided for from time to time by Congress, in authorizing necessary additions to the examining force. This force for the present is deemed sufficient. But there are still departments of the business and labor of the office which have increased in a corresponding ratio with the examinations, and no provision made by Congress to relieve them. Hence the suggestions in relation to an increase of clerical force, in the preceding pages.

Table showing the number of patents, reissues, designs, and additional improvements granted at the Patent Office in Washington during each month of the year 1851.

	January.	February.	March.	April.	May.	June.	July.	August.	September.	October.	November.	December.	Total.
Total patents	56	38	46	64	57	57	81	60	75	76	72	69	751
Reissues	5	2	6	1	5	1	2	......	......	1	1	1	25
Designs	7	4	10	8	8	12	15	1	11	5	5	4	90
Additional improvements	......	......	......	......	1	......	......	......	1	......	1	......	3
Extensions, 9; disclaimers 3; not included in this table.	......	......	......	......	......	......	......	......	......	......	......	......	......
	68	44	62	73	71	70	98	61	87	82	79	74	869

Table showing the number of patents issued to citizens of different States during the year 1851.

State.	No.	State.	No.	State.	No.	State.	No.
Maine	9	Delaware	3	Arkansas	......	Florida	......
Vermont	12	Maryland	10	Tennessee	4	Texas	2
New Hampshire	17	Virginia	8	Kentucky	8	Iowa	2
Massachusetts	121	North Carolina	2	Ohio	76	Wisconsin	4
Rhode Island	9	South Carolina	4	Michigan	5	District of Columbia	11
Connecticut	53	Georgia	8	Indiana	13	Foreign	18
New York	235	Alabama	2	Illinois	10		
New Jersey	15	Mississippi	1	Missouri	8	Total	869
Pennsylvania	77	Louisiana	4				

Patents, reissues, designs and additional improvements are all included in this table.

IV.

CLASSIFIED LIST OF PATENTS THAT HAVE EXPIRED IN THE YEAR 1851.

CLASS I.—*Agriculture, including instruments and operations.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Corn husking	Jonathan Cutler	Putney, Vt.	July 31
Cultivator for thinning cotton plants	John Weaver	Washington, D. C.	July 5
Cutting cradle for hemp	Wilson L Larimore	Paris, Ky.	April 25
Cutting scythe snath	Dexter Pierce	Montague, Mass.	Mar. 11
Hulling clover seed	William M. Barton	Clark's Cross Roads, Tenn.	Dec. 20
Hulling rice	C. H. Harvey and E. Tracy.	Poughkeepsie, N. Y.	May 30
Lime spreading	Francis H. Smith	Baltimore, Md.	July 5
Lime spreading and sowing	Levi Rice	Chester, Pa.	Aug. 31
Plough	Bancroft Woodcock	Mount Pleasant, Pa.	June 14
Plough	Sam. Hartpence and John D. Bowne.	Kingwood, N. J.	July 5
Plough	John C. Smith	Kingwood, N. J.	July 11
Plough	John B. Norton	Philadelphia, Pa.	July 17
Plough	Isaac Snider	Mount Pleasant, Pa.	July 17
Plough	Stephen McCormick	Auburn, Pa.	Dec. 1
Rake, horse	David Dewey	Poultney, Vt.	Nov. 23
Rake, revolving	Stephen Coats	Shoreham, Vt.	April 17
Smut machine, (antedated August 1, 1837.)	Benjamin M. Smith	Rochester, N. Y.	Sep. 8
Smut machine	Charles D. Childs	Mount Morris, N. Y.	Aug. 15
Smut machine, for garlic	Henry Staub	Shepherdstown, Va.	Nov. 11
Strainers for milk-pails	Isaiah Burmel	Derby, Ct.	Aug. 18
Straw cutting	Henry Silliman	Perry village, N. Y.	Mar. 30
Threshing and hulling clover seed	Jonathan Brooks	Brownsburg, Va.	Dec. 15
Threshing machine	Alexander W. Bowling	Front Royal, Va.	Dec. 26
Threshing and winnowing	Moses Davenport	Phillips, Mass.	Nov. 23
Threshing and winnowing, (antedated June 29.)	J. A. & Hiram A. Pitts.	Winthrop, Maine	Dec. 29
Winnowing, separating, &c , wild peas from grain.	Lester Butler	Coble's hill, N. Y.	June 3
Yoke, horse and oxen	Gideon Hotchkiss	Windsor, N. Y.	Aug. 31

CLASS II.—*Metallurgy and manufacture of metals.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Blow pipe for blast furnaces	John Barker	Baltimore, Md.	Mar. 3
Door plates	William C. Austin	Greensville, Va.	Jan. 31
Door springs	Thomas Thorpe	West Cambridge, Mass.	Dec. 7
Door, springs for shutting	Ithiel S. Richardson	Boston, Mass.	Oct. 20
Fire proof safe	Benjamin Sherwood	New York	May 8
Fire proof safe	Daniel Fitzgerald	Mount Morris, N. Y.	Aug. 15
Furnace blast	John Barker	Baltimore, Md.	April 20
Furnace for shear steel, &c.	Simeon Broadmeadow	New York	April 5
Furnace, smelting ore	George E. Sellers	Philadelphia, Pa.	April 20
Furnace, smelting ore	Simeon Broadmeadow	New York	April 5
Hinges or butts, double-centred joints	Egbert Hedge	Hartford, Conn.	Nov. 23

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Iron, carbonating and smelting	Asa Whitney	Southfield, N. Y.	July 17
Iron ore, smelting	Joseph Lyon	Pottsville, Pa.	July 31
Iron, &c., washing ores	Frederick Fredly	Logan Township, Pa.	April 20
Joints for rules, double-centred	Lemuel Hedge	Hartford, Conn.	April 29
Knobs, door, drawer, commode, &c.	David Holtman	Baltimore, Md.	July 31
Knobs, glass, to metallic sockets, attaching.	Enoch Robinson & G. W. Robinson.	Boston, Mass.	Oct. 20
Latch mortise	Charles S. Gay	Nashua, N. H.	Sep. 28
Latch mortise	David N. Ropes	Portland, Maine	Sep. 28
Lock, door	Turner Whitehouse	Boston, Mass.	Sep. 8
Lock, door	James McClony	New York	June 14
Locks, mail-bag and clasp	Henry C. Jones	Newark, N. J.	Oct. 23
Locks, secret safety	William Hobbs	Springfield, Mass.	Dec. 20
Nails and brad cutting	Joseph Berry & Oliver P. Rand.	Newmarket, N. H.	Mar. 20
Nails, wrought	N. W. Bishop & Simeon Brooks.	Saybrook and Chester, Conn.	Sep. 21
Rivets, making	Levi Severance	Pittsburg, Pa.	July 11
Screws, cutting	Joseph Blackall	Albany, N. Y.	July 29
Screws, cutting, of screw bedsteads.	Palmer Williams	Towanda, Pa.	Feb. 16
Screws, cutting wood	Jacob Sloat & Thomas Springstead.	Ramapo and Poughkeepsie, N. Y.	Mar. 30
Screw, wood, turning heads	Thomas W. Harvey	Poughkeepsie, N. Y.	Mar. 25
Screw, wood	Clement O. Reed	Providence, R. I.	Dec. 15
Shoes, horse	Barzillai Young & Sam Titus.	Brooklyn, Conn.	July 29
Vice, bench. &c.	Linus Dean	Utica, N. Y.	Feb. 16
Window blinds, fastener	Elijah Jaquith	Brattleborough, Vt.	Dec. 26
Window fastening, combined spring.	Philip F. Hazard	Philadelphia, Pa.	July 11
Window sash, spring for upper sash	Henry Hammond	Lewisburg, Pa.	Sep. 8
Wire, cutting and heading	Thomas W. Harvey	Poughkeepsie, N. Y.	Mar. 25

CLASS III.—*Manufactures of fibrous and textile substances, including machines for preparing fibres of wool, cotton, silk, fur, paper, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Flax and hemp-breaking	John Warren	Westbrook, Me.	June 14
Flax and hemp-breaking	Harvey Lull	Ithaca, N. Y.	June 14
Flax and hemp-breaking and cleaning.	David M. Langley and Samuel Davis.	Westbrook, Me.	Sept. 21
Flax and hemp-breaking and dressing.	Chap'n Warner, Abraham F. Mixwell, and Edwin J. Horn.	Belvidere, N. J.	July 31
Flax and hemp-dressing	William and Robert Brittain.	Armwell, N. J.	Oct. 12
Fur-cutting from skins	Samuel Johnson	Walnut Lane, N. C.	Feb. 24
Gin, cotton	Alexander Jones	New Orleans, La.	April 25
Gin, cotton	John Stevens	Poughkeepsie, N. Y.	Nov. 25
Gin, cotton	Lucillius H. Mosely	Poughkeepsie, N. Y.	Nov. 25
Gin, cotton, saw-cylinder for	Jacob Idler	Philadelphia, Pa.	Dec. 1
Hair-seating, weaving	Charles R. Harvey	Poughkeepsie, N. Y.	Nov. 25
Hat bodies	Hugh Moore	New York city	April 20

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Hat bodies	Henry A. Wells, J. James, and R. W. Peck.	Brooklyn, N. Y	April 20
Hat bodies, batting or web for	Phineas Blanchard	New York city	June 14
Hat bodies, batting or web for	Henry A. Wells and Robert W. Peck.	Brooklyn, N. Y	Sept. 22
Hemp-hatcheling	Phineas G. Rice and Gabriel Rice.	Danville, Ky	July 11
Knitting machine	John McMullin and Joseph Hallen, jr.	Sinking Valley and Logan's Valley, Pa	Feb. 11
Loom, (ante dated March 21, 1837).	Christian W. Shauberr.	Subject of the King of Saxony.	May 8
Loom, (ante dated Feb. 10, 1837)	Enoch Burt	Manchester, Conn	Aug. 8
Loom-power, figure	William Compton	Taunton, Mass	Nov. 25
Loom, regulating yarn beam	Welcome A. Potter	Cranston, R. I	Nov. 23
Loom shuttle-tongue	Comfort B. Thorpe	Smithfield, R. I	April 17
Loom temple, self-adjusting	Samuel P. Mason	Newport, R. I	July 22
Loom treadles and harness	B. Harford and W. B. Tilton.	Enfield, N. H	Dec. 29
Napping cloth	Benjamin Swazy	Mt. Vernon, Vt	Aug. 8
Oil-cloth, drying	Daniel Sampson	Winthrop, Me	May 30
Paper sizing	John Ames	Springfield, Mass	Dec. 1
Spinning woollen roving	Edgar M. Titcomb	Andover, Mass	July 29
Thread, preventing from waste, &c.	John Golding	Dedham, Mass	Aug. 15
Thread, waste, reducing to cotton-wool.	Ogden Griswold	Hartford, Conn	July 17
Thread, waste, reducing to cotton-wool.	William Gray	Connecticut	July 29
Wool, cleaning	J. Wolcott and C. W. Brown.	Roxbury, Mass	Oct. 18
Wool, cleaning burr from	Erastus Tracy	Pougkeepsie, N. Y	Dec. 20

CLASS IV.—*Chemical processes, manufactures, and compounds, including medicine, dying, color-making, distilling, soap and candle-making, mortars, cements, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Bitterings from kettles, process of separating.	David Dear	Salina, N. Y	Oct. 18
Candle-moulding	J. Moore and S. P. Bower.	Strasburg, Pa	Mar. 3
Candle-moulding	Joseph H. Tuck	Nantucket, Mass	July 11
Caoutchouc, divesting of its adhesive properties.	Charles Goodyear	New York	June 17
Cement for cisterns	Thomas Coyle	Baltimore, Md	Aug. 16
Cement, hydraulic, from basanite	Ebenezer C. Warner	Albany, N. Y	Oct. 6
Coloring-matter, manufacture of	Henry Stevens	G. Britain, England	Oct. 28
Composition matter for fire-brick, &c.	Christ'phr W. Fenton.	Bennington, Vt	Sept. 22
Composition, protecting metallic sheathing of vessels.	Edward M. Robinson	New Bedford	Aug. 8
Composition, water-proof, for boots,	Patrick G. Nagle	Philadelphia, Pa	Feb. 1

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Gum senegal, substitute for, (antedated May 30, 1837.)	Walter Leveridge	Dorchester, Mass	Aug. 8
India rubber, manufacture of	Stephen C. Smith	New York	Dec. 7
Leaching ashes	Garret Clements	Canandaigua, N. Y	June 10
Lead, carbonate of	Charles Ripley	Saugerties, N. Y	July 11
Lead, white	Peregrine Phillips	Campbell co., Ky	April 17
Matches, locofoco, dipping	John Hatfield	Stillwater, N. Y	June 3
Medicine, worm-destroying	John J. Oellig	Waynesborough, Pa.	Oct. 28
Oleagenous seeds, preparing for pressing.	James Creswell	Pittsburg, Pa	July 31
Paint, composition	William Cox	Dayton, Ohio	Oct. 23
Paint, protection of buildings	Lonis Painboeuf	Washington, D. C	Nov. 11
Paint, white, water-color	Forrest Sheppard	New Haven, Conn	July 17
Pills, tonic and aperient	John J. Oellig	Waynesborough, Pa.	Oct. 28
Plaster, adhesive, spreading	B. Morison	Milton, Pa	Aug. 8
Preserving iron from rust	M. Sorel	Paris, France	Dec. 7
Preserving timber and other vegetable products.	John Knowles & Robt. Gilbert, executors of Robert Bill.	London, Eng., and New York city.	Sept. 21
Preserving timber from worms	August Gotthilff	New York	June 14
Salt water, purifying	Nils Sholtewskü Von Shaultz.	Salina, N. Y	July 29
Soap, making	Daniel E. Stillwell	Utica, N. Y	July 17
Sugar, manufacturing	John Penny	Parish Ascension, La.	Sept. 25

CLASS V.—*Calorific, comprising lamps, fireplaces, stoves, grates, furnaces for heating buildings, cooking apparatus, preparations of fuel, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Air to wood and coal stoves, (antedated March 25, 1837.)	Federick A. Frickhardt.	Easton, Pa	Sept. 25
Cooking apparatus	William W. Parrott	Boston, Mass	Mar. 11
Cooking, fire apparatus for	Daniel Stephens	Kitland, O	Oct. 18
Cooking, generating steam for	John Bovis	Baltimore, Md	Sept. 21
Cooking, steam vessel for	John Morris	Derby, Conn	Oct. 28
Cooking stove	Benjamin H. Wood	Bath, Steuben co., New York.	Jan. 31
Cooking stove	Abraham T. Mixell	Belvidere, N. Y	July 19
Cooking stove	Edwin Reed	West Bridgewater, Massachusetts.	July 29
Cooking stove	John Richardson	Paultney, Vt	July 29
Cooking stove	Samuel Utter	New York city	Aug. 8
Cooking stove	James Wilson	New York city	Aug. 15
Cooking stove	John S. Leavitt	Turner, Me	Aug. 31
Cooking stove	Elijah Skinner	Sandwich, N. H	Oct. 18
Cooking stove	James N. Olney	New York city	Nov. 20
Cooking stove	David Hastings & Soloman Sikes.	Deerfield, Mass	Nov. 23
Cooking stove	Nathaniel Walker	Dighton, Mass	Dec. 1
Cooking stove	Jonathan G. Hathaway.	Painesville, O	Dec. 7
Cooking stove	Jesse Hutchinson, jr.	Lynn, Mass	Dec. 20
Cooking stove	Carrington Wilson, jr.	New York city	Dec. 29
Cooking stove, coal	William Kenney	Louisville, Ky	July 29
Cooking stove, combination	Jordan L. Mott	New York city	Nov. 20
Cooking stove and galley	Benjamin Spratley	Portsmouth, Va	Sept. 25

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Cooking stove and galley	James Barron	Philadelphia, Pa.	Oct. 6
Cooking stove, heat to	Jonathan G. Hathaway.	Painesville, O.	Dec. 7
Cooking stove, heating	William B. Kimball	Peterborough, N. H.	July 19
Cooking stove, heating	Rufus S. Payne	West Springfield, Massachusetts.	July 31
Cooking stove, heating	Philip Wilcox	Springfield, Mass	Sept. 12
Cooking stove, heating buildings	Washington Auld and Jas. Cox.	Philadelphia, Pa.	May 30
Cooking stove and warming rooms.	John Morris	Derby, Conn.	Nov. 4
Fireplace and grate, open	Roger M. Sherman	Fairfield, Conn	June 30
Fuel, burning, &c	Thomas Pearson	Monroe Works, N. York.	July 17
Furnaces, cooking	Horace Gleason	Boston, Mass.	Dec. 15
Furnaces, heatrd air to	John Silsbe	Tyrone, N. Y.	Aug. 8
Grates and fireplace	Ellison Conger	Newark, N. J.	July 22
Grates, &c., register and air-box for.	Allen Pollock	Boston, Mass.	Mar. 3
Grates, revolving and shifting	Enos B. M. Hughes	New Haven, Conn.	July 29
Grates, sliding flute	Daniel Dermand	New York city	Dec. 26
Grates and stoves	Edward H. Dixon	New York city	Aug. 8
Lamps	Samuel Rust	New York city	Apr. 20
Lamps	Samuel Rust	New York city	June 30
Lamps and lamp torches	Jeremiah Martin	Boston, Mass.	June 30
Lamps, patent	Samuel Rust	New York	Sept. 25
Ovens, railway	Sewell Short	Nantucket, Mass.	Sept. 6
Ovens for stoves	David W. Barker	Clyde, N. Y.	July 29
Steaming and mashing apples	John Drum	Greenwood, Pa.	Dec. 1
Stoves	John Collum	Grafton, Mass.	July 31
Stoves, anthracite coal	Aaron O. Price	Newark, N. J.	June 14
Stoves, anthracite coal	Jordan L. Mott	New York city	July 22
Stoves, construction of (antedated March 8, 1837.)	George F. Hopkins	New York city	Sept. 8
Stoves, construction of	Thomas Mills	Havana, New York.	Sept. 25
Stoves, construction of	Henry R. Roath	Norwich, Conn	Nov. 4
Stoves and grates, boilers and ovens.	Caleb Slade	Troy, N. Y.	Nov 11
Stoves, heating apartments	Philip Wilcox	Springfield, Mass.	July 31
Stoves, heating irons for tailors	Bartholomew W. Tabor	Falmouth, Mass.	June 10
Stoves, non-radiating hot-air	Benjamin Blany	Boston, Mass	Sept. 8
Stoves, parlor	Jordan L. Mott	New York city	Dec. 7
Stove-pipes and drums	Merret Bradford	Saugerties, N. Y.	Mar. 25
Stoves, quadrant hinge for	Ebenezer Burrows	Boston, Mass	Aug. 31
Stoves, radiators	Ethan A. Andrews	Boston, Mass	May 30
Stoves, rotary	Rensselaer D. Granger.	Troy, N. Y.	July 17

CLASS VI.—*Steam and gas engines, including boilers and furnaces therefor, and parts thereof.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Boilers, steam	James J. Rush	Philadelphia, Pa	June 3
Boilers, steam	James M. Whittemore	Brighton, Mass	Nov. 23
Explosion of boilers, preventing	Augustus Eitelgeorge	Cincinnati, Ohio	May 22
Heating water for steam engines	Ross Winans	Baltimore, Md	July 29
Locomotive power, engine for removing houses.	Stephen Compton, jr	Almira, N. Y.	July 21
Pistons, metallic, for steam engine pumps.	John Swainson	New York	Mar. 30

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Pistons, packing	John Williamson	New York	Aug. 31
Pump, air, for steam engines	Thos. B. Stillman	....do	May 15
Spark-catcher, &c	William Duff	Baltimore, Md.	Dec. 20
Spark-catcher, centrifugal, &c	James Stimpson	....do	April 17
Steam engine, locomotive	Ross Winans	....do	July 29
Steam engine, locomotive	Ross Winans	....do	July 29
Steam engine, locomotive	Samuel Wright	Philadelphia, Pa.	Dec. 26
Steam engine, locomotive, blowing fire.	Ross Winans	Baltimore, Md	July 29
Steam engine, locomotive, framing.	Ross Winans	....do	July 29
Steam engine, rotary	Roger M. Sherman	Fairfield, Conn	April 25
Steam engine, rotary	D. Gramis & D. E. Brand	Collins, N. Y.	July 29
Steam engine, rotary	Asa Miller	Lockport, N. Y.	Aug. 8
Steam, generating	William Creed	Boston, Mass	Dec. 26
Valve puppet	John Kirkpatrick	Baltimore, Md	Sept. 25
Valve slide	John Kirkpatrick	....do	Sept. 22

CLASS VII.—*Navigation and maritime implements, comprising all vessels for conveyance on water, their construction, rigging, and propulsion; diving dresses, life preservers, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Boats, canal, bays, &c	Abraham Morrison	Johnstown, Pa	May 15
Capstans for ships, &c	Increase Wilson and Francis D. Beckwith.	New London, Conn.	June 15
Constructing ships	Samuel E. Howell	Vincent Town, N. J.	Aug. 31
Grapling irons for raising bodies, &c.	Eben. & Thos. J. Lobdell	Kymton and Boston, Mass.	Aug. 18
Ice-breaker	Barnabas Gillespie	New York	Mar. 8
Mallet, screwing and worming	John B. Petitval	Charleston, S. C.	July 11
Parcelling rope, (antedated March 25, 1837.)	Obed Kempton	New Bedford, Mass.	Sept. 25
Propelling boats, canal, &c	John Finley	Baltimore, Md.	April 17
Propelling boats	J. J. Greenaugh	Boston, Mass.	Aug. 18
Propelling paddles used as ice-breakers.	Washington Van Duzen	Kensington, Pa.	July 29
Propelling paddle-wheels	Jesse Ong	N. Huntington, Pa.	May 22
Propelling paddle-wheels, steam-boats.	Wm. A. Douglas	Albany, N. Y.	July 31
Sounding instrument for ascertaining the depth of water, &c.	John B. Ogden and John Ericson	New Jersey, and subject of the kingdom of Sweden.	July 19
Steering apparatus for ships, &c	Samuel Nicolson	Boston, Mass	Sept. 12
Steering wheel for ships, &c	Andrew Morse	....do	Dec. 1
Vessels used as life preservers	John McIntosh	New York	Nov. 11

IV.—*Classified list of patents, &c.*—Continued.

Class VIII.—*Mathematical, philosophical, and optical instruments, including clocks, chronometers, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Circumferenter	James McCann	New Market, Va	Dec. 20
Electro-magnetism	Thomas Davenport	Brandon, Vt	Feb. 25

Class IX.—*Civil engineering and architecture, comprising works on rail and common roads, bridges, canals, wharves, docks, rivers, weirs, dams, and other internal improvements, buildings, roofs, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Bridges	Francis Good	New London, Pa	Nov. 4
Dock, floating, dry	James Barron	Philadelphia, Pa	July 17
Dock, floating, dry	John Thomas	New York city	Dec. 20
Inclined planes, ascending and descending of cars and canal boats.	Gideon Brown	New York city	Oct. 6
Inclined planes, ascending and descending upon railroads, &c.	Elisha F. Aldrich	New York city	Oct. 12
Railroad	Isaac Cooper	Johnstown, Pa	July 22
Railroad frog	George S. Griggs	Roxbury, Mass	July 31
Railroad, rails for	John Ruggles	Thomastown, Me	May 22
Railroad rails, constructing and fastening.	Peter Henry Dreyer	New York	Oct. 18
Railroad road, stops for	Thomas J. West	White Hall, Va	Mar. 11
Railroad, single	Uri Emmons	Freehold, N. J	Apr. 17
Railroad, turnabout for	Jeremiah Myers	Attleborough, Mass	May 8

Class X.—*Land conveyance, comprising carriages, cars, and other vehicles used on roads, and parts thereof.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Axle, and thorough boxes for carriages.	William Slicer	Baltimore, Md	July 5
Axletrees, &c, setting	Timothy Fessenden	Boston, Mass	Sept. 25
Car and circular railroad	James Rowe	Triana, Ala	Oct. 28
Car, railroad, &c., mode of connecting.	Robert Grant	Philadelphia, Pa	July 22
Car, railroad safety	William Kinkead	Elkton, Md	Dec. 29
Car, railroad, supporting the bodies	Richard Imlay	Philadelphia, Pa	Sept. 21
Carriages, construction of	Saml. C Brown and Levi J. Hicks.	Macedon, N. Y	July 17
Link, self-separating, for connecting railroad cars, &c.	Conrad H. Hunt and Wm. Brown.	Fredericksburg, Va	Dec. 26

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Mail carriages, waterproof	Bazil B. Pleasants	Brookville, Md	Dec. 7
Sleds, hold-back for	James Andrews	Camden, Me	Feb. 16
Springs, carriage, railroad cars, &c.	Porter Hill	Veteran, N. Y	Nov. 25
Springs, spiral, to ellipucal or bow for carriages.	William Creasdale	Hartsville, Pa	Feb. 3
Tire bending	Thomas C. Barton	New York city	July 31
Tire, for wheels, drilling	Thomas C. Barton	New York city	July 31
Wheels, driving of locomotive engines, increasing the adhesion.	Andrew M. Eastwick	Philadelphia, Pa	Nov. 20
Wheel hubs	Howard Delano	Skaneateles, N. Y	Oct. 28
Wheel hubs, boring	James Hinds	Troy, N. Y	Nov. 25
Wheel hubs, boring and mortising	James Tompkins	Conesville, N. Y	Oct. 6
Wheel hubs, carriage or wagon	Abraham Randel	Vernon, N. Y	Sept. 8
Wheels of locomotives, ascending inclined planes.	Elisha Town	Montpelier, Vt	July 31

Class XI.—*Hydraulics and pneumatics, including water-wheels, windmills, and other implements operated on by air or water, or employed in raising and delivery of fluids.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Cistern, rain water	George O. Blennis	Salina, N. Y	Aug. 18
Compressed air for drawing liquids.	Jasper Johnson	Genesee, N. Y	May 30
Fluids, measuring	James Bogardus	New York	Oct. 12
Pump, forcing, double	D. L. Farnam	New York	Oct. 23
Pump, preventing water from freezing.	Samuel Adams	Townsend, Mass	Mar. 11
Pump for ships	David Gay	Bath, Me	Sept. 8
Pump, suction and force	Abraham Kassler	Canajoharie, N. Y	Oct. 28
Pump, suction and force	Jonathan Stevens	Newark, N. J	Dec. 20
Pump, valves for	Henry Hickman	Newburg, Pa	July 17
Waterwheel	Nehemiah P. Stanton	Syracuse, N. Y	May 22
Water-wheel	Clayton Parker and R. W. Engle	Wayne township, O.	July 31
Water-wheel, current	Warren P. Wing	Greenwich, Mass	Sept. 22
Water-wheel, horizontal	Chapman Warner	Oxford, N. J	Sept 22
Water-wheel, horizontal	Samuel Curtis	Eagle, N. Y	Dec. 15
Water-wheel, letting on water	Samuel Curtis	Eagle, N. Y	Sept. 28
Water-wheel, reacting	Gideon Hotchkiss	Windsor, N. Y	Jan. 9
Water-wheel, reacting	Nelson Johnson	Erwin Centre, N. Y.	Nov. 23
Water-wheel, spiral bucket	Joseph C. Greene	Fayette, Me	May 30
Water-wheel, tub	David P. Napier	Liberty, Ky	May 22
Wind-wheel	Ebenezer B Sperry	Wenham, Mass	Aug. 31
Wind-wheel	Jacob D. Makely	Cairo, N. Y	Nov. 23

IV.—*Classified list of patents, &c.*—Continued.

CLASS XII.—*Lever, screw, and other mechanical power, as applied to pressing, weighing, raising, and moving weights.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Balance	B. Morison	Milton, Pa	Feb. 16
Balance, platform	Benjamin Bull	New York city	May 3
Elevating hay	George Wilbur	Macedon, N Y	July 17
Packing flour and pressing	Oliver Jewett	Rochester, N. Y	Mar. 30
Press, cheese	Sullivan White	Bridgewater, Vt	Aug. 31
Press, cotton and hay	Gideon Fitz	Clinton, Miss	June 3
Press, hay	Jacob Grovenor	New York city	Aug. 31
Press, rotary, for woollen goods	Moses Bayley	Salisbury, Mass	July 5
Press, standing	Joel Barns	Philadelphia, Pa	Ap'l 17
Press, tobacco	James H. Washington	Baltimore, Md	Oct. 12
Press, tobacco, cast-iron cases	Granville D. Allen	Richmond, Va	June 30
Press, tobacco, for rolled	James T. Bowman	Pattonsburg, Va	July 5

CLASS XIII.—*Grinding mills and mill-gearing, containing grain mills, mechanical movements, and horse-powers, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Bark-mill	Charles Parker	Meriden, Ct	Nov. 25
Coffee-mill	Hiram Twiss	Meriden, Ct	Nov. 19
Grist-mill	Oliver Wyman	E. Cambridge, Mass.	Dec. 20
Grist-mill	Elijah S. Curtis	Boston, Mass	Nov. 23
Horse-power	Levi Rice	Attleborough, Pa	July 17
Horse-power	Levi Rice and David Congdon.	West Chester, Pa	July 17
Horse-power	Barnabas Langdon	Troy, N. Y	July 19
Horse-power	Henry Smith	Bethel, Ohio	Oct. 6
Horse-power	Benjamin Hinkley	Fayette, Me	Nov. 25
Horse-power, endless chain	Jacob G. Hall	Zanesville, Ohio	Sept. 21
Horse-power, endless chain	Aaron Palmer	Akron, N. Y	Sept. 22
Horse-power, endless chain	Henry G. Hall	Putnam, Ohio	Sept. 28
Horse-power, portable frame-work of.	John A. Nelson & Jas. P. Ross.	Lewisburg, Pa	June 30
Wheel-band, mode of hanging	Isaac Straub	Lewiston, Pa	July 11

CLASS XIV.—*Lumber, including machines and tools for preparing and manufacturing, such as sawing, planing, mortising, shingle and stave, carpenters' and coopers' implements.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Boring and mortising	John H. Power	Norwalk, Ohio	Jan. 31
Clapboards, sawing	Samuel Gross	Milford, N. H	June 3
Clasps in saw-mill gates	Hyz & Nelson Johnson	Erwin, N. Y	May 15
Dye-woods, cutting	Lucilius H. Mosely	Poughkeepsie, N. Y.	June 23
Dye-woods, cutting and reducing	Abner McMillen	Bedford, N. H	Dec. [illegible]

IV.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Lathe, turning mouldings and beads	Eli Coddington	Thompson, N. Y	July 31
Mortising posts and sharpening rails	Wandle Mace	New York	Mar. 11
Mortising timber	Thos. H. Hoskings	Springfield, Ohio	June 30
Pegs, cutting and pointing	Joseph Essex	Killingly, Ct	July 17
Planing machine	Alonzo G. Hull	Brooklyn, N. Y	Sept. 20
Planing boards, &c.	Samuel Whitney	Dunstable, N. H	June 3
Planing, mouldings in wood, &c.	Ambrose Church, jr	Canandaigua, N. Y	July 29
Sawing trees	Samuel H. Hamilton	New York	Dec. 7
Saw mills	John Ambler	Philadelphia, Pa	Dec. 1
Shingles, &c., cutting from steam timber.	Joseph S. Raymond	Lodi, N. Y	Aug. 15
Shingles, dressing and smoothing	George L. Day	Union, N. Y	July 29
Shingles, gauges of machines for sawing.	Elkanah Leonard	Canton, Me	Nov. 4
Shingles, riving, planing, and jointing, antedated June 15, 1837.	Enoch R. Morrison	Pittsburg, Pa	Aug. 8
Shingle sawing	Apollos Wilbur	Burrelville, R. I	Mar. 25
Shingle sawing	Samuel Goss	Milford, N. H	June 3
Shingle sawing	Zebulon Sargent	Contoocookville, N. Hampshire.	Dec. 1
Shingles, shaving	Aaron H. Aiken	Sparta, Pa	Nov. 4
Shingles and staves, &c., cutting	George Pack	Peterborough, N. Y	Nov. 11
Spokeshave	Ira L. Beckwith	Quincy, Mass	April 29
Staves, cutting, for barrels	Thomas Peck	Lenox, N. Y	Nov. 20
Staves, sawing	Harvey Holmes	New Marlborough, Mass.	Dec. 20
Staves, sawing, for barrels	Jesse J. Smith	Brutus, N. Y	Mar. 3
Veneers, cutting	Joseph Skinner	Stockbridge, Mass	Sept. 21
Weather strips to bottom of doors	Isaac D. Brower	New York city	July 29

CLASS XV.—*Stone and clay manufacture, including machines for pottery, glass making, dressing and preparing stone, cements, and other building materials.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Brick machine	Gaylord V. Harper	Franklinville, N. Y	Oct. 23
Brick making and drying	James Hodges	Fairplay, S. C	June 3
Brick mould	Benjamin H. Brown	Alexandria, D. C	Oct. 23
Brick moulding and pressing	Nathaniel Adams	Cornwall, N. Y	Sept. 8
Brick moulding and pressing	Henry Waterman	Bath, Me	Nov. 4
Brick press	Andrew F. Mervine	St. Louis, Mo	Sept. 12
Granite cutting and dressing	Wm. C. Poland and Earle Blossom.	Portland, Me	Nov. 11
Granite cutting and polishing	John D. Buzzel	Cape Elizabeth, Me	May 15
Lime, process of burning	Samuel Garber & Henry Swartzengrouer.	Norristown, Pa	Mar. 25
Stone cutting and dressing	Mighill Nutting	Portland, Me	May 15
Stone, dressing	Nathan Jacobs	Newark, O	Mar. 11
Stone, facing and dressing	David Hull and Jo. Critcherson.	Portland, Me	May 8

IV.—*Classified list of patents, &c.*—Continued.

CLASS XVI.—*Leather, including tanning and dressing, manufacture of boots, shoes, saddlery, harness, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Boots, crimping leather for	Jesse Van Winkle	Rochester, N. Y.	April 17
Boots, crimping leather for	Moses S. Woodward	Marshallton, Pa.	July 31
Boot trees	David Hastings	Deerfield, Mass.	Dec. 15
Coloring and finishing leather	Harmon Hibbard	Attica, N. Y.	Dec. 15
Cutting leather	Levi N. Leland	Grafton, Mass.	Sept. 28
Harness fastenings	Warner Hayden	New Milford, Pa.	Jan. 21
Harness for horses in shafts	Robert Beale	Washington, D. C.	June 15
Hides, breaking and softening	Eli Kendal	Newton, Mass.	June 10
Hides, scraping	Reuben Shailer	Haddam, Ct.	June 19
Saddles, bow and worm, spring for	Jonathan Keedy	Russelville, Ky	Aug. 18
Saddles for removing the sick	Hezekiah L. Thistle	New Orleans, La.	Jan. 21
Saddles, spring	John G. Manlove	Bainbridge, O.	Mar. 25
Saddles, spring	Henry Sheets	Staunton, Va.	Mar. 30
Saddles, spring	Moses Baldwin	Cincinnati, O.	April 29
Saddles, spring	Harman C. Fisher	Warwick, R. I.	Nov. 25
Saddles, spring	John D. Payne	Warm Springs, Va.	Nov. 25
Saddles, spring seat, riding	Robert Wilson	Milton, Pa.	Mar. 11
Saddle trees	William Kelly	New Columbus, Pa.	May 30
Saddle-bag fastening	Alvin North	North Britain, Conn.	Dec. 29
Shoemakers, clamp for	Richard Emans	Mansfield, N. J.	Oct. 6
Skins, extracting hair from	Edward Flint	New York city	June 30
Skiving, removing wool	Benjamin F. Emery	Bath, Me.	July 30
Trunks, valises, &c	Matthias Steiner	New York city	Dec. 20

CLASS XVII.—*Household furniture, machines, and implements for domestic purposes, including washing machines, bread and cracker machines, feather dressing, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Cutting meat	John Morris	Derby, Ct.	Nov. 20
Feathers, dressing and cleaning	Samuel Swett, jr.	Readfield, Me.	July 31
Mopheads	Jacob Howe	Worcester, Mass.	June 15
Refrigerator	J. D. Burns	Baltimore, Md.	Nov. 11
Washing machine	William Hovey	Worcester, Mass.	Feb. 4

IV.—*Classified list of patents, &c.*—Continued.

CLASS XVIII.—*Arts, polite, fine, and ornamental, including music, painting, sculpture, engraving, books, paper, printing, binding, jewelry, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Binder for newspapers	Ezra Ripley	Troy, N. Y.	Dec. 26
Blocks for printing colors on silks	John Crabtree	New York	Dec. 7
Book-binding	William Hancock	Great Britain	Oct. 28
Coloring maps, process, &c	Lucius Stebbins	Hartford, Ct.	July 11
Inking rollers, temperature of, &c	Eliphaz Weston Arnold.	Boston, Mass	Sept. 21
Piano forte, action of	Thomas Loud	Philadelphia, Pa	Dec. 7
Printing both sides of a continuous sheet.	Thomas French	Ithaca, N. Y.	Nov. 20

CLASS XIX.—*Fire-arms and implements of war, and parts thereof, including the manufacture of shot and gunpowder.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent
			1837.
Cannon, cast-iron	Cyrus Alger	Boston, Mass.	May 30
Cannon, pointing	John Hobday	Portsmouth, Va.	May 3
Carriage, gun, on ship-board	John Bubier	Marblehead, Mass.	Oct. 20
Fire-arms	Elijah Fisher and D. H. Chamberlain.	Boston, Mass.	April 17
Fire-arms	Henry Harrington	Southbridge, Mass.	July 29
Fire-arms, loading, mode of	Thomas McCarty	Elmira, N. Y.	Mar. 11
Fire-arms, many-chambered	John W. Cochran	New York	April 29
Fire-arms, many-chambered	Daniel Leavitt	Cabotsville, Mass.	April 29
Fire-arms, many-chambered	Curtis Parkhurst	Lawrenceville, Pa.	Sept. 25
Fire-arms, many-chambered, cylinder, (antedated April 28, 1837.)	John W. Cochran	New York	May 8
Fire-arms, many-chambered, cylinder.	Otis W. Whittier	Enfield, N. H.	May 30
Fire-arms and ordnance	Henry C. Fay	Lancaster, Mass.	May 22
Fire-arms, self-loading, and priming	Silas Day	City of New York	Aug. 31
Knives, or dirks, attaching to pistols	Robert W. Andrews	Stafford, Ct.	July 31
Locks for fire-arms	Ethan S. Chapin	Stafford Spring, Ct.	July 17
Locks for fire-arms	Ethan Allen	Grafton, Mass.	Nov. 11
Pistols, knife, or cutlass	George Elgin	New York	July 5
Pistols, sabre	Robert W. Lawton	Newport, R. I.	Nov. 30

IV.—*Classified list of patents, &c.*—Continued.

CLASS XX.—*Surgical and medical instruments, including trusses, dental instruments, bathing apparatus, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Bandages, pads	Robert Thompson	Columbus, Ohio	Jan. 29
Teeth, artificial	Charles M. Graham	Philadelphia, Pa	Mar. 9
Truss for hernia	Elijah Jaquith	Brattleborough, Vt	Mar 11
Truss for hernia	Heber Chase, M. D.	Philadelphia, Pa	June 10
Truss for hernia	Richard Salisbury	Providence, R. I.	Nov. 4
Truss for hernia	Josiah Hungerford	Dover, N. H	Dec. 26

CLASS XXI.—*Wearing apparel, articles for the toilet, &c., including instruments for manufacturing.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Bodkin for inserting corset rings into cloth.	Jonathan S. Turner	Middletown, Ct	April 25
Garments, cutting	Andrew Wiswell	Exeter, N. H	July 11
Garments, draughting coats, geometrical measure for.	William C. Bishop	Ovid, N. Y	April 25
Garments, draughting forepart of coats.	Allen Ward	Moyamensing, Pa	Sept. 28
Garments, pantaloons measurer	Edward Grimston	Danvers, Mass	Sept. 21
Garments, standard measure for coats.	Erastus Barber	Boston, Mass	Dec. 36
Tailoring, system of	Amos Sherman	Newark, N. J	July 17

CLASS XXII.—*Miscellaneous.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
			1837.
Ice, preparing, for shipping	Nathaniel J. Wyeth	Cambridge, Mass	Dec. 1
Splints for friction matches	Stephen Dole	Concord, N. H	May 30
Tobacco spinning	Hiram M. Smith	Richmond, Va	Dec. 20

List of designs that have expired during the years 1849 *and* 1850, *heretofore inadvertently omitted, together with a list of those that expire in* 1851.

Designs.	Patentees.	Residence.	Date of patent.	Expired.
Types, for	George Bruce	New York	Nov. 9, 1842	1849
Bathing tub	Jordan L. Mott	New York	Aug. 17, 1843	1850
Corpse preserver	John Good	Philadelphia, Penn	Aug. 17, 1843	1850
Carpets, painted	James Albro, jr	Elizabethtown, N. J	Oct. 6, 1843	1650
Coffee pots	John R. Remington	Lowndes county, Ala	Oct. 6, 1843	1850
Carpets	John P. Ferguson	Thompsonville, Conn	Oct. 20, 1843	1850
Cloths, floor, printing	James Albro, jr	Elizabethtown, N. J	Dec. 20, 1843	1850
Cloths, floor, printing	James Albro, jr	Elizabethtown, N. J	Dec. 20, 1843	1850
Girandoles, (assigned to H. N. Hooper & Co., Boston, Mass)	Wm. Blake	Boston, Mass	Mar. 17, 1843	1850
Lamps	Wm. W. Bacon	Middletown, Conn	Oct. 18, 1843	1850
Metals, impression on, (assigned to L. C. Ives, Bristol, Conn.)	Waterman L. Ormsby	New York	Feb. 24, 1843	1850
Springs, door	Isaac B. Hartwell	Woodstock, Vt	April 10, 1843	1850
Stove columns, (assigned to Johnson, Geer & Cox)	Ezra Ripley	Troy, N. Y	July 15, 1843	1850
Statues	Alonzo L. Blanchard	Albany, N. Y	Aug. 26, 1843	1850
Stoves, cooking	Alanson Skinner	Brownsville, N. Y	Sept. 14, 1843	1850
Stoves	Jordan L. Mott	New York	Dec. 1, 1843	1850
Bust of Theodore Frelinghuysen, (assigned to J. G. Wellstood)	Salathael Ellis	New York	Aug. 12, 1844	1851
Bust of Robert Burns	John C. King	Boston, Mass	Jan. 31, 1844	1851
Carpets, canvass	Jacob D. Edwards	Elizabethtown, N. J	Mar. 20, 1844	1851
Carpets	Henry G. Thompson	New York	April 4, 1844	1851
Grates	Adam Hampton	New York	May 17, 1844	1851
Pencil cases	George W. Simons	Philadelphia, Penn	Nov. 18, 1844	1851
Stoves	Amaziah Whitney	Albany, N. Y	July 19, 1844	1851
Stove-plate, (assigned to Johnson, Geer & Cox, Troy, New York)	Ezra Ripley	Troy, N. Y	Nov. 26, 1844	1851
Spoons, forks, &c	Michael Gibney	New York	Dec. 4, 1844	1851
Whistle, child's	Henry Dubosq	Philadelphia, Penn	May 6, 1844	1851

Alphabetical list of persons whose patents have expired during the year 1851, with their inventions or discoveries, and class.

Patentees.	Inventions or discoveries.	Class.
Abbott, Andrew	Cooking stove	V.
Adams, Isaac	Hulling coffee berry	I.
Adams, Samuel	Pumps	XI.
Adams, Nathaniel	Brick, moulding and pressing	XV.
Akin, Aaron	Shingle shaving	XIV.
Aldrich, Elisha F.	Inclined planes	IX.
Allen, Granville D.	Tobacco press	XII.
Alger, Cyrus	Cannon, cast	XIX.
Allen, Ethan	Locks for fire-arms	XIX.
Ames, John	Paper sizing	III.
Ambler, John	Saw mill	XIV.
Andrews, Ethan A.	Stove radiators	V.
Andrews, James	Sleds, hold back for	X.
Andrews, Robert W.	Knives or dirks, attaching, to pistols	XIX.
Arnold, Eliphaz W.	Inking rollers, temperature of, &c.	XVIII.
Austin, William E.	Door plates	II.
Auld, Washington, and James Cox	Cooking stove, heating buildings, &c.	V.
Barton, William M.	Hulling clover seed	I.
Barker, John	Blow-pipe for blast furnaces	II.
Barker, John	Blast furnace	II
Barron, James	Cooking stove and galley	V.
Barker, David W.	Ovens for stoves	V.
Barrows, Ebenezer	Stoves, quadrant hinge for	V.
Barron, James	Dock, floating, dry	XIX.
Barton, Thomas C.	Tire bending	X.
Barton, Thomas C.	Tire for wheels, drilling	X.
Bayley, Moses	Press, rotary, for woolen goods	XI.
Barnes, Joel	Press, standing	XII.
Baldwin, Moses	Saddles, spring	XVI.
Barber, Erastus	Garments, standard measure for coats	XXI.
Berry & Rand	Nails and brads, cutting	II.
Beckwith, Ira L.	Spokeshave	XIV.
Bishop & Brooks	Nails, wrought	II.
Beale, Robert	Hames for harness in shaft	XVI.
Bishop, William C.	Garments, draughting coats, &c.	XXI.
Blackall, Joseph	Screws, cutting	II.
Blanchard, Thomas	Hats, bodies, batting, or web for	III.
Blaney, Benjamin	Stoves, non-radiating, &c.	V.
Blenis, George O.	Cistern, rain-water	XI.
Bowling, Alexander W.	Threshing machine	X.
Bogardus, James	Fluids, measuring	XI.
Bowman, James T.	Press, tobacco, for rolled	XII.
Brooks, Jonathan	Threshing and hulling clover seed	I.
Broadmeadow, Simeon	Furnace for shear-steel, &c.	II.
Broadmeadow	Furnace for smelting ore	II.
Brittain, William and Robert	Flax and hemp dressing	III.
Branch, Hardin	Cooking, generating steam for	V.
Bradford, Merrit	Stove pipes and drum	V.
Brown, Gideon	Inclined planes	IX.
Brown & Hicks	Carriages, disengaging horses from	X.
Brower, Isaac D.	Weather strips, &c.	XIV.
Brown, Benjamin H.	Brick mould	XV.
Bunnel, Isaiah	Strainers for milk pails	I.
Butler, Lester	Winnowing, separating, &c.	I.
Burt, Enoch	Loom	III.
Bull, Benjamin	Balance platform	XII.
Buzzell, John D.	Granite cutting and polishing	XV.
Burns, R. D.	Refrigerator	XVII.
Bubier, John	Carriage, gun, on ship-board	XIX.
Childs, Charles D.	Smut machine	I.
Church, Ambrose, jr.	Planing, mouldings on wood	XIV.

Alphabetical list of persons, &c.—Continued.

Patentees.	Inventions or discoveries.	Class.
Chapin, Ethan S.	Locks for fire-arms	XXI
Chase, Heber	Truss for hernia	XX.
Clements, Garret	Leaching ashes	IV.
Coats, Stephen	Rake, revolving	I.
Coyle, Thomas	Cement for cisterns	IV.
Cox, William	Paint, composition	IV.
Conger, Ellison	Grates and fireplace	V.
Collum, John	Stoves	V.
Compton, Stephen, jr.	Locomotive power, &c.	VI.
Cooper, Isaac	Railroad	XIX.
Coddington, Eli	Lathe, turning, mouldings and	XIV.
Cochran, John W.	Fire-arm, many-chambered	XIX.
Cochran, John W.	Fire-arms, many-chambered, &c.	XIX.
Crompton, William	Loom, power, figure	III.
Creswell, James	Oleagenous seed, &c.	IV.
Creed, William	Steam, generating	VI.
Creasdale, William	Spring, spiral, &c.	X.
Crabtree, John	Blocks for printing colors, &c.	XVIII.
Curtis, Samuel	Water-wheel, horizontal	XI.
Curtis, Samuel	Water-wheel, letting on water	XI.
Curtis, Elisha S.	Grist mill	XII.
Davenport, Moses	Threshing and winnowing	I.
Davenport, Thomas	Electro-magnetism	VIII.
Day, Silas	Fire-arms, self-loading, &c.	XIX.
Deats, John	Plough	I.
Dewey, David	Rake, horse	I.
Dean, Linus	Vice, bench and other	II.
Dear, David	Bitterings from kettles, &c.	IV.
Desmond, Daniel	Grates, sliding flute	V.
Delano, Howard	Wheel hubs	X.
Dixon, Edward H.	Grates and stoves	V.
Douglass, William A.	Propelling paddle-wheels, &c.	VII.
Dole, Stephen	Splints for friction matches	XXII.
Dunn, John	Steaming and mashing apples	V.
Duff, William	Spark-catcher, &c.	VI.
Dreyer, Peter Henry	Railroad rails, &c.	IX.
Eastwick, A. M.	Wheels driving locomotive engines, increasing adhesion	X.
Eitelgeorge, Augustus	Explosion of boilers, preventing	VI.
Elgin, George	Pistols, &c.	XIX.
Emmons, Uri	Railroad, single	IX.
Emans, Richard	Shoemakers, clamp for	XVI.
Emery, B. F.	Skiving, removing wool	XVI.
Essex, Joseph	Pegs, cutting and pointing	XIV.
Farnham, D. L.	Pump, forcing, double	XI.
Fay, Henry C.	Fire-arms and ordnance	XIX.
Fessenden, William G.	Bark, extract of	IV.
Fessenden, Timothy	Axletrees, &c., setting	X.
Fitzgerald, Daniel	Fire-proof safe	II.
Frickhardt, F. A.	Air to wood and coal stoves	V.
Finley, John	Propelling boats, screw for	VII.
Fitz, Gideon	Press, cotton	XII
Fisher, H. C.	Saddle, spring	XVI.
Fisher & Chamberlain	Fire-arms	XIX.
Flockton, Webster	Metallic solution for preserving timber	IV.
Flint, Edward	Skins, extracting hair from	XVI
Fredly, Frederick	Iron, &c., washing ores	II.
French, Thomas	Printing both sides of a continuous sheet	XVIII.
Gay, Charles S.	Latch mortice	II
Gay, David	Pumps for ships	XI.
Garber & Swartzengrover	Lime, process of burning	XV.
Gillespie, Barnabas	Ice breaker	VII.

Alphabetical list of persons, &c.—Continued.

Patentees.	Inventions or discoveries.	Class.
Gleason, Horace	Furnaces, cooking	V.
Golding, John	Thread, preventing from waste	III.
Goodyear, Charles	Caoutchouc, divesting of its adhesive properties	IV.
Gotthilf, August	Preserving timber from worms	IV.
Good, Francis	Bridges	IX.
Goss, Samuel	Clapboards, sawing	XIV.
Goss, Samuel	Shingles, sawing	XIV.
Griswold, Ogden	Thread, waste, reducing to cotton wool	III.
Gray, William	Thread, waste, reducing to cotton wool	III.
Grannis & Brand	Steam-engine, rotary	VI.
Greenaugh, J. J	Propelling-paddles, for boats	VII.
Griggs, George S	Railroad frog	IX.
Grant, Robert	Car, railroad, &c., mode of connecting	X.
Greene, Joseph C	Water-wheel, spiral bucket	XI.
Grosvenor, Jacob	Press, hay	XII.
Graham, C. M	Teeth, artificial	XX.
Grimston, Edwin	Garments, pantaloons measurer	XXI.
Harvey & Tracey	Hulling rice	I.
Hartpence & Bawne	Plough	I.
Harvey, Thomas W	Screw, wood, turning heads	II.
Hazard, Phillipe F	Window-fastening, combined spring	II.
Hammond, Henry	Window-sash, spring for upper sash	II.
Harvey, Thomas W	Wire, cutting and heading	II.
Harvey, Charles R	Hair-seating, weaving	III.
Hartford & Tilton	Loom treadles and harness	III.
Hatfield, John	Matches, locofoco, dipping	IV.
Hastings & Sikes	Cooking stove	V.
Hathaway, John G	Cooking stove	V.
Hathaway, John G	Cooking stove, heat to	V.
Hall, Jacob G	Horse-power, endless chain	XIII.
Hall, Henry G	Horse-power, endless chain	XIII.
Hamilton, Samuel H	Sawing trees	XIV.
Harper, Gaylord V	Brick machine	XV.
Hastings, David	Boots, trees	XVI.
Hayden, Warner	Harness and fastenings	XVI.
Hancock, William	Book-binding	XVIII.
Harrington, Henry	Fire-arms	XIX.
Hedge, Egbert	Hinges, or butt, double-centred joints	II.
Hedge, Lemuel	Joints for rules, double-centred	II.
Heckman, Henry	Pumps, valves for	XI.
Hill, Porter	Spring-carriage, railroad car, &c	X.
Hinds, James	Wheel-hubs, boring	X.
Hinkley, Benjamin	Horse-power	XIII.
Hibbard, Harmon	Coloring and finishing leather	XVI.
Hotchkiss, Gideon	Yoke, horse and oxen	I.
Holtman, David	Knobs, door, drawer, commode, &c	II.
Hobbs, William	Locks, secret, safety	II.
Hopkins, George F	Stoves, construction of	V.
Howell, Samuel E	Constructing ships	VII.
Hotchkiss, Gideon	Water-wheel, reacting	XI.
Hoskings, Thomas K	Mortising timber	XIV.
Harvey, Holmes	Stave-sawing	XIV.
Hodges, James	Brick-making and drying	XV.
Howe, Jacob	Mop heads	XVII.
Hovey, William	Washing-machine	XVIII.
Hobday, John	Cannon-pointing	XIX.
Hutchinson, Jesse	Cooking stove	V.
Hughes, Enos B. M	Grates, revolving and shifting	V.
Hunt & Brown	Link, self-separating, for connecting cars, &c.	X.
Hull, Alonzo G	Planing-machine	XIV.
Hungerford, J	Truss for hernia	XX.

Alphabetical list of persons, &c.—Continued.

Patentees.	Inventions or discoveries.	Class.
Hull & Critcherson	Stone-facing and dressing	XV.
Idler, Jacob	Gin, cotton, saw-cylinder	III.
Imlay, Richard	Car, railroad, supporting bodies	X.
Jaquith, Elijah	Window blinds fastener	II.
Jacobs, Nathan	Stone, dressing	XV.
Jaquith, Elijah	Truss for hernia	XX.
Jewett, Oliver	Packing flour and pressing	XII.
Jones, Henry C	Locks, mail-bag, and clasp	II.
Johnson, Samuel	Fur, cutting, from skins	III.
Jones, Alexander	Gin, cotton	III.
Johnson, Jasper	Compressed air for drawing liquids	I.
Johnson, Nelson	Water-wheel, reacting	XI.
Johnson, H. and N	Clasps in saw-mill gates	XIV.
Kassler, Abraham	Pump, suction, and force	XI.
Kempton, Obed	Parcelling rope	VII.
Kendall, Eli	Hides, breaking and softening	XVI.
Keedy, Jonathan	Saddles, bow and worm, spring for	XVI.
Kelly, William	Saddle-trees	XVI.
Kinney, William	Cooking stove, coal	V.
Kimball, William B	Cooking stove, heating	V.
Kirkpatrick, John	Valve, engines	VI.
Kirkpatrick, John	Valve, puppet	VI.
Kinkead, William	Car, railroad	X.
Knowles & Gibbut	Preserving timber, &c	IV.
Larimore, Wilson L	Cutting cradle for grain	I.
Langdon, Barnabas	Horse-power	XIII.
Lawton, Robert W	Pistols, sabre	XIX.
Leveridge, Walter	Gum Senegal, substitute for	IV.
Leavitt, John S	Cooking stove	V.
Leland, Levi N	Cutting leather	XVI.
Leavitt, Daniel	Fire-arms, many-chambered	XIX.
Longley & Davis	Flax and hemp, breaking and cleaning	III.
Lobdell E and T. J	Grappling irons	VII.
Loud, Thomas	Piano forte, action of	XVIII.
Lull, Harvey	Flax and hemp, breaking	III.
Lyon, Joseph	Iron ore, smelting	II.
Mason, Samuel P	Loom, temple, &c	III
Martin, Jeremiah	Lamps, &c	V.
Mackintosh, John	Vessels used as life-preservers	VII.
Mace, Wandle	Mortising posts, &c	XIV.
Manlove, John G	Saddles, spring	XVI.
McCormick, Stephen	Plough	I.
McClery, James	Lock, door	II.
McMullen & Hollen	Knitting machine	III.
McCann	Circumferator	VIII.
McMillen, Abner	Dye-woods, cutting, &c	XIV.
McCarty, Thomas	Fire-arms, loading, &c	XIX.
Mervine, Andrew F	Brick-press	XV.
Minell, Abraham T	Cooking stove	V.
Mills, Thomas	Stoves	V.
Miller, Asa	Steam engine	VI.
Mosely, Lucilius H	Gin, cotton	III.
Moore, Hugh	Hat bodies	III.
Moore & Bower	Candles, moulding	IV.
Morison, B	Plaster, adhesive, spreading	IV.
Morris, John	Cooking, steam vessel for	V.
Mott, Jordan L	Cooking stove	V.
Morris, John	Cooking stove, &c	V.
Mott, Jordan L	Stoves	V.
Mott, Jordan L	Stoves	V.
Morrison, Abraham	Boats, canal, &c	VII.
Morse, Andrew	Steering wheel	VII.

Alphabetical list of persons, &c.—Continued.

Patentees.	Inventions or discoveries.	Class.
Morison, B.	Balance	XII.
Mosely, Lucilius H.	Dye-woods, cutting	XIV.
Morrison, Enoch R.	Shingles, sawing	XIV.
Morris, John	Cutting meat	XVII.
Myers, Jeremiah	Railroad, turnabout for	IX.
Nagle, Patrick G	Composition for boots	IV.
Napier, David P.	Water-wheel tub	XI.
Nelson & Ross	Horse-power	XIII.
Nicolson, Samuel	Steering apparatus	VII.
Norton, Job B.	Plough	I.
North, Alvin	Saddle-bag fastenings	XVI.
Nutting, Mighill	Stone cutting, &c	XV.
Oellig, John J	Medicine, worm destroying	IV.
Oellig, John J	Pills, &c	IV.
Ogden & Ericson	Sounding instrument, &c	VII.
Olney, James N	Cooking stove	V.
Ong, Jesse	Propelling paddle-wheels	VII.
Paimbœuf, Lewis	Paint, protection of buildings	IV.
Parrott, Wm. W	Cooking apparatus	V.
Payne, Rufus S	Cooking stove, heating	V.
Parker & Engle	Water-wheel	XI.
Parker, Charles	Bark mill	XIII.
Palmer, Aaron	Horse-power, endless chain	XIII.
Pack, George	Shingles and staves, &c., cutting	XIV.
Payne, John D.	Saddles, spring	XVI.
Parkhurst, Curtis	Fire-arms, many chambered	XIX.
Penny, John	Sugar manufacturing	IV.
Pearson, Thomas	Fuel, burning, &c	V.
Petival, John B	Mallet, screwing, &c	VII.
Peck, Thomas	Staves, cutting, &c	XIV.
Phillips, Perigrine	Lead, white	IV.
Pierce, Dexter	Cutting, scythe snath	I.
Pitts, J. A. & H. A.	Threshing and winnowing	I.
Pleasants, Bazil B	Mail carriages, &c	X.
Potter, Welcome A	Loom, regulating, &c	III.
Pollock, Allen	Grates, &c., register, &c., for	V.
Power, John H	Boring and mortising	XIV.
Poland & Blossom	Granite cutting, &c	XV.
Price, Aaron O	Stoves, anthracite coal	V.
Randel, Abraham	Wheel hubs, carriage or wagon	X.
Reed, Clement O	Screw, wood	II.
Reed, Edwin	Cooking stove	V.
Rice, Levi	Lime, spreading, &c	I.
Richardson, J. S	Door, springs for shutting	II.
Rice, Phineas G. & Gabriel	Hemp, hatcheling	III.
Ripley, Charles	Lead, carbonate of	IV.
Richardson, James	Cooking stove	V.
Rice, Levi	Horse-power	XIII.
Rice & Cogden	Horse-power	XIII.
Ripley, Ezra	Binder of newspapers	XVIII.
Robinson, E. & G. W	Knobs, glass, metallic, &c	II.
Ropes, David N	Latch, mortise	II.
Robinson, Edward M	Composition, protecting metallic, &c	IV.
Roath, H. R	Stoves, construction of	V.
Rowe, James	Car and circular railroad	X.
Rust, Samuel	Lamps	V.
Rust, Samuel	Lamps	V.
Rust, Samuel	Lamps, patent	V.
Rush, James J	Boilers, steam	VI.
Ruggles, John	Railroad, rails for	IX.
Sampson, Daniel	Oil cloth, drying	III.
Sargent, Zebulon	Shingles, sawing	XIV.
Salisbury, Richard	Truss for hernia	XX.

Alphabetical list of persons, &c.—Continued.

Patentees.	Inventions or discoveries.	Class.
Sellers, Geo. E.	Furnace, smelting ore	II.
Severence, Levi	Rivet making	II.
Sherwood, Benjamin	Fire-proof safe	II.
Shanher, Christian W	Loom	III.
Sheppard, Forrest	Paint, white, water color	IV.
Sherman, R. M	Fire-place and grate, open	V.
Short, Sewall	Ovens, railway	V.
Sherman, Roger M	Steam engine, rotary	VI.
Shailer, Reuben	Hides, scraping	XVI.
Sheets, Henry	Saddle, spring	XVI.
Sherman, Amos	Tailoring, system of	XXI.
Silliman, Henry	Straw, cutting	I.
Silsbee, John	Furnace, heated air to	V.
Skinner, Elijah	Cooking stove	V.
Skinner, Joseph	Veneers, cutting	XIV.
Sloat & Springsteen	Screws, cutting wood	II.
Smith, Francis H	Lime, spreading	I.
Smith, John C	Plough	I.
Smith, Benjamin M	Smut machine	I.
Smith, Stephen C	India rubber, manufacture of	IV.
Smith, Henry	Horse-power	XIII.
Smith, Jesse J	Staves, sawing, for barrels	XIV.
Smith, Hiram M	Tobacco, spinning	XXII.
Snider, Isaac	Plough	I.
Sorel, M	Preserving iron from rust	IV.
Spratley, Benjamin	Cooking stove and galley	V.
Sperry, Ebenezer B	Wind-wheel	XI.
Staub, Henry	Smut machine and garlic	I.
Stephens, John	Gin, cotton	III.
Stephens, Henry	Coloring matter, &c	IV.
Stillwell, Daniel E	Soap, making	IV.
Stillman, Wm. B	Pump, air, for steam engines	VI.
Stimpson, James	Spark-catcher, centrifugal, &c	VI.
Stevens, Jonathan	Pump, suction and force	XI.
Stanton, Nehemiah P	Water wheel	XI.
Staub, Isaac	Wheel-band, mode of hanging	XIII.
Steiner, Matthias	Trunks, valises, &c	XVI.
Stebbins, Lucius	Coloring maps, process, &c	XVIII.
Swazy, Benjamin	Napping cloth	III.
Swainson, Jno	Pistols, metallic, for steam, &c	VI.
Swett, Samuel, jr	Feathers, dressing and cleaning	XVII.
Tabor, Bartholomew W	Stove, heating irons for tailors	V.
Thorp, Thomas	Door springs	II.
Thorpe, Comfort B	Loom shuttle tongue	III.
Thomas, John	Dock, floating, dry	IX.
Thistle, Hezekiah L	Saddles for removing the sick	XVI.
Thompson, Robert	Bandages, pads	XX.
Titcombe, Edgar M	Spinning woollen roving	III.
Tompkins, James	Wheel hubs, boring, &c	X.
Town, Elisha	Wheels of locomotives, &c	X.
Tracy, Erastus	Wool, cleaning burs from	III.
Tuck, Joseph H	Candles, moulding	IV.
Turner, Jonathan S	Bodkin, &c	XXI.
Twiss, Hiram	Coffee mill	XIII.
Ulter, Samuel	Cooking stove	V.
Van Dusen, Washington	Propelling paddles used as ice-breakers	VII.
Van Winkle, Jesse	Boots, crimping leather for	XVI.
Von Shoultz, N. S.	Salt water, purifying	IV.
Warren, John	Flax and hemp breaking	II.
Warner, C. A., T. Mixell, and Edwin J. Horn	Flax and hemp breaking	III.
Warner, Ebenezer C.	Cement, hydraulic, from basanite	IV.

Alphabetical list of persons, &c.—Continued.

Patentees.	Inventions or discoveries.	Class.
Walker, Nathaniel	Cooking stove	V.
Warner, Chapman	Water-wheel, horizontal	XI.
Washington, James H	Press, tobacco	XII.
Watterman & Learned	Brick moulding, &c	XV.
Waterman, Henry	Brick press	XV.
Ward, Allen	Garments, draughting fore part of coats	XXI.
Wells, H. A., J. James, and R. W. Peck	Hat bodies	III.
Wells & Peck	Hat bodies, batting or web for	III.
West, Thomas J	Railroad, road stops for	XIX.
Whitney, Asa	Iron, carbonating and smelting	II.
Whitehouse, Turner	Lock, door	II.
Whittemore, James M	Boilers, steam	VI.
White, Sullivan	Press, cheese	XII.
Whitney, Samuel	Planing boards, &c	XIV.
Whittier, Otis W	Fire-arms, many-chambered, &c	XIX.
Williams, Palmer	Screws of screw bedsteads	II.
Wilson, James	Cooking stove	V.
Wilson, Carrington, jr	Cooking stove	V.
Wilcox, Philip	Cooking stove, heating	V.
Wilcox, Philip	Stoves, heating apartments	V.
Winans, Ross	Heating water for steam engines	VI.
Williamson, John	Pistons, packing	VI.
Winans, Ross	Steam engine, locomotive	VI.
Winans, Ross	Steam engine, locomotive	VI.
Winans, Ross	Steam engine, blowing fire	VI.
Winans, Ross	Steam engine, framing	VI.
Wilson & Beckwith	Capstans for ships, &c	VII.
Wing, Warren P	Water-wheel, current	XI.
Wilbur, Geo	Elevating hay	XII.
Wilbur, Apollos	Shingles, sawing	XIV.
Wilson, Robert	Saddle, spring seat, riding	XVI.
Wiswell, Andrew	Garments, cutting	XXI.
Woodcock, Bancroft	Plough	I
Wolcott & Brown	Wool, cleaning	III.
Wood, Benjamin H	Cooking stove	V.
Woodward, Moses S	Boots, crimping leather for	XVI.
Wright, Samuel	Steam engine, locomotive	VI.
Wyman, Oliver	Grist mill	XIII.
Wyeth, Nathaniel J	Ice, preparing for shipping	XXII.
Young & Titus	Shoes, horse	II.

V.—CLASSIFIED LIST OF PATENTS GRANTED DURING THE YEAR 1851, WITH THE NAMES OF PATENTEES, PLACE OF RESIDENCE, AND DATE OF PATENTS.

Class I.—*Agriculture, including instruments and operations.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Bee hives, construction of	A. J. Surles	Florence, Ga	Mar. 18, 1851.
Bee hives, use of slides in	Nathaniel Potter	Buffalo, N. Y	Mar. 11, 1851.
Broom corn, machines for assorting	Lorenzo D. Grosvener	Shaker Village, Mass	Jan. 1, 1851.
Broom corn, machines for stripping seed from	L. D. Grosvener	South Groton, Mass	Sept. 23, 1851.
Churns	Daniel Fisher	College Corner, Ohio	Jan. 1, 1851.
Churns	Ithiel S. Richardson	Boston, Mass	June 10, 1851.
Churns	Davis Dutcher	Springfield, N. Y	June 10, 1851; antedated 15th Feb., 1851.
Churns	Samuel G. Dugdale	Richmond, Ind	July 15, 1851.
Churns	George B. Clark	Leonardsville, N. Y	Sept. 23, 1851.
Churns	Henry Skinner	Attica, Wyoming co., N. Y	Dec. 16, 1851.
Churn and butter worker	A. Willard	Boston, Mass	Sept. 23. 1851.
Cultivators	Isaac Constant	Buffalo, Hart Grove, Sangamon co., Ill.	Nov. 4, 1851.
Grain seives	Thomas B. Wheeler	Albany, N. Y	Dec. 16, 1851.
Grain separators and fans	Roswell T. Merrill	Bloomfield, Mich	April 8, 1851.
Grain threshing and separating	Cyrus Roberts and John Cox	Belleville, St. Clair co., Ill	Oct. 28, 1851.
Harvesters, mowing machines, and	J. H. Manny	Waddam's Grove, Stephenson co., Ill.	Sept. 23, 1851.
Harvesters, grass	Edward Neely	Savannah, Mo	Jan. 7, 1851.
Harvesters, grain	Sidney S. Hurlbut	Racine, Wis	Feb. 4, 1851.
Harvesters, grain	Nicholas F. Allen	Ludlowville, N. Y	June 10, 1851.
Harvesters, grain	William H. Start	Smyrna, Kent co., Del	June 24, 1851.
Harvesters, grain	A. Palmer and S. G. Williams	Brockport, N. Y	July 1, 1851.
Harvesters, grain and binders	William Watson	Chicago, Ill	May 13, 1851.
Harvesting, machines	William Jones	Bradford, Vt	July 8, 1851.
Harvesting, machines, rakes to	William H. Seymour	Brockport, N. Y	July 8, 1851.
Harvesting, machines, rakes to	Sylvanus Miller	Urbanna, Ohio	July 15, 1851.
Harrows, rotary	Jona. F. Ostrander, assignor to A. B. & C. E. Hutchinson	New York, N. Y	Aug. 26, 1851.
Hullers, rice	Peter McKinlay	Charleston, S. C	April 1, 1851.
Ox yokes	Andrew L. Simpson	Durham, N. H	Jan. 7, 1851.
Planters, seed	James P. Ross	Lewisburg, Penn	Jan. 1, 1851.
Planters, seed	Archibald Wieting	Middletown, Penn	April 1, 1851.
Planters, seed	Jacob Barnhill	Circleville, Ohio	May 27, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Planters, seed	David Horner	Union, Knox co., Ohio	July 29, 1851.
Planters, seed	Myron Cory	Jerseyville, Jersey co., Ill	Oct. 28, 1851.
Planters, seed	N. Foster, G. Jessup, H. L. Brown, and C. P. Brown	Palmyra, Wayne co., N. Y	Nov. 4, 1851.
Planters, seed	Wm. Redick	Uniontown, Penn	Nov. 18, 1851.
Planter, seed, devices for sewing in a	Wm. P. Clements	Ellersly, Harris co., Ga	Oct. 7, 1851.
Planters, seed, gearing of	Marshal J. Hunt	Rising Sun, Md	June 3, 1851.
Planter, seed, seeding apparatus of a	Samuel and Morton Pennock	Kennet Square, Penn	Feb. 11, 1851.
Planters, seed, seed distributors of	David and Herman Wolf	Lebanon, Pa	June 3, 1851.
Planter, seed, the seeding apparatus of a	Cornelius C. Van Every	Victor, Ontario co., N. Y	Oct. 21, 1851.
Ploughs	John Cooper, admr. of Benj. Yiger	Springfield, Ill	June 24, 1851.
Ploughs	Henry Goldson	Greensboro', Miss	Nov. 18, 1851.
Ploughs	Elijah Goldthait	Fort Wayne, Ind	Nov. 25, 1851.
Ploughs, adjustible land sides of	George Heffley, Samuel Conrad, and James Wigle	Berlin, Penn	Mar. 25, 1851.
Plough-stock, convertible	E. T. Parker	Berkley, Ala	Jan. 21, 1851.
Ploughs, wheeled, cultivating	G. W. C. Gillespie	Burlington, Des Moines, Iowa	Sept. 9, 1851.
Potato diggers	Daniel D. Bell	Wawarsing, Ulster co., N. Y	Dec. 9, 1851.
Scythe fastenings	Ebenezer G. Lamson	Shelburn, Mass	Mar. 18, 1851.
Scythe fastenings	Oliver Clark	Medina, Ohio	Mar. 18, 1851.
Scythe fastenings	Nathaniel Lamson	Shelburn Falls, Mass	Mar. 25, 1851.
Scythe fastenings	Nathaniel Lamson	Shelburn Falls, Mass	Mar. 25, 1851.
Scythe fastenings, construction of	David Anthony	Springport, N. Y	Nov 11, 1851.
Scythes, to the snath, fastenings of	E. S. Clapp	Montague, Mass	Mar. 18, 1851.
Seeding machines	Samuel & M. Pennock	Kennet's Square, Penn	July 8, 1851.
Straw-cutters	T. F. Wingo	McLemorsville, Tenn	April 22, 1851.
Straw-cutters	Jonathan Sulivan	Lexington, N. C	May 13, 1851.
Wheat fans	Jesse White	Barnsville, Ohio	April 1, 1851.
Wheat fans	Jehu Hollingsworth	Zanesville, Ohio	April 1, 1851.
Winnowing machines	Jonathan L. Booth	Cuyahoga Falls, Ohio	April 8, 1851.
Winnowing machines	Oliver Etnier	Shirley, Pa	April 29, 1851.
Winnowing machines, screens of	Jonathan Bean	Montville, Waldo county, Maine	Nov. 11, 1851.
Winnowers and separators, grain	Augustus B. Childs	Rochester, N. Y	Aug. 5, 1851.

Class II.—*Metallurgy and manufacture of metals, and instruments therefor.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Blind and shutter operator	Noah W. Speers	Cincinnati, Ohio	Dec. 16, 1851.
Blind slats, apparatus for operating	Samuel Avery	Phenix, N. Y	April 15, 1851.
Bolt-heading machines	Nathan Starks	Albany, N. Y	Dec. 23, 1851.
Cans or canisters, tops of	Alfred Bliss	Newark, N. J	Oct. 21, 1851.
Casting the backs upon the teeth of curry combs, method of	James M. Gardner	Troy, N. Y	Mar. 18, 1851.
Curry combs, construction of	William Wheeler	Troy, N. Y	Oct. 28, 1851.
Cut nail machine	John P. Sherwood	Fort Edward, Washington co., N. Y	Aug. 26, 1851.
Designs in sheet metal, apparatus for punching	William T. Rudd	Amsterdam, Bottetourt co., Va	July 8, 1851.
Dies, construction of	Hiram W. Hayden	Waterbury, Conn	June 17, 1851.
Door knobs, manufacture of	Orrin Newton	Pittsburg, Pa	Nov. 25, 1851.
Doors or shutters, attachment for opening or closing	William Post	Flushing, N. Y	Feb. 18, 1851.
Drill, hand	William Bushnell	New York, N. Y	Dec. 2, 1851.
Fasteners, blind or shutter	Washburn Race	Seneca Falls, N. Y	Sept 23, 1851.
Files, machinery for cutting	John Crum	Ramapo, Rockland co., N. Y	July 1, 1851.
Foundry apparatus	Chapman Warner	Louisville, Ky	Dec. 2, 1851; Eng. pat. dated Oct. 5, 1849.
Furnaces employed in welding shanks to tools	Jonathan White	Antrim, Hillsborough, N. H	Oct. 14, 1851.
Furnace, revolving reverberatory	Ambrose S. Beadleston	Ausable Forks, Essex co., N. Y	Dec. 9, 1851.
Gold amalgamator	William Ball	Chicopee, Hampden co., Mass	Sept. 9, 1851.
Hammers, trip, method of adjusting the stroke of	Luther Briggs, jr	Braintree, Mass	Mar. 11, 1851.
Hinge, crane, for doors, shutters, etc	Ezra Ripley	Troy, N. Y	May 13, 1851.
Hinge, double-acting spring	Theodore F. Engelbrecht	New York, N. Y	Feb. 25, 1851.
Hinges, spring	Harvey W. Sabin and George Drew	Canandaigua, N. Y	Feb. 25, 1851.
Hooker-up, mechanical	David J. Happersett	Downingtown, Chester co., Pa	July 8, 1851.
Horse shoe machine	Robert G. Babcock	New London, Conn	Apr. 29, 1851; antedated Feb. 24, 1851.
Iron, glazed sheet, process of manufacturing	John and Wm. W. Wood	Conshohocken, Pa	April 15, 1851.
Iron, manufacture of	S. T. Jones	New York, N. Y	Sept. 16, 1851; Eng. pat. dated July 23, 1850.
Iron, measuring and cutting	Levi B. Griffith	Honeybrook, Pa	Nov. 4, 1851.
Iron, wrought, direct from the ore, apparatus for making	James Renton	Newark, N. J	Dec. 23, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Jackchains, tools for making	William Todd, assignor to Charles Atwood and George Kellogg	Stanford, Conn.; Derby, Conn	April 8, 1851.
Kettles, and articles of like character, from disks of metal, machinery for making	Hiram W. Hayden	Waterbury, New Haven co., Conn	Dec. 16, 1851.
Kettles with spouts, method of moulding	Webster H. Pease	Dayton, Montgomery co., Ohio	Oct. 28, 1851.
Key, swivel-nibbed	James Hanly	New York, N. Y.	Jan. 28, 1851.
Lead machines, sheet, combination of dies for	John Robertson	New York, N. Y.	May 27, 1851.
Lock, bank, powder proof	William Hall	Boston, Mass	July 29, 1851.
Locks, chronometric	William L. Bass	Boston, Mass	Dec. 23, 1851.
Locks, door	Charles H. Beatty	Wheeling, Va.	Oct. 14, 1851.
Lock for safes, &c	F. C. Goffin, assignor to Charles J. Gayler	New York, N. Y.	Dec. 2, 1851.
Locks, key	Jas. R. Bugbee, assignor to Jas. R. Bugbee and Enoch Robinson	Boston, Mass	April 22, 1851.
Locks, key	Linus Yale, jr	Newport, N. Y	May 6, 1851.
Lock, maze	Thomas Nicholson	Falmouth, Stafford co., Va.	Sept. 30, 1851.
Lock on sheet metal, machine for forming	Jabez Walker	East Bloomfield, N. Y.	April 1, 1851.
Locks, permutation safety	Robert Newell	New York, N. Y.	June 10, 1851; in England April 15, 1851.
Locks, rotating tumbler	David H. Richards & Jos. H. Flanders.	Newburyport, Mass	Dec. 16, 1851.
Metal tubes, method of liberating, from forming mandrel	Job Cutler	Birmingham, England	July 29, 1851; English patent Feb 28, 1849.
Milling tool	John Buckingham and Jos. H. Baird, ass'rs to Scovill Manufacturing Co.	Watertown, Conn.; Waterbury, Conn.	April 15, 1851.
Nail machine, horse shoe	Daniel Wilson, jr., assignor to D. Wilson, jr., and H. M. Bird	North Chelmsford, Mass,	Jan. 21, 1851.
Nail machine, horse shoe	Marshall Burnett	Boston, Mass	April 1, 1851.
Nut and washer machine	Henry Carter and James Rees	Pittsburg, Penn,	Aug. 26, 1851.
Nuts, washers, &c., machines for making	Wm. Kenyon, assignor to Joseph P. Haight, A. Hartupee, and J. Morrow	Steubenville, Ohio	Oct. 14, 1851.
Ores, copper, process for smelting	Samuel F. Tracy	New-York, N. Y	Dec. 16, 1851.
Ores, minerals, &c., arrangement of pans for washing	Samuel Porter	Hartford, Conn	Dec. 9, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Ores, process of reducing by zinc, compounds	E. S. Seymour	Williamsburg, N. Y	Aug. 26, 1851.
Ore washer	Arnold Buffum	Brooklyn, N. Y	Oct. 21, 1851.
Padlock	Geo. McGregor, Robert Lee, and Thos. G. Clinton	Cincinnati, Ohio	Aug. 26, 1851.
Padlock	David Tilton, assignor to Tilton and Smetser	Stoneham, Mass	Aug. 26, 1851.
Padlock	Thomas Slaight	Newark, N. J	Oct. 14, 1851.
Patterns, metal and second for castings	Francis N. Still	New York, N. Y	Jan. 28, 1851.
Pins, machine for sticking on paper	Chauncy O. Crosby	New Haven, Conn	April 1, 1851.
Pins, mode of papering	C. O. Crosby	New Haven, Conn	July 8, 1851.
Pins, mode of papering	C. O. Crosby	New Haven, Conn	Dec. 2, 1861.
Rods, tapered metallic, apparatus for rolling	William Clay	Clifton Lodge, England	April 22, 1851; in England Dec. 16, 1848.
Safes, fire-proof	Louis Lillie, assignor to Jno. W. Bates	Troy, N. Y	July 15, 1851.
Sash lock	Michael Norton	Cambridge, Mass	Mar. 25, 1851.
Sash stopper	Joseph Osbourne	Weymouth, Mass	June 3, 1851.
Sash, upper, arrangement of catches in, operated by moving the lower sash	W. Race	Seneca Falls, N. Y	July 1, 1851.
Sashes, window, method of hanging	Samuel D. Nims	Palmer, Hampden co., Mass	Dec. 23, 1851.
Screw blanks, machine for arranging and feeding	Thomas J. Sloan	New York, N. Y	Feb. 25, 1851.
Screw blanks, &c., machine for assorting	Thomas J. Sloan	New York, N. Y	May 6, 1849.
Screw blanks and articles of a similar character, machine for arranging	Thomas J. Sloan	New York, N. Y	Sept. 30, 1851.
Screws, machinery for shaving, nicking and reshaving wood	Thomas J. Sloan	New York, N. Y	Oct. 21, 1851.
Screws, machinery for threading wood, and feed apparatus therefor	Thomas J. Sloan	New York, N. Y	Sept. 23, 1851.
Screws, method of finishing the heads of	Thomas J. Sloan	New York, N. Y	June 10, 1851.
Screws and pins, machines for counting	Thomas J. Sloan	New York, N. Y	Dec. 23, 1851.
Shutters, apparatus for securing, in any required position	Charles W. Krebs	Baltimore, Md	Mar. 25, 1851.
Shutters, &c., apparatus for moving and securing	N. W. Speers	Cincinnati, Ohio	Mar. 25, 1851.
Spike machines, gauging and heading movement for	Purnel Jefferson	Bridgeton, N. J	May 20, 1851.
Spike machines	Mark M. Ison	Etowa, Cass co., Ga	Aug. 12, 1851.
Spike machinery	James H. Jewett	Concord, N. H	Aug. 26, 1851.
Spike machine, hook heading motion for	Moore Hardaway	Troy, N. Y	Sept. 9, 1851.
Spoons, &c., manufacture of wire, strengthened	Luther Boardman	East Haddam, Conn	May 20, 1851.
Spring bolt	Oliver H. Bush	Fall River, Bristol co., Mass	Aug 5, 1851.
Spring, machinery for forming joints of, eliptical	Wm. T. Richards	New Haven, Conn	Aug. 26, 1851.
Swaging machine, rotary	Perry G. Gardner	New York, N. Y	Dec. 23, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Tuyers	Joseph Dorwart	Morgantown, Pa	Jan. 14, 1851.
Tyres, by continuous rolling, machinery for making	P. G. Gardner	New York, N. Y	Mar. 11, 1851.
Tuyers, tight joint for	William Graham	Carlisle, Penn	Aug. 5, 1851.
Vaults, safes, &c., compound metallic doors for	Ira L. Cady	New York, N. Y	April 29, 1851.
Vice, bench	N. F. Cone	Kingsville, Ashtabula co., Ohio	Sept. 16, 1851.
Vice, parallel	Samuel R. Simpson	Springfield, Ohio	Jan. 7, 1851.
Wheel tires, machine for making	Maria Vaughn, assignor to James C. Bell and Robert Christie, jr	Greenbush, Rensselaer co., N. Y	Sept. 30, 1851.

Class III.—*Manufacture of fibrous and textile substances, including machine for preparing fibres of wood, cotton, silk, fur, paper, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Bats for felting, making	Leander W. Boynton	South Coventry, Conn	April 29, 1851.
Bats for felt cloth, &c., crossing the fibres in forming	Alonzo C. Arnold	Norwalk, Conn	June 10, 1851.
Card grinders	R. Kitson	Lowell, Mass	Nov. 11, 1851.
Cloth folding machine	D. R. Ambrose and O. S. Reynolds	Portsmouth and Dover N. H	July 22, 1852.
Cloth, machine for folding and measuring	Henry Boot	New Bedford, Mass	April 1, 1851.
Cloth, machine for stretching and drying	Thomas Barrows	Dedham, Norfolk co., Mass	Dec. 2, 1851.
Cords, coupling for	Lawton J. Ware	Warren, R. I	May 20, 1851.
Cotton duck, dressing	Horatio N. Gambrill	Baltimore, Md	Oct. 21, 1851.
Fibre, vegetable, processes for treating	Peter Claussen	Blackfriars, England	June 3, 1851; in England, August 16, 1850.
Flock, machine for grinding	John C. Fonda	Albany, N. Y	July 29, 1851.
Flocks, machine for opening and cleaning	Ephraim C. Brett	Great Barington, Berkshire co., Mass	Oct. 7, 1851.
Flocks to cloth, apparatus for applying	D. and R. Pratt	Elmira, N. Y	Oct. 7, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Fulling vegetable and other textures, chemical process for	John Mercer	Oakenshaw, Lancaster co., England	Aug. 19, 1851; in England, Oct. 24, 1850.
Hemp brakes	Paris M. Walker	Marshall, Mo	May 27, 1851.
Hemp, &c., machines for dressing Sissal	S. A. Clements	Springfield, Hampden co., Mass	July 15, 1851.
Hemp and flax, machines for breaking and reducing the length of the fibres	Jas. S. Treat and Stephen Randall	Voluntown, Windham co., Conn	Sep. 16, 1851.
Hemp and flax, machine for scutching and hackling	Owen W. Grimes	Paducah, Ky	Sep. 23, 1851.
Hemp, manufacture of, from okra	John Blanc	New Orleans, La	June 24, 1851.
Jacquard machines	John Scott and John Tannahill	Philadelphia, Pa	Mar. 18, 1851.
Knitting machines	John Pepper, assignor to Charles Warren and H. G. Sanford	Portsmouth, N. H., and Boston, Mass	Feb. 25, 1851; antedated Aug. 25, 1850.
Knitting machines	Rufus Ellis, assignor to W. M. Chase	Boston, Mass	July 17, 1851.
Knitting machines	John H. Barsantie	Portsmouth, N. H	June 29, 1851.
Knitting machines	John Pepper, assignor to Hosea Crane, John Pepper and J. G. Crane	Portsmouth, N. H	June 24, 1851.
Looms, cylinders for figuring	Eliakin M. Hastings and John Shepherdson	Jamestown, N. Y	Mar. 18, 1851.
Looms for weaving bags	Cyrus Baldwin, assignor to "Stark Mills"	Manchester, N. H	Dec. 2, 1851; antedated Aug. 30, 1851.
Looms for weaving cut pile fabrics	M. C. Bryant	Lowell, Mass	Aug. 5, 1851.
Looms for weaving piled fabrics	Erastus B. Bigelow	Clinton, Mass	Jan. 14, 1851.
Looms for weaving piled fabrics	John Johnson, assignor to E. Johnson	Troy, N. Y	Aug. 5, 1851.
Looms for weaving seamless bags	Shelden Northrop	New Milford, Conn	Jan. 1, 1851.
Looms for weaving tapestry carpets with particolored warp	Erastus B. Bigelow	Clintonville, Mass	Jan. 7, 1851.
Looms, hand	Isaac H. Garretson	Clay, Iowa	Feb. 16, 1851.
Looms, Jacquard, for weaving cut pile fabrics	Erastus B. Bigelow	Clinton, Mass	Mar. 18, 1851.
Looms, power, fancy check	Enoch Burt	Manchester, Conn	Feb. 4, 1851.
Looms, shuttle, motions of	George W. Perry	Thompson, Windham co., Conn	Nov. 11, 1851.
Looms, shuttle, motions of	George J. Wardwell	Hanover, Oxford co., Maine	Aug. 5, 1851.
Paper moulds	William Brewer and John Smith	Malcome place, Clapham, Eng.; Southville, South Lambeth, England	Mar. 4, 1851; in England, Feb. 12, 1849.
Pulp screws	Geo. West	Tyringham, Mass	Aug. 19, 1851.
Sewing machines	William O. Grover and W. E. Baker	Boston, Mass.; Roxbury, Mass	Feb. 11, 1851.
Sewing machines	W. H. Aikins and J. D. Felthousen	Ithaca, N. Y	Aug. 5, 1851.
Sewing machines	Isaac M. Singer	New York, N. Y	Aug. 12, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Sewing machines	Allen B. Wilson	Watertown, Litchfield co., Conn	Aug. 12, 1851.
Shawls, &c., machines for twisting fringes of	Jno. Nesmith and Wesley Sawyer	Lowell, Mass	Oct. 14, 1851.
Spinning machines, drawing regulators for	Newell Wyllys	South Glastenbury, Conn	Jan. 28, 1851.
Spinning rope yarns	Richard S. Tucker	Brooklyn, N. Y	Dec. 23, 1851.
Spinning wool, hand machines for	Margaret Hulings	Randolph co., Ind	June 3, 1851.
Waste pickers	Chas. G. Sargent and Rob. Thompson	Lowell, Mass	Sep. 16, 1851.
Weaving, delivering parti-colored warps in	Erastus B. Bigelow	Clinton, Mass	Mar. 18, 1851.
Weavers' headdles	Charles T. Judkins	Lowell, Mass.; patented in England to David Christie.	Feb. 18, 1851; in England, Feb. 10, 1849.
Weavers' temples	A. Jillson	Woonsocket, R. I	Sep. 16, 1851.
Weavers' shuttles	Leroy Litchfield	Southbridge, Worcester co., Mass	Sep. 30, 1851.
Woven fabrics, wires for making pile in	E. B. Bigelow	Clinton, Mass	Nov. 25, 1851.
Weavers' temples	E. and W. W. Dutcher	North Bennington, Vt	Dec. 16, 1851.
Wool, machines for cleansing	Leander W. Boynton	South Coventry, Ct	Aug. 12, 1851.
Yarns, sizing and dyeing apparatus for	Alonzo Bascom	East Jaffrey, Cheshire co., N. H	Nov. 18, 1851.

Class IV.—*Chemical processes, manufactures and compounds, including medicine, dyeing, color making, distilling, soap and candle making, mortars, cements, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Acid and naptha from rosin, distilling	L. S. Robins	New York, N. Y	Nov. 4, 1851.
Alloys of iron, zinc and nickel	Otis Boyden	Newark, N. J	May 27, 1851.
Bronze powder, processes of making	L. Branders	New York, N. Y	Sep. 16, 1851.
Calico printing, material for transferring colors in	Charles A. Broquette	France	April 15, 1851; France, April 1, 1849.
Cane juice, machine for expressing	Henry Bessemer	Middlesex co., England	June 3, 1851; in Ireland, Dec. 31, 1850.
Candle making, apparatus for	Willis Humiston	Troy, N. Y	Dec. 23, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Caviar, manufacture of	Rob. G. Westacott, assignor to Westacott, Lombard & Lombard	Worcester, Mass.; Boston, Mass	Jan. 7, 1851.
Cements, for grinding, cylinders	Jacob Stephan, assignor to P. Augustus Scwaze and Jacob Stephan	Boston, Mass	Oct. 28, 1851.
Compounds, lubricating	Jacob Selgrath	Pottsville, Pa	June 24, 1851.
Drying and oxydizing colored goods	James C. Kempton	Manyunk, Philadelphia co, Pa	Sep. 2, 1851.
Dyeing blue, processes for	Edward Swiney	Andover, Mass	Nov. 4, 1851.
Dyeing door mats	Reuben Shaler	Madison, New Haven, Conn	July 22, 1851.
Gas, illuminating, purifying	Florentine J. de Cavailon	Paris, France	May 6, 1851.
Gutta percha hollow ware	Samuel T. Armstrong	New York, N. Y	June 24, 1851.
Gutta percha, tubing and covering wire, machines for	James Reynolds	New York, N. Y	April 22, 1851.
India rubber, manufacture of	Jonathan T. Trotter	New York, N. Y	Jan. 1, 1851.
India rubber, manufacture of	David McCurdy	Newark, N. J	April 1, 1851.
India rubber, manufacture of	Nelson Goodyear	New York, N. Y	May 6, 1851.
Mashing tubs	Joseph Wright	Waterloo, Seneca co., N. Y	June 24, 1851.
Oil from rosin, lubricating	L. S. Robins	New York, N. Y	Nov. 4, 1851.
Oil from rosin, tanners'	L. S. Robins	New York, N. Y	Nov. 4, 1851.
Paint, manufacture of	G. F. de Douchet	Paris, France	Sep. 9, 1851; English patent dated June 1, 1850; French patent dated Oct. 5, 1850.
Paint, metallic alloy	Chas. Wetterstedt, assignor to Chas. Kenan	Marseilles, France; New York, N. Y	Aug. 5, 1851; Eng. patent dated Nov. 3, 1846.
Paint oil from rosin	L. S. Robins	New York, N. Y	Nov. 4, 1851.
Peppermint droppers	Henry H. Snow	New Haven, Conn	Mar. 4, 1851.
Pigments, manufacture of	H. L. Pattinson	Scott's house, England	Aug. 12, 1851; Eng. patent dated Feb. 14, 1849.
Sugar, apparatus for draining	Smith Gardner	New York, N. Y	Sept. 16, 1851.
Sugar drainers, centrifugal	William Van Anden	Poughkeepsie, N. Y	June 10, 1851.
Sugar drainers, centrifugal	Daniel King	Brooklyn, N. Y	Nov. 25, 1851.
Sugar vacuum pans	James M. Miller	New York, N. Y	Oct. 21, 1851.
Zinc, white, use of steam to make	Henry W. Adams	Boston, Mass	Oct. 28, 1851.

V.—*Classified list of patents, &c.*—Continued.

CLASS V.—*Calorific, comprising lamps, fireplaces, stoves, grates, furnaces for heating buildings, cooking apparatus, preparation of fuel, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Bagassee, machines for drying	Samuel H. Gilman	Cincinnati, Ohio	Oct. 28, 1851.
Candlesticks	James Manning	Middletown, Ct	Jan. 1, 1851.
Candlesticks	Francis A. Rockwell	Ridgefield, Fairfield co., Ct	Dec. 16, 1851.
Charcoal, manufacture of	W. P. McConnell	Washington, D. C	Nov. 4, 1851.
Chimney tops	Charles W. Russell	Washington, D. C	Dec. 16, 1851.
Dust, excluding from railroad cars	Ed. Hamilton, assignor to N. Goodyear.	Bridgeport, Ct.; New York, N. Y	May 27, 1851.
Dwellings, apparatus for warming air and water for.	L. C. St. John	Buffalo, N. Y	Oct. 7, 1851.
Fires, compound for extinguishing	Joshua Upham	Salem, Essex county, Mass	Nov. 4, 1851.
Fireplace, reflecting	Robert Jobson	Near Dudley, England	May 20, 1851; in England Dec. 28, 1848.
Fountain and evaporator combined	George H. Thatcher	Albany, N. Y	July 22, 1851.
Furnaces, hot-air	Samuel Pierce	Troy, N. Y	May 20, 1851.
Furnaces, hot-air	Joseph C. Treat	East Hartford, Ct	Aug. 5, 1851.
Furnaces, ventilating	Henry Ruttan	Coburg, Canada West	In Canada Jan. 31, 1851; in America May 20, '51.
Gas-burners, Argand	John G. Webb	Williamsburg, King's county, N. Y	Oct. 14, 1851.
Gas regulators	J. S. Conant	Lowell, Mass	Dec. 9, 1851.
Grate-bars, agitating	A. D. Spoor	Troy, N. Y	April 15, 1851.
Grates, stove	H. J. Ruggles	West Poultney, Vt	Nov. 18, 1851.
Grates, quadrant-hinged	George H. Thatcher	Albany, N. Y	Aug. 5, 1851.
Lamps for burning vapor of benzole, &c	Chapman Warner	Washington, D. C	Oct. 14, 1851.
Lamps, lard	Delamar Kinnear	Circleville, Ohio	Feb. 4, 1851.
Lamps, self-acting blow-pipes	D. W. C. McCloskey	New York, N. Y	Aug. 26, 1851.
Lamps, solar, for burning lard or oils	John G. Webb	Williamsburg, King's county, N. Y	Oct. 14, 1851.
Lamps, street, reflectors for	Hugh and James Sangster	Buffalo, N. Y	Jan. 14, 1851.
Lanterns	Henry and James Sangster	Buffalo, N. Y	June 10, 1851.
Ovens, portable, elevated	P. Killin	Mount Healthy, Ohio	Oct 7, 1851.
Radiating surfaces	J. K. Ingalls	New York, N. Y	Nov. 4, 1851.
Ranges, cooking	Nicholas Mason	Roxbury, Mass	Aug. 19, 1851.
Ranges, cooking	Moses Pond	Boston, Mass	Feb. 25, 1851.
Steam traps	Charles M. Guild and John Brown	New York, N. Y	May 20, 1851.
Stoves	George H. Thatcher	Albany, N. Y	Jan. 21, 1851.
Stoves	Elihu Smith	Albany, N. Y	Jan. 28, 1851.
Stoves	Gardner Chillson	Boston, Mass	Sept. 16, 1851.
Stoves	Elisha Vance	Cincinnati, Ohio	Oct. 14, 1851.
Stoves	Hale R. Rose	Guilford, Vt	Nov. 18, 1851.
Stoves, air-heating	Gordon Williston	Charlestown, Mass	Oct. 14, 1851.
Stoves, air-heating	Charles A. Bogart	West Dresden, Yates county, N. Y	Oct. 21, 1851.
Stoves, airtight, Franklin	Rensselaer D. Granger	Albany, N. Y	Mar. 11, 1851.
Stoves, coal	James Shields and Samuel Pierce	New York, N. Y.; Troy, N. Y	Jan. 7, 1851.
Stoves, cooking	Bachus A. Beardsley	Waterville, N. Y	Feb. 4, 1851.
Stoves, cooking	William Sours	Mount Jackson, Va	Feb. 25, 1851.
Stoves, cooking	James Green and Rufus J. King	Dayton, Ohio	Mar. 11, 1851.
Stoves, cooking	Rufus K. Paine	Cincinnati, Ohio	April 8, 1851.
Stoves, cooking	James J. Marsh	Lewisburg, Pa	April 15, 1851.
Stoves, cooking	Dennis J. Littlefield	Lowell, Mass	April 15, 1851.
Stoves, cooking	Charles W. Grannis	Gowanda, N. Y	April 22, 1851.
Stoves, cooking	Elias Young	Cincinnati, Ohio	June 17, 1851.
Stoves, cooking	Hosea H. Huntly	Cincinnati, Ohio	Aug. 19, 1851.
Stoves, cooking	Hosea H. Huntly	Cincinnati, Ohio	Nov. 25, 1851.
Stoves, cooking	George W. Carleton	Brunswick, Cumberland county, Me	Nov. 25, 1851.
Stoves, dairy	Joel Stevens & H. J. Ruggles	West Poultney, Vt	Oct. 28, 1851.
Stoves, double oven	C. Harris & P. W. Zoiger	Cincinnati, Ohio	Sept. 2, 1851.
Stoves, folding doors of	James Root	Cincinnati, Ohio	Nov. 4, 1851.
Stoves, grate bars	George W. Gardner	Albany, N. Y	Nov. 18, 1851.
Stoves, parlor, cooking	N. A. Boynton	Boston, Mass	July 22, 1851.
Stoves, with portable ovens	George H. Thatcher	Albany, N. Y	July 29, 1851.
Ventilating and excluding dust from railroad cars	Ransom Cook	Saratoga Springs, N. Y	Aug. 19, 1851.
Ventilators	Thatcher C. Hatch	South Braintree, Mass	June 17, 1851.

V.—*Classified list of patents, &c.*—Continued.

CLASS VI.—*Steam and gas engines, including boilers and furnaces therefor, and parts thereof.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Boilers, apparatus for steam	J. & J. J. G. Collins	Kensington, Pa	Nov. 25, 1851.
Boilers, &c., steam apparatus for indicating the height of water in	George Faber	Canton, O	May 13, 1851.
Boilers, method of tracing the water spaces of	Bernard O. Neill	Reading, Pa	March 4, 1851.
Boilers, revolving	Charles Anderson	Warren, Pa	June 17, 1851.
Boilers, revolving	Wiliam Scott	Rising Sun, Ohio co, Indiana	Oct. 7, 1851.
Boiler, steam, annular	Thomas Champion	Philadelphia, Pa	Feb. 18, 1851.
Boilers, steam, arrangement of the flues and water spaces of	William E. Milligan	New York, N. Y	July 15, 1851.
Boilers, steam, insulated fusible plug for	E. H. Ashcroft	Boston, Mass	Feb. 18, 1851.
Boilers, steam, water gauge for	A. S. Lyman	New York, N. Y	Aug. 12, 1851.
Boiler tubes, &c., spring expanding guage for	James McCarty	Reading, Pa	July 29, 1851.
Crank indicator, arrangement of machinery for actuating the	Samuel B. Hutchins	Oswegatchie, N. Y	June 3, 1851.
Cut-off, adjustable	Samuel H. Gilman	Cincinnati, O	Mar. 18, 1851.
Cut-off, gear	George H. Corliss	Providence, R. I	July 29, 1851.
Cut-off, variable, regulated by the governor	Henry Waterman	New York, N. Y	Mar. 4, 1851.
Engine, air	John Ericsson	New York, N. Y	Nov. 4, 1851; in England, December 26th, 1850.
Engines, apparatus for regulating the speed of	H. A. Luttgens	New York, N. Y	Oct. 21, 1851.
Engines, carbonic acid gas	Jno. C. Fr. Salomon	Cincinnati, O	Dec. 9, 1851.
Engines, in which compressed air or other gas, heated and expanded by admixture therewith of a heated fluid, is used as the motive agent	Wm. Mt. Storm	Troy, Rensselaer co., N. Y	Sept. 23, 1851.
Engines, valve for oscillating	William M. Smith	Georgetown, D. C	Nov. 25, 1851.
Equalizers or power regulators	Alfred Gregory	Brooklyn, N. Y	Sept. 9, 1851.
Gauge for indicating pressure of steam, &c	George Faber	Canton, Stark co., Ohio	Sept. 16, 1851.
Indicator, water level, for steam boilers	Albert H. Judd	Marinetown, Ill	Aug. 5, 1851

Kilns, grain	J. S. Stover	Erwenna, Bucks co., Pa	Nov. 11, 1851.
Packing of rotary engines, method of adjusting the	Henry G. Thompson	New York, N Y	Feb. 4, 1851.
Power, motive, method of obtaining	William Mt. Storm	Troy, N. Y	Feb. 4, 1851.
Spark-arresters	James A. Cutting	Philadelphia, Pa	May 6, 1851.
Steam engines	Rich'd. F. Loper & John W. Nystrom.	Philadelphia, Pa	April 15, 1851.
Steam engine, arrangement of the	Frederick P. Dimpfel	New York, N. Y	July 1, 1851.
Valves, balanced	Francis B. Stevens	New York, N. Y	Mar. 25, 1851.
Valve side, method of connecting the, with the rock-shaft	Samuel H. Gilman	Cincinnati, O	Jan. 1, 1851.

CLASS VII.—*Navigation and maritime implements, comprising all vessels for conveyance on water, their construction, rigging, and propulsion, diving dresses, life-preservers, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Boats to facilitate the discharge of cargo, and fittings for	William H. Bryan	Georgetown, D. C	July 29, 1851.
Hand-log	John R. St. John, assignor to James Renwick, Geo. T. Barnard, and E. B. St. John, trustees of the St. John Compass and Log Company	New York, N. Y	May 6, 1851; in Europe Dec. 27, 1850.
Lee-way indicator	A. A. Wilder	Detroit, Michigan	Jan. 21, 1851.
Masts and spars, telescopic connection of	Charles F. Brown	Warren, R. I	June 17, 1851.
Propeller	Ambrose W. Thompson	Philadelphia, Pa	Jan. 21, 1851.
Propeller screw	Gaspard Malo	Dunkirk, France	Nov. 18, 1851.
Propeller, the endless chain	Charles Frederick Fisher	New Orleans, La	Oct. 7, 1851.
Propelling and steering, apparatus for	John C. fr. Salomon	Cincinnati, O	Dec. 2, 1851.
Rudder, apparatus for relieving the helmsman from the shock of	Chandos Hoskins	New Orleans, La	May 13, 1851.
Rudder, balanced	Charles F. Brown	Warren, R. I	June 10, 1851.
Rudders, method of operating	Thos. H. Mortimer & Jas. M. Gardner.	Charleston, S. C	Nov. 25, 1851; French patent dated Jan. 11, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Sails, method of making	Eli F. Southward	Wellfleet, Mass	Sept. 9, 1851.
Ships, light	Leonard Goodrich	New York, N. Y	Feb. 4, 1851.
Ships, model, measurer	Abijah S. Hosley	New York, N. Y	Aug. 19, 1851.
Ships, ventilating	Amos J. Sexton and Wm. Ennis	Brooklyn, N. Y.; New York, N. Y	Sept. 23, 1851.
Ships' winches	Thomas G. Boone	Brooklyn, N. Y	Oct. 21, 1851.
Snatch-block	Philip Rhoades, jr	Pittsburg, Pa	Feb. 18, 1851.
Steering apparatus	Joseph E. Andrews	Boston, Mass	Jan. 14, 1851.
Velocimeters, aquatic, method of supporting the vanes of.	John R. St. John, assignor to James Renwick, Geo. T. Barnard, E. B. St. John, trustees of the St. John Compass and Log Company.	New York, N. Y	In Europe, Dec. 27, 1850; in U. States, May 13, 1851.
Vessels, flexible hose or float for supporting	Wm. Mt. Storms	Troy, N. Y	April 29, 1851.
Vessels, method of raising sunken	William Irwin	Philadelphia, Pa	Sept. 2, 1851.

Class VIII.—*Mathematical, philosophical, and optical instruments, including clocks, chronometers, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Calculating interest, rules for	Sam. S. Young, ass'r to John R. Stephens	Eaton, Ohio	Sept. 2, 1851.
Calculating machines	John W. Nystrom	Philadelphia, Pa	Mar. 4, 1851.
Electro magnetic engines	Jacob Neff	Philadelphia, Pa	Jan. 7, 1851.
Electro magnetic engines	Thomas C. Avery	New York, N. Y	Feb. 25, 1851.
Electro magnetic telegraphs, circuit changes for	Charles S. Bulkley	Macon, Bibb county, Georgia	Sept. 2, 1851.
Escapements for time pieces	James Fulton	Louisville, Kentucky	Oct. 7, 1851.
Lightning-rods, insulators for	George W. Otis	Lynn, Essex county, Mass	Aug. 26, 1851.
Poles, machines for climbing	Henry D. Chapman	Baltimore, Md	Mar. 11, 1851.
Plotting scales	Lemuel H. Parsons	Lambertville, Hunterdon county, N. J.	Sept. 30, 1851.
Spectacle frames	John P. Paine	Worcester, Mass	July 1, 1851.
Telegraph wires, insulators for	John M. Batchelder	Cambridge, Mass	Oct. 14, 1851.
Telegraph wires, insulators for	Zenas C. Robins	Washington, D. C	Oct. 14, 1851.
Telegraph wires, insulators for	John Yandell	St. Louis, Mo	Oct. 14, 1851.

Telescopes	Alvan Clark	Cambridge, Middlesex, Mass	Nov. 11, 1851.
Telegraphs, means for obviating difficulties arising from defective insulation	Charles S. Bulkley	Macon, Bibb county, Georgia	Aug. 26, 1851.
Watches, winding	Theodore Noel	Memphis, Tenn	Dec. 2, 1851.

Class IX.—*Civil engineering and architecture, comprising works, rail and common roads, bridges, canals, wharfs, docks, rivers, wiers, dams, and other internal improvements, buildings, roofs, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Blasting rocks	Charles Monson	New Haven, Ct	April 1, 1851.
Buildings, iron connexion for the beams and columns of	Joseph Banks	New York, N. Y	Feb. 25, 1851.
Buildings, metallic, construction of	Simon Willard	Cincinnati, Ohio	Mar. 18, 1851.
Bridge, counter-braces, adjusting the effective length of	D. C. McCallam	Owego, N. Y	July 15, 1851.
Bridge trusses, arrangement of arches in	Cunningham M. Pennington	Rome, Ga	Jan. 7, 1851.
Bridges, the construction of	Edwin Stanley	Bennington, Wyoming county, N. Y	Sept. 2, 1851.
Drilling apparatus, steam	Joseph W. Fowle	Boston, Mass	Mar. 11, 1851.
Excavating, machines	Benjamin W. Remy	Brookville, Brookville county, Ia	Oct. 21, 1851.
Fences, flexible	Mathias P. Coons	Lansingburg, Rensselaer county, N. Y.	July 29, 1851.
Fences, hurdle	Cyrus C. Cole	Rushville, Ontario county, N. Y	Dec. 2, 1851.
Fences, iron	J. B. Wickersham	New York, N. Y	July 1, 1851.
Fence, sod, machine for making	H. L. F. Gavett	Jackson, Mich	Sept. 9, 1851.
Frog-guard, self-acting	Chas. A. Postley	Spring Garden, Philadelphia, Pa	June 24, 1851.
Gates, apparatus for opening and closing	Enoch Woolman	Damascoville, Columbiana county, Ohio.	Dec. 2, 1851.
Pavements, method of securing ranges of short plank in	Joseph E. Ware	St. Louis, Missouri	Feb. 11, 1851.
Paving, &c., stone and metal, conglomerate for	Geo. H. Knight	Cincinnati, Ohio	April 1, 1851.
Railings	Sommers Crowell	Reading, Pa	June 10, 1851.
Railings, iron	John Krauser	Reading, Pa	April 15, 1851.
Roofs, construction of	Francis Wilbar	Roxbury, Norfolk county, Mass	Aug. 12, 1851.
Scraper	Charles Schofield and George J. John	Albion, Ill	Feb. 11, 1851.
Shutters for shop fronts	James Root	Cincinnati, Ohio	Aug. 5, 1851.
Vessels, method of raising sunken. (See class IX.)			
Window sashes	Sewall Short	New London, Ct	July 29, 1851.

V.—*Classified list of patents, &c.*—Continued

CLASS X.—*Land conveyance, comprising carriages, cars, and other vehicles used on roads, and parts thereof.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Axles, boxes for journals for railroad cars	Oliver N. French, assignor to O. N. French and Eb. Stevens	New London, Ct	July 15, 1851.
Axle boxes, for railroad cars	Robert Levington	Monroe, Mich	Oct. 14, 1851.
Buggy tops	Har. Hibbard, ass'r to Jar. A. Hibbard	Henrietta, N. Y	July 15, 1851.
Car couplings	Silas M. Cockran	Baltimore, Md	Jan. 1, 1851.
Car brakes, railroad	Francis A. Stevens	Burlington, Chittenden co., Vt	Nov. 25, 1851.
Cars, for transportation of coal	Laurence Myers	Philadelphia, Pa	June 24, 1851.
Cars, railroad, coupling	George Winters	Portsmouth, Dauphin county, Pa	Sept. 16, 1851.
Cars, railroad, coupling	Lorenzo D. Livermore	Hartland, Windsor county, Vt	Nov. 11, 1851.
Cars, railroad, excluding dust from. (See class V.)			
Cars, railroad, running-gear of	William Nebinger	Sharpsburg, Washington county, Md	Oct. 21, 1851.
Cars, railroad, running-gear of	Thomas A. Davies	New York, N. Y	Dec. 9, 1851.
Car seats	Rickason Stillwell and E. L. Brundage	New York, N. Y.; Troy, N. Y	April 22, 1851.
Car seats	Ezekiel Booth and Ezra Ripley	Troy, N. Y	Nov. 11, 1851.
Car seats	Ezra Ripley and E. L. Brundage	Troy, N. Y	Dec. 9, 1851.
Carriages	John Jones	Clyde, N. Y	Jan. 14, 1851.
Carriages	James C. Spencer	Phelps, N. Y	May 27, 1851.
Carriages	George B. Durkee	Alden, N. Y	May 27, 1851.
Carriages	Gustavus L. Haussknecht	New Haven, Ct	Dec. 16, 1851.
Carriages	Lewis King	Madison, Madison county, N. Y	Dec. 23, 1851.
Carriage bodies, hanging	John Jones	Clyde, Wayne county, N. Y	July 22, 1851.
Carriage bodies, hanging	John Jones	Clyde, Wayne county, N. Y	July 22, 1851.
Carriage perches	Lewis E. Stillwell	Franklinville, Cattaraugus co., N. Y	Dec. 2, 1851.
Carriages, railroad, running-gear of	Daniel W. Eames	West Turin, Lewis county, N. Y	July 1, 1851.
Carriages, steam, for railways	Jos. H. Moore and Wm. P. Parrott	Boston, Mass	Dec. 2, 1851.
Carriage tops, raising	John L. Allen	New Haven, Ct	Jan. 14, 1851.
Felloes, bending	A. W. Johnston	St. George's, Del	Nov. 11, 1851.
Hubs and axles, connecting and disconnecting	A. M. Billings	Claremont, N. H	Jan. 14, 1851.
Hubs and axles, applying friction rollers to	Jos. B. & S Wilson	Townsend's Inlet, N. J	Feb. 25, 1851.
Hubs, for boxes, machine for preparing	William R. Jones	Granville, Washington county, N. Y	July 22, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Hubs, for reception of boxes, machine for preparing	Henry Moore	Shepardtown, Pa	July 29, 1851.
Locomotives, moved by the power of animals	Clement Masserano, assignor to Clement Masserano, Josephine Wickliffe, administratrix of R. Wickliffe, jr., deceased, Charles Carenzi, André Cristedoro, Pallegro Rocca, & Louis B. Migone.	Turin, kingdom of Sardinia; and Lexington, Ky.; Genoa, Sardinia	Oct. 7, 1858.
Locomotives, running-gear of	George S. Griggs	Roxbury, Mass	June 17, 1851.
Locomotives, running-gear of	James H. Murrill	Manchester, Va	Oct. 7, 1851.
Locomotives, running-gear of	Ross Winans	Baltimore, Md	Dec. 2, 1851.
Omnibus steps	William H. Hoyt	New York, N. Y	May 27, 1851.
Omnibus drivers, registers for	Ira B. Person and Joel L. Brockett	Baltimore, Md	Aug. 19, 1851.
Springs	James Webster	Leicester, England	Nov. 4, 1851; English patent, Feb. 11, 1851.
Springs, carriage	Levi Bissell	New York, N. Y	May 20, 1851.
Springs, carriage	Chauncy H. Guard	Brownsville, N. Y	June 10, 1851.
Springs, carriage	Gustavus L. Haussknecht	New Haven, Ct	July 15, 1851.
Springs, carriage	M. G. Hubbard	Rochester, N. Y	July 22, 1851.
Springs, carriage	Levi Bissell, assignor to Levi Bissell and Lyman Kinsley	New York, N. Y	Nov. 4, 1851.
Switch, for railroads, self-adjusting and locking	John C. Past	White Haven, Pa	June 3, 1851.
Switch, railroad	David F. Phillips	Republic, Seneca county, Ohio	Nov. 18, 1851.
Switches, railroad	William N. Raines	Thompson, Columbia county, Ga	Dec. 2, 1851.
Tires, for railroad-car wheels	Theodore T. Abbott	Manchester, N. H	Jan. 14, 1851.
Trucks, connecting with car bodies	Thomas P. Howe	Buffalo, N. Y	Mar. 11, 1851.
Trucks, railroad car	Benjamin Hinkley	Troy, N. Y	Dec. 2, 1851.
Wheels and axles, connecting and disconnecting	Simeon Heywood	Claremont, N. H	April 1, 1851.
Wheels, car, machinery for making wrought iron	Maria Vaughn, administratrix of James C. Vaughn, deceased, assignor to James C. Bell and R. Christie, jr	Greenbush, N. Y.; New York, N. Y	June 24, 1851.
Wheels, cast-iron car	George R. McFarlane	Holidaysburg, Pa	Jan. 14, 1851.
Wheels, cast-iron car	P. G. Gardiner	New York, N. Y	Mar. 11, 1851.
Wheels, cast-iron car	Thomas J. Eddy	Waterford, N. Y	July 29, 1851.
Wheels, cast-iron car	Benjamin Severson	Schenectady, N. Y	Oct. 21, 1851.
Wheels, cast-iron car	Isaac Vankuran	Boston, Mass	May 20, 1851.
Wheels, cast-iron car	Albert Hebbard	Worcester, Mass	May 20, 1851.
Wheels, railroad car	Nehemiah Hodge	Adams, Berkshire co., Mass	Nov. 18, 1851.
Wheels, spring carriage	John Lamb and Charles H. Root	McDonough, N. Y	Jan. 1, 1851.
Wheels to axles, method of securing	Junius Foster and David Marsh, assignors to J. Foster	Greene Point, King's co., N. Y	Sept. 2, 1851.

V.—*Classified list of patents, &c.*—Continued.

CLASS XI.—*Hydraulics and pneumatics, including water wheels, wind mills, and other implements operated on by air or water, or employed in raising or delivering fluids.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Coupling, compound for hose or pipe	James W. Osgood	Columbus, Ohio	May 20, 1851.
Faucets	Charles W. Stearn	Springfield, Mass.	July 22, 1851.
Faucets or gates, molasses	Erastus Stebbins	Chicopee, Mass.	July 15, 1851.
Hydraulic ram	William Fields, jr.	Providence, R. I.	Jan. 28, 1851.
Hydraulic rams, operating the waste gates in	John Osborn	Hampden, Conn.	Feb. 11, 1851.
Liquids, apparatus for drawing and measuring	Richard F. Stevens	Syracuse, N. Y.	Mar. 25, 1851.
Pipes, lead, machines, nozzle for	John B. Collian	Reading, Pa.	Jan. 1, 1851.
Propellers of machinery to be used in currents	James Hardie	Victoria, Texas	Nov. 18, 1851.
Pumps	Nelson Newman	Cincinnati, Ohio	May 6, 1851.
Pumps for elevating water mixed with mineral substances	William Ball	Chicopee, Hampden co., Mass.	Dec. 23, 1851.
Pumps for raising water, &c.	J. F. Flanders	Newburyport, Mass.	June 22, 1851.
Pumps, rotary	J. Stuart Gwynne	New York, N. Y.	Jan. 14, 1851.
Pumps, rotary	Phineas Bennett	New York, N. Y.	Jan. 7, 1851.
Valves, shields for	Alexander Jimason	Parkesburg, Chester co., Pa.	Sept. 30, 1851.
Water, apparatus for raising and carrying	James D. Willoughby	Scotland, Pa.	Feb. 18, 1851.
Watering cattle, apparatus for	S. W. Wood	Rochester, N. Y.	Oct. 28, 1851.
Water metres	John Ericsson	New York, N. Y.	Jan. 1, 1851.
Water metres	John Ericsson	New York, N. Y.	Dec. 9, 1851.
Water wheels	James L. Parker	Shirley village, Middlesex co., Mass.	Oct. 14, 1851.
Water wheels, over shot	Edmund Sheetz	Campbellstown, Lebanon co., Pa.	Oct. 14, 1851.

CLASS XII.—*Lever, screw, and mechanical power, as applied to pressing, weighing, raising, and moving weights.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Jacks, lifting	Bolivar Newbury	Catskill, N. Y.	May 27, 1851.
Jacks, lifting	James St. John	New York, N. Y.	July 8, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Oil presses	David L. Latourette	St. Louis, Mo.	Oct. 28, 1851.
Presses, drop	Milo Peck	New Haven, Conn.	Nov. 25, 1851.
Press, portable hydraulic	Richard Dudgeon	New York, N. Y.	July 8, 1851.
Presses, self-acting	William Moore	Belleville, Richland co., Ohio.	Sept. 30, 1851.
Presses, self-acting, cheese	Bethuel Gillett and Lyman Allis	Windsor, Hartford co., Conn.	Aug. 26, 1851.
Weighing carts	A. B. Livingston	Portland, Fountain co., Ind.	Sept. 30, 1851.
Weighing machine for grain, self	William Biddle	Lafayette, Ind.	May 27, 1851.

CLASS XIII.—*Grinding mills and mill gearing, including grain mills, mechanical movements, and horse-powers.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Bolting flour, apparatus for	Lewis Fagin and Henry C. Hayman	Cincinnati, Ohio	April 8, 1851.
Boxes and axles for saving oil	Benjamin Kraft	Reading, Pa.	July 1, 1851.
Bran dusters	J. M. Carr and James Hughes	Cambridge, Ind.	April 1, 1851.
Bran dusters	Wm. A. McFarland and Thos. C. Carpenter	Wilmington, Del.	May 27, 1851.
Bran dusters	S. W. Kirk	Coatsville, Chester co., Pa.	July 22, 1851.
Corn sheller	Joshua M. C. Armsby	Worcester, Mass.	Jan. 7, 1851.
Flouring apparatus	James M. Clark	Lancaster, Pa.	May 13, 1851.
Flour bolts	Samuel Cook	Adams Basin, N. Y.	June 22, 1851.
Governors	William Gardner	New York, N. Y.	June 10, 1851.
Governors	George H. Corliss	Providence, R. I.	June 10, 1851.
Grinders, method of forming teeth upon cast iron	Ezra Ripley	Troy, N. Y.	Aug. 12, 1851.
Horse-powers	Cyrus Avery	Tunkhannock, Pa.	June 3, 1851.
Horse-powers	Aaron D. Crane	Newark, N. J.	April 8, 1851.
Mills, cider	Nathan Chapin	Syracuse, N. Y.	Sept. 2, 1851.
Mills, cider	David F. Phillips	Republic, Seneca county, Ohio	Nov. 25, 1851.
Mills for grinding corn and cobs	Sidney A. Bantz and Wm. Andrews	Frederick, Md.	July 22, 1851.
Mills for grinding paints and drugs	Gilbert D. Jones	Jersey City, N. J.	April 1, 1851.
Mills for grinding and bolting	Jehu Hollingsworth	Zanesville, Muskingum co., Ohio	Nov. 18, 1851.
Mills, grinding	William Newlove	Utica, N. Y.	Oct. 14, 1851.
Millstones	E. T. Hannon Valcke	Paris, France	April 15, 1851.
Millstones, dressing	Edmund P. Gaines	Milrose, Texas	Mar. 4, 1851.
Millstones, dressing	Moore Holden	Laurenceburg, Indiana	Aug. 5, 1851.
Millstones, finishing and balancing	George Todd	St. Louis, Mo.	Nov. 18, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Millstones, machines for dressing	E. W. Hazard and Charles H. Jenner	Binghampton, N. Y.; Rochester, N. Y.	Sept. 16, 1851.
Motion, changing a reciprocating into a rotary	Joseph Harris, jr.	Boston, Mass.	Jan. 14, 1851.
Motion, mode of changing reciprocating into rotary	J. V. Strait	Litchfield, Ohio	July 22, 1851.
Oil cups for journal boxes	Aaron Richardson	Bellows Falls, Vt	July 29, 1851.
Power, governors	Junius Judson	New York, N. Y.	Mar. 4, 1851.
Smut machines	Jehu Hollingsworth	Zanesville, Ohio	April 22, 1851.
Smut machines	Nelson Platt	Ottawa, Ill.	May 20, 1851.

CLASS XIV.—*Lumber, including machines and tools, for preparing and manufacturing, such as sawing, planing, mortising, shingle and staves, carpenters' and coopers' implements.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Augurs	Ransom Cook	Saratoga Springs, N. Y.	June 17, 1851.
Augurs, &c., to their handles, means of attaching	Merritt S. Brooks	Chester, Middlesex county, Conn.	Oct. 28, 1851.
Boring holes in posts, machines for	Thos. T. Strode	Coatsville, Chester county, Pa.	Dec. 2, 1851.
Grooving lumber, machines for	B. Holly and Jno. W. Wheeler	Seneca Falls, N. Y.	July 8, 1851.
Guages used in turning	C. R. Hurlbut	Rushford, N. Y.	Sept. 9, 1851.
Irregular forms, machines for turning	Jonathan Russell	Philadelphia, Pa.	Jan. 1, 1851.
Irregular forms, machines for turning	Philo S. Beers	Hampden, Conn	Feb. 18, 1851.
Irregular forms, machinery for turning	Abner Lane	Killingsworth, Conn	Feb. 25, 1851.
Lathes	T. R. Bailey	Lockport, N. Y.	July 1, 1851.
Lathes, chucks for	Thos. J. Eddy, administrator of Jos. Hyde	Troy, Rensselaer county, N. Y.	Dec. 9, 1851.
Lath machines	William Merril	Randolph, Portage county, Ohio	Sept. 23, 1851.
Lath machines	G. W. Tolhurst	Cleveland, Ohio	Dec. 9, 1851.
Lathes, securing pinions, &c., of watches in	J. H. Bottom	New York, N. Y.	July 15, 1851.
Mandrels, expanding	Walter Sherwood	Providence, R. I.	Dec. 2, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Matches, machinery for making	Ira H. Smith, assignor to Lemuel D. Smith	Wolcott, Conn.; Waterbury, Conn.	April 29, 1851.
Mitre boxes	Mathew Spear	Bowdoinham, Lincoln county, Me.	Sept. 30, 1851.
Planes, hand	Benjamin F. Bee	Harwick, Barnstable county, Mass.	Nov. 11, 1851.
Planing machines	Daniel H. Southworth	New York, N. Y.	Feb. 18, 1851.
Planing machines	John D. Beers and Isaac Winslow	Philadelphia, Pa.	Feb. 25, 1851.
Planing machines	Rufus Bixly, Cyrus Bixly, and John Garst	Dayton, Ohio	May 13, 1851.
Planing machines	Geo. W. Beardslee	Buffalo, N. Y.	May 20, 1851.
Planing machines	Nelson Barlow	St. Louis, Mo.	May 27, 1851.
Planing machines	George W. Beardslee	Albany, N. Y.	Nov. 4, 1851.
Planing machines, cutters for	Jas. M. Patton and Wm. F. Fergus, assignors to John C. Da Costa	Philadelphia, Pa.	Dec. 23, 1851.
Planing machines for dressing the edges of boards	William E. Cornell	Boston, Mass.	Jan. 1, 1851.
Saw-filing machine	Thomas M. Chapman	Old Town, Penobscot county, Me.	Sept. 2, 1851.
Saw-filing machinery, vice-jaw for	George W. Putnam	Morean, N. Y.	May 27, 1851.
Saws for sawing and smoothing boards	George F. Woolston	Orangeburg, dist. of Orangeburg, S. C.	Sept. 30, 1851.
Saw-mills	Isaac Straub	Cincinnati, Ohio	Feb. 18, 1851.
Saw-mills	Lemuel Hedge, assignor to George W. Hedge	Brooklyn, N. Y.	April 22, 1851.
Saw-mills	Martin Rich	Fairfield, Wis.	May 13, 1851.
Saw-mills, feeding logs in	Charles Ketchum	Pen Yan, Yates county, N. Y.	Dec. 9, 1851.
Sawing machines	Pearson Crosby	Fredonia, N. Y.	April 8, 1851.
Saws, &c., machinery for hardening and straightening	Henry Waterman	Williamsburg, N. Y.	May 27, 1851.
Saw-set	Elijah S. Holkins	Painesville, Ohio	April 8, 1851.
Saw-set	Hiram Strait	Covington, Ky.	April 8, 1851.
Saw-set vice	William Hinds	Cooperstown, N. Y.	July 1, 1851.
Saws, teeth of	George F. Woolston	Orangeburg, S. C.	Mar. 11, 1851.
Saw-mills, setting logs in	John W. Robbins	Campden, Ohio	April 14, 1851.
Sawing volutes, machine for	Elijah Whiten	Hingham, Plymouth county, Mass	Sept. 30, 1851.
Shingle machines	Franklin Skinner	Dunkirk, Chatauque county, N. Y.	Nov. 25, 1851.
Shingles, machines for dressing	Seymour Carver	Geneva, Ill.	June 17, 1851.
Splint machines	Henry Mellish	Walpole, N. H.	April 1, 1851.
Splint machines	Lewis L. Gilliland	Dayton, Ohio	April 29, 1851.
Staves dressing machine	William Hawkins	Milwaukie, Wis.	July 22, 1851.
Stave jointing machines	Daniel Drawbough	White Hill P. O., Cumberland co., Pa.	Nov. 11, 1851.
Staves, machines for dressing	Lewis S. Chichester	Williamsburg, Long Island, N. Y.	Nov. 4, 1851.
Staves, machines for jointing	William McGuire	Cincinnati, Ohio	Jan. 7, 1851.
Staves, machines for sawing and dressing	Dennison Woodcock	Independence Centre, N. Y.	July 15, 1851.
Staves, machines for jointing	Lewis S. Chichester	Williamsburg, King's county, N. Y.	Aug. 12, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Tenoning, boring, &c., machines for	Martin and Thomas R. Way	Paintersville, Ohio	Mar. 11, 1851.
Tonguing, jointing and rebating tool for	John A. Fry	Edinburg, Va	Feb. 18, 1851.
Tool, half adjustable	Peter H. Niles	Boston, Mass	Aug. 26, 1851.

CLASS XV.—*Stone and clay manufactures, including machines for pottery, glass-making, brick-making, dressing and preparing stone, cements, and other building materials.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Brick machines	Mahlon Gregg	Philadelphia, Pa	June 17, 1851.
Brick machines	John J. Riddle	Covington, Ky	July 22, 1851.
Brick machines	James Dane, Darius Healey, and Gary Cumings, assignors to Isaac and Francis Dane	Derby, Vt	Aug. 5, 1851; antedated June 17, 1851.
Brick machines	Luther Brown	Canandaigua, N. Y	Aug. 5, 1851.
Brick machines	Isaac Gregg	Pittsburg, Pa	Aug. 5, 1851.
Brick machines	Richard Long	Columbus, Ohio	Aug. 19, 1851.
Brick, machines for preparing clay for making	Heman Whipple	Port Richmond, N. Y	Mar. 25, 1851.
Brick presses	Jacob Scheitlin	Louisville, Ky	Jan. 21, 1851.
Brick presses	John J. Riddle	Covington, Ky	April 1, 1851.
Brick presses	J. Z. A. Wagner	Philadelphia, Pa	April 8, 1851.
Brick presses	Joseph Grant	Providence, R. I	May 13, 1851.
Clay, machines for working	Daniel and George Duchemin	Cincinnati, Ohio	Dec. 2, 1851.
Clay pipes, manufacture of	Joseph Putnam	Salem, Mass	Sept. 30, 1851.
Earthenware, baked, ornamenting	Ralph B. Beech	Kensington, Ky	June 3, 1851.
Glass, frosting plates of	Isaac Taylor	New York, N. Y	Nov. 11, 1851.
Glass, machinery for cutting	John P. Colne	New York, N. Y	Aug. 26, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Kilns, lime	Samuel Brown	Berwick, Pa	Aug. 26, 185 .
Kilns, lime	Richard E. Schroeder	Rochester, N. Y	May 6, 1851.
Marble, ornamenting	C. F. Hill and H. Hoffman	New York, N. Y	April 15, 1851.
Pottery and other ware, working clay for	John Akrill	Williamsburg, N. Y	Aug. 5, 1851.
Stone and other substances, machine for facing and polishing	Albert Eames	Springfield, Mass	June 10, 1851.
Stone drilling machine	Henry Goulding	Boston, Mass	Sept. 16, 1851.
Stone, machines for dressing	Joseph V. Tilton	Marcellus, Onondaga county, N. Y	Oct. 21, 1851.
Stone, machines for dressing	Wiliam Wheeler	West Poultney, Vt	Dec. 23, 1851.

CLASS XVI.—*Leather, including tanning and dressing, manufactures of boots, shoes, saddlery, harness, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Boot crimps	Nathan Dawes and Higgins Harrison	Little York, N. J	May 27, 1851; antedated Jan. 31, 1851.
Boot crimps	Hartwell Stanley	Wilmington, Vt	Aug. 19, 1851.
Boot forms, machine for dressing	Joseph Burgess	Leicester, Mass	July 22, 1851.
Boots and shoes, machines for cutting the soles of	Jos. Steger, assignor to Wm. Mitchell	Roxbury, Norfolk co., Mass; Boston, Mass	Nov. 11, 1851.
Boots and shoes, machines for pegging	Alpheus C. Gallahue	Matamoras, Washington co., Ohio	Oct. 28, 1851.
Boot-trees	Davis R. Hendrix	Pottstown, Montgomery co., Penn	Oct. 28, 1851.
Collars, for harness	Joseph W. Briggs	Cleveland, Ohio	June 3, 1851.
Collars, horse	Richard Rickey	Rutland, Ohio	Nov. 11, 1851.
Collars, horse, machines for forming	Isaac Davis	Mechanicsburg, Champaigne co., Ohio	Nov. 4, 1851.
Clogs, or patterns	Charles W. Stearns	Springfield, Mass	April 22, 1851.
Gauges, feather-edging for shoemakers'	J. Jenkins	Andover, Essex co., Mass	July 22, 1851.
Harness-saddles	John McLain	Circleville, Pickaway co., Ohio	Dec. 23, 1851.
Harness, saddle-trees for	Jas. A. Lawrence, assignor to Roberts & Lamsen	New Haven, Conn	July 22, 1851.
Hides, bating and tanning	William B. Milligan	Edinburg, Shenandoah co., Va	Nov. 4, 1851.
Hides, machines for cutting	Jacob C. Flint	Boston, Mass	Nov. 11, 1851.
Hides, machines for preparing	Thomas W. Jones	Philamath, Ga	Feb. 4, 1851.
Lap anvils for shoemakers	Henry Brunk	Albany, N. Y	May 27, 1851.
Lasts, blocks, fastenings for	Levi R. Rockwood, assignor to Joseph L. Woodward	Upton, Worcester co., Mass	Sept. 16, 1851.
Leather, machines for splitting	William Panton	Milton, Mass	July 15, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Leather, machines for stretching	Wm. Sirevell and Danl. Brown	Albany, N. Y	April 22, 1851.
Leather, machines for stretching	Bradford Rowe	Albany, N. Y	April 22, 1851.
Leather splitting machines	A. Richardson	North Enfield, Grafton co., N. H,	Sept. 16, 1851.
Leather tubes, machines for making	Newell Wylyss, assignor to Chas. Collins and Newell Wylyss	Glastenbury, Hartford co., Conn	Dec. 23, 1851.
Saddles	John C. fr. Salomon	Cincinnati, Ohio	Oct. 21, 1851.
Saddles, spring	Joseph C. Smith	Stoughstown, Penn	April 29, 1851.
Shoes, India rubber	Horace H. Day	Jersey City, N. J	May 20, 1851.
Shoe latches	Isaac Bannister	Newark, N J	Sept. 23, 1851.
Spring saddles	John C. fr. Salomon	Cincinnati, Ohio	Nov. 18, 1851.
Tanning	Nathan C. Towle	Washington, D. C	Oct. 7, 1851.
Trunk handles	Elijah A. Andrews	New Britain, Conn	Mar. 18, 1851.

CLASS XVII.—*Household furniture, machines and implements for domestic purposes, including washing machines, bread and cracker machines, feather dressing, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Bedsteads	Harvey W. Sabin	Canandaigua, Ontario co., N. Y	July 1, 1851.
Bedsteads	Ira Russell	Dedham, Mass	Sept. 16, 1851.
Bedsteads	Levi Newcomb, jr	New Bedford, Mass	Nov. 11, 1851.
Bedsteads, attaching cutters for cutting screws on rails of	Jacob Zimmer	Tiffin, Seneca co., Ohio	Dec. 23, 1851.
Bedstead fastenings	James R. Kai and Spencer Lewis	Tiffin, Ohio	May 6, 1851.
Bedsteads, machine for cutting screws on rails of.	Spencer Lewis	Rochester, N. Y	Oct. 7, 1851.
Bedsteads, machines for cutting screws on posts and rails of	O. Thornly	Lebanon, Ind	Oct. 7, 1851.
Bedstead rails, machines for cutting screws on	H. Gross and Wm. Campbell	Tiffin, Ohio	April 1, 1851.
Bread cutters	A. E. Lazell and D. Lazell	Chicopee Falls, Mass	July 1, 1851.
Brushes and brooms, handles of	L. F. Cavanaugh	Newfield, Tompkins co., N. Y	July 1, 1851.
Brushes, manufacture of	A. R. Davis	East Cambridge, Mass	Aug. 19, 1851.
Cabbage cutters	Hiram Carver	Edinborough, Va	Aug. 26, 1851.
Chair seats	John W. Drummond, assignor to Smith Ely	Skeneateles, Onondaga co., N. Y.; New Brighton, N. Y	Dec. 16, 1851.
Coffee roasters	Edward Whitely	Boston, Mass	April 22, 1851.
Cradles, swinging	Lucius F. Whitaker	Raleigh, Wake co., N. C	Oct. 21, 1851.
Cradles, swinging	S. W. Knowles	Middletown, Conn	Oct. 28, 1851.
Cutters, cheese, butter and bread	Benjamin F. Adams	Bangor, Me	Nov. 11, 1851.
Desks	John T. Hammitt	Philadelphia, Penn	Nov. 4, 1851.
Desks	J. H. Morris and D. Flanders	Parishville, St. Lawrence co., N. Y.	Nov. 18, 1851.
Drying fruits, and other articles, revolving frames for	J. C. Dickey	Washington, D. C	June 3, 1851.
Easy chairs, for invalids, &c	Patrick O'Neil	Brooklyn, N. Y	Sept. 23, 1851.
Fastening pedestals to columns	Wm. and Wm. H. Lewis	New York, N. Y	June 24, 1851.
Gongs	Vine B. Starr	East Hampton, Middlesex co., Conn	Nov. 18, 1851.
Mattresses, spring, for invalids	David Baird	New York, N. Y	Jan. 7, 1851; antedated Oct. 1, 1850.
Mattresses, stuffing, &c, machines for cutting wood into shreds, and crimping them for	Edwin K. Browning	Utica, N. Y	July 15, 1851.
Meat-cutting machines	Thomas Vanderslice	Valley Forge, Penn	May 6, 1851.
Peeling and cutting peaches	Joshua O. Ward	Pleasant Valley, Dutchess co., N. Y	Oct. 21, 1851.
Quilting frames and apparatus	Abraham Kaufman	Orrstown, Penn	Jan. 1, 1851.
Sad-irons	Edward Clapp, assignor to Ed. Clapp & George Alden	Dedham, Mass	Feb. 25, 1851.
Sad-irons, removable handles to	Theodore R. Timby	Meridian, N. Y	Mar. 18, 1851.
Tables, ladies' work	Celia R. P. Foster, late Celia R. P. Wood	Canandaigua, N. Y	April 8, 1851.
Tables, leaves, fastening down of	Lewis J. Mason	Franklinville, N. Y	April 8, 1851.
Tables, extension	Francis Hoguet	Philadelphia, Pa	Feb. 25, 1851.
Tables, extension	Lewis Thorn	Philadelphia, Pa	Mar. 25, 1851.
Wash-boards	William T. Barnes	Buffalo, N. Y	June 17, 1851.
Washing apparatus	James T. King	Baltimore, Md	Oct. 21, 1851.
Washing machines	John O'Neil	Xenia, O	June 10, 1851.
Washing machines	John Boardman	Little Valley, N. Y	June 15, 1851.
Washing machines	David Allen	St. Louis, Mo	Aug. 26, 1851.
Washing machines	Erastus Lawrence	Dublin, Ind	Sept. 9, 1851.
Window-curtain fastening	Hugh Guyer	Albany, N. Y	Mar. 11, 1851.
Window-curtain fixtures	S. S. Putnam	Boston, Mass	April 15, 1851.

V.—*Classified list of patents, &c.*—Continued.

Class XVIII.—*Arts, polite, fine, and ornamental, including music, painting, sculpture, engraving, books, paper, printing, binding, jewelry, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Account-books, machines for numbering the pages of	John McAdams	Boston, Mass.	Aug. 12, 1851.
Æolean attachments	Gustavus W. Ingalls	Concord, N. H.	Dec. 23, 1851.
Books, machine for finishing the backs of	Charles Starr	New York, N. Y.	June 24, 1851.
Carving machines	Lewis S. Chichester	Williamsburg, N. Y.	June 3, 1851.
Copying presses	A. A. Wilder	Detroit, Mich.	Mar. 11, 1851.
Daguerreotype apparatus	William, Wm. H. & H. J. Lewis	New York, N. Y.	Nov. 11, 1851.
Daguerreotype pictures	Charles J. Anthony	Pittsburg, Pa.	Jan. 1, 1851.
Daguerreotype plates, buffing apparatus for	William & Wm. H. Lewis	New York, N. Y.	July 22, 1851.
Daguerreotype, securing in monumental stones	Solon Jenkins, jr.	West Cambridge, Mass.	Mar. 11, 1851.
Embossing backs of books, tool for	Charles Starr	New York, N. Y.	Jan. 21, 1851.
Enameling mouldings, &c., machinery for	Robert Marcher	Cornwall, Orange county, N. Y.	Oct. 21, 1851.
Ink-stands	Henry Whitney, jr.	Cambridge, Mass.	July 1, 1851.
Ink-stands, fountain	Francis Draper	East Cambridge, Mass.	Jan. 7, 1851.
Jasper mineral, composition resembling	John Paige Pepper	New Britain, Hartford county, Conn.	Dec. 16, 1851.
Lenses, adjusting	William & William H. Lewis	New York, N. Y.	Dec. 16, 1851.
Marble, imitating	Hiram Tucker	Cambridge, Mass.	Oct. 14, 1851.
Musical instruments, bellows for	Marvin Smith	New Haven, Conn.	Feb. 25, 1851.
Organs and piano fortes, combining	R. M. Ferris	New York, N. Y.	Dec. 16, 1851.
Pens, fountain	N. A. Prince	New Gloucester, Cumberland co., Me.	Sept. 30, 1851.
Pens for ruling paper	Alfred Hathaway	Boston, Mass.	Jan. 28, 1851.
Photographic purposes, mercury baths for	John Moulson	Philadelphia, Pa.	Sept. 2, 1851.
Piano fortes	Michael Miller	Rochester, Monroe county, N. Y.	July 1, 1851.
Piano fortes	L. H. Browne	Boston, Mass.	Sept. 23, 1851.
Piano fortes	T. Gilbert	Boston, Mass.	Sept. 30, 1851.
Piano fortes	Frederick Mathushek	New York, N. Y.	Oct. 28, 1851.
Piano fortes	John Buck	New York, N. Y.	Mar. 11, 1851.
Piano forte action	Randolph Kretor	New York, N. Y.	Sept. 9, 1851.
Piano forte action	R. M. Kerrison	Philadelphia, Pa.	Sept. 9, 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Piano forte action	James A. Gray	Albany, N. Y.	Sept. 9, 1851.
Piano forte horizontal, square	George Bacon & Richard Raven	New York, N. Y.	Aug. 26, 1851.
Piano forte strings	Henry J. Newton	New York, N. Y.	Oct. 21, 1851.
Piano fortes, upright	Henry Klepfer	Cincinnati, Ohio	Mar. 25, 1851.
Printing house paper, machines for	Milton D. Whipple, assignor to Essex Company	Lowell, Mass.	Sept. 16, 1851.
Printing in colors, machines for	Richard S. Weaver	Maysville, Ky.	Oct. 28, 1851.
Printing names of subscribers on newspapers, &c.	Henry Moeser	Pittsburg, Pa.	June 24, 1851.
Printing presses	Stephen P. Ruggles	Boston, Mass.	Jan. 1, 1851.
Printing presses	George P. Gordon	New York, N. Y.	Aug. 5, 1851.
Printing presses	Jacob Worms, assignor to J. Phalem	Paris, France; New York, N. Y.	Sept. 23, 1851; French patent dated May 19, 1849.
Printing presses	John R. Hathaway & John P. Strippel	Norfolk, Va.	Oct. 21, 1851.
Printing presses	T. H. Dodge	Nashua, Hillsborough county, N. H.	Nov. 18, 1851.
Ruling machines, regulators for the penbeam in	W. O. Hickok	Harrisburg, Pa.	June 17, 1851.
Ruling paper, machines for	G. L. Wright and J. Ames	Springfield, Mass.	Dec. 23, 1851.
Sounding boards, for musical instruments, construction of	C. Bogart	Charlestown, Mass.	Dec. 9, 1851.
Stamps, hand	Stephen P. Ruggles	Boston, Mass.	Sept. 23, 1851.
Stamps, letter	Benjamin Chambers	Washington, D. C.	Sept. 23, 1851.
Stereotype plates, moulding and casting	Charles Hobbs	New York, N. Y.	Sept. 2, 1851.
Type-casting machines	John J. Sturgess, ass'r to H. H. Green	New York, N. Y.	Sept. 9, 1851.
Violins, &c., construction of	William B. Tilton	Carrollton, Ala.	Sept. 2, 1851.
Wind instruments, the mouth-piece for	Charles L. Meech	Preston, New London county, Ct.	Oct. 21, 1851.
Writing, apparatus for giving ease to the arm in	Jos. G. Goshen and Wm. H. Towers	Sherleysburg, Pa., Bucyrus, Ohio	April 29, 1851.

Class XIX.—*Fire-arms and implements of war, and parts thereof, including the manufacture of shot and gunpowder.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Cannon, for throwing chain-shot	Adam Lemmer	Newark, N. J.	Nov. 18, 1851.
Fire-arms, breech-loading	Edward Maynard	Washington, D. C.	May 27, 1851.
Fire-arms, breech-loading	Horace Smith, assignor to Courtland Palmer	New York, N. Y.	Aug. 26, 1851.
Fire-arms, revolving breech	P. W. Porter	Memphis, Tenn.	July 8, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Fire-arms, revolving breech	James Warnen	Springfield, Mass	July 15, 1851.
Lock, fly-tumbler, for fire-arms	Stanhope W. Marston	New York, N. Y	Jan. 7, 1851.
Pistols, revolving breech	Joshua Stevens, assignor to Massachusetts Arms Company	Chicopee, Hampden county, Mass	Oct. 7, 1851.
Repeating fire-arms, means for revolving the breeches of	James Warnen	Springfield, Mass	Jan. 7, 1851.

Class XX.—*Surgical and medical instruments, including trusses, dental instruments, bathing apparatus, &c.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Baths, shower	William H. Brown	Worcester, Worcester county, Mass	Oct. 14, 1851.
Dental hydraulic cups	James Harrison	Jamestown, Chatauque county, N. Y	Aug. 26, 1851.
Forceps, dental	J. C. Burch	Evansville, Ia	Sept. 9, 1851.
Scarificators	Frederick Leypoldt	Philadelphia, Pa	May 20, 1851.
Shoulder-braces, combined with abdominal supporters	John S. Dare	Knightstown, Ia	Aug. 12, 1851.
Sight, means of renovating and correcting	Jonathan Ball	New York, N. Y	April 22, 1851.
Soda powders, &c., machines for crimping package papers for	Carlos A Cook	Lowell, Mass	Dec. 2, 1851.
Stammering, instruments for the cure of	Robert Bates	Philadelphia, Pa	Sept. 30, 1851.
Stethescopes	Nathan B. Marsh	Cincinnati, Ohio	Dec. 16, 1851.
Supporters, abdominal	Moses L. Knapp	Painesville, Ohio	Jan. 28, 1851.
Supporter, abdominal	Allen J. Lonsbury	Somerville, Fayette county, Tenn	Nov. 11, 1851.
Teeth, mineral setting	John Allen	Cincinnati, Ohio	Dec. 23, 1851.
Teeth, porcelain inserting	William Willshire Riley	Columbus, Ohio	Nov. 18, 1851.
Teeth, setting	Adolph F. Ahrens	Philadelphia, Pa	May 13, 1851.
Teeth, setting	Adolph F. Ahrens	Philadelphia, Pa	May 13, 1851.

Class XXI.—*Wearing apparel, articles for the toilet, &c., including instruments for manufacturing.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Buttons, silk, covered	H. Heinemann	New York, N. Y	July 8, 1851.
Combs, cutting machines	Horace S. Cook, assignor to H. S. Cook and S. Colbron	Leominster, Mass	June 3, 1851.
Combs, cutting machines	Thomas W. Hill	Leominster, Mass	June 10, 1851.
Combs, machines for cutting	S. Curtis	Newtown, Fairfield county, Ct	Nov. 18, 1851.
Fastenings, for garments	Elias Howe, jr	Cambridge, Middlesex, Mass	Nov. 25, 1851.
Garments, apparatus for pressing	Joseph W. Thorpe	South Weare, Hillsborough co., N. H	Dec. 16, 1851.
Hat bodies, machines for making	Daniel Barnam	Philadelphia, Pa	July 1, 1851.
Hats, machines for pressing	John Stearns	Templeton, Worcester county, Mass	July 8, 1851.
Hooks and eyes, fastening to paper cards	Chester J. Carrington	Waterbury, Ct	Sept. 9, 1851.
Hooks and eyes, wire	Charles Atwood	Derby, New Haven county, Ct	July 1, 1851.
Suspenders	Julius Hotchkiss, ass'r to the Hotchkiss and Meriman Manufacturing Co.	Waterbury, New Haven county, Ct	Dec. 23, 1851.
Sword canes	S. A. Hudson	Worcester, Mass	Sept. 9, 1851.
Tailors' measures	James McGinnis	Lockport, N. Y	Dec. 2, 1851.
Tailors' measures	Edward Virtue	Philadelphia, Pa	Dec. 16, 1851.

Class XXII.—*Miscellaneous.*

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Ayes and noes, machine for taking	G. William Yerby	Washington, D. C	Aug. 5, 1851.
Boxes, machine for cutting out the corners and scoring the edges of paper for	Andrew Dennison	Brunswick, Me	Dec. 4, 1851, antedated April 15, 1851.
Box opener	Geo. C. Taft	Worcester, Worcester county, Mass	Oct. 21, 1851.
Baby jumper	C. Rice	Elizabethtown, N. J	Oct. 28, 1851.
Burglar alarms	John G. Bolen	New York, N. Y	Oct. 21, 1851.
Cork cutting machine	William King	New York, N. Y	July 8, 1851.

V.—*Classified list of patents, &c.*—Continued.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.
Corks, machines for cutting	George Hammer	Philadelphia, Pa	Oct. 14, 1851.
Fly trap	Harvey Snow and Luther P. Smart	Lowell, Mass	July 29, 1851.
Harpoon, exploding	Charles Burt	Belfast, Me	May 6, 1851.
Horn and shells, machines for splitting	Jabez Robins, assignor to Joel R. Morse	Leominster, Mass	June 24, 1851.
Ice, process for the artificial production of	John Gorrie	New Orleans, La	In England, Aug. 22, 1850; in U. S., May 6, 1851.
Ratans, machinery for cutting, &c.	Sylvanus Sawyer	Templeton, Mass	June 24, 1851.
Swings, portable	Enoch S. Farson	Philadelphia, Pa	May 27, 1851.
Tenpins, apparatus for setting up	Thomas J. Sloan	New York, N. Y	April 8, 1851.
Tenpins, method of setting up	Thomas E. Shull	Lewistown, Mifflin county, Pa	Dec. 23, 1851.
Water closets, portable	George R. Wilmot	Meriden, New Haven county, Conn	Oct. 21, 1851.
Yeas and nays, machines for taking	Thos. B. Stout and Jas. F. Morrell	Keyport, N. J	Oct. 28, 1851.

PATENTS REISSUED DURING THE YEAR 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.	Reiss'd.
				1851.
Augers, method of attaching to their handles	Esther L. Larkin, administratrix of Jno. E. Larkin, deceased.	Milton, N. Y	Nov. 19, 1850	June 17
Bats for felting, &c., machinery for forming	Thos. R. Williams, assig'r to J. B. Hyde	New York, N. Y	Dec. 14, 1840	May 6
Bats in felting, &c., machinery for hardening	Thos. R. Willliams, assig'r to J. B. Hyde	New York, N. Y	Dec. 14, 1840	May 6
Boiler, steam, and furnace thereof	Horace Boardman	Plattsburg, N. Y	Aug. 14, 1849	Feb. 25
Carriages	John Jones	Clyde, N. Y	Jan. 14, 1851	Mar. 4
Composition for covering hams, &c	Horace Billings	Beardstown, Ill	April 9, 1850	Mar. 25
Cut-off and working the valves of steam-engines	George H. Corliss	Providence, R. I	Mar. 10, 1849	May 13
Door locks	John P. Sherwood, assignor to Calvin Adams.	Pittsburg, Pa	Dec. 17, 1842	May 13

Inventions or discoveries.	Patentees.	Residence.	Date of patent.	Reiss'd.
Evaporators and condensors	Edward Lynch	Brooklyn, N. Y	July 18, 1848	Mar. 11
Felloes for the wheels of carriages and wagons, machine for setting or bending.	Edward Reynolds	Haddonfield, N. J	July 17, 1835, extended.	Jan. 1
Fire-arms	William W. Hubbell	Philadelphia, Pa	July 1, 1844	Mar. 11
Guages, steam and vacuum	Paul Stillman	New York, N. Y	May 9, 1848	July 29
Jacquard, machinery for weaving all kinds of figured cloth.	Alexander Calderhead	Philadelphia, Pa	Feb. 3, 1841	May 13
Manifold permutation locks	Robert Newell	New York, N. Y	Sept. 25, 1838	Dec. 2
Mouldings, machinery for making	Alfred T. Serrell	New York, N. Y	May 16, 1848	Jan. 7
Mowing machine	Wm. F. Ketchum	Buffalo, N. Y	July 10, 1847	Oct. 21
Paper-folding machines	Edward N. Smith, assignor through others to American Paper-folding Co.	West Brookfield, Mass. Springfield, Mass	Nov. 27, 1849	Jan. 7
Paper, rag; machines for cleaning	James Phelps	West Sutton, Mass	Nov. 24, 1843	Mar. 25
Sewing machines	Sherburn C. Blodget and John A. Lerow.	Georgetown, Mass., and Boston, Mass.	Oct. 2, 1849	Jan. 4
Sofa bedsteads	Russell Scarritt	St. Louis, Mo	Oct. 8, 1850	Jan. 7
Stone dressing	Charles Wilson	Springfield, Mass	Mar. 13, 1847	Mar. 4
Scythes to the snath, fastenings of	E. S. Clapp	Montague, Franklin co., Mass.	Mar. 18, 1851	July 8
Screw wrench	Solyman Merrick	Springfield, Mass	Original patent, Aug. 17, 1835; reissued May 17, 1842; extended 7 years from August 17, 1849.	Nov. 25
Tanning processes	Harmon Hibbard, assignor to W. W. Reid.	Rochester, N. Y	Oct. 16, 1849	Feb. 11
Thread, machinery for doubling, twisting, and reeling.	Frank Cheney	Manchester, Conn	Oct. 9, 1847	Apr. 29

CLASSIFIED LIST OF PATENTS.—DESIGNS.

Designs.	Patentees.	Residence.	Date of patent.
Bedsteads	P. M. Hutton	Troy, N. Y	May 20, 1851.
Bedsteads, cast iron	Pelatiah M. Hutton	Troy, N. Y	Sep. 2, 1851.
Bust of Jenny Lind	Thomas Ball	Boston, Mass	April 29, 1851.
Clock frame	Nathaniel A. Batchelor	New York, N. Y	May 13, 1851.
Comb for ladies	Aaron Cook	Newtown, Fairfield co., Conn	Aug. 19, 1851.

V.—*Classified list of patents, &c*—Continued.

Designs.	Patentees.	Residence.	Date of patent.
Floor oil-cloth	James Hutchinson, assignor to D. A. E and N. Powers	Troy, N. Y.; Lansingburg, N. Y.	May 13, 1851.
Fences, cast iron	John T. Davy	Troy, N. Y.	Oct. 21, 1851.
Floor oil-cloth	James Hutchinson, assignor to Deborah, Albert E., and N. B. Powers	Troy, N. Y.; Lansingburg, N. Y.	Sep. 2, 1851.
Furnace registers	Gardner Chilson	Boston, Mass	Mar. 4, 1851.
Furnace registers	Gardner Chilson	Boston, Mass	Mar. 4, 1851.
Furnace registers	Gardner Chilson	Boston, Mass	Mar. 4, 1851.
Furnace registers	Gardner Chilson	Boston, Mass	Mar. 4, 1851.
Gates, metallic	Ebenezer Weeman	Charlestown, Mass	Sep. 16, 1851.
Grates, parlor	Joseph Pratt	Boston, Mass	Mar. 25, 1851.
Grates, parlor	Winslow Ames, assignor to Hartshorn and Ames	Nashua, N. H.; Boston, Mass	April 1, 1851.
Hat stand	Charles Muller	Tompkinsville, Richmond co., N. Y.	Nov. 18, 1851.
Iron railing	Frederick Fitzgerald, assignor to Silas C. Herring and John Ryer	New York, N. Y	Nov. 18, 1851.
Pedestals and columns	W. and W. H. Lewis	New York, N. Y	Mar. 25, 1851.
Presses, mantel-pieces, &c., for frames for	Edmund L. Freeman	Bellville, Jefferson co, N. Y.	Dec. 23, 1851.
Shovel, stands for	Charles Zeuner, assignor to M. Greenwood & Co.	Cincinnati, Ohio	Sep. 9, 1851.
Stoves	R. J. Blanchard, assignor to Learned and Thatcher	Albany, N. Y.	July 29, 1851.
Stoves	R. J. Blanchard, assignor to Learned and Thatcher	Albany, N. Y.	July 29, 1851.
toves	R. J. Blanchard, assignor to Learned and Thatcher	Albany, N. Y.	July 29, 1851.
Stoves	Silas Merchant	Cleveland, Ohio	Sep. 2, 1851.
Stoves	Sam. H. Sailor, assignor to North, Harrison, and Chase	Kensington, Philadelphia co., Pa.; Philadelphia, Pa.	Sep. 2, 1851.
Stoves	Anthony W. Jones, assignor to James McGregor, jr.	New York, N. Y.; Troy, N. Y.	Sep. 2, 1851.
Stoves	Lyman Cobb	Akron, Summit co., Ohio	Oct. 14, 1851.
Stoves	Charles J. Woolson	Cleveland, Ohio	Oct. 14, 1851.

Stoves	William Savery	New York, N. Y.	Oct. 21, 1851.
Stoves	Ezra Ripley, assignor to Chollar, Sage, and Dunham	Troy, N. Y.	Oct. 28, 1851.
Stoves	S. W. Gibbs, assignor to North, Harrison, and Chase	Albany, N. Y.; Philadelphia, Pa.	Nov. 11, 1851.
Stoves	W. Ames, assignor to J. Hartshorn and W. Ames	Nashua, Hillsborough co., N. H.	Dec. 9, 1851.
Stoves	Jeremiah D. Green, assignor to Bachus, Bacon & Co.	Troy, N. Y.; Le Roy, N. Y.	Dec. 9, 1851.
Stoves	Samuel W. Gibbs, assignor to Jagger, Tredwell, and Perry	Albany, N. Y.	Mar. 4, 1851.
Stoves	Samuel W. Gibbs, assignor to Jagger, Tredwell, and Perry	Albany, N. Y.	Mar. 4, 1851.
Stoves	Samuel W. Gibbs, assignor to Jagger, Tredwell, and Perry	Albany, N. Y.	Mar. 4, 1851.
Stoves	Samuel W. Gibbs, assignor to Jagger, Tredwell, and Perry	Albany, N. Y.	June 10, 1851.
Stoves	John S. Perry	Albany, N. Y.	Mar. 4, 1851.
Stoves	J. Wager, D. Pratt, and V. Richmond	Troy, N. Y.	May 20, 1851.
Stoves	Ezra Ripley, assignor to D. Stafford & Co.	Troy, N. Y.	May 27, 1851.
Stoves	N. P. Richardson	Portland, Maine	May 27, 1851.
Stoves	William L. Hathaway	Deighton, Mass.	May 27, 1851.
Stoves	W. L. Sanderson, assignor to R. R. Finch	Troy, N. Y.; Peekskill, N. Y.	June 3, 1851.
Stoves	A. Cox, E. Johnson, and D. B. Cox	Troy, N. Y.	June 10, 1851.
Stoves	A. Cox, E. Johnson, and D. B. Cox	Troy, N. Y.	June 10, 1851.
Stoves	W. G. Hallman	Philadelphia, Pa.	June 10, 1851.
Stoves	Jno. F. Rathbone	Albany, N. Y.	June 10, 1851.
Stoves	D. Stuart and J. Beesley, assignors to W. P. Cresson	Philadelphia, Pa.	June 10, 1851.
Stoves	Joseph G. Lamb	Cincinnati, Ohio	June 17, 1851.
Stoves	Joseph G. Lamb	Cincinnati, Ohio	June 17, 1851.
Stoves	Samuel A. House	Mechanicsville, N. Y.	June 24, 1851.
Stoves	W. C. Davis	Cincinnati, Ohio	July 8, 1851.
Stoves	N. S. Vedder, assignor to A. T. Dunham & Co.	Troy, N. Y.	July 29, 1851.
Stoves	Charles Gilbert and Mitchel G. Hallman, assignors to Charles Gilbert	Philadelphia, Pa.	Jan. 1, 1851.
Stoves	Elihu Smith	Albany, N. Y.	Jan. 7, 1851.
Stoves	Joseph G. Lamb	Cincinnati, Ohio	Jan. 21, 1851.

V.—*Classified list of patents, &c.*—Continued.

Designs.	Patentees.	Residence.	Date of patent.
Stoves	Sam. W. Gibbs, assignor to North, Harrison & Co	Albany, N. Y.; Philadelphia, Pa	Jan. 21, 1851; antedated Dec. 31, 1850.
Stoves	Conrad Harris and Paul W. Goiner	Cincinnati, Ohio	Jan. 28, 1851.
Stoves	Seth Williams, assignor to William Bird & Co	Nashua, N. H.; N. Chelmsford, Mass	April 8, 1851.
Stoves	James V. De Witt	Buffalo, N. Y	July 8, 1851.
Stoves	Samuel W. Gibbs, assignor to Jagger, Tredwell, and Perry	Albany, N. Y	April 8, 1851.
Stoves, air tight	N. P. Richardson	Portland, Maine	April 1, 1851.
Stoves, air tight	Frederick Schultz	Philadelphia, Pa	April 1, 1851.
Stoves, cooking	S. W. Gibbs, assignor to North, Harrison, and Chase	Albany, N. Y.; Philadelphia, Pa	July 8, 1851.
Stoves, cooking	John F. Rathbone	Albany, N. Y	July 8, 1851.
Stoves, cooking	William C. Davis	Cincinnati, Ohio	Jan. 1, 1851.
Stoves, cooking	Sam. W. Gibbs, assignor to Jagger, Tredwell, and Perry	Albany, N. Y	Jan. 21, 1851.
Stoves, cooking	Sam. A. House	Mechanicsville, N. Y	Feb. 4, 1851.
Stoves, cooking	S. H. Sailor, assignor to Warwick, Seibrandt & Co	Philadelphia, Pa	Feb. 25, 1851.
Stoves, cooking	Dutee Arnold	Providence, R. I	April 15, 1851.
Stoves, cooking	John Abendroth	Port Chester, N. Y	April 15, 1851.
Stoves, cooking	John F. Rathbone	Albany, N. Y	July 8, 1851.
Stove doors and panels	M. C. Burleigh	Somersworth, N. H	May 13, 1851.
Stove fronts	Ezra Ripley	Troy, N. Y	Sep. 30, 1851.
Stove, parlor	Ezra Ripley and N. S. Vedder, assignors to Lowe and Hicks	Troy, N. Y	Nov. 25, 1851.
Stoves, parlor	Joseph Pratt	Boston, Mass	July 8, 1851.
Stoves, parlor, plates of	Apollos Richmond, assignor to A. C. Barstow & Co	Providence, R. I	July 15, 1851.
Stove or furnace for a ventilating	E. P. Penniman, assignor to H. Ruttan	Rochester, N. Y.; Coburg, Canada	Sep. 16, 1851.
Stove plates	Lyman S. Hapgood	Boston, Mass	June 3, 1851.
Stove plates	Elijah P. Penniman	Rochester, N. Y	July 15, 1851.
Stove plates	Elijah P. Penniman	Rochester, N. Y	July 15, 1851.

Stove, plates of, Franklin	John F. Rathbone	Albany, N. Y	July 8, 1851
Stove registers	David Stuart and Jacob Beesley, assignor to W. P. Cresson	Philadelphia, Pa	Dec. 2, 1851.
Stove plates	Calvin Fulton	Rochester, N. Y	Sep. 2, 1851.
Stove plate, parlor	Apollos Richmond, assignor to A. C. Barstow & Co	Providence, R. I	Nov. 18, 1851.
Stoves, parlor	Samuel A. House	Mechanicsville, N. Y	Feb. 4, 1851.
Table	Nathan Chapin	Syracuse, Onondaga co., N. Y	Sep. 30, 1851.
Tomb, cast iron	H. K. Flinchbaugh	Conestoga, Pa	June 22, 1851.
Umbrella stands	Edward J. Delany, assignor to Hareis and Adamson	Philadelphia, Pa	Feb. 18, 1851.
Water coolers	W. Burnett	Cincinnati, Ohio	July 8, 1851.

PATENTS EXTENDED DURING THE YEAR 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of original patent.	Term of extension.
Brick machines	Nathaniel Adams	Cornwall, Orange co., Ct	Sept. 8, 1837.	7 y'rs from Sept. 8, 1851.
Car, railroad, supporting bodies	Richard Imlay	Philadelphia, Pa	Sept. 21, 1837.	7 ...do... Sept. 21, 1851.
Horse rake	Thos. D. Dewey, adm. of David Dewey	East Poultney, Vt	Nov. 23, 1837.	7 ...do... Nov. 23, 1851.
Looms	Edson Fessenden, conservator of Wm. Crampton	Hartford, Ct	Nov. 25, 1837.	7 ...do... Nov. 25, 1851.
Loom power for weaving coach-lace	Erastus B. Bigelow	Clinton, Mass	Ap'l 20, 1837.	7 ...do... Ap'l 20, 1851.
Plough	Bancroft Woodcock	Late of Mt. Pleasant, Pa., now of Wheeling, Va	June 14, 1837.	7 ...do... June 14, 1851.
Pressing cloth, paper, &c	Moses Bailey	Salisbury, Mass	July 5, 1837.	7 ...do... July 5, 1851.
Spinning woollen roving	C. H. Titcomb, adm'r of E. M. Titcomb, deceased	Late of Andover, Mass	July 29, 1837.	7 ...do... July 29, 1851.
Threshing and cleaning grain, machine for	John A. & Hiram A. Pitts	Springfield, O., and Alton, Ill.	June 29, 1837.	7 ...do... June 29, 1851.

V.—*Classified list of patents, &c.*—Continued.

ADDITIONAL IMPROVEMENTS GRANTED DURING THE YEAR 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.	Improvements added.
Churns	John O'Neil	Xenia, Ohio	July 30, 1850.	May 13, 1851.
Bedsteads	Henry Pace, sen.	Cincinnati, Ohio	Dec. 10, 1846.	Nov. 4, 1851.
Dye-stuff from spent madder, preparation of	Frederick Pianner	Providence, R. I.	Sept. 13, 1845.	Sept. 2, 1851.

DISCLAIMERS ENTERED DURING THE YEAR 1851.

Inventions or discoveries.	Patentees.	Residence.	Date of patent.	Disclaimers entered.
Crackers, cutting	William R. Nevins	New York, N. Y.	Oct. 17, 1835.	June 6, 1851.
Hide-handling cylinders, beaters in	James R. Innis	Easton, Pa.	Mar. 19, 1850.	Jan. 24, 1851.
Heddles wire, machinery for making	Abijah H. Williams	Utica, N. Y.	Sept. 11, 1849.	Mar. 6, 1851.

VI.

Alphabetical list of patentees for the year 1851.

No.	Patentees.	Inventions or discoveries.	Class.
7896	Abbott, Theodore T.	Tires for railroad car wheels	X.
368	Abendroth, John	Stoves, cooking	Design.
8501	Adams, Benjamin F.	Cutters, cheese, butter, and bread	XVII.
	Adams, Calvin. (See John P. Sherwood.)		
8477	Adams, Henry W.	Zinc, white, use of steam to make	IV.
	Adams, Nathaniel	Brick machine	Extension.
8091	Ahrens, Adolph F.	Teeth, setting	XX.
8091	Ahrens, Adolph F.	Teeth, setting	XX.
8282	Akins, William H., and J. D. Felthousen	Sewing machines	III.
8280	Akrill, John	Pottery and other ware, working clay for.	XV.
8309	Allen, David	Washing machines	XVII.
8621	Allen, John	Teeth, mineral, setting	XX.
7897	Allen, John L.	Carriage tops, raising	X.
8157	Allen, Nicholas T.	Harvesters, grain	I.
8240	Ambrose, D. R., and O. L. Reynolds	Cloth-folding machines	III.
	American Paper-folding Co. (See Edward N. Smith.)		
8619	Ames, J., and G. L. Wright	Ruling paper, machines for	XVIII.
362	Ames, Winslow, assignor to Hartshorn & Ames	Grates, parlor	Design.
429	Ames, W., assignor to Hartshorn & Ames	Stoves	Design.
8169	Anderson, Charles	Boilers, revolving	VI.
7981	Andrews, Elijah A.	Trunk handles	XVI.
7905	Andrews, Joseph E.	Steering apparatus	VII.
7865	Anthony, Charles I.	Daguerreotype pictures	XVIII.
8502	Anthony, David, sen	Scythe fastenings, construction of	I.
7881	Armsby, Joshua M. C.	Corn shellers	XIII.
8180	Armstrong, Samuel T.	Gutta-percha hollow ware	IV.
8147	Arnold, Alonzo C.	Bats for felt cloth, &c , crossing the fibres in forming	III.
367	Arnold, Dutee	Stoves, cooking	Design
7934	Ashcroft, E. H	Boilers, steam, insulated fusible plug for.	VI.
8198	Atwood, Charles	Hooks and eyes, wire	XXI.
	Atwood & Kellog. (See Chas. Todd.)		
8136	Avery, Cyrus	Horse power	XIII.
8045	Avery, Samuel	Blind slats, apparatus for operating	II.
7950	Avery, Thos. C.	Electro-magnetic engines	VIII.
8067	Babcock, Robert G.	Horse-shoe machine	II.
8320	Bacon, Geo., and Rd. Raven	Piano fortes, horizontal, square	XVIII.
	Backus, Bacon & Co., assignors. (See Jere. D. Green.)		
8196	Bailey, T. R.	Lathes	XIV.
7882	Baird, David	Mattresses, spring, for invalids	XVII.
	Baker, Wm. E. (See Grover & Baker)		
8553	Baldwin, Cyrus, assignor to Stark Mills	Looms for weaving bags	III.
8049	Ball, Jonathan	Light, means of renovating and correcting	XX.
369	Ball, Thomas	Bust of Jenny Lind	Design.
8344	Ball, William	Gold amalgamator	II.
8602	Ball, William	Pumps for elevating water mixed with mineral substances	XI.
8381	Banister, Isaac	Shoe latchets	XVI.
7951	Banks, Joseph	Buildings, iron, connexion for the beams and columns of	IX.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8243	Bantz, Sidney A., and Wm. Andrews	Mills for grinding corn and cobbs	XIII.
8125	Barlow, Nelson	Planing machines	XIV.
8161	Barnes, William T	Wash boards	XVII.
8116	Barnhill, Jacob	Planters, seed	I.
8195	Barnum, Daniel	Hat bodies, machines for making	XXI.
8563	Barrows, Thomas	Cloth, machines for stretching and drying	III.
8262	Barsantee, John H	Knitting machines	III.
8520	Bascom, Alonzo	Yarns, sizing and dyeing, apparatus for	III.
8603	Bass, William L	Lock, chronometric	II.
8418	Batchelder, John M	Telegraph wires, insulators for	VIII.
372	Batchelor, Nathaniel A	Clock frames	Design.
	Bates, John W., assignor. (See L. Lillie.)		
8394	Bates, Robert	Stammering, instrument for the cure of.	XX.
	Bayley, Moses	Pressing cloth, paper, &c	Extension.
8573	Beadleston, Ambrose S	Furnace, revolving reverberatory	II.
8504	Bean, Jonathan	Winnowing machines, screens of	I.
7923	Beardsley, Backus A	Stoves, cooking	V.
8098	Beardslee, George W	Planing machines	XIV.
8497	Beardsley, George W	Planing machines	XIV.
8426	Beatty, Charles H	Lock, door	II.
8503	Bee, Benjamin F	Planes, hand	XIV.
8140	Beech, Ralph B	Earthenwares, baked, ornamenting	XV.
7949	Beers, John D., and Isaac Winslow	Planing machines	XIV.
7937	Beers, Philo S	Irregular forms, machines for turning	XIV.
	Bell & Christie. (See Maria Vaughn.)		
	Bell & Christie. (See Maria Vaughn.)		
8574	Bell, Daniel D	Potato diggers	I.
7883	Bennet, Phineas	Pumps, rotary	XI.
8137	Bessemer, Henry	Cane juices, machines for expressing	IV.
8123	Biddle, William	Weighing machines for grain, self	XII.
7898	Bigelow, Erastus B	Looms for weaving piled fabrics	III.
7884	Bigelow, Erastus B	Looms for weaving tapestry carpets with particolored warp	III.
7982	Bigelow, Erastus B	Weaving, delivering particolored warps in	III.
7983	Bigelow, Erastus B	Looms, jacquard, for weaving cut-pile fabrics	III.
	Bigelow, Erastus B	Loom power for weaving coach lace	Extension.
8539	Bigelow, E. B	Woven fabrics, wires for making pile in.	III.
7899	Billings, A. M	Hubs and axles, connecting and disconnecting	X.
195	Billings, Horace	Composition for covering hams, &c	Reissue.
	Bird, Henry M. (See Daniel Wilson, jr.)		
8105	Bissell, Levi	Springs, carriage	X.
8498	Bissel, Levi, assignor to Levi Bissel and Lyman Kinsley	Springs, carriage	X.
8086	Bixby, Rufus, Cyrus Bixby, and John Garst	Planing machines	XIV.
8184	Blanc, John	Hemp, manufacture of, from okra	III.
401	Blanchard, Reuben J., assign'r to Learned & Thatcher	Stoves	Design.
402	Blanchard, Reuben J., assign'r to Learned & Thatcher	Stoves	Design.
403	Blanchard, Reuben J., assign'r to Learned & Thatcher	Stoves	Design.
8440	Bliss, Alfred	Cans or canister, tops of	II.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
188	Blodget, Sherburne C., and John A. Lerow	Sewing machines	Reissue.
190	Boardman, Horace	Boiler, steam, and furnace thereof	Reissue.
8215	Boardman, John	Washing machines	XVII.
8102	Boardman, Luther	Spoon, &c., manufacture of, wire strengthened	II.
8575	Bogart, C	Sounding boards for musical instruments, construction of	XVIII.
8441	Bogert, Charles A	Stoves, air heating	V.
8439	Bolen, John G	Burglar alarms	XXII.
8442	Boone, Thomas G	Ships' winches	VII.
8005	Boot, Henry	Cloth, machines for folding and measuring	III.
8508	Booth, Ezekiel, & Ezra Ripley	Car seats	X.
8033	Booth, Jonathan L	Winnowing machines	I.
8216	Bottum, J. H	Lathes, securing pinions, &c., of watches in	XIV.
8114	Boyden, Otis	Alloys of iron, zinc, and nickel	IV.
8068	Boynton, Leander W	Bats for felting, making	III.
8287	Boynton, L. W	Wool, machines for cleansing	III.
8242	Boynton, N. A	Stoves, parlor cooking	V.
8365	Brandeis, L	Bronze powder, processes of making	IV.
8404	Brett, Ephraim C	Flocks, machines for opening and cleaning	III.
7959	Brewer, William, and John Smith	Paper molds	III.
8133	Briggs, Joseph W	Collars for harness	XVI.
7965	Briggs, Luther, jr	Hammers, trip, method of adjusting the stroke	II.
8142	Brown, Charles F	Rudder, balanced	VII.
8164	Brown, Charles F	Masts and spars, telescopic connexion of.	VII.
	Brown, Daniel. (See Strevell & Brown.)		
	Brown, H. L. & C. P. (See Foster, Jessup, Brown & Brown.)		
	Brown, John. (See Guild & Brown.)		
8269	Brown, Luther	Brick machines	XV.
8383	Browne, L. H	Piano fortes	XVIII.
8319	Brown, Samuel	Kilns, lime	XV.
8421	Brown, Wm. H	Baths, shower	XX.
8217	Browning, Edwin K	Mattress-stuffing, &c., machines for cutting wood into shreds, and crimping them for	XVII.
8464	Brooks, Merrit S.	Augers, &c., to their handles, means for attaching	XIV.
8036	Broquette, Charles A	Calico printing, material for transferring colors in	IV.
	Brundage, Edwin L. (See Stilwell & Brundage.)		
	Brundage, E. L. (See Ripley & Brundage.)		
8111	Brunk, Henry	Lap anvils for shoemakers	XVI.
8266	Bryan, Wm. H.	Boats to facilitate the discharge of cargoes, &c., fittings for	VII.
8283	Bryant, M. C.	Looms for weaving cut-pile fabrics	III.
8036	Buckingham, John, and Joseph H. Baird, assignor to Scovill Manufacturing Co	Milling tool	II.
8443	Buffum, Arnold	Ore washer	II.
8321	Bulkley, Chas. S.	Telegraphs, means for obviating difficulties arising from defective insulation	VIII.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8340	Bulkley, Chas. S.	Electro-magnetic telegraphs, circuit changes for	VIII.
8351	Burch, J. C	Forceps, dental	XX.
8246	Burgess, Joseph	Boot-forms, machine for dressing	XVI.
370	Burleigh, M. C.	Stove doors and panels	Design.
8006	Burnett, Marshall	Nail machine, horse-shoe	II.
392	Burnet, William	Water coolers	Design.
8073	Burt, Charles	Harpoon, exploding	XXII.
7925	Burt, Enoch	Looms, power, fancy check	III.
8286	Bush, O. H	Spring bolt	II.
8554	Bushnell, William	Drill, hand	II.
8060	Bugbee, James R., assignor to James R. Bugbee and Enoch Robinson	Lock and key	II.
8062	Cady, Ira L	Vaults, safes, &c., compound metallic door for	II.
202	Calderhead, Alexander	Jacquard machinery for weaving all kinds of figured cloth	Reissue.
	Campbell, Wm. (See Gross and Campbell.)		
8542	Carleton, George W	Stoves, cooking	V.
	Carpenter, T. C. (See McFarlan & Carpenter.)		
8014	Carr, J. M., and Jas. Hughes	Bran dusters	XIII.
8354	Carrington, Chester J	Hooks and eyes, fastening to paper cards	XXI.
8322	Carter, Hy., and Jas. Reese	Nut and washer machine	II.
8081	Cavaillon, Florentine J. de	Gas, illuminating, purifying	IV.
8200	Cavanaugh, L. F	Brushes and brooms, handles of	XVII.
8310	Carver, Hiram	Cabbage cutters	XVII.
8165	Carver, Seymour	Shingles, machine for dressing	XIV.
8384	Chambers, Benjamin	Stamps, letter	XVIII.
8339	Chapin, Nathan	Mills, cider	XIII.
415	Chapin, Nathan	Tables	Design.
7935	Champion, Thomas	Boiler, steam, annular	VI.
8330	Chapman, Thomas M	Saw-filing machine	XIV.
7966	Chapman, Henry D	Poles, machine for climbing	VIII.
	Chase, William M. (See Rufus Ellis.)		
197	Cheney, Frank	Thread, machinery for doubling, twisting, and reeling	Reissue.
8288	Chichester, Lewis S	Staves, machines for jointing	XIV.
8141	Chichester, Lewis S	Carving machines	XVIII.
8499	Chichester, Lewis S	Staves, machines for dressing	XIV.
8270	Childs, Augustus B	Winnowers and separaters, grain	I.
352	Chilson, Gardiner	Furnace registers	Design.
353	Chilson, Gardiner	Furnace registers	Design.
354	Chilson, Gardiner	Furnace registers	Design.
355	Chilson, Gardiner	Furnace registers	Design.
8366	Chilson, Gardiner	Stoves	V.
	Chollar, Sage, & Dunham, assignors. (See E. Ripley.)		
7952	Clapp, Edward, assignor to Edward Clapp and George Alden	Sad irons	XVII.
7984	Clapp, E. S.	Scythes to the snath, fastening of	I.
204	Clapp, E. S.	Scythes to the snath, fastening of	Reissue.
8509	Clarke, Alvan	Telescopes	VIII.
8373	Clark, George B	Churns	I.
8089	Clark, James M	Flouring apparatus	XIII.
7985	Clark, Oliver	Scythe fastening	I.
8134	Claussen, Peter	Fibre, vegetable, processes for treating	III.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8055	Clay, William	Rods, tapered, metallic, apparatus for rolling	II.
8218	Clemens, S. A	Hemp, &c., machines for dressing Sisal.	III.
8408	Clements, William P	Seed-planter, devices for sewing in a	I.
	Clinton, Thos G., and Robert Lee. (See McGregor, Lee, & Clinton.)		
417	Cobb, Lyman	Stoves	Design.
7866	Cochran, Silas M	Car-couplings	X.
8555	Cole, Cyrus C	Fences, hurdle	IX.
7867	Collan, John B	Pipe, lead, machines, nozzles for	XI.
8543	Collins, J. & J. J. G	Boilers, apparatus for steam	VI.
8323	Colné, John P	Glass, machinery for cutting	XV.
8578	Conant, J. S	Gas regulators	V.
8367	Cone, N. F	Vice, bench	II.
	Conrad, Samuel. (See Heffley, Conrad & Wigh.)		
8483	Constant, Isaac	Cultivators	I.
405	Cook, Aaron	Combs for ladies	Design.
8556	Cook, Carlos A	Soda powders, &c, machines for crimping package papers for	XX.
8129	Cook, Horace, assignor to H. S. Cook and S. Colburn	Comb-cutting machines	XXI.
8162	Cook, Ransom	Augers	XIV.
8241	Cook, Samuel	Flour bolts	XIII.
8298	Cook, Ransom	Ventilating and excluding dust from railroad cars	V.
8254	Coons, Mathias P	Fences, flexible	IX.
8170	Cooper, John, administrator of Benjamin Giger	Ploughs	I.
8148	Corliss, George H	Governors	XIII.
8253	Corliss, George H	Cut-off gear	VI.
200	Corliss, George H	Cut-off and working the valves of steam-engines	Reissue.
7868	Cornell, William E	Planing machines for dressing the edges of boards	XIV.
8463	Cory, Myron	Seed-planters	I.
382	Cox, A., E. Johnson, and D. B. Cox	Stoves	Design.
383	Cox, A., E. Johnson, and D. B. Cox	Stoves	Design.
	Cox, John. (See Roberts and Cox.)		
8028	Crane, Aaron D	Horse-powers	XIII.
	Crane, Pepper & Crane. (See John Pepper.)		
8022	Crosby, Pearson	Sawing machines	XIV.
	Cresson, W. P., assignor. (See David Stewart and Jacob Beesley.)		
	Crompton, William—Edson Fessenden, conservator of	Looms	Extension.
8564	Crosby, C. O	Pins, mode of papering	II.
8202	Crosby, C. O	Pins, mode of papering	II.
8007	Crosby, C. O	Pins, machine for sticking on paper	II.
8149	Crowell, Sommers	Railings	IX.
8199	Crum, John	Files, machinery for cutting	II.
	Cummings, Gary. (See Dane, Healy & Cummings.)		
8522	Curtis, S	Combs, machines for cutting	XXI.
8250	Cutler, Job	Metal tubes, method of liberating from forming mandrel	II.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8077	Cutting, James A	Spark-arresters	VI.
8271	Dane, James, Darius Healy, and Gary Cummings, assignor to Isaac and Francis Dane	Brick machines	XV.
	Da Costa, John C., assignee. (See Patton & Fergus, assignors.)		
8297	Dare, John S	Shoulder-braces, combined with abdominal supporters	XX.
8576	Davies, Thomas A	Cars, railroad, running-gear of	X.
8299	Davis, A. R	Brushes, manufacture of	XVII.
8482	Davis, Isaac	Collars, horse, machines for forming	XVI.
341	Davis, William C	Stove, cook	Design.
390	Davis, William C	Stoves	Design.
419	Davy, John T	Fences, cast-iron	Design.
8127	Dawes, Nathan, and Higgins Harrison	Boot-crimps	XVI.
8100	Day, Horace H	Shoe, india-rubber	XVI
	De Douchet, G. F. (See Douchet, G. F. de.)		
350	Delany, Edward J., assignor to Heine & Adamson	Umbrella stands	Design.
8044	Dennison, Andrew	Boxes, machine for cutting out the corners, and scoring edges of paper for	XX.
	Dewey, Thomas D., adm'r of David Dewey	Horse-rake	Extension.
393	De Witt, James V	Stoves	Design.
8139	Dickey, J. C	Drying fruits and other articles, revolving-frame for	XVII.
8201	Dimpfel, Frederick P	Steam engines, arrangement of	VI.
8521	Dodge, T. H	Printing presses	XVIII.
8356	Douchet, G. F. de	Paint, manufacture of	IV.
7900	Dorwart, Joseph	Tuyers	II.
7885	Draper, Francis	Inkstand fountain	XVIII.
8505	Drawbaugh, Daniel	Stave-jointing machines	XIV.
	Drew, George. (See Sabin & Drew.)		
8585	Drummond, John W., assignor to Smith Ely	Chair-seats	XVII.
8565	Duchemin, Dan'l and George	Clay, machines for working	XV.
8203	Dudgeon, Richard	Press, portable hydraulic	XII.
8219	Dugdale, Samuel G	Churns	I.
	Dunham, A. T. & Co. (See N. S. Vedder.)		
8118	Durkee, George B	Carriages	X.
8586	Dutcher, E. & W. W	Weavers' temples	III.
8143	Dutcher, Davis	Churns	I.
8150	Eames, Albert	Stone and other substances, machines for facing and polishing	XV.
8197	Eames, Daniel W	Carriages, railroad, running-gear of	X.
8255	Eddy, Thomas J	Wheels, cast-iron car	X.
	Eddy, Thomas J., assignee. (See Joseph Hyde.)		
8163	Ellis, Rufus, assignor to William M. Chase	Knitting machines	III.
	Ely, Smith, assignee of John W. Drummond. (See Drummond.)		
7953	Engelbrecht, Theodore F	Hinge, double-acting spring	II.
7869	Ericsson, John	Water-metres	XI.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8481	Ericsson, John	Engines, air	VI.
8579	Ericsson, John	Water-metres	XI.
	Essex Company, assignee. (See M. L. Whipple.)		
8063	Etnier, Oliver	Winnowing machines	I.
8088	Faber, George	Boilers, &c., steam apparatus for indicating the height of water in	VI.
8361	Faber, George	Gauge for indicating pressure of steam	VI.
8025	Fagin, Lewis, & H. C. Hayman	Bolting flour, apparatus for	XIII.
8117	Farson, Enoch S	Swings, portable	XXII.
	Felthousen, J. D. (See Akins & Felthousen.)		
	Fergus, Wm. F. (See Patton & Fergus, assignors to J. C. Da Costa.)		
8587	Ferris, Richard M	Organs and piano fortes, combining	XVIII.
	Fessenden, Edson. (See W. Crompton.)		
7918	Fields, William, jr	Hydraulic ram	XI.
	Finch, R. R. (See Wm. L. Sanderson.)		
8407	Fisher, Charles Frederick	Propeller, the endless chain	VII.
7870	Fisher, Daniel	Churns	I.
423	Fitzgerald, Frederick, assignor to Silas C. Herring and John Ryer	Iron railing	Design.
8239	Flanders, J. F	Pumps for raising water, &c	XI.
	Flanders, Joseph F. (See Rickards & Flanders.)		
400	Flinchbaugh, H. R	Tomb, cast iron	Design.
8510	Flint, Jacob C	Hides, machines for cutting	XVI.
8261	Fonda, John C	Flock, machine for grinding	III.
8030	Foster, Celia R. P., late Celia R. P. Wood	Tables, ladies' work	XVII.
8331	Foster & Marsh, assignors to J. Foster	Wheels to axles, method of securing	X.
8484	Foster, N., G. Jessup, H. L. Brown, and C. P. Brown	Seed planter	I.
7972	Fowle, Joseph W	Drilling apparatus, steam	IX.
430	Freeman, Edmund L	Presses, mantel-pieces, &c., for frames for	Design.
8220	French, Oliver N., assignor to O. N. French & Eb. Stevens	Axle-boxes, for journals for railroad cars	X.
7938	Frye, John A	Tonguing, jointing, and rebating tools for	XIV.
406	Fulton, Calvin	Stove-plates	Design.
8409	Fulton, James	Escapement for time-pieces	VIII.
7980	Gaines, Edmund P	Mill-stones, dressing	XIII.
8465	Gallahue, Alpheus C	Boots and shoes, machines for pegging	XVI.
8444	Gambrill, Horatio N	Cotton duck, dressing	III.
7967	Gardiner, P. G	Wheels, cast-iron car	X.
7968	Gardiner, P. G	Tyres by continuous rolling, machinery for making	II.
8605	Gardiner, Perry G	Swaging machine, rotary	II.
8523	Gardner, George W	Stove grate-bars	V.
7986	Gardner, James M	Casting the backs upon the teeth of curry-combs, method of	II.
8362	Gardner, Smith	Sugar, apparatus for draining	IV.
8151	Gardner, William	Governors	XIII.
7936	Garretson, Isaac H	Looms, hand	III.
	Garst, John. (See Bixby & Garst.)		
8341	Gavett, H. L. F	Fence, sod, machine for making	IX.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
	Gaylor, Charles J., assignee of F. C. Goffin. (See F. C. Goffin)		
346	Gibbs, Saml. W., assignor to Jagger, Treadwell & Perry	Stoves, cooking	Design.
356	Gibbs, Saml. W., assignor to Jagger, Treadwell & Perry	Stoves	Design.
357	Gibbs, Saml. W., assignor to Jagger, Treadwell & Perry	Stoves	Design.
359	Gibbs, Saml. W., assignor to Jagger, Treadwell & Perry	Stoves	Design.
366	Gibbs, Saml. W., assignor to Jagger, Treadwell & Perry	Stoves	Design.
380	Gibbs, Saml. W., assignor to Jagger, Treadwell & Perry	Stoves	Design.
345	Gibbs, Saml W., assigner to North, Harrison & Co	Stoves	Design.
422	Gibbs, Saml. W., assignor to North, Harrison & Chase	Stoves	Design.
394	Gibbs, Saml. W., assignor to North, Harrison & Chase	Stoves	Design.
	Giger, Benj. (See Jno. Cooper.)		
8398	Gilbert, T	Piano fortes	XVIII.
342	Gilbert, Charles, and Mitchell G. Hallman, assignors to Charles Gilbert	Stoves	Design.
8311	Gillett, Bethuel, and Lyman Allis	Presses, self-acting, cheese	XII.
8069	Gilliland, Lewis L	Splint machines	XIV.
8348	Gillespie, G W. C	Ploughs, wheeled, cultivating	I.
7871	Gilman, Samuel H	Valves, side, method of connecting the, with the rock-shaft	VI.
7987	Gilman, Samuel H	Cut-off, adjustable	VI.
8466	Gilman, Samuel H	Bagasse, machines for drying	V.
8559	Goffin, F. C., ass'r to Charles J. Gaylor	Lock, for safes, &c	II.
8524	Goldson, Henry	Ploughs	I.
8544	Goldthait, Elijah	Plough	I.
7927	Goodrich, Leonard	Ships, light	VII.
8075	Goodyear, Nelson	India rubber, manufacture of	IV.
	Goodyear, Nelson. (See Ed. Hamilton.)		
8285	Gordon, George P	Printing presses	XVIII.
8080	Gorrie, John	Ice, process for artificial production of	XXII.
8065	Goshon, Joseph G., & Wm. H. Towers	Writing, apparatus for giving ease to the arm in	XVIII.
8363	Goulding, Henry	Stone-drilling machine	XV.
8268	Graham, William	Tuyer, tight joint for	II.
7973	Granger, Rensselaer D	Stoves, air-tight Franklin	V.
8050	Grannis, Charles W	Stoves, cooking	V.
8093	Grant, Joseph	Brick presses	XV.
8019	Grass, H., & Wm. Campbell	Bedstead rails, machines for cutting screws on	XVII.
8352	Gray, James A	Piano forte action	XVIII.
8284	Gregg, Isaac	Brick machines	XV.
8158	Gregg, Mahlon	Brick machines	XV.
8345	Gregory, Alfred	Equalizers, or power-regulators	VI.
7975	Greer, Jas., & Rufus J. King	Stoves, cooking	V.
	Green, H. H. (See John J. Sturgis.)		
428	Green, Jeremiah D., assignor to Backus, Bacon, & Co	Stoves	Design.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
	Greenwood, M., & Co., ass'ees. (See Charles Zeuner.)		
8485	Griffith, Levi B	Iron, measuring and cutting	II.
8166	Griggs, George S	Locomotives, running-gear of	X.
8374	Grimes, Owen W	Hemp and flax, machines for scutching and hackling	III.
8375	Grosvenor, L. D	Broom corn, machines for stripping seed from	I.
7872	Grosvenor, Lorenzo D	Broom corn, machines for assorting	I.
7931	Grover, Wm. O., and Wm. E. Baker	Sewing machines	III.
8152	Guard, Chauncey H	Springs, carriage	X.
8103	Guild, Charles M., and John Brown	Steam traps	V.
7971	Guyer, Hugh	Window curtain fastening	XVII.
7901	Gwynne, J. Stuart	Pumps, rotary	XI.
	Haigh, Jos. P., A. Hartupee, and J. Morrow, assignees. (See William Kenyon.)		
8257	Hall, William	Lock, bank, powder-proof	II
	Hallman, Mitchell G. (See Gilbert & Hallman.)		
381	Hallman, W. G	Stoves	Design.
8121	Hamilton, Ed., assignor to N. Goodyear	Dust, excluding from railroad cars	V.
8422	Hammer, George	Corks, machines for cutting	XXII.
8486	Hammitt, John T	Desks	XVII.
7917	Hanley, James	Key, swivel-nibbed	II.
8037	Hanon, Valcke E. T	Mill-stones	XIII.
378	Hapgood, Lyman S	Stove plates	Design.
8204	Happersett, David J	Hooker-up, mechanical	II.
8342	Hardaway, Moore	Spike machines, hook-heading, motion for	II.
8525	Hardie, James	Propellers of machinery, to be used in currents	XI.
8332	Harris, C., and P. W. Zoiner	Stoves, double-oven	V.
347	Harris, Conrad, and Paul W. Zoiner	Stoves	Design.
7902	Harris, Joseph, jr	Motion, changing reciprocating into a rotary	XIII.
	Harrison, H. (See Dawes and Harrison.)		
8312	Harrison, James	Dental hydraulic cups	XX.
7988	Hastings, Eliakim M., and John Shepherdson	Looms, cylinders for figuring	III.
	Hartshorn and Ames. (See Winslow Ames.)		
	Hartshorn, J., and W. Ames, assignees. (See W. Ames.)		
7920	Hathaway, Alfred	Pens for ruling paper	XVIII.
375	Hathaway, William L	Stoves	Design.
8445	Hathaway, John R., and Jno. P. Strippel	Printing presses	XVIII.
8167	Hatch, Thatcher C	Ventilators	V.
8245	Hawkins, Wm	Stave dressing machines	XIV.
8588	Haussknecht, Gustavus L	Carriages	X.
8221	Haussknecht, Gustavus L	Springs, carriage	X.
8159	Hayden, Hiram W	Dies, construction of	II.
8589	Hayden, Hiram W	Kettles and articles of like character from discs of metal, machinery for making	II.
8364	Hazard, E. W., C. H. Jenner	Millstones, machine for dressing	XIII.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
	Healy, Darius. (See Dana, Healy, and Cummings.)		
8106	Hebbard, Albert	Wheels, cast-iron car	X.
8056	Hedge, Samuel, assignor to George W. Hedge	Saw-mills	XIV.
7994	Heffley, George, Samuel Conrad, and James Wigle	Ploughs, adjustable land sides of	I.
8205	Heinemann, H	Buttons, silk covered	XXI.
	Heins & Adamson. (See Ed. J. Delany.)		
8467	Hendrix, Davis R	Boot-trees	XVI.
	Herring, Silas C., and John Ryer, assignees. (See Frederick Fitzgerald.)		
8015	Heywood, Simeon	Wheels and axles, connecting and disconnecting	X.
189	Hibbard, Harmon, assignor to W. W. Reid	Tanning processes	Reissue.
8222	Hibbard, Harmon, assignor to Jared A. Hibbard	Buggy tops	X.
8168	Hickok, W. O	Ruling machines, regulators for the pen beam in	XVIII.
8046	Hill, Charles F., and Henry Hoffman	Marble ornamenting	XV.
8144	Hill, Thomas W	Comb-cutting machine	XXI.
8185	Hinds, William	Saw-set, vice	XIV.
8560	Hinkley, Benjamin	Trucks, railroad car	X.
8333	Hobbs, Charles	Stereotype plates, moulding and casting	XVII.
8526	Hodge, Nehemiah	Wheels, railroad car	X.
	Hoffman, Henry. (See Hill and Hoffman.)		
7954	Hoguet, Francis	Tables, extension	XVII.
8272	Holden, Moore	Millstones, dressing	XIII.
8026	Holkins, Elijah S	Saw-set	XIV.
8008	Hollingsworth, Jehu	Wheat fans	I.
8061	Hollingsworth, Jehu	Smut machines	XIII.
8527	Hollingsworth, Jehu	Mill for grinding and bolting	XIII.
8206	Holly, B., and J. B. Wheeler.	Grooving lumber, machine for	XIV.
8264	Horner, David	Seed planter	I.
8307	Hosley, Abijah S	Ship's model measurer	VII.
8087	Hoskyns, Chandos	Rudder, apparatus for relieving the helmsman from the shock of	VII.
8606	Hotchkiss, Julius, assignor to the Hotchkiss and Merriman Manufacturing Co	Suspenders	XXI.
8348	House, Samuel A	Stoves, cooking	Design.
7349	House, Samuel A	Stoves, parlor.	Design.
8388	House, Samuel A	Stoves	Design.
8540	Howe, Elias, jr	Fastening for garments	XXI.
4969	How, Thomas P	Trucks, connecting them with car bodies.	X.
239	Hoyt, William H	Omnibus steps	X.
834	Hubbard, M. G	Springs, carriage	X.
8193	Hubbell, William W	Fire-arms	Reissue.
146	Hudson, S. A	Sword canes	XXI.
	Hughes, James. (See Carr & Hughes.)		
1830	Hulings, Margaret	Spinning wool, hand machines for	III.
8107	Humiston, Willis	Candle making apparatus	IV.
838	Hunt, Marshall J	Planters, seed, gearing of	I.
8100	Huntley, Hosea H	Stoves, cooking	V.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8541	Huntley, Hosea H	Stoves, cooking	V.
8355	Hurlbut, C. R	Gauges used in turning	XIV.
7928	Hurlbut, Sidney S.	Harvesters, grain	I.
8131	Hutchins, Samuel B	Crank indicator, arrangement of machinery for actuating the	VI.
371	Hutchinson, James, assignor to D. A. E. and N. Powers.	Floor oil-cloth	Design.
	Hutchinson, A. B. and C. E. (See J. F. Ostrander.)		
411	Hutchinson, James, assignor to Deborah, Albert E., and N. B. Powers.	Floor oil-cloth	Design.
374	Hutton, P. M	Bedsteads	Design.
407	Hutton, Pelatiah M	Bedsteads, cast iron	Design.
	Hyde, J. B. (See Thos. R. Williams.)		
8580	Hyde, Jos., assignor to Thos. J. Eddy	Lathes, chucks for	XIV.
	Imlay, Richard	Car, railroad, supporting, bodies	Extension.
8608	Ingalls, Gustavus W	Æolian attachment	XVIII.
8487	Ingalls, J. K	Radiating surfaces	V.
	Innis, James R	Hide handling cylinders, beaters in	Disclaimer.
8336	Irwin, William	Vessels, method of raising sunken	VII.
8289	Ison, Mark M	Spike machines	II.
	Jagger, Treadwell, & Perry. (See Samuel W. Gibbs.)		
8107	Jefferson, Purnel	Spike machines, gauging and heading movement for	II.
8247	Jenkins, J	Gauges, feather edging, for shoemakers.	XVI.
7974	Jenkins, Solon, jr	Daguerreotypes, securing, in monumental stones	XVII.
	Jessup, G. (See Foster, Jessup, Brown, & Brown.)		
8368	Jillson, A	Weavers' temples	III.
8402	Jimason, Alexander	Valves, shields for	XI.
8101	Jobson, Robert	Fire-places, reflecting	V.
	Johns, George J. (See Schofield & Johns.)		
	Johnson, E. (See Cox, Johnson, & Cox.)		
8281	Johnson, John, assignor to Elias Johnson	Looms for weaving pile fabrics	III.
8511	Johnston, A. W	Felloes, bending	X.
408	Jones, Anthony W., assignor to Jas. McGregor	Stoves	Design.
8009	Jones, Gilbert D	Mills for grinding paints and drugs	XIII.
7906 191	Jones, John	Carriages	X & re-issue.
7924	Jones, Thomas W	Hides, machines for preparing	XVI.
8234	Jones, John	Carriage bodies, hanging	X.
8236	Jones, John	Carriage bodies, hanging	X.
8357	Jones, S. T	Iron, manufacture of	II.
8267	Jones, Wm. R	Hubs for boxes, machine for preparing.	X.
8207	Jones, William	Harvesting machines	I.
8273	Judd, Albert H	Indicator, water-level, for steam boilers.	VI.
7960	Judson, Junius	Power governors	XIII.
7939	Judkins, Chas. T. Patented in England to David Christie	Weavers' treadles	II.
8076	Kain, James R., and Spencer Lewis	Bedstead fastening,	XVII.
7873	Kaufman, Abraham	Quilting frames, and apparatus	XVII.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
	Keenan, Chas. (See C. Wetterstedt.)		
8334	Kempton, Jas. C	Drying and oxidizing colored goods	IV.
8427	Kenyon, William, assignor to Jos. P. Haigh, A. Hartupee, and J. Morrow	Nut-washers, etc., machines for making	II.
8353	Kerrison, R. M	Piano forte action	XVIII.
8581	Ketcham, Charles	Saw-mills, feeding logs in	XIV.
206	Ketchum, Wm. F	Mowing machine	Reissue.
8415	Killin, P	Ovens, portable elevated	V.
8545	King, Daniel	Sugar drainers, centrifugal	IV.
8446	King, James T	Washing apparatus	XVII.
8609	King, Lewis	Carriages	X.
	King, Rufus J. (See Greer & King.)		
8208	King, William	Cork cutting machine	XXII.
7921	Kinnear, Delamar	Lamps, lard	V.
8248	Kirk, S. W	Bran dusters	XIII.
8512	Kitson, Rd	Card grinders	III.
8002	Klepfer, Henry	Piano fortes, upright	XVIII.
7916	Knapp, Moses L	Supporters, abdominal	XX.
8020	Knight, Geo. H	Paving, &c., stone and metal conglomerate for	IX.
8468	Knowles, S. W	Cradles, swinging	XVII.
8187	Kraft, Benjamin	Boxes and axles for saving oil	XIII.
8038	Krauser, John	Railings, iron	IX.
7995	Krebs, Charles W	Shutters, apparatus for securing in any required position	II.
8350	Kreter, Randolph	Piano forte, action	XVIII.
7874	Lamb, John, and C. H Root	Wheels, spring, carriage	X.
344	Lamb, Joseph G	Stoves	Design.
386	Lamb, Joseph G	Stoves	Design.
387	Lamb, Joseph G	Stoves	Design.
7989	Lamson, Ebenezer G	Scythe fastenings	I.
8000	Lamson, Nathaniel	Scythe fastenings	I.
8003	Lamson, Nathaniel	Scythe fastenings	I.
7956	Lane, Abner	Irregular forms, machinery for turning	XIV.
203	Larkin, Esther L., adm'x of John E. Larkin, deceased	Augers, method of attaching to their handles	Reissue.
8469	Latourette, David L	Oil presses	XII.
8347	Laurence, Erastus	Washing machines	XVII.
8238	Lawrence, James A., assignor to Roberts & Lampson	Harness, saddle trees for	XVI.
8193	Lazell, A. E, and D. Lazell	Bread cutters	XVII.
	Learned & Thatcher. (See R. Blanchard.)		
	Learned & Thatcher. (See R. Blanchard.)		
	Learned & Thatcher. (See R. Blanchard.)		
	Lee, Robert, and Thomas G Clinton. (See McGregor, Lee & Clinton.)		
8528	Lemmer, Adam	Cannon for throwing chain shot	XIX.
8428	Levington, Robert	Axle boxes for railroad cars	X.
8416	Lewis, Spencer	Bedsteads, machines for cutting screws on rails of	XVII.
	Lewis, Spencer. (See Kain & Lewis.)		
360	Lewis, Wm. & W. H	Pedestals and columns	Design.
8181	Lewis, Wm. & W. H	Fastening pedestals to columns	XVII.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8235	Lewis, Wm. & W. H	Daguerreotype plates, apparatus for buffing	XVIII.
8513	Lewis, Wm., Wm. H., & H. J	Daguerreotype apparatus	XVIII.
8590	Lewis, Wm. & Wm. H	Lenses, adjusting	XVIII.
8095	Leypold, Frederick	Scarificators	XX.
8223	Lilley, Louis, assignor to Jno. W. Bates	Safes, fire-proof	II.
8390	Litchfield, Laroy	Weavers' shuttles	III.
8047	Littlefield, Dennis G	Stoves, cooking	V.
8514	Livermore, Lorenzo D	Cars, railroad, coupling	X.
8391	Livingston, N. B	Weighing carts	XII.
	Lombard & Lombard. (See R. G. Westacott.)		
8301	Long, Richard	Brick machines	XV.
8515	Lonsbury, Allen J	Supporter, abdominal	XX.
8039	Loper, Richard F., and John W Nystrom	Steam engines	VI.
	Low & Hicks, assignees. (See Ripley. Ezra, and N. S. Vedder.)		
8447	Luttgens, H. A	Engines, apparatus for regulating the speed of	VI.
8290	Lyman, A. S	Boilers, steam, water-gauge for	VI.
194	Lynch, Edward	Evaporators and condensers	Reissue.
8566	Maginnis, James	Tailors' measures	XXI.
7886	Maguire, William	Staves, machines for jointing	XIV.
8529	Malo, Gaspard	Propeller, screw	VII.
7875	Manning, James	Candlesticks	V.
8385	Manny, J. H	Harvesters, mowing machines and	I.
8448	Marcher, Robert	Enamelling mouldings, &c., machinery for	XVIII.
8040	Marsh, James S	Stoves, cooking	V.
8591	Marsh, Nathan B	Stethoscopes	XX.
7887	Marston, Stanhope W	Lock-fly, tumblers for fire-arms	XIX.
8023	Mason, Lewis J	Table leaves, fastening down of	XIV.
8302	Mason, Nicholas	Ranges, cooking	V.
	Massachusetts Arms Co., assignees. (See Joshua Stevens.)		
8417	Masserano, Clement, assignor to Clement Masserano, Josephine Wickliffe, admx. of R. Wickliffe, jr., deceased, Charles Carenzi, André Crestadora, Pellegro Rocca, and Lewis B. Migone.	Locomotives moved by the power of animals.	X.
8470	Mathushek, Frederick	Piano fortes	XVIII.
8126	Maynard, Edward	Fire-arms, breech loading	XIX.
8291	McAdams, John	Account books, machine for numbering the pages of	XVIII.
8224	McCallum, D. C	Bridge, counter braces adjusting the effective length of	IX.
8256	McCarty, James	Boiler-tubes, &c., spring expanding swage for	VI.
8324	McCloskey, D. W. C	Lamps, self-acting blow-pipe	V.
8492	McConnell, W. P	Charcoal, manufacture of	V.
8016	McCurdy, David	India rubber, manufacture of	IV.
7903	McFarlane George R	Wheels, cast-iron car	X.
8124	McFarlan, William A., and Thomas C. Carpenter	Bran dusters	XIII.
8314	McGregor, Geo, Robert Lee, and Thos. G. Clinton	Padlock	II.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
	McGregor, Jas., jr., assignee. (See Anthony Jones.)		
8010	McKinlay, Peter	Hullers, rice	X.
8610	McLain, John	Harness, saddles	XVI.
8449	Meech, Charles L.	Wind instruments, the mouthpiece for	XVIII.
8017	Mellish, Henry	Splint machines	XIV.
8303	Mercer, John	Fulling vegetable and other textures, chemical processes for	III.
410	Merchant, Silas	Stoves	Design.
207	Merrick, Solyman	Screw wrench	Reissue.
8376	Merrell, William	Lath machines	XIV.
8031	Merrill, Rosewell T.	Grain separators and fans	I.
8450	Miller, James M.	Sugar vacuum pans	IV.
8194	Miller, Michael	Piano fortes	XVIII.
8225	Miller, Sylvanus	Harvesting machines, rake to	I.
8500	Milligan, Wm. B.	Hides, bating and tanning	XVI.
8226	Milligan, William E.	Boilers, steam, arrangement of the flues and water spaces of	VI.
	Mitchell, Wm., assignee of J. Steger. (See Steger, Jos.)		
8175	Moeser, Henry	Printing names of subscribers on newspapers, &c	XVIII.
8011	Monson, Charles	Blasting rocks	IX.
8265	Moore, Henry	Hubs for the reception of boxes, machine for preparing	X.
8561	Moore, Jos. H., and Wm. P. Parrott	Carriages, steam, for railways	X.
8392	Moore, William	Presses, self-acting	XII.
	Morse, Joel R. (See Jabez Robins.)		
8546	Mortimer, Thos. H., and Jas. M. Gardiner	Rudders, method of operating	VII.
8335	Moulson, John	Photographic purposes, mercury bath for	XVIII.
425	Muller, Charles	Hat stand	Design.
8410	Murrill, Jas. H	Locomotives, running gear of	X.
8177	Myers, Laurence	Cars for the transportation of coal, improvements in	X.
8451	Nebinger, William	Cars, railroad, running gear of	X.
7888	Neely, Edward	Harvesters, grass	I.
7989	Neff, Jacob	Electro magnetic engines	VIII.
8424	Nesmith, John, and Wesley Sawyer.	Shawls, &c., machines for twisting fringes of.	III.
	Nevins, William R	Crackers, cutting	Disclaimer.
8110	Newbury, Bolivar	Jacks, lifting	XII.
8516	Newcomb, Levi, jr	Bedsteads	XVII.
208	Newell, Robert	Manifold permutation locks	Reissue.
8145	Newell, Robert	Locks, permutation safety	II.
8425	Newlove, William	Mills, grinding	XIII.
8078	Newman, Nelson	Pumps	XI.
8452	Newton, Henry J	Piano forte strings	XVIII.
8547	Newton, Orin	Door knobs, manufacture of	II.
8396	Nicholson, Thomas	Lock maze	II.
8315	Niles, Peter H	Tool haft, adjustable	XIV.
8611	Nims, Samuel D	Sashes, window, method of hanging	II.
8567	Noel, Theodore	Watches, winding	VIII.
8530	Norris, J. H., & D. Flanders.	Desks	XVII.
	North, Harrison, & Co. (See Samuel W. Gibbs.)		
	North, Harrison, & Chase. (See S. W. Gibbs.)		

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
	North, Harrison, & Chase. (See Samuel H. Sailor.)		
	North, Harrison, & Chase, assignee. (See S. W. Gibbs.)		
7876	Northrop, Sheldon	Looms for weaving seamless bags	III.
7996	Norton, Michael	Sash lock	II.
7961	Nystrom, John W	Calculating machines	VIII.
	Nystrom, John W. (See Loper & Nystrom.)		
7962	O'Neill, Bernard	Boilers, method of bracing the water spaces of	VI.
97	O'Neil, John	Churns	Add'l imp't.
8153	O'Neil, John	Washing machines	XVII.
8377	O'Neil, Patrick	Easy chairs for invalids, etc	XVII.
7932	Osborn, John	Hydraulic rams, operating the waste gate in	XI.
8135	Osborn, Joseph	Sash stopper	II.
8096	Osgood, James W	Coupling, compound for hose or pipe	XI.
8313	Ostrander, Jona. F., assignor to A. B. & C. E. Hutchinson.	Harrows, rotary	I.
8316	Otis, George W	Lightning rods, insulators for	VIII.
99	Pace, Henry Sen'r	Bedsteads	Add'l imp'ts.
8191	Paine, John P	Spectacle frames	VIII.
8034	Paine, Rufus R	Stoves, cooking	V.
8192	Palmer, A., & S. G. Williams.	Harvesters, grain	I.
	Palmer, Courtland. (See H Smith.)		
8227	Panton, William	Leather, machines for splitting	XVI.
7910	Parker, E. T	Plough stock, convertible	I.
8429	Parker, James L	Water-wheels	XI.
8398	Parsons Lemuel H	Plotting scales	VIII.
8128	Past, John C	Switch for railroads, self-adjusting and locking	X.
8292	Pattinson, H. L	Pigments, manufacture of	IV.
8612	Patton, James M., and Wm. F. Fergers, assignors to John C. Da Costa	Planing machine, cutters for	XIV.
8471	Pease, Webster H	Kettles with spouts, method of moulding.	II.
8548	Peck, Milo	Presses, drop	XII.
397	Penniman, Elijah P	Stove plates	Design.
398	Penniman, Elijah P	Stove plates	Design.
414	Penniman, E. P., assignor to H. Ruttan	Stove or furnace, for a ventilating	Design.
7890	Pennington, Cunningham M.	Bridge trusses, arrangement of arches in.	IX.
7930	Pennock, Samuel and Morton	Planter, seed, seeding apparatus of a	I.
8209	Pennock, Samuel and Morton.	Seeding machines	I.
7945	Pepper, John, assignor to Charles Warren and Horatio G. Sanford	Knitting machines	III.
8172	Pepper, John, assignor to Hosea Crane, John Pepper, and J. G. Crane	Knitting machines	III.
8592	Pepper, John Paige	Jasper, mineral composition resembling.	XVIII.
8506	Perry, George W	Looms, shuttle motion of	III.
351	Perry, John S	Stoves	Design.
8304	Person, Ira B., and Joel L. Brocket	Omnibus drivers, registers for	X.
98	Pfanner, Frederick	Dye stuffs from spent madder, preparation of	Add'l imp't.
	Phalen, J., assignee. (See Jacob Worms.)		
1985	Phelps, James	Paper rags, machines for cleaning	Reissue.
163	Phillips, David F	Switch, railroad	X.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.
8549	Phillips, David F	Mills, cider	XIII.
	Pierce, Samuel. (See Shields & Pierce.)		
8104	Pierce, Samuel	Furnaces, hot-air	V.
	Pitts, Hiram A., and John A.	Threshing and cleaning grain, machine for	Extension.
8097	Platt, Nelson	Smut machines	XIII.
7946	Pond, Moses	Ranges, cooking	V.
8210	Porter, P. W	Fire-arms, revolving breech	XIX.
8582	Porter, Samuel	Ores, minerals, &c., arrangement of pans for washing	II.
7940	Post, William	Doors or shutters, attachment for opening or closing	II.
8171	Postley, Charles A	Frog-guard, self-acting	IX.
7970	Potter, Nathaniel	Bee-hives, use of slides in	I.
	Powers, D., A. E., and N. (See James Hutchinson.)		
8405	Pratt, D. and R.	Flocks to cloth, apparatus for applying	III.
	Pratt, David (See Wager, Pratt & Richmond.)		
361	Pratt, Joseph	Grates, parlor	Design.
391	Pratt, Joseph	Stoves, parlor	Design.
8399	Prince, N. A	Pens, fountain	XVIII.
8113	Putnam, George W	Saw-filing machinery, vice-jaw for	XIV.
8403	Putnam, Joseph	Clay pipes, manufacture of	XV.
8041	Putnam, S. S	Window curtain fixtures	XVII.
8186	Race, W	Sash, upper, arrangement of catches in the, operated by moving the lower sash	II.
8387	Race, Washburn	Fasteners, blind or shutter	II.
8557	Raines, William N	Switches, railroad	X.
	Randall, S. (See Treat & Randall.)		
384	Rathbone, John F	Stoves	Design.
389	Rathbone, John F	Stoves, cooking	Design.
395	Rathbone, John F	Stoves, cooking	Design.
396	Rathbone, John F	Stoves, plates of Franklin	Design.
8532	Redick, William	Seed planters	I.
	Rees, James. (See Carter & Reese.)		
	Reid, W. W. (See Harmon Hibbard.)		
8453	Remy, Benjamin W	Excavating machines	IX.
8613	Renton, James	Iron, wrought, direct from the ore, apparatus for making	II.
	Renwick, E. S. (See Watson, Renwick & Watson)		
184	Reynolds, Edward	Felloes for the wheels of carriages and wagons, machine for setting or bending	Reissue.
8051	Reynolds, James	Gutta percha tubing and covering wire, machines for	IV.
	Reynolds, O. L., and D. R. Ambrose. (See Ambrose & Reynolds.)		
7941	Rhoades, Philip, jr	Snatch-block	VII.
8478	Rice, E	Baby-jumpers	XXII.
8094	Rich, Martin	Saw-mills	XIV.
8251	Richardson, Aaron	Oil-cups for journal boxes	XIII.
8325	Richards, William T	Springs, machinery for forming joints of eliptical	II.
8369	Richardson, A	Leather and splitting machines	XVI

VI.—*Alphabetical list*—Continued.

No	Patentees.	Inventions or discoveries.	Class.
8146	Richardson, Ithiel S	Churns	I.
376	Richardson, N. P	Stoves	Design.
363	Richardson, N. P	Stoves, air-tight	Design.
399	Richmond, Apollos, assignor to A. C. Barstow & Co	Stoves, parlor, plates of	Design.
424	Richmond, Apollos, assignor to A. C. Barstow & Co	Stove, plates, parlor	Design.
	Richmond, Volney. (See Wager, Pratt & Richmond.)		
8593	Rickards, David H., and Joseph F. Flanders	Locks, rotating tumbler	II.
8517	Rickey, Richard	Collars, horse	XVI.
8231	Riddle, John J	Brick machines	XV.
8021	Riddle, John J	Brick presses	XV.
8533	Riley, Wm. Willshire	Teeth, porcelain, inserting	XX.
8090	Ripley, Ezra	Hinge crane, for doors, shutters, &c	II.
377	Ripley, Ezra, assignor to D. Stafford & Co	Stoves	Design.
8293	Ripley, Ezra	Grinders, method of forming teeth upon cast-iron	XIII.
416	Ripley, Ezra	Stove fronts	Design.
421	Ripley, Ezra, assignor to Chollar, Sage & Dunham	Stove	Design.
426	Ripley, Ezra, and N. S. Vedder, ass'rs. to Low & Hicks.	Stove, parlor	Design.
8583	Ripley, E., & E. L. Brundage.	Car seats	X.
8042	Robbins, John W	Saw-mills, setting logs in	XIV.
8174	Robbins, Jabez, assignor to Joel R. Morse	Horn and shells, machines for splitting.	XXII.
8491	Robbins, L. S	Paint-oil from rosin	IV.
8490	Robbins, L. S	Acid and naptha from rosin, distilling	IV.
8489	Robbins, L. S	Oil from rosin, lubricating	IV.
8488	Robbins, L. S	Oil from rosin, tanners'	IV.
8419	Robbins, Zenas C	Telegraph wires, insulators for	VIII.
8480	Roberts, Cyrus, and Jno. Cox	Grain, threshing and separating	I.
	Roberts & Lampson. (See J. A. Lawrence.)		
8112	Robertson, John	Lead machines, sheet combination of dies for	II.
	Robinson, Enoch. (See Jas. R. Bugbee.)		
8594	Rockwell, Francis A	Candlesticks	V.
8370	Rockwood, Levi R., assignor to Joseph L. Woodward	Last-blocks, fastening for	XVI.
8534	Rose, Hale R	Stoves	V.
7877	Ross, James P	Planters, seed	I.
	Root, Charles H. (See Lamb & Root.)		
8274	Root, James	Shutters for shop fronts	IX.
8493	Root, James	Stoves, folding doors of	V.
8052	Rowe, Bradford	Leather, machines for stretching	XVI.
7976	Ruck, John	Piano forte action	XVIII.
8211	Rudd, Wm. T	Designs in sheet metal, apparatus for punching	II.
8535	Ruggles, H. J	Grates, stove	V.
7878	Ruggles, Stephen P	Printing presses	XVIII.
8388	Ruggles, Stephen P	Stamps, hand	XVIII.
8595	Russell, Charles W	Chimney caps	V.
8358	Russell, Ira	Bedsteads	XVII.
7879	Rossell, Jonathan	Irregular forms, machines for turning	XIV.
8109	Ruttan, Henry	Furnaces, ventilating	V.

VI.—*Alphabetical list*—Continued.

No.	Patentees.	Inventions or discoveries.	Class.

8329	Young, Samuel S., assignor for J. R. Stephens	Calculating interest, rule for	VIII.
412	Zeuner, Chas., assignor to M. Greenwood & Co.	Shovels, stand for	Design.
8620	Zimmer, Jacob	Bedsteads, attaching cutters for cutting screws on rails of	XVII.
	Zoiner, Paul W. (See Harris & Zoiner.)		

VII.

INVENTIONS AND CLAIMS

FOR THE YEAR 1851.

No. 7865.—*Improvement in Daguerreotype Pictures.*

What I claim as new, and of my own invention, and desire to secure by letters patent of the United States, is the application of transparent or translucent materials, of varying thicknesses and forms, separately, or in combination with each other, and the application of substances or materials, more or less opaque, either separately or in combination with transparent or translucent materials; both, or either, when such applications and combinations are separately, consecutively, or conjointly employed, for the purpose of manipulating the action of light or chemical substances, substantially in the manner, and with similar effects, to those described and shown.

CHARLES J. ANTHONY.

No. 7866.—*Improvements in Car-couplings.*

Having thus described my invention and improvement, and shown the operation of the same, I wish it to be distinctly understood that I do not claim "*the method of coupling railroad cars, &c.*, by means of *double coupling irons or jaws in combination with a sliding bar*" for disengaging or unlocking said double irons or jaws to relieve the connecting bolt from the draught beam of the leading car, by the deflection of said leading car from the proper line. But what I do claim as my improvement, and desire to secure by letters patent, is in *combination* with the *curved arms* or *ends*, X', X', of the *jaws*, X, X, the *turning slotted* bar, L, attached to the *casing*, T, (fig. 2,) having its ends, L', L', curved in such a manner as to act as levers, and the spring, B, for keeping the slotted bar, L, and jaws, X, in their proper position; the disconnexion of the cars being effected by the contact of the curved arms, or ends, L', of the turning bar, L, with the draught beam, P, when the preceding car runs off the track; when either of the curved arms, X', of the jaws will be relieved from the slot of the turning-bar, L, and permit its curved end, X', to move outward, and open its outer end, and permit the connecting bolt to pass therefrom.

SILAS M. COCHRAN.

No. 7867.—*Improved Nozzle for Lead Pipe Machines.*

What I claim as my invention, and desire to secure by letters patent, is the corrugated nozzle, with its mandrel, through which melted lead is pumped, for the purpose of making pipe, as herein set forth.

JOHN B. COLLAN.

No. 7868.—*Improvement in Planing-Machines for dressing the edges of Boards.*

What I claim, therefore, as my invention, and desire to secure by letters patent, is the method, substantially as described, of communicating motion from the bottom to the top roller by the two pinions combined with the wheel, having the inner and outer rim of cogs, by means of the joint links, substantially as described. and for the purpose specified.

I also claim operating the machinery for carrying the cutter wheel towards or from the line of motion of the plank by the passage of the plank over and in contact with a spur wheel or wheels, substantially as described; whereby the motion of the cutter wheel for edging tapering planks will be made to correspond with the motion of the plank itself, as described.

I also claim interposing between the wheels, or wheels actuated by the plank and the carriage of the cutter wheel, a reversing motion, substantially as described, by means of which the machine can be made to act on the plank from the narrow towards the wide end, or *vice versa*, or, by suspending its operation, edge the plank with parallel sides, as described.

WILLIAM E. CORNELL.

No. 7869.—*Improvement in Water Metres.*

What I claim as my invention, and desire to secure by letters patent, is connecting the two pistons with the two cranks of a crank-shaft, in manner substantially as described; so that at the end of each stroke of either of the pistons it shall remain at rest, while the crank-shaft is being impelled by the other piston; so that the valves shall be shifted, whilst the piston is at rest, for the purpose, substantially as described.

I also claim, in an instrument for the purpose, herein specified, determining the range of motion of the pistons by means of stops connected with the cylinders and the pistons, substantially as described, in combination with the connexion of the pistons with the crank or cranks by means of a joint, having sufficient play to permit the pistons alternately to remain at rest, while the crank-shaft continues to rotate, substantially as described.

I also claim enclosing all the moving parts of an instrument, substantially such as above described in the surrounding casing, through which the water or other fluid passes to be measured, constructed and operating in the manner, and for the purpose, substantially as described.

J. ERICSSON.

No. 7870.—*Improvement in Churns.*

Having thus fully described the construction and operation of my improved double dasher churn, what I claim therein as new, and desire to secure by letters patent, is connecting two vertical chains by a horizontal tube at their bottoms, substantially as described, (said tube being about ten inches long, and about one-fifth of the capacity of one of the vertical cylinders,) in combination with the perforated cutters, E, E, operating in the manner and for the purpose herein fully set forth.

DANIEL FISHER.

No. 7871.—*Method of connecting the Slide Valve with the Rock Shaft.*

Having thus fully described the nature and construction of my improvements in oscillating steam engines, what I claim therein as new, and desire to secure by letters patent, is the tubular nut, (13.) serving the two-fold purpose of a guiding rod and of a clamp for the ball joint at the foot of the valve-pitman.

SAMUEL H. GILMAN.

No. 7872.—*Improvement in Machines for assorting Broom Corn.*

What I claim as my invention is the combination of the endless platform, the roller, G, and the series of pressure rollers, or any mechanical equivalents therefor, as arranged and made to operate together, substantially in the manner and for the purpose as herein before described. And, in combination therewith, I claim the rotary shears and the weighted roller, *m'*, or their mechanical equivalents, the whole being applied and made to operate together, essentially as hereinbefore specified.

LORENZO D. GROSVENOR.

No. 7873.—*Improvement in Quilting Frames and Apparatus.*

What I claim as my invention, and desire to secure by letters patent, is the movable frame, working on the connecting piece O, containing two slides, with wickers, for the purpose of stretching the quilt to any desirable length or breadth, as the case may be, in combination with the slides Nos. 1 and 2, working in sections, C, C, by which the quilt may be enlarged or diminished on the rollers Nos. 1 and 2 as set forth.

ABRAHAM KAUFMAN.

No. 7874.—*Improvement in Spring Carriage Wheels.*

What we claim as our invention, and desire to secure by letters patent, is the construction of the spokes, B, B, B, B, B, B, B, B, of flat steel, split, or divided and curved, as at *a*, *a*, and secured, as at *b*, *b*, Fig. 1, for the purpose and in the manner herein shown.

JOHN LAMB,
CHARLES H. ROOT.

No. 7875.—*Improvement in Candlesticks.*

Having thus described the nature and operation of my invention, what I claim as new, and desire to secure by letters patent, is the combination of the flanch, B, with the circular cap, C, having its orifice, E, eccentric with its periphery, and a guard, G, operating in the manner and for the purpose as above described.

JAMES MANNING.

No. 7876.—*Improvements in Looms for weaving Seamless Bags.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement in one loom of the two series of cams, substantially as described; one series for weaving the cloth double, and the other single, as herein described, in combination with the shifting the treddles from one series of cams to the other, or the equivalent thereof, substantially as herein described.

SHELDEN NORTHROP.

No. 7877.—*Improvement in Seed Planters.*

Having thus fully described my improved seed drill, what I claim as new therein, and desire to secure by letters patent, is—

First. The pinion, K, working between fixed and movable racks, in combination with the elevating yoke (*e*) and the loop (*f*) on its end, for the purpose of raising the teeth from the ground, and simultaneously throwing the feeding apparatus out of gear, substantially as set forth.

Second. I claim the feeding gear, as described, in combination with the lever, (*g*.) and its adjustable fulcrum, permitting the pinions to be reversed, by which double the number of changes can be made as can be done by the same number of pinions on the ordinary arrangement.

J. P. ROSS.

No. 7878.—*Improvement in Printing Presses.*

Having thus described my improvements in printing presses, I shall stake my claim as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is the gauge bar, for cards, hereinabove referred to, in combination with the vibrating platen and stop finger, and crank, which operates the same, in the manner and for the purpose hereinabove described.

I also claim the use of a segment of a cylinder, in combination with the stationary form bed, so that the rotary inking apparatus may move over the form, and then, after taking ink from the fountain, distribute it on said cylinder as hereinabove set forth.

I also claim the movable bearers on the side of the form bed, arranged and operated substantially as herein above described, so as to be moved outwards when the inking rollers are passing over the form, and drawn inwards when the sheet or tympan is moved up to said form.

I also claim regulating the delivery of the ink by combining with the delivering roller a grooved ratchet wheel and weighted pawl band, operating with the lever stud, cam roller, and stop lever, substantially as hereinabove specified.

I also claim supporting the journals of one of the inking rollers on sliding bearers, so that it may be moved up against the delivering roll by means of studs on said bearers and cams, operating the same as hereinabove set forth.

STEPHEN P. RUGGLES.

No. 7879.—*Improvement in Machines for turning Irregular Forms.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the horizontal carriages, G, G, working inside of and moving vertically with the carriage, F, and operating as herein described, for the purpose of making the pattern and rough material pass and repass the tracers and cutting tools, or *vice versa*, when the same are used in combination with a pattern and rough block which do not revolve, and are presented to and operated upon by said tracers and cutters as herein described and represented, and for the purposes fully set forth.

JONATHAN RUSSELL.

No. 7880.—*Improvement in manufacture of India Rubber.*

Having described my improved process for curing rubber, I will state what I claim and desire to secure by letters patent. What I claim, therefore, is the use and employment of zinc, substantially as prepared by the process above described, in combination with India rubber, for the purpose of curing or vulcanizing it, in form and manner as herein set forth, without the use of free sulphur in any way in combination with the rubber.

JONA. T. TROTTER.

No. 7881.—*Improvement in Corn Shellers.*

Having thus described my improvements, I shall state my claims as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is casting the fly wheel of the corn sheller solid with the feeding wheel, so as to bring it between the two bearings of said wheel, as hereinbefore set forth.

JOSHUA M. C. ARMSBY.

No. 7882.—*Improvement in Spring Mattresses for Invalids.*

Having thus fully described my improvements, what I claim, and desire to secure by letters patent, is—

Firstly. The employment of the end stays, (*b*,) having rule joints allowing a limited range of motion, and standing in a bracing position, substantially in the manner and for the purposes set forth.

Secondly. I claim the centre supports for rendering that part of the mattress permanent when desired.

DAVID BAIRD.

No. 7883.—*Improvements [illegible] otary Pumps.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the curved water ways in the annular space above the fan or paddle, when substantially as described, in combination with the rotating fan or paddle wheel, substantially as described, and for the purpose specified.

And I also claim the self-adapting valves substantially as described, and governing the apertures leading to the annular space above, in combination with the rotating fan or paddle wheels, and the curved water ways, substantially in the manner and for the purpose specified.

PHINEAS BENNET.

No. 7884.—*Improvement in Looms for weaving Tapestry Carpets with parti-colored warp.*

What I claim as my invention, and desire to secure by letters patent, is regulating the delivery of giving out of one or more warps or chains by the separate tension of each, substantially as specified, in combination with a ground or controlling warp, which determines the length of cloth made at each beat of the lathe, by having the delivery of the said ground or controlling warp regulated by its tension, and controlled by a break, or the equivalent thereof, when the lathe beats up, substantially as specified.

I also claim the employment of an index wheel, or measuring apparatus, or the equivalent thereof, to indicate the length of figuring warps given out or taken up in the process of weaving, substantially as and for the purpose specified, when this is combined with an index or measuring apparatus, to indicate the amount of cloth woven, substantially as and for the purpose specified.

And, lastly, I claim the employment of fingers moving or vibrating independently of the lathe, substantially as and for the purpose specified.

E. B. BIGELOW.

No. 7885.—*Improvement in Fountain Inkstands.*

What I claim as my invention, and desire to have secured to me by letters patent, is the arrangement for cutting off the communication between the cup and the main fountain of ink, by means of a layer of cork or other similar substance in the bottom of said fountain, and a cork or other similar stopper fitted on the bottom of the cup tube, or the lower end of said extended cup tube, pressing against said layer, as set forth, in combination with above specified arrangement; the inner cylinder in which said stopper moves as a piston, by which the air is more effectually excluded from the main fountain of ink.

FRANCIS DRAPER.

No. 7886.—*Improvement in Machines for jointing Staves.*

Having thus fully described the nature, construction, and operation of my invention, what I claim therein as new and original, and desire to secure by letters patent, is the arrangement, substantially as herein described, of a circular rest, having a sliding motion to and fro in the plane of its axis, and having around its perimeter catches, for the retention of the stave during the process of jointing, and rotating the distance from stave to stave at every forward stroke, and held fast for the action of the rotating jointers upon the stave at every return stroke; the jointers and circular rest being so arranged as to impart at the same time to the stave edges any given bevel and taper, according to the size and bilge of the cask.

WILLIAM MAGUIRE.

And I also claim the self-adapting valves substantially as described, and governing the apertures leading to the annular space above, in combination with the rotating fan or paddle wheels, and the curved water ways, substantially in the manner and for the purpose specified.

PHINEAS BENNET.

No. 7884.—*Improvement in Looms for weaving Tapestry Carpets with parti-colored warp.*

What I claim as my invention, and desire to secure by letters patent, is regulating the delivery of giving out of one or more warps or chains by the separate tension of each, substantially as specified, in combination with a ground or controlling warp, which determines the length of cloth made at each beat of the lathe, by having the delivery of the said ground or controlling warp regulated by its tension, and controlled by a break, or the equivalent thereof, when the lathe beats up, substantially as specified.

I also claim the employment of an index wheel, or measuring apparatus, or the equivalent thereof, to indicate the length of figuring warps given out or taken up in the process of weaving, substantially as and for the purpose specified, when this is combined with an index or measuring apparatus, to indicate the amount of cloth woven, substantially as and for the purpose specified.

And, lastly, I claim the employment of fingers moving or vibrating independently of the lathe, substantially as and for the purpose specified.

E. B. BIGELOW.

No. 7885.—*Improvement in Fountain Inkstands.*

What I claim as my invention, and desire to have secured to me by letters patent, is the arrangement for cutting off the communication between the cup and the main fountain of ink, by means of a layer of cork or other similar substance in the bottom of said fountain, and a cork or other similar stopper fitted on the bottom of the cup tube, or the lower end of said extended cup tube, pressing against said layer, as set forth, in combination with above specified arrangement; the inner cylinder in which said stopper moves as a piston, by which the air is more effectually excluded from the main fountain of ink.

FRANCIS DRAPER.

No. 7886.—*Improvement in Machines for jointing Staves.*

Having thus fully described the nature, construction, and operation of my invention, what I claim therein as new and original, and desire to secure by letters patent, is the arrangement, substantially as herein described, of a circular rest, having a sliding motion to and fro in the plane of its axis, and having around its perimeter catches, for the retention of the stave during the process of jointing, and rotating the distance from stave to stave at every forward stroke, and held fast for the action of the rotating jointers upon the stave at every return stroke; the jointers and circular rest being so arranged as to impart at the same time to the stave edges any given bevel and taper, according to the size and bilge of the cask.

WILLIAM MAGUIRE.

No. 7879.—*Improvement in Machines for turning Irregular Forms.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the horizontal carriages, G, G, working inside of and moving vertically with the carriage, F, and operating as herein described, for the purpose of making the pattern and rough material pass and repass the tracers and cutting tools, or *vice versa*, when the same are used in combination with a pattern and rough block which do not revolve, and are presented to and operated upon by said tracers and cutters as herein described and represented, and for the purposes fully set forth.

JONATHAN RUSSELL.

No. 7880.—*Improvement in manufacture of India Rubber.*

Having described my improved process for curing rubber, I will state what I claim and desire to secure by letters patent. What I claim, therefore, is the use and employment of zinc, substantially as prepared by the process above described, in combination with India rubber, for the purpose of curing or vulcanizing it, in form and manner as herein set forth, without the use of free sulphur in any way in combination with the rubber.

JONA. T. TROTTER.

No. 7881.—*Improvement in Corn Shellers.*

Having thus described my improvements, I shall state my claims as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is casting the fly wheel of the corn sheller solid with the feeding wheel, so as to bring it between the two bearings of said wheel, as hereinbefore set forth.

JOSHUA M. C. ARMSBY.

No. 7882.—*Improvement in Spring Mattresses for Invalids.*

Having thus fully described my improvements, what I claim, and desire to secure by letters patent, is—

Firstly. The employment of the end stays, (*b*,) having rule joints allowing a limited range of motion, and standing in a bracing position, substantially in the manner and for the purposes set forth.

Secondly. I claim the centre supports for rendering that part of the mattress permanent when desired.

DAVID BAIRD.

No. 7883.—*Improvements* [illegible] *otary Pumps.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the curved water ways in the annular space above the fan or paddle, when substantially as described, in combination with the rotating fan or paddle wheel, substantially as described, and for the purpose specified.

And I also claim the self-adapting valves substantially as described, and governing the apertures leading to the annular space above, in combination with the rotating fan or paddle wheels, and the curved water ways, substantially in the manner and for the purpose specified.

PHINEAS BENNET.

No. 7884.—*Improvement in Looms for weaving Tapestry Carpets with parti-colored warp.*

What I claim as my invention, and desire to secure by letters patent, is regulating the delivery of giving out of one or more warps or chains by the separate tension of each, substantially as specified, in combination with a ground or controlling warp, which determines the length of cloth made at each beat of the lathe, by having the delivery of the said ground or controlling warp regulated by its tension, and controlled by a break, or the equivalent thereof, when the lathe beats up, substantially as specified.

I also claim the employment of an index wheel, or measuring apparatus, or the equivalent thereof, to indicate the length of figuring warps given out or taken up in the process of weaving, substantially as and for the purpose specified, when this is combined with an index or measuring apparatus, to indicate the amount of cloth woven, substantially as and for the purpose specified.

And, lastly, I claim the employment of fingers moving or vibrating independently of the lathe, substantially as and for the purpose specified.

E. B. BIGELOW.

No. 7885.—*Improvement in Fountain Inkstands.*

What I claim as my invention, and desire to have secured to me by letters patent, is the arrangement for cutting off the communication between the cup and the main fountain of ink, by means of a layer of cork or other similar substance in the bottom of said fountain, and a cork or other similar stopper fitted on the bottom of the cup tube, or the lower end of said extended cup tube, pressing against said layer, as set forth, in combination with above specified arrangement; the inner cylinder in which said stopper moves as a piston, by which the air is more effectually excluded from the main fountain of ink.

FRANCIS DRAPER.

No. 7886.—*Improvement in Machines for jointing Staves.*

Having thus fully described the nature, construction, and operation of my invention, what I claim therein as new and original, and desire to secure by letters patent, is the arrangement, substantially as herein described, of a circular rest, having a sliding motion to and fro in the plane of its axis, and having around its perimeter catches, for the retention of the stave during the process of jointing, and rotating the distance from stave to stave at every forward stroke, and held fast for the action of the rotating jointers upon the stave at every return stroke; the jointers and circular rest being so arranged as to impart at the same time to the stave edges any given bevel and taper, according to the size and bilge of the cask.

WILLIAM MAGUIRE.

No. 7887.—*Improved Fly Tumbler Lock for Fire Arms.*

What I claim as my invention is the fly tumbler, arranged and combined with respect to the sear and the cock, in the manner and for the purposes set forth in my specification.

STANHOPE W. MARSTON.

No. 7888.—*Improvement in Grass Harvesters.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the manner herein described of suspending the cutter ring, *h*, from the wheel, *f*, by means of straps, or other yielding material, for the purpose herein described.

I also claim the combination of the cutters, *i*, *i*, *i*, &c., bevelled cutter ring, *h*, and straps, *g*, *g*, &c., for the purpose of raising the cutter ring over any obstruction coming against the edge of the knife, as herein described.

I also claim the manner of arranging the guide-board, *m*, standard, *n*, arm, *o*, and strap, *r*, secured as described, for the purpose of guiding the machine, and allowing the parts to yield to a sudden stopping of the machine, or to irregularities in the ground, for the purpose and in the manner herein described.

EDWARD NEELY.

No. 7889.—*Improvement in Electro-Magnetic Engines.*

I do not confine myself to the use of any particular battery. What I claim as my improvement, and wish to secure by letters patent, is the insulated disks, in combination with the platina points, to act in concert with the magnetic wheels, in manner and form and for purposes herein described.

JACOB NEFF.

No. 7890.—*Improved arrangement of Arches in Bridge Trusses.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the method herein described of combining and arranging the several arches of a bridge, so as to make each arch, alternately, the upright and inverted arch, as it passes from one span of the bridge to another, and *vice versa*, when one set of said arches have their remotest distance from each other, and their greatest sustaining point directly over and under the points where the other set of arches are changing from upright to inverted arches, or *vice versa*.

C. M. PENNINGTON.

No. 7891.—*Improvement in Coal Stoves.*

We have described such arrangements of flues, &c., as we have essayed with success in the application of the principle of our invention; but we do not wish to limit ourselves to these. as they may be variously modified. But what we claim as our invention, and desire to secure by letters patent, is the method, substantially as herein described, of supplying currents of atmospheric air to the products of the combustion at or near the throat leading from the fire chamber to the flues, in combination with what is known as Nott's fire chamber, having the draught-throat leading therefrom between the top and the grate, that the upper part of the fire-pot may constitute a feeder or chamber of preparation, substantially in the manner and for the purposes specified.

JAMES SHIELDS,
SAMUEL PIERCE.

No. 7892.—*Improved Parallel Vice.*

What I claim as my invention, and desire to secure by letters patent, is the attaching the lower end of the moving jaw of the vice to a block that is attached to, and moves with, the end of the screw, in the manner and for the purposes herein described.

SAMUEL R. SIMPSON.

No. 7893.—*Improvement in Ox Yokes.*

What I claim as my invention, and desire to have secured to me by letters patent, is arranging in the beam of the yoke two draught staples, some six inches apart, in lieu of one at the centre; and the combination, or use therewith, of a branch chain of proper length, connected to the main draught chain at a proper distance from the beam, and the adjustable hook for modifying the length of the branch chain, as hereinabove specified, and for the purpose set forth.

ANDREW L. SIMPSON.

No. 7894.—*Improved means for revolving the Breeches of Repeating Fire-Arms.*

What I claim as of my own invention, and desire to secure by letters patent of the United States, is the cranked shaft (*e*, *c*, *b*) operated by the tumbler having its axis of vibration in the line, or nearly so, with the axis of rotation of the cylinder, substantially in the manner herein set forth.

JAMES WARNER.

No. 7895.—*Improvement in the manufacture of Caviar.*

What I claim, therefore, as my invention, is the improvement in the process of salting the roe or ova, whereby extraneous matters are separated; the same consisting in suffering it to stand in pickle, or a strong saline solution, until it undergoes a process or change by which the ova, and such extraneous matters, separate from one another—the former rising to the surface of the pickle, while the latter falls to the bottom of it.

And I also claim the combination of the male sturgeon oil, as above mentioned, with the salted ova, for the purpose of improving the manufacture thereof as specified

R. G. WESTACOTT.

No. 7896.—*Improvement in Tires for Railroad Car Wheels.*

What I claim, therefore, as my invention, and for which I wish to obtain letters patent, is making the tire of car wheels, by the combination of several distinct pieces, so arranged and disposed as mutually to support and confine each other, substantially in the manner above described.

T. T. ABBOT.

No. 7897.—*Improvement in raising Carriage Tops.*

What I claim as my invention, and wish to secure by letters patent, is the application of a spiral spring to operate upon the braces of a carriage top, so as to assist in supporting and elevating the top, substantially as described and shown.

JOHN L. ALLEN.

No. 7898.—*Improvement in Looms for weaving Piled Fabrics.*

I do not wish to limit myself to the particular mode of connecting the series of bars or plates to admit of the required vibration, as other modes of connecting them may be employed; as, for instance, instead of hanging them back of the lathe by pendulous jointed links, the rods by which they are connected may be adapted to work in slides; but I have described and represented the mode which I have essayed with success and deem the best.

What I claim as my invention, and desire to secure by letters patent, is connecting the intersecting bars or plates with the loom, substantially as described, so that they shall be free to vibrate and yield to the beat of the lathe and shedding of the warps, as described.

And I also claim, combining with the said vibrating bars or plates, a stop or stops, to arrest them at the required point, substantially as described, that the continued beat of the lathe may cause the fabric to move forward over them, as described.

E. B. BIGELOW.

No. 7899.—*Improvement in connecting and disconnecting Hubs and Axles.*

What I claim as my invention, and desire to secure by letters patent, is my device for detaching a wheel from its axle-tree by means of the plate, C, C, acting as a wrench for unscrewing the nut, B, which holds the wheel to the axle; said plate being advanced and withdrawn by the screw, D, substantially in the manner herein described.

A. M. BILLINGS.

No. 7900.—*Improvements in Tuyers.*

What I claim in the foregoing as my invention, and desire to secure by letters patent, is the curved partition in the air chamber, placed opposite the orifice of the windpipe, with its lower edge extending beneath this orifice; the arrangement and construction of the partition being such that it serves the double purpose of directing the blast upwards and facilitating the descent of the cinders, as herein set forth.

JOSEPH DORWART.

No. 7901.—*Improvement in Rotary Pumps.*

I do not claim to be the inventor of the centrifugal pump.

I do not claim simply using collars extending from the openings in the outer case to the openings in the piston case, to prevent the water or air from passing between said cases; nor extending the inlet or suction-pipe inwards in such a manner as to supply the place of one of said collars—this having already been done; but I only claim thus extending said pipe when the collar on the opposite side is made adjustable, and the parts so arranged that the joints of the piston-case with said pipe and collar may be tightened, as they wear by tightening the adjustable collar only, as described; the piston and case, and the suction-pipe being constructed substantially as herein described.

J. STUART GWYNNE.

No. 7902.—*Improvement in changing a reciprocating into a rotary motion.*

What I claim as my invention, and desire to secure by letters patent, is the application to steam or other engines, or machines of a mechanical arrangement, whereby the effect of the applied power is rendered equal, (or nearly so,) both on the outward and return strokes of any reciprocating or vibrating movement, using for that purpose the aforesaid combination of the cranks, connecting rods, and oscillating lever, or their equivalents, as described in the above specification, and shown in the accompanying drawings.

JOSEPH HARRIS, Jr.

No. 7903.—*Improvement in Cast Iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is the mode of constructing a cast iron car wheel, by the use of spokes or arms, composed in part of portions of a hollow cone, connected by brackets, and in part by straight spokes or arms, forming a continuation of plates and spokes, possessing the advantages and obviating the objection of both.

GEO. R. McFARLAN.

No. 7904.—*Improvement in Reflectors for Street Lamps.*

What we claim as our invention, and desire to secure by letters patent, is making the faces of the reflector in concave rings, substantially in the manner and for the purposes herein set forth.

HUGH SANGSTER,
JAMES SANGSTER.

No. 7905.—*Improved Steering Apparatus.*

What I claim as new in my invention, and desire to secure by letters patent, is the combination of the cranks, H, H, and the connecting rods, K, K′, which are attached by universal joints to the projections or arms, X, X, on the rudder post, the cranks having a worm-wheel, G, on their shaft or axis, which gears with and is actuated by an endless screw, F, on the axle or shaft of the steering-wheel, the whole of the parts being arranged in the manner substantially as described.

JAS. E. ANDREWS.

No. 7906.—*Improvement in Carriages.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of two bars or reaches, placed in connexion with the straight reach, as above described, and combination with the spring-rod and cross-bar, substantially in the manner described.

JOHN JONES.

No. 7907.—*Improved Propeller.*

What I claim as my invention, and desire to secure by letters patent, is a propeller, constructed as herein described, in such manner that any one of its blades in any line drawn either parallel or perpendicular to its entering edge shall have the curvature of a parabola produced, as herein set forth.

A. W. THOMPSON.

No. 7908.—*Improvement in Brick Presses.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is—

First. I claim, in combination with the clay ducts and alternating carriage of moulds, the rods, *g'*, with their knives, H', (for the purpose of cutting off and forcing into the moulds the regular quantity of clay,) and sliding plate or gate, Z, for the purpose of opening and closing the communication between the clay ducts and moulds, as herein described and represented.

Second. I claim the arrangement of the pins, *n*, *n*, connecting rods, *o*, *o*, and standard, N, with its arm, Q, for the purpose of removing the brick after it is raised from the moulds, when the same are operated by means of the cranks, as herein described and shown.

J. SCHEITLIN.

No. 7909.—*Improvement in Stoves.*

Having thus described my improvements in the combined open and air-tight stoves, and shown the advantages of the same, I wish it to be understood that I do not claim the device of sliding doors between parallel jambs or plates for the purpose of concealing the same.

But what I do claim as new, and desire to secure by letters patent, is the providing of the sliding doors, A, with flanges, H, H, on their vertical edges, the real flanges serving the purpose of hinges—in opening and closing the same, and also serving to form air-tight joints when the doors are closed; and the front flanges serving, in connexion with the projecting ends, E, E, of side plates, B, B, to relieve the appearance of a joint when the doors are opened, as before described.

I also claim the providing of the side plates, B, B, with projecting front plates, F, F, for the purpose of forming fronts to the spaces into which the doors are slid when open, to conceal the same; and in connexion with the rear flanges, H, H, to form the hinges of the doors when closing the same; and also to conceal a portion of the front flanges when the doors are opened and slid back, as described.

GEORGE H. THATCHER.

No. 7910.—*Improvement in Convertible Plough Stock.*

What I claim as my invention, and desire to secure by letters patent, is so constructing a subsoil plough, with removable mould board and cutter, in combination with the tri-pronged cultivating teeth, that the same stock may be used either for a subsoil plough or common ploughing and cultivating the land, as herein set forth.

EDWARD T. PARKER.

No. 7911.—*Improvement in Tools for embossing Backs of Books.*

I do not claim forming various devices by gluing or securing loose or detached tools to a surface, as that is common.

But what I do claim as my invention, and desire to secure by letters patent, is forming circular embossing, gilding, or lettering tools of any required pattern for embossing, gilding, and lettering book-covers, by having a case or hollow metal cylinder, B, fitting on a roller, A, and having an opening, *b*, *b*, or openings, in it of any required form for a panel or other border, the part of the periphery of the roller, A, within the opening or openings in the case, having any required number of small tools, *c*, *c*, *c*, of any suitable form or pattern secured to it; the surfaces of the said tools standing even with the outer face of the case or cylinder, B, or by the employment of any number of tools consisting of parts of a hollow cylinder secured to a solid cylinder, substantially in the manner herein described.

CHARLES STARR.

No. 7912.—*Improved Lee-way Indicator.*

What I claim as my invention, and desire to secure by letters patent, is hanging the vane, E, loose at the bottom of the rod, C, which carries or communicates with the pointer, and holding it either in position for operation or secure within the vessel, above the bottom of the keel, by means of a spring, *d*, or its equivalent, operating substantially as herein shown, and for the purposes set forth.

A. A. WILDER.

No. 7913.—*Horse Shoe Nail Machine.*

What, therefore, I claim is the simple combination of the punch, the slotted bed-die, the heading die, the header slide, discharging orifice, and header as arranged, constructed, and made to operate together, substantially as specified; or, in other words, their arrangement and construction essentially as explained, whereby they are made to separate the nail blank from the rolled plate; to move it downwards upon the header slide; to cause the header slide to advance in the mean time; to hold the nail blank by means of the punch and header slide; to cause the header slide to slide underneath the nail while it is so held; to carry the header against the nail, and head it; to cause the header slide to retrack or move backwards far enough to carry or move the discharging orifice directly under the nail, so that the nail may be forced down into or through such orifice by the further depression of the punch, which next takes place; and, finally, to elevate the said punch to its first or highest position.

DANIEL WILSON, Jr.

No. 7914.—*Improvement in Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the combination of a transparent water vessel, with mica-covered or other transparent openings, in the top of a stove plate, and a mirror placed upon a stove top, as herein represented and described.

ELIHU SMITH.

No. 7915.—*Improvements in Metal, or Second Patterns for Castings.*

What I claim as my invention, and desire to secure by letters patent, is preparing second patterns, by moulding metal patterns in two-part moulds. and then separating the two parts of the mould, the pattern being left in the sand, to cast a plate fitted to the metal pattern, so moulded as specified; so that the pattern can be attached to the plate, and the two be used in moulding to produce castings, substantially as described.

FRANCIS N. STILL.

No. 7916.—*Improvement in Abdominal Supporters.*

Having described the construction, and also the operation, of my improvement, what I claim as my invention, and desire to secure by letters patent, is the construction of hip springs, with split or divided ends, forming elongations of the same strip of steel, the front prongs having slots and pivot holes, and the back prongs having two or more graduating pivot holes, to be used in combination with the adjusting screw and pivot screws, as herein substantially set forth.

MOSES L. KNAPP.

No. 7917.—*Swivel-nibbed Key.*

I therefore claim as my invention, and desire to secure by letters patent, the making the exposed ends of keys in such a manner that they may revolve freely upon the other parts of the key substantially in the manner and for the purposes described.

JAMES HANLEY.

No. 7918.—*Improvement in the Hydraulic Rams.*

I claim as my invention and improvement the hinge valve, C, opening upwardly and inwardly, at or near the upper end of the inclined plane or drive pipe, C, D, of the hydraulic ram; said valve being placed in a box made of brass, or any other suitable materials; which valve, by closing on the reaction of the water in the drive-pipe, prevents the said reaction from distributing the water in the spring or reservoir. The box of said valve is bolted to the drive-pipe, as represented in the annexed drawing; and said valve may be a hinge-valve, or any other suitable valve.

WILLIAM FIELDS, Jr.

No. 7919.—*Improvement in drawing Regulators for Spinning Machines.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the trumpet, as herein described, in connexion with the system of weighted levers, escapements, and reversed cone-pulleys, whereby the force required to move the trumpet is made to vary, under different circumstances, to a sufficient extent to prevent over-sensitiveness in the mechanism, which changes the relative speed of the drawing-rolls to inequalities in the slivers; while at the same time but little force is required to effect such changes, thus proportioning the draw more nearly than heretofore to the quantity of fibre in the slivers, and thereby rendering the latter of more uniform diameter and density.

NEWELL WYLLYS.

No. 7920.—*Improvement in Pens for Ruling Paper.*

Whatever may be the number of thicknesses of metal of which the back bar and pens are composed, my improvement, and what I claim, consists in not only making the upper one longer than the others, but in making it the marking part, and soldering the next one below it to it, as specified. Such improved mode of making the pen or pens, I claim as my invention, whether the plates of metal placed upon another be of different metals, or of different thicknesses of metal, as described. And I also claim the improvement on the construction of the back bar; the same consisting in making it with a slit, or opening, *u*, between any two pens, and extending nearly or quite up to the vertex of the angle or bend of the bar, as specified; the same producing the advantage above mentioned.

And when the pen is composed of more than two thicknesses of metal, I claim the improvement by which one single soldering of the upper and lower parts together, suffices to bind or keep all the parts together, or in place; the said improvement consisting in making the lowest thickness of metal longer than any of the others, except the first or upper, and marking one, as described.

And I also claim the method of making the pens and back bar, as shown in figures 5 and 6, when the same are composed of two *different* thicknesses of metal, or of two plates of different metals; the said improvement consisting in making the lower plate to enclose or lap over the one or other above it, as seen at *g*, in figure 6, and thus make the back bar of one more thickness of metal than the pens are composed of.

And I also claim to make the different thicknesses of the pen of different metals, as specified.

ALFRED HATHAWAY.

No. 7921.—*Improvement in Lard Lamps.*

Having thus described my invention and improvement in lamps, I disclaim the invention of every part of the lamp except the angular chambers, *i*, or grooves, above the reservoir, *a*, on either side of the wick tubes, *b c*, for preventing the spilling or waste of the oil when the stem of the lamp is held in a horizontal or inclined position; and also the dove-tailed slide, *d*, and the aforesaid angular channels or grooves. *i*—I claim as my invention, in combination with a lamp of the peculiar form and construction represented in the annexed drawings, or other form, substantially the same; said channels or grooves serving also to receive and hold the sliding cover, *d*, used for closing the supply opening, instead of the ordinary screw-cap, and in combination with the aforesaid angular channels.

I also claim the said sliding cover, *d*, when made with correspondingly shaped sides to fit and move in said channels, all as herein described and represented.

DELAMAR KINNEAR.

No. 7922.—*Improved method of obtaining Motive Power.*

Having thus fully described the nature of my invention, and pointed out its distinctions from all others, what I claim, and desire to secure by letters patent of the United States, is actuating an engine, such as are now usually driven by steam, or of any convenient form, by means of the combustion allied to an explosion of a measured or detailed quantity of a charcoal (or other solid, carbonaceous fuel, similar in nature, and of like effect) in a measured quantity of highly compressed air, (or oxygen;) said combustion being effected in a vessel which, at that time, is not in connexion, either with the reservoir or main source of compressed air, or with that of the charcoal; and the gases resulting from each separate and distinct explosion being allowed to act on the pistons, or their equivalents, before the other charges are introduced into the exploding or combustion vessel; the whole operation being effected through the agency of apparatus in nature substantially such as are herein specified, or apparatus that shall effect the whole operation in the manner claimed.

I also claim in actuating an engine, as just claimed, using the combustible in a granulated or pulverized form, for the purposes and various reasons made known.

WM. MT. STORM.

No. 7923.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the construction of the adjustable and sliding partitions, (G and G, fig. 3,) by which the draught of the stove and the distribution of the heated air under the bottom of the lower oven is varied and controlled at pleasure, adjusting the same to the particular place and circumstances of each stove; the whole being arranged and constructed substantially as set forth and described.

BACHUS A. BEARDSLEY.

No. 7924.—*Improvement in Machines for Preparing Hides.*

I do not, therefore, wish to limit myself to the precise arrangement and construction herein set forth; but what I claim as my invention, and desire to secure by letters patent, is the method of consolidating and smoothing leather by drawing it with a continuous motion beneath a series of stampers, which alternately rise, fall, and rest upon its surface, a portion of the stampers being at all times in contact with the leather, so that the smoothing of its surface is constantly going on simultaneously with the consolidation by the blows of the falling stampers.

THOMAS W. JONES.

No. 7925.—*Improvement in Fancy Check Power Looms.*

I have thus fully described my improvement in fancy check power looms, and have adverted to many things in this description which I do not mean to claim as new. Some of them are of my own invention, and heretofore used by me—such as the revolving box, shuttle boxes on each end of the lay, to weave thread about the pin wheel, or chain bands of pins by themselves, having long since used them all myself; and, in a word, I disclaim, together with the forenamed, considered singly, everything pertaining to the common power-loom.

But I do claim as my invention the connecting a series of shuttle-boxes by joints at their lower corners, or attaching them to a flat-jointed chain, and connecting their extremities so as to form an endless chain of boxes, and bringing them into a parallelogramic figure by means of two square heads of a size to fit the space between the joints of the boxes, or the chain, and hung on journals, one on the end of the race-beam, and the other on the sword of the lay, substantially as heretofore described.

Second. I claim the combination of the irregular worm, the two sets of double rectangular levers, the connecting bars, and the vertical-notched levers on which the bars operate, the pin band and knees, and the wires connecting the knees and vertical-notched levers, through which the notched levers are moved forward and backward, to embrace the bars, giving them, with the heddles, an upward and downward movement, in any irregular manner desired, substantially as described in the specifications, constituting a new and advantageous *modus operandi* of forming a variegated shed.

ENOCH BURT.

No. 7926.—*Improved method of adjusting the packing of Rotary Engines.*

What I claim as my invention, and desire to secure byetters patent, is the method, substantially as above described, of regulating the packing-ring interposed between the steam-wheel and head of the cylinder, or outer casing of rotary steam-engines, by combining with the said packing-ring a series of segment wedges, operated simultaneously, in manner substantially as described.

HENRY G. THOMPSON.

No. 7927.—*Improved Ship's Light.*

Having thus fully described my invention, I will now proceed to state what I claim as new, and desire to secure by letters patent.

I claim hanging the screwed socket, or frame, C, containing the glass, so as to turn freely within a frame, H, which swings on a hinge, K, K, I, provided with a slot, K, or its equivalent, whereby the socket, C, can be screwed into, or unscrewed from, the fixed socket, B, and, when unscrewed, be swung back, substantially as herein described.

LEONARD GOODRICH.

No. 7928.—*Improvement in Grain Harvesters.*

Having thus described my improved reaping machine, I first claim combining with a reaping machine a self-acting weighing apparatus, for weighing the grain into any required quantity, to form sheafs or bundles of a uniform weight, as described, and depositing the same upon the ground in readiness to be tied, whilst the reaping machine is drawn forward and cuts the grain—the said weighing apparatus being made adjustive so to increase or diminish the size of the bundles at pleasure: and this I claim, whether the weighing apparatus be made and arranged as described, or in any other way which is substantially the same, or whether combined with the aforesaid reaping machine, or any other of a similar character.

Second. I likewise claim the combination of the beat-holders, W, W, with the inclined endless conveyor for holding the grain thereupon, whilst conveying it to the weighing and depositing apparatus, as aforesaid.

SIDNEY S. HURLBUT.

No. 7929.—*Improved Scraper.*

Having thus fully described our invention, what we claim as new, and desire to secure by letters patent, is the combination and arrangement of the scoop, A, standard, B, beam, G, arm, E, and handles, H, in such manner that when the scoop is tripped it will revolve sufficiently far to allow the earth to slide off, and then remain in such position that the operator, by a slight movement of the handles, can level down the earth with the scoop, and without the aid of another hand, or another scraper, as herein described and represented.

CHARLES SCHOFIELD,
GEORGE J. JOHNS.

No. 7930.—*Improvement in Seeding Apparatus of a Seed Planter.*

Having thus fully described the manner of constructing and operating our revolving multiplied distributor, and several of the modified forms of the same for distributing seed, and grain, and manures, and other substances, for various purposes, what we claim as our invention, and desire to secure by letters patent, is the employment of the ring, or cylinder, A, having projections on its periphery in combination with the notched and toothed cylindrical gauge caps, C, D, constructed, arranged, and operated substantially in the manner herein set forth, for increasing and diminishing the size and number of the distributing receptacles as represented in figures 1, 2, 3, 4, 5, and 6.

We likewise claim the combination of the helical spring, I, screw-shaft, E, flanged nut, N, and clamp nut, H, with the notched and toothed cylindrical gauge caps, to which the ends of the springs are attached for turning the gauge cap, in order to change the relationship of the teeth or projections of one of the caps with the teeth or projections on the adjacent cap, for enlarging the distributing receptacles, as described in the foregoing specifications, and represented at fig. 5 in the annexed drawings.

We also claim the combination of the screw-shaft, E, clutch-nut, G, clutch washer, F, and clamp-nut, H, with the toothed cylinder cups, C, D, for enlarging or diminishing the distributing receptacles, as described and represented in fig. 6.

We likewise claim the modifications of the distributing apparatus, in their simplified forms, as represented in figures 14 and 15, the several parts being operated in the manner herein set forth.

SAMUEL PENNOCK,
MORTON PENNOCK.

No. 7931.—*Improvement in Sewing Machines.*

What we claim as our invention, and desire to have secured to us by letters patent, is the use of two needles operating alternately—one working vertically, and the other horizontally, substantially as hereinabove described, and uniting two pieces of cloth, or forming the seam, by means of the double loop stitch, as hereinabove set forth.

WILLIAM O. GROVER,
WILLIAM E. BAKER.

No. 7932.—*Improvements in operating the Waste Gate in Hydraulic Rams.*

What I claim as my invention, and desire to secure by letters patent, is, the use of the regulating slide, M, and nut, or other similar arrangement, in combination with the levers, wires, springs, rods, weights, or other devices, substantially similar to those described for adjusting the "waste" valve, and operated on, and in connexion with a float, F, at the spring, or source, which float rises and falls with the water.

I also claim the use of the hammer, R, resting or falling on a springing piece, S, for opening the "waste" valve, D, or starting the hydraulic ram, and worked as described, or in any other similar manner.

JOHN OSBORN.

No. 7933.—*Method of securing Ranges of Short Plank in pavements.*

What I claim as my invention, and desire to secure by letters patent, is the method, above described, of securing ranges of short pieces of the planking of a street or road, in longitudinal lines, over water or gas pipes, by means of screws, or keys, with staples, aided by the double bevel of the short planks, and the ends of the permanent, interval planks securely holding and permitting the easy removal of such short piece.

JOSEPH E. WARE

No. 7934.—*Insulated Fusible Plug for Steam Boilers.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement, herein described, for surrounding a fusible plug and its case by a stratum of air, in such manner that the plug shall promptly melt and give warning, after the water gets low in the boiler, but before the boiler plate, to which the apparatus is applied, is left bare of water, substantially as herein set forth.

I also claim the arrangement of the stopper and plug case, substantially as herein described, for stopping the escape of steam, to admit of the replacement of the fusible plug, without blowing off the steam or water from the boiler after the plug has melted, substantially as herein set forth.

I likewise claim the method of preventing the waste of the metal of the plug, after it has melted, by supporting it in a closed socket, the lower unoccupied part of which is of sufficient capacity to receive and retain the metal when melted, and to allow the steam to pass over it to escape.

E. H. ASHCROFT.

No. 7935.—*Improved Annular Steam Boiler.*

Having thus described the nature of my invention and improvement in the construction of steam boilers, what I claim as new, and of my invention, and desire to secure by letters patent, is—

First. The employment of the tapered rings, B, for closing the ends of any of the water spaces of the concentric boilers, in the manner set forth.

Second. I also claim connecting the lower parts of the annular water spaces, each to each, from the upper and inner to the lower and outer one, substantially as described, by metallic rings or collars, thus giving free ebullition, assisting evaporation, and allowing the dirt to settle down into the blow-pipe, from whence it may be blown out; the aforesaid rings or collars bracing the boiler, as well as forming the connexion between the cylinders.

THOMAS CHAMPIN.

No. 7936.—*Improvements in Hand Looms.*

What I claim as my invention, and desire to secure by letters patent, is the device, consisting, substantially, of the tappet shaft, with its ring block and ratchet, together with the connecting cord-weight and marches, whereby the heddles are raised and depressed in the proper order to form the shed by the movement of the lay, substantially as herein set forth.

I likewise claim the device, consisting, substantially, of the levers, with the breast-beam cords and picker-stick cords, whereby the picker-sticks are moved to drive the shuttle by the movement of the lay.

ISAAC H. GARRETSON.

No. 7937.—*Improvement in Machines for turning Irregular Forms.*

What I claim as my invention, and desire to secure by letters patent, are—

First. The three cutter cylinders, A, B, C, with cutters arranged as within described, in combination with the sliding frame, compound

cams, and cam-rails, constructed and arranged substantially in the manner and for the purpose herein described.

Second. I claim the combination of the compound cams and cam-rails with the sliding frame and devices, within described, for holding and revolving the timber material, whereby such vertical motion is produced in the latter, while being subjected to the action of revolving or vibrating cutters, as to reduce the timber to the required form.

PHILO S. BEERS.

No. 7938.—*Improvement in Tools for tonguing, jointing, and rebating*

What I claim as my invention, and desire to secure by letters paten is so making a jointing, tonguing, and rebating plane, that the jointing and tonguing of a board, while resting on its edge, and also the jointing and rebating of it, while it lies on its flat side, may all be performed with one planing tool, in the manner substantially as herein described, and for the purposes herein set forth.

I also claim making the tonguing hand plane in such a manner as to enable the workman to make, therewith, tongues of various thicknesses, substantially in the manner herein set forth, whereby I prevent the necessity of providing different tools to tongue planks of different thicknesses.

I also claim, in combination with a divided body, or plane-stock, the two cutters, having each a cross-cutting and a side-cutting edge, and the means, substantially as herein described, for adjusting the distance apart of the two cutters and bodies, whereby the plane is made capable of dressing the sides of a tongue to any desired thickness, and, at the same time, to cut the shoulders as herein specified.

I also claim, in combination with the gauge, G, the use of the body, B′, and the cross edge of the cutter, P′, to constitute a jointer to straighten the edge of a board, preparatory to tonguing it, and while resting on its edge in a situation to receive the tonguing.

I also claim the gauge, G, in combination with the notch, *p*, and the side edge of the cutter, P, acting as herein described, as a jointing plane to straighten the edge of a board or plank, resting on its flat side, in a position to have a rebate cut in the manner substantially as herein set forth.

JOHN A. FRY.

No. 7939.—*Improvement in Weavers' Heddles.*

Having now described the nature of my invention, and in what manner the same is carried into effect, I declare that I do not claim metal in combination with harness or heddles, when used in the solid state, and fixed to the harness or heddle yarn at each end, such heddle yarn not being continuous, as in my invention.

But what I do claim as my invention, is covering, coating, or lining the loop eyes in heddles or harness with metal by the process I have shown, or by any equivalent process.

CHARLES TIOT JUDKINS.

No. 7940.—*Improved attachment for opening and closing Doors or Shutters.*

What I claim as my invention, and desire to secure by letters patent, is the use of swinging attachments, or jibs, F, G, for moving sliding-doors or shutters, constructed and operating substantially in the manner herein shown and described.

WM. POST.

No. 7941.—*Improved Snatch Block.*

What I claim as my invention, and desire to secure by letters patent, is the closing up of the opening in the side of a ship's snatch-block, by means of a gate, (E,) arranged and operating substantially as herein set forth, by which I am enabled to make the block shorter and more compact than it has heretofore been made.

I also claim the securing the pulley axle, *f*, in its place, without the aid of screw and nut, or rivet heads, and in such a manner that it can be readily removed by means of the combination of the said pulley-axle with the enclosing strap, C, and the gate strap, D, substantially in the manner herein set forth.

PHILIP RHODES, Jr.

No. 7942.—*Improvement in Planing Machines.*

I claim—First. The use of circularly grooved rollers in front of the cutter to divide and cut the unplaned surface of the board into narrow longitudinal strips, whereby the outer shavings are taken off in narrow strings or threads, in the manner and for the purposes herein set forth.

Second. I do not claim simply the arrangement of the plane stocks, with their cutters, upon the travelling frame in such order that one gang or set of cutters will plane one plank by their movement in one direction, and another gang of cutters plane another plank by their movement in the opposite direction, and remove the first plank planed from the bed; but this I claim only when these are used in connexion with the circular groove scoring roller, as within described.

D. H. SOUTHWORTH.

No. 7943.—*Improvement in Saw-Mills.*

What I claim as my invention, and desire to secure by letters patent, is the method of imparting a rocking or curved motion to the saw, and of straining the same by mechanical devices, substantially such as herein described.

ISAAC STRAUB.

No. 7944.—*Improvement in Apparatus for raising and carrying Water.*

What I claim as my invention, and desire to secure by letters patent, is the double draught cord so arranged and connected with the car windlass, that it effects the two-fold purpose, of propelling the carriage to and fro, and of turning the car-windlass to unwind and wind up the bucket cord, thus insuring the descent of the bucket into the well.

J. D. WILLOUGHBY.

No. 7945.—*Improvements in Knitting Machines.*

Having thus described the construction and operation of my improved machine, I claim as my invention the following new improvements:

My first improvement consists in the manner of producing the upward and downward motion, as above described, of the lead sinkers and the jack sinkers, so far as they move simultaneously; and

I claim the half-jack, U, vibrating on the comb-bar, P, and connected with the sinker-frame and with the movable cross bar, 28, and springs, 29, for the purpose of depressing the tail-ends of the jacks, and thereby raising their forward ends with the jacks' sinkers, as aforesaid.

I also claim the movable cross-bar, 28, containing the springs, 29, connected as aforesaid, and for the purposes aforesaid.

My second improvement consists in the manner of producing the backward and forward motion of the jack and lead sinkers, as above described; and

I claim the cams, 7, in combination with the cross-bar, 60, with the projections thereon; the hanging bars, S, vibrating on pivots; the comb-bar, P, and the half jacks, U, connected with the sinker-frame, as aforesaid, and for the purposes aforesaid.

My third improvement consists in the manner of moving the carrier-needle and slur-knob, as aforesaid; and

I claim the combination of the cam, V, and the shoe and shoe-plate, for the purposes aforesaid.

I also claim the combination of the cam, V, with the shoe, 5; the movable shoe plate, *f*; the chains, *h* and *l*; the semi-circles and hubs, or wheel and hub; the bar, W, connected with the slur-carriage and the slur-knob, Q, and the horizontal bar, X; the carriage, *q*, connected with the carrier-needle, q^2, for the purposes aforesaid.

My fourth improvement consists in the manner of moving the ribbed work attachment, and producing the ribbed stitch, simultaneously with the plain stitch, without the machine slide, and with one presser, as above described; and

I claim the combination of the cams, 9, with the levers, 18, connected with the frame, 17, and with the ribbed needle bar, 16, for the purposes aforesaid; also, the same in combination with the presser, *r*, connected, moved, and operating as aforesaid, and for the purposes aforesaid.

JOHN PEPPER.

No. 7946.—*Improvement in Cooking Ranges.*

What I claim as my invention, is the improvements by which the hot-water back is connected with the plate, G, and by means of which said hot-water back may be either readily removed at any time, or applied in such manner that the directions of its water pipes may be disposed so as to accommodate the bath boiler, into which they are usually led, on whatever side of the range the said bath-boiler may be placed; the said improvements consisting, *first*, in the connecting piece, H, and the attachment of it and the hot water back, the whole being made to operate together, substantially in the manner as above set forth; *second*, in a second set of attachments (fixed in the opposite face of the water back) in combination with the first set thereof, as described.

I also claim the peculiar arrangement of flues, which lead the smoke and volatile products of combustion directly around the oven; the said arrangement of flues causing the heat to course against one half of the bottom of the oven; next into another flue, which takes it *backwards* and against the other half of the bottom of the oven; thence up a flue against the back of the oven, through a flue extending over and against half of the top of the oven; thence into and through another flue, which carries it backwards and over and against the top of the oven and conveys it to the chimney or discharge flue—not meaning to include in such arrangement the radiating chamber or space, Y, Z, hereinbefore mentioned.

And I also claim the two recesses, *l*, *m*, and two flue-plates, *p*, *q*, applied to the plate, K, in combination with the two valve openings, X, A′, their damper and cam-plate, as applied to the top plate of the oven-frame and used under an arrangement of oven flues, substantially as described; the same allowing of the adaptation of the oven to either side of the fire-place, or the use of two such ovens and their frames, in connexion with the fire-place, all essentially as hereinbefore stated.

I also claim the improvement by which the oven can be raised and readily removed, and by which the smoke is prevented from passing underneath the partition which separates the flues on top of the oven, the same consisting in the sliding or gravitating plate, G′, affixed to the partition, and made to operate substantially in the manner as specified.

MOSES POND.

No. 7947.—*Improvement in the Bellows for Musical Instruments.*

What I claim as my invention, and desire to secure by letters patent, is the method, herein described, of making or constructing the *wind chest* commonly used in seraphim melodeons, and all similar musical instruments, with one or more sides, made of *gum elastic*, or other elastic material, and in such way and manner as to be capable of expanding and contracting, or of being increased or diminished in size; and, with the aid of metallic or other springs, to answer all the purposes of the common bellows generally used in those and similar instruments, substantially as described.

MARVIN SMITH.

No. 7948.—*Improvement in applying Friction Rollers to Hubs and Axles.*

We do not wish to confine ourselves to the use of spiral springs to the exclusion of springs of other forms, nor to two springs, as one can be made to produce the same result.

What we claim as our improvement, and desire to secure by letters patent in the herein-described method of applying friction rollers to the axles of wheel-carriages, is the interposition between the bearing of the axle and the faces of the friction rollers of a loose sleeve, through which the axle is free to slide endwise; while it at the same time carries the sleeve round with it in its rotation, the sleeve having a groove in its outer periphery to receive the friction rollers and prevent them from moving endwise on the collar.

JOSEPH B. WILSON,
STACEY WILSON.

No. 7949.—*Improvements in Planing Machines.*

What we claim, and desire letters patent for, is—

First. The combination of the shifting bed plate with the planes, Z, fig. 1, constructed in the manner herein described, the planes presenting any desired part of their edge for cutting the surface of the board after tonguing and grooving has been performed by the circular saws.

We also claim the rotating arm, *h*, fig. 1, with their cover, fig. 4, combined with the planes, Z, fig. 1, substantially in the manner and for the purposes herein set forth.

JOHN D. BEERS,
ISAAC WISNLOW.

No. 7950.—*Improvement in Electro-Magnetic Engines.*

Having now described my invention, I will proceed to state what I claim as new, and desire to secure by letters patent:

I claim the use and manner of arranging the helices and poles of the electro magnets, in combination with the revolving bars, or sets of bars—that is to say, the helices being upon the bends of the magnets from which the poles of the magnets extend towards and near to the centre of motion, and the revolving bars or armatures extending outwards from the centre of motion, and embracing the poles of the magnets sucessively as it rotates for producing a magnetic multiplying power engine, substantially in parts and principle as herein set forth.

THOMAS C. AVERY.

No. 7951.—*Improved connexion for the Beams and Co umns of Iron Buildings.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the method, herein described, of securing together the beams and columns of cast-iron fronts for houses by means of the lugs, with their flanges on the upper and under sides of the ends of the beam, and the projections on the inside at the top and base of the columns, as herein fully shown and represented.

JOSEPH BANKS.

No. 7952.—*Improvements in Sad Irons.*

What I claim as my invention is the above-described improvement in the construction of the bottom of the polishing iron, the same consisting in making it with ridges or projections and concavities, substantially as herein before explained.

EDWARD CLAPP.

No. 7953.—*Improved double acting Spring Hinge.*

Having thus described my improvements in the spring hinge for the entrance-doors of hotels, &c., I wish it to be understood that I do not claim the "combination of an adjustable curved inclined plane with a portion of a hinge, and an adjustable bearing roller with the other portion of the hinge."

But what I do claim as new, and desire to secure by letters patent, is the manner of combining the helical springs, L and M, with the cylindrical rotating tumbler, J, and cylindrical sectional case, so that, by the rotation of the cylindrical tumbler, J, the heart-shaped projection, K, will be made to traverse over the inclined plane, I, and cause the tumbler, J, to rise and fall, and thus compress and expand the helical springs lengthways their coils, and simultaneously therewith wind and unwind said helical springs around the spindle, F, and thus cause them to act (by the motion of the door in either direction) by torsion and expansion to close the door when it shall have been opened, as described and represented.

THEODORE F. ENGELBRECHT.

No. 7954.—*Improvement in Extension Tables.*

Having thus fully described the construction and operation of my improvement in extension tables, what I claim therein as new, and of my invention, and desire to secure by letters patent, is the arrangement of a screw, or other equivalent device, in combination with the slides, in such a manner that a screw, or its equivalent, of sufficient length to move out *one* pair of slides, will move out *any number* desired, substantially in the manner and for the purpose set forth.

FRANCIS HOGUET.

No. 7955.—*Improvement in Cooking Stoves.*

Having thus fully described my improvements, what I claim as new therein, and desire to secure by letters patent, is the transverse partition, (*c*,) in combination with the arrangement of front and back flues, as above described, for causing the several currents to unite after having traversed courses of nearly equal length, as set forth.

WILLIAM SOURS.

No. 7956.—*Improvements in Machinery for turning Irregular Forms.*

I do not claim merely the employment of two or more cutter wheels, or cutter shafts, or cylinders, provided with any number of cutters of any required form for cutting the whole surface of, and forming articles of any irregular form, without the use of the model of the article to be formed. But I claim this only when the cutting cylinders are sustained, revolved, and carried to and from the block, to be turned by a revolving cylinder, in whose periphery they are placed, without any longitudinal motion, while the block revolves slowly, without any longitudinal or lateral motion, substantially as described.

ABNER LANE.

No. 7957.—*Improvement in Spring Hinges.*

Having thus described our improvements, what we claim as new therein, and desire to secure by letters patent, is the piece *(f)* to one side of which the spring is attached, and which has on the other side a

projection, with a hole therein, by means of which and a pin the springs can be engaged and disengaged when the door is shut, substantially in the manner and for the purposes described.

HARVEY W. SABIN.
GEORGE DREW.

No. 7958.—*Machine for arranging and feeding Screw Blanks.*

I do not wish to be understood as limiting myself to the precise construction and arrangement of parts herein specified, as these may be variously modified within the principle of my invention; but I have described that particular mode of construction, which I have essayed with success.

What I claim as my invention, and desire to secure by letters patent, are the lifters, which select and lift the blanks, &c., from the hopper, substantially as specified, in combination with ways or conductors, or the equivalents thereof, substantially as specified, into or on to, which the blanks, &c., are transferred, as specified.

And I also claim giving to the lifters, or to the inclined ways, or their equivalents, a lateral motion, in combination with a stop, or detector, substantially as specified, for the purpose of arresting the operation of the lifters until a further supply is required, as specified.

THOMAS J. SLOAN.

No. 7959.—*Improvement in Paper Moulds.*

Having now described the nature of our said invention, and in what manner the same is to be performed, we wish it to be understood that we do not claim as of our own invention, nor do we claim the exclusive use of the apparatus and machinery herein described, and referred to for stamping and filing, except when employed in, and for the production of, our improved plates or moulds. We hereby declare that we claim as our invention the improved moulds for the manufacture of paper, as made in the manner herein specified—that is to say, by stamping or forming such moulds partly, or wholly, in and by dies, and afterwards removing the back of such moulds by filing, or other process analogous thereto.

WILLIAM BREWER,
JOHN SMITH.

No. 7960.—*Improvements in Power Governor.*

Having thus explained my improvement, what I claim as my invention, and desire to secure by letters patent, is communicating the action of governors to the valves, or other parts of machinery, governed thereby in such manner as to cause, by accelerating or retarding the motion of said valves, large amounts of regulating power to be added to or taken from the engine by a given change of the speed when the motion of the engine becomes too much retarded, whether such retardation arises from increase of work or resistance, or from diminution of the tension of the moving force; and also small amounts of regulating power to be added to or taken from the engine by a like change of speed, when the motion is too much accelerated, whether such acceleration arises from diminution of work, or resistance, or from increase in the tension of the moving force, as herein set forth.

Second. I also claim connecting the valve arm, or parts to be regulated, to the regulator by a cam or its equivalent, having progressive rates of action, when the same is employed for transmitting the action of governors to the parts of machinery to be governed, and for the purpose of causing the motions of valves, gates, weirs, or other analogous parts to take place rapidly for the regulation of low speeds, and slowly for the regulation of high speeds, substantially in the manner and for the purposes set forth.

Third. I also claim making the eccentric curve of the vibrating cam to vary its position with respect to its centre of vibration, for the purpose of varying the rapidity and extent of opening of the valve according to the pressure of steam, in the manner herein set forth.

JUNIUS JUDSON.

No. 7961.—*Improvement in Calculating Machines.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The logarithmic curves of the outer scale in combination with the diagonals and graduated arms to the curves, being laid out substantially in the manner herein set forth.

Second. I claim the trigonometric curves of the inner scale in combination with the graduated arms and logarithmic curves of the outer scale, the curves being laid out substantially in the manner herein described.

Third. I claim the two graduated arms constructed in such manner that they can be moved in connexion, or independently, substantially in the manner and for the purposes herein set forth.

J. W. NYSTROM.

No. 7962.—*Improved method of bracing the water spaces of Boilers.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the method, herein described, of bracing and securing the shells of boilers or fire-boxes of locomotive and other engines, by means of ribbons of sleeves, or stationary sleeves, so that, when a bolt or bolts are to be removed to cure leaks, or to renew the sheets in the fire box, the sleeves will remain in place, serving as a guide to punch the new sheets by, and affording greater support to the shells, both in backing out the old and riveting the new bolts, as herein fully described and shown.

BERNARD O'NEILL.

No. 7963.—*Improvement in Peppermint Droppers.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The construction of a "peppermint dropper," by combining a gar kettle (fig. 2, A) with a revolving cutter, (fig. 3;) and,

Second. The combination of such dropper either with a railway, (fig. 1,) the dropping sheet being stationary, or with a movable dropping sheet, the dropper itself being stationary, or with a railway and a movable dropping sheet combined, all substantially as herein described.

HENRY H. SNOW.

No. 7964.—*Variable Cut-off, regulated by the Governor.*

What I claim as my invention, and desire to secure by letters patent, is regulating a variable cut-off valve by a motion derived from and corresponding to that of the governor, by means of a toe or vibrating lever attached to the rock shaft, acted upon by revolving pins or cams, when either the cams are made to vary in position with respect to the toe, or the toe in length with respect to the cams; the whole machinery being constructed and acting substantially as herein described.

HENRY WATERMAN.

No. 7965.—*Method of adjusting the stroke of Trip Hammers.*

Having thus described my invention, some of its advantages I claim to be as follow:

First. Simplicity and cheapness of its construction; and,

Second. Its peculiar adaptability to water power, while at the same time it seems to combine nearly all the capacities and facility of regulation of the steam hammer.

What I claim as my invention, and desire to secure by letters patent, is the construction of a trip hammer, in which the hammer is raised by cams, not acting directly upon the hammer or the helve, or a projection from the same, commonly called the lifting leg, but by the intervention of a movable joint, so constructed as to grasp or clutch the lifting leg at any required height, the position of the same being governed by the regulator, which may be constructed in the form of an inclined plane or any equivalent contrivance for raising and depressing the joint at the will of the operator; the whole being constructed to perform the peculiar services substantially in the manner herein before set forth in this my specification.

LUTHER BRIGGS, Jr.

No. 7966.—*Improvement in Machines for Climbing Poles.*

What I claim as my invention, and for which I desire to secure letters patent, is the combination of the grappling levers with the sandals and handles, for the purpose of climbing telegraph poles, masts, &c., and holding the climber at any desired height, so as to give him free use of his hands when at rest, as herein described and represented.

HENRY D. CHAPMAN

No. 7967.—*Improvement in Cast Iron Car Wheels.*

I do not make any claim to the combination self-considered of wrought iron tire with a cast iron body, or yet for full plate sides, or for internal rams in section when cast solid with the side plates, of a railroad car wheel, for such have all been known and used before; but what I do claim as new, and desire to secure in letters patent, is the precise manner in which I have constructed and put together the parts of my wheel, by which, thus formed, they are free of strain from shrinkage in cooling, and have semi-internal flanges, as described, to protect the wheel when in use against lateral strain, and are bolted together and combined with a wrought-iron tire, in the manner set forth.

P. G. GARDINER.

No. 7968.—*Improvement in Machinery for making Tires by continuous rolling.*

Having described the operations of the machine sufficiently, as I here proceeded with the description of the construction of the same, I proceed to point out the new parts contained therein.

What I claim as new, and desire to secure in letters patent, is stopping the advancing movement of the movable towards the stationary roller when the tire shall have attained its proper section, by means of self-acting mechanism, acting and constructed substantially as herein described.

I also claim the combination of belts, pulleys, clutches, screws, and screw wheels, with the sway bar and triggers, by which a self-acting, advancing, and retrograding motion is given to the movable roller, each motion changing to the other, when caused so to do, by the hand of the operator, but self-arrested and stopped by the set of the triggers, substantially as specified.

P. G. GARDINER.

No. 7969.—*Improvement in connecting Trucks with Car Bodies.*

What I claim as my invention, and desire to secure by letters patent, is connecting the bodies of cars to the trucks by two bolts to each truck, working in the holes or mortices above described and represented, the whole being constructed and operating substantially as herein set forth.

THOMAS P. HOW.

No. 7970.—*Improved use of Slides in Bee-Hives.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of arranging the moth apartment with glass, paper, or other thin material, overlaying the vent holes in the top of the box, said glass or paper having placed upon it old comb or other suitable material, so as to be warmed by the bees in the boxes below, and ventilated as described, thus attracting the moths into said apartment while they are at night entirely excluded from the bee boxes by means of ventilating buttons, as described.

I also claim the arrangement by which the upper box or boxes are held in their places while the one below is removed and another inserted in its place.

Also, the arrangement at the rear and bottom of each box by which the tin slide is removed, thus allowing a convenient opportunity for clearing the bottom of the bee boxes as described.

NATHANIEL POTTER.

No. 7971.—*Improved Window Curtain Fastening.*

I claim the construction of rack-pulleys for window-shades, by fixing the pulley, over which the cord of the shade-roller runs, upon a stem, having a plate sliding on the front outer face of the rack box, attached to a thin plate or fin passing through a slot in said face, extending the length of the box, the said fin projecting upwards, and terminating in a point, which acts as a pall against ratchet teeth made in the bottom of said box, or else the said fin projecting downwards and having a cross pin through it, acting against ratchet teeth in the upper and inner side of said box; the said stem and plate, in addition to the sliding motion along the box, having an oscillating motion on the upper or lower edge of the plate, by means of which the upward pressure of the cord on the pulley holds the pall or pin against the ratchet teeth or the downward pressure of the hand, carries the pall or pin out of the line of the teeth and permits the pulley to be moved upwards when required, substantially as set forth in this specification.

HUGH GUYER.

No. 7972.—*Improvements in Steam Drilling Machines.*

What I claim as my invention, and desire to have secured to me by letters patent, is the combination of a direct action steam-drill, in which both engine and drill are mounted on a frame, which slides in a swinging frame, capable of being adjusted in any required position with the apparatus, substantially as herein above described, which is connected with, and actuated by, the cross head of the engine for causing the sliding frame to move along the swinging frame towards the rock.

JOSEPH W. FOWLE.

No. 7973.—*Improvement in Air-tight Franklin Stoves.*

What I claim as my invention, and desire to secure by letters patent, is making the fire-box with closed plate in front and behind, with a grate surface at bottom, occupying about one-third of the space between the front and back stove-plates, to constitute hot air chambers front and back, when such fire-box is combined with a sliding damper at bottom, substantially as and for the purpose specified.

And I also claim, in combination with a fire chamber constructed as above specified, and governed at bottom with a sliding damper, as specified, the open front, with vertically sliding doors as described, and for the purpose specified.

RENSSELAER D. GRANGER.

No. 7974.—*Improvements in securing Daguerreotypes in Monumental Stones.*

What I claim as my invention, and desire to secure by letters patent, is the mode, herein described, of securing the portrait plate against injury (from moisture or otherwise) by means of the two glass plates, D and F, the plaster, I, and back plate, H, the whole being arranged and combined substantially as herein set forth.

SOLON JENKINS, Jr.

No. 7975.—*Improvement in Cooking Stoves.*

Having thus fully and clearly described the nature, construction, and operation of our joint invention, what we claim therein as new, and desire to secure by letters patent, is the combination of the driving flue, d,) as described, with the driving flues, (a) and (f,) as described, the said flues occupying the whole breadth of the stove, with the exception of the space occupied by the fire-doors and the central reverting flue in the back.

We also claim the gravitating damper, (l,) operated as described; that is to say, by the rod, (n,) with its curved eye, (m,) and the pendant lever (i,) with its bend, (p,) and catch, (O,) the said damper being located upon the division plate between the back diving flues and the central back reverting flue.

JAMES GREER,
RUFUS J. KING.

No. 7976.—*Improvement in Piano-Forte Action.*

What I claim as new in my invention, and desire to secure by letters patent, is:

First. Hanging the hammer-shank on a hinge or joint, d, at a distance from its end, and effecting its communication with the fly lever or jack by means of a lever, L, which is hung on a fulcrum, i, at a distance from either end, and is connected at one end by a hinged or jointed link with the end of the hammer shank, in such a manner that when the fly-lever is raised by the key, the end of the hammer shank is drawn down, and the hammer thrown up to the string, or by any other means substantially the same.

Second. The universal repeating spring, m, attached to the lever or butt upon which is formed the projection, K, or its equivalent, through which the fly-lever communicates with the hammer, for the purpose of raising it, and working upon the end of the fly-lever, in the manner substantially as and for the purpose herein set forth. This I claim, without reference to the precise form of the projection, or of the spring herein shown, as various modifications may be made for producing the same effect.

Third. Attaching the check-wire to a hanging or hinged butt, Q, operated upon by the key, in the manner substantially as described, so as to produce the same effect as if attached to the key, for the purpose of allowing the key to be easily taken out.

Fourth. Securing or placing the regulating screw, r, for controlling or regulating the escapement of the fly-lever, in an arm, N, or its equivalent, upon the lever upon which the fly-lever acts, by which the action of the said screw upon the fly lever is more gradual and easy, and the jarring or concussion produced when the screw is stationary is avoided.

JOHN RUCK.

No. 7977.—*Improvement in Machines for Turning, Boring, &c.*

What we claim in the foregoing as our invention, and desire to secure by letters patent, is the tool and block-holder herein described, consisting

of two upright frames, capable of movement towards each other, and of being clamped at a greater or less distance apart, as may be required to adapt them to holding blocks of different sizes, and tools of different lengths or forms, each frame being provided with upright parallel guides, carrying adjustable jaws for holding, boring, or turning tools, at different heights and angles, and to aid in holding blocks of irregular forms; these frames being mounted upon a carriage capable of being turned or moved right or left, so as to hold the tool or present the substance to be bored in the required position, substantially as herein set forth.

MARTIN WAY,
THOMAS R. WAY.

No. 7978.—*Improvement in Copying Presses.*

What I claim as my invention, and desire to secure by letters patent, is the use of a lever handle, I, having its fulcrum on the pressing-plate, B, attached to the opposite plate, F, by links, H, H, as shown, working in the manner described, in *combination* with the adjusting arrangements, C, E, G, g, for the purposes expressed, and operating together, as shown, or in any substantially similar manner.

A. A. WILDER.

No. 7979.—*Improvement in the Teeth of Saws.*

I claim as my invention the insertion of teeth in circular saw blades, of the form and for the purpose above set forth.

GEORGE F. WOOLSTON.

No. 7980.—*Improvement in Dressing Mill Stones.*

What I claim as my invention, and desire to secure by letters patent, is the new and improved mode of dressing mill-stones, which I have described above as fully and correctly as I can.

E. P. GAINES.

No. 7981.—*Improvement in Trunk Handles.*

What I claim as my invention, and desire to secure by letters patent, is casting the article in two parts, in such a form that they may be put together without any alteration of the parts, and so that they cannot get out of place, when the handle is attached to a trunk or other article, when the whole is constructed substantially as herein described.

ELIJAH A. ANDREWS.

No. 7982.—*Improvement in delivering Parti-colored Warps in Weaving.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein specified, of producing figures that will match on tapestry carpets, or other fabrics woven with printed warps, by the employment of a clamp or clamps, to be clamped on to the warps, as specified, in combination with belts, or their equivalent, having a positive delivery motion, and to which the said clamp or clamps can be attached at given distances, as specified.

E. B. BIGELOW.

No. 7983.—*Improvement in Jacquard Looms for weaving Cut Pile Fabrics.*

I do not wish to be understood as limiting myself to the precise construction and arrangement of parts herein specified, as these may be greatly varied within the principle of my invention.

What I claim as my invention, and desire to secure by letters patent, is combining with the power loom for weaving cut pile fabrics double, substantially as described, a jacquard machine for producing the figures on such fabrics as described.

I also claim, in the weaving of cut pile fabrics double, with the figures produced by the jacquard, dividing the figuring warps so that one half (or nearly so) of the figuring warps shall be in connexion with each of the cloths or fabrics, substantially in the manner and for the purpose specified.

I also claim, for the weaving of cut pile fabrics double, as described, the double and reversed arrangement of the jacquards, substantially as described.

I also claim, in the weaving of fabrics of the kind herein described, passing the double fabric between two vibrating bars, having curved faces, to determine the length of pile between the two cloths, in combination with the two rollers or their equivalents, over and under which the fabrics pass after they have been separated, substantially as described; and this I also claim in combination with a vibrating knife or knives for cutting the pile to separate the two fabrics as described.

E. B. BIGELOW.

No. 7984.—*Improvement in fastening of Scythes to the Snath.*

What I claim as new in my invention, and desire to secure by letters patent, is setting the edge of the blade up or down, or more or less obliquely, by means of the adjusting screw, (*f*,) in combination with the edge of the aperture, *a*, which form the bearings of the two sides of the shank of the blade, substantially in the manner herein set forth.

E. S. CLAPP.

No. 7985.—*Improvement in Scythe Fastening.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Making the shank, C, of curved or arch form longitudinally, as described, which enables it to be fitted to the snath so as it may be set in or out by giving it a slight motion in a curved direction.

Second. The mode of securing the shank, C, so as to admit of the edge of the blade being set up or down, by making the cavity in the projection, *a*, through which the shank passes, widest at the back, and making the back edge of the shank and the inner side of the tightening key, E, of corresponding arch form transversely, so that the shank may be held secure in any position.

OLIVER CLARK.

No. 7986.—*Improvements in the method of Casting the Backs upon the Teeth of Curry Combs.*

Having thus described the manner of procedure according to my invention, such as I have essayed with success, I wish it to be understood that I do not limit myself to the precise mode herein described, but that I cover all modes which are essentially the same, effecting the same end by means substantially the same.

What I claim as my invention, and desire to secure by letters patent, is the employment of a bar in combination with the cope of a two-part flask for casting the back on to the plates of curry-combs, the said bar being notched to receive and hold the said plates during the process, all substantially as described.

JAMES M. GARDNER.

No. 7987.—*Adjustable Cut off.*

Having thus particularly described the nature of my improvement, what I claim therein as my invention, and for which I desire letters patent, is:

First. The tappet (*t*) vibrated by the impact of projections upon the slide valve rod, and lifting thereby a poppet valve which admits steam to the slide valve chamber during periods varying with the height to which the tappet is placed by the elevation or depression of the sliding rod or other object to which it is pivoted, said rod being raised or depressed by a motion derived from the governor, or communicated to it in such other manner as may be deemed expedient.

Secondly. I claim the mechanism, substantially as described, for prolongation of the admission of steam beyond the period at which it would be cut off by the tappet, to wit: the sliding plate (*w*) and the intervening bar (*o*,) the former with a pair of receding inclined planes or edges, and the latter with an equal and parallel pair of salient planes, which, by sliding upon the former, hold up the poppet valve after the tappet has ceased to act for a period, likewise depending upon the movement of the rod, which latter may be actuated as set forth in the former claim.

SAMUEL H. GILMAN.

No. 7988.—*Improvement in Cylinders for Figuring Looms.*

What we claim as new, and desire to secure in letters patent, is the mode of connecting the movable cams, *d*, and the slide pieces, I, with the drum, H, substantially as set forth, and for the purpose herein stated.

E. M. HASTINGS,
JOHN SHEPHERDSON.

No. 7989.—*Improvement in Scythe Fastenings.*

I do not wish to limit myself to the specific construction of the parts as described and represented, as this may be varied without changing the principle of my invention; as for instance any other mode of securing the plate, which forms the bed of the scythe shank, when set in any given position, may be substituted for that herein described. As I have simply described and represented the mode of construction which I have essayed with success, what I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein specified, of securing or fastening the scythe to the snath by means of the clamp jaws acting on the beveled or curved edges of the wedged formed shank, in combination with the method of holding down the end of the shanks by mean of the till thereon, which works on to the toothed plate of the recess as described, whereby the scythe is held more firmly to the snath, to resist all strain, than by any other method heretofore practised.

And I also claim the method, substantially as described, of spotting the scythe, that is, regulating the line that it shall have relatively to the curves of the snath, by means of the movable or adjusting plate, *c*, the edge of which forms the bed for the shank of the scythe when drawn down by the clamps as described.

EBEN'R. G. LAMSON.

No. 7990.—*Improvements in Jacquard Machines.*

What we claim as new in our invention, and desire to secure by letters patent, is—

Firstly. The manner of operating the cylinder by means of the double lockers, O, O, in combination with the springs, P, P, whereby its complete operation is effected by the upward motion of the trap board, C, substantially as and for the purpose herein described.

Secondly. The application of the weights, *l, l, l, l*, to the tail cords above the harness, for the purpose of more effectually keeping them tight, or straight, and thereby insuring the more correct operation of the trap boards and needles upon them, substantially in the manner herein set forth.

JOHN SCOTT,
JOHN TANNAHELL.

No. 7991.—*Improvement in the Construction of Bee Hives.*

What I claim as my invention, and desire to secure by letters patent, is having the comb placed within the trap, I, fortified or protected from the moth, or other insects, by the diaphragm, M, substantially in the manner herein fully explained.

A. J. SURLES.

No. 7992.—*Improvement in Removable Handles to Sad Irons.*

What I claim as my invention, and desire to secure by letters patent, is the method, herein described, of constructing sad, tailors', and other hand-smoothing irons with handles, which can be readily and securely attached to the iron, and easily detached therefrom, substantially as herein specified.

T. R. TIMBY.

No. 7993.—*Improvement in the Construction of Metallic Buildings.*

Having thus described the nature of my improvements in the construction of metallic buildings, what I claim as new, and of my own invention, and desire to secure by letters patent, is carrying up the vertical *u*-shaped flange-binders between the flanges of the roof-plates, to which they are attached, thus supporting the roof, and binding it firmly to the building.

I also claim such binders attached in such a manner in connexion with the tie plates, or rods, Q, attached at the same spot between the flanges, and by the same bolts; and this I claim, whether the suspension bars, R, be employed or not.

SIMON WILLARD.

No. 7994.—*Improvement in Adjustable Land Sides of Ploughs.*

Having thus described our improvements in the plough, we wish it to be understood that we do not claim the employment of an adjustive plate for elevating the rear portion of the plough to regulate the depth of the furrow.

But what we do claim as our invention, and desire to secure by letters patent, is providing a right angled heel-plate, L, with a hook, P, for the purpose of interlocking with a hooked shaped projection, Q, attached to the land-bar, forming a hook joint, said heel-plate, L, forming the bottom and side of the land bar, and having its rearward portion susceptible of vertical adjustment by means of a screw, T; and, when adjusted, being clamped by a horizontal screw bolt, N, its shank being placed in a segmental slot, to admit of its moving with the heel-plate, as described.

GEORGE HEFFLEY,
SAMUEL CONRAD,
JAMES WIGLE.

No. 7995.—*Apparatus for securing Shutters in any required position.*

What I claim is the right to the rods, pintles, sockets, screws, and apertures, connected, arranged, and acting substantially in the manner and for the purposes described.

CHARLES W. KREBS.

No. 7996.—*Improved Sash Lock.*

What I claim consists in the spring, F, to throw the turning hook *outwards*, the spring catch, G, (applied to the frame of the hook,) and the projection, H, (extending either from the curved rail or the lower window sash,) in combination together and with the said clamp-hook and rail, the whole being made to operate substantially in the manner as herein before specified.

MICHAEL NORTON.

No. 7997.—*Improvement in Extension Tables.*

Having thus fully described the construction and operation of my improved extension table, what I claim as new, and of my invention, and desire to secure by letters patent, is—

First. The slides, E and F, in combination with the cross bars, G, and folding rails, I; and, second, the recess for the reception of the loose leaves, being formed substantially in the manner and for the purpose set forth.

LEWIS THORN.

No. 7998.—*Apparatus for moving and securing Shutters, &c.*

What I claim as my invention, and desire to secure by letters patent, is the manner of opening and closing window shutters from the inside, and securing them firmly at any point in their semi circuit by means of the horizontal screw shaft, B, inserted in an opening in the lower portion of the window frame, metallic nut, E, surrounding the same, and the bar or plate, F, attached to the shutter, substantially as described.

A. W. SPEERS.

No. 7999.—*Improved Apparatus for drawing and measuring Liquids.*

What I claim as my invention, and desire to secure by letters patent, is the combination of measures with faucets, cocks, or gates used in drawing liquids from cans, casks, barrels, &c., in such a manner that by opening the faucet attached to the cask, the measure will be filled; then, by closing the same, the desired amount may be drawn by opening the corresponding faucet in the measure, the whole combined substantially as described, and for the purpose set forth.

RICHARD F. STEVENS.

No. 8000.—*Improvement in Scythe Fastenings.*

What I claim as my improvement, is the combination of the two wedge shaped bearers, H, I, the confining bolt, F, and the support at the extreme, or other end of the shank, as constructed, substantially in the manner as specified, the whole being for the purpose of enabling a person to change the position of the blade of the scythe in a direction transversely of the plane of the blade.

NATHANIEL LAMSON.

No. 8001.—*Improvement in Machines for preparing Clay for Making Brick.*

What I claim as my invention, and desire to secure by letters patent, is the use of a revolving screen, constructed of bars, *a, a, a, a*, set at a slight inclination from the horizontal position, having lugs or crushers, *c, c, c, c, c*, within it; each lug being hung or suspended at one end, on a bar, *o*, and prevented from touching or rubbing the screen by cord or chain, *i*, attached to its other extremity, and rod, *p*, supporting or constructed, and operating in any manner substantially the same and for the purpose set forth.

HEMAN WHIPPLE.

No. 8002.—*Improvement in Upright Piano Fortes.*

What I claim is the arrangement of the sounding board in upright pianos, between the strings and the performer, substantially in the manner described.

HENRY KLEPFER.

No. 8003.—*Improvement in Scythe Fastenings.*

I claim the arrangement of the hole or holes, *f, f, f*, at the head of the confining clasps in such manner, with respect to the axis, *g*, of the screw, H, that when the said screw is turned one hundred and eighty degrees, the position or positions of the same (*i. e.* the hole or holes) may be changed in such manner as to secure one or more new and different positions for the shank, the same being for the purpose as specified.

NATHANIEL LAMSON.

No. 8004.—*Improvement in Balanced Valves.*

I do not claim as my invention valves having seats of such relative diameters that they shall be retained thereon by the pressure of steam; but what I claim as my invention, and desire to secure by letters patent, is in the above description of valve, where the disk is held by a support running up through the hollow valve, so forming the valve that the upper seat shall be larger in diameter than the lower one, by means of the ring, *r*, attached to the valve, and by means of the ring, *s*, attached to the seat, or by any means substantially the same, for the purpose of retaining the valve on its seat, by the pressure of steam, whenever its position or location in respect to the steam passages is such that the pressure of steam is below the valve when closed.

FRANCIS B. STEVENS.

No. 8005.—*Improvement in Machines for Folding and Measuring Cloth.*

Having thus fully described my invention, I will proceed to state what I claim as new, and desire to secure by letters patent:

I claim—first. Folding the cloth as it passes through or between the calender rollers during the process of calendering, or by passing it through or between a pair of revolving rollers, E, E′, similar to calender rollers, the said calender or other rollers being hung in a carriage, F, F, G, which receives a reciprocating motion above or across a table, C, and a tilting motion at each end of its stroke, so as to bring each roller alternately to bear on the table as it (the carriage) moves in different directions across it, thereby laying the cloth under the rollers on the table in folds or layers, in the manner substantially as herein described.

I claim—second. Making the reciprocating motion of the calender rollers of a certain fixed length; such length determining the length of the fold, and thereby measuring the cloth, substantially in the manner herein described. At the same time I wish it to be understood that I do not claim the measurement of cloth by folding it in layers or folds of a certain length, unless such layers or folds are laid by calender or other similar rollers.

HENRY BOOT.

No. 8006.—*Improved Horse Shoe Nail Machine.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is making a horse-shoe nail by means of a stationary, former, and a series of travelling and rotating cams, arranged and operating substantially as herein described and fully shown.

MARSHALL BURNETT.

No. 8007.—*Improved Machine for sticking Pins on paper.*

In the machine which I have now fully and exactly described—for sticking pins crosswise of narrow fillets of paper, to prepare it, when so stuck, for winding, and winding the same into coils—there are several parts which are common, or such as have been used by others, which I do not claim separately nor in other combinations.

I do not claim the upper feeding channel, or inclined conductors, when made of straight bars; nor cylinders with parallel sides, which have been used for conducting wood screws and similar headed articles; nor the downward curved conductors; nor any other feeding channels, unless they are combined with the conical form of rollers or the separator.

I do not claim the crimps, nor any peculiarity in inserting the pins through them, if made crosswise of the sheet, and the pins inserted lengthwise of it, and not crosswise of both the crimps and fillet, or ridges raised in it.

I do not claim nor use any kind of crimping "bars," "jaws," or "clamps," as they have been heretofore used.

And, generally, I wish it to be distinctly understood, that I do not limit myself to the precise form or arrangement of parts, nor the particular devices for moving them; for these may be much varied without changing the principle of my invention as set forth; nor do I limit myself to the single process of inserting only one pin at once, or only one edge of the fillet: for on the same principles, with only circumstantial variations of the machinery, I can insert several pins at once on the same edge of the fillet, or on both edges of it; and other similar variations can be made by any competent machinist without any essential or substantial variation from the character of my invention, as herein described and set forth.

First. I do claim the conical form of rollers to constitute my feeding channel for arranging the pins and moving them forward in the channel, with the most suitably decreasing rates of descending velocity, as herein described.

Second. I do claim also as my improvement and invention, and desire to secure by letters patent, the combination of the parts and the adaptation of my machine for feeding the pins, separating and delivering them, crimping the fillet, and sticking the pins crosswise of such fillet, and finally rolling the fillet into a coil, substantially in the manner described.

I claim also the screw separator, as described, placed in the feeding channel to restrain the natural descent of the column of pins, so that they may be delivered as fast, and no faster than they are required for sticking, substantially as herein described and set forth

C. O. CROSBY.

No. 8008.—*Improvement in Wheat Fans.*

Having thus fully described my invention, what I claim herein as new, and desire to secure by letters patent, is two or more chambers and areas, in combination with a fan, for the purpose of cleaning and separating grain, by using one and the same blast (to clean it) over and over again any number of times, as herein fully described and represented.

JOHN HOLLINGSWORTH.

No. 8009.—*Improvement in Mills for grinding Paints and Drugs.*

I do not intend to confine myself to the precise forms of construction herein described, as those may be varied in many ways to produce the same results; as, for instance, the rotation of the mullers may be effected by the use of gearing, or the spindles of the mullers may be firmly fixed and the bed stone be made to revolve—all of which methods involve the principles of my invention.

What I claim as of my own invention, and desire to secure by letters patent of the United States, is the construction of a mill in which the grinding surfaces shall consist of a plane or planes operating upon a cone, as herein described.

I claim also the lever (k) in combination with the muller, for the purpose of regulating the feed; the whole being constructed substantially in the manner as set forth herein.

G. D. JONES.

No. 8010.—*Improvement in Rice Hullers.*

Having described my invention, I will now state what I claim as new, and desire to secure by letters patent.

I claim operating the pestle by having it attached to a rod passing through the bottom of the mortar, and receiving motion through a crank, or its equivalent, placed below it, substantially as and for the purpose herein set forth.

PETER McKINLAY.

No. 8011.—*Improvements in Blasting Rocks, &c.*

Of course I do not mean to suggest the use of cartridge as anything new in blasting; and I am aware that clay has been used around a charge in wet holes, by way of puddling, to fill the little fissures and stop the leaks; and also as to the use of water, where a *depth* of it can be had sufficient to make its *weight* available, I am aware that this would not be new. But as to my device of packing around the cartridge for the object before indicated, and with water—irrespective of the consideration of its weight—I do not know whether this device is new or not; and that I may be upon the safe side, I shall not claim it. Moreover, it is not important for me to claim it, inasmuch as it is a device which can in no other way be so conveniently available as in connexion with the use of said *binder*, which I do claim.

And now, to sum up in brief what I claim as my invention, and desire to secure by letters patent, it may be sufficient to state—

First. I claim the use of an artificial binder, by means of which to restrain the action of the blast in opposite directions, by off-setting said action against itself, substantially as herein before explained.

Second. I claim the use of the little packing wedge, or wedges, within the charge or blast chamber, substantially as described.

CHARLES MONSON.

No. 8012.—*Improved Machine for forming a Lock on Sheet Metal.*

Having thus fully described my invention, I will now proceed to state what I claim therein as new, and desire to secure by letters patent. I claim the employment of a cam or cams, *g*, *g*, on the tumbler, D, operating on levers, E, E, connected with the under side of the movable jaw, C, in combination with a spring or springs, *l*, substantially in the manner described, for the purpose of closing the lip, *e*, and securing the plate while folding, and raising the lip and releasing the plate after the folding is completed.

JABEZ WALKER.

No. 8013.—*Improvement in Wheat Fans.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the fan, air-trunk, and head, constructed and operating substantially in the manner and for the purpose herein described.

JESSE WHITE.

No. 8014.—*Improvement in Bran-Dusters.*

Having thus fully described our improvements, we wish it understood that we do not claim the beater and fan revolving within an upright stationary beater and bolt, as these have before been used; but what we do claim, and desire to secure by letters patent, is the combination of the openings, (*d* and *l*,) both provided with valves or registers, with the runner and fan revolving within an upright cylindrical casing, the upper part of which acts as a beater, and the lower part as a bolting apparatus, substantially as described, for the purpose of separating the flour which adheres to the bran after undergoing the ordinary bolting; the said process being regulated and adjusted to suit the circumstances of weather, &c. by admitting more or less air, either above or below, by means of the registers, as set forth.

JNO. M. CARR,
JAS. HUGHES.

No. 8015.—*Improvement in connecting and disconnecting Wheels and Axles.*

I do not claim the cap, the nut, or the axle; but what I *do* claim as my invention, and desire to secure by letters patent, is the dog and the spring combined, and operating as above set forth.

SIMEON HEYWOOD.

No. 8016.—*Improvement in the Manufacture of India-rubber.*

Having described my invention, and the best mode known to me of manufacturing the same, what I claim as my invention, and desire to secure by letters patent, is the combination of potash with rubber and sulphur, and submitting the same to a high degree of heat, whereby to produce the change upon rubber known as vulcanizing.

DAVID McCURDY.

No. 8017.—*Improvements in Splint Machines.*

What I claim, and desire to secure by letters patent, is the combination of the cylinders, F and G, with their cutters, J, J, attached, (for the purpose of giving a rounded form to the splints,) and the cylinder, K, with its spurs, *l*, (for the purpose of dividing the splints in one direction,) with the circular cutter or saw, N, (for the purpose of separating the splints from the timber,) and the guide, *v*, to guide the splints in the channel, *u*; the whole being arranged substantially in the manner and for the purposes above set forth.

HENRY MELLISH.

No. 8018.—*Improvement in Seed Planters.*

Having thus described the nature of my invention and improvement, and the operation of the same, what I claim as new, and of my own invention, is placing two or more hollows, drill teeth, in a direct line, one behind the other, managed and drawn by the same drag-bar; the front tooth being made the longest, and so placed as to run somewhat deeper in the soil than its successor or follower, for the purpose of depositing fine manure, or chemical agents, beneath the grain when planted in rows or otherwise, as herein fully set forth and represented.

ARCHIBALD WIETING.

No. 8019.—*Improvement in Machines for cutting Screws on Bedstead Rails.*

Having thus fully described our improvements in cutting screws, what we claim as new therein, and which we desire to secure by letters patent, is the peculiar form and manner of securing the V-cutter to the cylindrical head, as described; that is to say, making the cutter as represented, and letting the tapered end of the shank into the recess, bringing the angular shoulder against the cylinder, and sustaining the bevelled points against the interior bevelled surface of the cylinder head, by which arrangement the instrument, during the operation of cutting, is forced firmly against the head, the strain upon the confining screw being thereby greatly reduced, and the cutting tool itself strengthened.

H. GROSS,
W. CAMPBELL.

No. 8020.—*Stone and Metal Conglomerate for Paving, &c.*

Having thus described the nature of my invention, what I claim therein as new, and for which I desire letters patent, is forming a block suitable for paving, masonry work, or analogous purposes, of a conglomerate of iron and stone, by running the molten metal among broken stone within a mould, either with or without the devices, substantially as herein described, for jointing and locking together the contiguous blocks.

GEORGE H. KNIGHT.

No. 8021.—*Improvement in Brick Presses.*

Having thus fully described the nature of my invention, what I claim herein as new, and desire to secure by letters patent, is the lip, *e*, hugging closely the rim of a wheel containing moulds; the said lip being a prolongation of a gradually narrowing feed-trough, formed and operated after the manner and for the purposes substantially as herein described—namely, the formation (by pressure of untempered clay) of a uniform and coherent brick.

JOHN J. RIDDLE.

No. 8022.—*Improvement in Sawing Machines.*

Having thus pointed out the nature of my invention, and the manner in which I have essayed the same with success, I will state that I do not wish to limit myself to the precise mode of constructing and arranging the parts, as these may be variously modified without departing from the principle of my invention.

But what I claim as my invention, and desire to secure by letters patent, is making the circular saw with both faces convex, in the manner and for the purpose substantially as specified, when this is combined with the guide, substantially as specified, for spreading apart the plank to prevent the binding of the saw, as specified.

PEARSON CROSBY.

No. 8023.—*Improvement in fastening down Table Leaves.*

What I claim as my invention, and desire to secure by letters patent, is the combination of devices, by means of which table-tops of different forms and dimensions can be readily secured to and disconnected from the same frame, as herein set forth.

LEWIS J. MASON.

No. 8024.—*Improvement in Brick Presses.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the mould wheel with the grooved and smooth pressure roller, substantially as herein described; the grooved roller gauging and partially compressing the clay into the moulds, and forming a projecting band of clay, which is subsequently compressed into the moulds by the smooth-pressure roller.

I also claim the grooves in the mould wheel, in combination with the flanges of a hopper, which is supported on the frame of the machine, independently of the mould wheel, by which arrangement the clay is prevented from escaping laterally, and working in between the teeth of the driving wheels; hence the latter can be placed near to the moulds, and the machine thus made more compact, while, at the same time, the danger of breakage is diminished.

I likewise claim detaching the bricks from the pistons of the mould wheel by means of the tappets and lever, as herein set forth.

J. Z. A. WAGNER.

No. 8025.—*Improvement in Apparatus for Bolting Flour.*

Having thus clearly and exactly described the nature and operation of our joint invention, we wish it distinctly understood that we do not claim the broad principle of bolting meal by an air blast, as this has been imperfectly done before; but what we do claim as new, and desire to secure by letters patent, is the application of a blast cylinder with spiral issues, as described, to the process of bolting flour or other pulverized materials; by means of which, during a continuous blast, the meal is consecutively thrown against the bolting cloth, and so much as is not passed through at once is given an interval of time to fall from the cloth, and leave open the meshes, and is thus, as it were, refed to the impulse of the blast from each succeeding issue; the intermittent action at the same time causing eddies that loosen, and, as it were, rip up the bran and flour from the cloth, separate the bran from the flour, and twirl the particles of bran in such a manner as to leave the flour free to pass through; while the bran, from the twirl thus given it, is caused to present its broadest surface to the bolting cloth, the specking of the flour being thereby prevented and avoided; the several parts being arranged substantially in the manner and for the purpose described.

We also claim the insertion of a set of beaters at a suitable distance down the bolting cloth and blast cylinder, which, during the bolting process, shall interrupt the same at a time when the bran requires beating, in order to loosen the flour from it preparatory to the further continuance of the bolting process, substantially in the manner and for the purpose described.

We also claim the chambers (Y) and (I,) by means of which the light flour, carried up by the escape of the blast, is regathered, and returned to the usual gathering chamber (S,) substantially in the manner and for the purpose described.

LEWIS FAGIN.
HENRY C. HAYMAN.

No. 8026.—*Improved Saw Set.*

Having thus described the construction and operation of my improved saw-set, what I claim therein as new, and desire to secure by letters patent, are the following particulars:

First. Supporting the lever, by which motion is given to the jaws, by means of an adjustable stirrup, constructed substantially as described; whereby said stirrup serves as a gauge, in addition to performing its ordinary duties.

Second. I claim the arrangement of the jaws, constructed of one bent piece of metal, with the lever and stirrup; the handle of said lever projecting backwards, towards the rounded part of the jaws; the whole being constructed substantially as herein described.

ELIJAH S. HOLKINS.

No. 8027.—*Apparatus for setting up Tenpins.*

What I claim as my invention, and desire to secure by letters patent, is elevating the pins of a bowling alley by means of a set of elevating sockets, operated from the head of the table when this is combined with any well-known device or devices, which will permit the pins to fall, and sustain them in a vertical position, after they are elevated, substantially as described.

THOMAS J. SLOAN.

No. 8028.—*Improvement in Horse Powers.*

What I claim as my invention, and desire to secure by letters patent, is the manner of arranging and connecting the whipple-tree and brake, so that when the horse is drawing, the brake is off the wheel or pulley; and when not, is on, and acting as a governor, as hereinbefore described, for the purposes herein before set forth.

AARON D. CRANE.

No. 8029.—*Tool for making Jack Chains.*

Having now fully described my invention, I disclaim all right to the grooved pin. But I claim the combination of the stud pins, *i* and *i'*, with the bending stud and holding dog, arranged and acting substantially as described.

WILLIAM TODD.

No. 8030.—*Improvement in Ladies' Work Tables.*

Having thus fully described my improvement, what I claim as new, and desire to secure by letters patent, is the mounting of the upper leaf, B, and disk, G, with the drawers, R, R, Q, on the rotary standard, X, thus raising or lowering the whole, to suit different persons, by the screw, L.

Second. I claim the rotary disk, with drawers hung thereon by the screw, U, supported by the pin, K, which can turn round the standard, independent of the leaf or standard, B, X, and raised or lowered, as herein set forth.

CELIA R. P. WOOD,
(Now CELIA R. P. FOSTER.)

No. 8031.—*Improvement in Grain Separators and Fans.*

What I claim as my invention, and desire to secure by letters patent, is constructing the elevator with double troughs, *c*, *e*, in the manner herein described, for the purpose of preventing the grain from falling through between the cells.

I moreover claim the combination of the herein described elevator, J, wind-channel, L, and plate valve, *m*, with a grain-threshing and winnowing machine; the former being constructed and arranged as herein described.

ROSWELL T. MERRILL.

No. 8032.—*Improved Saw Set.*

What I claim as of my own invention in the saw doctor, and wish to secure by letters patent of the United States, is the "adjustable double beveled slide saw rest," constructed and used substantially as herein described, by means of which its beveled bed, the tooth rest, upper jaw, and punch saws of all kinds can be firmly held, and their teeth be either set in V-form, shouldered in U-form, or be both shouldered and set to any amount required to insure any degree of smoothness or roughness in sawing, whether their points are sharp or rounded.

HIRAM STRAIT.

No. 8033.—*Improvement in Winnowing Machines.*

What I claim as my invention, and desire to secure by letters patent, are the blast passages, F, G, and *k*, arranged and controlled by the shutter, J, in the manner and for the purposes substantially as herein set forth.

JONATHAN L. BOOTH.

No. 8034.—*Improvement in Cooking Stoves.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, are the air passages *p*, *q*, *r*, between the fire-back, *l*, and the upper oven, the said passages receiving external air at the sides of the stove, and discharging it into the back flue, in combination with the damper, *m*, and flues *b*, *c*, *d*, *e*, *f*, *g*, *h*, substantially as herein described and represented, for the purpose of equalizing and regulating the heat to all parts of the ovens.

RUFUS K. PAINE.

No. 8035.—*Improvement in Material for transferring colors in Calico Printing.*

Having thus described the nature of my invention, and the manner in which the said invention must be used, I claim the use of extract of fibrine to form, with or without any other oily or fat matters, by the means which I have described, or any other equivalent means, a mastic adequate to thickening and retaining on fibres, threads, tissues, of every description, and of every material or substance, the archil color, and such other colors as are incorporated with that mastic.

I also claim the above process of preparing and purifying the extract of caseine, in order, by the means which I have specified, or any other equivalent means, to impart to fibres, threads, and tissues, of vegetable nature of every description, by means of a preparation of mordant, the property of better uniting to, or attracting, the coloring matter of archil, and, in general, other coloring matters, either in printing or dyeing, whether this preparation, or mordant, be applied on the fibres or threads of vegetable nature, previous to the weaving, or whether it be applied after the weaving on tissues of vegetable nature, or on tissues composed partly of vegetable and partly of animal substances.

C. A. BROQUETTE.

No. 8036.—*Improved Milling Tool.*

The rotary die for making impressions on metals and other substances is a well known instrument, and we make no claim founded on that instrument in itself considered.

But what we do claim, and desire to secure by letters patent, is the combination of such die with an axle, on which the same may vibrate, which axle is at right angles with the axis of rotation, and not in the same plane, substantially in the manner and for the purposes herein set forth.

JOHN BUCKINGHAM,
JOSEPH H. BAIRD.

No. 8037.—*Improvement in Mill Stones.*

What I claim as my invention, and desire to secure by letters patent, is constructing the running-stones of mills with oblique apertures, or passages, through the body of the stone, and provided with hoods or funnels, to collect the air during the rotation, and connected on the grinding face of the stone with furrows, substantially as described, when this arrangement is combined with the use of vertical pipes, leading from the extremity of one of the apertures or passages, to a funnel leading to the next succeeding oblique passage in the body of the stove, substantially in the manner and for the purpose specified.

E. T. HANON VALCKE.

No. 8038.—*Improvement in Iron Railings.*

What I claim as my invention, and desire to secure by letters patent, is securing the pailings permanently to the horizontal rods or bars of iron, for the purpose of constructing an entire section of railing by means of the methods of operating the rods or bars with the pailings, having jaws, recesses, and bearings, as described therein, and, together with other devices in castings, termed saddles or troughs, having dovetails and tenons cast to them for the purposes herein named; and this I claim, whether the several parts be formed and adapted to each other and operated precisely as represented and described, or otherwise; the results always produced being effected by means equivalent to those within named.

JOHN KRAUSER.

No. 8039.—*Improvements in the Steam Engine.*

What we claim as our invention, and desire to secure by letters patent, is—

First. The construction and arrangement of the columns by which the steam cylinder is connected with the bed frame in such manner that they constitute the air-pump and condenser, substantially as herein set forth.

Second. The method, herein described, of actuating the cut-off valve of one steam cylinder by a motion derived from the valve or valve-rod of the other cylinder, substantially as herein set forth.

Third. The adjustable supplementary valve (*i*) in connexion with apertures or ports (*o*) in the steam valves, by means of which the steam can be worked at full pressure throughout the whole length of the stroke without disengaging the cut-off valve.

R. F. LOPER,
J. W. NYSTROM.

No. 8040.—*Improvement in Cooking Stoves.*

Having thus fully described my improvements, what I claim as new therein, and desire to secure by letters patent, is the apertures (*l'*) and passages (*n* and *o*) by which the air containing the surplus heat from the oven (*b*) is conveyed to the back of the fire-chamber, where it receives an access of heat, and afterwards to the flues, (*e*,) by which arrangement the heat is equalized between the two ovens, and the upper one is ventilated, as set forth.

JAMES S. MARSH.

No. 8041.—*Improvement in Window Curtain Fixtures.*

Having thus described my improvement in window-curtain fixtures, I shall state my claim as follows: I do not claim generally confining one end of the curtain to the roller on which it is wound and unwound by means of a groove in said roller, and a confining strip; but what I do claim, and desire to have secured to me by letters patent, is the method or means, herein-above described, of fastening the confining bar in the groove of the roller in which the cloth is pressed—that is, by having the ends of said bar rebated as described, and fitting the caps at the ends of said roller, over said rebated ends of said bar, as above set forth; this arrangement of the caps and bar (the said caps, or one of them, being loose, so as to move laterally, but not to revolve, the sides of the rebated ends of the bar operating as shoulders to prevent a revolution) enables me to adapt my improved fixture to windows of different widths.

S. S. PUTNUM.

No. 8042.—*Improvement in setting Logs in Saw-Mills.*

Having thus fully, clearly, and exactly described the nature and operation of my invention, what I claim therein as new, and desire to secure by letters patent, is—

First. The vibrating dog (*i*) having the distance of its head or tongue, (*i'*) with respect to the saw, adjustable laterally by a set screw, (*g*,) substantially as represented, so that, by placing the tongue of the head in each successive curf, and bringing the face of the log in contact therewith, the thickness of each consecutive board is exactly counterpart with the first.

Second. I claim, for analogous purposes, at the rear end of the log, which is destitute of a curf, the vibrating dog, (*p*,) whose distance in respect to the stationary block (*q*) is adjustable by means of a set screw, (*l*,) the range between the head of the dog and the block affording an easy and determinate means of giving exactly the same thickness to the boards at the rear end of the log.

JOHN W. ROBBINS.

No. 8043.—*Improvement in agitating Grate Bars.*

I do not claim the employment of a movable grate formed by bars C, C, and strips, *c*, *c*, the bars, C, C, working within the bars of the stationary grate; but what I do claim as my invention, and desire to secure by letters patent, is the application to the movable grate of two separate mechanical movements, whereby it may receive a rocking or a vertical vibratory motion at pleasure, the several parts constructed and operating substantially in the manner shown and described.

A. D. SPOOR.

No. 8044.—*Machine for cutting out the corners and scoring the edges of Paper for Boxes.*

Having thus fully described my machine for cutting boxes, what I claim as my invention, and desire to secure by letters patent, is the combination of the knife and dye, substantially in the manner and for the purpose herein described.

ANDREW DENNISON.

No. 8045.—*Improvement in Apparatus for operating Window Blind Slats.*

I am aware that cog-gearing has been employed for the purpose of operating window-blind slats from the interior of a building. I therefore do not claim such device in general.

But what I do claim as my invention, and desire to secure by letters patent, is making the cog wheel, E, with such a length of teeth that, when its spindle is forced outwards by the spring, they shall engage with the teeth on both sides of the cog wheel, F, thereby locking the same, and securing the slats in any desired position, substantially as herein described.

SAMUEL AVERY.

No. 8046.—*Improvement in Ornamenting Marble.*

What we claim as ours, and wish to secure by letters patent, is the above-described ink, and the wax color and etch water used in combination therewith, substantially as described above.

HENRY HOFFMAN,
CHARLES FREDERICK HILL.

No. 8047.—*Improvement in Cooking Stoves.*

My improvement, and what I claim, consists in the peculiar arrangement or manner of combining the fire-place—the descending or diving flues, the ash-pit, the lateral chambers, the ascending flues, the central discharge flue, the oven, or air heating chamber, and its surrounding flue space, all as represented in the drawings, and as hereinbefore specified.

DENNIS G. LITTLEFIELD.

No. 8048.—*Improvements in the process of manufacturing Glazed Sheet Iron.*

What we claim as our invention, and desire to secure by letters patent, is the employment of thick plates of iron as shield plates; or, in other words, placing four (more or less) thin plates between two shield plates of double weight, in forming packs for rolling, so that each shield plate will make two plates of proper size to constitute the inside plates of another pack, for the smoothing and finishing process of rolling.

JOHN WOOD,
WILLIAM W. WOOD.

No. 8049.—*Improvement in means of Renovating and Correcting Sight.*

What I claim as my invention, and wish to secure by letters patent, is the cups and caps to produce a pressure upon the periphery, in case of old age or front of the eye in case of nearsight, which will increase or diminish its convexity, as the nature of the case may require, with their application, as set forth in the accompanying specifications and drawings, using for that purpose any of the materials named in the above specifications.

JONATHAN BALL.

No. 8050.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The arrangement of the flues which conduct the heated air to the space under the oven bottom, from which it is discharged into the oven at the corners thereof, and without any enlargement to permit the expansion of the air before it reaches the oven, as described, when this is combined with the arrangement of fire flues on each side thereof, as described, whereby the air passing to the oven is heated along the whole distance of its passsage by the products of combustion from the fire place, as described.

I also claim as my invention the heating of the air in its passage through the back hot air chambers, by combining with such air chambers and the main fire flues the branch fire flues which pass back of the said air chambers, substantially as described.

CHARLES W. GRANNIS.

No. 8051.—*Improvement in machines for Gutta Percha tubing and covering Wire.*

What I claim as my invention, and desire to secure by letters patent, is the use, for the purposes specified, of feed rollers, C, C, in combination with the stomach, G, G, having a lip, or mouth, *h*, arranged and operating substantially as shown and described.

JAMES REYNOLDS.

No. 8052.—*Improvement in Machines for Stretching Leather.*

I do not claim the shafts, wheels, chains, and vises by which the process of stretching is done; that may be effected by various mechanical arrangements.

I claim the method, or device, of stretching leather, especially for belting, by the use of apparatus so arranged that after a piece of leather has received, by an equable strain, applied to its ends for their whole width, the proper stretch that the material can bear on or along one edge thereof; if it be found that the other edge, and parts intermediate between it and the first edge, (from the difference in quality of fibre,) has not received its proper tension, the further stretching of the first side shall be stopped, whilst by the application of the mechanical stress at the other edge of the leather, it, and the parts between it and the first side, shall be duly stretched, substantially in the manner set forth in this specification.

I claim the holding board as essential in all leather-stretching apparatus, where it can be applied in keeping the material, whilst being stretched, from contracting in width, and becoming defective thereby.

I claim the holding board, with its clamps and wedges, in combination with the apparatus of stretching, for the uses and purposes substantially as set forth in the above specification.

BRADFORD ROWE.

No. 8053.—*Improvement in Clogs or Pattens.*

What I claim, therefore, as my invention, and desire to secure by letters patent, is the application of an elastic loop or strap attached to the sole piece, and going around the heel, substantially as in the manner above described.

CHARLES W. STEARNS.

No. 8054.—*Improvement in Machines for Stretching Leather.*

We claim the construction of the stretching apparatus, by connecting the free rod to the clamp, by entering the end or tenon of the rod into a mortise with angular sides, and securing them together by a pivot pin, substantially as set forth in this specification.

WILLIAM STREVELL,
DANIEL BROWN.

No. 8055.—*Improved Apparatus for rolling Tapered Metallic Rods.*

What I claim as my invention, and desire to secure by letters patent, is permitting the rollers to recede from each other by means of the hydraulic apparatus, constructed and arranged substantially as described.

And, secondly, the adjustable screw, K, figures 1 and 2, in conjunction with the apparatus claimed above, whereby bars of metal are enabled to be rolled taper for a portion of their length, and parallel for the remaining part thereof.

WILLIAM CLAY.

No. 8056.—*Improvement in Saw Mills.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of driving belt saws by the friction surface of two cylindrical pulleys or drums, which gripe the saw plate below the wood which is being cut, but at some part of its tangent line, so that the strain to which it must be subjected in cutting to keep it in the line of the tangent shall not beat any part of its curved path; but this I only claim in combination with straining rollers, which gripe the saw above the lumber on which it acts, the said rollers being controlled by a brake, or the equivalent thereof, substantially as described, whereby the saw, during its action, is kept in a strained condition along its entire line of action, that it may cut in a straight line, and to avoid its being under tension where the flexions take place along the curved portions of its track, as specified.

I also claim, in combination with the mode, herein specified, of driving a belt saw by means of cylindrical rollers or pulleys, the employment of a belt passing around the outer one of said driving rollers, and applied to the outer surface of the saw when it passes around the lower deflecting or guide pulleys, substantially as herein described, by means of which the saw is bent by the pressure of the belt, applied to its outer surface, instead of being communicated through the metal itself, thus avoiding, in a great measure, the tendency to break the metal.

And, finally, I claim, in combination with the mode, substantially such as herein described, of driving a belt saw, the employment of fenders or scrapers, interposed between the driving rollers and the wood to be sawed, and placed each side of the saw, as described, to catch the sawdust and conduct it away from the bight of the driving rollers or the saw, and thus avoid clogging.

LEMUEL HEDGE.

No. 8057.—*Improvement in Coffee Roasters.*

What I claim is the combining or arrangement of the fire place or chamber of combustion, the roasting cylinder, and its surrounding chamber, substantially in the manner as above described, and as represented in the drawings; also the arrangement of the flue of the fire chamber, with respect to the latter, and the enclosing chamber of the roaster, the said arrangement of the said flue consisting in carrying it over and in contact with the top of the said enclosing chamber, as specified.

I also claim the arrangement of the proving tube within the hollow journals and central part of the roaster; not meaning to claim the device termed the proving tube, but simply its arrangement, as specified.

EDWARD WHITELEY.

No. 8058.—*Improvement in Straw Cutters.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of arranging one or more cutters on the periphery of a vertical wheel, at such angle with, and so extending over, the face of said wheel as will give a "drawing cut" through the straw or other material to be cut, and at the same time catch and carry the material as it falls to the opposite side of the wheel from where it is cut, thus removing the cut material out of the way of the feeding box and uncut material, as fully set forth and shown

T. F. WINGO.

No. 8059.—*Improvement in Car Seats.*

Having thus described the nature of our invention, what we claim as new, and desire to secure by letters patent, is the mode, herein described, of reversing the back of car seats from one side of the seat to the other, without turning them over, by means of arms, constructed and arranged as set forth, by which any desired height of back is obtained, as described.

Secondly. We claim the manner, herein described, of reversing the concave back on a movable frame, in combination with the side locking projections, as described.

RICKASON STILWELL,
E. L. BRUNDAGE.

No. 8060.—*Improved Lock and Key.*

What I claim as my invention is the wedged or cam key, I, and the separate bitt, or secondary wedged or cam key, H, in combination with the vibrating block, F, the key recess, and the tumbler elevator; the whole being constructed, arranged, and operating substantially as herein before specified.

JAMES R. BUGBEE.

No. 8061.—*Improvement in Smut Machines.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of scouring and freeing wheat of smut and other impurities, by throwing up the grain into the inclined face of a chimney, fitted to an opening along the top of the concave, in combination with the inclined aprons, U, for transferring the grain from end to end of the cylinder, that it may be discharged as set forth.

JEHU HOLLINGSWORTH.

No. 8062.—*Improved Compound Metallic Door for Vaults, Safes, &c.*

What I claim as my invention, and desire to secure by letters patent, is a door or wall for a vault or safe, made by securing to each other, at a certain distance apart, two plates of sheet metal, provided with a rim or curb, and filling the vacant space between them with immalleable cast-iron, poured in while melted, substantially in the manner herein described.

IRA L. CADY.

No. 8063.—*Improvements in Winnowing Machines.*

Having thus fully described my improved wheat-fan, what I claim as new therein, and which I desire to secure by letters patent, is, first, placing the screen (*d*) in an inclined position above the fan, and extending the whole length of the machine, by which the wheat is thoroughly sifted before being acted on by the blast, in combination with the direction of the blast at right angles, to the screen as above set forth.

OLIVER ETNIER.

No. 8064.—*Improvement in Spring Saddles.*

Having thus described my bridge-spring saddle tree, what I claim therein as new, and desire to secure by letters patent, is the pommel-spring, in combination with the seat-springs, substantially as herein set forth.

I also claim the method of suspending the stirrups by connecting them with the same springs which support the seat, whereby the elevation and depression of the one is simultaneous with the elevation and depression of the other.

JOSEPH C. SMITH.

No. 8065.—*Improvement in Apparatus for giving ease to the Arm in Writing.*

Having thus described our invention and improvement, and shown the application of the same to the arm of the pendulum, what we claim as our invention, and desire to secure by letters patent, is constructing an arm-supporter, or rest, so formed and shaped as to fit the arm below the elbow-joint, and serve as an elastic or flexible support, or rest, on which the arm of the penman is supported and balanced, and permitted to move or turn with the motion of the arm, with the utmost freedom and ease to the writer, by which all numbness, contraction of the muscles of the fingers, and crampness or stiffness of the arm are effectually prevented, and the arm rendered free in its movement, and under the complete control of the writer, as fully described and represented.

JOSEPH G. GROSHEN.
WILLIAM H. TOWERS.

No. 8066.—*Improvement in Machinery for Making Matches.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The mode of feeding in the plates of wood, by means of the feeding apron, with its cleats, spring pulley, F, and rollers, *g*, *g*.

Second. The mode of separating and dipping the splints by means of the grooved cylinder, C, cutter, *n*, endless bands, B, and revolving wheels, *e*, *e*.

IRA H. SMITH.

No. 8067.—*Improved Horse-shoe Machine.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is in combination with a rotating travelling-draw roller, adjustable pattern, and champering tool, for forming the shoe, the gauge plate, for holding up the roller, so as to allow it to return over the shoe thus formed, and smooth down the feathered edges, raised by the champering tool, as herein described and represented.

ROBERT G. BABCOCK.

No. 8068.—*Improvement in Bats for Felting.*

I am aware that flock has been incorporated with wool in the manufacture of felting, by passing it through the carding machine with the wool, and also that it has been fulled on to the surface of the cloth during the process of finishing.

I therefore do not claim either of these, as such, as my invention; but what I claim as my invention, and desire to secure by letters patent, is preparing the web for felt fabrics, by the introduction of layers of flocks between or upon the layers of wool, without passing the flock through the carding-machine, but by preparing it in a separate machine, and introducing it immediately from that machine on to the web of wool, while it is passing from the carding-machine, in the manner substantially as herein described.

And I also claim as my invention the combination of the endless apron, (K,) which feeds the flock to the cylindrical brushes, with the series of cylindrical brushes, by which the flock is taken up from the inner extremity of the endless apron, and (passing through the series) is prepared, and sent down through the spout, or conductor, (A,) and deposited on the web of wool, (as before described,) when the same is constructed and combined substantially as herein described.

LEANDER W. BOYNTON.

No. 8069.—*Improvements in Splint Machines.*

What I claim as my invention, and desire to secure by letters patent, is a cutter wheel, constructed substantially as herein set forth, to split, point, and gauge the size of match splints, in combination with the method of preventing the splitting knives from cutting across the grain of the wood by supporting the block upon a stock, which is constructed to turn, as herein set forth, to present the grain of the wood, where the splitting knife is acting, in line with the plain in which the knives revolve.

LEWIS L. GILLILAND.

No. 8070.—*Flexible Hose, or Float for supporting Vessels.*

Having thus fully described my invention, that which I claim, and desire to secure by letters patent of the United States, is as follows:

First. I claim a plan of supporting a vessel, in whole or part, upon or by means of a *flexible*, movable, endless hose, or "air float," or on an endless, movable chain of flexible, buoyant compartments, for the purposes set forth.

Second. I claim making my flexible hose, "air-float," or its equivalent, *collapsible*, for the purposes herein before mentioned; not limiting myself, in or by these claims, to any particular forms or arrangement of the buoys or floats, &c., so long as the peculiar features of my invention, as described and claimed, are substantially fulfilled.

WM MT. STORM.

No. 8071.—*Improved Lock and Key.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The self-detaching and attaching key for the purpose and object described.

Secondly. In combination with said key, I claim a powder-proof keyhole, consisting of two or more parts, so constructed that the outer part is turned by the key, while at the same time the inner parts, with the pod or pods of the key enclosed, are disconnected and moved entirely away from the outer; the same movement causing solid metal to occupy the space left, and thus to effectually bar an entrance of any kind to the lock when its parts are in a position possible to be unlocked.

LINUS YALE, JR.

No. 8072.—*Improvement in Meat-Cutting Machines.*

What I claim as my invention, and desire to secure by letters patent, is the herein-described mode of adjusting the cutters, J, by means of the adjusting plates, K, as described.

THOMAS VANDERSLICE.

No. 8073.—*Exploding Harpoon.*

I do not claim the invention of the harpoon as ordinarily made, but what I claim as my invention, and wish to secure by letters patent, is—

First. The interior of the harpoon made as a pistol barrel, with percussion lock, protected from water or outward accident, and the trigger of which can be actuated by means of a pull on the line and the resistance of the flesh, substantially as described.

Second. I claim the making the point of the harpoon, the projectile which is shot into the whale, in the manner and for the purposes substantially as described.

Third. I claim the arrangement of the trigger, in the shank under the barb, in the mode described, preventing the explosion of the charge till the line is drawn by the whale or the harpooner.

CHARLES BURT.

No. 8074.—*Improvement in Hand Logs.*

All the parts, taken separately, and described herein, as used by me for this purpose, are well known, and have long been applied to other uses. But I do not know of any invention in which the application, arrangement, and combination of these parts have been used to produce an instrument, that, through mechanical means, denotes, with nearly or quite mathematical certainty, the rate in miles per hour at which a ship travels through the water during a fixed, limited, and known time.

I therefore claim as new, and of my own invention, and desire to secure by letters patent of the United States—

First. The arrangement of the log glass, F, lever, *g*, pinion, *e*, and wheel, *f*, whereby the motion given to the clock-work by the reel, G, is communicated to the index, 9, during a definite period of time, determined by turning the log-glass on or off the lever, *g*, the parts being so proportioned, and the dial so divided, that the index, moving while the sand is running in the log-glass, F, shows the rate of speed at which a vessel is moving per hour of time, during 14 seconds, or any other known space of time, the parts being arranged and operating substantially as described, or in a manner equivalent, to produce the same results by like means.

Second. The application of a parachute, K, to the purpose of a "*log-ship*," and the combination therewith of the cylindrical wedge, *m*, or its equivalent, to enter between the tubes, *k* and *n*, to keep the "*log-ship*," K, spread when in the water, and disengaged when hauled on to "*fetch home*," so that the log ship closes, and turns end for end in the water, and is easily hauled on board, said log-ship being used with the reel and registering parts herein described and shown, or with any other means of supplying and determining the amount of line run out, during a known period of time, substantially as described and shown.

JOHN R. ST. JOHN.

No. 8075.—*Improvement in the manufacture of India Rubber.*

I do not claim the heating or curing process, as it is termed; that having been patented by Charles Goodyear.

What I do claim as my invention, and desire to secure by letters patent, is the combining of India rubber and sulphur, either with or without shellac, for making a hard and inflexible substance, hitherto unknown, substantially as herein set forth.

And I also claim the combining of India rubber, sulphur, and magnesia, or lime, or a carbonate, or a sulphate of magnesia, or of lime, either with or without shellac, for making a hard and inflexible substance, hitherto unknown, substantially as herein set forth.

NELSON GOODYEAR.

No. 8076.—*Improvement in Bedstead Fastenings.*

Having thus described our improvement on the bedstead fastening, what we claim therein as new, and desire to secure by letters patent, is providing the upper section or part, B, of the cylindrical box with a triangular and two parallel wedge-shaped wings, D, E, E, made sharp, and projecting from its periphery in such a manner that the triangular projection, D, shall open a groove or way in the post, which shall be closed by the entrance of the parallel wedge-shaped wings, E, E, which follow, as the section, B, is driven into the post, and thus crowd the wood in front of the shoulder (*a*) of the triangular projection, D, and form a complete lock thereto, as described.

We also claim dividing the cylindrical box longitudinally into two equal parts or sections, B, F, the line of division inclining upward at an angle of about ten degrees from a horizontal plane, by which the edges of the upper section, B, are made to serve the purpose of wedges for forcing the teeth of the lower section, F, into the post and holding it securely, as described.

JAMES R. KAIN,
SPENCER LEWIS.

No. 8077.—*Improved Spark-Arrester.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is—

First. The air-flues (F) in the lower part of the diaphragm, (O,) constructed in the manner and for the purposes herein described.

Second. I claim the pipes or conductors, (H,) in combination with the air-chamber, (I,) and (B,) arranged substantially as herein described.

Third. I claim the combination and arrangement of the air flues, F, with the air-chamber, (B,) reverberating cone, (C,) inclined and curved flues, (D,) for the purpose and in the manner herein fully set forth and described.

JAMES A. CUTTING.

No. 8078.—*Improvement in Pumps.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the valve chest, water-passages, pump-cylinder, and air-vessel, as herein described, so that the whole can be cast in a single piece, and the valves and suction pipe supported and secured in place by another piece, also cast in the form herein described, whereby the cost of making the pump, and its liability to get out of order, are both lessened, without impairing its efficiency, or rendering it more difficult to repair.

NELSON NEWMAN.

No. 8079.—*Improvement in Lime-Kilns.*

Having thus fully described the construction and operation of my improved lime-kiln, what I claim therein as new, and desire to secure by letters patent, are the flues, *d, d*, encircling the cupola, and provided with apertures or flues, *e, e, e, e, e*, for admitting the heat and flame to the action upon the lime-stone from various points, substantially as described, in combination with the air-chamber, K, encircling the cupola, as described; and I claim also the aperture, *p*, and passage therefrom, for saving the heat arising from the manufactured lime while being removed; all operating conjointly in the manner and for the purpose herein fully set forth.

RICHARD E. SCHROEDER.

No. 8080.—*Improved process for the artificial production of Ice.*

Having thus fully made known my improved process of manufacturing ice, and explained and exemplified suitable machinery for carrying the same practically into operation, I wish it to be understood that I do not claim, as my invention, any of the several parts of the apparatus in themselves; but what I do claim as my invention, and desire to secure by letters patent, is—

First. The employment of a liquid, uncongealable at the low temperature at which it is required to keep the engine, to receive the heat of

Second. I claim the employment of an engine for the purpose of rendering the expansion of the condensed air gradual, in order to obtain its full refrigeratory effects, and, at the same time, render available the mechanical force with which it tends to dilate to aid in working the condensing pump, irrespective of the manner in which the several parts are made, arranged, and operated.

Third. I claim supplying the water gradually and slowly to the freezing vessels, and congealing it by abstracting the heat from its under surface, substantially as herein set forth; and,

Lastly. I claim the process of cooling or freezing liquids, by compressing air into a reservoir, abstracting the heat evolved in the compression by means of a jet of water; allowing the compressed air to expand in an engine, surrounded by a cistern of unfreezable liquid, which is continually injected into the engine and returned to the cistern, and which serves as a medium to absorb the heat from the liquid to be cooled or frozen, and give it out to the expanding air.

JOHN GORRIE.

No. 8081.—*Improvement in Purifying Illuminating Gas.*

What I claim as of my own invention and discovery, and desire to secure by letters patent of the United States, is the purifying powder for illuminating gas, said powder consisting of sulphate of lime, either natural or artificial, in connexion with some inert substance or substances, partly inert and partly rendered purifiers when compounded in the proportions substantially as described herein.

FLORENTINE JOSEPH DE CAVAILLON.

No. 8082.—*Machine for assorting Screw Blanks, &c.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the series of shifting ways with the main or stationary ways, for the purpose and in the manner substantially as specified.

And I also claim the detector, substantially as specified, in combination with the stationary and the shifting ways, substantially in the manner and for the purpose specified.

THOMAS J. SLOAN.

No. 8083.—*Improvement in Grain Harvesters and Binders.*

Having thus specified our improvements in harvesting machines, what we claim as our invention, and desire to secure by letters patent, is—

First. The method of raking and binding grain at one operation by the mechanism herein specified, or its equivalent, substantially as herein set forth.

Second. We claim the arms, *m*, in combination with the levers, *p*, by means of which the rake teeth are alternately raised and depressed as the rake is moved alternately in opposite directions by endless rake chains, which move continually in the same direction.

Third. We claim the method of adapting the binding apparatus to the length of the cut grain by varying the respective positions of the cutting and binding apparatus, substantially as herein set forth; that is to say, by moving the front of the platform with the cutting apparatus, backward or forward, or by moving the binding apparatus nearer to or further from the front of the platform in such manner that the sheaf may be bound near the middle of its length, whether it be long or short.

Fourth. The method of binding grain by the mechanical devices herein specified, or their equivalents, acting in connexion, and automatically by motion derived from, or dependent upon, the movement of the machine to which they are attached.

Fifth. We claim the cord finger (B,) operating substantially as herein set forth, by the aid of which the grain is encircled by the binding cord.

Sixth. We claim the tying forceps, or the equivalent thereof, operating in connexion with mechanism for encircling the grain with cord or band, substantially as herein set forth.

WILLIAM WATSON,
E. SABINE RENWICK,
P. HILL WATSON.

No. 8084.—*Improvement in Straw Cutters.*

Having thus fully described my improved straw cutter, what I claim therein as new, and desire to secure by letters patent, is, in combination with the toothed grooved cylinder, and curved stationary knives, the cleaners, *g*, *g*, arranged and operating substantially as herein represented and fully shown.

JONATHAN SULLIVAN.

No. 8085.—*Improved method of supporting the Vanes of Aquatic Velocimeters.*

Having thus described my invention, and set forth the means I employ, and the differences between my invention and those that are known to have preceded it, I do not intend to claim any of the parts herein described as taken separately; all are well known, and in common use; but what I do claim as new, and of my own invention, and desire to secure by letters patent of the United States, is the attaching the disk or plate, *a*, to the sliding frames, *b* and *c*, which frame, *c*, carries the shaft, *d*, of the paddle blades, B, when said frame and plate are fitted to be lowered into or raised out of a tube, A, in such a manner that when in place for use, the plate, *a*, prevents any indirect current of water from ascending into, or descending out of the tube, A, to disturb or destroy the accuracy of the instrument, leaving the paddle blades, B, subject only to the direct action of the vessel's progress through the water, substantially as described and shown.

JNO. R. ST. JOHN.

No. 8086.—*Improvement in Planing Machines.*

What we claim as our invention, and desire to secure by letters patent, is the employment on one or both sides of the grooving cutters, *b*, *b*, *b*, of a chain or band, *c*, applied and operated in the manner substantially as and for the purpose herein described.

RUFUS BIXBY,
CYRUS S BIXBY,
JOHN GARST.

No. 8087.—*Improved Apparatus for relieving the helmsman from the shock of the Rudder.*

What I claim as my invention, and desire to secure by letters patent, is the combination of two sets of pawls, between which two sets of pawls a wheel is placed loose upon the shaft, having an endwise motion thereon, by means of the male and female screw, as described; said wheel being provided with a hub, so fitted as to disengage the pawls when the hub arrives at the limit of its end play, in either direction; the result being that the rudder secures itself through the agency of the pawls, and is unlocked, so as to be free to move in either direction by the first motion of the same wheel which afterwards moves the rudder; in other words, I claim the combination of the hub secured to the wheel, the male and female screws, or their equivalents, and the ratchets and pawls, substantially in the manner and for the purposes describe in this specification.

CHANDOS HOSKYNS.

No 8088.—*Improved Apparatus for indicating the height of water in Steam Boilers, &c.*

What I claim as my invention, and desire to secure by letters patent of the United States, is the combination of the chamber, D, with the boiler or other vessel, in which the height of fluids is to be measured, by means of tubes, so formed and attached as to act as springs, to indicate the weight of the water at any time within said chamber, for the purpose and substantially in the manner herein set forth.

GEORGE FABER.

No. 8089.—*Improvements in Flouring Apparatus.*

Having thus described my improvements, what I claim as new therein, and desire to secure by letters patent, is—

First. I claim the arrangement of the "hopper boy," revolving on the same centre as the stone, and the chamber beneath the stone, by which the flour is cooled as it is conveyed to the centre opening of the bolt, substantially as set forth.

Second. I claim the annular or endless conveyers for conveying the flour, &c., in the several annular chambers to the spouts, the same being operated in the manner herein described.

Third. I claim, in combination therewith, the air passage (W) for returning the particles of flour which would otherwise escape to the centre hole of the floor of the bolting chamber, to be drawn in again by the draught, substantially in the manner set forth.

JAMES M. CLARK.

No. 8090.—*Crane Hinge for Doors, Shutters, &c.*

What I claim as my invention, and desire to secure by letters patent, is the crane door-hinge, constructed in the manner and for the purpose as herein substantially represented and set forth.

No. 8091.—*Improvement in Setting Teeth.*

What I claim as my invention, and desire to secure by letters patent, is attaching artificial teeth to a plate in the roof of the mouth, by means of a wedge-formed recess in the tooth, and a pivot of corresponding shape, soldered, or otherwise attached to the plate, when the union of the two is effected by the use of platinum and tin, or solder, substantially in the manner and for the purpose specified.

ADOLPH F. AHRENS.

No. 8092.—*Improvement in Setting Teeth.*

What I claim as my invention, and desire to secure by letters patent, is securing artificial teeth to a plate in the roof of the mouth by means of a rebate in the inner face of the tooth and a slide, fitting the same and soldered, or otherwise attached to the plate in the mouth, for the purposes and in the manner described.

ADOLPH F. AHRENS.

No. 8093.—*Improvement in Brick Presses.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The form of the pressing plates, *n*, *n*, *n*, thicker at one edge than the other, as shown, and for the purpose described.

Second. The motion of the followers, or plungers, E^2, E^2, E^2, by rollers moving in fixed grooved channels, F, F, and acted upon by revolving cams, *k*, *k*, producing a drop movement, and operating as herein shown and explained.

Third. Propelling the machine forwards by means of wheels, D, D, keyed on the mould cylinder-shaft, for the purpose of depositing the bricks, as made in regular layers, for drying.

JOS. GRANT.

No. 8094.—*Improvements in Saw Mills.*

Having thus fully described the nature of my improvements, and the manner in which they operate, in producing the desired effect, what I claim as my invention is—

First. The tightener and key, and the manner in which they are used in tightening the dogs, as herein set forth.

Second. I claim the movable arm to regulate the thickness to be sawed, when changing from one thickness to another in the same log, without taking the dog out of the log, as herein described.

Third. I claim the placing the second dog upon the main plate and adjusted by the bolt and key, constructed in the form and manner and for the objects and purposes hereinbefore particularly set forth.

No other part of the said above-described dogs do I in this, my specification, claim as new or original, excepting such as above enumerated.

MARTIN RICH.

No. 8095.—*Improvement in Scarificators.*

What I claim as my invention, and wish to secure by letters patent, is the use of the said hollow pivot, lever, and slide racks, combined and arranged as described, secured in their proper places by the plate and screws, and operating in connexion with the trigger and springs, substantially as hereinbefore specified.

FREDERICK LEYPOLDT.

No. 8096.—*Improved Compound Coupling for Hose or Pipe.*

What I claim as my invention, and desire to secure by letters patent, is the manner, if desired, of keeping the several threads or screws always in contact, whether the coupling be formed or disconnected, for obtaining the advantages set forth, by employment of an interior box, C, situate in an outer box, B, and having a loose ring or collar, D, or its equivalent, on it, in combination with a washer, F, connecting nut, E, and box, A, formed with the lips for locking the coupling, the several parts constructed, fitting, and operating together substantially as shown and described.

JAMES W. OSGOOD.

No. 8097.—*Improvement in Smut Machines.*

What I claim as my invention, and desire to secure by letters patent, is—

First. In connexion with a close case surrounding the machine, the arrangement of the fan, as herein described, in the annular space surrounding the beaters between the outer case and the fluted cylinder, and at the entrance of the pipe, M, through which the dust is discharged, so that currents of air will set into the machine through any cracks or openings in the same from the room in which it is placed, by which means the escape of pulverized dust or smut into the room is effectually prevented.

Second. I claim the arrangement of the air chamber, W, having currents of air passing through and across it, between the upper part of the beater and the space through which the descending current of air passes to the fan, for the purpose of collecting any portion of the grain accidentally thrown out of the scouring cylinder by the blast or beaters, and returning the same, so that it may pass through the machine with the rest of the grain in the proper direction.

Third. I claim the conical rim or shield for the purpose of protecting the conical screen below it from abrasion by the descending grain, and at the same time keeping the pores of the screen open for a free passage of air through it into the fluted cylinder.

Fourth. I claim the tube or passage (K) for discharging the cleaned grain, as set forth, and also for receiving and transmitting air to and through the tube, J, as described.

NELSON PLATT.

No. 8098.—*Improvement in Planing Machines.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the yielding stock and cutter, when made to yield upon an axle, the centre of which is in line with the cutting edge of the knife; and this I claim, whether the socket bolt, hinged bar, and nut are, or are not, used for the purpose of graduating and adjusting the cutters, as herein set forth.

GEORGE W. BEARDSLEE.

No. 8099.—*Coupling for Cords.*

What I claim as my invention, and desire to secure by letters patent, is the use of half couplings, A, A, (each of similar shape and construction,) formed with lips, *a*, *a*, having slots, *b*, *b*, into which projecting hooks, C, C, fit, having notches, *c*, *c*, serving for the bolts, D, D, to enter and lock the coupling, or constructed and operating for the purposes shown, in any manner substantially the same.

LAWTON J. WARE.

No. 8100.—*Improvement in India Rubber Shoes.*

Having described the advantages of my improvement, and the best way known to me of manufacturing the same, what I claim as my invention, and desire to secure by letters patent, is the manufacture of rubber boots and shoes without cloth, being made of separate pieces of different degrees of elasticity, and each piece having its peculiar and requisite degree, the shoe to possess different degrees of elasticity in different parts, and uniform elasticity in each different part, and having no part without some elasticity in every direction, by the means herein described, or any other substantially the same, whereby I lesson the cost, obtain a shoe not liable to break, which can be kept clean, stretched in every direction at the same time, easier to the foot, adjustable to larger boots, and yet not rendered useless to wear over smaller, light and elegant, and retain permanently their shape.

HORACE H. DAY.

No. 8101.—*Improvement in Reflecting Fire Plates.*

I do not claim as my invention a reflector made to partially surround the fire; but what I claim as my improvement is the extension of the curved reflector entirely around the fire grate, in combination with having an opening through it, immediately under the fire grate, for the passage of the ashes, as specified.

And, in combination with the fire grate and the extension of the reflector under or below the grate, essentially as explained, I claim the ash-guard, F, the same being applied in manner and for the purpose as set forth.

And, in combination with the reflector, B, and its sustaining frame, I claim the hinged slide, H, and the sustaining rollers, K, K, K, K, or their mechanical equivalent; the same being applied so as to enable the reflector to be moved outward for the purpose of providing easy access to the chimney, or for convenience of removing the ashes, whenever such may be deemed necessary.

ROBERT JOBSON.

No. 8102.—*Improvements in the Manufacture of Wire-Strengthened Spoons.*

I do not claim employing a wire within the handle, as such has already been done; but what I do claim as my invention, and desire to secure by letters patent, is the manner, substantially as herein shown and specified, of enclosing a wire of the required exact length within the handle, by supporting it on "points" secured to the mould, and projecting midway or partly into the form.

LUTHER BOARDMAN.

No. 8103.—*Improvement in Steam Traps.*

We do not claim to be the first to remove the water of condensation from steam-warming or other apparatus by means of a float and valve or cock, but we do not know of any means by which this water of condensation is taken off through the float by a cock. Therefore, what we claim as new, and of our invention, and desire to secure by letters patent of the United States, is the construction and application of the float, E, with its mouth, 6, opening, 5, pipe, *l*, and barrel, *k*, on the plug, *i*, with the openings, 3 and 4, for the purpose of retaining the steam in warming apparatus, or in other steam pipes, and passing out the water of condensation through the float near the bottom, substantially as described and shown.

CHARLES M. GUILD.
JOHN BROWN.

No. 8104.—*Improvement in Hot Air Furnaces.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement, substantially as herein described, of the heating chambers in connexion with the furnace, when this is combined with the method, substantially as described, of connecting the heating chambers with each other with the furnace and with the exit pipe leading to the chimney, whereby the gaseous products of combustion are carried into and through, and made to spread out in thin films in the said heating chambers, and therein retained to give out heat without seriously impeding the draught, substantially as described.

SAMUEL PIERCE.

No. 8105.—*Improvement in Carriage Springs.*

What I claim as new, and desire to secure by letters patent, is the constructing of springs, whether of wood or part wood and part metal, or other elastic or non-elastic substances, as adapted and applicable to carriage springs, and springs for other purposes, in the manner substantially as herein described.

LEVI BISSELL.

No. 8106.—*Improvement in Cast Iron Car Wheels.*

What I claim as my invention is the above-described improvement or wheel, made with a chilled rim, either a solid hub or one divided crosswise of its axis, two plates or disks, B, C, united in a serpentine curve at their outer peripheries, a third plate, D, not only made serpentine concentrically with the hub, but curved in radical directions, as described, all cast or founded, and combined together in one piece, substantially in the manner as hereinbefore specified.

ALBERT HEBBERD.

No. 8107.—*Improved Gauging and Heading Movement for Spike Machines.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the spring gauge and catch, *o, p, r*, constructed as herein described, with the dies and with the header, F, for the double purpose of gauging the length of the spikes or nails, and aiding in forming the heads thereon, substantially as herein set forth.

PURNEL JEFFERSON.

No. 8108.—*Improvement in Cast Iron Car Wheels.*

Having thus explained my invention, I claim a cast iron railroad wheel, constructed with the solid hub, A, and the tube, C, the said tube being united to the hub by a curved plate, B, with curved projecting braces, *b, b*, on it, and connected to the tread, T, by a curved plate, D, with the curved braces, *d, d*, on it, the whole being constructed substantially as described, for the purpose set forth.

ISAAC VAN KURAN.

No. 8109.—*Improvement in Ventilating Furnaces.*

What I claim is the arrangement and mode of operating the valves, A, A, in reference to the air-heating space around the stove, by which the amount of air from within and without is graduated by a single movement.

I claim also the arrangement of the horizontal air heating trunk, the vertical, D, leading thereto, and its valve, S, in combination with the air-heating space, G.

H. RUTTAN.

No. 8110.—*Improvement in Lifting Jacks.*

I do not claim any of the parts employed, irrespective of the manner in which they are combined and arranged. But what I claim as new, and desire to secure by letters patent, is the combination, in the manner substantially as herein described, of the pawls, *f, f'*, the spring, *o* and *i'*, *i'*, and the spring lever, *k*, having projections, 1, 2, on each side of its fulcrum, with the lever, D, and the ratchet, *a, b*, on the lifting rod, B, whereby the lifting rod may be forced out from or drawn into the post, or standard of the jack, according to the position of the spring lever.

BOLIVAR NEWBURY.

No. 8111.—*Improvement in Lap Anvils for Shoemakers.*

What I claim as my invention, and desire to secure by letters patent, is a metal anvil, shaped substantially as set forth and described in the within specification, with its drawings—that is, with a form adapting it to be held conveniently upon and between the knees and thighs of a workman, having a projection above the mass of metal, conveniently formed into an anvil face, with a small prismatic block near the extremity of one of the arms, as a fulcrum for nippers, when the same are used in stretching or manipulating leather.

HENRY BRUNK.

No. 8112.—*Improved Combination of Dies for Sheet Lead Machines.*

Having thus described my invention, and the manner of its application to the foregoing machines for the manufacture of sheet lead, what I claim as my invention, and desire to secure by letters patent, is the adjustable interior cylindrical and the exterior stationary conical dies, in combination, and for the purposes described, irrespective of the precise manner in which they are applied, or by which the adjustment is effected.

JOHN ROBERTSON.

No. 8113.—*Improved Vise Jaw for Saw Filing Machinery.*

What I claim as my invention, and desire to secure by letters patent, is the jaws of the vise shaped to correspond to the shape of the saw teeth, and support the same, so as to prevent vibration during the operation of filing, as herein set forth, whereby a better edge is given to the tooth, the wear of the file is diminished, and the process of sharpening expedited.

GEO. W. PUTNAM.

No. 8114.—*Improvement in alloy of Iron, Zinc, and Nickel.*

What I claim as my invention, and desire to secure by letters patent, is the making of wrought or malleable iron, either from ordinary iron or from the ore, by the use of application of metallic zinc or spelter, and by the use of zinc and nickel, combined as hereinbefore described and set forth.

OTIS BOYDEN.

No. 8115.—*Improvement in Machinery for Hardening and Straightening Saws, &c.*

Having thus fully described my improvements in the method of straightening and hardening saws, &c., what I claim therein as new, and for which I desire to secure letters patent, is the employment of the apparatus above set forth for straightening and hardening steel plates for saws, &c., at one operation, consisting of the fingers or cams, substantially as described, which support the article to be straightened, compressed, and hardened, combined with and griped by the drop, in the manner and for the purpose above specified.

HENRY WATERMAN.

No. 8116.—*Improvement in Seed Planters.*

Having thus fully described the nature, construction, and operation of my seed drill, what I claim therein as new, and desire to secure by letters

patent, is the conical cups attached to segmental rods, extending from levers working on a horizontal shaft, raised and lowered by the eccentrics and rods, substantially as described, operating in the manner and for the purpose herein fully set forth and represented.

JACOB BARNHILL.

No. 8117.—*Improvement in Portable Swings.*

Having thus fully described the construction and operation of my improvement in portable swings, what I claim therein as new, and of my invention, and desire to secure by letters patent, is the suspension of a swing to the hinged frame, supported or strengthened by the adjustable brace, C, substantially as herein set forth.

ENOCH S. FARSEN.

No. 8118.—*Improvement in Carriages.*

What I claim as my invention, and desire to secure by letters patent, is making the sides of the bodies or boxes of carriages of a series of springs, slats, or bars, when the same are constructed, and operate, substantially as herein set forth and described.

GEORGE B. DURKEE.

No. 8119.—*Improvement in Omnibus Steps.*

Having thus described the nature of my invention, and the manner in which it is constructed, what I claim as new, and desire to secure by letters patent, is the manner of constructing the step as described, viz: by having a portion (B) of the body of the omnibus projecting downwards a suitable distance, the bottom of said projection, B, forming the step, C, and so arranged as to be perfectly covered and protected by the door, D, when closed, substantially as described.

W. H. HOYT.

No. 8120.—*Improvement in Carriages.*

What I claim as my invention and desire to secure by letters patent, is the manner of construction, as described, viz: forming the body of two separate parts, A, B, united by a joint which allows the body to vibrate and act upon a single spring, and also admits of a direct attachment of the body to the axles, substantially as set forth.

JAMES C. SPENCER.

No. 8121.—*Improvement in excluding Dust from Railroad Cars.*

What I claim as my invention, and desire to secure by letters patent, is the application of vertical blinds, shutters, or screens on the outside of railroad cars, employing the same to prevent the entrance of dust, smoke, cinders, &c., into the windows of the cars, as herein described.

EDWARD HAMILTON.

No. 8122.—*Improvements in Hemp Brakes.*

What I claim as my invention, and wish to secure by letters patent, is the combining a sufficient number of slats to break the full length of the hemp at once, in combination with the manner of feeding, substantially as set forth.

PARIS M. WALKER.

No. 8123.—*Improvement in Self-weighing Machines for Grain.*

Having thus described my self-weighing machine for grain, and shown the operation of the same, I desire that it shall be understood that I do not claim a self-weighing machine operated by the weight of the grain, so as to form an automatic weighing machine, by which, with the aid of a register or index, the amount weighed is ascertained, nor do I claim opening a gate or door in the bottom of a receiving hopper by the descent of a steelyard simultaneously with the discharge of the grain from a rotating hopper; but what I do claim as new, and of my own invention, is the employment of the metallic plate, C, or its equivalent, attached to the receiving hopper, B, and made to rise and fall by the action of said hopper and a gauge, Q', in such a manner that on the descent of a suspended hopper, F, the gauge-plate, Q, connected therewith, will disengage a catch-plate (*f*) from the right end of the metallic plate, C, and permit the latter to fall and cut off the discharge of the grain, and simultaneously therewith open a trap-door, H, in the bottom of the suspended hopper, and on the ascent of the same the receiving hopper, B, will be made to tilt frontward by the weight of the grain, so as again to raise the plate, C, and open the hinged door, D, of the said plate, C, simultaneously with the closing of the trap-door, as fully described and represented.

I also claim the employment of the gauge-plate, Q', when combined with the lower or discharging hopper, F, for the purpose of determining the quantity of grain to be weighed by limiting the descending movement of the suspended hopper, F, and consequently gauging the action of the projection, Q^2, on said gauge-plate, Q', to actuate the plate, C, to cut off the discharge of the grain from the receiving hopper.

I also claim the employment of the vertical pendant rods, P, R, confined to either side of the frame when combined with a suspended hopper, F, provided with a trap-door, H, for the purpose of opening and closing said trap door by their descent alternately, said vertical pendant rods, P, R, being respectively actuated by the descent of the metallic plate, C, to disengage the spring catch (*t*) from the rod, P, to open the trap-door, and by the tilting frontward of the receiving hopper, B, to disengage the spring bar, O, from the vertical rod, R, and allow its descent to close the trap-door, H, as set forth in the specification and shown in the drawings.

WILLIAM BIDDLE.

No. 8124.—*Improvement in Bran Dusters.*

What we claim as our invention, and desire to secure by letters patent, is the combination of the scouring, beating, and distributing brush with the perforated guard plate surrounding it, whereby the bran to be dressed is more equally distributed and fed to the bolt than has been done by devices heretofore in use for the purpose.

WILLIAM A. McFARLAN,
THOMAS C. CARPENTER.

No. 8125.—*Improvements in Planing Machines.*

Having thus fully described my improved machine for planing, tonguing and grooving planks, &c., what I claim therein as my invention, and desire to secure by letters patent, is—

First. The jointing or hinging of the plane stock-supporting frame, E, J, *f*, *f*, or its equivalent, at one end, and giving it an elastic bearing at its opposite end, substantially as herein set forth, whether the said plane stock-supporting frame to be used in connexion with individually vibrating plane stocks, or with other descriptions of plane stocks, or planing-knives, or cutters, for the purpose of reducing or planing planks, or boards, upon their sides or edges.

Second. I claim the combination of the supporting frame, containing the adjustable plane stocks, H, H, with the self-adjusting supporting frame, containing the plane stocks, G, G, by which the inner or under surfaces of the plane stocks, G, G, are made to form a self-adjusting bed, one side of a plank; whilst the knives in the stocks, H, H, are operating upon and facing the opposite side of the same, and by which the inner or under surfaces of the plane stocks, H, H, are made to form an unyielding bed on one side of a plank; whilst the knives in the plane stocks, G, G, are operating upon and reducing its opposite side; and by which a plank can be faced on one side, and reduced and faced upon its opposite side, at simultaneous operations, substantially as herein set forth.

Third. I claim the combination of the supporting frame, containing the self-adjusting plane stocks, G, G, with the arbor of the roller, A, at its forward end, and with the supporting frame, containing the plane stocks, H, H, at its rear end, for the purpose, in the first place, of so guiding the transversely reciprocating movements of the said plane stock supporting-frames as to keep the inner sides of the respective series of plane stocks contained therein, parallel with each other, and parallel with the surfaces of the pairs of rollers, A, A', and B, B'; and in the second place, for the purpose of enabling the supporting frame, containing the self-adjusting plane stocks, G, G, to be detached from the supporting frame containing the adjustable plane stocks, H, H, and be swung outwards upon the shaft of the roller, A, to afford free access to the inner sides of the plane stocks in both the said plane stock supporting frames, substantially as herein set forth.

Fourth. I claim the combination of the rollers, *d*, *d*, with the plane stocks, G, G, when they are so arranged that the roller in one plane stock will form a rotating and self adjusting mouth-piece to the planing knife that succeeds it, and at the same time form a bed on one side of a plank for a planing knife, acting upon its opposite sides, substantially as herein set forth.

Fifth. I claim the giving to straight-edged planing or reducing knives, or cutters, that are arranged athwart the surfaces of the boards or planks operated upon, a transversely reciprocating movement, whilst a continuous longitudinal movement is imparted to the said boards or planks.

Sixth. I claim the manner of producing a uniform elastic pressure upon the upper and lower bearing boxes of the arbors of the pressure rollers, A, B, C, viz: by means of pairs of screws, k, k', arranged as herein described, and having threads inclining at angles of about thirty degrees with their axes, which are banded together, and operated upon by a weight, (N,) substantially as herein set forth.

Seventh. I claim the within-described improved stock, that receives the tonguing cutters, v, v and r, r, composed of the central governing plate, S, combined with the projections, o, o, on the side plate, Q, and the projections, o'', o'', on the side plate, R, substantially as herein set forth.

Eighth. I also claim the manner of combining the stationary cutters, v, v, with the governing centre plate, S, by means of the inclined projections, o, o'', on the sides of the said plate, the flaring notches in the plate, and the gibs, p, p, having lugs at each extremity, placed in the said flaring notches, and acting upon the edges and front sides of the said cutters, v, v, substantially as herein set forth.

NELSON BARLOW.

No. 8126.—*Improvement in Breech-Loading Fire Arms.*

What I desire to secure by letters patent, and claim as my invention in that class of breech-loading fire arms in which the barrel is disconnected from the breech, and is pivoted at some point intermediate between its but and its muzzle to the stock, is a lever beneath the stock, by means of which the barrel is turned upon its pivot, to raise and to depress its but, and is locked to its breech when the but is depressed, and is unlocked therefrom to allow the but to be raised, the several members of the implements being arranged and operating substantially as herein set forth.

In combination with the above-claimed device, I claim a piston breech pin, which, by the movements of the lever to depress the but of the barrel, and to lock it in place, is made to move the cartridge forward in the barrel and to close the but thereof, and which, by the movement of the lever, to unlock and raise the barrel, is made to unclose or open the but of the barrel before the latter rises under the action of the lever.

I likewise claim the sliding bolt, I, constructed with slot and hook, or their equivalents, and arranged as herein set forth, in combination with a lever handle, for the purpose of imparting motion to the piston breech-pin from the lever beneath.

EDWARD MAYNARD.

No. 8127.—*Improvement in Boot Crimps.*

Having thus fully described our invention, what we claim therein as new, and desire to secure by letters patent, is the combination of the spring frame, B, crimping plates, C, and boot tree, D, with the adjustable side springs, F, F, for the purpose of crimping boot fronts, and adjusting the pressure of the crimping plates to the particular point in

which the creases have a tendency to run; the whole being arranged in the manner herein described and represented, or in any other manner essentially the same.

NATHAN DAWES,
HIGGINS HARRISON.

No. 8128.—*Improved Self-adjusting and Locking Switch for Railroads.*

Having thus fully described this form of self-adjusting railroad switch, what I claim as my invention, and desire to secure by letters patent, is the combination of the counterpoise weights, R, R, R, R, or their equivalents, with the toggle levers, D, D, and stops, Q, Q, substantially as described, operating in the manner and for the purpose herein substantially set forth and made known.

JOHN C. PAST.

No. 8129.—*Improvement in Comb Cutting Machines.*

I do not claim the invention of a single chisel, made to operate by successive blows or cuts, each of which is in advance of another, and so as to create a series of cuts through a plate of horn or shell, such as will separate such plate into two combs without what is termed a bottoming—that is to say, with the roots of the teeth of each of the said combs in a *straight* line and not in a *curved* line, as they are when made with the "*bottoming;*" nor do I claim a die so made of stationary chisels or cutters, (that is to say, those which are removable with respect to one another,) and for the purpose of enabling a person, by pressure of the *whole series* of cutters at once, against a plate of horn or shell, to separate it into two combs, either with or without a bottoming; but what I do claim is my improvement in comb cutting machinery, the same consisting in making the cutters to operate or move separately and independently of each other, and in regular succession, in combination with making them of different and the required lengths, so as to produce the separation of two combs from a comb plate, substantially in the manner, and with the bottoming to their teeth, as hereinbefore specified.

HORACE S. COOK.

No. 8130.—*Improvements in Hand Machines for Spinning Wool.*

What I claim as my invention, and desire to secure by letters patent, is the clamp, D, D', the inclined planes, E, E, the lifters, F, F, the adjustable stop, G, the trip, H, the hand and ratchet, L, with the hand and ratchet, K''', M, M', and N, combined and arranged as set forth and described, or any analogous device for the purpose of spinning wool.

MARGARET HULINGS.

No. 8131.—*Improved arrangement of Machinery for Actuating the Crank Indicator.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of bevel wheels, c, f, g, e, and their shafts, F, I, H, herein represented and described; the first, c, in the series being actuated by a motion derived from the eccentric by means of a crank, *a*, and pin, *b*, and the last, *e*, giving motion to the indicator hand; the whole being constructed in the manner and for the purposes herein set forth.

SAMUEL B. HUTCHINS.

No. 8132.—*Improvement in Seed-distributors of Seed planters.*

Having thus described our improvements on the machine for planting corn and other grain, what we claim therein as new, and desire to secure by letters patent, is in combination with the notched transverse bar, X, the employment of the jointed clearers, (*n*,) projecting from the recesses of said bar, X, into the apertures (*a*) of slide bars, T, for preventing the choaking of the apertures.

DAVID WOLF,
HERMAN WOLF.

No. 8133.—*Improvement in Collars for Harness.*

I do not claim generally the hame in one piece with pads of limited length, but what I do claim as my invention, and desire to secure by letters patent, is the U-shaped metallic breast plate, B, suitably padded and made to fit around the neck of the horse, the same being so limited in length as not to reach the shoulder blades of the animal, and being suspended from the neck by a neck strap.

JOSEPH W. BRIGGS.

No. 8134.—*Improvement in Processes for treating Vegetable Fibre.*

What I claim as my invention and discovery, and desire to secure by letters patent of the United States, is—

Firstly. The preparation of vegetable fibre capable of being spun or felted by submitting the plant from which the fibre is to be derived to the action of caustic, soda, or other solutions of like properties, and then to that of sulphuric or sulphurous acid, in the manner set forth, whereby the gummy, glutinous, and other matters which connect the fibre with the woody portion of the plant, are dissolved and discharged, and at the same time effecting the discharge of the oleaginous and other coloring matters contained within the woody portions, or "straw," without straining the "fibre," as more fully described herein.

Secondly. I claim splitting the fibres of vegetable matter in preparing them for spinning, by the generation and liberation of carbonic acid or other gas within the cellular portions of said fibres, in the manner described, or in any other manner by which gas may be generated and liberated for the purpose set forth.

P. CLAUSSEN.

No. 8135.—*Improved Sash Stopper.*

What I claim as my invention, and desire to secure by letters patent, is arranging a sash stopper, composed of a friction plate, bolt, and helical spring, with the friction plate parallel to the side of the sash, and the bolt rising obliquely upward therefrom, in the manner herein set forth, so that the upward motion of the sash will relieve the same from the frictional resistance of the friction plate by counteracting the force of said spring, and that the downward motion or tendency of the sash will augment the frictional resistance of said friction plate by aiding the force of said spring.

JOSEPH OSBORN.

No. 8136.—*Improvement in Horse Powers.*

What I claim as my invention, and desire to secure by letters patent, is, first, the employment of rollers, G, G, mounted or hung on the main shaft, B, and lower guide shaft, F, in combination with the flanches on the wheels, *k*, to retain said wheels upon their axles when passing from one platform to the other, and to check their revolution, as described.

CYRUS AVERY.

No. 8137.—*Improvement in machines for expressing Cane Juice.*

What I claim as of my own invention, and desire to secure by letters patent of the United States, is—

Firstly. The extraction of the juice from cane by submitting the stalks of the same in perforated tubes, or other vessels constructed on the principle described herein, to a continuous pressure in the manner set forth, whereby time is afforded for the juice to flow from the cellular tissues, and reabsorption into the exhausted cane is avoided.

Secondly. The perforated compressing tubes, having either a straight or a tapering bore.

Thirdly. The combination of the pistons with the perforated tubes and hoppers, whereby the operations of regulating the feed, cutting the canes into equal lengths, pressing and discharging the same, are effected substantially as herein set forth.

HENRY BESSEMER.

No. 8138.—*Improvement in the gearing of a Seed Planter.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the combination and arrangement of the double bolt, *h*, with its slotted arm, *k*, rock shaft, *n*, with its arms, *m* and *p*, and pitman, *g*, for the double purpose of giving motion to the feeding apparatus, and also regulating the quantity of seed to be sown, when said pitman is operated by a long crank, upon which it travels, as herein fully shown and represented.

MARSHALL J. HUNT.

No. 8139.—*Improvement in Revolving Frames for drying Fruits and other articles.*

What I claim as my invention, and desire to secure by letters patent in the above described portable frame, is the centre, E, with three or more arms, to support a cord, netting, or cloths for the purpose of exposing, cloths, clothes, glue, fruits, seeds, &c., with facility to be dried, so constructed that the arms may be raised up and brought together, to expedite the collection of the articles dried, and so that it may be conveniently removed when not in use, substantially as described.

I do not intend to limit my invention to the precise form of construction described, but to vary it to suit the circumstances in which it is to be used, while I accomplish the desired object by means substantially the same.

J. C. DICKEY.

No. 8140.—*Improvement in Ornamenting Baked Earthenwares.*

I do not intend herein to claim the general application of oil-painting to china or earthenware; but what I do claim as my invention, and desire to secure by letters patent, is—

First. The application of coloring water mixed with varnish, or its equivalent, to the surface of baked earthenwares, for the purpose of giving to such ware a surface of sufficient body, and of sufficient brilliancy, for ornamental purposes; thus obviating the necessity of the glazing process, substantially as herein described.

Second. The inlaying of pearls, gems, &c., on china and baked earthenware, for ornamental purposes, substantially as herein above described.

Third. The peculiar cement and process by which I affix pearls and gems to the china or baked earthenware.

RALPH B. BEECH.

No. 8141.—*Improvement in Carving Machines.*

What I claim as my invention, and desire to secure by letters patent, is the use of the pendant lever, suspended from a ball and socket joint, in combination with a horizontal table for the pattern and block; the said table being affixed to the end of the pendant-lever by a ball and socket joint; the whole being arranged with respect to the tracer and cutter, substantially in the manner, and for the purpose described.

I also claim preventing the pendant lever from changing its centre of motion, or from rotating on its own axis, or on any line passing through the centre of its motion, by the use of the bent arms, working in balls in spherical sockets, substantially as described.

I also claim combining with the pendant-lever two or more tables, substantially in the manner described, or in any other, substantially the same, and arranged each with a tracer and cutter, respectively, in order that large carvings may be obtained from a small pattern, or *vice versa*, or both at the same time, and with the same machine, substantially as described.

LEWIS S. CHICHESTER.

No. 8142.—*Balanced Rudder.*

What I claim as my invention, and desire to secure by letters patent, is the employment, for the purpose of steering ships and other vessels in water, of two rudders, hung upon, and at equal distances from, the same centre of motion, and with their surfaces parallel, or nearly so, with each other, in such a manner that the same resistance is offered to each by the vessel's motion through the water, and both are balanced, substantially as herein described.

C. F. BROWN.

No. 8143.—*Improvement in Churns.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the combination and arrangement of the arms, H, H, with their rollers, I, I, which are controlled by the crank and the swinging arms, G, G, with their floats, *g*, *g*, kept in proper place, both in churning and gathering, and working the butter by the resistance of the cream, as herein described and shown, and for the purposes herein represented.

DAVIS DUTCHER.

No. 8144.—*Improvement in Comb-cutting Machines.*

I do not claim the mere use in a die of a clearer for forcing out of the die the articles produced thereby; but what I do claim as my invention is the combination of the two series of lifters and bent levers, *n*, (arranged upon the travelling carriage, A,) with the pressure roller, in such manner that the continued motion of the carriage shall operate the lifters after the combs are cut, substantially as hereinbefore described.

THOMAS W. HILL.

No. 8145.—*Improvements in Permutation Safety Locks.*

What I claim as new, and of my own invention and improvement, and desire to secure by letters patent of the United States, is—

First. The application of the lever, *b*, 5, and dog, *b*, 6, with the tusk, 40, to be acted on by the talon, 39, and allow the spring, 38, to throw the tusk, 40, into the notches on the lower part of the followers, and auxiliary followers, so as to prevent any motion of these parts, if any of the tumblers are lifted, after any end-shake motion has been given to the bolt, by any improper attempt to unlock it.

Second. The combination of the tumblers, *a*, slides, *b*, 1, and followers, *a*, 9, through the tenons, 18, notches, 30, tongues, 29, and jaws, 24, to lift the slides, *b*, 1, and followers, *a*, 9, to the same extent as the tumblers, *a*, are lifted by the key sections on locking the bolt; and to sustain the slides, *b*, 1, until the tusk, 33, takes the notches, 31, on the slides, and holds them, so that the bolt cannot be retracted until all the tumblers, *a*, are lifted to meet the notches, 30, and allows the springs, 25, levers, *a*, 0, and auxiliary followers, *a*, 8, to lift and place the followers, *a*, 9, in the same positions as when the bolt was projected, substantially as described and shown.

Third. The mode, described and shown, of so arranging and combining the cylinder, *c*, 4, by the flanches, *c*, 5, angles, 60, tumblers, *c* and *a*, and pins, 47 and 49, with the detector-lever, D, at the part, *c*, 1, so that no one of the tumblers, *a*, can be separately lifted without placing the part, *c*, 3, of the detector-lever over the key-hole, with the edges of the notch, 55, covering the open space around the drill pin, 57, by which arrangement no movement of the cylinder, c, 4, can be made without producing the same effect; so that if powder is introduced into the cylinder, c, 4, and the cylinder is moved with the intent of entering a blow-pipe to spread the powder on either side of the cylinder, the part, :, 3, and notch, 55, instantly cover the key-hole, and prevent the entry of the blow-pipe for such a purpose; these parts being constructed, arranged, and operating substantially as described and shown.

Fourth. The combination of the cylinder, c, 4, block, 62, and hole, 63, to receive and pass out any gunpowder put in for the purpose of exploding, to destroy the lock, and, at the same time, prevent the powder from reaching any other part of the interior of the lock.

Fifth. The application of the safety-valve block, 64, to vent the explosion of any gunpowder that may be confined in the cylinder, c, 4, by plugging both the key-hole and the hole, 63.

Sixth. The mode of fitting the key-hole cover, c, 3, with the notch, 55, on the detector-lever, D, to match the neck, 56, on the key-shank; such means also preventing the introduction of any pick, or false instrument, after any movement has been given to the cylinder, c, 4, by the notch, 55, being as small as the drill pin, 57.

Seventh. The application of the guard piece, 65, on the detector-lever, D, to prevent a pick reaching the pin, 45, of the detent dog, b, 8.

Eighth. The application of the cam-pointed piece, c, 6, on the detector-lever, D, to move the pin, 47, and detent dog, b, 8, so attached that if the key-hole cover is cut or drilled off the piece, c, 6, falls away, and leaves the detent dog, b, 8, still holding the bolt.

ROBERT NEWELL.

No. 8146.—*Improvement in Churns.*

Now, what I claim as my invention, and desire to secure by letters patent, is the combination of the rock shaft, levers, connecting rod, and swing, for the churn, for the purpose of producing the perpendicular movement of the dasher, substantially in the manner herein described, to be denominated "the oscillating perpendicular dash churn."

J. S. RICHARDSON.

No. 8147.—*Improvement in crossing the fibres in forming the bats for Felt Cloth, &c.*

What I claim as new in my invention, and desire to secure by letters patent, is—

First. The employment, for the purpose of carrying webs, sheets, or layers of any fibrous material, of an apron, B, B, of material pervious to air, having a box, E, in which a vacuum is produced, placed at the back, the side of the box next the apron being perforated, or otherwise rendered pervious, so that the external air, rushing through the apron to fill the vacuum within the box, forces the material close to the apron, and confines it there, in combination with the manner herein described of throwing off or releasing the material from the apron by suddenly closing the valve, S, in the pipe, G, communicating between the box, E, and the apparatus for producing the vacuum, and at the same time opening the valve, l, in the said pipe, to admit air into the box, or by any means substantially the same.

Second. The flap, t, operating in the manner and for the purposes substantially as herein specified.

ALONZO C. ARNOLD.

No. 8148.—*Improvement in Governors.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein specified, of steadying the movement of governors or regulators of motion, by apparatus herein described, or the equivalent thereof.

GEORGE H. CORLISS.

No. 8149.—*Improvements in Railings.*

What I claim as my invention, and desire to secure by letters patent, is making the dove-tailed tenons, whether to the paling or top and bottom rails, wedge-shaped in the length of the railing, the taper at the opposite ends being reverse, and making the grooves in the rails or palings in the same manner, that the palings cannot slide in either direction, binding the whole firmly together, substantially in the manner described.

SOMMERS CROWELL.

No. 8150.—*Improvement in Machines for Facing and Polishing Stone and other Substances.*

What I claim as my invention, and desire to secure by letters patent, is the method, substantially as herein described, of grinding, facing, or polishing the surface of stones, and other substances, by means of a grinder, rubber, or polisher, connected and combined with a spindle, from which it derives a rotary motion by means of universal and sliding joints, substantially as described, that the said grinder, rubber, or polisher may be carried over any and all parts of the surface, to be worked whilst its surface is self-adapting, as described.

ALBERT EAMES.

No. 8151.—*Improvement in Governors.*

What I claim as my invention, and desire to secure by letters patent, is the employment of a loose wheel or pulley, A, propelled by the prime mover, and driving its shaft, B, through the action of a separate elastic force, weight, or pressure, such as procured by the spring, H, in combination with the several racks and pinions, or their equivalents, as described, for operating the adjusting or regulating slide, J, substantially in the manner shown and specified, and for the purposes set forth.

WILLIAM GARDNER.

No. 8152.—*Improvement in Carriage Springs.*

Having thus fully described my improvements in buggies, &c., what I claim as my invention, and desire to secure by letters patent, is the connecting of the axles of wheeled vehicles by means of curved spring perches, which are combined with the supporting springs of the vehicle, that have a greater degree of curvature than themselves, substantially in the manner and for the purposes as herein set forth.

CHAUNCEY H. GUARD.

No. 8153.—*Improvement in Washing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the triple and concentrated action of pressure blocks upon the clothes, being constructed and operated substantially in the manner herein set forth and described.

JOHN O'NEIL.

No. 8154.—*Improvement in Lan'erns.*

What we claim as our invention, and desire to secure by letters patent, is the mode of attaching the lamp to the lantern by means of the springs and flanges, as herein substantially set forth.

HUGH SANGSTER,
JAMES SANGSTER.

No. 8155.—*Improvements in the method of finishing the Heads of Screws.*

I have herein described the construction and arrangement of machinery which I have essayed with success; but I do not wish to limit myself to the specified construction and arrangement, as these may be modified without changing the principle of my invention.

What I claim as my invention, and desire to secure by letters patent, in the method, herein described, of finishing the heads in the manufacture of wood screws, is partly shaving the head with a cutter before nicking, and after nicking subjecting it to a second shaving operation, to complete the shaving by means of a cutter, whose edges form with each other a more acute angle than the edges of the cutter first employed, as herein specified.

THOMAS J. SLOAN.

No. 8156.—*Improvement in Centrifugal Sugar Drainers.*

What I claim as my invention, for which I desire to secure letters patent, is the contrivance for discharging, and at the same time cleansing, the strainer whilst in motion, by means of an elevator rising in a spiral groove, substantially as described, or by an elevator rising in vertical or inclined grooves, which is essentially the same.

WILLIAM VAN ANDEN.

No. 8157.—*Improvement in Grain Harvesters.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is gearing the operating parts of the machine from both the wheels, in combination with the arrangement by which portions may be driven by either, so as to equalize the driving power upon each, and thus to allow the machine to be much more easily guided and controlled.

N. T. ALLEN.

No. 8158.—*Improvement in Brick Machines.*

Having thus described my improvements in the machine for making bricks, what I claim, and desire to secure by letters patent, is the rotating mould wheel, A, G, H, I, *e*, constructed, as herein described, with a series of moulds in its periphery and an annular plane, A, outside of the moulds, and furnished with pistons, J, arranged, as herein described, for the purpose of discharging the bricks from the moulds, as set forth.

I also claim the mode, herein described, of changing the positions of the pistons, J, by means of the bar, (*m*,) (attached to the horizontal presser,) with its block (*o*) and plate, (*u*,) which are made to impinge upon the vertical plates, (*n*,) which are attached to the pistons for that purpose.

I also claim the combination of the hopper, L, horizontal presser, P, vertical presser, V, and hook rod, (*w*,) with the traverse horizontal lever, Y, and with the mould wheel; the whole being constructed and arranged in the manner and for the purposes herein described.

MAHLON GREGG.

No. 8159.—*Improvement in the construction of Dies.*

I do not claim to be the first to construct a die with a lined surface, to deaden the metallic surface operated on; but what I do claim as new, and of my own invention, and desire to secure by letters patent of the United States, is the application of a die with a lined or corrugated surface, with the figure or pattern cut out counter sunk, so that the lined surface deadens the plate of polished metal, and leaves the polished surface of the figure untouched, for producing ornamental designs on polished metallic surfaces.

HIRAM W. HAYDEN.

No. 8160.—*Improvement in Cooking Stoves.*

Having thus described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, are the cold air passages, substantially as here arranged, to wit: having each an external aperture near their upper part on each side, beneath which projects a plate, (*f*,) which carries the air to the centre of the stove, whence, by a second plate, (*g*,) beneath the middle of the passage, it is again deflected to the outer ends of the passage, (thus counter-balancing the cooling effects at its entrance,) whence it is distributed in hot blasts to the fire.

ELIAS YOUNG.

No. 8161.—*Improvement in Wash Boards.*

What I claim, and desire to secure by letters patent, is—

First. I claim fastening cloth, or its equivalent, on the board to prevent fabrics from slipping and from being torn or rubbed too much; but I do not claim lining the grooved wash board with India rubber, or other equivalent material.

Second. I claim hinging the wash board, A, to the frame, B, C, for the purpose of holding the clothes while being washed, and, at the same time, allowing the board to be turned over, substantially as herein se forth.

WILLIAM T. BARNES.

No. 8162.—*Improvement in Augers.*

What I claim as my invention, and which I desire to secure by letters patent, is the form of the lips, or cutting edges, of boring implements, as illustrated in figures 1, 2, and 4—that is, such lip commencing at the screw or centre point, and running nearly at right angles thereto, until, about half way from the centre to the outer part of the boring implement when it assumes a curve upward, or toward the handle-end of the instrument, which curve is continued until it is nearly semi-circular, or until it turns within the periphery of the auger, or bitt, as shown in fig. 1, the curved edges being also under-cut or back-sloped, as illustrated in figs. 2 and 4, between A and B, but without being confined to any particular angle of such back-sloping or under-cutting; all as hereinbefore set forth.

RANSOM COOK.

No. 8163.—*Improvements in Knitting Machines.*

What I claim as my improvement is the arrangement of the needles in the plane of the endless belt, instead of at right angles to it, in combination with the arrangement of the driving pinion, *b*, and the projecting joints, *x*, *x*, *x*, *&c.*, of the links of the belt, on the outside of the belt; the belt being supported, and the whole being applied to the stitch hook, yarn guide, and presser, and made to operate together, and with the work hanging on the inside of the belt, substantially as hereinbefore specified.

RUFUS ELLIS.

No. 8164.—*Improved Connexion of Telescopic Masts and Spars.*

What I claim as my invention, and desire to secure by letters patent, is connecting and adjusting the several joints of masts, yards, and all spars constructed for telescopic tubes, or tubes fitting one within another, by means of a screwed rod, C, or screwed rods, C and C′, nuts and female screws, F, and set screws, *d*, or their equivalents; the whole being inserted in, and secured or attached to, the tubes, and operating in the manner substantially as herein set forth.

C. F. BROWN.

No. 8165.—*Improvements in Machines for Dressing Shingles.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the head block, *t*, with the springs, *u*, *u*, cams, *v*, *v*, the rollers, *o*, *o*, and stops, *x*, *x*, for the purpose of passing the shingles between and out from the cutting cylinders, in combination with the arrangement for depressing the upper cylinder while in motion, for the purpose of giving a taper to the shingle; the whole combined and arranged substantially as set forth in the above specification.

SEYMOUR CARVER.

No. 8166.—*Improvement in Running Gear of Locomotives.*

What I claim as my invention is the combination of the bent levers, (*o*,) the connecting rods, (P, P′,) and tractile bar or spring, or other equivalent contrivance or contrivances, with the main frame, or its housings, and the boxes or pedestals of the journals of the driving wheels, and for the purpose substantially as hereinbefore specified.

GEORGE S. GRIGGS.

No. 8167.—*Improvement in Ventilators.*

Having thus described my improvements in ventilators, I shall state my claim as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is a ventilator, as herein above described, composed of two series or sets of curved slats, arranged one within the other, and running from the edge of the flue, or other orifice, to a small circle, or plate, over the centre of the same, the whole forming a conical or globe-shaped ventilator, the spaces between the several outer slats being protected by the inner slats, leaving spaces or apertures between the two sets of slats, the only openings to said apertures being in an oblique or sideways direction; all as hereinabove described and set forth.

THATCHER C. HATCH.

No. 8168.—*Improvement in Regulators for the Pen Beam in Ruling Machines.*

I do not claim to be the inventor of the flexible hooked regulator attached to the pen-beam, as heretofore constructed, but what I claim as my invention, and desire to secure by letters patent, is—

First. I claim the pieces, G, H, A, B, in combination with the hinge joints, (1, 2, 3,) arranged and combined substantially and for the purpose as herein described.

Second. I claim the sliding piece, B, the bearings, C, C, C, and the finger wheel, F, in combination with the pieces, G, H, A, uniting by hinge joints, or in any other manner substantially the same, using in the construction of the whole machine any material adapted to the purpose of forming, as herein described, a pen beam regulator for ruling machines.

W. O. HICKOK.

No. 8169.—*Improvements in Revolving Boilers.*

Having thus fully described my invention, I will proceed to name what I claim as new, and desire to secure by letters patent. I claim lining the inside of that part of a revolving boiler which comes in contact with the fire or heat with wire gauze or cloth, or any perforated or pervious metal work, I, in the manner and for the purpose substantially as herein described.

CHARLES ANDERSON.

No. 8170.—*Improvement in Ploughs.*

What is claimed as the invention of Benjamin Giger, and as not previously known, is the peculiar form and construction of the standard, with its sockets at the upper extremity, and flanges at the lower, and the method of uniting them so as to form a double machine, capable, also, of being used for cultivation in its separate parts, as set forth.

The whole machine, as above described, constitutes "Giger's Corn Planter."

JOHN COOPER,
Administrator of the estate of Benjamin Giger, deceased.

No. 8171.—*Self-acting Guard Frog.*

What I claim as my invention, and wish to secure by letters patent, is the combination of the rising and falling guards, $f', f,^2$ with the levers, e, e, and $h', h,^2$ by means of an arrangement of levers, connecting rods, &c., substantially such as herein specified, and acting in the manner and to produce the results herein set forth.

CHARLES A. POSTLEY.

No. 8172.—*Improvements in Knitting Machines.*

What I claim as my invention, and desire to secure by letters patent—

First. Is a sinker, to be used in machines for knitting, so constructed as to form the loops upon the needles, used in knitting two separate fabrics at the same time and at one operation, and of sufficient weight to draw the requisite quantity of yarn from the supply to form the loops required.

Second. Is a slur, to be used in knitting machines, so constructed as to let each sinker drop to the falling bar, and draw the requisite quantity of yarn from the supply to form the loop, or loops, between the needles, before it allows the succeeding sinker to drop, and act upon the yarn.

Third. Is a falling bar, so constructed that the slurs and slur boxes traverse upon it, instead of traversing a separate bar.

Fourth. Is the combination of the sinkers, stop bars, combs, and needles that traverse, so arranged as to knit two separate fabrics at the same time with one and the same set of sinkers and slur.

Fifth. I do not intend to limit myself to the precise construction described in the foregoing specifications, but to use such forms of construction as will answer the purpose intended.

JOHN PEPPER.

No. 8173.—*Machinery for making Wrought Iron Car Wheels.*

I claim the machinery and apparatus set forth and described in figures 1, 2, 3, 4, 5, 6, to wit, the mould blocks or welders, the hammer, or ram, with the wedges thereto attached, and the mandrel, in combination with each other, for the purpose of making wrought-iron sheets, substantially as set forth in this specification.

MARIA VAUGHN.

No. 8174.—*Improvement in Machines for splitting Horn and Shell.*

What I claim as my invention or improvement is the cylindrical rotary bed, or drum, A, in combination with the water cistern, or trough, and its furnace and machinery over the drum for bearing the shell or material down upon it during its revolution, as specified, the said drum being provided with a roughened or friction-curved surface, such as will adhere to the shell, and cause it to move with it, and against the knife, as described.

JABEZ ROBINS.

No. 8175.—*Improvement in printing Names of Subscribers upon newspapers, &c.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement and construction of a machine for printing names of persons or places on newspapers and other papers after the manner substantially as described, viz: of a form containing the column of names to be printed, set up in types, and being brought under the action of a stamp by means of a slide, moving by degrees, together with the application of a slitted plate, allowing the paper (to be printed) to be pressed down on the line right beneath the slit of the plate, and shielding the paper from the lines adjoining that under action of the stamp, as hereinbefore described.

HENRY MOESER.

No. 8176.—*Improvement in Lubricating Compounds.*

Having thus described the mode in which my anti attrition is compounded and used what I claim therein as new, and desire to secure by letters patent, is the combination of ingredients herein described, whether the proportions be the same as herein set forth, or varied to any extent that the same may admit of without changing the peculiar character of the compound as a lubricator.

J. SELGRATH.

No. 8177.—*Improvement in Cars for Transportation of Coal.*

Having thus fully described my invention, I wish it to be distinctly understood that I do not claim the use of cylinders for conveying material upon common roads, as this has been done heretofore; but what I do claim as of my invention, and desire to secure by letters patent, is the combination of a partition or partitions with a metallic cylinder or cylinders provided with flanged rims, as herein described, for the purpose of carrying material in bulk on rail or other roads where high velocities are attained, said material being held in place by centrifugal force whilst in motion, and prevented from falling or rolling in the cylinder by the partition or partitions whilst in the act of stopping or starting, as herein fully described and shown, or by any other means essentially the same.

LAURENCE MYERS.

No. 8178.—*Improvement in Machinery for Cutting Ratan, &c.*

What I claim as my invention, and desire to secure by letters patent, is—

First. I claim the combination of the cutters, *a*, as described, with the levers, C, and springs, *e*, and cams, D, or their equivalents, and also handles, D′, and links, *d′*, for the purpose of applying said cutters or scrapers, so as to act upon the stick of ratan, in the manner herein described, and by which they may all be operated simultaneously, substantially in the manner herein described.

Second. In the process of cutting cane or ratan into strands, as described, I claim beading the stick at the point at which the cutter is removing the strand from the surface.

Third. I claim the combination of the elements which compose each simple section of the cutting apparatus; that is to say, of the cutter, H, and gauge, I, with the stock, G, and guide, *g*, and bed roller, F, or their equivalents, substantially as described, for the purpose of bending the stick and removing the strand therefrom, whether said section is used alone or is combined with others as described.

Fourth. I claim the combination of that part of the machine called the "scraper" with the feeding rollers, or their equivalents, and the several sections of the cutting apparatus, said sections being so arranged in relation to each other as that the stick, in passing from one to the other, shall be properly bent; and also that the several cutters shall act upon different points of its circumference; the whole being arranged and operating substantially in the manner herein described and set forth.

SYLVANUS SAWYER.

No. 8179.—*Improvement in Machines for finishing the backs of Books.*

I do not claim to be the inventor of "backing books" by means of a roller, as rollers having concave peripheries have been used, which were passed longitudinally over the back; nor do I claim the construction of the clamps or jaws between which the book is held; nor do I claim to have invented the use of circular engraved tools or rollers for embossing books; but what I do claim is—

First. The use, for the purpose described, of a roller, G, of the whole length or part of the length of the back of the book, either plain for a plain back book, or grooved for a raised banded book, or having a figure or figures cut or engraved, or otherwise made upon it, rolling over the back of the book from side to side, or from the centre to the sides, and having a yielding pressure applied to it by weighted levers, or their equivalents, in the manner substantially as described.

Second. I claim clamping or holding the book in a swinging book-holder, E, E, or its equivalent, which hangs on pivots or journals, *o*, *o*, and is capable of being swung back and forth so as to cause the back of the book held in it to describe an arc of a circle, and bring each part of the back to the roller, so that it shall receive an equal pressure all over its surface, substantially as and for the purpose herein set forth.

Third. The gauges, *v*, *v*, sliding upon an inclined bar or bars, *w*, *w*, that they may be set to form guides for placing both ends of the back of the book at an equal or nearly equal elevation in the clamp, so as to cause each part to receive a uniform pressure, and may be drawn back from the book without dragging or rubbing the surface of the back, in the manner substantially as herein shown.

CHARLES STARR.

No. 8180.—*Improvement in making Gutta Percha Hollow Ware.*

What I claim as my invention, and desire to secure by letters patent, in the process above described, is the method, as described, of moulding articles of gutta percha, or the compounds of gutta percha with other substances, by first making the same in the form of a pipe, and whilst in a partially heated and plastic state, giving to it the form required in a mould, by forcing a liquid inside to expand the gutta percha, as described.

S. T. ARMSTRONG.

No. 8181.—*Improvement in Fastening Pedestals to Columns.*

Therefore, what we claim as new, and of our own invention, is the application of the piece, *c*, and different shaped lugs, 8 and 9, on the end of the column to enter the hole, 2, and notches, 3 and 4, so that, on turning the column, the lugs, 8 and 9, take the inclined seats, 5 and 6, to attach the column to the pedestal, in combination with the locking piece, *d*, to prevent the column turning, substantially as described and shown.

WM. LEWIS,
W. H. LEWIS.

No. 8182.—*Improvement in Grain Harvesters.*

Having thus described my improved grain and grass cutter, what I claim as my invention, and desire to secure by letters patent, is—

First. The standard to which the steering wheel is attached, constructed as herein described, so as to perform its own office proper, and also to adjust the cutter at the required height above the surface of the ground.

Second. The discharging rake, which is moved, as described, in combination with the endless apron, for collecting and discharging the cut grain, as set forth.

WILLIAM H. START.

No. 8183.—*Improvement in Mashing Tubs.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The employment of buckets, formed by the revolving arms, *g*, *g*, working within the hopper, H, for delivering the grain, through suitable openings, *d*, *e*, into, and operating in combination with, the mashing cylinder, A, A, having an outlet, C, (or outlets,) for supplying the cooler, J, J, substantially as shown and described.

Second, The use of a mashing cylinder, A, A, having beaters within it, and operating in combination with a cooler, J, J, carrying any number of barrels, or shafts, L, L, fitted with projecting pins, *m, m, m, m,* essentially as shown and described for the purposes set forth.

JOSEPH WRIGHT.

No. 8184.—*Improvement in making Hemp from Okra.*

What I claim as my invention, and desire to secure by letters patent, is the preparing of hemp from the bark of the okra plant, in its green state, and the herein-described method of preparing it for use.

JEAN BLANC.

No. 8185.—*Vise Saw Set.*

What I claim as my invention, and wish to secure by letters patent, is constructing a vise for the purpose of compressing saws to be set or filed, in the following manner, namely: with only one supporting arm to each jaw, hinged at their lower extremities, and having an extra arm on one side of, and parallel, or nearly so, to said supporting arms; to the upper extremity of which is attached an eccentric lever, or its mechanical equivalent, for compressing the two jaws together, constructed substantially as herein described.

WILLIAM HINDS.

No. 8186.—*Arrangement of Catches on the Upper Sash, operated by moving the Lower Sash.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement, herein described, of the catches and window sashes, for the purpose described.

WASHBURN RACE.

No. 8187.—*Improvement in Boxes and Axles for Saving Oil.*

I claim causing the beveled edges of the oil-box to enter the grooves of the axles and rest against their outer shoulders, but not against their inner shoulders—thus at the same time preventing end play and the escape of the oil; the journal bearing being lower than the beveled edges of the oil box, and sufficiently above the bottom of it to prevent the oil coming from the box to the journal.

BENJAMIN KRAFT.

No. 8188.—*Improvement in Inkstands.*

I do not claim the invention of the elastic diaphragm for inkstands, but I claim my inkstand as a new article of manufacture, in which the following features are for the first time associated, viz: an elastic diaphragm, covered and secured from injury by a metallic cap, and regulated by a screw passing through the cap, and, in combination with the diaphragm, the funnel-stop, *l*, and waste-cap, *n*.

HENRY WHITNEY, Jr.

No. 8189.—*Improvement in Iron Fences.*

Having thus fully described the nature of my invention, and the manner of constructing the same, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of securing the rails of iron fences by means of sectional or divided posts, having slots therein, which are so arranged that, when in place, they break joint with each other, the slot in one section extending upward, and the slot in the other downward, so closing the slots as to prevent the rails, which have a loop or dead-eye turned on each end for that purpose, from passing through or coming out, as herein fully set forth.

JOHN B. WICKERSHAM.

No. 8190.—*Improvement in Bedsteads.*

What I claim as my invention, and desire to secure by letters patent, is the knuckle joints for holding the rails of the bedstead together, in combination with the rods, G and L, substantially in the manner and for the purpose described; said rods being also employed to support the slats forming the bottom of the bedstead.

HARVEY W. SABIN.

No. 8191.—*Improvement in Spectacle Frames.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the spring, B, and cylinder, C, with the temple bow, A, and the glass frame, the whole being substantially as specified.

JOHN P. PAINE.

No. 8192.—*Improvement in Grain Harvesters.*

What we claim as our invention, and desire to secure by letters patent, is the discharging the cut stalks and heads of grain from the platform, D, by means of the combination of the rake, C, with the lever, B, and the co-operation therewith of the series of teeth, *p, q*, on the face of the wheel, A, and the inclined rail, *d*, rising above the curved guard of the platform, D, substantially in the manner herein set forth.

AARON PALMER,
S. G. WILLIAMS.

No. 8193.—*Improvement in Bread Cutters.*

What we claim as our invention, and desire to secure by letters patent, is the use of a series of knives or cutters, (E,) made in the form of eccentric circles or scrolls, with the cutting edge on the periphery, so as to represent a spiral line or curve (as seen in the drawings) when combined with the bars or ribs (C, C) of the bed piece, which serve to sustain the loaf, and also to guide the knives, and with the fingers or prongs, (D,) which hold the loaf against the knives whilst cutting, and also act as outside guides, when the whole is constructed, arranged, combined, and operating substantially as herein described.

A. E. LAZELL,
DAVENPORT LAZELL.

No. 8194.—*Improvement in Piano Fortes.*

What I claim as my invention, and desire to secure by letters patent, is the spring acting on the valve at D, in combination with the weight of the key, resting on the valve at F, for the purposes substantially as herein described and represented.

MICHAEL MILLER.

No. 8195.—*Improvement in machines for making Hat Bodies.*

Having thus fully described my inventions, and pointed out some of the modes in which I contemplate using them, and having referred to what was previously known in this branch of the arts, in order that my invention may be the better understood, I do hereby declare that I do not claim the combination of a picker and chamber having an aperture for the admission of air, such a combination having long been known and used for opening and cleaning the fibres of furs; nor do I claim the combination of these with a perforated exhausted former, such a combination having been described, and referred to as applicable to forming hats, and other irregular forms, in an application for a patent by T. R. Williams, in 1840, though it was not then claimed as invention; nor do I claim the use of water to harden or to wet the hat body, such use being as old as the felting process, and is indispensably necessary in all hardening and felting processes; nor do I claim the hardening of a hat body on a cone, such a process having been described and patented to Wells, James, & Peck, in 1837, they using a solid cone upon which a web was wound to form the body, and numerous jets of steam were used to harden the same or to wet it as it was wound on the cone, there being no exhaust; and processes for hardening bodies on a perforated cone have also been described—in 1840 by Williams, and by Wells in 1846, they both using outer pressure to hold the fibres, while the cone and fibres are immersed; nor do I claim any of the parts as my invention, except as they are used in new combinations and producing new and important results.

But what I do claim as my invention, and desire to secure by letters patent of the United States, is the exhausting and suspending fan, C, with its casing and aperture, M, constructed, arranged, and operated substantially as and for the purposes hereinbefore particularly described, in combination with the picker, B, chamber, R, perforated exhausted former, E, and exhaust fan, F, arranged substantially as described and shown, by which arrangements and combinations the several parts, or their equivalents, perform their several and combined functions in a better manner, and produce better results, than have been heretofore attained without any chamber trunk, or tunnel, or any other means to control the fibres after being suspended in the air by the fan, or between the fan and perforated exhausted cone or former, substantially as described and shown.

I also claim the combined action of the currents of air and the currents of numerous jets of hot water in the hardening or wetting process, the currents of air performing the triple duty of holding the fibres on the former and of aiding the water to penetrate the hat body, and at the same time to carry the surplus water through the perforations into the exhaust, thus effectually preventing injury to the hat body from the accumulation of the surplus water—to wash it while the wetting or hardening process is greatly facilitated and the perfection of the work is secured; the whole process being accomplished by the combination of the several parts named, or their equivalents, for producing the currents of air and water with the perforated former over the exhaust, in the manner and for the purposes substantially as herein described and shown.

The effect of these improvements are the production of a machine combining the best means for opening fibrous materials and suspending them in the air surrounding a perforated and exhausted former, and also of a new combination of means for hardening the fibres and completing the process without removing the hat or applying any pressure preparatory to the suspension of the pressure of the air, by which means a great improvement is effected as well in the forming of the hat and in the process of hardening as in the facility of operation; the whole being by combination of machinery heretofore unknown.

DANIEL BARNUM.

No. 8196.—*Improvement in Lathes.*

What I claim as my invention, and desire to secure by letters patent, is controlling the poppet centre, L, so that it releases itself, after the turning is finished, by connecting it with a sliding bar, N, having a weight, W, or its equivalent, attached, and carrying a ratchet, T, which is held by a catch, *t*, attached to the stationary bed; the said catch having an arm, *v*, attached, which is struck by part of the cutter head after the cut is finished, and released from the ratchet, substantially as herein shown.

THOMAS R. BAILEY.

No. 8197.—*Improvement in Running-gear of Railroad Carriages.*

Having thus fully explained the general features of the several parts used in my invention, and specifically the novelty and advantages possessed by my improvements, I will proceed to state that I do not claim exclusively the employment of inclined wheels, either with or without flanges, as such have already before been used; but what I claim as my invention, and desire to secure by letters patent, is the employment of wheels in any number of pairs, attached on either side to the truck or frame of railway vehicles, and set at any inclination to the horizon, converging to a point in or below the rail; so that both wheels of any one pair will rest or travel on opposite sides of the upper surface of either one or the same rail, essentially as shown and described.

DANIEL W. EAMES.

No. 8198.—*Improvement in Wire Hooks and Eyes.*

Having thus declared the nature or character of my invention, and specified the forms and manner of application of my improvements on wire hooks and eyes for garments, and their purposes and uses, I do not claim any of the forms of hooks and eyes heretofore made of wire, nor any peculiar difference in what belongs to any of the various kinds of them, except in the eyelets or loops. What I do claim as my invention, and desire to secure by letters patent, is—

First. The addition of side springs to the common forms of hooks for wire hooks and eyes, substantially in the manner and for the purposes set forth.

Second. I claim the small ridges, or elevations on each side of the beak of the hook, made by binding the wire of the side springs, or by other means equivalent thereto, for the purposes set forth.

Third. I claim the jewsharp form, or partly circular eyelets, extended to form loops, adapted to receive tape, in connexion with the small elevations to keep the tape in its proper place, substantially as set forth.

CHARLES ATWOOD.

No. 8199.—*Improvements in Machinery for Cutting Files.*

What I claim as my invention, and desire to secure by letters patent, is connecting the file blank to be cut with a bed, which has a positive feed motion, substantially as described, in combination with an incidental rolling motion, depending upon the shape of the blank, and the angle which the cutter forms therewith, substantially as described.

I also claim connecting the chisel with its stock by a joint, as described, in combination with a rolling bed, as described, by which they are rendered self-adapting, as described.

I also claim holding the file down on to the bed during the operation of cutting, and near to the cutter, by means of a roller, or its equivalent, combined with the rolling bed, substantially as herein described; but this I only claim when the end of the file is so connected with its bed, that it shall be free to move up and down, that the pressure of the roller may keep that part of the file that is being cut firmly down on to the bed, as herein specified.

I am aware that before the date of my invention the cutter of file-cutting machines has been jointed to a helve or bar, but in such cases it has not been combined with a rolling bed; and, therefore, I do not wish to be understood as claiming broadly the making of the cutter with a joint; but to claim this only under the limitations pointed out above.

I am also aware that the file blank has been made to slide during the feeding motion over a rolling-bed to adapt the transverse plane of the file blank to the line of the cutting edge, for cutting the different ranges of teeth; and, therefore, I do not wish to be understood as claiming broadly the employment of a rolling-bed; but to claim such rolling bed, when made to move with the file during the feed motion, from end to end, under the limitations above specified.

JOHN CRUM.

No. 8200.—*Improvement in Handles of Brushes and Brooms.*

Having thus described my improvements, what I claim as new therein, is the lever jaws, held together by the head-piece of the screw, *(g,)* in combination with the conical end of the handle, substantially in the manner and for the purpose set forth.

LUKE F. CAVANAUGH.

No. 8201.—*Improved arrangement of the Steam Engine.*

What I claim as my invention, and desire to secure by letters patent, is the method, herein described, of connecting the steam piston of a steam engine with the crank thereof by means of a piston rod, fixed cross head, side bars forked, connecting rod, and belts, or the equivalent thereof, the several devices being arranged and operating substantially as herein set forth, in such manner that the cross piece of the connecting rod, which is placed transversely to the crank-shaft, shall be on opposite side of the axial line of said shaft, at opposite extremities of the stroke of the piston

I also claim the belts or gimbal rings, or the equivalents thereof, arranged substantially as herein set forth, for the purpose of transmitting the movement of the cross head to the connecting rod of a steam engine.

FR. P. DIMPFEL.

No. 8202.—*Improved mode of papering Pins.*

I am aware that by other mechanical devices, such like pin rolls (as represented by figs. 3, 4, and 5) may be coiled or wound up nearly as well, and substantially the same, as by the process herein described, but which do not constitute the novelty nor the substance of this my invention.

What I claim, therefore, as my invention, and desire to secure by letters patent, is the producing of a new manufacture of "pin rolls," either oblong, oval, cylindrical, square, or other shape or form, (so that it combines in effect the common sheeted pin paper, or fillet, stuck or inserted pin paper, or pins wound in closely between the layers, laps, or folds of fillet paper, with the common pin cushion,) whether the centre of the cushion is elevated or plain—that is, whether coned up or level, or whether the pins are inserted through crimps or not, and embraced by the fillet paper—the fillet embracing the shank or barrels of the pins, while the heads of the pins are not so embraced, but open and conveniently accessible to be withdrawn for use without unfolding, unwinding, or disturbing the pin roll, substantially as herein described by the specification and drawings.

C. O. CROSBY.

No. 8203.—*Improved Portable Hydraulic Press.*

What I claim as my invention, and desire to secure by letters patent, is a hydraulic press, quite portable, in which the ram is hollow, and serves as the reservoir to supply the cylinder with water or other liquid, while the force pump and its appendages are contained within the ram, so that, by working this force pump, the ram is forced up until the liquid in such ram is exhausted, and by moving the handle of the pump down it will come in contact with a rod attached to a valve in the pump piston, and the latter comes in contact with a valve in the end of the ram, opening them both and allowing the water to return into the ram again through passages.

RICHARD DUDGEON.

No. 8204.—*Mechanical Hooker-up.*

What I claim as my invention, and desire to secure by letters patent, is in combination with a plate, or the equivalent thereof, for receiving the mass issuing from a rolling mill, the friction drums, the periphery of one of which is shaped substantially as described, and operating substantially as herein set forth, in such manner that by their action the plate, or its equivalent, is quickly raised and held stationary, at the proper height to permit the mass upon it to be passed to the front side of the mill, and is rapidly lowered to the proper position to receive the mass issuing from the rolls.

DAVID J. HAPPERSETT.

No. 8205.—*Improvement in Silk-covered Buttons.*

I do not mean to limit myself to the shape of the mould, nor to the pattern or color formed on the silk covering; neither do I claim to be the first who has used the split shank, plate, and washer, as that has been used with a glass bead for ornamental purposes; but I do not know of any one who has used this plate, shank, and washer as a means for fastening a silk-covered button, and at the same time secure and hide the ends of the silk cover in the hole of the mould, thereby making a durable, finished, and handsome ornamental button.

Therefore, what I claim is the application of the plate, shank, and washer, to a silk covered button, for the purposes specified, and as described and shown.

H. HEINEMANN.

No. 8206.—*Improvement in Machines for Grooving Lumber.*

Having thus fully described our improvements, what we claim to have invented, and desire to secure by letters patent, is the method, herein described, of forming grooves by circular saws and a deflecting throat, in combination with suitable cutters, as set forth.

BIRDSELL HOLLY,
JOHN W. WHEELER.

No. 8207.—*Improvement in Harvesting Machines.*

Having thus fully described the construction and operation of my grain harvester, what I claim therein, and desire to secure by letters patent, is the use of rotating cutters, in connexion with the rotating rake and teeth, (*d*,) operating substantially as described.

I also claim the novel manner of gearing the horses, or animal power, under the machine, so as to conduct the grain over them and discharge it in a straight line in the wake of the machine, substantially as herein described and made known.

WM. JONES.

No. 8208.—*Improvement in Cork Cutting Machines.*

I do not confine myself strictly to the precise form of construction herein described, but claim to vary the same as desirable, while I produce the like results by equivalent mechanical means.

What I claim as of my own invention, and desire to secure by letters patent, is the lifting block, (*h*,) susceptible of such adjustment, with reference to the edge of the knife, while the machine is in motion, that, from squares of varying sizes, perfectly formed corks may be cut, of the largest size each square will afford; the whole being constructed and operating substantially in the manner herein set forth.

WILLIAM KING.

No. 8209.—*Improvement in Seeding Machines.*

Having thus fully described the construction, use, and operation of our several improvements on the seeding machine, what we claim therein as new, and desire to secure by letters patent, is—

First. We claim the employment of the oblique, recessed washer, K, in combination with the cylindrical cap, I, provided with inclined wings or projections, I^2, which match with the oblique recesses, *k*, of the washer, K, in such a manner that the pressure produced thereupon shall securely hold the cylindrical cap in the required position when adjusted to increase or diminish the size of the seed receptacles.

Second. We claim scalloping the end of the cylindrical cap, L^2, of the distributing cylinder, and using, in connexion therewith, clamp-screws, (*o*, *o*,) for holding the cylindrical cap in the required position.

Third. We claim the employment of the pin, (m^2,) fig. 12, or its equivalent, when used in connexion with a clamp screw, o^4, and interior cylindrical cap, M^2, when properly adjusted, to increase or diminish the size of the seed receptacles.

Fourth. We likewise claim providing one of the journal pins, q^1, of each depositing tube, U, with a cog, q^2, which is made to fit an opening in the the arm, *j*, of the drag bar, j^2, when it shall be turned frontward nearly horizontal, for the purpose of detaching the depositing tube from the drag bar, j^2, with facility, as described and shown in fig. 18.

Fifth. We further claim the employment of the trifurcated holding lever, L, in combination with the drag bar, j^2, and suspended depositing tube, U, for the purpose of holding the depositing tube in its proper position during the operation of forming the drill and depositing the seed, and by which said trifurcated holding lever, L, may be disengaged from the pin, c^2, when an obstruction is visible, and allow the depositing tube to turn rearward when it shall have been struck, and thus save the pin (C^2) from being broken; and this trifurcated holding lever we claim, or its equivalent.

Sixth. We likewise claim causing the depositing tube to assume its proper position, after it shall have cleared the obstruction, by the action of the long arm (i^4) of the trifurcated holding lever, L, upon the cam or projection (*r*) of the depositing tube; and this we claim as in the arrangement herein described and represented.

Seventh. Lastly, we claim so combining a separate, double arm, P, with the frontward end of each drag bar, *j*, that it may be detached therefrom, as well as from the eyes or loops, R, of the front transverse beam of the frame, as described in the specification, and shown in the drawings at figures 16, 17, and 19.

SAMUEL PENNOCK,
MORTON PENNOCK.

No. 8210.—*Improvement in Revolving Breech Fire Arms.*

Having thus described my self-loading repeating fire arm, what I claim as my invention, and desire to secure by letters patent, is—

First. In combination with a cocking lever, I claim the two triggers, (M, M',) arranged and operating in such manner that the tripping of the hammer can be effected either in the ordinary manner, by pulling a trigger, or by the return movement of the cocking lever.

Second. I claim the combination of the sliding bolt (K) with the cap primer, (X.) the two being so arranged that as the hammer is tripped, by pulling the trigger, a cap is applied to one of the nipples of the chambered breech, by which means the chambers are revolved by the back motion of the cock, and capped by its forward motion, the capping by this arrangement being effected in one half the time in which it can be done by others, heretofore devised.

Third. I claim the construction of the cap and bullet passages, the powder magazine, and the exterior case, in such manner that the bullet and cap passages, and the included powder chamber, can be withdrawn from the exterior case which encloses them, to give free access to every part of said passages, and to facilitate the removal of obstructions therefrom, as described.

Fourth. In combination with a revolving disk breech, I claim a spring powder charger, constructed and operated by the movement of the breech, as herein set forth.

Fifth In combination with a revolving chambered breach, I claim the stationary cap stripper, constructed and operating as herein set forth.

Sixth. In combination with a revolving breech fire arm, I claim the spring dust plate, (Z,) which permits the escape of smoke, but prevents the entrance of dirt.

Seventh. I claim the forward inclination of the spout of the bullet passage, in connexion with a turning breech, the two being so arranged that when the latter is turning, the bullet, dropped into the chamber, is pressed against the inclined portion of the spout, and is by it forced down in the chamber of the breech, the inclined surface of the spout thus performing the office of a rammer.

PARRY W. PORTER.

No. 8211.—*Improved Apparatus for Punching Designs in Sheet Metal.*

What I claim as my invention, and desire to secure by letters patent, is the leather bed, or die, in combination with a set of punches, for puncturing purposes, when such set of punches, and the die, are used in connexion with proper rollers, substantially in the manner and for the purposes herein set forth.

WM. T. RUDD.

No. 8212.—*Improvement in Rakes to Harvesting Machines.*

What I claim as my invention, and desire to secure by letters patent, is the rake attached, for raking the grain from the machine without hand labor, constructed and operated substantially as described.

WM. H. SEYMOUR.

No. 8213.—*Improvement in Machines for Pressing Hats.*

What I claim as my invention, and desire to secure by letters patent, is the method of alternately lowering the pressing irons upon the hat block, and raising them therefrom by mechanism, operating substantially as herein described, which is readily controlled by the attendant.

JOHN STEARNS.

No. 8214.—*Improvement in Lifting Jacks.*

What I claim as my invention, and desire to secure by letters patent, is the catch or button, S, operated by the index bar, K, for the purpose of directing the action of the lever, I, J, substantially in the manner herein set forth.

JAMES ST. JOHN.

No. 8215.—*Improvement in Washing Machines.*

I do not claim the constructing or using of a revolving wash barrel, with or without a rolling or tumbling pounder therein; but what I do claim, and desire to secure by letters patent, is the peculiar form of the revolving barrel, with its fluted semi-cylindrical recesses, in combination with a pounding frame, constructed with a weighted hub and three parallel pounders, as herein described.

JOHN BOARDMAN.

No. 8216.—*Improvement in securing Pinions, &c., of Watches in Lathes.*

What I claim as my invention, and desire to secure by letters patent, is the employment of adhesive cement for securing staffs and pinions of watches or time pieces for lathe operation, in combination with a chuck, A, with a sliding tube, B, and a female centre, *a*, as described and set forth, or in any manner substantially the same.

JAMES M. BOTTUM.

No. 8217.—*Improvement in Machines for cutting wood into shreds, and crimping them for Mattress Stuffing, &c.*

I do not claim the combination of fluted cutters with smooth cutters for the purpose of making this article; nor do I claim or use the fluted cutters at all; nor do I cut the wood into round threads, but into flat strips, which are light and more elastic; nor do I claim the arrangement of fluted and smooth cutters in the plane stock; nor the apparatus for holding timber, and feeding it up to the plane, as it has heretofore been used and patented; but what I claim as my invention, and desire to secure by letters patent, is the use of the splitters with the plane iron, and the holder, *i*, and the movable weighted lid, *f*, or anything which is substantially the same, combined and arranged in the plane stock, E, for the purpose of producing the article herein described.

EDWIN K. BROWNING

No. 8218.—*Improvements in Machines for dressing Sisal Hemp, &c.*

What I claim as my invention, and desire to secure by letters patent, is the hinged jaw connected with the driving shaft, substantially as described, in combination with the cylinder to which it is hinged, and provided with a corresponding jaw, substantially as described, whereby the driving power, in carrying around the substances to be dressed, clamps and holds them firmly during the entire operation, as described.

And I also claim, in combination with the cylinder and clamp for presenting and carrying around the substances to be dressed, as described, the knives and combs attached to one or more hinged bars, and provided with the necessary means for operating them, substantially as described.

And I also claim, in combination with the cylinder, as described, the vat of water, in which, at each rotation of the cylinder, the substances to be dressed are immersed, substantially as described, and for the purpose specified.

S. A. CLEMENS.

No. 8219.—*Improvement in Churns.*

What I claim as my invention, and wish to secure by letters patent, is the application of the spring wire, fig. 5, which connects the crank with the dashers, in the manner and form and for the purpose above set forth.

SAMUEL G. DUGDALE.

No. 8220.—*Improvement in Axle Boxes for Journals for Railroad Cars.*

What I claim as my invention or improvement is to support the case, A, on the bearing, B, by projections, *c*, *c'*, or analogous contrivances applied to its sides, in combination with making the top plate, *a*, of the case and the cap or side plate, *b*, in one piece, separate from the rest of the case, and holding them in place by recesses and projections, or analogous contrivances, substantially as described; the whole being to enable me to entirely dispense with the use of the screws, or screws or nuts, in the construction of a railway car axle box, and thereby avoid not only the injurious consequences which frequently result from their becoming loose, but also the necessity of that care and attention on the part of the carman or attendant so necessary when boxes are used having any of their parts secured by screws.

OLIVER N. FRENCH.

No. 8221.—*Improvement in Carriage Springs.*

What I claim as my invention, and desire to secure by letters patent, is the employment of a semi-elliptical spring, F, G, in combination with a C-spring, H, formed by the extension of one of the arms, G, the combined springs thus produced being set transversely with the axle, and attached thereto, and the body of the vehicle, in the manner substantially as shown and described.

GUSTAVUS L. HAUSSKNECHT.

No. 8222.—*Improvement in Buggy Tops.*

What I claim as my invention, and desire to secure by letters patent, is the mode of connecting carriage tops with the seats by means of bearers, D, and clasp, F, so that they may with facility be removed from one carriage body and applied to another, in the manner substantially as described.

HARMON HIBBARD.

No. 8223.—*Improvement in Fire Proof Safes.*

Having thus described the nature of my invention, what I claim as new, and desire to secure by letters patent, is the combination of wrought and cast iron, the same forming a safe, in the manner and for the purpose substantially the same as described.

LEWIS LILLIE.

No. 8224.—*Improved means for adjusting the effective length of Bridge Counter Braces.*

What I claim as my invention, and desire to secure by letters patent, is the method of lengthening or shortening the counter braces of a girder or bridge truss, so as to produce and maintain any desired, vertical strain or deflection of the girder or truss by means of the counter brace, H, whether all of wood or provided with a metallic end or sheath, the plate of metal, *b*, bearing upon the metallic end or sheath, (or upon the end of the wood when the metallic end or sheath is not used,) at the top of the girder, and the nuts, and the bolts, *e*, *e*, passing through the clamping pieces, *c*, *c*, the upper cord and the posts, by which the plate of metal, *d*, is drawn down upon the metallic end or sheath, and the adjustment of the length of the counter brace is effected, substantially as herein described.

D. C. McCALLUM.

No. 8225.—*Improved Rake to Harvesting Machines.*

Having thus described the nature and construction of my harvesting apparatus, what I claim therein as new, and desire to secure by letters patent, is the guide, (*p*, *q*, *r*, *s*,) arranged, as described, in connexion with the tilting roller, (*u*,) for the guidance of the rake in a path similar to that which it would receive from the human hand, by which it removes periodically the grain or grass from the bed, and frees itself by the retraction of the teeth of the rake endwise.

SYLVANUS MILLER.

No. 8226.—*Improved arrangement of the Flues and Water Spaces of Steam Boilers.*

I do not mean or intend to limit myself to the precise form of construction herein set forth, as it is obvious that, if desirable, the flues (*c*) and (*d*) may be placed vertically, and the others may be horizontal.

What I claim as of my own invention, and which I desire to secure by letters patent of the United States, is the general arrangement of the tubes and flues of the boiler in the manner described—that is to say, the water tubes, connected with an upper and lower tube sheet, in combination with the flues of less length than the tubes, which flues are also connected with an upper and lower flue sheet, whereby two horizontal flues are formed in such connexion with each other, by means of the vertical flues, that the product of combustion from the fire-place shall pass into the upper horizontal flue, and thence down the vertical flues into the lower horizontal flue, having thus the facility of parting with its heat on the one hand by radiation though the flues to the water spaces surrounding them, and the other through the tubes to the water circulating through those—and this whether the said tubes and flues are placed vertically or horizontally; the whole being constructed and operating substantially as herein set forth.

W. E. MILLIGAN.

No. 8227.—*Improvement in Machines for splitting Leather.*

I do not claim as my invention, in connexion with the upper feed roller, the use of a lower one, such as is usually termed a spring or pressure roller, or one having a hard or practically inelastic surface.

But what I do claim as my improvement in machinery for splitting or dressing wet hides is the employment of an elastic surface roller, (or roller made of gum-elastic, or other like material, placed around an axle, or shaft,) and an inelastic roller, (as feed rollers,) in connexion with the cutting-knife, made either stationary, or, what is better, to have a vibratory or reciprocating motion, all substantially as hereinbefore specified.

WILLIAM PANTON.

No. 8228.—*Improvement in Molasses Gates, or Faucets.*

What I claim as my invention is the arrangement of the spring, which bears the gate against the seat, (said spring being arranged so as to bear against the outer edge, instead of the central part of the gate,) in connexion with making the said gate separate from the lever, and to work on a projection or screw therefrom, essentially as specified.

ERASTUS STEBBINS.

No. 8229.—*Improvement in Revolving Breech Fire Arms.*

What I claim as of my own invention, and desire to secure by letters patent of the United States, is the arrangement for securing the barrel to the stock, viz: the combination of the stud *(c)* with the notch in the back strap *(f)* and with the notch *(d)* and pin, *(i,)* as described, the whole being constructed and operating substantially as set forth herein.

JAMES WARNER.

No 8230.—*Improvement in Machines for sawing and dressing Staves.*

I do not claim the use of a cylindrical saw, H, as such has frequently been used; but what I do claim as my invention, and desire to secure by letters patent, is the employment of the saw, H, seated loose upon a pulley, G, so as to form an eccentric position with the same, as specified,

in combination with the cutters, L, L, the several parts constructed and operating together, for the purposes set forth, substantially as shown and described.

DENNISON WOODCOCK.

No. 8231.—*Improvements in Brick Machines.*

Having thus fully described the nature and construction of my improvements in brick machines, what I claim therein as new, and desire to secure by letters patent, is the block, or lip, *(d,)* substantially as described, hugging closely the mould wheel immediately behind its point of contact with the pressure roller, in order to prevent any disturbance of the mass after having passed the point of contact.

JOHN J. RIDDLE.

No. 8232.—*Improvement in Combined Fountain and Evaporator.*

Having thus described my invention and improvement of a self-supplying evaporating fountain, what I claim therein as new, and desire to secure by letters patent, is constructing a vase, or other like article, with two apartments, or chambers, B, C, having a continuous as well as a periodical communication with each other, by which it is rendered a self-supplying evaporating fountain, the continuous communication of the lower chamber, C, with the upper apartment, B, or evaporator, being effected by the pressure of steam upon the surface of the water in the lower chamber, and the periodical communication, by means of the valve, H, secured in the screw nut, F, which will be opened by the pressure of the accumulated water in the upper apartment when relieved of the pressure of the steam in the lower chamber, as fully described and represented.

GEO. H. THATCHER.

No. 8233.—*Improvements in mode of changing Reciprocating into Rotary Motion.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The employment of curved or inclined forks, D′, D², and E, E², having a reciprocating rectilinear movement, operating on or operated by cams, *a*, *b*, *c*, in the manner and for the purposes herein set forth.

Second. The use of cams, *a*, *b*, *c*, constructed or attached so that they may be turned or set in order to produce a change in direction of the motion, and acting in connexion with forks, D′, D², and E, E², (or their equivalents,) substantially for the purposes expressed, as shown and described.

JOEL V. STRAIT.

No. 8234.—*Improvements in Hanging Carriage Bodies.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of raising the body on to the springs, or lowering it on to the reaches, as may be desired, and for the purposes herein fully set forth.

JOHN JONES.

No. 8235.—*Improvement in Buffing Apparatus for Daguerreotype Plates.*

We do not claim heating the buffer, as that has been done by lamps operating on the plate on which the buffing material is stretched; but in that form the heat is uneven, and the vapor from the spirit lamp is liable to come in contact with the buffing material. But what we claim as new, and of our own invention, and desire to secure by letters patent of the United States, is the enclosing drum, constructed with the sliding segment or cover, (*g*,) flanch, 12, and lip, 11, sliding in the grooved plate, 10, and retained by the spring, 13, for the purpose specified, in combination with the drum, *m*, and pipe, *n*, to pass the heat from a spirit lamp, or other heater, to the drum, *m*, for the purpose of heating the buffer, the drum, *m*, being fitted with a pipe, or other means, to pass any vapor from the spirit lamp, outside the case enclosing the buffer, substantially as described and shown.

WM. LEWIS,
W. H. LEWIS.

No. 8236.—*Improvements in Hanging Carriage Bodies.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is—

First. The combination, herein described, of the turning compensating plate, M, with the rock shaft, B, C, and the connecting rods, N, for the purpose of equalizing the action on the helical spring, I.

Second. I claim the stop lever, P, in combination with the turning plate, M, used in fastening down the body, substantially in the manner herein described.

Third. I claim the stays, O, O, for the purpose of keeping the axle trees in their true set or upright position, as herein described and fully set forth.

JOHN JONES.

No. 8237.—*Improvement in Faucets.*

What I claim, therefore, as my invention, and desire to secure by letters patent, is the application of a hollow conical packing around the waist of the valve stem, in combination with an open space between its lower end and the stem, the interior of the tubular projection being smooth, or of such form as to allow a tight joint between it and the conical packing, substantially as above described.

CHARLES W. STEARNS.

No. 8238.—*Improvement in Saddle Trees for Harness.*

I do not claim as my invention the yoke, the terrett, or the pad iron, separate from each other; but what I do claim as my invention, and wish to secure by letters patent, is the combination and arrangement of the yoke, the terrett, and the pad iron, in such manner that the pad iron may be adjusted at any angle required for use, and immediately secured firmly in its place by a screw on the terrett iron, passing through the yoke into the pad iron, substantially as shown in the drawings and herein set forth.

JAMES A. LAWRENCE.

No. 8239.—*Improvement in Pumps for Raising Water, &c.*

What I claim as my invention or improvement, is as follows: I claim the rod, H, and its arms, or other equivalent contrivances, and its valve collar, as applied to or combined with the rod, F, of the lower box, and the valve or valves made to operate therewith, substantially as above set forth.

JOSEPH F. FLANDERS.

No. 8240.—*Improvement in Cloth Folding Machines.*

What we claim as our invention, and desire to secure by letters patent, first, is the measuring and folding of cloth, paper, and other articles, by means of two revolving cylinders, each of which is provided with a tongue and jaws, the tongue to feed the cloth into the jaws, which seize it and form the fold, and deliver it upon the table, leaving it properly measured and folded.

D. R. AMBROSE,
O. L. REYNOLDS.

No. 8241.—*Improvement in Flour Bolts.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the combination and arrangement of the inclined boards, I, with a case of graduated screens, constructed and arranged substantially as herein described and represented, and for the purpose specially set forth.

SAMUEL COOK.

No. 8242.—*Improvement in Parlor Cooking Stoves.*

Having thus described my improvements in parlor cooking stoves, I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is the arrangement of flues, as herein above described, about the oven of a parlor cooking stove, by which the heat, smoke, &c., are first made to pass over the top of the oven, and then down the passage formed between the front side plate and the side of the oven, across the bottom of the oven up through the passage formed, between the rear side plate and the other side of the oven, and finally out through the smoke-pipe, the heat, &c , being made to pass to the part of the oven most remote from the fire chamber by the partitions, *w*, *w*, *x*, *x*, on the top and bottom of said oven, substantially as herein above described.

N. A. BOYNTON.

No. 8243.—*Improvements in Mills for Grinding Corn and Cobs.*

What we claim as our invention, and desire to secure by letters patent, is the chopping and feeding apparatus, constructed and operating as herein described, in connexion with a grinding apparatus.

We also claim the recess (p) in the concave, which prevents the escape of fragments when struck by the teeth of the cylinder.

SIDNEY A. BANTZ.
WILLIAM ANDREW.

No. 8244.—*Improvements in Carriage Springs.*

Having thus fully described my improved spring reaches for carriages, what I claim therein as new, and for which I desire to secure letters patent, is the combination of the rockers and spring bars of a carriage, substantially as herein set forth, and for the purposes described.

M. G. HUBBARD.

No. 8245.—*Improvements in Stave Dressing Machines.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the arrangement for starting each stave, or introducing it to the feed at the proper moment, consisting of the wheel, k', with its stud, k'', the bent lever, l, the pitman, l', lever, l'', shaft, l''', lever, l'''' sliding rod, m, spring, m'', and adjustable starting bar; in combination with the apparatus for giving the reciprocating motion to the jointing cutters, so that the greatest width of the stave may be given on different lengths of staves, uniformly at the middle, or such other point as may be desired; the whole being combined, arranged, and operated in the manner substantially as herein specified.

WM. HAWKINS.

No. 8246.—*Improved Machine for dressing Boot Forms.*

What I claim as my invention is the circular motion of the cutters attached to one end of a lever, the other end being so confined on the opposite side of the boot form as to allow the cutters to play up and down, and dress one or both sides of a boot form at a time, as herein set forth.

JOSEPH BURGESS.

No. 8247.—*Improvement in Feather-edging Gauges for Shoemakers.*

What I claim as my invention is the arrangement of the adjustable gauge rest, the pressure roller, and knife, or cutter, in the case, or handle, substantially as described, and so as to constitute a tool for feather-edging or reducing soles of shoes, as specified.

JACOB JENKINS.

No. 8248.—*Improvement in Bran Dusters.*

I do not claim exclusively the employment of intermediate vanes acting in connexion with the brushes on the reel for forming a blast, as such has already been used; but what I do claim as my invention, and desire to secure by letters patent, is the employment of adjustable vanes, which may be set in or out, and obliquely, in direction of their length, or be set either way only, as described and represented by the vanes, lettered f, g, in the drawing, such adjustable vanes acting in combination with the brushes on the reel, for the purposes and in the manner substantially as set forth.

S. W. KIRK.

No. 8249.—*Improvement in dyeing Door Mats.*

What I claim as my invention, and desire to secure by letters patent, is the coloring of borders and figures in a variety of colors and forms upon the wool of lamb-skins and skeep-skins for mats, and other similar purposes, by the use of pans, (which are to contain the dyes, being made and shapened in the form of the borders or figures designed to be colored,) in combination with the matching tin or form, fig. 2, or an equivalent device, for parting the wool, substantially in the manner and for the purpose herein set forth.

REUBEN SHALER.

No. 8250.—*Improved method of liberating Metal Tubes from forming Mandrel.*

Having now described the nature of my invention, and in what manner the same is to be performed, I wish it to be understood that I do not claim the exclusive use of the rolls for cross rolling, hereinbefore described and represented, except when the same are employed in the manufacture of pipes or tubes of copper, brass, or other alloys of metal, as herein described, to be used as the flues of steam boilers.

But what I do claim in the manufacture of pipes, or tubes, of brass, copper, and alloys of metal, for the use of the flues of steam boilers, by rolling hot on a mandrel, whether parallel or taper, is the enlarging of them by means of cross rolling, as above described, for the purpose of extracting the mandrel.

JOB CUTLER.

No. 8251.—*Improvement in Oil Cups for Journal Boxes.*

I do not confine myself to any form of valve or spring, but what I claim as my invention, and desire to secure by letters patent, is the employment, within the mouth of an oil cup, of a valve, B, operated upon by a spring, C, or its equivalent, in the manner and for the purpose substantially as herein described.

AARON RICHARDSON

No. 8252.—*Improvement in Fly Traps.*

What we claim as our inventions, and desire to secure by letters patent, are the tube, C, in combination with the glass, B, and the bottom, A, and rod, F, for the purpose above described, meaning to vary the construction while keeping the fixture substantially the same.

We also claim the ring, H, which is to close the apertures in the bottom, at E, for the purpose which it is applied, or anything similar in ts application.

HARVEY SNOW,
LUTHER T. SMART.

No. 8253.—*Improved Cut-off Gear.*

The arrangement of the lifting rods, and the method of operating them by the disk plate, as represented in the accompanying drawings, is peculiarly suited to this method of effecting the disengagement of the valves from the mechanism by which they are opened, for the disk plate imparts a transverse motion to the connecting rods, which causes them to rock upon the stops, and thus slide off their respective toes on the rock-shaft arms. But while I prefer this arrangement of eccentric gear, I wish it to be understood that I do not restrict myself to its employment, as my improvement may be applied to many other systems of mechanism by which valves are opened. As such systems may not possess the peculiar rocking motion I have mentioned, it will be necessary, in some cases, to disengage the lifting rods by a positive movement, which may, at the proper moment, be imparted to the lifting rods by some moving member of the engine, through the combination of any convenient and suitable mechanical device.

In combination with the reciprocating motions communicated to the lifting rods by the eccentric gear, I claim imparting a lateral movement to the free extremities of said lifting rods, to disconnect them from the valves and permit the latter to close, to cut off the steam or other expansive fluid by which the engine may be driven; whereby these rods are made to perform their usual duty of opening the valves, and, in addition, that of catches or latches in alternately connecting the valves with, and disconnecting them from, the mechanism by which they are opened, thus greatly simplifying the construction of the valve gear, rendering the same more durable and less liable to get out of order.

GEORGE H. CORLISS.

No. 8254.—*Improvements in Flexible Fences.*

Having thus fully set forth and described the nature of my invention, and its practical operation, I do not claim any particular form or construction of a post in connexion herewith, the same not being essential, nor whether the same be of wood or any other substance, (I having heretofore invented a metal post, being a convenient device to use in connexion herewith.)

But what I do claim as my invention, and desire to secure by letters patent, is the form and construction of the two concave plates, with pins near their open ends, forming one coupling-cap, or clasp, for the purpose of uniting together the upper bars of fence, or railing, whether the same be of wood or metal, and also of securing the same by the use of a pin, with a screw thereon, or other device, on the top of a post, in the manner and for the purpose as herein described.

And, in connexion therewith, I claim perforating the bars, or rails, with conical, tapering holes, mortises, or orifices, for the insertion of pickets, or banisters, in the manner and all for the purpose as is herein substantially set forth and described.

MATTHIAS P. COONS.

No. 8255.—*Improvement in Cast-iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is—

First. A cast-iron car wheel, made with a hollow, chilled rim and hollow spokes, in the manner and form herein set forth.

Second. The method of forming wheels for railroad cars, by casting the rim and spokes upon a grooved hub, which has been formed separately, as herein described.

THOMAS J. EDDY.

No. 8256.—*Spring expanding Swage for Boiler Tubes, &c.*

What I claim as my invention, and desire to secure by letters patent, is an expanding swage, constructed as herein set forth, and consisting essentially of radiating sections, which are connected with each other, and to a common centre, by spring shanks, as herein described.

JAMES McCARTY.

No. 8257.—*Improved Powder-proof Bank Lock.*

Having thus described my improvements in locks, I shall state my claim as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is moving the key bit to the tumblers, by means of a follower sliding between the walls, as herein described, which follower acts in such a manner as to close the space into which powder might be introduced, where this is combined with a keyhole cover, sliding as described, by which combination I make a powder-proof lock, with tumblers, which cannot be reached by a pick, and whose slide cannot be blown off so as to secure access to the tumblers.

I also claim the combination with the plate, a', a', of the transverse, sliding, vertical slotted plate, c', c', which, jointly, cut off all communication with the tumblers in every position of the bolt.

WM. HALL.

No. 8258.—(Suspended.)

No. 8259.—*Improvement in Window Sashes.*

Having thus fully described my improved method of setting glass, what I claim therein as new, and for which I desire to secure letters patent, is fastening the bars of two parts, as herein described, by binding them together by a screw at the junction of their ends, their opposite ends being hooked into the frame of the sash, substantially in the manner and for the purpose set forth; and, in combination with this device, I claim the elastic bed for the glass to rest against, as above specified.

SEWELL SHORT.

No. 8260.—(Suspended.)

No. 8261.—*Improvement in Machines for grinding Flock.*

I do not limit myself to grinding or cutting flock, but any article to which the machine can be advantageously applied.

I claim a cylinder or drum, with knives or beaters attached, extending its length; said knives being set at an oblique angle, both with the radical lines and the axis of the drum, in combination with an outer cylinder, within which the drum revolves; the outer cylinder also revolving in an opposite direction, and having on its inner surface, at intervals, knives extending its length; the said knives being parallel with its axis, but oblique to its radius; said outer cylinder also having, in the intervals between its knives, panels, containing projecting ribs oblique to its axis, and so arranged that the action of the revolving knives, upon any material lying between the ribs, shall gradually carry it from the inner to the outer end of said cylinder; thus subjecting the material to repeated cuttings between the revolving knives, substantially as set forth in the above specification.

I claim the method of constructing the outer cylinder of alternate panels—the *one* set being permanent, and having on its inner surface oblique ribs; the *other* set being movable and adjustable (these panels are called cross-bars in above description,) by screws and springs, and having on its inner surface oblique knives; the fixed panels being connected with an outer and concentric ring of metal by chambers or passages, the same being in combination with another cylinder or ring of metal, within which it fits and revolves; which last ring has a hopper upon it to receive the material to be operated on, opening into the said chambers or passages, and by them into the cylinder containing the knives, substantially as set forth in the above specification.

I claim the combination of outer and inner rings, with the inner and outer revolving cylinders, and their knives and ribs, making a machine for grinding flock or any other material, substantially as set forth and described in the above specification.

JOHN C. FONDA.

No. 8262.—*Improvements in Knitting Machines.*

Having thus described my improvements, what I claim as new therein, and desire to secure by letters patent, is:

First. The sliding, independent yarn carriers, each governing an independent thread for each needle, substantially in the manner and for the purpose as described.

Second. I claim operating the yarn carriers simultaneously by means of the conical ring, (U',) working in the inclined slit in the carriers, substantially as set forth.

JOHN HENRY BARSANTEE.

No. 8263.—*Improvements in Stoves with Portable Ovens.*

Having thus described my improvements in the portable oven for cooking stoves, what I claim therein as new, and desire to secure by letters patent,

is in combination with a portable oven. I claim the permanent damper plate or shut off, M, which forces the heat and smoke, after striking against the bottom of the oven, to pass up the front flue and over the oven, and then down the back, passing down behind the permanent damper plate or shut-off, M, and out through the ordinary draught or top flue, B, of the stove, being so simple in its construction that it may be made by an ordinary tinman to suit any ordinary stove, as described and represented.

GEO. H. THATCHER.

No. 8264.—*Improvement in Seeding Apparatus of a Seed Planter.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the measuring seed roller with the distributing seed roller, the two being arranged and operated in the manner and for the purpose herein described.

DAVID HORNER.

No. 8265.—*Improvement in Machines for preparing Hubs for the reception of Boxes.*

What I claim as my invention, and desire to secure by letters patent, is the sliding shaft, with the slot, marked 4, passing longitudinally into the mandrel, together with the screw thread cut upon the mandrel to feed the knives, and the knives, which are so adjusted as to act at both ends at the same time, and also cross-stays, similar in construction (which may be formed of wood) to those marked 1 and 2, in the above description, which are intended for the purpose of fastening and truing the hub; all of which will appear by the above description, except the cross-stays, for the purpose of securing and truing the hub during the process of boring.

HENRY MOORE.

No. 8266.—*Improved Fittings for Boats, to facilitate the discharge of Cargo, &c.*

I am aware that vessels have heretofore been constructed with permanent cargo decks, placed at a distance from the bottom of the vessel, and provided with hatchways, through which cargo in bulk could be dropped into cars, arranged to run upon railways secured to the bottom of the vessel; but such decks are expensive in the first instance, are not so well adapted to the unlading of cargo in bulk, and are not susceptible of removal and replacement to fit the vessel, alternately, for carrying cargo in packages and cargo in bulk. These or other objections have proved to be so serious that this mode of fitting up vessels has not been adopted to any extent, and I make no claim to it, my invention being limited to a deck of narrow sections, and wholly removable; therefore,

What I claim as my invention, and desire to secure by letters patent, is the cargo-deck, formed of loose, narrow sections, so that it may be removed to adapt the vessel to carrying cargo in packages, or may be put in place to facilitate the unlading of cargo in bulk, in combination with the railway on the floor, for transporting the lading to the point whence it is removed from the hold.

WM. H. BRYAN.

No. 8267.—*Improvement in Machines for preparing Hubs for Boxes.*

Now, what I claim as new, is the combination of the movable cutters with the saws and small pins, arranged and operating substantially in the manner and for the purpose herein described.

I do not claim the cutters singly, or the arbor or disk, or the saw, such things having been used separately before.

WM. R. JONES.

No. 8268.—*Improvement in Tight Joint for Tuyers.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the combination of the inner and outer beads on the top plate, between which is placed clay or other plastic material, and the grooves in the edges of the sides of the tuyer, for the purpose of making an air-tight joint; the whole being secured by bolts, with a projection upon them, catching over a cam cast on flanges, on the under plate, as herein described and represented.

WM. GRAHAM.

No. 8269.—*Improvement in Brick Machines.*

Having thus described my improvements, what I claim as new therein, and desire to secure by letters patent, is, *first*, the arrangement of the apparatus for moving the moulds and the pressing apparatus, all constructed substantially as herein described, and worked by the revolving shaft, in the manner and for the purposes set forth.

LUTHER BROWN.

No. 8270.—*Improvement in Grain Winnowers and Separators.*

I claim the elevator, constructed substantially as herein set forth, with oblique plates or blocks, to support the straw and facilitate the separation of the grain.

I also claim the arched grating, in connexion with a blast, to effect the separation of the lighter impurities from the grain.

I likewise claim the arrangement, substantially as herein described, of the air-chamber between the fans, the suction-pipe, to supply the chamber with air, and the spout, to conduct the once winnowed grain from the screen into the lower extremity of the suction-pipe, to be winnowed a second time by the entering current of air; whereby the grain is subjected to the full force of two independent blasts, acting consecutively, which insures its effectual winnowing, as herein set forth.

A. B. CHILDS.

No. 8271.—*Improvement in Brick Machines.*

First. What we claim as our invention, and desire to secure by letters patent, is the arrangement of mechanism, substantially as herein described, viz: the toothed wheel, M, and the cams, *h*, and *i*, operated by the changing gear, or the equivalent thereof, connected with the mill, so as to be moved alternately back and forth, for the purpose of operating

the mould carriage and the pressing piston, P, substantially in the manner herein set forth.

Second. We also claim the adjustable rod, S, or its equivalent, connected with the piston-rod, R, for the purpose of acting upon the catch lever, K², or its equivalent, so as to disengage the weigh, C, or its equivalent, by which the operating machinery is thrown out of gear, for the purpose of arresting the pressing motion as soon as the piston has been depressed far enough to fill the moulds.

Third. Is the circular projection, V, or its equivalent, upon the wheel, L, to throw the wheel, L, out of gear, and stop the moulding apparatus while the grinding proceeds.

JAMES DANE,
DARIUS HEALY,
GARY CUMINGS.

No. 8272.—*Improvements in dressing Mill-Stones.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of my invention—being an improvement in dressing mill-stones—what I claim therein as new, and desire to secure by letters patent, is the dress given to mill stones, according to the definite and fixed rule described in the foregoing specification, and illustrated in the drawing by the furrows (*a*) (*b*) (*c*) of each quarter.

I also claim diminishing the draught of the runner and increasing the number of the quarters, in comparison with that given the bedstone, for the purpose of giving the furrows of each stone, as determined by the rule laid down in the specifications, a shears-motion upon each other.

MORE HOLDIN.

No. 8273.—*Improved Water-Level Indicator for Steam Boilers.*

What I claim as my invention, and desire to secure by letters patent, is the connecting the ordinary float, placed within a steam boiler, with an index placed on the outside of the same, through the medium of the valve of a gauge-cock, by which I am enabled to remove any impurities which may at any time hinder the effective action of the float, substantially as herein set forth.

ALBERT H. JUDD.

No. 8274.—*Improvement in Shutters for Shop Fronts.*

Having thus fully described my improved shutter, what I claim therein, is, in combination with the sliding shutter, substantially as above described, the door by which it is fastened, and which permits it to slide back.

JAMES ROOT.

No. 8275.—*Improvements in Metallic Alloy Paints.*

Having thus described my invention, what I claim as new, and desire to secure by letters patent, is making paints out of metallic antimony, whether prepared separately or combined with other metals, to form alloys suitable for making paints, substantially as herein set forth.

I also claim combining antimonial alloys with oxide of copper, to constitute, with the painting vehicles herein specified, the exterior coatings for ships' bottoms, for the purpose of more effectually defending them against the adhesion of shells and weeds, substantially as herein set forth.

CHARLES WETTERSTEDT.

No. 8276.—*Improvement in Hot Air Furnaces.*

What I claim as my invention, and desire to secure by letters patent, is the employment of a flue or chamber, J, having a valve, *b*, and apertures, *a*, *a*, *a*, in combination with an internal flue, K, constructed and operating substantially as shown and described, for the purposes set forth.

JOSEPH C. TREAT.

No. 8277.—*Improvement in quadrant-hinged Grates.*

Having thus described my improvement in the quadrant-turning grate, I wish it to be understood that I do not claim a grate turning upon pivots, projecting from its upper front corners in such a manner that, when it is desired to discharge its contents, the lower rear portion will be made to recede from the back wall, while the front portion of the grate will project frontward beyond the breast of the chimney, and the contents discharged therefrom upon the hearth; but what I do claim as new, and of my own invention, and desire to secure by letters patent, is suspending the quadrant grate by pivots, B, projecting from the ends thereof, near the centre of the circle of the grate, in such a manner that, when it shall be desired to discharge the contents from the grate, its rear and lower portion will be made to recede from the back wall, C, and rise in the throat of the chimney; and thus the contents will be discharged into the rear portion of the fire-place, and the dust carried directly up the chimney; and the grate moving outward having to drag through the accumulated coal ashes, &c., in the fire-place, as described.

I also claim the combination of the guard plate, G, with the quadrant grate; said guard plate projecting from the back of the fire-place horizontally above the lower rear edge of the grate, and vertically within the ends of the same, for the double purpose of forming a support for the fire brick, or back of the grate, and protecting the inner edges of the bottom and ends of the grate, and preventing it from being opened by the lumps of coal that would otherwise fall between its edges and back wall, and force the grate open as described.

GEORGE H. THATCHER.

No. 8278.—*Improvement in Shuttle Motion of Looms.*

What I claim as my invention, and desire to secure by letters patent, is operating the picker-staff, or staves, H, by a cam or cams, M, upon a shaft, K, hung in bearings, L, attached to the lay, and carrying a ratchet

wheel, N, which receives motion at suitable intervals through an arm, Q, worked by the same motion which operates the lay, substantially in the manner herein described.

GEORGE J. WARDWELL.

No. 8279.—*Improvement in Machines for taking Ayes and Noes.*

Having thus fully described my improvements, what I claim as new therein, and which I desire to secure by letters patent, is the peculiar form and action of the springs, which carry the pencil by which a draw mark is made, without risk of breaking the point.

G. WM. YERBY.

No. 8280.—*Improvement in working clay for Pottery and other Ware.*

It will be seen that my process of heating clay while working is equally applicable to making bricks, pottery, clay retorts, and every article of clay goods; and, consequently, no machinery or heating apparatus can be described or shown, as it must be varied according to the particular manufacture; and I do not mean to limit myself in this particular, but to use such means as may be best adapted to heating and working the clay for the particular purpose; nor do I mean to limit myself to the precise temperature of the clay, as that must be regulated by the kind of clay, and the condition of the atmosphere, but to work the same at or about the boiling point of water; neither do I mean to limit myself to any peculiar clay, compounds of clay, or mixtures of clay and other substances.

Therefore, what I claim as my invention, and desire to secure by letters patent of the United States, is the application of heat to clay during the process of mixing, working, or tempering the clay; so that it is raised to a heat at or about the boiling point of water at the time of moulding or forming the same, substantially as described and shown.

JOHN AKRILL.

No. 8281.—*Improvement in Looms for weaving Pile Fabrics.*

Having thus set forth the principle of my invention, and the manner of constructing and using the same, I wish it to be understood that I do not limit myself to the special construction and arrangement of parts herein specified, as these may be varied without changing the principle or mode of operation.

What I claim as my invention, and desire to secure by letters patent, is the employment, on one or both sides of the loom, of two carriers, to which the figuring wires are secured, and two guides, substantially as described, and operated alternately; the said carriers having a motion towards and from the selvage of the cloth, to draw out and insert the wires, and, together with the guides, a motion towards and from the lay, to carry the wires from the woven pile to the open shed, and back, as described.

And I also claim, in combination, giving to the guides a vertical movement, after the wire has been drawn out, to admit of their passing each other, substantially as specified.

JOHN JOHNSON.

No. 8282.—*Improvements in Sewing Machines.*

Having thus fully described our invention, what we claim therein as new, and desire to secure by letters patent, is—

First. The combination and arrangement of the pitman, driving-bar, shuttle, and adjustable set screw, for the purpose of allowing the pitman a continuous motion, whilst the shuttle-bar and shuttle is momentarily stopped, to allow the needle to draw up the stitch, as herein described and represented.

Second. We claim bringing up the needle with a sudden jerk, after the stitch is formed, for the purpose of tightening up the stitch, after the manner of hand-sewing, and adjusting the same to any thickness of material to be sewn.

WILLIAM H. AKINS,
J. D. FELTHOUSEN.

No. 8283.—*Improvements in Looms for weaving Cut Pile Fabrics.*

Having thus described my invention, I do not mean to limit myself to this particular method and construction described, but to the characteristics or principles of the operation—for instance, in proper construction of a loom, there would be necessary a pair of fingers, or shields, on each side of the cloth, and it might be found advisable to make a movement of the fingers, or shields, only when a shuttle was thrown from the respective side. This could be done by connecting the movement of the shield to the cam-shaft.

What I claim as my invention, and desire to secure by letters patent, is—

First. The use in looms of a finger or shield, which shall be introduced between the warps, for the purpose of bringing the warp threads at the edge of the cloth in such a position that the filling yarn will be drawn in to form a smooth selvage, substantially as described.

Second. The use of hooks formed on the intersecting plates, or their equivalents, which shall hold the filling thread from returning towards the reel, substantially as described.

M. C. BRYANT.

No. 8284.—*Improvement in Brick Machines.*

What I claim as my invention, and desire to secure by letters patent, is the placing the auxiliary pressure roller, *p*, or its equivalent, between the main roller, B, and the knife, *n*, for the purpose of subjecting the surplus clay, after it is elevated above the tops of the moulds, to the action of pressure before moving the same by the said knife, substantially as herein set forth.

I also claim the subjecting the upper surface of the clay in each mould to a rubbing pressure by means of a plate, *m*, or its equivalent, placed above the tops of the moulds, in combination with some mechanical device for forcing up the movable bottoms of the said moulds whilst passing under the said plate, substantially in the manner and for the purpose herein set forth.

ISAAC GREGG.

No. 8285.—*Improvement in Printing Presses.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Giving to the platen a rotating reciprocating motion, which enables it to assume the two positions of receiving the sheet and the impression alternately, when operated by the cam, sectional arm, and its own segment, geared with the segment of the sectional arm, by giving to it the movement described of an arc of the circle when traversing from one of these positions to the other.

Second. I claim affixing the vibrating bed on its own axis, so that it may recede into the proper position for receiving the inking rollers for inking the form, and become perpendicular and directly face to face with the platen, when the toggle is straight, for the purpose of giving the impression.

Third. I claim the arrangement of two side arms so combined as to form a frame to hold and carry the inking rollers, and giving to them the motion, both forward and backward, over the form for each impression during the rest of the other parts, whether the same be done in this precise manner, or equivalents, to produce a like result.

Fourth. I claim the grooved cam shaped arms or guides, or their equivalent, for the purpose of carrying the frisket in the right direction, and holding it in the desired positions during the intervals of rest given to the platen—that is, opening it to relieve the printed sheet, and holding it open to lay the succeeding sheet, and closing it firmly against the platen to grip the sheet, and holding it closed until the bed has moved forward, given the impression, and receded to its original position.

Fifth. I claim the combination of the bed vibrating on its own axis with the roller frame, composed of two arms, substantially as herein described and set forth.

GEO. P. GORDON.

No. 8286.—*Improved Spring Bolt.*

What I claim as my improvement is the combination of the lever with the spring bolt, and its case, so as to operate therewith, substantially in the manner as specified.

OLIVER H. BUSH.

No. 8287.—*Improvement in Machines for cleansing Wool.*

I do not claim either of the parts of the apparatus, as such, as my invention; but what I claim as my invention, and desire to secure by letters patent, is the combination of the tub, C, with the shaft, E, and tube, F, when these are combined with the vat, A, (with its trough, *a*, and *a'*,) and the whole is constructed, arranged, combined, and operated substantially as herein described, for the purpose of cleansing or for coloring wool and other analogous substances, as herein described.

L. W. BOYNTON.

No. 8288.—*Improvements in Machines for Jointing Staves.*

What I claim as my invention, and desire to secure by letters patent, is combining with the adjacent ends of any two plates of the chain the hinged pieces provided with self-acting toes, for clamping the stave while it is being jointed, and then releasing it, substantially in the manner and for the purpose described.

LEWIS S. CHICHESTER.

No. 8289.—*Improvements in Spike Machines.*

Having thus fully described my invention, I do not claim the header, N, or the holding die, Q, irrespective of their arrangement and operation; but what I do claim as new, and desire to secure by letters patent, is the arrangement of the carrier, H, within the hollow table, B, substantially in the manner described, and also the combination of a carrier, so arranged with a single griping die, Q, arranged with respect to it in the manner substantially as shown; the die and the carrier assisting each other in holding the spike while being headed.

MARK M. ISON.

No. 8290.—*Improved Water Gauge for Steam Boilers.*

I claim the combination of the glass tube and reservoir of fluid below it, heavier than that contained in its upper part, with the legs of a syphon, so that they become a part of that syphon, substantially as described, by which means I am enabled to protect the glass tube from the heat of the steam and impurities of the water, and also to show at any point above the boiler the height of the water in the boiler.

I also claim the combination with the gauge of the sediment depositor, constructed and arranged substantially as described, for the purpose of preventing the impurities of the water from entering the tube leading to the gauge.

A. S. LYMAN.

No. 8291.—*Improvement in machines for numbering the pages of Account Books.*

Having thus described my new machine, I shall state my claims, as follow:

What I claim as my invention, and desire to have secured to me by letters patent, is—

First. The use of type chains in a machine for printing the pages of account books; and,

Second. A machine for paging account books, having the essential elements hereinabove described, viz: the imprinting cylinders and rollers, against which they bear, together with the type chains, arranged together substantially in the manner hereinabove described.

JOHN McADAMS.

No. 8292.—*Improvement in the manufacture of Pigments.*

I am aware that a mixed chloride and oxide of lead has been long known, under the name of "Turner's Yellow," which is made by mixing oxides of lead and common salt.

I therefore do not claim this composition of matter; but what I do claim as my invention is the new manufacture of either a white or colored pigment, by the addition of one half of an equivalent of lime, or other earthy or alkaline base, with one equivalent of chloride of lead, or chloride of lead diffused in water, or however the solution may be obtained; the whole being substantially as hereinbefore specified.

H. L. PATTINSON.

No. 8293.—*Improvement in method of forming Teeth upon Cast Iron Grinders.*

I do not claim the casting of ribs or floats; but what I do claim as my invention, and desire to secure by letters patent, is the mode, herein substantially described, of making or forming teeth or grinders upon surfaces of cast iron, by nicking, craking, or chipping out parts of ribs or floats cast thereon, so as to leave the teeth or grinders projecting, as above set forth.

EZRA RIPLEY.

No. 8294.—*Improvement in Sewing Machines.*

What I claim as my invention, and desire to secure by letters patent, is giving to the shuttle an additional forward motion after it has been stopped, to close the loop, as described, for the purpose of drawing the stitch tight, when such additional motion is given at and in combination with the feed motion of the cloth in the reverse direction, and the final upward motion of the needle, as described, so that the two threads shall be drawn tight at the same time, as described.

I also claim controlling the thread during the downward motion of the needle by the combination of a friction pad, to prevent the slack above the cloth, with the eye on the needle carrier, for drawing back the thread, for the purposes and in the manner substantially as described.

I also claim placing the bobbin from which the needle is supplied with thread on an adjustable arm attached to the frame, substantially as described, when this is combined with the carrying of the said thread through an eye or guide attached to, and moving with, the needle carrier, as described, whereby any desired length of thread can be given for the formation of the loop without varying the range of motion of the needle, as described.

ISAAC M. SINGER.

No. 8295.—*Improvement in construction of Roofs.*

What I claim as my invention is the above-described peculiar arrangement of the arched trusses or framing of my improved roof, in combination with the suspending of both inclined sides of the roof from the ridge timber, so that each inclined side shall be made to counterbalance the other inclined side, and by so doing operate to prevent lateral and horizontal thrust upon the side walls, all essentially as specified.

FRANCIS WILBAR.

No. 8296.—*Improvements in Sewing Machines.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The combination of the rotating hook, to extend the loop on one thread, with a reciprocating bobbin, to carry the other thread through the loop so extended, for the purpose of interlacing the two threads together, whether the parts be severally arranged and operated as herein set forth, or in any other way substantially the same.

Second. The hollow mandrel, constructed substantially as herein set forth, with a groove on its periphery, to give a reciprocating motion to the bobbin, a segmental screw thread, to feed the cloth forward as the sewing progresses, and a hook and groove on its extremity, to form loops on the needle thread, in combination with a reciprocating bobbin; the whole arranged and operating substantially as herein set forth.

ALLEN B. WILSON.

No. 8297.—*Improvement in Shoulder Braces, combined with Abdominal Supporters.*

Having thus fully described the nature of my improvements, what I claim therein as new, and desire to secure by letters patent, are—

Firstly. The bars (*a*) having a common point of junction to a centre bar at the back, passing thence under the armpits, and thence forward, upward, and backward, until their padded extremities bear upon the clavicle; the bar being so formed as to fit snugly without direct pressure upon the body, except at the points at front and back, as herein explained, giving the desired support to the shoulders without unnecessary confinement of the person or obstruction of its various functions, and at the same time affording, through the medium of the bar, (*d, e,*) a firm point of attachment and support for a uterine or abdominal supporter.

Secondly. The jointed bar, (*d, e,*) having pads (*c, c, i, i*) located on each side of the spine, at the junction of the said bar with the braces, (*a,*) (*g,*) the said bar being jointed midways, so as to admit of easy flexion sideways, without compromising the rigidity which is necessary in other directions, and affording, by the limited extent of its pressing surfaces, free scope to the circulation, perspiration, muscular action, and other bodily functions.

JOHN S. DARE.

No. 8298.—*Improvement in ventilating and excluding Dust from Railroad Cars.*

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the blower, bellows, or forcer, with the pipes or tubes for conveying the pure air along the train of cars, the pipes or apertures for the admission of air into the cars, the valves or inverted mufflers for controlling such admission of air, together with the valves and apertures for regulating the atmospheric pressure within the cars, and its escape from them, all as hereinbefore set forth.

RANSOM COOK.

No. 8299.—*Improvement in the manufacture of Brushes.*

What I claim as my invention is the above-described improvement in the manufacture of brushes, the same consisting in laying two or more brush blocks or plates together, or upon one another, and either boring them before or afterwards, and each with the same number of holes, and so that each hole in each block shall be in range with a hole in each of the other blocks, and passing or inserting bunches of bristles through all the blocks, and fastening the ends of said bristles in the last block, through which they are made to enter, and separating the said blocks asunder, and cutting the bristles between the blocks, all substantially as hereinbefore set forth.

ABB'T R. DAVIS.

No. 8300.—*Improvement in Cooking Stoves.*

Having thus fully, clearly, and exactly described my improvements in double oven cooking stoves, what I claim therein as new, and desire to secure by letters patent, are the closed chambers (*l*) and (*m,*) and opening, (*i,*) in connexion with the space between the hearth plate, (*c,*) fire back, (*d,*) and boiler flue plate, (*e,*) and the upper portion of the ovens at their plates, (*f,*) (*g,*) and (*h,*) the whole being arranged substantially in the manner, and for the purposes described.

HOSEA H. HUNTLEY.

No. 8301.—*Improvement in Brick Machines.*

What I claim as new in my invention, and desire to secure by letter patent, is—

First. The mode of controlling the operation of the mould bed carriage, and driving it in either direction by the combination, substantially as described, of the toothed wheel, G, on the mud mill shaft, the rack bars, *k, k'*, and their racks, *l, l*, and arms or ears, *m, m*, attached to the carriage, and the slides, *o*, on the stationary framing.

Second. The mode of operating the cut-off plate, L, L, for the purpose of opening and closing the apertures communicating between the mud mill and the moulds, by means of the levers, N, N', attached to them, and to the framing, in combination with the wheels, *o, o', o'', o'''*, on the mould bed carriage, substantially as herein shown.

RICHARD LONG.

No. 8302.—*Improvement in Cooking Ranges.*

First. I do not claim to be the inventor of brick oven; but what I do claim as my invention, and desire to secure by letters patent, is the attachment of a brick oven to cooking range, to be heated from the same fire with which the cooking is done, as herein described.

Second. I also claim the hot air-chamber, I, at the sides of perpendicular plates, *i*, *h*, and extending as high as horizontal plate, *i*, and all over curved plate, *i*, *i*, and extending all around inclined pipe, F, and perpendicular pipe, *i*, F, and communicating with pipes, J, in the manner and for the purpose herein set forth.

NICHOLAS MASON.

No. 8303.—*Improvement in Chemical Processes for fulling Vegetable and other Textures.*

I may, in conclusion, remark, that the description of the apparatus or machinery and the strength and temperature of the soda or potash, sulphuric acid, or chloride of zinc solution, may be varied to a considerable extent, and will produce proportionate effects without at all deviating from my invention; for instance, caustic, potash, or soda, may be used even as low as twenty degrees, Twaddle's hydrometer, and still give improved properties to cotton, &c., in receiving colors in printing and dyeing, particularly if the heat be low; for the lower the temperature, the more effectively the soda or potash acts on the fibrous material above described: I therefore do not confine myself to any particular strength or temperature of the substances I employ, but the particular strength, heat, and process here described, are what I have found the best, and which I prefer.

And I claim, as of my invention, the process of fulling cotton, linen, and other vegetable fibrous material, either in the fibre or any stage of its manufacture, or either alone or mixed with silk, woollen, or other animal fibrous material, by means of astringent or styptic materials, as set forth.

JOHN MERCER.

No. 8304.—*Improvement in Registers for Omnibus Drivers.*

What we claim as our invention, and desire to secure by letters patent, is the arrangement of a series of doors, with the attachment to the axes or hinges thereof of levers or other mechanism, in such a manner and in such connexion, by means of a rod or rods, and springs, or other suitable contrivance or device, with a dial, or some like mechanism, that each door, upon being opened, will act upon such dial or other mechanism in such manner as to indicate thereon and thereby the number indicated by such door, the several doors indicating different numbers respectively; also the arrangement of a strip of metal or other suitable substance, vertically or in some other position, in connexion with such dial, so that by means of a wedge upon the dial and pins upon the said strip, or *vice versa*, under which, or over which, the wedge successively passes, the said strip will rise or be forced outward from the circumference of the dial a given distance at each revolution of the dial, and indicate, by the figures on the surface of such strip, near the outward or upward end of the same, successively coming in sight above or beyond the circumference of the dial, the number of such revolutions of the dial, using for the construction of the same any metal or metals or other substance of a suitable and durable description.

IRA. B. PERSON,
JOEL L. BROCKETT.

No. 8305.—*Improvement in Boot Crimps.*

What I claim as my invention, and desire to secure by letters patent, is the lever, C, the knob, F, the bolt, G, and the two circular rods, E, E, in combination with each other, and with the other parts of the machine, as described, for the purpose of drawing the corners of the front to their proper place at the same time the brake is passing down over it by turning the screw I; and I make no further claim.

HARTWELL STANLEY.

No. 8306.—*Improvement in Pulp Screens.*

I prefer to have the screen plates, *e*, constructed of brass; the other parts described may be of wood, with the exception of the bellows; but I do not confine myself to any particular material.

Having thus described the nature and operation of my invention, what I claim as new, and desire to secure by letters patent, is the application of the vibrating bottom or bellows, C, to the box, A, A; said box being constructed as described, with the partition, B, and the screen, D, upon its upper surface; by which arrangement the pulp is forced by atmospheric pressure between the plates of the screen upon the partition, B, and off the partition into a receiving box, E, substantially as described.

GEORGE WEST.

No. 8307.—*Improvement in Ships' Model Measurer.*

What I claim as new in my invention, and desire to secure by letters patent, is the employment, for the purpose of taking the dimensions of models of ships and all other vessels, of a pillar or post, A, having a graduated scale, B, on one side, and an adjustable rest, D, sliding on it, and having also a rule, *o*, with any number of graduated scales on its face, and a leg, G, connected with it, both the rule and leg being capable of adjustment in lines at right angles to the face of the pillar or post; the whole being constructed, arranged, and operated in the manner substantially as set forth.

ABIJAH S. HOSLEY.

No. 8308.—*Improvement in process of reducing Ores by Zinc Compounds.*

What I claim as my invention, and desire to secure by letters patent, is the use, in combination, of the several processes described, for the manufacture of zinc white, as a specific means of treating ores containing any number of metals, and separating the metals from each other by virtue of the chemical affinity of zinc, or its oxide for sulphuric acid, as described; and this I claim, with or without the aid of other chemical agents or affinities, substantially as described.

E. LOUIS SEYMOUR.

No. 8309.—*Improvement in Washing Machines.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of my improvements in washing machines, what I claim therein as new, and desire to secure by letters patent, is the chamber or tub, (*d*,) with its narrowed neck, and otherwise constructed substantially as described, in combination with the plunger, (*c*,) which latter, with the clothes wrapped round it, passes through the narrowed neck of the chamber, and. pressing forcibly on the water confined within the body of the chamber, drives it violently in the direction of the arrows and through the body of the clothes, carrying the dirt with it.

DAVID ALLAN.

No. 8310.—*Improvement in Cabbage Cutters.*

Having thus described my improvement on the machine for mincing cabbage, what I claim therein as new, and desire to secure by letters patent, is the two vertical bars, L, L, confined to the sides of the feeding box, E, so as to rise and fall with the movement of the feeder, R; said vertical bars, L, L, having handles, M, by which the operator actuates the feeding box, and, by the same exertion of his arms, renders the material self-feeding simultaneously with the reciprocating motion of the box, E.

HIRAM CARVER.

No. 8311.—*Improvement in Self-acting Cheese Presses.*

What we claim as our invention, and desire to secure by letters patent, the combination of the falling frame with the toggle-joint, and levers, and the fixed eccentric wedge, acting together and making the upward movement and pressure, substantially as herein set forth and described.

BETHUEL GILLETT,
LYMAN ALLIS.

No. 8312.—*Improvement in Dental Hydraulic Cups.*

What I claim as my invention is the construction of said machine, of two or more plates, with vacancies between the same, and with pipes annexed thereto.

And also I claim as my invention the application of water, or any suitable liquid, to the space or vacancy between the plates, for the purpose of hardening and rendering more firm the contents of the cup while on the jaw. I claim nothing for the outward form of the said plates, nor for the application of the same to the mouth merely to take impressions. And also I claim as my invention the method of using the gate as described.

JAMES HARRISON.

No. 8313.—*Improvement in Rotary Harrows.*

Having now described my invention, and the operation of the same, I will proceed to state what I claim, and desire to secure by letters patent of the United States. What I claim, therefore, is the use of the combination of the spur-wheel, H, and cog-wheel, D, with the hollow axis, G, for the purposes and in mode of construction substantially as herein set

forth, and their combination with the circular frame, B, having the face cog-wheel, C, and arms, A, attached, for the purpose of producing a rotating harrow, substantially in principle of construction as herein set forth.

JONATHAN F. OSTRANDER.

No. 8314.—*Improved Pad-Lock.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of our improved mail-bag, spring, and safety padlock, what we claim therein as new, and desire to secure by letters patent, is the combination of the bolt (*p*) and cavity (*y*) on the rotating end of the hasp, with the tumblers, (*a*) and (*g*) having the characteristics described, or their equivalents; the tumblers, hasp, and bolt constituting a system of fastenings within and without the casing of the lock; the whole being arranged and operated substantially in the manner and for the purpose described.

GEORGE McGREGOR,
ROBERT LEE,
THOS. G. CLINTON.

No. 8315.—*Improved Adjustable Tool-Haft.*

I do not confine myself to the formation of the eccentric on the gripe, for the effect will be the same if the groove be made on the inside of the revolving tube, C, and the pin, *d*, be fastened to the gripe, A. I do not claim the gripe as any novelty; but what I do claim as my invention, and desire to secure by letters patent, is the mechanism by which its jaws are closed, the same consisting of the eccentric groove, the pin, and the revolving tube, as described in the above specification, and shown in the accompanying drawings.

PETER H. NILES.

No. 8316.—*Improvements in Insulators for Lightning Rods.*

What I claim as my invention is the insulated support and point for lightning rods, consisting of the insulated point, and opening in its shank; the insulating cylinder of glass, with its lip, or flange; and the wooden collar, for securing the whole to the building; all as described.

GEORGE W. OTIS.

No. 8317.—*Improvements in Breech-loading Fire Arms.*

What I claim as my invention, and desire to secure by letters patent, is operating the breech pin directly by the finger lever, as herein described, in combination with the breech pin and abutting lever, formed and operating substantially as herein described, and for the purpose specified.

I also claim elevating the charge lifter, by the direct contact of the breech-pin carrier with an arm of the lifter lever, and depressing it by the direct contact of the finger lever with the other arm of the said lifter lever, as described.

HORACE SMITH.

No. 8318.—*Pad Lock.*

What I claim as my invention is the combination of the turning hasp, or contrivance, C, the tumbler, E, and the slide, G, and its projection, *l*, or any mechanical equivalents; the whole being made to operate together substantially as described.

DAVID TILTON.

No. 8319.—*Improvement in Lime Kilns.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is—

First. So forming the fire space in lime kilns which are fired at both ends as to rise gradually from the centre of the kiln to points above the eyes in each end thereof, substantially as herein described, for the purpose of so distributing the draught and heat as to secure the even burning of the stone.

Second. I claim dividing the fire space, by a partition wall in the centre, into two chambers, for the purpose of shifting and regulating the heat required in either end of the kiln, substantially as herein described, for the more evenly burning of the stone.

Third. I claim, in combination with the fire chambers and partition wall, the ash pits at each end of the kiln, connected by a narrow flue, so that when the eye at either end may be closed for shifting the heat, sufficient draft will be kept up from the opposite end of the flue to allow the fire to burn moderately, without being entirely extinguished, as herein fully set forth.

SAMUEL BROWN.

No. 8320.—*Improvement in Horizontal Square Piano Fortes.*

What we claim as our invention, or improvement, and desire to secure by letters patent, is connecting and combining in the horizontal square piano forte, in one piece of cast iron, or other metal or metals, the bridge, A, the brackets, C, the upper bearing by the flanges, F, the reverse bearing on the buttons, G, the application to the long bridge of the horizontal square piano forte of the method of firmly securing the whole to the rest plank by means of the screws, I, and the application of the diagonal position of the face of the flange, so as to make both strings of each note of equal length to metal bridges on horizontal square piano fortes, as seen at H, in the manner and for the purpose intended, described in this specification, and seen in the model and drawings by which it is accompanied.

GEORGE BACON,
RICHARD RAVEN.

No. 8321.—*Improvement in means for obviating difficulties arising from defective insulation of Telegraphs.*

Having thus fully described my improvements in the working of telegraphs, what I claim as new therein, and desire to secure by letters patent, is reversing the connexion of the main wire with the poles of the battery, so that the battery acts in opposition to the battery at the other end of the line, in the intervals between the contacts made by the key in writing, (in place of merely breaking the circuit,) by means of the apparatus and arrangement of wires, batteries, &c., substantially as above described, for the purpose of counteracting the effects of imperfect insulation, as set forth.

CHARLES S. BULKLEY.

No. 8322.—*Improved Nut and Washer Machine.*

We claim the two punches, moved at the same time, with different velocities, and in the same direction, in combination with a die box, within which the nut is formed, substantially as herein set forth.

HENRY CARTER,
JAMES REES.

No. 8323.—*Improvement in Machinery for Cutting Glass.*

What I claim as my invention, and desire to secure by letters patent of the United States, is—

First. The combination and arrangement of the several parts for giving the reciprocating and circular movements herein described—that is to say, the combination of the bed plate, H, and revolving plate, I, with the carriage, consisting of the pieces, K, L, M.

Second. The method of guiding the movements, and adjusting the several parts of the machine, for the purpose of directing the course of the object to be shaped, or figured, in passing the edge of the cutting wheel, by means of movable lettered or named stops and gauges, prepared for particular patterns, and applied to the machine, as required; the whole being constructed and operating substantially as herein set forth.

J. P. COLNE.

No. 8324.—*Improvement in Self-acting Blow-pipe Lamps.*

Having now described the mode of construction and operation of my improved lamp, I will proceed to state what I claim, and desire to secure by letters patent of the United States:

What I claim, therefore, is the use of the safety valve and escape pipe and stop cock, in combination with the blow-pipe of a self-acting blow-pipe lamp, substantially as hereinbefore set forth.

D. W. C. McCLOSKEY.

No. 8325.—*Improvements in Machinery for forming points of Elliptical Springs.*

I claim the combination of the hollow die with the lower die, and have circular shears, actuated in the manner substantially as herein described, and for the purpose herein set forth.

W. T. RICHARDS.

No. 8326.—*Improvement in Cut Nail Machines.*

What I claim as my invention, and desire to secure by letters patent, is—

First. In combination with knives, or the equivalent thereof, for cutting blanks sidewise from nail plate, I claim a travelling, griping, and heading tongs or jaws, opening and closing in a direction perpendicular to the face of the nail plate, and constructed and actuated substantially as herein set forth, to gripe the blank on its flat sides without the necessity of turning it upon edge, as is customary with nail machines heretofore constructed, to draw it from beneath the knives, and hold it while being headed.

Second. I claim the direct acting knife stock, with knives secured to its opposite sides, in such positions with respect to the stationary knives or to each other that the knife upon one side cuts after the knife upon the opposite side, in combination with a double graded cam, or other equivalent actuating mechanism, which shall cause the cutter bar to descend with two impulses, at each of which one knife acts to cut a nail blank.

Third. I claim the relative arrangement of the travelling griping jaws and heading tool, the latter being actuated within the former, and travelling with it.

Fourth. In combination with two sets of knives acting, alternately to sever nail plates, I claim a reciprocating griping and heading carriage, which, travelling to and fro between the two sets of knives, gripes heads and delivers a nail at each single stroke in alternate succession at its opposite extremities, whereby much time and labor are saved, and the machinery to cut a given number of nails is condensed into a less space.

JOHN P. SHERWOOD.

No. 8327.—(Suspended.)

No. 8328.—*Improvements in Spike Machinery.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, is the method of delivering the spike from the die by means of the tilting rod, O, and the movable nippers, 3, 3, so as to allow the nippers to draw in the succeeding blank underneath the spike, and tip or tilt it out of the die, which prevents the possibility of a spike and blank being in the die at the same time, and the consequent breaking up of the machine.

JAMES H. SWETT.

No. 8329.—*Improvement in Rules for Calculating Interest.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of parallel slides, substantially in the manner and for the purposes herein set forth, one slider being for units, another for tens, another for hundreds, &c., and each slider being so graduated and numbered as to show through the vertical opening, *n*, *y*, *f*, *o*, the sum denoting the interest or tax on the numeral figure that appears on the same slider at the side of the bar, *m*, *n*, *o*, *p*, as herein described.

S. S. YOUNG.

No. 8330.—*Improved Saw Filing Machine.*

Having thus described the nature and operation of my invention, what I claim as new, and desire to secure by letters patent, is the swinging frame, constructed as described, and for the purpose specified, viz: by having the arms, J, J, J, firmly attached to a rod, I, the ends of the said rod working freely in holes or bearings in the ends of the arms, H, H, which are attached to the horizontal rod, C, by which arrangements the swinging frame has an up-and-down motion, owing to the rod, C, turning in its bearings; also a horizontal reciprocating motion, the same as the rod, C, and a forward and backward motion, by which, with the aid of the file turning on its axis in the frame, the file may be so adjusted as to operate both upon the front and back of the saw teeth, substantially as set forth.

THOMAS M. CHAPMAN.

No. 8331.—*Improvement in method of securing Wheels to Axles.*

We do not claim the securing of a hub to an axle by means of a groove around the inner end of the hub, or a bead on the axle; but what we do claim as new, and of our own invention, and desire to secure by letters patent of the United States, is the application of the cylinder, 5, and flanch, *f*, on the axle, in combination with the cylinder, *e*, flanch, 3, coupling, 7, keys, 12, and coupling box, *g*, to retain the plate, *d*, of the hub, and allow its rotation between the flanches, 3 and *f*, without any tendency to uncouple the hub from the axle, substantially as described and shown.

JUNIUS FOSTER,
DAVID MARSH.

No. 8332.—*Improvement in Double Oven Stoves.*

Therefore, having thus fully, clearly, and exactly described our joint invention and improvements in double oven stoves, wherein the front oven extends under the fire-place, or fire-place and hearth, as may be desired, what we claim therein as new, and desire to secure by letters patent, is the damper, (*a*,) constructed and arranged as described, so that one or both ovens may be used at pleasure.

We also claim the flue (K) between the ovens, substantially as constructed and arranged. to communicate directly with the exit flue, (*l*.)

We also claim projecting the cold air chamber into the flue under the fire-place, and there discharging the received air, so as to protect the oven from being over-heated at that point.

CONRAD HARRIS,
PAUL WILLIAM ZOINER.

No. 8333.—*Improvement in moulding and casting Stereotype Plates.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The moulding, in plaster, of one or more forms of type, wood cuts, medals, &c., at one operation, in air tight vessels, by means of exhaustion.

Second. I claim the making of the plaster moulds with two faces.

Third. I also claim the casting, from one or more moulds, in a box sufficiently tight to hold fluid metal, and bringing the face perfect, by means of the weight of fluid metal confined above them in column or otherwise.

Fourth. I also claim the grooved wedges, for retaining the moulds in their places while casting from them.

Fifth. I also claim the non admission of fluid metal to the moulds until the orifice through which it enters is sunk beneath the surface of the fluid metal, thus preventing the dirt and dross from entering with it.

CHARLES HOBBS.

No. 8334.—*Improvement in drying and oxidizing Colored Goods.*

What I claim as my invention is the application of atmospheric pressure, or the mechanical pressure of air, in the coloring of cotton, wool, or other substances, for removing the excess of liquor absorbed from the vat, and for oxidizing or fixing the color by its forced passage through the mass, and by the use of apparatus, substantially such as herein described.

JAS. C. KEMPTON.

No. 8335.—*Improvement in Mercury Baths for Photographic purposes.*

What I claim as my invention, and desire to secure by letters patent, is my moving and movable lever, cup, or its equivalent, and bath, for photographic and Daguerreotype purposes.

I claim the agitation of the mercury upon a cooler surface, immediately previous to its use, in the heated cup, (or part of it,) for the development of photographic impressions, by means of my movable lever cup, or its equivalent.

I claim the lever cup, or elongated cup, movable perpendicularly, on an axis or centre of motion, which centre of motion need not be confined to a particular part of the cup, but it may be varied and placed in any manner, giving and admitting the movement of the cup, but must be so arranged as that the mercury, or other substance, may flow from the heated surface of the cup to the cooler surface of the tube, or elongated cup, and *vice versa*, by elevating or depressing the exterior end of said cup.

I claim the balancing of said lever cup, or its equivalent, on the centre of motion, wherever placed, so that it will remain stationary, when the weight of the mercury, or other substance, is let on to either end of it, that end containing the mercury, or other substance used, being held down.

JOHN MOULSON.

No. 8336.—*Improvements in method of raising Sunken Vessels.*

I claim the combination of the inflatable air receiver, purchase, roller, and wedge, or their equivalents, as herein described, for the purpose of raising and supporting vessels.

WM. IRWIN.

No. 8337.—*Improvement in the construction of Bridges.*

What I claim as my invention, and desire to secure by letters patent, is the method, above described and shown, of making the thrust arches of bridges—that is to say, I claim the arch constructed partly of wood and partly of iron, when arranged in the manner herein specifically set forth; the iron parts of the arch being constructed in such a manner as to afford a firm bearing for the braces and uprights, with a projecting flanch of sufficient width to shelter the wooden part of the arch, as herein set forth, and the wood being bolted upon the sides, under cover of the flanches of the iron, in such a manner that the wood upon one side can be removed and be replaced without disturbing that on the other. The whole being constructed and put together substantially in the manner and for the purposes herein set forth.

EDWIN STANLEY.

No. 8338.—*Improvement in the construction of Violins, &c.*

Having thus described the construction and effect of my improvements of the violin, &c., what I claim as my invention, and desire to secure by letters patent, is the introduction into the body of the instrument of the brace bar or supporter, C, constructed of any suitable material, and of any requisite form between the upper and lower extremities thereof, inserted either into blocks of wood, A and B, or, instead of A, into an elongation of the neck, to answer the same purpose, by which means I am enabled to give strength to the instrument to resist the strain of the strings, and disconnect the sound board, E, E, and the table or back, from the blocks, A and B, said brace or supporter, C, sustaining the tension of the strings, preserving in tune, and also materially improving the tone, in quality, volume, and melody of instruments to which this improvement is applicable.

I also claim the manner of increasing the vibration of the sound board, E, E, and the table or back, by the cutting away or removing the before-described portions of blocks, A and B, in the manner and for the purpose set forth in the foregoing specification and accompanying drawings.

WM. B. TILTON.

No. 8339.—*Improvements in Cider Mills.*

What I claim as my invention, and desire to secure by letters patent, is the cast-iron grinders, arranged and constructed as described, viz: so as to force the apples, while being crushed, from the centre towards the periphery of the plates, and at the same time to force a portion of the pummace through the holes in the lower plate of the grinders.

I also claim the method of removing the cheese of pummace from the press-crib, viz: by detaching the platform from the press-crib, and using the same for a sled, to draw the cheese from the mill, substantially as described.

NATHAN CHAPIN.

No. 8340.—*Improvement in Circuit Changers for Electro-Magntic Telegraphs.*

Having thus fully described my improvements, what I claim as new therein, and which I desire to secure by letters patent, is the "circuit changer," substantially as above described, in combination with the arrangement of wires, magnets, &c., as set forth, for the purpose of enabling the operator at either one of two distant stations to arrange the connexions at the intermediate stations, so that he can write through to the other end-station at pleasure.

CHAS. S. BULKLEY.

No. 8341.—*Improvement in Machine for making Sod Fence.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the combination of the cutters and mould-boards, for cutting and turning the sod on edge, with the inclined adjustable spring rollers, for raising, packing, and forming the sods into a fence, as herein described and represented.

H. L. F. GAVETT.

No. 8342.—*Improved Hook-heading motion for Spike Machines.*

Having thus described my improvements on the machine for making hook-headed spikes, what I claim as new, and of my own invention, and desire to secure by letters patent, is the employment of a header, made to have a descending, and afterwards a horizontal frontward movement, for the purpose of first bending the end of the piece of iron downward, and then forcing it horizontally against the end of the die, C', and thus form a hook-head, as described and represented.

MOORE HARDAWAY.

No. 8343.—*Improved method of making Sails.*

What I claim as my invention, and desire to secure by letters pa ent, is the bringing straight cloths upon the leeches, and making all the head cloths parallel therewith, and uniting the goring cloths in the bunt of the sail, as described above.

ELI F. SOUTHWARD.

No. 8344.—*Gold Amalgamator.*

What I claim, therefore, as my invention, is as fellows: I claim the combination of the partition, S, (dipping below the surface of the water,) with the lower distributor, provided at the centre with a discharge aperture for the water and light particles, and at the periphery with apertures for the discharge of the water and heavier particles, for the purpose of preventing the escape of gold over the central or waste-pipe.

I also claim the arrangement of the sliding-tube, ferrule, or waste-gate directly upon the hollow axle of the lower distributor, T, the same being for the purpose of regulating the head of water within the said distributor. I am aware that it is not unusual in gold washers to use a succession of baths; therefore I do not claim such arrangement in general. But I also claim arranging the secondary mercury bath concentric with and below the primary one, in such a manner that the currents of water, &c., return towards the centre of the apparatus, thereby saving room, and causing the said currents to pass more slowly.

WM. BALL.

No. 8345.—*Improvements in Equalizing, or Power Regulators.*

I will proceed distinctly to state that I do not claim the mere employment as an "equalizer" or regulator of a piston operated by and acting against pressure, alternately, each stroke, the said piston having two strokes for one of the engine, or other mover it works in connexion with, as such has already been done; nor do I claim separately exposing the equalizer piston to the vacuum of the condenser. But what I do claim as my invention, and desire to secure by letters patent, is the use of steam or other gas to operate upon the piston of the power regulator, or "equalizer," the said steam or gas being derived from the same reservoir that supplies the engine.

ALFRED GREGORY.

No. 8346.—*Improvement in Sword Canes.*

What I claim as my invention, and desire to secure by letters patent, is a sword-cane, constructed substantially as herein set forth, viz: consisting of the rod, with blade attached, passing through the entire shaft, and giving point beyond it, whether the said rod be, or be not, connected with a spiral spring to draw the blade back into the handle.

I do not claim the application of the spiral spring as an adjusting power, nor do I claim the screw applied as a stop; neither of which being substantially new.

SAMUEL ADAMS HUDSON.

No. 8347.—*Improvement in Washing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the combination, substantially as described, of the levers, link bar, and rubbing board, for the purposes herein specified.

ERASTUS LAWRENCE.

No. 8348.—*Improvement in Axles of Wheeled Cultivating Ploughs.*

What I claim as my invention, and desire to secure by letters patent, is hanging one or both of the axles of the wheels to the carriages of cultivator, gangs of ploughs, seed drills, &c., to the frame of the carriage, so as to vibrate the axle or axles, or suffer them to vibrate and keep them at right angles to the motion of the ploughs when moving in a direct line, and, when turning the ploughs, to keep the axle or axles in the direction of the radius of the circle, or nearly parallel with the radius of the circle, formed by the track of the wheel turning upon said axle when the ploughs constituting the gang are placed diagonally, one behind the other in succession, and the whee's to the carriage of the same are also placed diagonally, one behind the other.

G. W. C. GILLESPIE.

No. 8349.—*Improvement in Type-casting Machines.*

Having now described my invention, and the operation of the same, I will proceed to set forth what I claim, and desire to secure by letters patent. What I claim, is—

First. The employment of the lever, P, having an adjusting slot, adjuster, R, matrix spring-holder, O, and their combination with the horizontal slide, D, slide ways, H, H², and matrix spring, N, substantially in form and manner and for the purposes herein set forth.

I claim also the employment of the adjusting supporting piece, L, and the combination therewith of the horizontal slide, and levers, K, J, and M, substantially in form and manner and for the purposes herein described.

And I also claim the combination and arrangement of the horizontal slide ways, and levers operated thereby, for the purpose of obtaining a horizontal and oblique action of the machine.

JOHN J. STURGIS.

No. 8350.—*Improvement in Piano Forte Actions.*

What I claim as my invention, and desire to secure by letters patent, is the repeating check or tongue, connected with a lever, hinged to the hammer rail, and resting on the key, the under side of the hammer being provided with an arm, which rests against the upper end of the face of the repeating checks, substantially as and for the purpose specified.

RANDOLPH KRETER.

No. 8351.—*Improvement in Dental Forceps.*

What I claim as my invention, and desire to secure by letters patent, is the "compound lever forceps" above described, or the compound lever and the movable fulcrum applied to forceps, by means of which the roots of decayed or broken teeth may be readily and easily reached and extracted.

J. C. BURCH.

No. 8352.—*Improvement in Piano Forte Action.*

What I claim as my invention, and desire to secure by letters patent, is in having the shoulder under which the hopper plays attached to the hammer but by a centre pin, forming an independent oscillating shoulder to the hammer but, said shoulder being usually detached from the hammer but, or composing a part of it.

I also claim the extension of the back part of the shoulder down, so as to connect with a spring.

JAMES A. GRAY.

No. 8353.—*Improvement in Piano Forte Action.*

What I claim as my invention, and desire to secure by letters patent, is the jack, consisting of a crooked lever, and a straight, or nearly straight lifter, or pusher, acting conjointly on the general principle above illustrated.

And I also claim, and desire to secure, the peculiar application of the spring to govern the alternate bending and straightening of the jack, by acting one prong or tooth, between two other prongs or teeth, with due allowance of play, or shake, according to the desired degree of drop of the hammer from the string, known as the scrape.

R. M. KERRISON.

No. 8354.—*Improvement in fastening Hooks and Eyes to Paper Cards.*

I claim nothing for the machinery with which the work is done, nor for the mortise-like holes which belong to Atwood's patent; but what I do claim as my invention, and desire to secure by letters patent, is the confining of the eye by means of the longitudinal cut or slit, or cuts or slits, (whether one or more is used,) in the card, parallel with the rows of holes, admitting through it or them a portion of the eye, as herein described and applied, or in any manner substantially the same.

CHESTER J. CARRINGTON.

No. 8355.—*Improvement in Gauges used in Turning.*

What I claim as my invention, and desire to secure by letters patent, is the gauge, (*c*,) with its graduated slide, (*c*,) capable of being set to any given diameter, the whole being suspended upon a horizontal wire, operating as herein set forth.

C. R. HURLBUT.

No. 8356.—*Improvement in the manufacture of Paints.*

What I claim as my invention, and desire to secure by letters patent, is the manufacture, by the processes substantially as herein described, of new colors fit for painting, whether with oil, varnish, spirits of turpentine, or water, by means of the deoxidation of the soluble metallic sulphates of zinc, copper, iron, and other metals, and by the precipitation of their basis, either by alkaline hydro sulphurets whose sulphates are soluble, such as those of soda, potash, and ammonia, to obtain colors with a single metallic base, or to obtain colors with a double base, partly metal and partly alkaline sulphate, by using the alkaline hydro sulphurets whose sulphates are insoluble, such as those of baryta, strontian, and of lime, and even by the hydrated sulphurets and poly-sulphurets of lime prepared directly, substantially as herein set forth.

G. F. DE DOUHET.

No. 8357.—*Improvement in the manufacture of Iron.*

Having thus fully described the nature of my invention, what I claim as new therein, and desire to secure by letters patent, is the application of franklinite to the improvement of iron in the processes of reduction from its ores, and in the finery or puddling of crude or pig iron, according to the methods, as above described.

S. T. JONES.

No. 8358.—*Improvement in Bedsteads.*

What I claim as my improvement is the suspension spring or strip, *d*, the thrust spring, *a*, and the spring, *e*, between them, as combined or applied together, and to the bedstead and slats imposed upon them, substantially as hereinbefore specified.

IRA RUSSEL.

No. 8359.—*Improvement in Railroad Car Coupling.*

What I claim as my invention, and desire to secure by letters patent, is the shape and construction of the improved car platform, in combination with the jointed self-acting pin, stationary pin, and grooved half coupling, all as herein described, for the purpose of coupling and disconnecting cars.

GEORGE WINTERS.

No. 8360.—*Improvement in Machines for breaking Hemp and Flax, and reducing the length of the fibres.*

Having thus fully described our invention, what we claim therein, and desire to secure by letters patent, is the art or method of separating the fibres of flax, hemp, &c., from the boon, and reducing them to suitable length of staple to be used on cotton, woollen, and other machinery by the use of combined sets of grooved and graduated rollers, or their equivalents, operating in the manner and for the purpose herein fully set forth and represented.

JAMES S. TREAT,
STEPHEN RANDALL.

No. 8361.—*Gauge for indicating Pressure of Steam, &c.*

What I claim as my invention, and desire to secure by letters patent, is combining with the steam tube the disk and spring, so arranged that the force of the current of steam impinging upon said disk can be ascertained by the extent to which the spring is expanded, and this can be known by the comparative pressure in the boiler or other vessel necessary to give the required velocity to the current to produce different degrees of expansion of the springs, substantially as herein set forth.

GEORGE FABER.

No. 8362.—*Improvement in Apparatus for Draining Sugar.*

What I claim as my invention, and desire to secure by letters patent, is combining two or more straining pans with molasses or receiving vessels, below each, substantially as described, the said pans being provided with a discharge pipe or tube, substantially as described, so at the current of air shall pass from the lower part of the first to the upper part of the next through the series, and so arranged as to retain the molasses or other liquid parts; and this combination I claim, whether the said succession of pans be used in one or more series, as described.

SMITH GARDNER.

No. 8363.—*Improvement in Stone Drilling Machines.*

Having thus described my new drilling machine, I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is—

First. A power drilling machine, in which the drill is driven by a vibrating hammer, operated substantially as hereinabove described.

Second. I claim stopping the "feeding forward" of the sliding frame and drill, when the latter does not penetrate the rock sufficiently, or to the usual depth at each blow, by keeping the pawl out of the feeding ratchet, excepting when the drill goes in the requisite length, by means of the combination of the forked vertical lever, c', d', connected with the drill shaft, the horizontal lever, d', a', a', and the spiral spring, h', h', operating substantially as hereinabove set forth.

I also claim drawing the edge of the drill away from the bottom of the hole, when the tool is being turned, by means of the inclined claw or fork, l', operating with a collar, n', on said drill, substantially as hereinabove described.

HENRY GOULDING.

No. 8364.—*Improvement in Machines for dressing Mill Stones.*

We claim, in combination with the feed lever, (e',) operated by the cam, (d',) to work the feed bands, the employment of a weighted stop lever, or the equivalent thereof, acting in the notch, (m',) of the lever, (e',) substantially as described, which said stop shall be self-acting, to stop the feed motion, that the cuts may continue in the same place until the feed motion is restarted and thus insure the cutting of the stone to the required depth, whatever may be the texture thereof, as described.

ERASTUS W. HAZARD,
CHARLES H. JENNER.

No. 8365.—*Improvement in processes of making Bronze Powder.*

What I claim as my invention is making metallic bronze powder of copper, tin, spelter, or their alloys, by running them through iron or steel rollers, substantially as described; also the application, and manner of application, of soap, to make the bronze bright, and brilliant, and durable.

L. BRANDEIS.

No. 8366.—*Improvement in Stoves.*

Having thus described my improvements, I shall state my claims as follow: What I claim as my invention, and desire to have secured to me by letters patent, is forming the tapering radiator, produced by extending the fire chamber, as above set forth, in branches arranged with their centre lines, parallel to each other, or nearly so, and connected by arches, substantially in the manner above set forth.

GARDNER CHILSON.

No. 8367.—*Improved Bench Vise.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the latch pin, the ratch bar, acted upon by a spring that constantly tends to disengage it from the latch pin, and the foot lever, with the movable jaw of a vise; these several parts being constructed, arranged, and operating as herein set forth.

N. F. CONE.

No. 8368.—*Improvement in Weavers' Temples.*

What I claim as my invention, and desire to secure by letters patent, is connecting the movable jaw to its point of suspension by an arm, or equivalent, in such a manner that the point of suspension will be nearer the middle of the cloth than its other extremity, which extends out towards or beyond the selvage at such an angle that the jaws of the temple will be released by the cloth as it is spread by the action of the reed upon the warp, when it strikes up a thread of weft, and closed by the contraction of the cloth, caused by its own elasticity, as the reed leaves it, so that the cloth, by its own action, is released, when the reed advances, and is griped and held as it recedes, thereby dispensing with the strong spring wedge and other devices heretofore used for operating the jaws of temples.

ARNOLD JILLSON.

No. 8369.—*Improvement in Leather-Splitting Machines.*

Having thus described my improved leather-splitting machine, I shall state my claims as follow: What I claim as my invention, and desire to have secured to me by letters patent, is—

First. Making the gauge-roller of a leather-splitting machine, with the sectional tubes or friction rollers, to be placed on each end thereof, substantially as herein above set forth, and for the purpose specified.

Second. I claim combining with the ordinary cast-iron spring plate of a leather-splitting machine a cast steel spring plate, forming a double lip spring plate, and fitted thereon so as to be adjustable horizontally, as herein above set forth; and so that the front edge of the lower or cast iron plate may project under the edge of the knife, and hold up the split, as hereinabove set forth.

ALPHA RICHARDSON.

No. 8370.—*Improvement in Fastenings for Last Blocks.*

Having thus described my improvement, I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is fastening the block to a boot or shoe last by a hasp on said block, in combination with a spring attached to the last, as hereinabove described, or in any other manner substantially the same.

LEVI R. ROCKWOOD.

No. 8371.—*Improvement in Waste Pickers.*

Having thus described our improved machine, we shall state our claim, as follows: What we claim as our invention, and desire to have secured to us by letters patent, is the use of a blast of steam or air passing into and out of the hollow shell, as hereinabove specified, so as to blow the ends or fibres of the material out, in order to enable the teeth of the picking cylinder to engage with them.

CHAS. G. SARGENT,
ROBERT THOMPSON.

No. 8372.—*Improvement in Machines for printing House Papers.*

Having thus described my improvements in house paper printing machinery, I shall state my claims as follow: What I claim as my invention, and desire to have secured to me by letters patent, is the use of two sets of spur clamps—one set being sliding and feeding clamps, and the other set being stationary and holding clamps, and the two sets having a connected operation, so that one set shall be open when the other set is closed; all as hereinabove set forth.

I also claim the mode, hereinabove described, for supplying the coloring fluid to the patterns—that is, by means of a cloth band, alternately drawn forward from the vat over an elastic bed, on which the platen descends, and then back again through the color in the said vat; all as hereinabove set forth.

I also claim giving the second or double application of the color to the patterns, for each impression, by suddenly lowering the elastic bed after the first touch of the patterns on the cloth band, and then raising it again for the second touch, substantially in the manner hereinabove set forth.

MILTON D. WHIPPLE.

No. 8373.—*Improvement in Churns.*

Having thus described my invention, I will now state what I claim, and desire to secure by letters patent:

First. I claim the employment of a revolving vessel, A, containing the cream or milk, with or without cleats, *d*, *d*, *d*, *d*, constructed either plain or with pins, *e*, *e*, *e*, *e*, or having any other suitable internal projections, and operating in combination with a toothed or plain stationary cross-bar, F, removably or permanently secured to the fixed axles, B, B, and situated in the space forming the upper half of the vessel, A, at any desired distance from the centre thereof.

Second. I likewise claim the employment of a tempering cylinder, K, and tubes, L^1, L^2, in combination with the revolving vessel, A, and cross-bar, F, for cooling or warming and agitating the milk, by its precipitation thereon, as caused by the circular motion conveyed to the milk, and interruption or arresting effect produced, substantially as shown and described.

GEO. B. CLARKE.

No. 8374.—*Improvements in Machines for scutching and hackling Hemp and Flax.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the method herein described, or any other means essentially the same, of throwing the teeth in and out of the cylinder or drum at pleasure, whilst in motion, so as to present a greater or less length of teeth to the hemp, or of drawing them entirely within the cylinder in case the hemp should become entangled and likely to break up the machine.

Second. I claim, in combination with the bar holding the teeth, the spiral spring for allowing said bar to yield to knots, or other obstructions, and for drawing back into proper position the said bar after it is released from said obstruction.

Third. I claim, in combination with the bar and teeth, arranged as herein described, the adjustable guides, S, for setting the teeth at such angle as will give them more or less hold upon the hemp, as herein fully described and represented.

OWEN W. GRIMES.

No. 8375.—*Improvement in Machines for stripping Seed from Broom Corn.*

Having thus described the nature and operation of my invention, what I claim as new, and desire to secure by letters patent, is the endless bearded belt, D, D, constructed of any proper material, and having "lugs" or spikes, G, G, as described, in combination with the comb-rollers, B, B, set diagonally upon the frame, A, A, A, in the manner and for the purposes substantially as set forth.

L. D. GROSVENOR.

No. 8376.—*Improvements in Lath Machines.*

Having thus fully described my invention for sawing laths, I desire it to be understood that I do not claim mounting a rotary cutter, C, on the same spindle of the rotary saw, as herein described; nor do I claim the returning table, consisting of a series of rollers, G, G, G, arranged and operated in the manner described; but what I do claim, and desire to secure by letters patent, is the director, J, and carrying belt, in combination with the apparatus for registering, substantially such as described, for delivering bundles ready counted.

I also claim the rounded surface of the receiving table, in conjunction with the bent form of the strip, J, as represented in figure 2, at (*k*,) which effects, in the simplest manner, the delivery on the returning rollers, G, G, G, of the unsawed slab to the attendant, for another cut.

WILLIAM MERRILL.

No. 8377.—*Improvement in Easy Chairs for Invalids, &c.*

Having described the construction and uses of my adjustable combination chair, what I claim therein as new, and desire to secure by letters patent, is the manner of combining the jointed chair with the jointed ottomans, whereby the whole is made to subserve the several purposes hereinbefore described, and illustrated in the drawings.

I also claim furnishing the back of the chair with an additional joint, F^{2}, whereby the back of the chair is rendered susceptible of such adjustment as to form a support to the spine of the occupant of the chair, as described and shown in the drawings.

I likewise claim the employment of the triple-jointed hinges, K, K, in combination with the spiral springs, L, L, for securing the flexible bolster, J, by which it is steadied and retained in its proper position when expanded or contracted, as set forth.

PATRICK O. NEIL.

No. 8378.—*Improvement in Ventilating Ships.*

We do not claim to have invented either the caboose water back, ventiducts, or valves, although we do not know of the several parts referred to having been used for the purpose described. But what we do claim as our joint invention is the combination and application of the caboose water back, ventiducts, and valves, in connexion with our water surface and the cowl and vane, for the introduction of pure air, and the expelling of impure air, as described, and for the purpose hereinbefore mentioned.

AMOS J. SEXTON,
WILLIAM ENNIS.

No. 8379.—*Improvement in Machinery for threading Wood Screws, and Feed Apparatus therefor.*

Having thus described the principle, or mode of operation, of my said improvements, and the manner of constructing and working the same, together with old parts, so far as it was necessary to describe these latter, what I claim as my invention, and desire to secure by letters patent, is the employment of two cams in combination, substantially as described, for the purpose of operating the fingers which supply and present the blanks to the griping jaws, as described.

I also claim the employment of one cutter, to form the thread on the conical point, when combined and operating simultaneously with a second cutter, for forming the thread on the main part of the shank, substantially as described, and for the end specified, provided the motion of one of the cutters is extended into the track of the other, to insure the making of the thread on the conical point a continuation of the thread on the main part of the shank.

THOS. J. SLOAN.

No. 8380.—*Engine in which Compressed Air, or other Gas, heated and expanded by admixture therewith of a heated fluid, is used as the Motive Agent.*

Having thus fully described the nature of my invention, what I claim, and desire to secure by letters patent of the United States, is actuating an engine, such as are now usually driven by steam, or of any convenient form, by means of a measured or detailed quantity of air, previously compressed, and having had its tension, due to such compression, highly increased and augmented by the jetting, or flashing into, or commixture with it of a measured or detailed quantity of a "medium," or, in other words, of a heated liquid, as water, or a vapor, (simple or "superheated,") as steam, said jetting of the steam into the air, (or *vice versa*, the air into the steam, which I claim as equivalent,) and their commixture being effected in a vessel or vessels disconnected, previous to and during that process, or at least prior to its final consummation, from the reservoir, or main source of compressed air, and from that of the steam, &c., and each separate and distinct charge, or detailed quantity of compressed air, heated by its corresponding charge, or detailed quantity of steam, being allowed to act upon the piston, or its equivalent, prior to the admission or introduction of another charge of air and steam into the vessel or vessels in which their commixture is effected; the whole operation being carried out by means of mechanism, in substance such as here represented, or any more fitting mechanism that shall effect the same in the manner here claimed.

WM. MT. STORM.

No. 8381.—*Improvement in Shoe Latchets.*

What I claim as my invention, and desire to secure by letters patent, is the confining a shoe to the foot by means of a flexible latch, B, secured to one portion of the said shoe, acting in conjunction with a socket, or eyelet, *d*, and a catch, or hook, *c*, secured to other parts of the shoe, and operating substantially in the manner herein set forth.

ISAAC BANISTER.

No. 8382.—*Improvement in the Churn and Butter Worker.*

I am aware that, in some respects, it resembles some other machines or engines for such purpose, but still such parts as constitute such resemblances form no portion of my invention or improvements, and what I claim, which are as follow:

That is to say, I claim the combination of one or more fluted rollers, R, S, with one or more floats, *i*, *k*, to operate so as not only to aid in the process of separating the butter from the cream, but afterwards, and when the motion of the dasher is reversed, to throw into ridges the butter spread on the bottom of the floats.

And I claim the improvement of giving a longitudinal hollow or curve to the external surface of each float, *i*, *k*, for the purpose of gathering the spread butter towards its middle, and preventing the butter from adhering to the ends of the reservoir, as specified.

ASA WILLARD.

No. 8383.—*Improvement in Piano Fortes.*

Having thus described my improvements, I shall state my claim as follows:

What I claim as my invention, and desire to have secured to me by letters patent, is—

First. Arranging the sounding board in a springing form, and supporting its back on a straining lever, made to bear with more or less force against it, in the manner and for the purpose hereinabove specified.

Second. I claim the combination of the short subsidiary iron frame, having a rectangular socket on its front rail, with the long main iron frame, having a wooden block on the under side of its front rail, which fits and is glued into the aforesaid socket, as hereinbefore set forth.

Third. I claim casting the bridge of the long iron frame with curved brackets, so as to have it raised above the level of the bottom of the front rail of said frame, and permit the strings to be strained or strung under the same, as hereinabove explained.

Fourth. I claim easing the escapement of the fly of the jack from under the centre block of the hammer by means of a spring, combined with said block and the stem of the hammer, as hereinabove stated.

Fifth. I claim arranging the back catch on a lever, having a fulcrum in the jack, and arranged so as to cause the catch to follow the hammer in a stroke of the same, and cause it to repeat the stroke or note, if desired, when the fly of the jack fails to operate, so as to effect said second stroke.

Sixth. I claim using a piece of gutta percha on the top of the hammer head, in lieu of some of the layers of leather, in the manner and for the purpose specified.

LOUIS H. BROWNE.

No. 8384.—*Improvement in Letter Stamps.*

I do not claim punching out types from a cavity by a follower; but what I do claim as my invention, and desire to secure by letters patent, is so making and operating the detruding rods or followers of a letter stamp so as to act wholly within the body of the stamp block, whereby I avoid cutting away the handle, and the weakening which would be caused thereby.

I also claim making the detruding rod, R, wing, N, and thumb slide, O, in a single piece, whereby I greatly economize the labor of making this part of the stamp, as herein set forth.

B. CHAMBERS.

No. 8385.—*Improvement in Mowing Machines and Harvesters.*

What I claim as my invention, and desire to secure by letters patent, is hanging the cutter bar of a reaping machine to the side of a triangular frame in such manner that neither extremity of the cutter shall be liable to sag below the other extremity, as herein set forth.

JOHN H. MANNY.

No. 8386.—*Improvement in Printing Presses.*

It must also be understood that I do not claim individually or separately any of the parts of the apparatus or machinery; but what I do claim as my invention, and what I desire to secure by letters patent, is—

First. In combination with the ink troughs, E, and printing cylinders, A, the arrangement of the cam cylinders, D, reciprocating cylinders, K, (operated by the levers, J,) and L, (operated by the levers, M,) and cylinders, G and N, for receiving, carrying, and distributing the ink from the said trough to the said cylinder.

Second. I claim, in combination with the printing cylinders, the cylinders, O, P, provided with a spring knife or saw, Q, operated by cams, R, and also with alternate ribs or projections and grooves, for the purpose of nearly severing the filaments of the paper as it passes through between said rollers, and for the purpose also of creasing the paper for the more easily folding of it.

Third. I claim, in combination with the partially cutting and creasing cylinders, O, P, the different-sized cylinders, C, D, geared together for the purpose of tearing apart the partially cut paper, the cylinders, C, holding, and the increased motion of the cylinders, D, at their periphery (they being the larger) drawing the paper sufficiently to separate it.

Fourth. I claim, in combination with the separating cylinders, C, D, the tunnel, G, for guiding, and the wheel, E, divided into a suitable number of compartments, for receiving the sheets as they are delivered from the machine; the whole being constructed substantially as herein described, and for the purposes fully set forth.

JACO WORMB.

No. 8387.—*Blind or Shutter Fasteners.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the fast and free hooks with the inner plate, the same being arranged, as herein set forth, in such manner that the fast hook forms the pivot for the free one, and the two are connected to the inner plate in such manner that the movement, breakage, or removal of the free hook does not affect the security of the fastening, while, at the same time, the two hooks are secured to the inner plate by the fastening of the latter to the shutter.

WASHBURN RACE.

No. 8388.—*Improvement in Hand Stamps.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, is securing the plate of a hand-stamp to the shank or handle, by means of a universal ball and socket, or other joint, so as to allow the stamp to make a fair impression at whatever angle it may strike the material to be stamped, as herein fully set forth and explained.

STEPHEN P. RUGGLES.

No. 8389.—*Improvement in Piano Fortes.*

What I claim as my invention is the combination of the return screw, S, and button, T, or equivalent contrivance or contrivances, with the hammer and fly, and its retractive spring, so as to operate in manner, and in connexion with the same and other parts, substantially as herein described.

TIMOTHY GILBERT.

No. 8390.—*Improvement in Weavers' Shuttles.*

What I claim as my invention, and desire to secure by letters patent, is making the spindle and spring both in one piece, by extending the spindle behind the hole, for the pin that fastens it into the shuttle, and reducing it to a proper thickness, and bending it to form the spring required to hold the spindle in its proper positions in the shuttle, either with or without the catch on the end of the spring, in combination with the pin, D, or its equivalent, against which the spring acts to hold the spindles in the different positions required, substantially as described, thereby avoiding the inconvenience arising from the loosening of the screw which holds the spring in other shuttles, and saving the additional labor required to fit it in when the spring is made separate from the spindle.

LAROY LITCHFIELD.

No. 8391.—*Improvement in Weighing Carts.*

Having thus fully, clearly, and exactly described the nature, construction, and operation of my improved weighing car, what I claim therein as new, and desire to secure by letters patent, is the construction and arrangement, substantially as described, by which a weighing apparatus is capacitated for easy removal from place to place, by the adaptation to each other of the containing and weighing apparatus and of the running gear—that is to say, by making the fulcra (*i*) for the lever or weighing beam (*h*, *h'*) upon the axle near the wheel, the arm with its sliding weight lying upon the pole or tongue, (*l*,) and the axle affording, by its bent form, free egress to the contents of the box when discharged by means of the valve.

N. B. LIVINGSTON.

No. 8392.—*Improvement in Self-acting Presses.*

Having thus described the construction of my press, I desire it to be understood that I do not claim either the cams or the temple-joint, when used singly; but what I claim as new, and desire to secure by letters patent, is the combination of the eccentric cams, rolling on each other, so as to avoid friction in connexion with the braces or temple-joint, as above described, for the purpose and substantially in the manner aforesaid.

WM. MOORE.

No. 8393.—*Improvement in Saws for sawing and smoothing Boards.*

I claim, for the purposes above set forth, forming and arranging teeth of saws, substantially as herein described.

GEORGE F. WOOLSTEN.

No. 8394.—*Improvement in Instruments for the cure of Stammering.*

Having thus fully described my instruments for the cure of stammering, and their application and method of use, what I claim as my invention, and desire to secure by letters patent, is—

First. The employment of a tube in the mouth, which will admit of speaking, and of the passage of air, when either the tongue or lips would prevent the passage of air, substantially as hereinabove set forth.

Second. The employment of the adjustable springpad, substantially as hereinabove set forth.

Third. The joint employment of the mouth tube and the adjustable spring pad, at the same time curing the guttural, lingual, and labial disease of stammering, substantially as hereinabove set forth.

ROBERT BATES.

No. 8395.—*Machine for making Wheel Tires.*

What I desire to claim, and secure by letters patent, is the combination of the upper and lower dies with the welders, receiving motion from wedges attached to the upper and falling die, the whole acting to shape a tire on all parts of its surface at the same time, substantially as described in the within specification.

MARIA VAUGHN.

No. 8396.—*Improved Maze Lock.*

What I claim as my invention, and desire to secure by letters patent, is the disk, D, with its concentric and radial passages, or their equivalents, in combination with the bolt end, *o*, operated substantially in the manner and for the purposes herein described.

THOMAS NICHOLSON.

No. 8397.—*Machine for arranging Screw Blanks and articles of a similar character.*

Having thus described the principle, or mode of operation, of my said invention, and the manner of constructing and using the same, I wish it to be distinctly understood that I do not limit myself to the precise mode of construction and arrangement specified, as these may be varied without changing the character of my invention.

What I claim as new, and desire to secure by letters patent, is the combination of the inclined ways, substantially such as herein described, with a trough, substantially such as described, and provided with a pin or pins, or their equivalent, as described, so that, by the motion of the trough towards the ways, or *vice versa*, the screws or other articles will be forced up the inclined ways, hanging by their heads, as described.

THOS. J. SLOAN.

No. 8398.—*Improvement in Plotting Scales.*

What I claim to be my invention, and desire to secure by letters patent, is not the division into equal parts, with or without subdivisions of one or more of those parts, of the continuous edge of a scale or rule, nor the use of a vernier for measuring or describing right lines, nor the manner of attaching the vernier-slide to the main plate of the instrument, nor the use of a lever or slow motion screw, for adjusting the motions of the vernier-slide; but the combined application in one and the same instrument of the graduation upon the edge, (to obviate the imperfection and inconvenience attending the use of dividers or compasses,) and the slide carrying with it the several primary divisions of the unit, and those divisions carrying with them, respectively, by means of the vernier, the several secondary divisions into hundredths, or otherwise, so as to enable the operator to distinguish and apply hundredths, or half-hundredths of the smallest unit, with a great rapidity, precision, and ease, as tenths of the same unit, with the scale graduated on the edge, without a slide; and so, likewise, that whatever parts of a unit are required, or whatever the whole length of line to be measured, the whole amount of motion required in lengthening or shortening the instrument is only equal to the number of additional or intermediate hundredths, or other subdivisions, never exceeding one-tenth of the unit of measure.

LEMUEL H. PARSONS.

No. 8399.—*Improvement in Fountain Pens.*

What I claim as my invention is the improvement of the hollow flexible, and long extension of the reservoir or tube, as seen at *g*, to extend up and be secured to the arm of the writer, substantially in manner and for the purpose as specified.

NEWELL A. PRINCE.

No. 8400.—*Improvements in Machines for sawing Volutes.*

I do not claim the carriage, D, for carriages have been, and are now, applied to saw mills; but what I do claim as new, and desire to secure by letters patent, is—

First. The manner in which I produce the two motions necessary to be given to the block, in order that it may be sawed in the required form, viz: the screw rod, F, with its right and left screws cut upon it, mashing into the pinions, *t*, *t'*, by which motion is communicated to the horizontal rods, G, G', the toothed wheels, pinions, or spurs, *u*, *u*, grasping the edge of the block, and causing it to rotate, in combination with the bevel pinions, *l*, *m*, screw rods, *k*, and arm, *o*, by which a rectilinear motion towards the saw is given, the carriage and block producing the result described.

ELIJAH WHITEN.

No. 8401.—*Improvement in Mitre Boxes.*

What I claim is one or two rotary saw-guides, A, B, with sliding gauge rests, N, N, &c., and mechanism for rotating the guides, and fixing them in any desirable position, or positions, as specified, in combination with the improvement of making or applying the uprights, *c*, *d*, *e*, *f*, &c., or vertical supports of the saw to the bars, *a*, *b*, so as to be capable of being turned down to an angle with the horizon, for the purpose as described.

MATTHEW SPEAR.

No. 8402.—*Improvement in Shields for Valves.*

What I claim, and desire letters patent for, is surrounding the valve by a shield, constructed substantially in the manner as herein described and set forth, and fitting closely enough to regulate the ingress and egress of the water or steam, to such a degree as to prevent the slamming of the valve in opening and closing.

ALEXANDER JIMASON.

No. 8403.—*Improvement in the manufacture of Clay Pipes.*

Having thus described my improvements in apparatus for moulding clay pipes, I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is the use of the wire gauge frame, constructed substantially as above described, in moulding clay or earthen pipes, in the manner and for the purpose above specified.

I also claim the improvement above specified in the sack in which said pipes are suspended to be dried, said improvement consisting in confining said sack to two rails, kept parallel by means of cross bars, forming with them a rectangular frame, as hereinabove described.

JOSEPH PUTNAM.

No. 8404.—*Improvement in Machines for opening and cleaning Flocks.*

Having thus described the nature of my invention, what I claim as new, and desire to secure by letters patent, is the arrangement and combination of the conical revolving grater within the close grater case, combined with the blowers, in the manner and for the purpose substantially the same as described and represented.

EPHRAIM C. BRETT.

No. 8405.—*Improvements in apparatus for Applying flocks to Cloth.*

Having thus described the nature and operation of our invention, what we claim as new, and desire to secure by letters patent, is the revolving screen, D, having a beater within it on a shaft, E, as described, in combination with the corrugated rollers, B, B, B′, constructed and operating in the manner and for the purpose substantially as set forth.

DANIEL PRATT,
RANSOM PRATT.

No. 8406.—*Improvement in Tanning.*

What I claim as my invention or discovery, as a new and useful improvement, and desire to secure by letters patent, is the use of arsenic or arseneous acid, substantially in the manner and for the purposes herein set forth; the peculiar properties of arsenic, by which it tends to suspend the natural tendency of the animal fibre to decomposition upon the extinction of animal life, are well known, and of course they are not patentable; but their application to the processes of tanning, and otherwise preparing skins and hides for useful purposes, by which they are rendered stronger and more durable, is believed not to have been heretofore known and used.

I do not, therefore, intend to limit my claim to any particular mode or period of using the article; but I shall apply it in such form, or in such

strength of solution, as the nature of the case may require, to effect the objects named. Workmen should guard against the absorption of the poisonous qualities of the arsenic, while immersing or handling the skins in the liquor, by using tools or wearing India rubber gloves. After the skins are taken out of the liquor and rinsed thoroughly, the danger ceases.

N. C. TOWLE.

No. 8407.—*Improvements in the Endless Chain Propeller.*

Having thus fully described my improvements in horizontal operating or endless chain propellers, I do not mean to claim the invention of the endless chain propeller, or the application of the endless chains to communicate power from one wheel to another; but what I do claim as new, and which I desire to secure by letters patent, is suspending the endless chain propeller, which is to be put in motion by an endless chain running on the side wheel on the principal drum under water, in a rigid frame inside of the water tight chamber, the frame being capable of an upward and downward motion, parallel to itself, by means of the four racks and pinions, or their equivalents, acted upon by gearing connected each to each, said frame being connected with an indicator, by which the situation of the propeller may be ascertained; the whole constructed substantially in the manner and for the purposes herein described.

Second. I claim the sliding lid to the aperture in the bottom of the vessel, through which the propeller projects when lowered for operation; but when the propeller is raised inside of the vessel, the lid closes the aperture, so that the speed of the vessel may not be impeded, when under sail alone, by the action of the water on the aperture in the bottom, said sliding lid being worked by a screw, or its equivalent, in connexion with an indicator, by which the position of the lid can be seen, substantially as herein described.

CHARLES F. FISHER.

No. 8408.—*Improvement in devices for sowing, in a Seed Planter.*

Having thus described the construction and operation of my drill, what I claim therein as new, and desire to secure by letters patent, is the novel manner of discharging the seed by the natural motion of the horse or animal, while in the act of walking and propelling the drill, without the aid of wheels, with the arrangement of levers, arms, &c., for discharging the seed, or their equivalents, operating in the manner and for the purpose herein fully set forth and represented.

W. P. CLEMENTS.

No. 8409.—*Improvement in Escapements for Time Pieces.*

What I claim, and that for which I respectfully pray a patent may be granted, is the combination of the pallets and lever or levers here set forth with the above-described mode of communicating impulse to the balance in time pieces which keep time by means of a balance.

JAMES FULTON.

No. 8410.—*Improvement in Running Gear of Locomotives.*

What I claim as my invention, and desire to secure by letters patent, is the manner of employing the unflanged driving wheels, A, connected and arranged as described, with the flanged truck wheels, D, at the forward end of the engine, in combination with the flanged driving wheels, B, for the purpose of increasing the traction or adhesion of the driving wheels to the rails for overcoming steep grades without increasing the weight of the engine.

JAMES H. MURRILL.

No. 8411.—*Improvements in Revolving Boilers.*

Having thus fully described the nature of my improvements in steam boilers, what I claim therein as new, and desire to secure by letters patent, is the combination of the small cylinders, (*c, d*,) provided with apertures and rims as described, with the distributing chambers, (*f, f'*;) the whole revolving around a common axis, and operating substantially as described.

WILLIAM SCOTT.

No. 8412.—*Improvement in Revolving Breech Pistols.*

I do not claim to make the latch hook alone revolve on the barrel, but I claim the improvement of so connecting or combining the latch hook, the slide bearing of the rammer, and the lever with the barrel, by means of the swivel tube, or any analogous contrivance, as to enable them to be all simultaneously turned laterally, or revolve around the axis of the barrel, and thereby remove any obstruction to the elevation or upward movement of the barrel, such as may be necessary in order to effect the removal of the cylinder of charging chambers from the arbor on which it is supported.

JOSHUA STEVENS.

No. 8413.—*Improvement in Apparatus for warming Air and Water for Dwellings.*

What I claim as my invention, and desire to secure by letters patent, is the construction of a fire-proof apartment in houses, extending from the lowest extremity of the house to the roof, with furnaces at the bottom, the smoke pipes of other fires entering it, and winding along its walls to a chimney at the top, and with openings to let the heat in the apartment into the house, or up the chimney; and also for the construction of cisterns within the fire proof apartments, with pipes as above described.

LE GRAND C. ST. JOHN.

No. 8414.—*Improvement in Machines for cutting Screws on Posts and Rails of Bedsteads.*

What I claim as my invention, and desire to secure by letters patent, is the trifurcated travellers, G, in combination with the right and left screw axle, B, B, the carriage, H, saddles, I, hollow axle, *t*, and cutters, *s* and *v*, whereby the threads of two beam tenons and two sockets are cut by one and the same operation; the several devices being constructed and arranged in the manner and for the purposes herein set forth.

ORION THORNLEY.

No. 8415.—*Improvement in Portable Elevated Ovens.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement, as herein described, of the inner and outer concentric tubes with respect to the oven and pot hole, as described, whereby the oven is equally heated by a small fire, and the heat is directed by the inner upright pipe against the bottom of the kettle or other vessel; thus enabling the user to conduct simultaneously the several operations of baking and boiling with a small fire, and with economy of fuel.

PATRICK KILLIN.

No. 8416.—*Improvement in Machines for cutting Screws on Rails of Bedsteads.*

Having thus fully described the construction and operation of my hand implement for cutting right and left-handed screws on tenons of bedstead rails, what I claim as my invention, and desire to secure by letters patent, is—

First. In combination with the central screw shaft, D, through which the rotation of the cylinder, A, is effected, the hollow screw shaft, E, provided with an inverse and male screw thread and cylindrical case, F, having an inverse screw thread matching with the male screw thread of the hollow shaft, E; the whole being arranged as above set forth, and operated by means of the bolts, C and *b*, and cam, H, on the cross head, in such a manner as to feed the cylinder, A, frontward simultaneously with a right or leftward rotation thereof, as fully described and shown in the drawings.

Second. I also claim the employment of the screw shanks, J, J, provided with toothed wheels, K, K, made to match with toothed or ribbed plates, L, L, forming one of the sides of each box; the outer ends of said screw shanks, J, J, being confined in inverse screws, formed in plates *d, d;* whilst their inner or pointed ends are supported by plates, *k, k*, having projections k^2, k^2, against which the shoulder of the rail acts, for the purpose of actuating said screw shanks rotarily for imparting thereto a lateral movement, in such a manner as to cause their pointed ends to enter the rail, and be locked thereto by the spring levers, M; said screw shanks, J, being detached from the rail, when unlocked, by simply withdrawing the implement therefrom, as fully described and shown in figs. 2 and 3.

Third. I further claim the employment of the semi-circular plate, O, of the cross head, *c*, in combination with the spring levers, M, M, for the purpose of actuating said spring levers, M, in locking and unlocking the plates, *k, k*, of the screw shanks, J, J, at the terminus of the receding movement of the cylinder, A, whether cutting the right or left screw, as described and represented.

Fonrth. I also claim confining each V-shaped cutter, P, to the reversible cylinder, A, by means of the segmental brace plate, R, notched at one end, so as to interlock with the end of the shank of the cutter, projecting through an opening, S[a], in the cylinder, whilst its opposite end is made to fit against the frontward portion of the cutter, at S[a], said segmental brace-plate, R, being secured by means of a screw bolt, *s*, passing through it and the cylinder, and pressing upon the shank of the cutter, P, in such a manner as to form a complete lock thereto; there being a binding pressure at four points upon the cutter, viz: at either extremity thereof, at the connexion of the brace-plate, R, with the frontward end of the cutter, and the centre, by the confining screw bolt S, thus rendering it impossible to move the cutter without fracturing the segmental brace-plate, R, and displacing the screw bolts, S, as described and represented.

S. LEWIS.

No. 8417.—*Improvements in Locomotives moved by the power of Animals.*

Having thus described my apparatus for applying the force exerted by animals to the purposes of locomotion, what I claim therein as new, and desire to secure by letters patent, is—

First. The combination with the endless platform of an adjusting apparatus, by means of which the inclination of the platform to the frame of the power carriage may be varied, to enable the horses to work to the least advantage, whether to accelerate or to retard the movement of the impulsoria in traversing ascending or descending grades.

Second. I also claim the method of connecting the frame of the impulsoria with the pilot by means of a longitudinal shaft, which is fitted with mechanism, by means of which the impulsoria can be adjusted, transversely, to keep the driving axle level, and to prevent the endless platform from sloping crosswise when traversing a road, one of whose sides is higher than the other.

And, lastly, I claim, in an apparatus adapted to propulsion by animals, substantially as herein described, the employment of a single driving wheel, arranged in such manner as to admit of being leaned toward the hill, in travelling across slopes, to prevent a transverse sloping of the endless platform, in which the animals walk when the wheel thus arranged is steadied by a pilot before and a follower behind, or their equivalent, substantially as herein set forth.

CLEMENT MASSERANO.

No. 8418.—*Improvement in Insulators for Telegraph Wires.*

What I claim, and desire to secure by letters patent, is the re entering angle, at or near the base of the cup, as described, for the purpose of giving the wind a direction downwards, thereby preventing the rain that is driven by the wind from entering the cavity of the cup.

I also claim the annular disk, or washer, supported upon the centre shank or rod, and so placed within or at the open or lower end of the inverted cup as to prevent the free access of wind and rain to the inside of the the cup.

I do not claim the mode of embedding the shank in glass cast around it; but I do claim the application of the enamel, or glazing of porcelain, glass, or other vitrified, non-conducting material, to a surface of metal, when the same is used for insulating the wires of the electric telegraph.

JOHN MONTGOMERY BATCHELDER.

No. 8419.—*Improvement in Insulators for Telegraph Wires.*

What I claim as my invention, and desire to secure by letters patent, is my improved insulating supporter for telegraphic wires, composed of the supporting and protecting cover, A, the winged tube, B, the wire holder, C, and the insulating segments, *d*, *d*, arranged and combined with each other substantially in the manner herein represented and described.

Z. C. ROBBINS.

No. 8420.—*Improvement in Imitating Marble.*

What I claim as my invention is the process, substantially as described, of preparing and applying colors to glass, or other suitable transparent medium, so as to imitate the varied or colored appearance of polished marble or other mineral.

HIRAM TUCKER.

No. 8421.—*Improvement in Shower Baths.*

What I claim as my invention, and desire to secure by letters patent, is the manner of hitching and unhitching the bath, for the purpose of suspending it when raised, and lowering it when desired, by means of the hooks, L, P, in combination with the looped strap, I, carrying a pulley, K, arranged and operating in connexion with another pulley, M, substantially as shown and described.

WM. H. BROWN.

No. 8122.—*Improvements in Machines for Cutting Corks.*

Having thus fully described my improved cork-cutting machine, what I claim therein as new, and for which I desire to secure letters patent, is the cylindrical crown cutters, substantially as herein described, formed of an adjustable, cylindrical, smooth knife, surrounded by a burr cutter, the relative positions being adjustable, and the two being separable for sharpening, as fully set forth in the above description.

GEORGE HAMMER.

No. 8423.—(Suspended.)

No. 8424.—*Improvement in Machines for twisting Fringes of Shawls, &c.*

But what we claim as our invention, and desire to secure by letters patent, is the method of selecting from the mass the threads which are to be twisted into separate strands, by means of a reciprocating or vibratory finger, or the equivalent thereof, substantially as described, in combination with the first shell and wheel, or their equivalents, substantially as described, for giving the twist to the strands, as described.

We also claim, in combination with the first twister, the employment of the finger or fingers, or the equivalent thereof, for selecting and drawing together the strands which are to be twisted together to form the fringe, as described; and in combination therewith, we also claim the second twisting wheel and shell, or their equivalent, substantially as described.

JOHN NESMITH,
WESLEY SAWYER.

No. 8425.—*Improvement in Grinding Mills.*

I do not claim the original invention of the crushing cylinders, nor of a conical cast iron mill for grinding substances. But what I do claim as my invention, and desire to secure by letters patent, is the mode and manner of feeding the material to be ground directly from the crushing cylinders, through the opening in the outer cone, C, into the cavity in cone B, through the four openings therein, as they pass in turn under the opening in C, aforesaid, and thence, through the same openings, out of said cavity, between the two grinding cylinders, B and C; and also the mode and manner of making the said openings by the introvenient points, *e, e, e, e*.

And I also claim the arrangement of the teeth of the outer cone, C, into two sets: the first section at the smaller end being large and coarse, and turned so as to cut against the edges of the corresponding teeth of cone B; while the other section of teeth, or those towards the larger end, are finer, and turned in the opposite direction, so that their backs, and not their edges, are cut and ground upon by the edges of the corresponding teeth of cone B.

WILLIAM NEWLOVE.

No. 8426.—*Improved Door Lock.*

What I claim as my invention, and desire to secure by letters patent, is the combination in the same lock of the bolts, provided with two sets of diagonal slats, or their equivalents, the slide, running at right angles thereto, having pins, or their equivalents, and two key notches, and the drops acting as described, by which I make a right and left-hand lock, which must be locked before the key can be withdrawn, and which forces the operator to turn the key in a certain but different direction, according as either edge of the lock is uppermost.

CHARLES H. BEATTY.

No. 8427.—*Improvements in Machines for making Nuts, Washers, &c.*

What I claim as my invention, and desire to secure by letters patent, is the compressing and discharging the nut, or washer, by means of the follower or hollow piston, the bracket, the cross-head, and the moving die box, constructed and operating substantially as described.

WILLIAM KENYON

No. 8428.—*Improvement in Axle Boxes for Railroad Cars.*

Having thus fully described my improved oil box, what I claim therein as new, and desire to secure by letters patent, is the sliding partition, (*e*,) operated upon by a screw, or its equivalent, in combination with the inclined bottom at the inner end of the packing space, condensing the packing more at the inner end of the packing space than at the partition, whereby the oil is prevented from escaping, as well as insuring a constant supply of oil to the journal, substantially as herein set forth.

ROBERT LEVINGTON.

No. 8429.—*Improvement in Water Wheels.*

What I claim as my improvement is the combination of the curved partition, *d*, and the air space or passage, *p*, with each two buckets, and for the purpose of causing the escape of air from the bucket into the next one in rear, all substantially as specified.

JAMES L. PARKER.

No. 8430.—*Improvement in Overshot Water Wheels.*

What I claim as my invention, and desire to secure by letters patent, is the self-acting gates attached to the buckets of an overshot water wheel, in the manner described, and for the purposes herein set forth.

EDMUND SHEETZ.

No. 8431.—*Improved Pad Lock.*

Having thus fully described my improved pad lock, and its mode of operation, what I claim therein as new, and desire to secure by letters patent, is the arrangement of the bolt, tumblers, and springs, as herein set forth, the tumblers and bolt being operated by the same springs, which also serve the purpose of throwing out the shackle, the tumblers projecting beyond the end of the bolt for that purpose; all substantially as herein described.

THOMAS SLAIGHT.

No. 8432.—*Improvement in Stoves.*

What I claim therein as new, and desire to secure by letters paten of the United States, is making, as described, a space between the fire place and the back oven, the terminus of all the flues, and causing the vertical flue between the ovens to be an ascending or decending flue. by means of the register damper, as described. And I furthermore claim the combination of the first with the second feature, for the purpose and in the manner described.

ELISHA VANCE.

No. 8433.—*Improvement in Lamps for burning Vapor of Benzole, &c.*

What I claim as my invention, and desire to secure by letters patent, is the generator and lamp herein described, consisting essentially of chambers long and narrow at their lower extremities, and fitted with pipes, or their equivalents, for the introduction of air, the said chambers communicating at their upper extremities with a common reservoir, or vapor space, or chest, in which the vapors from the chambers are mingled prior to burning, and the relative volumes of the inflammable vapors being regulated by the adjustment of the respective currents of air, whereby the regular, proportionate, and economical consumption of the fluids is insured, and an equable light of the requisite intensity and volume is maintained, substantially as herein set forth.

CHAPMAN WARNER.

No. 8434.—*Improved Furnace employed in welding Shanks to Tools.*

Having thus described my improvements, I shall state my claims, as follow:

What I claim as my invention, and desire to have secured to me by letters patent, is the combination of the groove formed in the brick work above the fire with the aperture, *h*, *h*, leading thereto, and the reverberatory channel and exit flue leading therefrom, arranged with reference to each other and the fire, substantially in the manner described, whereby the flames, gases, &c., are caused to act upon both sides of such portions of the blade and shank as are to be welded to each other, and the other portions of the blade are protected from the heat, substantially as described.

JONATHAN WHITE.

No. 8435.—*Improvement in Air-heating Stoves.*

What I claim as my invention is as follows—that is to say: I claim the air space, I, I, the curved chamber, H, the series of descending pipes, K, K, and the ascending pipe, N, in combination with the air space, X, the chamber of combustion, and ash pit or chamber; all essentially in manner as specified.

GORDIN WILLISTON.

No. 8436.—*Improvement in Solar Lamps for burning Lard or Oils.*

Having thus described my invention, I do not claim either the use or construction of the deflector, button, or any part of the lamp separately considered; but what I do claim as my invention, and desire to secure by letters patent, is the combination of the stationary or an adjustable button, E, with a deflector of metal, B, placed above the base of the flame, attached to any lamp constructed with an argand burner for consuming lard or crude oil, substantially arranged as set forth in the foregoing specification.

JOHN G. WEBB.

No. 8437.—*Improvement in Argand Gas Burners.*

I therefore claim the construction and use of an argand burner and button, with a cone to regulate a supply of air to the base of the flame, in combination with an outside draught between the cone and a suitable glass chimney, to complete the combustion and turn the flame over the button, such parts being applied to burning carburetted hydrogen, or similar gas, substantially as described and shown.

JOHN G. WEBB.

No. 8438.—*Improvement in Insulators for Telegraphs.*

What I claim as my invention, and desire to secure by letters patent, is casting the glass insulators of magnetic telegraph and other wires of a cylindrical form, with a flange at one end eccentric with the periphery of the same, its upper part being even with the top, and its lower part dropped slightly below the cylinder, and forming the bore of the cylinder, likewise eccentric with the periphery, so as to allow a greater body of glass to form at its lower part than its upper part, where it is slit from its outer to its inner periphery, to allow the insertion of the wire, and inserting the insulator so formed into a horizontal hole, into which the wire is previously introduced through a slit at its side, bored through the post, or through a bracket secured on its side, or to a tree, and corresponding with the form of the flange which fits therein in such a manner as to insulate the wire from contact with the post, and prevent the glass from slipping round, and consequently the escape of the wire from the glass, as herein described, or in any other form, substantially the same as the form and modifications above described.

JOHN YANDELL.

No. 8439.—*Improvement in Burglar Alarms.*

My claims in the above-described invention I shall confine to a group or train of barrels or firing chambers, in combination with the pierced fuse and vent holes, constructed, prepared, and operated essentially in the manner and for the purposes above set forth and described.

JOHN G. BOLEN.

No. 8440.—*Improvement in the Tops of Cans or Canisters.*

Having thus fully described my invention, and the advantages thereof, what I claim therein as new, and desire to secure by letters patent, is the swaging or striking up the collar to receive the cover on the conical frustum, in place of soldering a separate one on, as heretofore.

ALFRED BLISS.

No. 8441.—*Improvement in Air-heating Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the combination of a revolving cylinder or cylinders with a fire-grate, to form a heating apparatus, as above described.

CHARLES A. BOGERT.

No. 8442.—*Improvement in Ships' Winches.*

Having described my invention, its mode of construction and operation, I do not claim the rigging of a winch or windlass with counter falls, for the hoisting and lowering of burdens on the counterpoise principle, at whatever relative distance of hoisting and lowering it may be fixed, simply as such; but I claim the combination in a ship winch of the principle of adjustability with the principle of counterpoise, whereby I am enabled to vary the relative distances of the hoisting to that of the lowering motion, so as to adapt its action to various changes of the relative distances of the hoisting to that of the lowering, as required in the lading and unlading of vessels.

I claim also therewith the principle of using a hoisting in connexion with a lowering fall, so that the burden is hoisted by one fall and lowered by the other, instead of interchanging the falls so that each load or parcel is both raised and lowered by the same fall, as has been practised in other counterpoise machines, by which means my winch is more convenient to use than it would otherwise be when the hoisting and lowering distances are dissimilar.

Second. I claim a fall or chain and hook, suspended over the deck or scaffold, working as a suspension chain and medium of transfer from the hoisting to the lowering fall of a ship winch, whereby I am enabled, as described, to transfer packages or burdens in sling from the hoisting to the lowering fall without reslinging or otherwise resting them.

THOMAS G. BOONE.

No. 8443.—*Improved Ore Washer.*

What I claim as my invention, and desire to secure by letters patent, is the combining in the same separating cistern the spiral channel, having a discharge aperture at the centre, and the revolving dasher, whose arms are immediately above the channel, for the purpose of separating metals from the impurities with which they are mechanically mixed, by acting in the manner substantially as described.

And I claim this construction, irrespective of the use of quicksilver in the channel, which may in some cases be dispensed with.

ARNOLD BUFFUM.

No. 8444.—*Improvements in dressing Cotton Duck.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the process, herein described, of softening and stretching cotton duck, by subjecting it, whilst strained, to jets of steam, and passing it over, under, or around heated stationary friction rollers, and between and around rotary pressing calender rollers, for the purposes herein specially set forth and described.

HORATIO M. GAMBRILL

No. 8445.—*Improvement in Printing Presses.*

What we claim as our invention, and desire to secure by letters patent is arranging upon a horizontally reciprocating carriage a blanket frame, D, pressing cylinder, C, set of inking rollers, J, and sheet-flyer, N, in such a manner that the two ends of the pressing cylinder shall roll upon the side rails, B, thus constituting a pair of the carrying wheels of the carriage, and producing a rotary motion of the pressing cylinder as it

passes over the type-form, and whereby the requisite motion is given to the blanket; the several parts being constructed and arranged substantially in the manner and for the purposes herein set forth.

JOHN R. HATHAWAY,
JOHN P. STRIPPEL.

No. 8446.—*Improvement in Washing Apparatus.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the application of boiler, (*h*,) with or without divisions, placed over the revolving boiler, resting on frame, (*i*,) the bottom of which boiler forms the upper half of the flue, (*m*,) by which both boilers are heated by the same fire, and from which the revolving boiler may be supplied with water, as herein fully described and represented.

JAMES T. KING.

No. 8447.—*Improvements in Apparatus for regulating the Speed of Engines.*

What I claim as my invention, and desire to secure by letters patent, is governing the throw of the variable cut off eccentric, C, for the purpose of operating the cut-off so as to regulate or equalize the speed and power of the engine, by means of the balance of or difference between the constant friction produced by the revolution of a pulley, Y, which is hung loosely upon the same shaft with the said eccentric, and driven at a speed which always bears the same proportion to, but is greater than the speed of the shaft, and the variable friction of a brake shaft, T, upon a wheel, D, which is also hung loosely upon the same shaft, and which receives or is acted upon by the aforesaid constant friction of the pulley, the tightness of the brake strap, and the friction produced by its being controlled by a common steam engine governor; the whole operating substantially as described, the said balance or difference of friction producing either a uniformity or difference between the speed of the shaft and of the wheel, D, and the said difference in speed causing motion to be given to any train of mechanism, substantially such as is described, in communication with the eccentric.

H. A. LUTTGENS.

No 8448.—*Improvement in Machinery for enamelling Mouldings, &c.*

What I claim as my own invention is the arrangement of the conveyor, constructed so as to form, in connexion with the moulding or the article to be enamelled, a reservoir to contain the composition, said moulding forming, as it were, a sliding bottom to the reservoir, by which means the composition is spread upon its surface, as set forth. I claim also the clamp for fastening and releasing the end of the article to be enamelled; the whole being constructed and operating substantially in the manner and for the purpose described therein.

ROB'T MARCHER

No. 8449.—*Improvement in the Mouth-Piece for Wind Instruments.*

What I claim as my invention, and desire to secure by letters patent, is a mouth-piece, with an artificial embouchure, or lips, attached to it, using for that purpose any elastic and water-proof material which will produce the intended effect.

CHARLES L. MEECH.

No. 8450.—*Improvement in Sugar Vacuum Pans.*

Having thus fully described my improved apparatus, and its purposes, I claim as my invention, and desire to secure by letters patent, firstly, the evaporating and condensing tubes, constructed and arranged in the manner and for the purpose set forth; they, being attached at one point only, through which the steam enters, have freedom to expand or contract without injury; and the evaporating tubes being combined at the centre of the series, as above especially set forth, with the boiler, the steam is conveyed from the boiler to the extremities of all the tubes in the most direct manner.

I also claim connecting the filters with the vacuum pan, in the manner and for the purpose set forth, so that the vacuum pan shall perform the double office of making the vacuum in the filter and boiling in vacuo.

I also claim the construction and arrangement of the condenser tubes, above specified, the ends of said tube being turned back inward nearly the whole length of the outer portion, as distinctly shown in the drawing.

J. M. MILLER.

No. 8451.—*Improvement in Running Gear of Railroad Cars.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the bar, B, B, and ball and socket joint, D, E, attached to the end of B, B, with a hinge in combination with the pivot, C, on the truck-frame, for directing and turning said frames, (but not drawing the train by said ball and socket-joint, as I do not dispense with the ordinary traction or coupling bar, H,) and thus bring the axis of each truck coincident with the radii of the curve of the track, and lead the whole train over any point on the track previously passed by the locomotive, without requiring the action or aid of the flanges, or any of the wheels, except those on the locomotive; thus preventing the abrasion or wear of the rails and liability of the train being thrown off.

W. NEBINGER.

No. 8452.—*Improvement in Piano Forte Strings.*

I do not claim, as my invention, simply the application of silver to the strings of pianos, for the purpose stated, as that has before been done by wrapping the strings with silver wire; but, when wrapped with wire, are liable to rattle when struck by the hammers.

What I do claim as my invention, and desire to secure by letters patent, is coating the smaller strings of pianos with silver, or an alloy thereof, for the purpose of improving the tone and preventing the rusting of the strings, substantially as specified.

HENRY J. NEWTON.

No. 8453.—*Improvement in Excavating Machines.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, is the within-described arrangement of parts, by which the elevators can be raised or lowered to correspond with any irregularity or unevenness of ground.

And I also claim making the operation of dumping self-operating, by means of the friction roller acting on the periphery of a pulley permanently attached to the shaft, as herein fully described and represented, and for the purpose made known.

BENJAMIN W. REMY.

No. 8454.—*Improvement in Saddles.*

What I claim as my invention, and desire to secure by letters patent, is the combination of levers and spring as set forth in the specification and drawings.

JOHN C. FR. SALOMON.

No. 8455.—*Improvement in Cast Iron Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, in the shape of cast-iron car wheels, is the forming of said wheels with corrugations in the direction of the radii, which corrugations are reversed in passing from the hub to the rim, so that the parts convex at the hub, in passing towards the rim, gradually lessen their convexity, and then become concave, and increase in their concavity till they reach the rim; and so that, on the other hand, the parts concave at the hub, in passing towards the rim, gradually lessen their concavity, and then become convex, and increase in their convexity till they reach the rim; the arches or central lines of the corrugations thus cutting obliquely and passing through, alternately, from one side and from the other, a plane supposed to be at right angles to the axis of the wheel, and to pass through the middle of the hub; and the said corrugations, in their radial direction, being either straight or curved; the whole constructed substantially in the manner and for the objects herein set forth.

BENJAMIN SEVERSON.

No. 8456.—*Improvements in Machinery for shaving, nicking, and re-shaving Wood Screws.*

Having thus described the principle or character of my invention, and the manner of constructing and using the same, I wish it to be distinctly understood that I do not limit myself to the precise construction and arrangement of the parts, as these may be variously modified without affecting the principle or mode of operation which I have invented and claim to be new.

What I do claim as my invention, and desire to secure by letters patent, is so combining the shifting mandrel that carries the blanks with a shaving and nicking apparatus, substantially as described, that the blank, after being shaved to give the required form to the head, and whilst held in the same mandrel, may be shifted to the nicking apparatus, and, after being nicked, reshifted back to the same shaving apparatus, to have the bars removed by the same cutter that performed the first shaving operation, as herein set forth.

I also claim the employment of two shifting mandrels, substantially as specified, in combination with the shaving and the nicking apparatus, substantially as herein described, so that the nicking operation can be performed on one blank whilst the first and second shaving operations are being performed on other blanks, as specified.

And I also claim giving to the mandrel, or mandrels, end-play in their boxes, in combination with the permanent rest at the back of the mandrel, and with the cutter, substantially as specified, by means of which the same position of the blank relatively to the cutter is obtained for the second shaving operation which it had for the first, as described.

THOS. J. SLOAN.

No. 8457.—*Improvement in Box Opener.*

What I claim as new, and desire to secure by letters patent, in an instrument for opening boxes, is the combination of the lever, A, with the brace, F, constructed and operating substantially as described, either with or without the heel, H.

GEO. C. TAFT.

No. 8458.—*Improvement in Machines for Dressing Stone.*

Having thus fully described the construction and operation of my machine, what I claim therein as new, and desire to secure by letters patent, is the manner of attaching the pick-head to a strong, but flexible steel spring, which falls on a box spring, whereby the desirable whip or spring blow is given to the pick, substantially as described.

I also claim the combination of the lever, F, and connecting lever, G, and crank screw, for graduating the action of the pick while cutting the furrow of mill stones, gradually decreasing the force of the blow as the pick approaches the feather edge of the furrow, substantially as described and represented.

JOSEPH Y. TILTON.

No. 8459.—*Improvement in the Seeding Apparatus of a Seed Planter.*

What I claim as my invention, which I desire secured to me by letters patent, is giving the seed-rollers an intermittent rotary motion, substantially in the manner and for the purposes set forth.

CORNELIUS C. VAN EVERY.

No 8460 —*Improvement in Machines for peeling and cutting Peaches.*

What I claim as my invention, and desire to secure by letters patent, is the application of a revolving rasping surface to the purpose of peeling peaches, or other like fruits; and also the method of cutting peaches by a knife revolving in a box, having an opening in the bottom, in such a manner that the stone of the peach is struck out and the pulp thereof cut into pieces proper for drying, in the manner above described. And

I claim and desire that such letters patent should secure to me the aforesaid methods of peeling peaches, and of cutting the same, as well separately as when combined together, in the manner hereinbefore particularly described.

JOSHUA O. WARD.

No. 8461.—*Improvement in Swinging Cradles.*

What I claim as my invention, and desire to secure by letters patent, is the self-adjusting pivot or connexion, produced by the ball or weight, M, suspended from the arc, o, o, by bent rods or hooks, P, P, said hooks having sufficient adhesion to communicate motion to the cradle from the motive-power before described; thus constituting a sliding instead of a fixed pivot upon the end of the cradle, making it a matter of indifference on which side of the cradle the child may be lying, without stopping the motion of the cradle, which, with the crank alone, would stop. The action of this cradle is so gentle, and works so steadily, as to be free from noise.

LUCIUS F. WHITAKER.

No. 8462.—*Improvement in Portable Water Closets.*

Having thus fully described the nature of my invention, and the manner in which it is constructed, what I claim as new, and desire to secure by letters patent, is the manner of construction as described, and for the purpose specified, viz: the vessel, B, resting upon the partition, *a*, in the interior of the case, A, and the circular rim, D, projecting a short distance over the edge of the cover, C, when on the vessel, B, and resting upon the top edge of the vessel, B, when the cover, C, is off of it, in order to form the seat; the whole arrangement being covered by the cover, E, of the case, A, substantially as set forth.

GEO. R. WILMOT.

No. 8463.—*Improvement in Seed Planters.*

Having thus described the nature and operation of my invention, I will now state what I claim as new, and desire to secure by letters patent.

I claim the employment of the indicator, I, having its ends bent as described, or in any other manner substantially the same, and secured on the main shaft in such a manner that it can be disengaged or thrown into connexion with the wheel as desired, for the purpose of indicating the place where the corn has been planted, in the manner and for the purposes substantially as set forth.

MYRON CORY.

No. 8464.—*Improved means for attaching Augers, &c., to their handles.*

Having thus described the nature of my invention, and the manner in which it is constructed, what I claim as new, and desire to secure by letters patent, is the method of securing augers, and other implements, to handles by means of a socket, D, and ferrule, or cylindrical slide, E, constructed as described, viz: the socket being placed underneath a mortise hole, C, in the handle, and perforated with an oblong slot, *(a,)* the edges of the slot being bevelled to correspond to notches *(c)* in the shank, B, of the implement, the upper surface of the socket being inclined, and the shank, B, moved along the slot *(a)* by means of the ferrule or cylindrical slide, by which the bevelled edges of the slot bind or wedge in the notches, and the taper form of the shank drawn firmly in the hole (*d*) through the ferrule or slide, substantially as described.

MERRITT S. BROOKS.

No. 8465.—*Improvement in Machines for pegging Boots and Shoes.*

Having thus described my improvement in the implement for pegging shoes, what I claim as new, and desire to secure by letters patent, is splitting the peg from the peg-wood, and driving it into the sole of the shoe, by a single blow of the plate, E, acting on the peg-wood, and forcing it upon the knife, I, substantially as herein described.

I also claim mounting the peg-wood or block in a vertically sliding carriage, or the equivalent thereof, in combination with the stop-plate, S', knife, I, and fingers, T', operated substantially as herein set forth.

A. C. GALLAHUE.

No. 8466.—*Improvement in Machines for drying Bagasse.*

Having thus fully described my improvements in apparatus for drying bagasse, &c., I wish it to be understood that I do not claim for such purposes a heated cylinder, revolving upon an inclined axis, such cylinders, in various forms, having been long in use; but what I claim herein as new and of my invention, and desire to secure by letters patent, is—

Firstly. The arrangement (substantially as herein described) of two cylinders, one so secured (by hollow bolts or rivets) concentrically within the other as to leave between them an annular steam space, crossed by ventilating apertures, and the whole made to revolve around an inclined axis, for the expeditious drying (free from the danger of accidental ignition) of bagasse, and other like substances.

Secondly. The steam and condensed water pipes, revolving together (one within the other) within a common journal bearing, and entering the steam space of the cylinder, in oppositely oblique directions, as described, for facilitating at the same time the discharge of the water and the omission of steam, during the revolution of the cylinder.

SAMUEL H. GILMAN.

No. 8467.—*Improvement in Boot Trees.*

What I claim as my invention, and desire to secure by letters patent is the set-screws, *m* and *n*, and plate, *x*, in combination with the screw, *g*, substantially in the manner and for the purpose herein described and set forth.

D. R. HENDRIX.

No. 8468.—*Improvement in Swinging Cradles.*

What I claim as my invention, and desire to secure by letters patent, is the combination of a cradle with pendulum rods and balls, or weights, attached thereto, and set in a frame so as to swing therein, in the manner and for the purpose above set forth.

SELDEN W. KNOWLES.

No. 8469.—*Improvement in Oil Presses.*

Having described my invention, what I claim as new, and wish to secure by letters patent, is as follows—

The combination of the heating plates with the steam chamber, substantially as herein set forth, the plates being moved parallel, and the steam tubes connecting them with the steam chamber sliding in stuffing boxes in a line with the motion of the plates above set forth, said steam chamber being placed in a proper relative position with the plates for that purpose.

D. L. LATOURETTE.

No. 8470.—*Improvement in Piano Fortes.*

What I claim as my invention, and desire to secure by letters patent, is, first, the manner, substantially as herein described, of placing or arranging the strings of a piano forte, to wit: the shorter string or strings of the higher octaves across the narrower portion of the instrument, and the longer strings, or those of the lower octaves, crossing them in the direction of the greatest length of the instrument, so as to include the greatest possible size of string within the instrument, for the purposes specified.

FR. MATHUSHEK.

No. 8471.—*Improvement in the method of moulding Kettles with Spouts.*

Having thus described my method of moulding tea kettles, I do not claim any peculiarity either in dividing the pattern or using a green-sand core; but what I do claim as my invention, and desire to secure by letters patent, is providing the pattern, B, with two projections or solid pieces—one, G, on the under side of the spout portion, D, to prevent sand entering the spout when forming the green core of the body, and the other, H, on the upper side of the spout, D, for forming a print in the sand to receive the projection, I, of a dry sand core, G', I, by the use of which, in connexion, the said dry sand spout core, G' I, can be inserted in the drag portion of the mould after the removal of B, but before the removal of A, and be held firmly in its required position, by which means the pattern, A, is made to adjust the spout core, and greater truth secured in setting the spout core, and fewer defective casts result; in the manner set forth substantially in this specification and accompanying drawings.

W. H. PEASE.

No. 8472.—*Improvement in Dairy Stoves.*

Having thus fully described the improved apparatus, and its mode of construction, what we claim therein, and desire to secure by letters patent, is, first, the arrangement of the flues and valves in combination with a water pan and fire-box, substantially in the manner and for the purpose set forth.

We also claim the combination of flues and valves as herein specifically mentioned, for the purposes described.

JOEL STEVENS,
H. J. RUGGLES.

No. 8473.—*Improvement in Machines for taking Yeas and Nays.*

What we claim as our invention, and desire to secure by letters patent, is the method of dividing the yea and nay votes, and showing the vote by weighing the yea and nay balls, or their equivalents, in the opposite pans of a scale beam, substantially as herein set forth.

We also claim the method of enumerating the votes upon a question by weighing the balls, or their equivalents, by spring balances, or their equivalents, whose indexes indicate the number of ballots in their respective scale pans, substantially as herein set forth.

We also claim the combination of the scale beam and spring balances, or the equivalent thereof, arranged substantially as herein described, for the purpose of showing simultaneously both the number of votes taken on each side of the question and the relative values of the two sets or classes of votes, as herein set forth.

We also claim the employment of mechanism for the purpose of recording the vote and showing whether it is yea or nay at a single operation, substantially as herein described.

We also claim the employment of mechanism for the purpose of recording the vote and showing the enumeration thereof at a single operation, substantially as herein described.

And, lastly, we claim the employment of mechanism for the purpose of recording and enumerating the vote, and showing whether it is yea or nay at a single operation, substantially as herein described.

THOS. B. STOUT,
JAMES F. MORELL.

No. 8474.—*Improvement in Cements for grinding Cylinders.*

Having thus fully described my improved composition, and the manner of applying it, what I claim therein as new, and for which I desire to secure letters patent, is the composition herein described, consisting of the whey of milk, vinegar, glue, spirits of wine, and ether, substantially in the manner and for the purpose set forth.

I also claim the combination thereof with emery to construct a grinding cylinder or other surface, in the manner described.

JACOB STEPHEN.

No. 8475.—*Improvement in Machines for printing in Colors.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is in combination with receiving, distributing, and inking rollers, arranged as herein described, the adjustable ink trough, provided with removable partitions, and perforated side, so as to give out the ink in lines or belts, corresponding with the lines or size of the type, in the form for the purpose herein described.

R. S. WEAVER.

No. 8476.—(Suspended.)

No. 8477.—*Improvement in the use of Steam to make Zinc White.*

Having thus fully described the nature of my invention, and some of the means by which the same may be put into practical use, what I claim therein as new, and desire to secure by letters patent, is mixing the vapor or gases of water or steam with the heated vapor of zinc, or of its ores, as set forth, for the purpose of manufacturing zinc white for commercial uses.

I also claim, in combination with the process for manufacturing zinc white, substantially as herein described, the making of hydrogen gas for light, heat, or motive power, as herein fully set forth.

HENRY W. ADAMS.

No. 8478.—*Improvement in Baby Jumpers.*

I do not claim the use of spring, or the means of giving motion for the purpose of exercise or amusement, as that has been before employed in a variety of ways; but I do claim the combining of springs with a frame and seat in the manner described, forming an apparatus for teaching children to stand and walk, and, at the same time, to prevent the child from bearing its whole weight upon its feet, as it sits upon the seat or saddle, and can at its option either stand upon its feet or sit down; and at the same time move itself in any direction with its feet and its body securely sustained in an upright position, after the upper top is locked around its waist, in the manner described; and it can at its option either move by a motion of its limbs, or use the machine as a jumper for amusement, as the accompanying description and drawing represent.

EUCLID RICE.

No. 8479.—*Improvement in Apparatus for watering Cattle.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is in combination with a pump, worked by an endless chain of elastic balls, and operated upon by the weight of cattle, the spiral spring, *(r,)* operating between a stationary collar and the movable cogged and threaded sleeve, (E,) for the purpose of more certainly running the sleeve into gear when the cattle step upon the platform, and for gradually stopping the platform as it rises, and the buckets as they run back into the stack or pipe, for the purpose of carrying back the water, as herein fully described and represented.

S. W. WOOD.

No. 8480.—*Improvement in Threshing and Separating Grain.*

First. What we claim as our invention, and desire to secure by letters patent, is the method, herein described, of constructing threshing cylinders with curved knives, or otherwise shaped in the end, for the purposes herein described.

Second. Also, the method, already described, of working the separator by means of the jumping wheels and concave tracked brackets, or by any modification of it whereby the action is substantially the same.

CYRUS ROBERTS,
JOHN COX.

No. 8481.—*Improvements in Air-Engines.*

What I claim as my invention, and desire to secure by letters patent, is the working cylinder and piston, and the supply cylinder and piston, of less piston surface, the two pistons being connected with each other, and working together, substantially as specified, in combination with the regenerator and heater, so that the air, or other circulating medium, shall pass from the supply cylinder to the working cylinder through the regenerator, substantially as specified, and give motion to the engine through the difference of area of the pistons; and this I claim, whether the air, or other circulating medium, be made to pass on the return stroke from the regenerator to the supply cylinder, or any other receiver, or into the atmosphere.

I also claim, in connexion with the working cylinder, the employment of two regenerators, substantially as specified, in combination with the valves, or their equivalents, for the purpose of causing the air, or other circulating medium, to pass, during a series of strokes, through one of the regenerators to the working cylinder, and back from the working cylinder through the other regenerators, and then reversing the action, as substantially specified.

I also claim interposing the heater between the regenerator and the working cylinder, substantially as specified, to heat the air, or other circulating medium, as it passes from the regenerator to the working cylinder, as specified, to supply the heat required.

And, finally, I claim communicating the power of the engine to the working beam or its equivalent, by the attachment thereof to one of the pistons, or piston-rods, between the open ends of the two cylinders, said pistons being connected or braced to each other, substantially as specified, whereby I am enabled to render the engine compact, and effectually to brace and connect the two pistons and avoid undue strain, as specified.

J. ERICKSON.

No. 8482.—*Improvement in Machines for forming Horse Collars.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the moving, tapering block with the adjustable stationary dies; the two being constructed and arranged substantially as herein set forth.

ISAAC DAVIS.

No. 8483.—*Improvement in Cultivators.*

What I claim, and desire to secure by letters patent, is the intermediate jointed ploughs, in combination with the main cultivating ploughs, as described, for enabling the ploughman to plough nearer to, or further from, the rows at will.

ISAAC CONSTANT.

No. 8484.—*Improvement in Seed Planter.*

Having thus described the nature and operation of our invention, what we claim as new, and desire to secure by letters patent, is in combination with the seed box, A′, and cap, *n*, arranging the rotating disk, *i*, vertically, and providing it with the projections, *j*, and the stationary vertical disk, *b*, provided with an opening, *h*, for receiving the grain and the flanches, *c*, *e*, between which the said projections rotate, and by which the grain is carried from the seed box to the cap, and thence to the seeding tube; the whole being arranged in the manner and for the purpose specially set forth and described.

NEWTON FOSTER,
GILBERT JESSUP,
HIRAM L. BROWN,
CALVIN P. BROWN.

No. 8485.—*Machine for measuring and cutting Iron.*

What I claim as my invention, and desire to secure by letters patent, is the measuring wheel, placed in any suitable position, in combination with the cutter, bed plate, and spring, or its equivalent; the whole being arranged and combined, substantially as described, for the purpose herein set forth.

LEVI B. GRIFFITH.

No. 8486.—*Improvement in Desks.*

Having thus fully described the construction and operation of my elevating desk, what I claim as new, and of my invention, and desire to secure by letters patent, is the raising of a horizontal surface at the back part of the desk or table when the front part is being raised, to form an inclined plane by means of the arrangement of the screw and lever, or any analogous device, the front part being hinged to the elevating frame, K; the same to be applied to standing or sitting desks or tables, substantially in the manner and for the purpose set forth.

JOHN T. HAMMITT.

No. 8487.—*Improvement in Radiating Surfaces.*

What I claim, and desire to secure by letters patent, is the application of the tapering form to radiating surfaces, constructed in the compact and available manner above described.

JOSHUA K. INGALLS.

No. 8488.—*Improvement in Tanners' Oil from Rosin.*

What I claim as my invention, and desire to secure by letters patent, is the new and original product or manufacture which I denominate Robbins's tanners' oil, or Robbins's curriers' oil, the process of producing which I have herein fully set forth.

I also claim every use and application of my said oil.

LEWIS S. ROBBINS.

No. 8489.—*Improvement in lubricating Oil from Rosin.*

What I claim as my invention, and desire to secure by letters patent, is the new and original product or manufacture which I denominate

Robbins's lubricating oil, the process of producing which I have herein fully set forth.

I also claim every use and application of the said oil.

LEWIS S. ROBBINS.

No. 8490.—*Improvement in distilling Acid and Naphtha from Rosin.*

Having thus fully described my new and improved process of distilling rosin, what I claim therein as my invention, and desire to secure by letters patent, is—

First. The process of separating the acid and water, arising from the decomposition of rosin, at the temperature of 325 degrees Fahrenheit, or thereabout, by means of fire heat, substantially in the manner herein set forth.

I also claim, in combination with the above, the process of separating the naphtha from the other component parts of the rosin by preserving the temperature of the liquid mass within the still at about the range of 325 degrees Fahrenheit, as above stated, and injecting steam into the same, by which I am enabled to throw off the naphtha at the same temperature employed for throwing off the acid.

I do not intend to limit my improved process of distillation, as hereinbefore described, to the production of oil from rosin, but shall employ it for redistilling the crude article known as rosin oil.

LEWIS S. ROBBINS.

No. 8491.—*Improvement in Paint Oil from Rosin.*

What I claim as my invention, and desire to secure by letters patent, is the new and original product or manufacture which I denominate Robbins's paint oil, the process of producing which I have herein fully set forth.

I also claim every use and application of my said oil.

LOUIS S. ROBBINS.

No. 8492.—*Improvement in the manufacture of Charcoal.*

What I claim as my invention, and desire to secure by letters patent, is the iron cylinder with a double bottom, the upper one being perforated, and these combined with several flues, covered at the top with dampers, and protected within with iron rings, the whole so constructed that the fire may be applied either on the top, under the bottom, or within the flues, or in all together, at pleasure; and the whole adapted, as herein described, to the uses and purposes specified, and these only.

WM. P. McCONNELL.

No. 8493.—*Improvement in Folding Doors of Stoves.*

Having thus fully described my improved doors for grates and stoves, what I claim therein as new, and for which I desire to secure letters patent, is the sliding and folding doors, in combination with pilasters, by which I prevent the heating of the doors and warping consequent thereon and admit a free radiation of heat from the side of the stove, substantially in the manner and for the purposes set forth.

JAMES ROOT.

No. 8494.—*Improvement in processes for Dyeing Blue.*

I claim as my invention the mode of producing a dark blue, or color to take the place of indigo, which color can be produced at a very great saving of expense, in comparison to that incurred by the employment of indigo in the usual way.

I do not mean to claim the use of a prussiate of potash dye alone; but do claim the employment of such dye, in combination with either one or more of the above-named woods, substantially in manner as specified.

EDWARD SWINEY.

No. 8495.—*Improvement in Compounds for Extinguishing Fires.*

What I claim is the application of a compound of sulphur and nitre, in a state of combustion, within a room or apartment on fire, for the purpose of extinguishing the fire tending to destroy the said room or building thereof.

JOSHUA UPHAM.

No. 8496.—*Improvement in Springs.*

Having described the nature of my said invention, and the manner of performing the same, I declare that I claim, as of my invention, the above specified mode of arranging or combining springs and inclined planes, or surfaces, curved or plane, so that the points, or arms, of the springs may be applied to or press against the inclines, or inclined planes, for the purpose of thereby obtaining the action of said springs, in manner hereinbefore described.

JAMES WEBSTER.

No. 8497.—*Improvements in Planing Machines.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, is the application of springs or weights to cutter stocks, both at their point, in line with the cutting-edge of the knife, and also to the heel, by which a double action is given to the stock, both at the heel and edge, allowing it to rise and oscillate to the inequalities of boards or plank, substantially as described and for the purposes herein set forth.

GEO. W. BEARDSLEE.

No. 8498.—*Improvement in Carriage Springs.*

My improvement, and, therefore, what I claim, consists in combining buttress blocks, C, D, with the wood bar, A, and the metallic strap bar, B, in such manner, substantially as specified, so that such blocks, when the spring is in use, shall act as levers, to compress the wood and counteract the tendency of the fibres to be elongated and ruptured by the downward strain.

LEVI BISSELL.

No. 8499.—*Improvement in Machines for Dressing Staves.*

What I claim as my invention, and desire to secure by letters patent is dressing staves by means of stationary knives, in combination with a pressure-roller, directly over the cut, when this is combined with the bed, constructed with a raised portion where the cutting is done, for the purpose of allowing a crooked or bent stave freedom of motion while being dressed, substantially as described.

LEWIS S. CHICHESTER.

No. 8500.—*Improvement in Bating and Tanning Hides.*

What I claim as my invention, and desire to secure by letters patent, is the method, herein described, of bating hides and other skins in the process of tanning, by subjecting them to a vapor bath, applied substantially in the manner herein described.

I also claim the combination of the rocking frame and the shaft above, the two being connected, as herein set forth, in such manner that the shaft may be used either to rock the frame or to raise it from the vat.

WM. B. MILLIGAN.

No. 8501.—*Improvement in Cheese, Butter, and Bread Cutters.*

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the circular revolving table (*e*) and knife, (*l*,) the said knife being attached to the sliding shaft, (*i*,) and operated by means of a treadle (*k*,) and weighted cord and pulley, or their equivalents, so that the cheese, or other article to be cut, may be placed upon the table and not removed until, by a single revolution of the wheel, and a few slight pressures of the foot upon the treadle, it is cut into as many parts as may be desired, without crumbling or waste.

B. F. ADAMS.

No. 8502.—*Improvement in the construction of Scythe Fastenings.*

What I claim as my invention, and desire to secure by letters patent, is the mode of adjusting the lever, D, by rotating the ring, C, around its own axis, by which the point of the scythe is thrown out or drawn in, as shown and described, the upper end of the lever, D, passing through an eye, *g*, attached to the ring, C, the fulcrum of the lever being near the end of the snath, as shown at *e*, and the scythe attached to the lower end of the lever, as set forth.

DAVID ANTHONY, SEN.

No. 8503.—*Improvement in Hand Planes.*

What I claim as my invention, and desire to secure by letters patent, is the application to carpenters' planes and moulding tools of a new method of confining the iron, by a metallic apparatus, acting upon the principles of the lever and cam, in combination with the set screw for adjusting the same, as herein described, using for the purpose the aforesaid contrivance or arrangement of parts, or any other substantially the same, and which will produce the same effects in like manner.

BENJAMIN F. BEE.

No. 8504.—*Improvement in Screens of Winnowing Machines.*

I do not claim any part or portion of the gear, fans, or forms of the hopper or shoe as an original invention, as I am aware that all these have been in common use.

But what I do claim as new, and desire to secure by letters patent, is the arrangement of guides, D, D, and side apertures on the upper movable screen, as seen in figure 3, and the lower screen, as seen in figure 4, attached to the shoe, and which screen may be attached to any common winnowing machine, in the manner and for the purposes before described.

JONATHAN BEAN.

No. 8505.—*Improvement in Stave Jointing Machines.*

What I claim as my invention, and desire to secure by letters patent, is the adjustable knife, in combination with the adjustable rest, as described, to adapt them to the jointing of staves for casks of different bilge.

DANIEL DRAWBAUGH.

No. 8506.—*Improvement in Shuttle motions of Looms.*

What I do claim, and desire to secure by letters patent, is hanging the picker staff or staves upon radius rods, D and E, having two distinct radial motions, substantially as herein set forth, for the purpose of causing the end which operates upon the shuttle to describe or make a rectilinear motion parallel with the raceway, and with less power than has heretofore been done.

GEORGE W. PERRY.

No. 8507.—*Improvement in Machines for cutting the Soles of Boots and Shoes.*

What I claim as my invention, and desire to have secured to me by letters patent, is the mode or means, hereinabove described, for insuring the unerring turning of the knife-frame for cutting both sides of the sole, said means consisting of the notched pawl lever and spring, *y*, *y*, operating on the journal plates of said frame, substantially as hereinabove described.

JOSEPH STEGER.

No. 8508.—*Improvement in Car Seats.*

Having thus described the nature of our invention, what we claim as new, and desire to secure by letters patent, is the arrangement of two levers in a cross position, so that any required height of back may be carried and reversed from and to either side of the seat, and secure it firmly in its position at any required angle, substantially the same as described and represented.

EZEKIEL BOOTH,
EZRA RIPLEY.

No. 8509.—*Improvement in Telescopes.*

What I claim as my invention, or improvement, consists in combining the glasses, or glasses and diaphragms, with a sliding or eye-piece tube, A, of a telescope, by means of a tube, or slide, B, perforated through its side or sides in such manner as to enable a person, when the said tube, B, is withdrawn from its enclosing tube, to obtain ready access through the openings, or perforations, to the glasses, or lenses; the whole being substantially in the manner and for the purpose as described.

ALVAN CLARK.

No. 8510.—*Improvement in Machines for cutting Hides.*

What I claim as my invention is the combination of mechanism for reducing dry hide to a strip, and mechanism for cutting or removing the hair from the under-side of the said strip, at one continued operation, substantially in the manner as described.

JACOB C. FLINT.

No. 8511.—*Improvement in bending Felloes.*

What I claim as new, and desire to secure by letters patent, is the curbs, C, D, in combination with the box, B, or its equivalent, said curbs being constructed in the manner and for the purpose substantially as described.

A. W. JOHNSTON.

No. 8512.—*Improvement in Card Grinders.*

What I claim, and desire to secure by letters patent, is an instrument for grinding or sharpening wool, cotton, or other cards, made with sectional card teeth, which are so bent at the heel as to make the sharp edge more prominent than its opposite and broad edge, together with its application to the card that is to be ground in such a direction as to cause the sharp edge of the teeth of the grinder to be first presented to and enter among the teeth of the card.

RICHARD KITSON.

No. 8513.—*Improvement in Daguerreotype Apparatus.*

Therefore, we claim—

First. The construction of a camera box, with a cross-opening, or mortise, to receive a sliding frame, that carries both an object glass and the Daguerreotype plate, as described.

Second. The construction and application of a sliding frame, *i*, with a division, to receive a frame carrying an oblong object glass, so formed as to be placed either vertically or horizontally, as described and shown.

Third. The construction of the slide, *i*, so as to receive in the other division a Daguerreotype plate in a frame, *n*, such frame, *n*, being pressed in place by springs, 16, and held in place by blocks, 17, taking notches in the frame, *n*, as described and shown.

WILLIAM LEWIS,
W. H. LEWIS,
HENRY J. LEWIS.

No. 8514.—*Improvement in coupling Railroad Cars.*

What I claim as my invention, and desire to secure by letters patent, is the combination of a stiff car coupling with the ends of a couple of cars, and with the trucks under the same, substantially in the manner herein set forth, by which the cars are made to guide the trucks under them, and keep them in their proper positions on the track—to wit, in such positions that a line drawn midway between and parallel with the truck axles will be at right angles to any straight track, and also at right angles to the tangent of any curved railroad track.

LORENZO D. LIVERMORE.

No. 8515.—*Improvement in Abdominal Supporters.*

What I claim as my invention, and desire to secure by letters patent, is the employment of a pubic brace of the peculiar form herein described, and as represented in figs. 2, 3, 4, 5, 6, and 7 of the drawings, so as to fit the ospubis, and press uniformly upon the inguinal region, while the upper edge of the brace is bent forward so as to effect no inconvenient pressure upon the abdomen of the wearer; said pubic brace being made of hammered leather, or other tenacious material, in the manner and for the purpose herein described.

A. J. LONSBURY.

No. 8516.—*Improvement in Bedsteads.*

Having thus described the nature of my invention, and the manner in which it is constructed, what I claim as new, and desire to secure by letters patent, is the manner of securing the lower bedstead to the upper one, so that it may slide underneath the upper one, or be drawn out from it, as described, viz: by having the clamps (*g*) attached to the upper part of the foot-posts, E, of the lower bedstead, said clamps fitting in the recesses (*a*) of the rails, A, of the upper bedstead, and the rails, D, of the lower bedstead, passing through the mortise holes (*b*) in the foot posts, C, of the upper bedstead, substantially as shown and set forth.

LEVI NEWCOMB, Jr.

No. 8517.—*Improvement in Horse Collars.*

What I claim as my invention, and desire to secure by letters patent, is connecting the sides of the breast plate, C, by a flat joint, A, in combination with the levers, D, attached to the sides of the breast plate, and rising over the neck without touching the shoulders of the animal, and connected at the top, by which means the breast plate is made adjustable to the size of the horse, substantially as herein set forth.

R. RICKEY.

No. 8518.—*Improvement in Grain Kilns.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the heating chamber, D, with the two drying beds, one above and the other below, as described.

ISAAC S. STOVER.

No. 8519.—*Improvement in Frosting Plates of Glass.*

What I claim as my invention, and desire to secure by letters patent, is the use of a rocker containing pebbles, sand, and water, for the purpose of frosting plates of glass, or embossed work, as above described.

ISAAC TAYLOR.

No. 8520.—*Improvements in Apparatus for sizing and dyeing Yarn.*

What I claim as my invention, and desire to have secured to me by letters patent, is—

First. The conducting of yarn or thread from section or warper beams directly into and through the size or coloring liquids to the pressure rollers, by a series of rollers, more or less in number, placed as nearly in contact with each other as the nature of the case will admit, the closer the better, sufficient space being allowed between the fixed rollers for the passage of the yarns or threads, thus enabling the said rollers to operate as guides to each and all the threads, to prevent them from matting or clinging together, and superseding the otherwise necessary use of reeds, raddles, or other separators.

Second. I claim the taking or making of a weaver's lease, or series of leases, at the commencement of the process of warping or beaming of yarn or thread on section or warper beams, and at proper intervals on the same, to correspond with required lengths of yarns or threads on weaving beams, and preserving the same throughout the sizing and drying, thus dispensing with the use of hacks or lease takers in the dresser, and the otherwise necessary stoppage of the dresser or sizer, for the purpose of tying or twisting together each separate thread.

ALONZO BASCOM.

No. 8521.—*Improvements in Printing Presses.*

Having thus fully described the nature, construction, and operation of my invention, I will proceed to state what I claim, and desire to secure by letters patent—

First. I claim hanging the type bed and platen upon cranks on rotating shafts, C, C', and D, D', arranged and operating in the manner substantially as herein described.

Second. I claim the spring presser, W, attached to the type bed or platen, for the purpose of pressing the band, *e*, communicating motion to the sheet, against the opposite surface of the platen or bed, and causing it to be moved at precisely the same speed as the bed and platen, substantially as described.

Third. I claim the arrangement for carrying and giving motion to the inking roller, consisting of the barrel, P, the bars, Q and *p*, the lever, R, springs, *r* and *t*, and band, *u*, combined together, and with the above type bed and platen, in the manner substantially as set forth.

THOMAS H. DODGE.

No. 8522.—*Improvement in Machines for cutting Combs.*

Having thus described the nature and operation of my invention, what I claim as new, and desire to secure by letters patent, is the wheel, B, with the cutters, *t*, placed on its periphery, as described; said wheel having a rotary motion, and also a vertical reciprocating motion, in a trans verse line with its axis, for the purpose of turning or cutting comb-teeth, substantially as described; said motions being given the wheel by means of the cams, H, I, levers, P, U, and pawls, *l*, *n*, or their equivalents, as set forth.

S. CURTIS.

No. 8523.—*Improvement in Stove Grate Bars.*

Having thus described my construction of fire-grate, what I claim as new, and desire to secure by letters patent, is the manner, described, of forming separate grate-bars for vibrating grates, rounded at their ends, secured and working in grooves of the frame, as described.

GEORGE. W. GARDNER.

No. 8524.—*Improvement in Ploughs.*

What I claim as my invention, and desire to secure by letters patent, is a cotton scraper, constructed as herein described, with a share and mould-board projecting from the side of the landside, opposite that to which the earth is thrown, the landside thus extending from the point of the scraper to that wing of the mould board opposite the one to which it usually extends; and the several parts being so arranged that the landside will run deep enough to hold the implement firmly to its work, the share will pare the ground and cut off the weeds near the roots of the plants, and the mould-board will conduct the same towards the middle of the space between the rows.

HENRY GOLDSEN.

No. 8525.—*Improvement in Propellers of Machinery to be used in Currents.*

What I claim as my invention, and desire to secure by letters patent, is the application, for the purpose specified, of one or more levers, A', A, with the floats or blades, B, B, at their lower ends, against which the current acts; said levers being attached, at about their centres, to an adjustable frame, D, by a universal joint, C, as described; the upper ends of the levers being attached to cranks, I, I, by which, through any suitable gearing, motion is communicated to the shaft, M, substantially as described.

JAMES HARDIE.

No. 8526.—*Improvement in Railroad Car Wheels.*

What I claim as my invention, and desire to secure by letters patent, is connecting the tread or rim of a car-wheel to the hub or central part thereof by means of India rubber, or other analogous elastic material, such elastic material being connected with the outer periphery of the central part of the wheel by a groove on the latter, or its equivalent, and to the inner periphery of the rim, also, by a groove thereon, or its equivalent; the India rubber holding itself in both grooves by its elasticity, and giving to the wheel lateral as well as radial elasticity, as herein described.

I also claim the grooved segments, constructed substantially as herein described, and interposed between the India rubber and the rim, for the purpose of facilitating the insertion of the India rubber into the space between the rim and central part of the wheel, and its removal therefrom, as herein set forth.

NEHEMIAH HODGE.

No. 8527.—*Improvements in Mill for Grinding and Bolting.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, is—

First. The grinding of grain, or other material, by means of a revolving stone, or metallic roller, and one, two, or more separately adjustable concaves, whereby "high and low" grinding may be performed simultaneously, and bolting the same the instant that any particles are ground fine enough, in combination with the returning on to the roller again all particles too coarse to be bolted through the bolting concave, so that they may be ground over again and again, until they are fine enough to be discharged; and this I claim, whether it is done by means of the revolving beaters and brushes, which throw it up and through the pipe, or by any other means essentially the same.

Second. I claim the guides or partitions in the pipe, as herein described, to prevent meal from scattering endwise in its transit from the bolting concave to the roller, in combination with the adjustable aprons, A, on which it falls, and which distribute and govern it in its passage to the discharging end, as herein described and set forth.

JEHU HOLLINGSWORTH.

No. 8528.—*Improvement in Cannon for throwing Chain Shot.*

Having thus fully described the nature and operation of my invention, what I claim as new, and desire to secure by letters patent, is in combination with the revolving head, S, and the bores, B, B, diverging as described, the rack, C, attached to the gun, and the worm-wheel, D, hung on the shaft, E, by which the gun is made to revolve or turn to the desired position, so that the chain-shot may be thrown either in a horizontal or vertical line.

ADAM LEMMER.

No. 8529.—*Improved Screw Propeller.*

And having now described the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim as my invention, and desire to secure by letters patent, is arranging two or more series of narrow blades, such as above described, each series on a separate shaft, and the shafts one within the other, and provided with keys, or other equivalent means of securing them to each other, substantially as specified, so that the two or more shafts may be turned on each other, and resecured, to place the series of vanes directly behind each other for sailing purposes, and at different points of the circle for propelling.

G. MALO.

No. 8530.—*Improvement in Desks.*

What we claim as our invention, and desire to secure by letters patent, is—

First. Forming the desk top in boxes, parts, or pieces, D, E, each of which may be separately raised or lowered, as required, through appropriate mechanical devices, substantially in the manner and for the purposes shown and set forth.

Second. The employment of hinged double leaves, F, G, in the front of the desk, the same, when extended, forming a rest for the hand, and being made capable of closing down or in, essentially as described.

ISAAC H. NORRIS,
DAVID FLANDERS.

No. 8531.—*Improvements in Railroad Switch.*

Having thus described my invention and improvements in the self-adjusting and locking switch for railroads, I wish it to be understood that I am aware that the relative position of the switch with the main track, or turn-out, or sideling track, has been changed by the action of mechanism attached to the cars, as well as by devices attached to the locomotive, in various ways; and therefore I do not claim changing the switch by apparatus or devices actuated by the cars or locomotive; nor do I claim constructing and operating a switch composed of a single movable section of the main rail; but what I do claim as my invention and improvement, and desire to secure by letters patent, is the employment of the additional movable sections, D, D, in combination with the sections, C, C′, forming the switch, whereby the lateral movement of each is halved or divided, in opposite directions, and a more regular curve is produced than that resulting from the use of the single movable section or switch, and thereby insuring safety, the weight of the train of cars on one section of the switch forming a lock to the other section, as one section cannot move without the other, till the train of cars shall have passed therefrom, as herein fully set forth.

I also claim the combination of the double central lever bars, A, B, A. B, with the central connecting rock-shaft, E, having two cranks, *f*, projecting in opposite directions, to which are attached the cross bars, g, g^2, for uniting the double sections, D, C, C′, whereby the switch is adjusted, as fully set forth and shown in the accompanying drawings.

D. F. PHILLIPS.

No. 8532.—*Improvement in Seed Planters.*

Having thus fully described my invention, what I claim as new, and desire to secure by letters patent, is the combination of the slides, *f*, *g*, with the grooves, *a*, (which "drill in" the grain,) and the cells, *c*, *e*, so that by moving the slats, *f*, towards the centre of the hopper to close the communication with the grooves, and open it with the cells, *c*, for planting in "check rows," or by moving both the slats, *f*, *g*, towards the centre of the hopper, to close the communication between said hopper and the grooves, *a*, and cells, *c*, and open it with the cells, *e*, for planting in "step rows;" the whole being arranged in the manner and for the purpose herein set forth and fully shown.

WILLIAM REDICK.

No. 8533.—*Improvement in inserting Porcelain Teeth.*

What I claim as my invention, and desire to secure by letters patent, is the mode of inserting teeth by forming the concave base, and of inserting the platina pins into the base of the platina surface of the teeth, in an oblique direction, and attaching them to the gum plates without stays.

W. WILLSHIRE RILEY.

No. 8534.—*Improvement in Stoves.*

What I claim as my invention, and desire to secure by letters patent, is placing the damper, F, between the fire and hot air flues, B and E, so as to control the amount of opening in each respectively, and governing the same by the expansion of the rod, *d*, substantially as herein described, for the purpose of regulating the heat of the oven.

I do not claim the expanding rod, *d*, irrespective of its connexion with the damper, placed as described.

H. R. ROSE.

No. 8535.—*Improvement in Stove Grates.*

Having thus fully described my new and improved fire chamber for stoves, &c., what I claim therein as new, and for which I desire to secure letters patent, is the inclined elevator, E, for raising the back grate, and coupling it with the front grate, and in combination the connecting the front and back grates with hooks or catches, constructed and arranged substantially as above specified.

H. J. RUGGLES.

No. 8536.—*Improvement in Spring Saddles.*

What I claim as my invention, and desire to secure by letters patent, is the movable pommel, the spiral spring, or springs, connecting the pommel and cantle, and the raw hide seat, all combined, substantially in the manner herein set forth, making a spring-seat saddle tree.

JOHN C. Fr. SALOMON.

No. 8537.—*Improvement in Gongs.*

What I claim as my invention, and desire to secure by letters patent, is making gongs of sheet or plate iron, or steel, with a rim, B, all round, strengthened by a ring or band, C, the whole being coated, and having the crevices, interstices, and all unsound parts filled with an alloy of copper and tin, or any alloy of a similar nature, or composed of similar metals to what is usually called "bell metal, substantially as herein set forth.

VINE B. STAR.

No. 8538.—*Improvement in finishing and balancing Mill Stones.*

What I claim as my invention, and desire to secure by letters patent, is the inserting the balance rine in the eye of a mill-stone in the early

stage of its construction, and then making use of the said balance-rine, in conjunction with a chuck, combined with the spindle, in completing the stone, substantially as herein set forth.

GEORGE TODD.

No. 8539.—*Improvement in Wires for making pile in Woven Fabrics.*

What I claim as my invention, and desire to secure by letters patent, is combining with the flat pile or figuring wire employed in weaving looped or piled fabrics, and attached to, or near one end thereof, a weight, for the purpose and in the manner substantially as described.

E. B. BIGELOW.

No. 8540.—*Improvement in Fastenings for Garments.*

Having thus described my improved mode of fastening garments, &c., I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is the opening, closing, and fastening together the two sides of a garment, or other article, by means of the clasps and ribs, operating in combination, substantially in the manner hereinabove described.

I also claim the method of connecting the clasps one to the other, in pairs, and in the series of pairs, by the links, cord, and beads, substantially in the manner hereinabove set forth.

ELIAS HOWE, Jr.

No. 8541.—*Improvement in Cooking Stoves.*

Having thus fully, clearly, and exactly described and represented my improvements in stoves, what I claim therein as new, and desire to secure by letters patent, are the diving flues (*i*) opening from the floor, as described, and, in combination with this, the chamber (*g*,) for the purpose described.

HOSEA H. HUNTLEY.

No. 8542.—*Improvement in Cooking Stoves.*

What I claim as my invention, and desire to secure by letters patent, is the employment of the three movable plates, C, D, E, constructed and arranged as described, viz: the plate, E, being hollow and affording a passage or flue, when not cut off by the damper, through which the heat passes, warming the ovens formed by the plates, the plates being capable of being withdrawn from the stove, or varied in a vertical position, by which arrangement the stove can be converted into an air-tight, or draught wood, or coal cooking stove, cooking range, or a wood, or coal, draught, or air tight radiating stove, or into a Franklin stove, substantially as set forth.

GEO. W. CARLETON.

No. 8543.—*Improved Safety Apparatus for Steam Boilers.*

First. We claim as our invention, and desire to secure by letters patent, the bent tube, formed and arranged substantially as described.

to contain mercury, in combination with the lever of the safety valve, or its equivalent, and connected with the steam boiler by means of a swivel and a pillar connexion, or its equivalent, whereby the varying pressure of steam varies the actual weight upon the valve.

Second. We also claim the combination of the connecting rod, Q, and the lever, O, I, and the shaft, R, for connecting the mercurial gauge, T, T, and U, with the catch box, N, and projecture, O, on the catch box, whereby the mercury in the gauge, T, T, being the weight, holds down the safety valve, or sets it at liberty, by the pressure of steam from the pillar, E, and swivel, S, S, said pillar being supplied with steam from the boiler or boilers, as described in the specifications.

Third. We also claim the combination of the rod, M, with the spiral spring upon it, and small pulley at the top of it, with the notched pulley, L, for holding the catch box together so long as the full part of the pulley, L, is on the small pulley, or setting it at liberty when that part of the pulley that is cut out comes opposite the small pulley, and thereby allowing it to ascend, as described in the specifications.

JONATHAN COLLINS,
JOHN J. G. COLLINS.

No. 8544.—*Improvement in Ploughs.*

What I claim as my invention, and desire to secure by letters patent—

First. Is the cutter, C^4, or its equivalent, to separate the sward for the first furrow at a proper distance from the coulter, acted upon by the prop, a^3, and lever, C^4, or their equivalents.

Second. Is the piece, D^3, fastened to the heel of the mould-board in combination with the cutter, C^4, to turn wide furrows.

Third. Is the mode of connecting the tongue and plough, respectively, to the axle, by means of the links and the loose tenon on the tongue, substantially as described, so as to allow the team to walk entirely aside from the furrow, or direct course of the plough, in ploughing prairie, marsh, or other land with soft under strata, and make the plough run smoothly and work well, and so as also to enable the ploughman to take an extraordinarily wide furrow, with one member of the team walking in the furrow with a common yoke, thus dispensing with the long yoke now commonly used for that purpose.

Fourth. Is the rope, D, and lever, D′, or their equivalents, in combination with the mode of connecting the tongue and plough to the axle, substantially as described, for the purposes set forth in the within specification.

ELIJAH GOLDTHAIT.

No. 8545.—*Improvement in Centrifugal Sugar Drainers.*

I would now state that what I claim, and desire to secure by letters patent, is centrifugal machines for separating fluid from other matter, constructed and operating as herein set forth, with detachable vessels containing the substance to be operated upon, irrespective of the exact mode of attachment, their number of vessels used, or the form.

DANIEL KING.

No. 8546.—*Improved Method of Operating Rudders.*

Having thus fully described our invention, we will proceed to state what we claim as new, and desire by letters patent: We claim controlling the operation of the rudders in such a manner as to bring either into operation while the other is stationary, by means of the pins or studs, *h*, *h′*, on their tillers, in combination with the grooves or slots, *g*, *g′*, in a wheel or disk, G, receiving motion upon an axis, *f*, or by the equivalents of the same, substantially as therein described.

THOMAS H. MORTIMER,
JAMES M. GARDNER.

No. 8547.—*Improvement in the manufacture of Door Knobs.*

I claim the combination and arrangement of the arms, sliding-plate springs, and lever, substantially as described, operating in the manner or in any analogous way, for the purpose set forth.

ORRIN NEWTON.

No. 8548.—*Improvements in Drop Presses.*

What I do claim as my invention, and desire to secure by letters patent, is the general arrangement and combination of the crank and shaft with its sweeps, moving always in the same direction with the moving gear, or pulley, and the ratchet wheel, joined together and running loose upon the shaft, constantly in the same direction, substantially as I combine them, for the purposes herein described.

I also claim the lock, in combination with its sweep and springs, and with the crank, to stop its motion not too abruptly, and to hold it until it is unlocked by the hand or foot of the workman, substantially as described.

MILO PECK.

No. 8549.—*Improvement in Cider Mills.*

Having thus described the portable cider mill, I wish it to be understood that I make no claim to originality of invention to any part of the mill, separately considered; nor do I claim as new any part of the arrangement of the press grinding cylinder or hopper. But what I do claim as new is—

First. The arrangement of the parallel slicing knives, D, in combination with the reciprocating follower, G, made as described, with channels and ribs on its inclined face, when used with a grinding cylinder, Y, and concave, T, made and arranged as described and represented, for first slicing the apples, and then delivering the slices successively to the grinding cylinder, Y, to be reduced to pummace in the manner herein described.

D. F. PHILLIPS.

No. 8550.—*Improvement in Shingle Machines.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The peculiar form and mode of adjusting of the riving plate E, the same being self-adjusting, by means of the spring, F, upon which it rests, and the end of the plate contiguous to the riving knife, being bent upward, (to accommodate irregularities in the grain of the shingle timber,) as herein specified.

Second. The employment (in combination with a shingle shaving machine) of the rolls, T, levers, X, Z, hanging rods, X, spring, *k*, and bent lever, *p*, or their equivalents, the whole being arranged and operated in the manner and for the purpose herein described: the levers, rod, and spring acting upon the rolls, and pressing them uniformly towards each other, for the purpose of unwinding or straightening the rived shingle, in the first instance, and the bent lever (being operated by the motion of the connecting rod, R, and acting upon the spring, *k*,) having the effect of increasing the force or pressure of the rolls upon the shingle, (as the latter passes between them,) for the purpose of preventing the splitting of the shingle in advance of the cutters as they approach the thin end of the shingle, as herein set forth.

FRANKLIN SKINNER.

No. 8551.—*Improved Valve for Oscillating Engines.*

I do not claim the circular valve, nor the manner of reversing the engine by turning the valve; but what I claim as my invention, and desire to secure by letters patent, is the arrangement of the piston valve with a ground face in a cylindrical steam chest, as described above, by which the necessity of packing about the trunnion and plummer block is avoided, consequently saving much friction in the trunnion.

WM. M. SMITH.

No. 8552.—*Improvement in Railroad Car Brakes.*

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the levers, link rods, and shoes, or rubbers, substantially as herein described, whereby each wheel of both trucks of a car is retarded with a uniform force when the brake is put into operation.

F. A. STEVENS.

No. 8553.—*Improvements in Looms for weaving Bags.*

What I claim as my invention, and desire to secure by letters patent, is—

First. Placing the cams upon one or more shafts in such manner that they can be moved so as to change their relative position in regard to each other with or around the shaft, if upon separate shafts; or around the shaft, if upon the same shaft, in combination with the devices, substantially such as are herein described, or their equivalents, for releasing, changing, and holding said cams, as may be required, for the purposes set forth in the foregoing specification.

Second. Is the pin, *r*, on the spring, f^1, in combination with the pawl, *m*, or their equivalents, to force back the rod, d^2, and propel the wheel, I, by the pin, d^2, acting against the inclined sides of the notches, h^2, h^2, so that the pin, d^2, will fall back on the groove, d^1, and allow the wheel, I, to be propelled by the pin, C^4.

CYRUS BALDWIN.

No. 8554.—*Improved Hand Drill.*

What I claim as my invention, and desire to secure by letters patent, is the combination of the helical spring, F, with the screw, *j*, upon the drill shaft and the opening and closing nut, or screw-nippers, H, H, the whole being applied in the manner substantially as described, and operating for the purpose of controlling all the required movements of the drill in the line of the axis of its revolution, in giving it the pressure upon its work, controlling the said pressure, and withdrawing it from its work, as herein fully set forth.

WILLIAM BUSHNELL.

No. 8555.—*Improvements in Hurdle Fences.*

Having thus fully described my improved fence, what I claim therein, and desire to secure by letters patent, is the method of locking and supporting the same by means of the notched sills and lock braces, as herein described.

CYRUS C. COLE.

No. 8556.—*Improvement in Machines for crimping package papers for Soda Powders, &c.*

What I claim as my invention is the combination and arrangement of the surfaces, *t*, *u*, *v*, *w*, *s*, *p*, *b*, *a*, *c*, *d*, in the manner substantially as represented in the drawings, and for the purpose of folding the paper in a trough like shape, and in other respects convenient for being filled with powder and folded together.

CARLOS A. COOK.

No. 8557.—*Improvement in Railroad Switches.*

Having thus described my invention and improvement, and pointed out the difference between the same and other railroad switches, what I claim therein as new, and desire to secure by letters patent, is—

First. The combination of the stationary single casting, *c*, with the single casting or switch, *g*, each having a guard on the inside thereof, whereby the said permanent single stationary casting, *c*, is made to subserve the purpose of the ordinary frog and auxiliary switch in connexion with the turn-out side of the main track as described.

Second. I also claim providing the movable casting, *g*, on the inside thereof with a guard, *m*, for the purpose of guiding the train of cars over the switch in a straight line when running in the direction of the arrow, y^2, and thus prevent the cars from passing on to the turn-out rails when the switch is in the position shown in fig. 2, the projection or frog, *f*, being of sufficient length, in connexion with guard, *m*, to guide the train on to the main rail, *a*, as described.

WM. N. RAINES.

No. 8558.—*Apparatus for Propelling and Steering.*

I do not claim the peculiar wheel here used as a water wheel and propeller; but what I claim as my invention, and desire to secure by letters patent, is the combination of the water ways in the rudder with a water wheel and submerged propeller, to be operated by hydraulic pressure, for propelling and steering vessels, substantially as herein set forth.

JOHN C. FR. SALOMON.

No. 8559.—*Improved Lock for Safes, &c.*

I do not claim the knobs, D, D, and collars, E, E, with the numbers on them, for the purpose of serving as indexes, as they have been previously used; neither do I claim a series of tumblers as those described, for these have also been previously used; but what I do claim as new, and desire to secure by letters patent, is the "tallon," N, with the stud, *q*, attached to it, in combination with a series of tumblers, O, having curved slots, *o*, in them; said tallon and tumblers operating as described, viz: the tallon being thrown up by the key during its second revolution, and the stud, *q*, in consequence, placed on the outer side of the tumblers, the tallon being held up by the catch, P, the catch, *y*, on the tallon bearing against the stump, *z*, and preventing the bolt from being moved back or withdrawn; the tallon, N, requiring to be let down, when the bolt is to be withdrawn, so that the stud, *q*, may work or slide in the curved slot, O, in the tumblers, and the catch, *y*, be free from the stump, *z*; the bit of the key, in turning, acting upon the end of the tallon, and shooting back the bolt, substantially as described.

F. C. GOFFIN.

No. 8560.—*Improvements in Railroad Car Trucks.*

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is hanging the frame of a six-wheeled truck immediately on the centres of the front and rear axles by a shank or socket, and to the centre axle by guides, in combination with horizontal, diagonal, or other bracing, connecting and operating said wheels so that they may adjust themselves to any lateral curvature in the track, and at the same time allow either of the sets of wheels to pass over any obstruction without raising the other sets from the track, and for the purpose, also, of allowing the set from which the weight is removed to still retain its position on the track for guiding the others, as herein fully set forth and described.

BENJ. HINKLEY.

No. 8561.—*Improvement in Steam Carriages for Railways.*

Now, we wish it distinctly understood that we do not claim the combination of a steam engine with the axles or body of a carriage; nor do we claim any arrangement of it by which it is directly applied to a "fixed" axle, or one so connected directly with the carriage body that, other than a rotary motion, it can have no horizontal and rocking movements, independently of the same; but what we do claim as our invention or improvement is the arrangement or arranging steam engine directly on a movable truck-frame of "a long car," or carriage, in combination with arranging the boiler, or steam generator, on or in the carriage body or frame, and connecting the engine and steam generator by a flexible pipe, or pipe having a ball and socket, or other equivalent connexion or joint, such as will allow of all the necessary rotary and rocking movements of the truck frame and carriage body; the whole being substantially as hereinbefore described.

JOS. H. MOORE,
WM. P. PARROTT.

No. 8562.—*Improvement in Expanding Mandrels.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The use of an expanding nut or shell, D, formed in segments whose interior faces have portions of a screw thread cut thereon, which fit within, and correspond with, the thread of a taper screw, *e*, of the mandrel.

Second. The manner of holding together, or retaining in their places, the several segments, *c*, *c c*, of the expanding shell or nut, by means of a coiled spring, or springs, *g*, *g*, encircling the segments, and made of sufficient length to admit of the nut expanding without destroying the confinement or hold of the segments, as described.

WALTER SHERROD.

No. 8563.—*Improvements in Machines for Stretching and Drying Cloth.*

What I claim as my invention is the combination of the two winding and lengthwise stretching contrivances, or stretchers, the two widthwise rotary stretchers, C, D, and the three or any other suitable number of drying cylinders, E, F, G, substantially as described, so as to enable a person to cause a piece of cloth to pass in one direction over and around the drying cylinders, and next in the opposite direction, as many times as may be desirable, in order to stretch, dry, and finish the same to the extent that may be required.

THOMAS BARROWS.

No. 8564.—*Improvement in the mode of papering Pins.*

I do not claim the crimps that the pins are inserted through; neither do I claim rolling up the paper of pins from both ends to the centre, that being old and well known. But what I do claim as my invention, and desire to secure by letters patent, is the *new* mode of papering pins, substantially as herein described.

I claim the new manufacture of "book pins," formed by folding the paper in parallel folds at regular distances from each other, producing fan-like or zig-zag folds, which allows the paper of pins to be closed into compact form, without rolling or winding, for the purposes herein set forth.

C. O. CROSBY.

No. 8565.—*Improvement in Machines for Working Clay.*

What we claim as our invention is—

First. The fixed double eccentric cams, I, I, in combination with the pitmans, J, J', attached to the slides, K, K', and by means of L, L', giving motion to the pawls, M, M′, and through them to the rack, Q, and the wheel, E, for the purposes herein set forth and described.

Second. We claim the particular arrangement and combination of machinery set forth and described in figs. 2, 3, and 4, in combination with the tempering wheel, E, fig. 1, especially the double eccentric, I. I, and the pitmans or connecting rods, J and J′, the slides, K and K′, with the pawls, M, M′, the connecting bar, O, the shifting rod, P, and the rack, Q, as applied to tempering clay for making brick, or any other purpose, or any equivalent device or arrangement of machinery for accomplishing the same purpose substantially in the same manner.

DANIEL DUCHEMIN,
GEORGE DUCHEMIN.

No. 8566.—*Improvement in Tailors' Measures.*

What I claim as my invention, and desire to secure by letters patent, is the gauge designated by the letters A and S in the drawings. This gauge has two arms slit through the centre, from the cross bar down, as illustrated by fig. 1 in the drawings; the front arm extends up and forms a semi-circle over and around the top of the inner arm. This semi-circle is slit through the centre, and forms a way for the two shoulder straps, which are attached by a pivot to the top of the inner arm to turn on, with screws to set them to the desired place; the semi-circle is designated by the letter D in the drawings. This gauge moves horizontally on strap E, from the front backward, or *vice versa*, until it strikes the front of the arm-hole and locates the same, and is set by screws to the desired place. Again, this gauge can be drawn perpendicularly, so as to increase the length of the shoulders for a very full breasted man, or contracted, so as to fit a hollow breasted man.

JAMES MAGINNIS.

No. 8567.—*Improvement in winding Watches.*

What I claim as my invention, and desire to secure by letters patent, is the application to watches of the machine keys, substantially as herein described and illustrated by the accompanying drawings, which keys and their boxes are enclosed by the watch case, and form a part of the watch, rendering the use of ordinary watch key unnecessary, without the expense and great friction of the complicated machinery heretofore used for the same object.

THEODORE NOEL.

No. 8568.—*Improvement in Carriage Perches.*

What I claim as my invention, and desire to secure by letters patent, is constructing the front extremity of the perch so as to form a spindle, which passes through a tube on the turning plate, to connect it with the front axletree, and at the same time to form a hinge on which the front axletree can rock, the latter being a new duty additional to that which the forward extremity of the perch has heretofore performed, thus increasing the efficiency without increasing the complexity or cost of the coupling.

LEWIS E. STILWILL.

No. 8569.—*Improvements in Machines for boring holes in Posts*

Having thus described my improvements on the machine for boring holes in posts for fencing, what I claim therein as new, and desire to secure by letters patent, is combining the pivoted bar, R, provided with a catch and inclined plate, S, T, and long arm, V, and stop or pin, *p*, with the gauge bar, U, provided with rows of pins, *q*, and mounted in bearings in the inclined carriage, G, whereby the movement of the latter is regulated in moving the timber laterally in boring a series of holes, as described in the specification.

I also claim the combination of the pivoted beam, P, inclined plane, *b*, inverse half nut screw, *f*, and propelling screw shaft, M, whereby the carriages are made to advance toward the boring tool, and is disengaged for the purpose and in the manner described and represented.

I do not, however, intend to confine my claim to the precise construction described in the foregoing specification, but to use such a form of construction as may be the best adapted to accomplish the desired object by means substantially the same; neither do I claim any portion of the machine above described that has been practised successfully by others prior to its being invented by myself.

THOMAS T. STRODE.

No. 8570.—*Improved Foundry Apparatus.*

Having thus described my improvements in the art of founding, what I claim therein as new, and desire to secure by letters patent, is—

First. The method of making moulds for castings by impressing the pattern into a measured quantity of sand, contained in a flask constructed with steps, or protuberances, and depressions, substantially as herein described, so that the mould, when finished, may be surrounded by sand, varying in thickness in proportion to the different degrees of compression which it receives by the impression of the pattern, in order that the density or hardness of the face of the mould may be rendered more uniform, substantially as herein set forth.

Second. I claim the method of charging the half flask with the requisite quantity of sand to form a half mould by surmounting said flask with a hopper, and passing the two to and fro beneath a sand-box, substantially as herein described.

Third. I claim the method of detaching the hopper from the flask after the mould is formed, and of applying it thereto before the sand is introduced, substantially as herein described.

Fourth. I claim the method of applying facing sand to the flask prior to the formation of the mould, by means of apparatus operating substantially as herein described.

Fifth. I claim the method of tempering, distributing, and sifting moulding sand by means of machinery, operating substantially as herein described.

Sixth. I claim the core spindle, constructed substantially as herein described.

Seventh. I claim the method of filling a series of flasks with melted metal by a single sprue by means of a sprue case, with which the flasks are connected, substantially as herein set forth.

Eighth. I claim the combination of apparatus for tempering the moulding sand, apparatus for distributing the tempered sand and sifting it into the sand reservoir, and apparatus for supplying to the flask a measured quantity of sand from the reservoir, with a flask and pressing apparatus, whereby the sand is worked and the mould produced by machinery, operating substantially as herein set forth.

CHAPMAN WARNER.

No. 8571.—*Improvement in Running Gear of Locomotives.*

What I claim as my invention, and desire to secure by letters patent, is the use of steam springs for the support of the weight carried by the driving wheels of a locomotive engine, in combination with bearing or supporting wheels placed both before and behind the aforesaid driving wheels, which bearing wheels support a portion of the weight of the engine, through the medium of steel, air, India-rubber, or other springs possessing the properties herein described, as belonging to steel springs, as distinguished from steam springs, for the purpose set forth in the specification.

I also claim the employment of steam springs, or steam pressure, operating separately from the propelling cylinders, for the purpose of varying the pressure of the driving wheels of a locomotive engine upon the rails of the road, in combination with bearing or supporting wheels placed both before and behind the aforesaid driving wheels, which bearing wheels support a portion of the weight of the engine, through the medium of steel, air, India-rubber, or other springs possessing the properties herein described, belonging to steel springs, as distinguished from steam springs, for the purpose set forth in the specification.

ROSS WINANS.

No. 8572.—*Improvement in Apparatus for opening and closing Gates.*

Having thus described my improved gate, what I claim therein as my invention, and desire to secure by letters patent, is making a blank space on the lever, *o*, and vibrating it so far as to disengage the cogs upon it from the cogs upon the plate, *l*, so that the gate may be opened and closed by persons on foot without the aid and without operating the lever, *o*, in combination with the connecting of the bar, *r*, (or latch) to the lever, *o*, by the rope, *g*, so as to unlatch the gate when the lever, *o*, vibrates before the cogs on the lever, *o*, gear into the cogs upon the plate, *l*, to open the gate, substantially as described.

ENOCH WOOLMAN.

No. 8573.—*Improved Revolving Reverberatory Furnance.*

What I claim as my invention, and desire to secure by letters patent, is the rolling or revolving furnace, revolving on friction wheels, or rollers, or their equivalent, in combination with an ordinary fire, such as is used in reverberatory furnaces, the two being combined in such a manner that the products of combustion, heated gases, &c., from the grate shall pass into the interior of said rolling or revolving furnace, substantially as herein described, said rolling or revolving furnace being applicable to any purpose for which ordinary reverberatory or wind furnaces are employed.

AMBROSE S. BEADLESTON.

No. 8574.—*Improvement in Potato Diggers.*

What I claim as of my own invention, and desire to secure by letters patent of the United States, is the arrangement and combination of the cutting and digging cylinders with the riddles, in the manner herein set forth.

DANIEL D. BELL.

No. 8575.—*Improvement in construction of Sounding Boards for Musical Instruments.*

What I claim as my invention, and desire to secure by letters patent, is the above-described mode of constructing the sounding-boards of stringed instruments by combining or arranging together any suitable number of pieces of wood prepared as above, all in manner and for the purpose as herein set forth.

CORNELIUS BOGART.

No. 8576.—*Improvement in Running Gear of Railroad Cars.*

What I claim as new and original, and desire to secure by letters patent, is adapting to each side of railroad car trucks four or more wheels, attached to a frame-work, inflexible vertically, but with a horizontal motion, in such manner that in case of depressions in the rails at their joinings, or otherwise, they (the wheels) will alternately, by couplets, triplets, or the like, receive the weight of the load above, and relieve the wheel passing over the depression from the weight of the load and frame-work, so that no concussive blow is struck with that weight, or jar created, substantially as above described.

THOMAS A. DAVIES.

No. 8577.—*Improved Carbonic Acid Gas Engine.*

I do not claim the invention of carbonic acid gas in its liquified or æriform character as a motive power; neither do I claim the use of the hydrostatic press for liquifying the gas, as these principles have long been known and commented upon by Sir Hy. Davy, Faraday, Brunnel, and others. But what I claim as my invention, and desire to secure by letters patent, is—

First. A carbonic acid gas engine, in which said fluid passes from a reservoir, where it exists in a liquid state, through suitable valves, into a heated cylinder, thence into a refrigerator, where it is cooled, and thence through pumps, where it is condensed by hydrostatic pressure, and forced back again to the reservoir before named; the said engine being constructed substantially as herein described.

Second. The combination of crimped leather washers, a spiral spring, or springs, and oil, or any lubricant, for packing the piston-rods, or plungers, as described.

JOHN C. Fr. SALOMON.

No. 8578.—*Improvement in Gas Regulators.*

What I claim as my invention, and desire to secure by letters patent, is the closing of the valve, *d*, when the fluid becomes too low in the gas regulator for safety, by the movement of the float, *j*, and the lever, *i*, *h*, and their action upon the thimble, *l*, on the valve rod, *c*, substantially as herein set forth.

JONATHAN S. CONANT.

No. 8579.—*Improvements in Water Metres.*

What I claim as my invention, and desire to secure by letters patent, is—

First. The uniform circular channel, *a*, *a*, in combination with the contracted channel, *b*.

Second. I claim the rotating paddle-wheel, having paddles projecting into and working in the said uniform and contracted channels.

Third. I claim the apertures, *m* and *n*, proportioned and formed as described.

Fourth. I claim the pipe, *q*, with its jet, *r*, for giving motion to the paddle-wheel before the fluid enters through the aperture, *m*.

Fifth. I claim the valve, *k*, by which any desirable power of jet may be obtained before any fluid enters through *m*.

J. ERICSSON.

No. 8580.—*Improvement in Chucks for Lathes.*

Having thus described my improved chuck, what I claim therein as new, and desire to secure by letters patent, is the mechanism, herein described, or the equivalent thereof, for connecting and disconnecting at will the whole or any part of the screws which operate the griping jaws, with the wheel which turns them, so that the screws and jaws may be moved either separately or in connexion, or in part separate and in part connected, whereby objects of either regular or irregular shape may be chucked, either eccentrically or concentrically with the axis of the mandrel, substantially as herein described.

I also claim the turning plate (I) of the chuck, constructed with a cog-wheel on its inner face, made in segments, part of which can be withdrawn out of gear with the pinions on the carrier screws, or held in gear therewith by means of set screws and springs, or the equivalent thereof, substantially as herein set forth.

JOSEPH HYDE.

No. 8581.—*Improvement in Feeding Logs in Saw Mills.*

Having thus fully described the nature of my invention, what I claim therein as new, and desire to secure by letters patent, is the combination of any number of adjustable rollers, F, which may be set at any angle with the feed rollers, Q, or with each other, for the purpose of feeding up the log, so that it may be cut with the curve or grain of the wood, substantially in the manner herein set forth and described.

CHARLES KETCHAM.

No. 8582.—*Improved arrangement of Pans for washing Ores, Minerals, &c.*

I do not claim the device of arranging a movable pan in a vibrating frame, and of operating the same, so as to give a double motion to the pan, since letters patent for this invention have been granted to Arnold Buffum and Philip Thorp.
