Iodurетted and other waters. Many springs have of late been found to contain a notable quantity of iodine or bromine, others contain both: Creuznach, in Germany, contains both, but most iodine; Llandrindod and Park Wells (near Builth), in Radnorshire, the springs issuing from the lias at Leamington, Gloucester, Tewkesbury, and Cheltenham, contain iodine; bromine, but not iodine, exists in small quantity, in the saline aperient waters near London, such as Epsom, also in the springs from the coal-formation of Ashby-de-la-Zouch, Newcastle-on-Tyne, and Kingswood, and Bonnington near Edinburgh: Woodhall, near Ashby-de-la-Zouch, contains most iodine of any British springs yet investigated.

Organic matters, termed *Baregine, glairine, zoogene, &c.*, have been found in many springs. Of these an account may be found in Dr. Lankester's 'Askern, and its Mineral Springs,' p. 103.

The waters of Selters (commonly called Seltzer) is exported to the amount of above a million and a half bottles. So also those of many other mineral springs; but they all experience some deterioration by time. To lessen this, artificial imitations are made [AERATED WATERS]. These are often very valuable, but always inferior in efficacy to the waters drank at the springs. They are without the *Juvantia*, the change of air, scene, relaxation from business, and more regular hours and appropriate diet, insisted on at the chief watering places; to say nothing of the external use of many of the waters as baths, when resort is had to the fountain head.

Durand-Fardel, Le Bret, Lefort, et François; Paris, 1860. *Report of Commission on Health of Towns.*)

WATER-COLOUR PAINTING (in Italian, *Acquarella*; French, *Aquarelle*; German, *Wasser-Farben*). Among the ancients the colours used in painting were usually rendered fluid by means of water; the names given to the different kinds of painting being derived from the vehicle or medium mixed with the water in order to bind the colours. TEMPERA, or distemper, in which glue or some other gelatinous binder is employed; FRESCO, in which the colours are laid on a moist ground of gesso, or plaster-of-Paris; MINIATURE, are all water-colour painting: their history, and an account of the several processes, will be found under their respective titles: see also the general article PAINTING. In ENCAUSTIC PAINTING, as the name implies, heat was employed, the binding material being wax, or wax and resin; but some even of the methods of encaustic, or at least of wax-painting, as practised by the ancients, were really water-colour, the wax or resin being rendered miscible by the addition of an alkali (nitrate of soda, or nitrate of potash). Oil-painting was not practised, or only practised in an imperfect form, before the 15th century, when Van Eyck introduced the use of oil and varnish, or a vehicle composed by boiling linseed, poppy, and nut oils with certain resinous mixtures. This vehicle was, however, found to be so much better adapted than any then in use for working, and so much more effective and durable, as to be generally adopted by artists as soon as it became known; and the various methods of water-colour painting were neglected, and fell into disuse, except for mural paintings, for which fresco was still employed, and theatrical paintings and miniatures, which were commonly painted in tempera. [PAINTING; VAN EYCK, in BIOG. DIV.]

Water-colour painting, as the term is now understood—that is, painting on paper with colours diluted with water—is a process of comparatively recent introduction. It is true that the Italian, Dutch and Flemish painters of the best period often executed their cartoons and finished sketches with water-colours, as may be seen in the cartoons of Raffaelle and of Mantegna at Hampton Court, which are painted on paper with opaque water-colours (or tempera), and in some of the sketches and drawings executed in transparent water-colours by leading Dutch and Flemish painters, of which examples are exhibited in the King's Library at the British Museum: these, however, were not completed pictures, but only the drawings from which fresco or oil-paintings, or tapestry hangings, were to be executed. The art of water-colour painting, in which the completed work is itself executed, with all the skill and care of the artist, in water-colours on paper, is a product of this country. It appears to have gradually grown out of the methods employed by miniature painters, and the earlier examples were rather a kind of tempera than what would now be called water-colour painting, the colours being all rendered opaque by the admixture of white. Many of the early works of Paul Sandby [SANDBY, PAUL, in BIOG. DIV.], who perhaps has the fairest claim to be regarded as the founder of the English school of water-colour painting, are wholly executed in solid opaque colour. The new method, from which was directly derived the present process of water-colours, grew into vogue in the latter part of the last century, and was at first known as "stained drawing," a term by which pictures of this kind are described in the catalogues of the early exhibitions of the Royal Academy. The entire drawing was first carefully made out in light and shadow by means of washes of Indian ink, or of a gray or what was termed a neutral tint, and over this the respective local colours were passed in thin washes of transparent colours—much of the effect being due to the neutral tint appearing through and modifying the harshness of the superposed colours. The sharp-markings, minuter details, &c., were put in with a reed-pen either immediately before or subsequently to the laying on of the local colours. The older works in this manner have generally a cold, gray, feeble appearance, but sometimes very pleasing atmospheric effects were obtained; and in the hands of Cozens, and still more of Turner, Girtin, and Prout, whose earlier drawings were all commenced with a monotint, pictures of great power and even grandeur were produced.

The improved method, and that which, in principle at least, is still practised, consisted in abandoning the preparatory neutral ground tint, and painting-in every object in the first instance in its proper local colour, leaving it to subsequent shades and tints, either laid in thin washes of transparent colour, or with a kind of *hatching* stroke (the distinctive "touch" of the artist), to modify the crudity of the first painting, and to impart the character and aspect which every part should assume from its place in the picture and the atmospheric influences under which it is seen. This method originated, there can be little doubt, in the adoption by the younger landscape painters, Turner, Girtin, and their compeers, of the practice of making out-of-doors sketches and studies of scenery in colours, for which purpose the old method of employing a preparatory monotint would be found too tedious, and for representing evanescent atmospheric phenomena impracticable; while the striking effects that were produced in sketching by painting-in the local colours at once would soon lead to the adoption of a like method for more finished works. Yet even Turner and Prout continued to lay-in the larger masses of shadow with a monotint, long after they employed local colour in the first instance in the lights and middle-tints. When once the new method came to be generally adopted, the progress of the art was very rapid; water-colour painting acquired a remarkable degree of popularity, and its professors became very numerous. In 1805 the most distinguished practitioners of this branch of art formed themselves into a "Society of Painters in Water-Colours," which has ever since continued to hold an annual exhibition of the works of its members at their rooms in Pall Mall East. In 1832 the younger practitioners, feeling that they were unable to bring their works fairly before the public, established another society under the title of "The New Society of Painters in Water Colours," and they have in like manner their annual exhibition. But both exhibitions are exclusively confined to the productions of the members. At the Manchester Art-Treasures Exhibition of 1857, a very instructive collection of paintings in water-colours was brought together with a view to illustrate the growth of the art, and it may be anticipated that a much more complete collection of a similar kind will be shown at the International Exhibition of 1862. The want of a permanent national collection of paintings in this essentially British branch of art has however long been felt, and though it has not yet been supplied, the nucleus of such a collection has, mainly by the spirit and munificence of private individuals, been at length formed. [SOUTH KENSINGTON MUSEUM.]

The practice of water-colour painting as at present pursued in this country differs so much according to the habits of individual artists, and so little guidance could be given in a brief description of any particular method, that it will be best to confine ourselves to a few general remarks. The paper employed is usually of a hard substance, and more or less granulated according to the size and character of the picture, and still more the manner of the artist: some using paper with only a fine and others with an exceedingly coarse grain or *tooth*. Some again prefer an absorbent paper, or paper of a peculiar tint, and others produce a peculiar texture by rubbing, sponging, or other manipulative process: some of the most remarkable effects in their pictures (as in the case of Turner and Copley Fielding for instance) being to a great extent due to some such procedure. The pigments employed are of the ordinary kind, prepared in cakes by the admixture of a little gum, or "moist" by the addition of honey or some other saccharine material. The colours, as we have said, are painted-in of their proper local hue, and subsequently modified till the objects acquire the intended appearance. This was by the older painters usually effected with transparent colours only; but Turner, Harding, and others began, at first cautiously, and then with more freedom, to mix white with their colours, and this has been carried so far that now opaque (or *body*) colours often form, as of old, the substance of the water-colour paintings of some of our most admired artists. Another innovation is that of using gum, or some other vehicle of a like quality (water-glass has been tried), to give *depth* to the shadows. These are however objected to by many as not legitimate materials for the water-colour painter; but the majority of painters consider that it is lawful to use any means by which they can best convey the impression they desire to produce; and, supposing that equal truth and permanency as well as brilliancy can be so obtained, there can be little doubt that they are right. It must, however, be admitted that in many of the more elaborate recent pictures, something of the exquisite freshness and transparency of the earlier water-colour paintings has been lost in the attempt to reach the force and depth of oil.

WATER, COMPRESSIBILITY OF. [ELASTICITY, col. 773.]

WATER AND WATERCOURSES. The right of conducting water through one piece of land for the use of another is an incorporeal hereditament of the class of easements, and was known in the Roman law by the name of the *servitus aquæ ductus*. The right of taking water out of the well or pond belonging to another person is an incorporeal hereditament of the class of profits called in the Roman law the *servitus aquæ haustus*. These rights, in our law, must be either derived from a grant or established by prescription. [PRESCRIPTION.]

It is the law of England that water flowing in a stream is originally *publici juris*, that is to say, a thing the property of which belongs to no individual, but the use to all. The legal presumption is that the proprietor of each bank of a stream is the proprietor of one-half of the land covered by the stream, but there is no property in the water. Every proprietor has an equal right to use the water which flows in the stream, and consequently no one can have the right to use the water to the prejudice of any other without his consent. No proprietor can either diminish the quantity of water which would otherwise descend upon the proprietors below, nor throw back the water upon the proprietors above, so as to overflow or injure their lands. For the same reason, no proprietor has a right to use the water of a stream so as to injure its quality to the detriment of other proprietors.

The only modes in which a right to the use of running water, in a manner inconsistent with the common law rights of others can be established, are either proof of an actual grant or licence from the persons whose rights are affected, or proof of an uninterrupted enjoyment of such a privilege for such a period as the law considers sufficient to constitute a right by prescription. The period of twenty years had been generally fixed upon by the courts of law and equity for this purpose, and the same period has been adopted in the Prescription Act (2 & 3 Will. IV., c. 71, s. 2). [PRESCRIPTION.] But if water has not been appropriated, it seems that the person who first appropriates and renders it useful acquires a right, and for a violation of such right an action may be maintained on an enjoyment of less than twenty years.

The privilege of a watercourse is not confined to private individuals. It may be vested in a corporation, or may be claimed by the inhabitants of a township or parish. If land with a run of water upon it be sold, the water *primâ facie* passes with the land; but it is laid down by Coke that if a person grants *aquam suam*, the soil will not pass, but only a right of fishing in that water; for the proper words in that case to pass the soil would be, so many acres of land *aquâ coopertas*: whereas the word *stagnum*, or pool, will pass both water and land. (1 'Inst.,' 4, b.) The exclusive right to a flow of water once acquired can only pass by grant as an incorporeal hereditament, and a licence, by parol or otherwise, to use or take the water at any place, may be revoked even without an express power of revocation being reserved, unless works have been constructed and expenses incurred upon the faith of it.

When the owners of property have, by long enjoyment, acquired special rights to the use of water in its natural state, as it was accustomed to flow, and not merely a use, which is common to all the king's subjects, an action may be maintained for a disturbance of the enjoyment; but where the injury, if any, is to all the king's subjects, the only remedy is by indictment. The mere obstruction of water which has been accustomed to flow through a person's lands does not in itself afford a ground of action. The plaintiff in such an action must be enabled to show, either that some benefit arose to him from the water going through his lands, of which he has been deprived, or at least that some deterioration was occasioned to the premises by the subtraction of the water; but where the proprietor of the lands can prove that he is injured by the diversion of the water, it is no answer to his action to show that the defendant was the first person who appropriated the water to his own use, unless he has had twenty years' undisturbed enjoyment of it in its altered course. If the injury occasioned by the diversion or obstruction of water is of a permanent nature and injurious to the reversion, an action may be brought by the reversioner, as well as by the tenant in possession, each for his respective loss.

The diversion of watercourses or injury to their banks so as to cause inundation are nuisances against which a court of equity will protect parties by injunction; and if there be a question as to the right to the flow of water, an issue will be directed to try it. Although a court of equity will not in terms decree the banks of rivers, watercourses, or navigable canals to be repaired, the effect of such an order may be obtained by an order that parties shall not be at liberty to use them while out of repair, or against their impeding the use of them by the obstructions consequent upon a state of disrepair. An injunction may also be obtained against conducting the water from one man's tenement upon that of another to his injury by drains or otherwise, in a manner in which it has not been accustomed to flow. And it may be laid down generally, that, with respect to water and watercourses, the aid of a court of equity may be obtained for the purpose either of restraining injury or of quieting possession.

WATERFALLS. In the article VALLEYS we have arranged a general view of the main features of the earth's surface, and a series of inferences touching the forces whereby the diversified forms of hills and valleys have been occasioned. But these forms, though on a large scale they appear permanent, because the great modifying agencies which produced them have passed away, are really undergoing continual change from causes in daily operation. The most solid stone is wasted by the feeble but unceasing power of decomposition possessed by the atmosphere. Rain washes away the disintegrations occasioned by varying temperature and chemical processes; the hills lose and the valleys gain, and the balance of decay and renewal of land is only finally adjusted on the shores and in the basin of the sea. Among the phenomena which show this mutability of the supposed solid land with most distinctness, are interruptions to the general uniformity of the inclinations of valleys and the even slopes of hills: for these changes of slope are points of variation of the intensity of the agencies excited by the slope. These interruptions of uniformity are all referrible to the unequal power of resistance which rocks of different hardness, or dissimilar position, or unequal thickness, or unlike modes of association present to external agencies. Thus have been formed round the high limestone hills of the northern counties a series of rocky terraces, not less regular than the escarpments made by military art; and thus the oolitic ranges of the Cotswold show horizontal mounds of sand and cliffs of stone above the broad plains of lias clays and red marls which margin the Severn and the Avon. On these grand features of the earth's surface the action of the atmosphere (including chemical and mechanical operations) produces only slight modifications; but when the terraced slopes in their flexures round the hills turn into the valleys, a new agency is brought to work upon them. Rivulets, however small in quantity, and torrents, even such as are of only temporary energy, exert a positive influence in wasting and transporting away earthy materials; and these effects rise to a maximum wherever, from any of the causes already alluded to, the surface of the earth presents successive points of less and greater power to resist the action of running water. Wherever, in a valley whose slope is considerable, the rocky masses successively crossed by the stream are of very unequal hardness, as, for example, when solid limestone is found resting on soft shale or feebly indurated sandstone, a more than ordinarily rapid current is occasioned over the lower beds of the limestone into the upper beds of the shale. This difference of slope in the running water is of a nature to increase continually to a certain point, depending on the relative firmness and thickness of the hard and soft rocks, the inclination of the valley, the magnitude of the stream, and other less important particulars. Thus rapids and cataracts are formed; and where the conditions combine in the most favourable degree waterfalls, to use that term in a more specific sense, are produced.

The character of these varies according to the disposition of the yielding and resisting portions of the rocks. Wherever stratification is absent, as in granite, or concealed, as in some metamorphic slates, the main features of the waterfall are determined by the direction of the natural joints in the stone. Hence the picturesque character of the falls of the Bruar (Highlands), Lodore (Cumberland), and the Rheidiol (North Wales). In some cases these natural joints yield in parallel lines, and give a deep narrow passage to the water. Scale Force, in Cumberland, is an example. But the most interesting, if not the most picturesque, class of waterfalls, is occasioned by the stratified rocks; and the most curious of them are observed where hard limestones or gritstones rest upon yielding shales or soft clays. By the continual action of the stream, the shales, kept constantly damp, crumble and fall away even at considerable heights and distances from the points where they are touched by the water. Thus, a hollow space is formed beneath the limestone which crowns the precipice; and this proceeds so far as to reach at last some of the natural joints which divide the rock. Then the limestone falls down, the waterfall recedes, and the process of removal and destruction is renewed. Thus, on the sides of the hills, in the limestone dales of the northern counties of England, the waterfalls are daily receding up the streams, and thus are the Falls of Niagara forced continually farther up the river. The process is by no means slow. Beneath Hardrow Force, in Yorkshire (a fall of 99 feet), the effect since the general valley of the Yore was excavated by other forces has been to produce a sinuous glen within vertical walls of rock, at the foot of which yet lie great heaps of fallen materials, which the feeble stream that formed the glen has not been powerful enough to remove. For an account of the natural process by which the Falls of Niagara have been displaced, and are still undergoing change, the volumes of Sir C. Lyell ('Principles of Geology;' 'Travels in North America;' the former of which are instructive on all points connected with the operations of running water) may be consulted. Exactly such effects as are here attributed to running streams happen on the sea-coasts where rocks of a particular nature occur under analogous circumstances.

The physics of waterfalls have received but little attention, though it might have been anticipated that they must involve considerations of an interesting nature, and of some philosophical importance; for in them we have the principal cases in nature of the mechanical agitation and division of water, resulting chiefly from its own inertia, gravity, and momentum. In the greatest waterfall in Europe, for example, the Vöring Fos, near the Hardanger Fiord, in Western Norway, we have a very large body of water, and a clear fall of 900 feet. It descends into a narrow bare chasm, the sides of which are very nearly perpendicular. "The spray dashes up from below with such force, that another waterfall, which descends on the opposite side of the chasm, is actually stopped by it and dispersed before it can reach the bottom." (H. F. Tozer, 'Vacation Tourists in 1860.')

The late Captain Basil Hall, in his 'Travels in North America,' thus describes the involution of air in the Horse-shoe Fall of Niagara, and its subsequent disengagement. "This enormous cataract, in its descent, like every other cascade, carries along with it a quantity of air, which it forces far below the surface of the water, an experiment which any one may try on a small scale by pouring water into a tumbler from a height. The quantity of air thus carried down by so vast a river as Niagara must be great, and the depth to which it is driven in all probability considerable. It may also be much condensed by the pressure; and it will rise with proportionate violence both on the outside of the cascade, and within the sheet or curtain which forms the cataract." He mentions also the blast of wind which rises accordingly from the pool on the outside of the sheet. To the explosion, as it may be termed, of the bubbles, thus constituting this enormous and perpetually renewed accumulation of bursting froth, we must ascribe the greater part of the sounds which combine to produce the roar of the Niagara falls. In doing this we apply to the subject the observations of Professor Tyndall, on the sound of breakers and the roar of the ocean. ('Vacation Tourists in 1860,' p. 307, note.) The impact of water against water, he has shown, is a comparatively subordinate source of sound; though in this case, from the enormous masses of water concerned, and the momentum which those of the river acquire from the height from which they descend, the sounds proper to the impact must be very considerable. The sonorousness of the roar, also, agrees with this ascription of it, principally, to the violent impact of air against air, the air impinged upon being that of the free atmosphere, by which the sound is communicated to the ear. The explosions of the bubbles must take place, in many instances, with enormous force, owing to the resistance presented by the immense cohesive power of films of water, and occasion corresponding loudness of the sounds, which, however, in coalescence and rapid succession are heard as an interminable roar.

To these, no doubt, enormous bubbles of condensed air, rushing upwards to the surface of the pool, and expanding as they rise, we must also probably attribute the production of the sharp-pointed cones of water which are continually projected upwards from the pool on the outside of the fall, sometimes to the height of a hundred and ten or twenty feet. They are further described by Captain Hall (who, however, expresses no opinion as to their origin), as resembling some comets in form, their point, or apex, which is always turned upward, being quite sharp, and not larger, he estimates, "than a man's fingers and thumb, brought as nearly to a point as possible. The conical tails which stream from these watery meteors may vary from one or two yards to ten or twelve, and are spread out on all sides in a very curious manner." The actual production of these cones, and their emergence from the surface of the pool, which must be their beginning above water, if the origin here ascribed to them be the true one, are concealed by the clouds of spray in which the bottom of the falling sheet is constantly hidden from the view. Out of this they are at all times seen darting up.

This cloud or mist of spray is itself an interesting phenomenon, characteristic more especially of great falls, like those of Niagara, uniting depth of fall and quantity of water. It arises from the bottom, where the impact of the descending upon the still or merely flowing water takes place; and it involves several physical considerations which seem to have escaped notice. As produced by the Niagara falls, its extent and visibility from a distance have often been described. The lower part of the great fall, according to Captain B. Hall, is always concealed by this rolling cloud of spray, which waves backwards and forwards, and rises at times to the height of many hundred feet above the falls. Isaac Weld describes it as consisting of thick volumes of whitish mist, having much the appearance of smoke rising from heaps of burning weeds; such smoke, it may be added, itself consisting principally of steam condensed into globules of water, or steam-cloud. The same traveller relates that this "cloud formed from the spray" of the Niagara falls was seen by him and his party on Lake Ontario, at the distance of fifty-four miles, as "a small white cloud in the horizon," which remained steadily fixed in the same spot, its shape, as observed by a telescope, "varied every instant, owing to the continued rising of the mist from the cataract beneath." But it is only seen at such a distance, he adds, when the "air is very clear and there is a fine blue sky." Weld also describes the now well-known appearance of coloured bows in the spray, similar to rainbows, and for which it will be convenient in this article to use that appellation.

Notwithstanding the production of these rainbows, proving the mist to consist of separate drops of water, in the condition, in fact, of small rain, it has frequently been described as vapour, and identified in nature with fog and the clouds of the sky,* although rainbows do not occur in them, and although we have no reason to believe that the conversion of water into vapour can ever take place by mechanical action, however violent and continued. Were this possible, indeed, it could not but take place at these falls, where the water is perpetually exposed to the consequences of greater mechanical force than under any other circumstances whatever, either in nature or art; where indeed all the circumstances are most favourable to such conversion, were it physically possible.

We have seen in the example of the Vöring Fos, how enormous is the force with which the spray into which the descending is divided by the momentum with which it falls upon the still water, and partly, no doubt by the resilient elasticity of the latter, is driven upwards. Such spray, but greatly varying in magnitude, number, and approximation of particles, and therefore in their aggregate effect and appearance, may be produced under conditions in which water impinges with great force upon water, or upon solid bodies, or solid bodies upon it; also as in storm-spray, by the action of the wind on the surface of the sea, by which, as by the perpetual action of waterfalls, persistent mist is frequently occasioned. Further, it is produced to a sufficient extent for the appearance of rainbows, when the waves of the sea, at their summits, curl and break into foam under the force of a breeze. But the spray-mist of great waterfalls is in all probability occasioned, in the greatest degree, and as consisting of the most minute particles, by the violent bursting of the multitudinous air-bubbles already described, forming the froth or foam of the falls, by which the films of water inclosing the air are rent into minute dust, as it were, of water, incalculable in the number of particles in a given space, and capable of suspension in the air, like the globules of which the clouds of the sky themselves consist. [CLOUDS.]

These particles, however, differ greatly from those of the clouds, and the connection of their history with the subjects of the smallness of the particles into which water is thus mechanically divisible, and the true nature of the clouds, and of the globules or particles composing them, is in several respects instructive. The spray of waterfalls and of the crests of waves consists of globules or particles of water, resulting, exclusively, from its mechanical division; but the production of perfect rainbows in it evinces that it is identical, within certain limits, in respect of the magnitude of the particles, their distance from each other, and their distribution in a given space, not with true cloud, but with the minute rain in which the rainbow of the sky occurs under ordinary circumstances. We have, therefore, in the production of that meteor, a kind of measure of the magnitude, constitution, and distribution of the particles, which, in all these cases, it is demonstrable must be geometrically solid.

We have, in several articles, already recorded our belief that the globules constituting the clouds are not hollow, and our disbelief of the existence of what has been termed 'vesicular vapour,' that is, of vesicles of water (whether containing vapour or not), resulting from the condensation of invisible vapour or water in its pure gaseous condition. Sir J. F. W. Herschel ('Meteorology,' par. 92,) after describing the production of mist or fog [MIST] by the precipitation of moisture from the atmosphere, offers the following important observation on the subject in question.

"It is a favourite dogma with many meteorologists, that the particles so precipitated assume the form, not of drops, but of hollow spheres or bubbles. De Saussure states that he has seen such floating before his eyes in clouds and fogs on the Alps; and the dusty appearance of the vapour floating over a cup of coffee in the sunshine is adduced in proof. The strongest argument in their favour, however (for there is great room for optical illusion in such matters), is that adduced by Kratzenstein, that the sun striking on a fog or cloud [†] produces no rainbow, which it ought to do were the water collected in spherical *drops*. This argument does not admit of a ready answer; but the difficulty, on the other hand, of conceiving any possible mode in which such bubbles can be formed, disposes us to believe that the extreme minuteness of the globules may perhaps be found to afford one, their diameters being probably of an order comparable with the breadths of the luminiferous undulations." *

* Sir C. Lyell, for example, in his 'Travels in North America,' first identifies the spray-cloud of Niagara falls with the clouds of the atmosphere, and then with the undoubted steam-cloud rising from Etna (and other volcanoes), which he also identifies with the clouds, regarding both phenomena as elucidating their nature. But while the steam-clouds of volcanoes are indubitably of the same nature with the clouds of the atmosphere, the spray-cloud of Niagara, as shown above, is different, notwithstanding its appearance.

[† The coloured bow similar to that produced by rain observed in mists lying upon low grounds, as mentioned in the article RAINBOW, is evidently caused by the drops of water resulting from the aggregation of the aqueous particles constituting the mist, by the same process as the production of rain from clouds.]

In the steam-cloud issuing from the boiler of a locomotive engine, whether immediately above the funnel, when blowing off, or at a distance from it, or in the puffs of steam given off during the course of the engine, no rainbow is ever visible, as the present writer can testify from observation: they appear to be physically identical with the clouds of the sky. With this agrees another point, the production in all these cases of opalescent vapour [VAPOUR, OPALESCENT; WEATHER], which also is always caused in the clouds of nature; intervening, as a middle term, in the conversion of invisible vapour into cloud, and in the resolution of cloud into invisible vapour. Its occurrence in both processes may be observed in and about the clouds at almost all times during the presence of the sun, or just before or after it; but less frequently, and only under favourable circumstances, in moonlight. The solar radiation, and the capacity of the air for more vapour on and above the upper surfaces of clouds, often render the intervention of opalescent vapour invisible in that situation, but it may always be seen in the reverse process, in the vapour-plane or vapour-zone [VAPOUR-PLANE] at the base of masses of clouds, especially of cumuli. But the production of opalescent vapour does not occur with the spray of waterfalls or waves. The reason seems obvious. The clouds of the atmosphere and of the steam-engine consist of globules so minute that very slight local changes of temperature will effect their resolution, and so near to each other that the amount of opalescent vapour produced by every one, individually, coalesces into an aggregate mass for all, so that, though only momentary for each globule, it is persistent for the mass, and therefore becomes visible. But the particles of the spray are, comparatively, so large, that much greater differences of temperature are required for their conversion into invisible vapour, and also so distant, comparatively, from each other, that the local momentary opalescence ceases, before, by the coalescence of that produced at many points, it can become visible.

We may safely conclude, therefore, it would appear, from all these facts and arguments, and in corroboration of opinions generally but not universally held, that the clouds are really composed of excessively minute globules of liquid water, not hollow, and not consisting in any respect of *vapour* (though necessarily intermingled with it), which, having resulted from the condensation of volumes of continuous vapour, or of vapour no otherwise discontinuous than as occasioned by the uniformly interspersed particles of the air, are formed at insensible distances from each other; and that these at length (under circumstances not altogether understood, and whether related primarily to heat or to electricity is also uncertain) coalesce into much larger globules, or drops, exceeding in diameter the breadths of the luminiferous undulations, and therefore capable, like the drops of waterfall- and wave-spray, of exhibiting the rainbow.

Minute globules or particles of water, it is now evident, exist of several orders of magnitude, each order having characteristic properties, whether of its own, or arising from the mutual distance of the particles and their consequent number in a given space, or from the mingling with them of pure transparent aqueous vapour, or air, or both.

The application to waterfalls of Professor Tyndall's observations on the sound of agitated water, was founded merely upon his note in the 'Vacation Tourists,' cited above, the writer of the above remarks on the physics of the subject not having seen the paper in the 'Philosophical Magazine' referred to in that note, until after they were in type. Professor Tyndall, after alluding in that paper ('Phenomena of a Water-Jet') to the roar of the ocean as being caused by the bursting of bubbles, himself applies his inferences to waterfalls in the following manner:—"It is the same as regards waterfalls. Were Niagara continuous and without lateral vibration, it would be as silent as a cataract of ice. It is possible, I believe, to get behind the descending water at one place [this is readily practicable, and frequently done]; and if the attention of travellers were directed to the subject, the mass might perhaps be *seen through*. For in all probability it also has its 'contracted sections,' after passing which it is broken into detached masses, which, plunging successively upon the air-bladders formed by their precursors, suddenly liberate their contents and thus create the thunder of the waterfall."

Professor Magnus, of Berlin, it appears, was the first to account for the production of bubbles when water is poured into a glass,—the same physical phenomenon as their production by waterfalls. It is

* This is one of the very few cases in which it has been possible to consider the sensible magnitudes of the particles of ponderable matter as proportioned to the measurable attributes of the ether, or to treat them as commensurate. Another case has been pointed out by Dr. Faraday, who has shown that seven and a half leaves of gold-leaf might be placed in the space occupied by a single undulation of the red ray of light, and five in one of the violet ray; so that a single leaf of beaten gold occupies in average thickness no more than from one-eighth to one-fifth part of a wave of light. ('Proc. of Roy. Inst.,' vol. ii., p. 310; 'Phil Trans.,' 1857, p. 147.)

briefly thus, as he proved by experiment: a concavity is formed by the falling water at the point where it strikes the water below; this closes in as soon as the least motion has been imparted to the surface, and the air within it is carried downwards. It will readily be seen how illustrative this explanation is of a part of Capt. B. Hall's account of the air-bubbles at the Niagara falls, and of the applications of it above; but no part of the air, it must be inferred from the experiments of Professors Magnus and Tyndall, is carried down by adhesion to the water.

In another part of his paper, Professor Tyndall, illustrating experimentally the subject of the contracted vein [HYDRODYNAMICS, col. 774], describes the resolution of the vein or stream of water, after passing the contracted section, into detached masses; and observes, "Following the jet downwards, we find that these masses become more and more attenuated; and were the height sufficient, they would finally appear as a kind of water-dust, an example of which on a large scale is furnished by the *Staub-bach*, near Lauterbrunnen, in Switzerland. Travellers usually attribute the breaking up of the Staub-bach to atmospheric resistance, but the latter has comparatively little to do in the matter; were the surrounding space a vacuum, the same would be exhibited." This indicates an additional and very effective cause of the production of waterfall spray, and is probably applicable to the phenomena of the Vöring Fos, noticed above, which appear not to be accurately understood. (See 'Phil. Mag.' Series 4, vol i. p. 1, and p. 105.)

WATER-GLASS PAINTING, a method of painting in which the vehicle, or binder of the colours, is a soluble alkaline silicate. This process, which has been in use for some years in Germany for mural-painting, and in which Kaulbach, among others, has painted all his later wall-pictures, appears to have been invented, or greatly improved, by Dr. Johann N. Von Fuchs, who termed it *Stereochromy*, and published a pamphlet explanatory of the process and pointing out its advantages. This has been translated for private circulation by direction of the Prince Consort (chiefly with a view to the consideration of the applicability of the process to the paintings in the New Palace at Westminster), under the title of 'The Manufacture, Properties, and Applications of Water-Glass (soluble alkaline silicate), including a Process of Stereochromic Painting.' Mr. D. Maclise, R.A., who was engaged on the preparatory labours connected with painting in fresco a large picture, 'The Meeting of Wellington and Blucher,' in one of the two spaces (45 feet in length) in the Royal Gallery of the House of Lords, and who had been greatly impressed with the failure, as regards permanency, of the recently-painted frescoes, was led by a perusal of this pamphlet to determine on submitting the water-glass process to a searching investigation. He accordingly made various experiments, and, not succeeding to his satisfaction, proceeded to Germany to make himself acquainted with the method as actually practised there, and to examine the works executed. The result was his conviction of its suitability. He has since executed various trial pictures, and he is now painting his great picture with water-glass. Mr. J. R. Herbert, R.A., who is engaged in painting the Peers' Robing-Room, also, having, "after repeated experiments, modified it according to his own views," expresses himself entirely satisfied with it. As its working capabilities have so far satisfied the practical artist, and the finished examples appear to have withstood successfully not only the effect of time,—as yet too brief to be conclusive,—but also the various tests hitherto applied, the process would seem to merit very attentive consideration. The frescoes painted within the last few years, not only in this country, but in Germany, where so much more attention has been given to them and artists are so thoroughly familiar with all the working details, have for the most become deteriorated to a very marked extent; and it will be an immense gain if the water-glass process proves to be a really permanent, as it would seem to be in other respects an efficient, substitute. It will be no doubt interesting to give a brief general statement of the process; for further particulars we refer to the 'Twelfth Report of the Commissioners on the Fine Arts' (1861), in an appendix to which Mr. Maclise has given a very full account of his experience and ample details of the modes of working.

The Water-Glass is composed of powdered quartz (silica) boiled in purified potass or soda, but, according to Dr. Pettenkofer, the chief authority on the subject, the potass solution is to be preferred. It is prepared by chemists of different degrees of strength, according as it is to be employed for laying-on the colours or for fixing. The pigments are the same as those used in fresco-painting, but zinc-white is the only white that can be relied on. The ground is an intonaco, formed of river-sand and Portland cement, precisely as for FRESCO, but somewhat more absorbent. Kaulbach has the ground prepared with a granulated surface, insisting that "it should feel to the touch like a coarse rasp;" but this does not appear to be necessary. A smooth ground, if carefully prepared, takes the colours with equal facility; and, in fact, the degree of roughness or smoothness may be regulated at the pleasure and according to the manner of the painter. After the intonaco has been well dried, and the cement hardened, the superficial sand is to be swept off, and the surface to be moistened with a saturated solution of carbonate of ammonia (Mr. Maclise, we believe, employs lime-water), when it is ready for painting on.

The painting itself may be executed in two ways. In the first, the water-glass in a diluted form is mixed with the colours, and used as a vehicle in working. But Mr. Maclise found that it was hardly possible to work with such a vehicle with sufficient facility, "because of its stiffening the brush, and, as it were, petrifying the contents of the palette before the painting could be accomplished even by the most rapid execution." The solution may, of course, be diluted so as to admit of the painting being executed with much greater facility; but this can only be done at the expense of the fixing qualities of the fluid.

The other method—that employed by Kaulbach and his assistants and adopted by Mr. Maclise—consists in simply using distilled water as the vehicle, and finishing the parts as they advance; and on the following day, when the finished work is quite dry, applying to it a solution of water-glass, formed of "two parts water and one of the concentrated liquor imported from Berlin, and this solution having been twice applied, the painting is now perfectly fixed." (Maclise.) Mr. Maclise applies the water-glass "freely with a large flat water-colour brush." The Berlin artists use a syringe of peculiar construction; and Mr. Maclise finds great advantage in "shedding, by means of a syringe, a spray of coloured water over any portion of the wall-painting," and thus producing "very easy and pleasing changes in hues" where it may be deemed necessary. The principal conditions of success appear to Mr. Maclise to be that the picture should be thinly painted, water be freely used, and the ground be carefully prepared and very absorbent.

In appearance water-glass painting bears a close affinity to fresco. It is flat, free from glossiness, and the colours appear opaque; but the surface may be rendered glossy by using a concentrated solution of the water-glass as a varnish. As it is for mural painting, however, that the water-glass method seems especially fitted, the flat unshining surface is an advantage. In comparison with fresco, its superiority seems to consist in the colours remaining quite unaltered whilst working and when dry; in the process allowing the picture to be retouched and carried out to any degree of finish not only during its progress but after the "fixing;" and, finally, that it promises to be permanent. On this last and most important point we may remark that whilst Kaulbach's great frescoes have become seriously deteriorated, his large water-glass paintings remain quite uninjured; and in Munich some stereochrome pictures are said to have existed for twenty years without exhibiting any symptoms of decay, whilst the frescoes are all more or less damaged.

WATER, HOLY (in French, *Eau bénite*, or blessed water; but in Italian, *Aqua santa*, as in English), is water blessed by the priest, which is used in many ceremonies of the Roman Catholic church, as in the offices of baptism and burial, and in various parts of the mass or ordinary service. There is commonly a font of holy water in the porch of Roman Catholic churches, into which the congregation as they enter the church dip their fingers, and then make the sign of the cross upon their foreheads. The holy water is mixed with salt; and this is said to have been first done by Pope Alexander I., in the beginning of the 2nd century. Some make Pope Alexander to have been the inventor of holy water altogether. Protestant writers have been accustomed to trace the holy water of the Romish church to the pontifical lustrations of the pagan Greeks and Romans; but both the pagan and the Christian practice may perhaps be more correctly referred to the natural feeling which points out water as the symbol of purification. In the ancient churches, in the middle of the Atrium, or square plot of ground between the porch and the church, was commonly a fountain or cistern of water, in which the people washed their hands and faces before they entered. Holy water is also used in the Greek church, but without salt. The mixture of the salt and water is interpreted by some Roman Catholic divines as typifying what is called the hypostatic union of the nature of Christ, the salt being the emblem of his divinity, the water of his humanity.

WATER-MACHINES. [TURBINES; WATER-WHEELS.]

WATER-MEADOWS. [IRRIGATION.]

WATER-MILLS. [WATER-WHEELS.]

WATER-PARTING, in physical geography and geology, the term recently substituted for that of Watershed, taken as the equivalent of the German *Wasserscheide*, in its primary and original signification, that of the line of separation between the contiguous basins of two rivers. [RIVERS; WATERSHED.]

WATER-PIPES. In addition to what has been said on the subject of the flow of water in pipes under PIPE and WATER SUPPLY, it may be desirable here to mention a few practical matters connected with their manufacture and use.

The wooden pipes formerly employed were made from elm trees, and of about 14 or 15 feet in length, the diameter rarely exceeding 9 inches; the interior was bored out by an auger; the joints were of the kind known as the spigot and faucit, in which one end of the tree was tapered for a length of about 9 inches, and the end of the pipe destined to receive that taper was *rimered out* to fit it. These pipes have now been entirely abandoned, on account of their not being able to resist the pressures they are exposed to in modern works, and of the bad flavour they communicate to the water.

The cast-iron pipes are laid with socket joints run with lead; the depth of the joint being proportioned to the diameter of the pipes, but even in the largest it does not exceed 6 or 8 inches. A great effort has lately been made to introduce turned and bored joints for water distribution; but the disturbance of the ground, and the unequal dilatation of the pipes, have hitherto prevented the successful application of that system. It is customary to cast the smaller pipes, that is to say those of from 2 to 3 inches in diameter, in lengths of 6 feet each; and the pipes of greater dimensions in 9 feet lengths. The thickness varies between $\frac{5}{10}$ths of an inch for a 2-inch pipe, $\frac{7}{10}$ths of an inch for a 6-inch, $\frac{5}{8}$ths of an inch for a 12-inch, and $1\frac{3}{8}$ for a 44-inch pipe; the latter dimension is the largest hitherto adopted, and the only instance recorded of the use of such pipes is in the great Rivington Pike supply to Liverpool. Of late years an attempt has been made to introduce the wrought-iron pipes of large diameter, coated externally with asphalte, on Chameroy's patent; but in practice so many inconveniences have been found to be attached to them, that the cast-iron pipes are now almost exclusively used in the ground, when the water is under pressure.

Glazed earthenware pipes are frequently used to convey water, when it is not under pressure; but the difficulty of keeping the joints watertight has hitherto prevented this material from being much used for water supply. From the nature of the earth used in the manufacture of stoneware pipes, their length cannot exceed 3 feet; and consequently the number and expense of the joints would be a fatal objection to any such application.

As to lead pipes, the joints are made by soldering the two ends of the pipes together, the ends *meeting butt*, as workmen say. Up to a diameter of 2 or 3 inches lead pipes can be drawn; beyond that dimension they are formed by rolling sheet-lead over a mandril, and then soldering the longitudinal lap. Joints so made are hardly able to resist the effect of the enormous pressures used in modern water-works, for at the present day the ordinary cast-iron pipes are tested to a pressure of 300 lbs. on the square inch; and in the case of the great Liverpool pipes the pressure was even carried to 600 lbs. per inch. As a general rule lead pipes are made $\frac{1}{4}$ of an inch in thickness. The junction of service-pipes upon cast-iron mains is effected by fixing a brass ferrule to the latter, and soldering the service-pipe to the ferrule; and it would appear that the intervention of the ferrule is sufficient to prevent the galvanic action between the iron and the lead, which would otherwise take place. All the small taps, valves, &c., upon service-pipes are made of brass; but the plugs, sluices, and valves, upon the mains are usually made of cast-iron. Zinc is rarely used for the purposes of water supply, and it is never used for the service-pipes; wrought-iron pipes themselves are not so much used for this purpose as lead, on account of the greater ductility of the latter metal.

WATER-POWER and WATER-PRESSURE ENGINES. The weight and the impetus of a stream of water are frequently employed in mechanics as a source of motive power for the machinery used in industrial operations, in the form of the various kinds of water-wheels; and of late years the law by which water and other similar (practically) incompressible fluids transmit pressure in every direction, and tend to assume a constant level in any reversed syphon, has been made to serve the purposes of mechanics by furnishing the power exerted by the so-called hydraulic cranes and the water-pressure engines. The term *water-power*, therefore, simply refers to the force developed by the water in its natural fluid state; and it acts either by its weight, its impact, or by its power of transmitting an effort exercised upon any part of its circumference. In an overshot wheel the water acts almost exclusively by its weight, which is applied on one side of an unbalanced wheel; in an undershot wheel the water may often exercise power by reason of the velocity with which it is animated when it strikes the floats; in a reaction wheel the power is produced by the escape of the water from a pipe reacting upon the air surrounding the apparatus; and in the hydraulic cranes, the power is obtained by forcing water into a raised cistern, from whence it is able to act, as workmen say "with a head," upon the underside of pistons bearing loaded surfaces. Virtually it is the weight of the water which produces the useful effect in all these cases; but the interferences with its action are so numerous as to justify the popular distinctions above referred to.

The various descriptions of WATER-WHEELS are described under that head; at present it is intended only to notice the water-pressure engines used in mining operations, and the hydraulic cranes; because they constitute applications of water-power of so peculiar a nature, as not to justify their being included under the more generally known classification of water-wheels or engines. The mode of their application is also different from that of the ordinary forms of water-engines; the latter being usually employed for the purpose of driving machinery or mill work, the former for raising water, or for hoisting weights only.

The *water-pressure engines* are constructed upon the principle of collecting, in a tube of a certain height, a quantity of water, and in allowing that water to escape when it has produced the desired effect. This is accomplished by placing the underside of a piston, moving in a vertical cylinder, in communication with a column of water, and in cutting off that communication when the piston has arrived at the head of its stroke. The pressure of the column of water acts, in fact, to raise the piston, to which the pump rods are attached; and the alternate downward motion is effected by the weight of the pump rods themselves, in the same manner that the pump rods of the Cornish engines work: the bottom of the cylinder is placed in communication also with the outflow, so as to allow the water to escape after it has done its work. The passages for the water are opened and closed by a series of tappets and equilibrium valves of a peculiar description, in order to avoid any abrupt hydraulic jar from the change in the conditions of flow in the descending main; these details are, however, of too complicated a nature to allow of their being represented here, but they may be studied in the notice of the water-pressure engine at Huelgoat in the 'Annales des Mines,' or in Burat's 'Géologie appliquée.' In the best engines of this description the useful effect obtained is usually about 0·45 of the power exerted; though it has been stated that in the pumps lately executed at Freyberg, as much as 0·75 of the real power has been used. Mountainous districts are the most favourable for the establishment of the water-pressure engines; for it is only in them that the necessary conditions for their economical working occur naturally. These are, that a sufficiently copious supply of water should exist at a considerable height above the seat of the piston; and that a free discharge for both the water which has served as the motive power and for the water raised should exist. The Huelgoat engine is placed at a distance of 360 feet from the surface, and it raises the water from a mine 754 feet below the level of the cylinders; the diameter of the piston is 3 feet $4\frac{5}{8}$ inches, its height 9 feet, and the length of the stroke 7 feet $6\frac{1}{4}$ inches; it makes, when in full work, $5\frac{1}{4}$ strokes in a minute, and raises through the total height of 754 feet, in one lift, 396 gallons per minute; there are two cylinders, but the galleries are not sufficiently advanced to keep them constantly at work: the descending and outflow pipes are 15 inches in diameter, the pump barrel is 18 inches in diameter, and the ascending pipe is $10\frac{3}{8}$ in diameter. M. Reichenbach has executed for the salt springs of southern Bavaria a great number of these water pressure engines; and it may be desirable to add that the one at Illsang is set in motion by a fall of water 328 feet in height, and that it raises, in one lift, not less than 1364 cubic feet of water.

The hydraulic or water-pressure cranes were invented by Sir W. Armstrong, and applied by him to the quays of Newcastle about the year 1846, in the first instance; but subsequently, their use has become general in other towns, wherein water is to be obtained under considerable pressure. In these engines the water is admitted to act upon one side of a piston working in a tight cylinder, and bearing a piston-rod, upon the end of which is fastened a chain passing over two fixed pulleys, under the pivot of the crane, and over a moveable one on the head of the piston itself, in order to increase the distance traversed by the load, at the expense of the power. The stroke of the cylinders is usually long, and by thus passing the chain over the three pulleys, the load is raised through a height equal to three times the stroke; but the load is correspondingly reduced in proportion to the effort exerted on the piston. There are valves placed at the bottom of the cylinder to close the access of the water to the piston, and to open the escape passages; and when the latter are opened the water escapes, and the weight of the piston, and of the machinery attached, brings the piston back to its original position. Relief-valves are placed near the slide-valves, which give access or egress to the water, to guard against any sudden shocks from changes of direction in the movement of the water which might be likely to produce a hydraulic jar. The water-pressure cranes used at Newcastle had cylinders 12 feet long by 1 foot in diameter, and they worked under a head of water equal to 240 feet.

The principle of the hydraulic press is, in fact, the same as the one involved in the water-pressure engine and the hydraulic crane. It consists in the faculty by which water transmits in all directions a power exercised upon any portion of its surface; the difference in the mechanical arrangement being simply that in the hydraulic press additional force is applied by means of levers and pumps, whereas in the pressure-engines the statical pressure of the source of supply is alone brought into operation. [HYDRAULIC PRESS; HYDRODYNAMICS.]

WATERPROOFING. Textile fabrics, whatever be their character, are pervious to water from two causes: namely, the existence of minute spaces between the individual fibres of the yarn, whether of silk, cotton, wool, or flax; and the rectangular meshes consequent on the process of weaving. To close up these minute channels, as likewise the pores of leather, so as to impart a waterproof quality to the material, has been the object of a large number of patents, as well as of recipes which have not been patented. Mr. Hellewell took out one of the earliest of these patents, for a solution which should render cotton and other fabrics waterproof. According to this plan, for a quantity of woven material equal to 1000 lb. weight, there are used 120 lb. of rock alum, 80 lb. of common whiting, and 200 gallons of water. This mixture is intended, by the chemical action of its ingredients, to yield a solution of alumine, with which the cloth is saturated. After the saturation the cloth is passed quickly through a vessel containing a solution, at a temperature of 100° Fahr., of yellow soap in water, the proportions being 3 lb. of soap and 30 gallons of water to 50 lb. of cloth. This latter process is for the purpose of fixing the alumine in the interstices of the cloth, and enabling it to resist the action of water. The cloth is finally washed, to free it from any impurities. Mr. Hall patented a method of waterproofing cloth by immersion. He describes two kinds of solution employed for this purpose. 1st, two ounces of pulverised alum are dissolved in a pint of distilled water; one ounce of dry white-lead is rubbed down in another pint of water; and the two solutions being mixed and allowed to settle, the supernatant liquor constitutes the required agent. 2nd, one ounce of dry white-lead is rubbed down in half a pint of water; one ounce of pounded alum is dissolved in another half-pint of water; and these two solutions, together with two fluid drachms of acetic acid, are mixed together, and allowed to settle. When the cloth has been immersed in the supernatant liquor resulting from either of the above solutions, it is passed through a solution of quicklime, and a third time through a solution of boiled Irish moss, which acts as a mucilage. One more example will suffice:—Boil half an ounce of Russian isinglass in a pound of soft water till dissolved; dissolve an ounce of alum in two pounds of water; dissolve a quarter of an ounce of white soap in a pound of water; strain these solutions separately through linen, and then mix them all together. Heat this liquid till it simmers, and apply it with a brush to the wrong side of the cloth, on a flat table. When dry, the cloth is brushed lightly with water. The intention of this process is to render the cloth impervious to water, but not to air.

The *surface*-application of a species of waterproof varnish has been the subject of many patents. Messrs. Mills and Fairman introduced a composition, formed of 100 lb. of linseed oil, 40 lb. of pipeclay, and a small quantity of burnt umber, white-lead, pounded pumice-stone, and one or two other substances. These ingredients were melted together and ground to a smooth paint-like state, and then applied to the surface of the fabric with large knives, the cloth being stretched over wooden frames. When one surface was thus coated and dried, the other was similarly treated. This was not intended as a waterproof composition for ordinary clothing, but rather for tarpauling, awnings, coach top-covers, boat-cloaks, and other coarse materials. Mr. Newberry's patent is for a mode of applying waterproof composition in such a way as to leave one side of the woven fabric free from its influence, thereby presenting to the eye a texture nearly resembling that of ordinary cloth. The method consists in saturating the cloth with the waterproof composition, and exposing one surface only; in such a way, that the atmosphere, or artificial heat, may harden the composition on that surface into a dry membranous film; while the other side, after being kept moist during the drying of the first, is cleansed from the composition by means of spirit of turpentine. Mr. Newberry describes three modes of effecting this object. In the first mode the cloth or woven fabric is stretched over a frame, and after being saturated with the composition, is allowed to float on a layer of oil till the upper surface is dry; after which the lower surface is cleansed from the composition. In the second mode the cloth is stretched double, or in two plies, over a frame, saturated with the composition, and then left to dry on the exterior surfaces, the contact-surfaces remaining moist until the time of removal. In the third mode recourse is had to a roller, on which the cloth is coiled, and a flat table of slate, stone, varnished wood, or other substance non-absorbent to the composition. The table is coated with a layer of the composition, and the cloth, being uncoiled and laid down upon it, is pressed and rolled till every part becomes wetted by the composition beneath. In this way the upper surface may be cleansed while the lower is in contact with the table, and the latter is then exposed to a drying process.

The application of a layer of cement, gum, or varnish between two other substances, with a view to render the inner one impervious to water, has been practised under many different modifications, including that which is known by the name of the inventor, Macintosh. Mr. Weise of Bermondsey devised a peculiar kind of fabric, which seems to belong to the class now under consideration. This fabric was to be used either as a material for hats and bonnets, in lieu of the usual felted beaver, or as a cloth for other garments. The materials consisted of beaver-fur, musk-fur, hare's wool, Spanish wool, flax, down, and waste silk, any or all of which were to be combined, according to the kind of fabric required. The materials were carded, roved, and spun into yarn, in the manner of cotton; and this yarn was soaked in a solution of caoutchouc, or Indian rubber, to render the interstices between its fibres waterproof. The yarn was then woven into a textile fabric; and in order to render the meshes impervious to water, the cloth was drawn over a heated cylinder, whereby the resinous composition was so far melted as to flow into them. The last part of the process was to raise a pile or nap on the surface by means of teasles or brushes.

In Mr. Macintosh's patent of 1824, the use of a cement between two layers of cloth was introduced. The cement, or thick elastic varnish, was made by dissolving caoutchouc in a small quantity of coal-oil, the proportions of the ingredients varying according to their quality. This invention led to the remarkable series of processes for waterproofing noticed under Caoutchouc Manufacture.

The attempts to render *leather* waterproof depend in general on the filling up of the small pores which have previously admitted the tannin; the substance imbibed being such as will repel or resist water. Many such methods have been proposed at different times, of which it will be enough to mention a few. Melt over a slow fire a quart of boiled linseed oil, a pound of mutton suet, three-quarters of a pound of yellow bees'-wax, and half a pound of common resin, or smaller quantities in the like relative proportions; and with this mixture saturate the leather of new boots or shoes, while the latter is slightly warm. Another method is to melt two ounces of yellow bees'-wax, two ounces of Burgundy pitch, and two ounces of turpentine, in a pint of linseed oil, and with this mixture to saturate the warmed leather. The 'Journal of the American Institute' gives the two following:—1. Boil together for half an hour one quart of linseed oil, two ounces resin, and half an ounce of white vitriol, to which add four ounces spirits of turpentine and two ounces of white oak sawdust, and apply this mixture to the leather by means of a brush. 2. Apply a coat of tallow to the leather; and after this has dried, coat it again with a mixture of one part of copaiba balsam with two of naphtha. Another mixture for this purpose consists of six ounces of caoutchouc boiled for two hours in two quarts of linseed or neats'-foot oil. Lastly, a mode has been much recommended of applying a hot mixture of six parts tallow and one part resin, with which the leather may be completely saturated, the resin imparting an antiseptic quality to the tallow.

One of Mr. Sievier's contrivances is for rendering leather at once elastic and waterproof. A thin sheet of leather is cemented to a thin sheet of solid caoutchouc by a caoutchouc solution, and kept under pressure for five or six days. The compound fabric thus formed is nearly inelastic, because the leather has temporarily suspended the elastic power of the caoutchouc; but by the application of a temperature about equal to 180° Fahr., the caoutchouc partially collapses, and the leather assumes a corrugated surface, similar to Morocco leather. The leather, rendered thus elastic and waterproof, is then manufactured into boots and shoes or other articles.

WATERSHED. It has been observed, in the article Rivers, that the margin of a river-basin generally lies contiguous to the basin of another river, and therefore constituting the boundary-line of two basins, the waters descend on both sides into their respective basins; and hence the whole line of these margins, it has been stated, is called a *watershed*—properly, the *water-parting*.

It might be supposed that this is simply a matter of nomenclature relating to a single and definite elementary phenomenon of physical geography. But this is far from being the case. The term we are explaining, originally introduced in the sense just described, has been extended, apparently, to every physical locality in which tributary streams having their confluence in a river-basin issue from, or descend on the face of, sloping land, without reference to those on the other side of a ridge, or on the counter-slope; and this extensive application often obscures, in geographical description, the original sense of the term. Of these various applications, examples will be found in the citations which follow.

The Rev. C. G. Nicolay, in the 'Manual of Geographical Science' (vol. i., Terminology, pp. 422-3), enters into the following elaborate and critical discussion of the manner in which this term is to be understood:—"The tendency of water to seek its level makes the position and quantity, as well as character, of the waters of the globe, dependent on its contour; every conical projection, every ridge, in short, every elevation of what sort soever it may be, becomes a watershed; and that knowledge of the height, slope, and direction of the various watersheds of the earth's surface the first step to its general contour. The word watershed, in geographical definition, implies the line by which any waters are divided from each other, and the watershed of any country is no doubt such a line; but as every slope sheds water, and many rivers have their rise on slopes below the main watershed, some further division of the word—some classification of the districts to which it is applicable—appears highly desirable. As this does not seem to have been ever attempted, the following is offered as a suggestion.

"That there is a line in every country which may be termed its principal watershed, will not be disputed; every country has some one district, usually in the direction of its greatest length, more elevated than another, from the sides of which the waters collected from snows, dew, rain, and springs pour down, until they are received into the basin of some inland water, or at last into the sea; this may, therefore, be properly termed its primary watershed; but as the mountains of the world cannot be satisfactorily considered, except in their relative connection, the highest ranges extending through the greatest length of the continental masses, the term primary watershed should be confined to these; beyond them others of less considerable elevation are found, the slopes of which are presented towards the primary watershed and form with it deep hollows, into which their united waters are poured, while from the opposite slope the waters collected descend in a different direction. These may, not inaptly, be termed secondary watersheds, as paying the tribute of part of their waters to the primary, and forming the inferior limit to the principal river basins; while others rising beyond may be called tertiary. It will be observed that this classification affords not only a systematic division of the elevated land, but also of the waters of the globe, as appertaining to any of its parts; rivers having their rise in the primary watersheds may also receive a similar designation, as may their basins; others may be termed secondary or tertiary, according to their position and the watersheds to which they belong."

In Dr. Beke's records of travel and geographical works, the term "water-parting" is substituted for "watershed," for which change he assigns the following reason:—"The line of division and separation between the contiguous basins of two rivers, called by the ancients *divortio aquarum*, the parting (or flowing in opposite directions) of the waters, is in German called *die Wasserscheide*, which means literally the same. English geographers, following the example of geologists, have adopted the expression 'watershed,' which is evidently a corruption of the German *Wasserscheide*, and was probably first introduced among us by miners from Germany. The term is, however, objectionable; because, to the mere English scholar, it appears to be a native compound of the words 'water' and 'shed,' as if meaning that the water is *shed* in opposite directions, and hence leads to the belief that the side of the basin of a river, rather than the division between the adjoining basins of two rivers, is intended. In fact, the expression has of late years been frequently used in that sense. The substitution of the term 'water-parting' renders the idea intended to be conveyed intelligible to all, and exactly expresses the Latin *divortio aquarum*, and the German *Wasserscheide*." ('Sources of the Nile,' p. 3, note.)

Dr. Beke's remarks are amply justified, it will be seen, by the previous discussion of Mr. Nicolay, and also in the following statement on the philosophy of the subject as one of the configuration of the globe, by Sir J. F. W. Herschel, who, it will be observed, while adopting by previous implication the term watershed, in its primary signification, evidently connects it also with the meaning of the English word *to shed*. "Possessed of a knowledge of the heights of stations above the sea, we may connect all stations at the same altitude by level lines, the lowest of which will be the outline of the sea-coast; and the rest will mark out the successive coast-lines which would take place were the sea to rise by regular and equal accessions of level over the whole world, till the highest mountains were submerged. The bottoms of valleys and the ridge-lines of hills are determined by their property of intersecting all these level lines at right angles, and being, subject to that condition, the shortest and longest, that is to say, the steepest and the most gently sloping courses respectively, which can be pursued from the summit to the sea. The former constitute 'the water-courses' of a country; the latter its lines of 'watershed,' by which it is divided into distinct basins of drainage." ('Outlines of Astronomy,' par. 289.)

Again, Captain H. Strachey, and his brother Lieut.-Col. R. Strachey, to whose contributions to scientific geography we have so often referred, designate the northern and southern faces, or slopes of the great table-land of Thibet [PLAINS] as the Turkish, and Himalayan or Indian 'watersheds' respectively; meaning the entire inclination, between the table-land and the low plains to the north and south, occupied by successive ranges of mountains, down and through which the great rivers maintaining a course along the summit of the table-land, and receiving the drainage of its corrugations, flow into those plains, namely, the plains of Hindostan on the one hand, and those of Turkistan or Yarkend on the other. ('Phil. Trans.', 1859, pp. 776, 777.) Here we have another modification of the sense in which the term we are discussing is to be understood, referring to a slope, not as giving rise to streams, or separating them, but as merely giving them passage. In the signification of *Wasserscheide*, the water-parting, the highest part of the table-land itself is the watershed. But Lieut-Col. Strachey defines the meaning in which he uses the term by referring to "the crest of the Indian watershed," which is merely the summit of the slope.

Finally, an eminent geographer and geologist, Professor H. D. Rogers, in his account of the parallel roads of Lochaber, [VALLEYS, col. 544] states that each of them coincides "in level with some watershed, or notch in the hills leading out from its glen into some other glen;" implying only by watershed an opening, by which water escapes to a lower level, and merely adopting one of the senses of the word shed.

We find, therefore, that at present the expression watershed is employed, by the first authorities, to denote any portion of inclined land on which water appears or descends from a higher to a lower level.

The spirit of Dr. Beke's remarks on the subject is applicable to other scientific terms which have been derived from the German language, and especially to those adopted from the phraseology of miners. Both geography and geology were cultivated as sciences in Germany before they had become such in England; and mining in the former country was already a systematic art with a copious terminology. Some of the principal founders also of modern geology in England had been students in the celebrated school of Freiberg under Werner, which became an additional cause for the introduction of German terms into scientific nomenclature. This, indeed, was inevitable, and might have been unexceptionable, but an erroneous procedure took place, of which we have an example in the term which is the subject of the present article. Barbarous imitations of German terms and phrases were made, instead of expressing their meaning in sound English words, or constructing compound terms derived from the perennial sources of the Greek or Latin languages. This was done even by men who were fully competent to take these preferable alternatives; thus, the late Rev. Dr. W. D. Conybeare, afterwards Dean of Llandaff, who was an ornament of the University of Oxford, and a geologist of great merit, substituted, about fifty years ago, the term *strike*, now universally employed by English geologists, for the German word *streich*, to denote the direction of stratified rocks, at right angles to their line of dip, as referred to the cardinal points. An unreasonable horror of technicality and abstruseness appears to have prevailed among the gifted men to whom we have alluded, who, in their anxiety to avoid burdening the new sciences they were fostering with unfamiliar expressions, left them almost without an appropriate vocabulary, the want of which, especially in geology, has still to be supplied, in many instances, by awkward and sometimes tedious periphrasis.

It is worth the remark that the propriety of Dr. Beke's substitution seems to be tacitly admitted by other geographers; for in the index to the 'Manual of Geographical Science,' published with the second volume, the passages above cited from Mr. Nicolay, explaining the applications of "watershed," are referred to by the words, "water-parting, meaning of term," although that term does not occur in them. This may be taken as an indication that it may not be too late to establish "water-purting" for the primary sense in which "watershed" has been received; but we think that the latter may be accepted also, confined, however, to the secondary meanings to which, as we have seen, it has been extended, and more particularly to those involving the obvious meaning of the English words of which it consists.

The importance to the inhabitants of a country of the geographical configuration or phenomenon described by the term water-parting, and the influence which a particular example of it may exert in the production of national ideas, is curiously illustrated by the Rev. A. P. Stanley's interpretation, adopted and extended by Dr. Beke, of the story told to the historian Herodotus, in Egypt, by the treasurer of Minerva's Treasury at Sais. This was, that there were two mountains, named Crophi and Mophi, rising into sharp peaks, situated between the city of Syene in Thebais, and Elephantine; and that the sources of the Nile issued from between those mountains, half of the water flowing over Egypt and to the north, and the other half over Ethiopia and to the south. Herodotus observes that by the deep unfathomable sources described to him in this story were meant the violent eddies of the cataracts; and Mr. Stanley argues, that to the ancient inhabitants of Lower Egypt, the sight or the report of such a convulsion as the rapids make "in the face of their calm and majestic river must have seemed the very commencement of its existence, the struggling into life of what afterwards becomes so mild and beneficent; and that if they heard of a river Nile further south, it was but natural for them to think it could not be their own river. The granite range of Syene formed their Alps—the water-parting of their world. If a stream existed on the opposite side, they imagined that it flowed in a contrary direction into the ocean of the south." ('Sources of the Nile,' p. 43; Stanley's 'Sinai and Palestine,' p. xliii.)

WATERSPOUT, a meteorological phenomenon of the same class probably as the whirlwinds which raise pillars of sand in the deserts of Africa: such whirlwinds, in fact, become waterspouts when they reach the sea; and when waterspouts reach the shore they in some cases become or produce whirlwinds. But there is much reason to believe that the name has been properly applied to several very different phenomena.

The following is a general description of the production of a waterspout at sea:—

Below a thick cloud, the sea appears to be greatly disturbed within a circular area, whose diameter varies from 100 to 120 yards, the waves tending rapidly towards the centre of the agitated mass, where there is formed a vast body of water or aqueous vapour: from hence there rises, with a spiral movement, towards the cloud, a column of a conical form, resembling a trumpet. Vertically above this ascending column there is formed in the cloud, but in an inverted position, a corresponding cone, whose lower extremity (the apex of the cone) gradually approaches the summit of the ascending column; and at length both are united, the diameter at the place of junction being only two or three feet. The waterspout is said to be accompanied, during its formation, by a rumbling noise; and, when complete, it assumes a magnificent appearance. The whole column, which extends from the sea to the clouds, is of a light colour near its axis, but dark along the sides, which gives it the appearance of being hollow.

The spout appears to move with the wind, though even when no wind is felt it sometimes varies its position, tending successively in different directions. It frequently happens that the upper and lower parts of a column move with different velocities, and then, after the whole has taken an inclined position, the parts separate from one another, often with a loud report. Previously to the rupture of the column, the dark parts seem to be drawn upwards irregularly, leaving only a slender tube in connection with the water below. The whole of the vapour is at length absorbed in the air, or it descends into the sea in a heavy shower of rain. The duration of the phenomenon is various: some spouts disappear almost as soon as they are formed, and others have been known to continue nearly an hour: occasionally they form themselves, continue for a short time, vanish, and again appear, and so on several times successively.

Waterspouts are occasionally seen above land (of which some remarkable examples will be described in the sequel), and consequently there is then no ascending column of water or vapour to meet that which descends from the clouds. In Dr. (Sir David) Brewster's 'Journal of Science' (No. 5) there is an account of one which was seen in France: it is stated to have appeared like a conical mass of vapour, and to have given out a strong sulphureous smell; flashes of lightning issued from it, and threw off a great quantity of water. It moved forward in one direction over high grounds and valleys, and it crossed the course of a river, but on coming to hills of a conical form, it passed round them. The alleged sulphureous smell was no doubt that of the electric *aura*, so called, perceived when lightning has taken effect very near the observer, and probably often that of ozone in reality. Waterspouts have occasionally been witnessed in this country. In 1718 one of them burst in Lancashire, when, at the place where it fell, the ground was torn up to the extent of about half a mile in length, and to the depth of seven feet, so as to lay bare the surface of the rock underneath. ('Phil. Trans.,' No. 363.)

The formation of waterspouts has been ascribed to a whirling motion produced in the air by currents coming in opposite directions; it has been supposed that the particles of vapour in the upper regions thus acquire, by the centrifugal force, a tendency to move towards the exterior parts of the column, leaving the interior void or in a rarefied state. The pressure of the atmosphere being thus removed from the surface of the sea or ground immediately below, that which takes effect on the surrounding water (when the spout is formed at sea) must impel the latter towards that part, and cause it to rise into the space where the partial vacuum exists. There is great probability that the elevation of the sea under the cloud is in part caused by the rarefaction of the air; but as the pressure of the atmosphere could only raise the water in a perfect vacuum to the height of about 30 feet, and as the height of a waterspout is known to be sometimes about half a mile, some other explanation of this part of the phenomenon must be sought for.

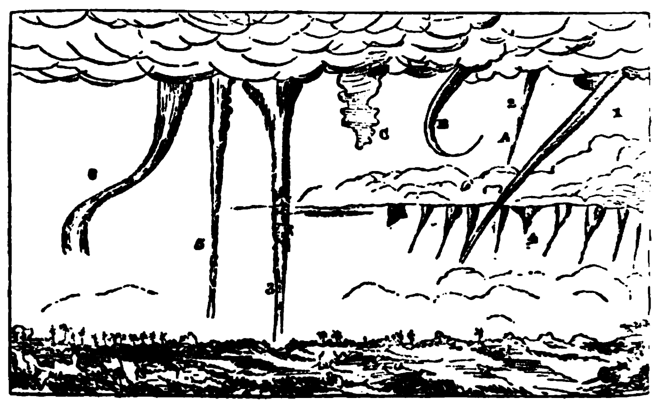
Some valuable observations on waterspouts formed over land have been recently made by Major Walter S. Sherwill, an officer to whom we are indebted for various contributions to science, respecting the physical geography and meteorology of India. Among other instances, he has described in a very instructive manner a waterspout of colossal dimensions which was seen to form and burst at Dum Dum, eight miles north-east of Calcutta, on the 7th of October, 1859. The circumstances preceding and attending the phenomenon were as follows:—

The south-west monsoon [MONSOON] during the week had received its first check by the north-east monsoon endeavouring to cross the Himalaya mountains, and to drive back the heavy masses of clouds "and moisture" (probably clouds becoming floating small rain, having the aspect of mist) that had been banked up along their flanks during the whole of the rainy season, or during the prevalence of the south-west monsoon. At Dum Dum, the visible heavens were wholly occupied by a dense mass of very grandly shaped and massively grouped strata of cumuli [CLOUD] at various elevations; the lowest stratum, from actual measurement by Major Sherwill, was 2000 feet above the earth, the highest probably reaching the altitude of 25,000 feet, the entire mass being about five miles in vertical thickness. The aspect of the heavens during the past few days had been most remarkable, presenting a scene of great disturbance; the clouds, evidently impelled from the south by the south-west monsoon, but, checked by the north-east, the whole mass, extending for as many miles as the eye could reach from north to south and from east to west, acquired a rotary and at the same time an undulatory motion; huge tracts of clouds revolving rapidly around a centre which appeared, from the observer's position, distant about 1¾ mile from Dum Dum, to be about 5 miles to the south-east. This rotary motion, performed in a very large circle, gave the clouds the appearance of moving in two distinct directions, those nearest to the observer appearing to be going north, and those furthest removed to be going south. In the early portion of the day, the wind had been from the south, bringing with it from the sea a large body of clouds; at noon it changed to the south-west, at 2 P.M. to the west, and at 4 P.M. to the north: there had been but little rain during the day.

The greatest disturbance in the clouds took place between the hours of three and four, the whole mass revolving and heaving violently; extensive masses of clouds were crushed and driven into others, but no lightning was observed. It now rained heavily to the north and east. "During this time," Major Sherwill says, "more than one waterspout endeavoured to form, but unsuccessfully. It was whilst observing the highly-agitated masses of clouds that were revolving and oscillating in a most peculiar manner, that I witnessed the commencement and termination of the remarkable waterspout now under consideration. At three P.M. it became suddenly quite calm, and during the calm a pale watery-looking, but very watery, cumulus, the base of which was a right line, and parallel to the horizon, was seen to bulge out downwards or towards the earth in a long well-defined and light blue coloured outline; from the centre of this hanging curve a broad column of a pale watery vapour rapidly sank towards the earth, closely resembling a very attenuated cone, dark at the edges and pale blue in the centre, plainly showing it to be a solid cylinder; as it neared the earth the lower half of this elegant column commenced to gyrate rapidly, the lower end oscillating violently to the right and to the left; this latter movement I imagine to be a mere optical illusion, caused by the lower end of the column revolving in a circle of large diameter; as the column neared the earth it expanded and contracted in an agitated and rapid manner about the centre into cloud-like protuberances, which partook at the same time of the motion of the revolving column. Upon arriving nearer the earth the end of the column parted into two slender columns about 150 ('or 200,' as stated in another place) feet each in length, and in this condition reached the ground. The shape of the column was now completely and instantaneously altered; for the whole cumulus burst, and was seen pouring down to the earth, not as a shower of rain, but as a heavy mass of water, resembling a waterfall more than a shower of rain, that completely exhausted and brought the whole cloud to the ground in a few seconds of time."

The estimated length of the cumulus, the lower portion of which had become a heavy nimbus, from which the waterspout depended, had been 3000 feet, and its height, from base to summit, 5000 feet. By trigonometrical means, Major Sherwill ascertained that the perpendicular height or length of the column or waterspout itself, from the point of its protrusion from the clouds to its lowest extreme point at the moment of bursting, was 1500 feet. Its period of duration, from its first formation to its bursting, was about 25 seconds. It burst upon the artillery practice-ground, a large grassy plain, of which it covered half a square mile with water to the depth of about half a foot, which took fourteen days to drain off by the usual drainage courses of the country. The cattle fled in all directions as it descended, but no noise was heard at the observer's position.

Major Sherwill's observations are illustrated by excellent lithographic representations of the waterspouts he observed. Some of these are somewhat roughly copied in the subjoined diagram, in which *fig.* 3 represents the waterspout now described. Half an hour after this had disappeared, he relates, "another formed to the east of the position: it was a very attenuated column, about 900 or 1000 feet in length, but the cloud from which it descended being upwards of 2000 feet above the earth, no contact was completed; the column, which lasted for half-an-hour, gradually faded away, being absorbed upwards into the cloud from whence it had descended. The cloud and column were moving rather rapidly towards the south, which probably accounts for the column never reaching the ground. The column gyrated and oscillated violently, lengthening and contracting as shown in the diagram (*fig.* 4), where eleven different positions of the column are given, sketched at intervals of from two to five minutes. Towards sunset, the clouds began to yield to the north wind, and were gradually driven out to sea, leaving a clear cloudless sky; and at nine o'clock at night not a cloud was to be seen. The north-east monsoon had fairly set in.



The following are the particulars of the other four waterspouts figured. *Fig.* 1. Seen from Sooksagur, 35 miles north of Calcutta, on the 27th September, 1855, at 3·30 P.M. Estimated length, 1000 feet. Moving south. Dependent from a heavy nimbus at an angle of 45° with the horizon. Upper portion gyrated rapidly. Lasted ten minutes. Did not burst, but was absorbed upwards. *Fig.* 2, A, B, C. Seen from Howrali (Calcutta) 24th September, 1856, P.M. Estimated length, 200 feet. Moving north. Depended from a very heavy and stormy looking nimbus, accompanied by vivid lightning. It was greatly agitated, throwing its lower end horizontally to the south, then to the north, at an angle of 45°; lasted about five minutes, and burst into heavy deluging rain.

Fig. 5. Seen from Dum Dum, and from Calcutta, on the 11th of August, 1860, at 5 P.M. Estimated length, 1000 feet. Moving south. Very perfect and grand. Depended from a heavy nimbus, unaccompanied by lightning. Gyrated rapidly at the top, dark at the edges and pale blue in the middle. "Divided at the lower end into two smaller columns of 50 or 80 feet in length." Lasted about ten minutes, and burst into heavy rain.

Fig. 6. Seen from Sulked, (Calcutta) on the same day, and at the same hour as the last; crossed the river Hooghly at that place, agitating the water beneath it. Estimated length 800 or 900 feet. Moving north-west. Depended from a heavy nimbus. "Had hanging fringe-clouds, dropping rain, on the south side of the upper part of the column." Gyrated rapidly at the summit of the column. Was bent by a south wind into an elegant double cone resembling the letter S. Lasted about ten minutes. Superior portion absorbed upwards, lower part burst into heavy rain. The figures in the diagram, it must be stated, have a more defined outline, and a greater appearance of solidity, than in the original lithographs.

Major Sherwill, in conclusion, has briefly described and also figured two other waterspouts, both attended by or exhibiting remarkable and instructive phenomena. One of these was seen by him from Darjeeling, in the Himalaya, on the 29th of May, 1852, at noon. This was a warm dry summer day, highly favourable to evaporation; and the invisible vapour with which the air had become charged was suddenly condensed, by a chilled stream of air descending from the snowy range of the Himalaya, distant 35 miles, into a huge cumulus cloud, at an elevation of 11,000 feet. The first effect of the cold blast was the formation of a small cloud "the size of the hand," which rapidly increased until it extended to the length of 15 miles and the vertical thickness of 5000 feet, or nearly one mile. This body of cloud was driven with great celerity to the south; and as it approached the mountain Ponglo (distant 11½ miles from Darjeeling, and slightly exceeding 10,000 feet above the sea) the lower portion, hitherto nearly horizontal, began throwing down about twenty waterspouts, each 1000 feet in length, which gyrated at a rapid pace, increasing in length at the same time, until the whole cloud burst into heavy rain. "The summit of the mountain," it is observed, "was evidently a point of attraction for the electricity contained in the cloud, as the waterspouts one mile north and south of the central group descended towards the mountain at an angle of 45° with the horizon, and all seemed striving to reach the very summit of the mountain; and upon reaching it they all burst into heavy rain. Time of duration, fifteen minutes." The other, and the last waterspout of Major Sherwill's list, was observed and sketched by the Rev. R. A. H. Norman, at Dum Dum, on the 28th of October, 1860. It was a group, depending from a heavy nimbus, and consisting of one central and large spout or column, 1500 feet in length, flanked to the eastward by many smaller ones, some of them 500 feet long, which were absorbed into the main column as fast as they were formed. Between the nimbus and the mass of light haze that covered the horizon, a long slip of blue sky was visible, and the waterspout, where it crossed this, was invisible, appearing as if the whole was divided into two portions. The entire group lasted twenty minutes, and eventually burst into heavy rain. ('Proceedings of the Asiatic Society of Bengal,' Sept. 5, 1861, Journal, new series, vol. xxix., pp. 366–375, 418, 419.)

The manner in which several of the waterspouts described by Major Sherwill burst into rain on coming into contact with the earth, is strongly indicative of electrical agency, to which, indeed, these phenomena, with more or less of vague conjecture or more or less of science, have long been attributed, and which may be both cause and consequence of the mechanical actions to which, in the former part of this article, they have in part been referred. The circumstance just mentioned points to an extension of the cloud towards the earth caused by electrical attraction, between two surfaces (those of the cloud and the earth), one of which has been charged by the other by induction, until, by the contact, a discharge of the electricity takes place, and the particles of water previously charged are at once precipitated upon the earth. Under other circumstances, the attractive force of the earth ceasing, or being insufficient, the spouts are absorbed into the cloud again by the force which holds the cloud together. But the column or spout itself, being colourless and transparent, when viewed by transmitted light, would appear to consist, not of cloud, but of water, nearly in the state of rain, and bristling into it on the discharge taking place. The entire system of cloud and water, and the flooded earth also, being one of excellent conductors of electricity, the discharge is comparatively or altogether silent.

Strong corroboration of these inferences as to the electrical production of waterspouts, may be found in their observed production in the sequence of the phenomena which attended the submarine volcanic eruption by which the temporary island, Sabrina, was elevated from the bed of the ocean, near St. Michael's, in the Azores, from the 9th to the 12th of June, 1811; the important bearing of which on this subject seems, hitherto, to have escaped attention. Captain Pillard, R.N., who witnessed the eruption, describes (under the name of smoke, like all other observers of volcanic eruptions until Mr. Poulett Scrope had shown it to be condensing steam), the immense steam-cloud issuing from the sea, which constituted a part of the eruption, together with, and through which the columns of stones, cinders, and ashes—the comminuted lavas—were projected in rapid succession. "During these bursts, the most vivid flashes of lightning continually issued from the densest part of the volcano; and the cloud of smoke [steam] now ascending to an altitude much above the highest point to which the ashes were projected, rolled off in large masses of fleecy clouds gradually expanding themselves before the wind in a direction nearly horizontal, and drawing up to them [and being drawn down into] a quantity of waterspouts, which formed a most beautiful and striking addition to the general appearance of the scene." These, according to the particulars stated ('Phil. Trans.,' 1812) must have been from three or four hundred to eight or nine hundred feet in height or length.

We have here, palpably, all the elements for the electrical causation of waterspouts—the immense evolution of electricity [VOLCANOES, col. 660], the charged surface of cloud, the dielectric atmosphere, the surface of sea below—and the actual production accordingly, of the phenomena sought to be accounted for. Much more might be said on this branch of the subject, which indeed is one of great extent and complication, the explanation now suggested being of a general nature only.

Much valuable information respecting waterspouts was introduced by the late Mr. Piddington, into part 5 of his 'Sailor's Horn-Book for the Law of Storms,' including a view of the contents of M. Peltier's work entitled 'Observations et recherches expérimentales sur les causes qui concourent à la formation des Trombes,' under which appellation whirlwinds and waterspouts are identified by the author; being applied, indeed, to them indifferently and convertibly, by French writers in general.

To a portion of this part of the subject we shall return when considering cyclones and whirlwinds in the article WIND.

WATER SUPPLY. The improvements which have lately been effected in the practical details of civilised life, have given rise to so great a demand for a copious domestic supply of water, that the branch of hydraulic engineering connected with that portion of modern social organisation has assumed a degree of importance, in excess even of the importance attached to it by the most civilised nations of antiquity. Yet from the earliest periods in the history of man, the attention of the governors of populous cities has been always directed to providing for them copious supplies of the fluid so indispensable for comfort, cleanliness, and safety; and no surer test can be found for the character of a national organisation, so far as its influence upon the physical happiness of its subjects is concerned, than the one to be discovered in the state of the water supply of its towns. Some of the lessons to be derived from an examination of the various systems hitherto adopted will be alluded to in the course of the following review of their history.

There are few indications left of the existence of a complete system of water-works in the ruins of the Assyrian, or of the Babylonian towns, although the numerous traces of canals upon the banks of the Tigris and Euphrates show that great attention was there paid to the irrigation of the land, and to securing a copious supply of water. In Egypt, the same conditions appear to have prevailed, and numerous canals were formed for the purpose of leading the waters of the Nile to tanks, and wells, situated at distances from the shores of the stream; but the water was not habitually raised to any height, unless in gardens, and then only in small quantities, and by very rude machinery. It is interesting, however, to observe that the hieroglyphical paintings of the Egyptians represent the use of the *shadouf*, or of the balance pole and bucket, still retained in that country, and by the market gardeners of the neighbourhood of London. The *noria* was not known to, or used by the ancient Egyptians, although so universally employed in that country at the present day; but Diodorus mentions that the machine known by the name of the Archimedean screw was invented by them. In Phœnicia, and in Judæa, traces of aqueducts, of tanks, and of wells, are frequently to be met with; and in those countries the first indications of works designed for the purpose of conducting the waters which outburst at a high level at some distance from the proposed place of consumption, may be observed. There were no pipes used in any of these water-works, or conduits; and the first instance on record of their application is to be found in the ruins of the aqueduct of Patara, in Lycia; upon which line there is a singular wall, or embankment of rough stone, across a valley 250 feet deep, and 200 feet across, bearing upon its curved top a line of marble blocks cramped together and perforated, so as to form, in fact, a reversed syphon. It would seem that the defective state of the metallurgic arts, alone retarded the application of the principles of hydrostatics known to the more ancient nations of the East; for the hieroglyphical paintings of Egypt certainly show that the syphon and the ordinary forms of pipes were occasionally employed by them; and the aqueduct of Patara equally proves that the Greeks were aware of the law by which water rose to equal heights in the two legs of a reversed syphon.

It was, however, under the dominion of the Romans that the ancient world undertook the most gigantic works for the supply of their towns with water; and, fortunately, the writings of Vitruvius, Frontinus, and Palladio have transmitted to our days much curious information with respect to the detailed methods of execution adopted by the Roman engineers. According to Frontinus, the inhabitants of the Eternal City for a long time contented themselves with a supply of water obtained from the Tiber, from land-springs, and from wells; but about the year 312 B.C., the censor Appius Claudius completed the first aqueduct, subsequently known as the *Aqua Appia*, which conducted to Rome the waters of a spring rising "in the field of Lucullus, between the 7th and 8th *milliaria* of the Prenestine road." Subsequently, the aqueducts of the Anio Vetus, Aqua Marcia, Aqua Tepula, Aqua Julia, Aqua Crabra, Aqua Virgo, Aqua Alsietina, Aqua Augusta, Aqua Claudia, Anio Novus, and the A. Alexandrina were added to the means of supply; and in the later days of the empire the daily distribution of water amounted to the enormous quantity of 332,307,624 gallons. As the population of Rome does not appear to have attained 1,000,000 under Aurelian, according to the calculations of M. Letarouilly, the average supply must have been about 332 gallons per head per day; but as the registers of the distributions show that only one-fifth of the total quantity was taken by private consumers, it must be evident that the bulk of the water was devoted to the public fountains, baths, gardens, and amphitheatres, &c. The text of Frontinus contains many curious details with respect to the manner in which the house services were connected with the reservoirs, or distributory cisterns; the regulation of the plumbers' works; and the precautions observed to insure the coolness and purity of the water; and there are few books illustrative of the manners and customs of the Romans which give so curious an insight into their municipal life as the 'Commentaries' of this author. It may be added that the total length of the eleven first-named aqueducts was not less than 456,987 yards, of which 53,421 yards were built upon arches. The highest point of ground in the city was the Mons Esquilinus, which was 144 feet 8 inches above the level of the invert of the Cloaca Maxima, but the aqueduct of the Anio Novus discharged its waters at the level of 155 feet 10 inches above the same datum. The flow of the waters attributed to the public service was constant, by night as well as by day; and the private consumer had the same privilege if he desired it.

The Roman emperors were far from confining their attention to the water supply of Rome itself, for numerous and gigantic works of that description, for the supply of important provincial towns, were executed by their orders. [AQUÆDUCT.] During the decline of the lower empire, even, the construction of aqueducts and of reservoirs was carried on with the same degree of energy as in the brighter periods of the Roman rule; and the neighbourhood of Constantinople possesses ruins of the aqueduct of Justinian, and in the valley of Bourgas, which may rival any of the earlier structures in magnitude at least, if not in constructive skill. Perhaps the most remarkable parts of the water-works of Constantinople were, however, the subterranean reservoirs there constructed to store the water. One of them is about 319,200 cubic feet in capacity, and the other about 1,028,970 cubic feet, and they are vaulted throughout.

Of course the art of distributing water suffered under the effects of the irruption of the barbarians; and all that was done by even the most enlightened of the rulers of the Gothic, Vandalic, and Lombardic tribes was to repair and maintain the aqueducts they found to be in existence when they overran the provinces of the Roman empire. There is a tradition connecting the erection of the aqueduct of Spoleto with the name of Theoderic the Goth; but the style of the monument, and many other indications it furnishes, would throw great doubts on the correctness of the story; nor can we discover any authentic records of the execution of any great works for the supply of water to towns during the mediæval period, until about the end of the 13th century. In fact, the great centres of population in modern times were but very insignificant villages in the early periods of history; and property was held by far too uncertain a tenure to justify the execution of great public works. The Italian cities seem to have been the first to attempt anything like a systematic distribution of water; and Michael Boccanegra, at Genoa, in 1278, the unknown authors of the Spoleto and of the Civita Castellana aqueducts, at other periods in the Middle Ages, revived the modes of construction adopted by the Romans. In the north of Europe there do not appear to have been made any attempts to rival the gorgeous monuments of the Roman empire; and in nearly all cases—as at London and at Paris—the system adopted seems principally to have been to lead to some stone reservoirs the waters of springs rising in the country, by means of wooden or of leaden pipes. When the populations of those towns had increased to a considerable extent, it was found, however, that, as in the former case of Rome, it was no longer possible to obtain the necessary quantity of water from the superficial gravels, or from the water-bearing strata around them; and we accordingly find that at the close of the mediæval period efforts were made to secure water-supplies to the large towns from larger areas than had previously sufficed. In France, the engineers seem to have considered themselves bound to return to the traditions of the Romans, and the aqueduct of Arceuil was built in avowed imitation of the analogous structures of the ancients. In England, the system of contouring the hills by open water-courses prevailed; and the Plymouth Leet, established by Sir F. Drake, and the New River by Sir H. Myddelton, may be cited as illustrations of the system long adopted here. The great aqueduct of Lisbon, erected between 1713 and 1732; the aqueduct of Caserta, erected by Vanvitelli about 1753; the aqueduct of Symete, erected by Prince Biscari, in Sicily; the Croton Aqueduct, and the Roquefavour Aqueduct, may be referred to as illustrations of the modern execution of works for the supply of water, designed upon the principles of the ancients; but the majority of the modern water-supplies are executed in a far less ostentatious manner, and with modifications required by the local habits or by the municipal organisation of the towns themselves. Of late years, also, the improvements which have been effected in the machinery used for the purpose of raising water, and the new applications of metallurgy to the building arts, have so profoundly changed the economical conditions of the distribution of water, that it is hardly possible to compare the systems which have respectively prevailed in ancient or in very modern times. The fundamental difference seems, however, to consist in this, namely, that the state undertook the execution of the water supplies of antiquity, whilst in modern times they have been left entirely to municipalities or to private industry. What the moderns may have gained in economy under these circumstances, they have lost in art; and just precisely as the economical element of the calculation prevails, so does the manner in which a modern water supply is effected lose all character of beauty as a monument.

Before entering upon the consideration of the technical questions connected with the subject of a water supply, and before quitting the past history of those operations, it may be desirable again to dwell upon a very generally received opinion with respect to the assumed ignorance, by the ancients, of the principle of the inverted syphon; or of the principle by which water will find the same level at the two ends of a continuous pipe, unless prevented by some external force. This opinion has been repeated in so many popular works upon science, that it is almost universally believed; yet, not only does the aqueduct of Patara entirely refute it, but the great syphon upon the course of the aqueduct of Lyon proves that the ancients were as well acquainted with the principle as the moderns themselves are. It is the more extraordinary that this singular opinion should have obtained such universal credence as it has done, because Vitruvius discusses in a very practical spirit the mode of executing the descending and ascending pipes, in chap. vii. lib. 8; and he points out the precautions to be taken to prevent the rupture of the pipes by the compression of the air in the lowest parts of the syphon.

The first inquiry at the present day, when it may be desired to execute a system of water supply to a town, after having ascertained the present and the probable future extent of the consumption (which is usually reckoned to take place at the rate of forty gallons per head of the population per day), must of course be, as to where a permanent supply of water of a proper quality is to be obtained. Much discussion has of late years taken place with respect to the question as to what constitutes the proper quality of such a water, and the formerly received opinions of physiologists and engineers have been boldly challenged by men who have had little claim to either of those titles. The discussion has principally turned on the subject of the hardness and of the softness of waters, consequent upon the presence in them of the salts of lime, in the form of the bicarbonates of that base; the former authorities upon such matters contending that a certain proportion of lime is necessary in a potable water, whilst the new lights contend that absolute purity should be aimed at. The truth, in this case, seems to be that there is still too considerable an amount of uncertainty with respect to the real action of the salts in question upon the human frame to allow of the formation of any very decided opinion on the subject, or of the establishment of any absolute law for the adoption, or rejection, of a particular source of supply, when its departure from the standard of absolute purity is very small. Local considerations of economy must, in the present state of knowledge, exercise great influence upon the choice of the source of supply; and it is only when the quantities, or some peculiar properties, of the extraneous impurities, are very objectionable, that it becomes desirable to reject a source which is close at hand. The qualities which are indispensable in a water designed to be distributed in a town, are, to quote the words of the 'Annuaire des Eaux de France,' that "it should be fresh, limpid, and without smell; that its flavour should be hardly perceptible, and that it be neither disagreeable, flat, brackish, nor sweet; that it should contain little foreign matter, but a sufficient quantity of air in dissolution; that it should dissolve soap without leaving curds, and should cook vegetables easily." A small portion of carbonic acid gas increases the wholesomeness of a water, by its influence upon the digestive organs; but it enables the water to take up an additional quantity of the salts of lime (which in their turn increase the hardness of the water), and to develope some forms of disease (such as gout, calculi, &c.) in the populations using it habitually. Waters containing salts of magnesia, or of sulphate of lime, are considered, on the other hand, to produce the loathsome disease, the goitre; and the very purest waters obtained from the melting of ice, or of snow, are deficient in some elements necessary to maintain the healthiness of the human frame. The waters which hold in solution notable proportions of organic matters, are, however, those which are the most objectionable; and diarrhœa, dysenteries, and other acute and chronic diseases may be traced to the use of the water obtained from ponds, marshes, or wells, containing excessive proportions of altered organic matters, either in suspension, or in solution. It was considered, by the authors of the 'Annuaire des Eaux,' that the small quantity of the chloride of sodium to be found in ordinary river or spring water was rather advantageous than otherwise; and they further remark, that the chlorides in water are almost always associated with the iodides and bromides, which unquestionably increase its salubrity. It may be added, that when the proportion of the bicarbonate of lime in a potable water exceeds 1 in 2000, it becomes positively injurious; that the bicarbonate of lime is thrown down by boiling; but that neither the salts of magnesia, nor the sulphate of lime, are thus expelled.

The opinion which it has lately been attempted to convert into a law, "that the nearer the source, the purer the supply," seems to be one of those half-truths which require to be accepted with a reservation. Thus, the waters rising from deep-seated springs in the chalk formation contain at their source an abnormal dose of the bicarbonate of lime, which they part with if allowed to flow in the open air in a clear channel. Indeed, so much do waters generally improve by the flow in open channels, that some of the ablest physiologists hold that river waters alone should be used for town supplies; but in such cases, it is essential to adopt precautions with a view to the prevention of the contamination of the latter, by the organic impurities washed down from the lands they traverse. A prolonged course over a rough channel also removes earthy impurities, and the hydrous oxides, which are often held in suspension in spring waters; but it does not seem to have any influence upon the sulphates of lime, or of magnesia, or upon the chlorides of calcium or of sodium. In all cases wherein such a course is able to do good, it must, however, be observed, that the water must flow with considerable velocity; and it would appear that the aëration of the water thus produced constitutes one of the superiorities of river waters over those obtained from ordinary wells; because the latter are exposed, occasionally, to become stagnant. When a water supply has to be obtained from a great distance, the considerations of the deposition of the earthy salts become of great importance, on account of the effect they are likely to produce upon the delivery of the conducting channels; and it was precisely because the engineer of the Marseille waterworks, M. de Montricher, feared that the waters of the Durance would choke a reversed syphon that he was led to erect the gigantic aqueduct of Roquefavour. The channel through which any stream is to be led must, it may also be added, be protected from accidental impurities derived from the atmosphere, or from any other source; and even at the present day, the hydraulic engineer might derive many useful lessons from the practice of the Romans in these details of their aqueducts. They took care, in fact, to cover their channels as far as possible; to provide ventilating shafts from distance to distance; and to place drips in the line of the invert, in order to produce small cataracts, with a view to increasing the aëration of the water.

The objections to the use of ordinary well-waters, on account of their tendency to become stagnant, apply with variable force (according to the quantities considered) to the waters of ponds, of reservoirs, or of lakes; and therefore they have an important bearing upon the system of the supply to towns, known in England by the name of the "*catch-water gravitation system.*" In works of this description, the water, falling upon elevated districts around the town to be supplied, is stored in large artificial reservoirs, in such a manner as to allow the excess of the winter's rains to be distributed in the dry season; and evidently these reservoirs must be established so as to ensure the disposal of the maximum quantity for distribution precisely at the season when there would be the least rainfall to renew the water. During the dry season, in fact, the water in the reservoirs cannot be renewed, and it must be exposed to all the deleterious actions which are known to take place in stagnant water from the development of animal and of vegetable life in them, under the influence of light and heat. The purity of the waters thus stored must, however, depend greatly upon the nature of the surface from whence they flow, upon the nature of the soil of the reservoirs themselves, and upon the exposure, the outline in plan, and the transverse sections of the reservoirs; for the primary qualities of the water depend on the first of these considerations, and its preservation in a wholesome state depends greatly upon the influence of the latter in maintaining a surface agitation. The lands which exercise the most deleterious action upon the waters to be impounded are those which are covered by peat, or by agricultural land; or those which are likely to give off mineral or earthy salts in large quantities; and, therefore, the primary or secondary crystalline rocks and the pure silicious sands are the best adapted for the purpose of forming gathering-grounds. In England, and in most countries where gravitation waterworks can be established from reservoirs, such as are above alluded to, it fortunately happens that the gathering-grounds occur in the hilly districts of the primary formations; but in India, and in tropical alluvial plains, it is often necessary to store the excessive rainfall of the wet season in *tanks*, for consumption during the dry season, because the superficial water-courses cease to yield water, and there are no perennial springs in such districts. The waters so stored must, under these circumstances, be filtered, or treated in some way, in order to counteract their otherwise deleterious effects upon the human frame; the great difficulty, however, arising from the temperature to which they are raised by the sun's action upon their surface.

It would appear, after all, that the waters which unite the greater number of favourable qualities for a town supply are those which flow from deep-seated springs, or from the insoluble clay slates, crystalline limestones, or are obtained by continuous pumping from wells sunk in the pure silicious strata, &c. It is not often that these wells yield water in sufficient quantities for a town supply; and there is always a danger of their being interfered with by the operations of neighbours, or by injurious infiltrations from cesspools or dead wells. The history of the Artesian wells round London, of those at Tours and Paris, and of the deep wells in the new red-sandstone at Liverpool, proves that there are serious objections to allowing the supply of a large population to depend on sources so uncertain, and so easily diverted, as these deep-seated springs evidently are. In no country in Europe is there any legislation creating a right of property in underground waters; for law-makers have not hitherto been geologists, and they have openly avowed their ignorance of the principles which regulate the flow of deep-seated springs. It thus happens that the inhabitants of large towns are compelled, practically, to resort for their water supply either to rivers or superficial water-courses, or to create reservoirs upon either the gravitation or the tank system, to impound the rainfall of the wet seasons.

In the previous portion of this article it was stated that the quantity of water to be distributed in a town was usually calculated at the rate of 40 gallons per individual per day; but evidently local circumstances may affect this rate of consumption to a very serious extent. It is more than questionable whether even the most luxurious persons require absolutely a greater quantity than 6 gallons per day for their own immediate consumption; and if the latter be carried to 10 gallons per day, it would suffice with proper care for any real demands. In calculating for a town supply, it is necessary, however, to allow for the consumption by trades using large quantities of water, and for municipal purposes, such as street-watering, flushing sewers, extinction of fires, &c.; and, in order to cover these demands, it was considered, so long as the old-fashioned intermittent supply existed, that an allowance of 20 gallons per head per day would be sufficient. The introduction of the constant-delivery system has of late years tended singularly to increase the quantity of water distributed, and indeed the waste of water which thus takes place is at times so great that it almost assumes the importance of a public calamity. In London, where the intermittent supply still prevails, the consumption of water is now not less than at the rate of 40 gallons per head per day on the average; in Croydon, at Boston, New York, &c., the rate under the constant delivery has been 80, 100, and even sometimes 500 gallons per head per day. No doubt a great part of this waste could be prevented, and it would never be allowed to exist if the water supply of towns were left in the hands of private companies; but the tendency of the age is certainly to withdraw municipal services from the control of speculative adventurers, and it therefore becomes important to direct attention to the eventual danger arising from the waste which seems to be inherently attached to the modern system of distribution.

Whatever may be assumed to be the normal rate of consumption by the inhabitants of a town, it must be observed that, in the summer months,—that is to say, in June, July, August, and September,—the average consumption per individual per day increases in about the ratio of 10 per cent. upon the ordinary average; whilst in December, January, and February it is about as much below the same average. In designing gravitation-works, especially, this becomes an important consideration; for the consumption actually increases when the supply decreases, and the dimensions of the reservoirs must be calculated of sufficient size to meet the demand of the season which is the most unfavourable. The compensations to be given to the ancient possessors of water privileges must also be taken into account in designing any new water-works, especially in the case of gravitation-works, which interfere more with the natural hydrographical conditions of a district than ordinary pumping-works do; and the loss of water by evaporation from the reservoirs in hot weather requires also to be allowed for. In most countries of Southern Europe, it is to be observed, moreover, that the rate of personal consumption of water, so to speak, is much less than the rate prevailing in the north, but that the quantity of water poured down the channels, or used in the monumental fountains, or in other contrivances for cooling and refreshing the air, is, on the contrary, very much greater. Thus, in Paris, it is stated officially that the supply of water takes place at the average rate of 13¼ gallons per head per day; but, in fact, the water is sold by the pail, and in no house in Paris is there a supply (in 1861) to the second floor, and nearly all the water which is brought into the city is poured into the street kennels or is employed in the fountains. All these details of the application of a town supply must, therefore, be carefully examined, and allowed for, in selecting the source and mode of distribution; for it must be evident that every particular climate, and every phase of civilisation, requires to be treated upon its own special principles.

The quantity and the quality of the water supply being determined, a very important question arises, as to whether it should be obtained, at a great original outlay, under such conditions as to allow the water to flow to the place of distribution, by gravitation; or whether it should be obtained by means of pumping-machinery, at a smaller original outlay, but at a greater annual expense for working. This question is one which it is impossible to decide *à priori*, because it must be so materially affected by local considerations as to render it dangerous to lay down any absolute rules in the matter. But it must be evident that, wherever it is possible, as it was in the case of ancient Rome, to lead into a town streams of water rising at a natural elevation above the proposed points of distribution, there must be an eventual economy in so doing over the cost of another system by which the water would be raised from even a nearer point by the aid of a complicated piece of machinery. The Romans, who were able to concentrate upon any work they undertook the resources of the known civilised world, adopted the former system; and the highly-centralised governments of modern Europe evidently prefer it, for the French are about to incur an enormous expense in order to lead to Paris, by gravitation, some springs which rise at a great distance from that town. In England and in America, however, where individual enterprise is so much more active, the tendency is to resort to sources of supply which admit of the application of machinery at a small primary outlay; and, in fact, the choice between the two systems must greatly depend upon the power of commanding capital, and upon the balance of motives which might lead to imposing a burden upon the present generation for the sake of its successors. In either case, the works required for the filtration, storeage, and distribution of the waters are the same; the only difference consists in the mode of leading the water to the point from whence the distribution is to take place.

Even in gravitation works there are various methods of solving this question, for the water may be led either in closed pipes or in open or in covered conduits. Open conduits may be resorted to when the district they traverse is not likely to furnish any elements of a nature to alter the purity of the water; but if small local watercourses should be likely to pour into the stream, or if the latter should be exposed to the danger of contamination from the dust, smoke, or other impurities of a town atmosphere, the conduit must be covered. The advantage of a pipe-conduit consists precisely in the protection it affords against such accidental sources of contamination, and, generally speaking, it will be found to be cheaper than a masonry conduit of ordinary dimensions. Moreover, the facility the pipes furnish for the execution of reversed syphons dispenses with the necessity for the construction of costly aqueducts. It is essential to make the dimensions of the pipe somewhat larger than would theoretically be necessary to convey the quantity of water required to be delivered; because there is a danger, in almost all cases, of the formation of an incrustation in the interior of the pipes, which would practically diminish their sectional area; and it is essential, also, to provide means for occasionally examining and clearing the pipes. In all descriptions of conduits it is necessary to provide stop-gates, or valves, and overflows, so as to arrest the passage of the water in case of accident. The material generally used for pipe-conduits is cast-iron; but glazed stone-ware is often employed with success, when the water does not flow under great pressure. The Romans frequently used lead-pipes for this purpose; but as a general rule they preferred covered aqueducts, and the Continental engineers still adhere to this system. In the great Liverpool gravitation water-works, and in the new supply to Glasgow from Loch Katrine, cast-iron pipes have been exclusively used where any great differences of level have been encountered.

In the majority of cases at the present day, the water brought from a distance for the supply of a town, is filtered before distribution; and this is effected in positions as close as possible to the pumping station, or to the entry of the distributing mains, unless the water should be so pure naturally as to allow this precaution to be dispensed with. There are numerous systems of filtration in use in England, but the one most generally adopted is to cause the water to pass through a succession of layers of sand and gravel (increasing in coarseness from above downwards) to a series of drains leading to a covered reservoir. The total thickness of the filtering media is usually made from six to seven feet, and the number of layers about eight or nine, the head of water over the upper surface of the sand being about two feet. Engineers, however, are not unanimous in their opinions as to the best relations between the depth of the filtering media and the head of water over them; for in some cases the depth of the sand and gravel is made only 4 feet 6 inches, and the working head four feet, instead of the dimensions quoted above; but evidently the degree of purity of the water itself must materially affect this question. It may even happen that the quality of the water may require the introduction of some ingredient in the filtering media which should be able to exercise a chemical influence upon the water itself; and in some cases it has been proposed to mix animal charcoal with the upper layers of sand, in order to remove any organic matters; or to mix the magnetic oxide of iron with the sand when peaty matters are present; or even to apply Dr. Clark's process when the bicarbonate of lime is present in notable excess. Local considerations must guide the engineer in his choice of the various systems; but however the water may be treated in this stage of the distribution, it is absolutely necessary that it should not be exposed to the air at all after having been filtered, and that it should be either at once passed into the distributing mains, or be stored in covered reservoirs until wanted for use. In the construction of the latter, the only important observation to be made is that they must be executed in such a way as to protect the water against the action of light and of the sun's rays; local facilities for the supply of building materials must regulate the precise details of the construction itself. In some peculiar cases it is desirable to provide, in addition to the filters and pure water reservoirs, depositing basins, in which the heavier materials, in mechanical suspension in the waters of the natural source of supply, may deposit themselves; but, again, this detail admits of no universal law; and it is even to be observed that the tendency of the London engineers is rather towards the suppression of both depositing basins and storeage reservoirs. They make the filters of sufficient area and thickness to complete rapidly and effectually the separation of the impurities; and they pump the filtered water at once into the distributing mains. Where storeage reservoirs are used, their dimensions may vary between the capacity required for three days' consumption, when the source of supply is liable to occasional interruptions; and the capacity required for a few hours' supply when the machinery is only subject to ordinary periods of rest or repair. In the latter case it may be necessary, however, to make the machinery in duplicate, or at least to keep a stock of duplicate parts. Care must be taken to provide for all such service reservoirs, valve pits, overflow pipes, waste weirs, scouring pits, and other conveniences for examination, cleansing, and repair.

Unless in the cases of gravitation works, it is necessary, in all modern domestic water supplies, to raise the water to such heights as to allow of its distribution in the loftiest rooms of the houses situated on the highest ground in the respective towns, by some description of machinery. When the quantity to be raised is small, and there is a watercourse of considerable volume, and great constancy of flow, in the neighbourhood, it may often be advisable to resort to hydraulic power, and to use one of the forms of water-wheel hereafter described. But it happens that water-power is exposed to frequent interruptions, so to speak, in its efficiency; and that in summer, when the largest quantity of water must be raised, the power is the least, whilst in winter the action of the wheels may be entirely suspended in consequence of floods or of frost. In England, therefore, where coal is cheap, and the use of steam-power is habitual, the latter is almost always resorted to, and it certainly presents many advantages, on the score of certainty of action, over all other sources of motive power. In France, Germany, Switzerland, and the United States, however, many water-wheels for the supply of towns are to be found; and even within a very few years London itself was dependent for a large portion of its water supply upon the water-wheels of old London Bridge. The towns of Toulouse, Geneva, Richmond, Va., and Philadelphia, may be mentioned as amongst the most important of those supplied with water by water-power; and in the works lately executed by Mr. Hawksley, at Weymouth, a very ingenious application of the turbine was made. The majority of the English towns are supplied by means of steam-engines; and the machinery lately erected for the supply of London may be cited as being the most extensive and the most beautiful of any hitherto erected. It is usually considered that there are advantages in the use of the Cornish pumping-engines when the power to be exercised exceeds 25 horses, and that for lower powers direct-acting engines, or fly-wheel engines, are preferable; but the remarkable results obtained by Messrs. Simpson and Boulton and Watt, show that the preference for large Cornish engines is at least open to question.

In estimating the power to be provided, and consequently in deciding the description of engine to be employed, it is necessary to take into account the weight of the water to be raised at the maximum rate of consumption; the total height to which it has to be raised; and the various causes of retardation of flow in the pumping main, from the friction upon the sides of the pipes, and the bends or changes of horizontal or vertical direction. It will be necessary to revert to the general laws affecting the flow of water in pipes; but here it is sufficient to observe that an allowance equivalent to an increase of 12 feet per mile in length of main, to the total weight to be lifted, is sufficient to cover the effect of these retarding causes. As the various classes of engines do not work up to their full power, calculated theoretically, it is necessary to affect the result of the above method of ascertaining the pumping power by the coefficients of the respective engines; which are, for steam-power, on the average, 0·85, and for the best water-wheels, 0·75.

In small pumping engines it is found that the most useful action is obtained when the power is exercised equably and continuously; and in order to secure this result, the main shaft is made to carry three cranks placed at angles of 120° from each other, upon which the pump rods are keyed. In the larger engines it seems that the most favourable conditions of motion in the pumps are, that they should begin by raising the load rapidly, in order to overcome its vis inertia; and that when the motion of the ascensional column has been once established, the effort of the motive power should gradually be diminished. These objects are effected in the Cornish engines by introducing steam to the underside of the cylinders, through large openings, at high pressures; the steam is then cut off when the inertia of the water has been overcome, and it is allowed to expand during the remainder of the stroke, exercising in so expanding sufficient power to maintain the ascensional movement; the return stroke is made by the dead weight of the plunger and of the rods. The initial pressure of these engines is usually from $2\frac{1}{2}$ to 3 atmospheres; the expansion begins at from $\frac{1}{8}$ to $\frac{1}{4}$ of the stroke of the piston; and at the end of the stroke the pressure of steam is not more than between $\frac{2}{10}$ and $\frac{3}{10}$ of an atmosphere; engines so worked being said to produce a duty equivalent to about 90,000,000 lbs. raised 1 foot high by the combustion of 1 cwt. of coal. But it is to be observed, that in consequence of the interposition of the air-vessel upon the delivery-pipe of a town pumping-engine, the delivery is, in fact, constant; and it is probable that the extraordinary results obtained of late by the application of the beam and fly-wheel engine, on a large scale, to pumping operations, may be explained by the fact that as they supply water to the air-vessel in a more continuous manner than the Cornish engines do, they allow the air-vessel to produce its effect with greater regularity. In the large engines erected by Messrs. Simpson for the Chelsea and Lambeth Water-works, the steam works at high pressure in the first of two cylinders, and at low pressure in the second; there is a beam and fly-wheel to each engine; and it is said that the duty they perform sometimes reaches 120,000,000 lbs. raised one foot high by the combustion of 1 cwt. of coal. Fly-wheel engines, it may be added, possess this great advantage over Cornish engines for the purpose of town distributions, namely, that they are capable of being worked at more variable rates of delivery than are the latter; and in a town delivery the rate of consumption is subject to such singular irregularities, that this susceptibility of variation in the power may often be a matter of importance. But again, it must be stated that the best modern Cornish engines have been so carefully and skilfully constructed, that they have even allowed the regulating service reservoirs to be dispensed with; and both the Kent and the East London Water-works pump directly into their supply mains by night and by day, trusting entirely to the skill of the engine-drivers to adapt the motive power to the variable conditions of the consumption of their districts. These variable conditions are of much greater importance than is generally considered to be the case; for it appears from careful examination that about three-fourths of the total daily consumption of a town takes place between the hours of eight in the morning and eight in the evening; and experienced engineers make their pipes and engines large and powerful enough to discharge one-fourth of the total daily consumption in one hour. Evidently, then, it must be desirable to employ the motive power which is able to adapt itself to such variable demands with the greatest elasticity.

In passing from the pumping station to the regulating reservoir, or to the point of distribution, the water usually flows through a simple pipe of a uniform sectional area; and, as far as it is possible to secure that condition, with a uniform, constant velocity. In its course, however, the water is retarded by a series of resistances, which practically may be resolved into those depending upon:—1. The friction on the sides of the pipes; 2. The existence of bends, or changes of direction; and 3. The gurgitation which occurs at every interruption in the uniformity of the flow. The two former of these interfering causes act upon water flowing in open channels, and have therefore to be taken into account in fixing the dimensions of those channels; but the last named cause acts exclusively upon water flowing in pipes. In the following remarks upon the flow in pipes it must, however, always be understood that they are supposed to run full bore, and to have got perfectly "in train," to use a technical phrase; that is to say, it is supposed that a constant velocity is maintained in those portions of the pipes wherein there are no side branches.

Now, the friction on the sides of the pipes depends principally upon their diameters, and upon their lengths, and upon the pressures upon the respective orifices of supply and discharge; and as the latter conditions (the pressures) are in fact analogous to the effect of a column of water, or "a head," as it is commonly called, it is customary to reason upon the pressures in terms expressing the heights of such columns. Practically it appears that the results obtained by allowing for the above cited elements of the resistance produced by friction, require to be affected by a term depending upon the initial velocity of the water; and according to some recent investigations by M. Dupuit, by another term depending upon the material of the pipe. For ordinary purposes it is often not necessary to take these causes of diminished supply into account, and it then suffices to consider that the quantity of water flowing through a pipe of uniform diameter, receiving its water from a reservoir at a high level, and discharging it into another reservoir at a lower level, the pipe being without any change of direction, may be represented by the formula $Q = c\sqrt{\frac{H + \zeta - H'}{\lambda}}\,D^5$; in which Q = the quantity sought; ζ = the difference of level between the extreme orifices; λ = the length of the pipe; H = the initial head; H' = the head over the lower orifice; D = the diameter of the pipe; and c = a coefficient ascertained by experiment when the velocity of flow, per second, is as follows:—

Velocity.	2 inch.	4 inch.	8 inch.	12 inches.	20 inches.	78 inches.
$c =$	15·06	17·92	18·83	19·50	19·84	20·79

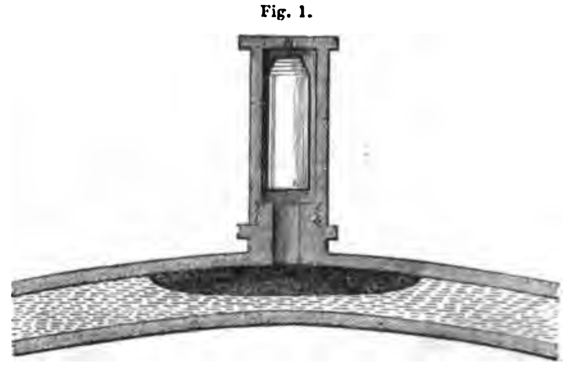
And for any velocity beyond 78 inches per second, $c = 21{\cdot}043$. But this formula can only be applied when the velocity is previously known; should this not be the case, or should it not be ascertainable by actual observation, it may be calculated by a second formula in which making $K = \frac{H + \zeta - H'}{\lambda}$ (the previous notation being retained), then, V, the velocity $= -0{\cdot}1541131 + \sqrt{0{\cdot}023751 + 32806{\cdot}6 \times \frac{DK}{4}}$. When it becomes necessary to take the friction on the sides of the pipe into account, it is ascertained by calling, firstly, the velocity due to the vertical head, without any allowance for friction, v, or expressing it in terms of the height $H = \frac{v^2}{2g}$, then $H - \frac{v^2}{2g}$ will be the portion of the head destroyed in producing that velocity, or the loss of head produced by the friction. Secondly, if we call the length of the pipe λ, the sectional area S, the wet contour C, and the two coefficients it is necessary to introduce respectively, a and b; the expression of the resistance would become $a\frac{C\lambda}{S}(v^2 + bv)$; and we should have $H - \frac{v^2}{2g} = a\frac{C\lambda}{S}(v^2 + bv)$. It is then only necessary to ascertain the value of the coefficients a, b, in order to apply the formula for general use; but unfortunately every observer has attached different values to them. In this state of uncertainty it is sufficient to adopt the formula and values attached to the coefficients by Weisbach, in his 'Treatise on Mechanics,' because the formula is simple, and is known to give safe results; that is to say, results which are rather in excess of those ascertained by direct experiment, but sufficiently accurate for practical purposes. Weisbach calls the loss of head h'; and confining his attention to the length and diameter of the pipes, he makes $h' = \left(0{\cdot}01482 + \frac{0{\cdot}017963}{\sqrt{v}}\right)\frac{l}{d}\cdot\frac{v^2}{2g}$; the result being in feet.

The friction, and the consequent loss of head, from the existence of bends, is found to be in a certain proportion dependent upon the ratio of the diameter of the tube to the radius of curvature of its axis. Navier says, that the formula $h_1 = \frac{v^2}{2g}\left(0{\cdot}0039\frac{1}{r} + 0{\cdot}0186\right)\frac{a}{r}$ (in which r = the radius of the curvature, and a = the development of the arc), will represent the loss of head thus occasioned; and according to him it would appear that h_1 is proportional to the square of the mean velocity, and to the length of the arc; that it is a function of the radius of the arc, and independent of the diameter of the pipes; and that h_1 decreases in proportion as r increases. In order to apply the above formula to the case of side mains branching off from a leading main, it is necessary to adopt the following ratios between the diameters and the radii:

Diameter.	2 to 3 in.	3 to 4 in.	6 inches.	8 inches.	10 in. and upwards.
Radius r .	1 ft. 6 in.	1 ft. 8 in.	2 ft. 6 in.	3 ft. 6 in.	5 feet.

The interference with the rate of delivery of a pipe by the gurgitation produced by the changes in the conditions of flow, may practically be neglected in the calculations for proportioning the details of a town distribution; because it is easy to effect the pumping in the leading main with sufficient regularity to avoid its serious occurrence, and to make the distributing mains large enough to destroy its influence. Attention has, however, been called to this interference on account of the lesson it affords of the danger of adhering too strictly to the dimensions of pipes which would appear to be indicated by abstract theoretical laws; and of the necessity which exists for providing for irregular disturbing causes. There is another danger to be encountered in the delivery of water through long leading mains, namely, the danger arising from the accumulation of air in the bends, especially when they are in a vertical direction, for the air then has a tendency to accumulate at the summit of the bend, and thus either to diminish the water way, or even to stop the passage of the water altogether. The remedy for this evil consists in the establishment of air-vessels upon the summit of the bends, through which the air may escape; and any slight retardation of flow created by the small quantity of air left in the water, or by the dead weight of the small column to be lifted, must be provided for by increasing the initial velocity of flow. In important works it is customary not only to introduce air-vessels, but also pressure regulators at the summit of the large bends, in order to ensure equality of flow. *Fig.* 1. represents a very simple air-valve which has been successfully applied.

Fig. 1.

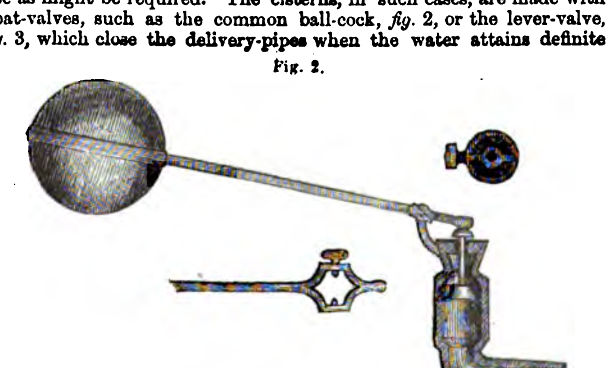


The formulæ for calculating the discharge of pipes under certain fixed conditions of head and diameter, cease to be applicable when there is a series of branch-mains, sub-mains, and service-pipes attached to the leading main, such as always occurs beyond the service reservoirs, or the first point of distribution in a town supply. In fact the dimensions to be given to the distributing pipes can hardly be decided upon other than upon empirical principles, and long experience is a better guide in these matters than any abstract theory. The method adopted by Mr. Hawksley may perhaps be cited as the one most generally satisfactory, and it has been described by himself by saying, that upon the constant delivery system (in which the pipes are always under charge, and no cisterns are used), he divides the length of the main in a street into portions of about 200 yards each, and he assigns to every such portion the quantity of water it would be likely to require, in proportion to the population to be supplied by it, on the supposition that the total quantity is to be delivered within four hours. He then allows for a loss of head of 4 feet in every 200 yards; and adopts, in calculating the diameters to be given to the pipes, the formula $d = \frac{1}{15}\sqrt{\frac{q^2 l}{h}}$; in which q = the number of gallons to be delivered; l = the length of the main in yards; h = the head in feet; and d, the diameter required, in inches. In Claudel's 'Formules à l'usage des Ingénieurs,' there is to be found a description of a more elaborate and theoretically correct method of ascertaining the diameters of sub-mains; but it is so much more complicated than the one used by Mr. Hawksley, that it will suffice for the purposes of this Cyclopædia to refer the reader to the work in which it is explained.

In carrying into effect a town distribution it is necessary to observe numerous precautions, in order to protect the pipes from injury by external causes. Thus, wherever gas- and water-pipes are laid in proximity to one another, the water-pipes should be laid at a lower level than those conveying gas. In England it is sufficient to place the gas-pipes at about two feet from the surface of the pavement; but in order to protect the water-pipes from the effect of frost, it is necessary to place them at least 4 feet below the same level; and in the latitudes of Berlin, or of St. Petersburg, it has been found that water-pipes have been frozen at even 6 feet from the surface of the ground. In towns wherein the street traffic is exceptionally heavy the vibrations of the ground may also require that the pipes should be laid at a considerable depth, and indeed this detail may be considered to vary in almost every case. It would appear that when the pipes are laid at about 4 feet from the surface in our latitudes, the temperature of the water as it leaves the pipes will be sensibly the same, at all seasons of the year, with its temperature at the moment of entry, provided the motion be maintained in the pipes uniformly; and it thence follows that one of the best precautions which can be adopted against frost is to maintain a constant circulation in the pipes. The dilatation of the pipes from an increase of temperature must be taken into account in laying down any system of town distribution; and it would appear from M. Girard's direct experiments that the average rate of dilatation is equal to 0·00000300228 of a foot for every additional degree of Fahrenheit's scale, when the pipes are free, and in the open air. In the ground M. Girard found that the temperatures of the pipes were functions of the difference of temperatures of the surrounding media; but that they were nearer to the temperature of the ground than to that of the water. The tendency of some waters to produce deposits in the pipes they traverse must also be taken into account, as it may affect the discharge in a very serious manner; in some instances, in Yorkshire, the bores of the leading mains have been known to have been thus diminished in a few years to one half their sectional area by the deposition of the hydrous oxide of iron; in mains supplied directly from chalk or limestone springs the same effect may be produced by the deposition of the bicarbonate of lime. M. Payen states also that the slightly alkaline and aërated waters are those which are the most likely to produce a development of tubercules of the hydrous oxide of iron in the interior of pipes of that metal; and that the oxidation takes place more rapidly upon gray cast-iron than upon the whiter varieties. It appears from experiment, and from the results obtained in practice, that by coating the interior of water-pipes with a solution of hydraulic lime, or with linseed oil containing litharge, the formation of the tubercules before mentioned will be retarded; and in London the precaution of thus coating the pipes is universally adopted. The chloride of sodium when present in the water in small quantities, it may be added, facilitates the formation of the tubercules.

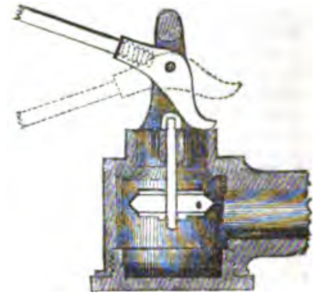
Until within a few years the distribution of water to the private consumers was effected by the intermittent system, or by means of a supply passed through the street-mains, at certain hours of the day, into cisterns placed in the houses, where it was stored for domestic use as might be required. The cisterns, in such cases, are made with float-valves, such as the common ball-cock, *fig.* 2, or the lever-valve, *fig.* 3, which close the delivery-pipes when the water attains definite

Fig. 2.



levels: and, in addition to these means of stopping the supply when a sufficient quantity of water has been delivered, the cisterns are provided with an open overflow pipe connected with the drainage of the houses, through which the excess of water may pass, if the machinery for intercepting the flow should not act. It is found, however, that, in the first place, there is so much carelessness in the manner in which the cisterns are fixed and maintained in order, that the quality of the water is very liable to be contaminated in private houses. The great cisterns are, in fact, too often placed close to water-closets or sinks; the service-pipes to the water-closets often form a direct communica-

Fig. 3.



tion between the pans of the closets and the water in the cisterns, so that the gases from the one must escape through the other; the cisterns are too often made of improper materials; they are left exposed far too often to receive atmospheric impurities, dust, or soot; and, incredible as it may sound, it is very rarely indeed that cisterns are cleaned out from one year's end to another. The best water in the world so treated must be rendered more or less unfit for human consumption; and it was principally to avoid this evil that the constant-delivery system was introduced, avowedly because that system allowed the cisterns to be dispensed with altogether. But it was also asserted that the constant-delivery system would effect an economy in the supply of water, because it is found practically that in the lower class of dwellings the ball-cocks are either stolen or tied up, so that the excess of water was forcedly passed through the waste- or overflow-pipe during a great portion of the time the street mains were undercharged. Unfortunately the economy has not been attained; on the contrary, whenever the water supply of a town has remained in the hands of a municipality, it is found to be so difficult to maintain the necessary control and supervision over the distributory apparatus, that the waste upon the constant-delivery system has proved to be so enormous that the system has practically been abandoned in many cases. It really would appear that the only means by which the abuses of the otherwise perfect method of delivery under constant pressure could be prevented would be by enforcing the sale of water by meter; and, indeed, as water is nearly as valuable as gas, there can be no reason for selling the one by measure and not the other. Gas, in London, costs 4*s.* 6*d.* per 1000 cubic feet; water, at the rate of 6*d.* per 1000 gallons, costs 3*s.* 1·38*d.* per 1000 cubic feet. But hitherto no water-meter has been devised by means of which the water can be measured without intercepting the pressure; so that at present there appears to be an almost insuperable difficulty in the way of the introduction of the constant-delivery system in many towns about to construct water-works *de novo*. In towns like London, the difficulties which would attend the modifications of the existing domestic arrangements of the water-pipes would be so great, that it is to be feared the present evils of the intermittent system will continue to be borne for many years still to come.

The water supplied to houses is, generally speaking, conducted from the street-mains to the cisterns, and thence distributed where required by means of leaden pipes, on account of the ease with which they can be bent, so as to accommodate themselves to the construction of the house. Some waters, however, especially those containing free carbonic acid gas in suspension, act upon the lead with remarkable energy; and instances of lead poisoning are by no means uncommon when the waters distributed are remarkably soft. When waters exposed to this danger must be used, it is necessary to employ either wrought-iron, or tin, or composition service-pipes; but these waters are far from being innocuous, even to these substitutes for the more flexible material, lead. The only other general remarks to be made with respect to house-distribution of water are: 1, that the apparatus for drawing the water should be of such a nature as not to produce a hydraulic jar on its being opened or closed; 2, that the pipes should not be placed so as to be exposed to the permeation of gases, or to the effects of heat or of frost; 3, that they should at all times be accessible for examination and repair. The thickness of service-pipes may be calculated upon the formula $x = \frac{pr}{c-r}$, in which x = the thickness sought, p = the pressure in lbs. per superficial inch, r = the radius or half the internal diameter of the pipe in inches, and c = the cohesive strength of the metal per superficial inch. Mr. Hawksley makes the thicknesses of his cast-iron pipes equal to $0·18\sqrt{d}$, or about $\frac{1}{6}$ of the square root of the diameter. In practice, lead-pipes are made equal to $\frac{1}{12}d$ in small pipes, and to $\frac{1}{20}d$ in very large ones.

The quantities of water required for the various details of domestic distribution are as follows:—

A bath requires, each time it is used, about	75	gallons.
A horse requires, per day	16½	„
A two-wheeled private carriage, per day	9	„
A four-wheeled „ „	17	„
Each individual in a house, „	4 to 8	„
A water-closet, every time it is used	1	gallon.
A yard superficial of garden ground	0·33	„
A yard superficial of roadway, every time it is watered	0·22	„

Generally speaking, the charge for a house supply is based upon its estimated rental, in England at least, and it very rarely attains 5 per cent. on that value. But an additional charge is made whenever more than one water-closet is in the house; when fixed baths are used; for coach-houses and stables, according to the number of carriages and horses; and for gardens. Such trades as tanners, fellmongers, hair-washers, curriers, glue-makers, dyers, hatters, brewers, distillers, manufacturers, inns, public baths, and steam-engines, are considered as large consumers, and are usually supplied with water by meter. The price under the latter arrangement is, in London, about 6*d.* per 1000 gallons. The supply of water for the extinction of fires is, in this country, cast upon water companies; and it appears that in the New River district of London there is at least one fire-plug in every length of sub-main equal to 73 yards, on the average; on the great mains there is a plug to every 157 yards. For the purpose of street-watering, stand-pipes ought to be placed at distances of about 500 yards apart: in our climate it appears that the streets require watering between 120 and 135 days in the course of the year, sometimes even twice in the day. The quantity of water varies with the nature of the road-surface; and where nicety of calculation is required, it may be considered that 600 square yards of macadamised road will only require one ton of water, whereas 400 square yards of paved road will require that quantity. It may be added, that the street-plugs (the *borne fontaines*) used in Paris to cleanse the channels are usually placed at distances of about 140 yards, and that they discharge at intervals during the day a total quantity of water equal to 650 gallons each: more than half the total supply of Paris is thus poured into the streets.

It would be idle to give any statistics of the capital invested in water-works, either in England or elsewhere, because new works of this description are being constantly undertaken. In London alone the capital invested in the various Water-Works Companies cannot be considered to be much less than eight millions sterling; and, as a general rule, it would appear that the average cost of conducting a water supply to the doors of the houses in a town varies between 2*l.* and 3*l.* per head of the population; whilst the house distribution gives rise to a further outlay varying from 4*l.* to 20*l.* per house, according to its character and to the system of distribution adopted. In newly-established works, the constant-delivery system admits of considerable economy in this respect. Of late years, also, it may be added that more attention has been paid than was formerly the case to the pressure under which water is delivered in towns; and that, to a great extent, the distinction between high and low service has ceased to exist. In new works the mains are always laid under such conditions of pressure upon the water they contain as to cause the latter to flow in the loftiest rooms of the loftiest houses in the respective towns.

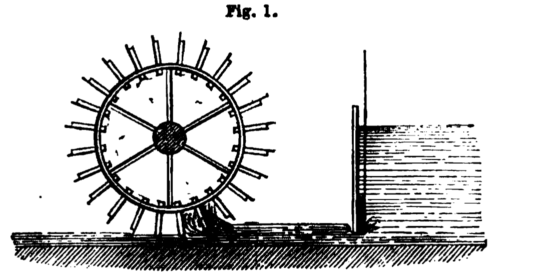
In Robison's 'Mechanical Philosophy,' in Playfair's 'Lectures,' in Jamieson's 'Mechanics of Fluids,' Weisbach's 'Mechanics of Machinery and Engineering,' D'Aubuisson's 'Hydraulique,' Geniey's 'Essai sur les Moyens de conduire et élever les Eaux,' Darcy, 'Sur les Fontaines Publiques de la ville de Dijon,' Dupuit's 'Essai sur la conduite et la distribution des Eaux,' and dispersed throughout the various Blue-Books and Parliamentary Evidence upon the subject of town water supplies, much information upon the practical details of that branch of the municipal service is to be found. Unfortunately, there is no work in English, treating this subject exclusively, which can be considered to be of any value; and the reader cannot be too seriously warned against accepting, absolutely, any of the doctrines lately promulgated here "by authority." The French writers upon hydraulics are still those who are to be the most implicitly followed in matters of theory; the practice of the best English engineers in matters of working detail must be consulted, in spite of the official censure passed by a class of empirics who seem to have objected to eminent engineers solely because they were eminent. Dwyer's 'Hydraulic Engineering,' Neville's 'Hydraulic Formulæ,' Downing's 'Practical Hydraulics,' and Beardmore's 'Hydraulic Tables,' may also be consulted with advantage.

WATER-WHEELS. The machines, by means of which the weight, or the impulse of water, is converted into circular, vertical, or horizontal motion, are known in mechanics by the name of *water-wheels;* and as the power thus employed is furnished by nature, and requires but little outlay to be rendered available, these machines have at all times attracted much attention from the manufacturing interests. They are of various descriptions, according to the conditions under which the waters flow, or the uses to which the power thus converted is to be applied; but they are all alike in this respect, namely, that the motion they receive is always circular, whereas in the other modifications of water-power, the motion is rectilineal, and alternate. Water-wheels are in fact subdivided into those with floats or blades; and those with buckets. The wheels with floats are divided into the classes which have either straight or curved floats; and into those working in free water, in races, or water troughs either straight or curved. The bucket-wheels may be adapted to receive the water at the summit, or at an intermediate point of their height; but the float-wheels are exclusively of the kind known as the *undershot-wheels,* whilst the bucket-wheels are either *overshot-* or *breast-wheels;* the latter distinctions depending upon the height at which the water strikes the wheel, for in the *undershot-wheels* the water acts below the horizontal line passing through the centre of the wheel: in the *overshot-wheel* it acts above the said horizontal line, and on the downside (to the current) of the vertical line passing through the centre: and in the *breast-wheel* the water acts at a variable angle above the horizontal line through the centre, but on the same side as the stream flows naturally. In addition to these are the horizontal wheels, which are either set in motion by an isolated vein of water, or are placed in a cylinder, or are placed around a cylinder conducting the water, in the manners already described under TURBINES. Sometimes a modification of the overshot-wheel is used, under the name of the *backshot-wheel,* in which the water is carried beyond the summit, and thence returns to strike the wheel at a point situated a little below that level, on the upper side of the vertical line passing through the centre of the wheel.

The parts of a water-wheel and its adjuncts which it may be desirable to define, are as follows. In the water channel there is, generally speaking, a *mill-head,* with tumbling bay and waste weir to regulate the supply of water to the *fore-bay,* or the channel leading the water directly upon the wheel; this fore-bay has a *hatch,* or sluice, by means of which the quantity of water falling upon the wheel can be regulated at will. The *mill-race* is the part of the channel immediately under the wheel; the *tail-bay* is the part by which the water escapes after it has produced its effect. The wheel consists of a *shaft,* upon which are fastened the *arms,* bearing in their turn the *periphery,* to which are attached the *floats* or the *buckets;* sometimes this periphery is close boarded, or *soled,* sometimes it has openings for the purpose of ventilating the buckets; the sides of the buckets which keep the water upon the wheel are called the *shrouds.* The motion is taken off from the wheel either by gearing working upon the segments of the wheel, or by first motion, or bevilled wheels fixed upon the axle; the last are generally known by the name of *pit-wheels.*

Formerly the vertical wheel, with straight floats working in a straight mill-race, was the description of undershot-wheel most generally adopted, but it is now seldom used, unless in cases where there is an abundance of water, and a fall not exceeding five feet (*fig.* 1.) In

Fig. 1.



these wheels, the water acts entirely by its shock, and evidently this must be proportionate to the velocity with which it issues from the hatch, under the pressure of the head in the fore-bay. The distance between the hatch and the wheel must therefore be made as small as possible, because the water in spreading out in the mill-race is exposed to lose a portion of its velocity. The fore-bay should be made with converging sides, upon the principle of ordinary conical ajutages, wider towards the dam than to the sluice; and from Poncelet's experiments, it would appear that a great increase of useful effect is obtained by making the hatches incline, so as to offer an angle, towards the dam, of 45°. Immediately beyond the centre line of the wheel, the race must fall away, so as to leave a more uninterrupted discharge into the mill tail; its width must be regulated by the quantity of water to be discharged, because it is found practically that the depth of the stream ought not to exceed 10 inches when the course is clear; the depth also should never be less than 6 inches, and in order to lose as little of the water as possible, the space between the outer edge of the wheel and the mill floor, should not be more than ½ or ¾ of an inch. In the most carefully constructed mills at the present day, a great improvement in the efficiency of the wheels is obtained by giving an inclination to the floor of the race from the hatch, to the level of the lower edge of the second float on the upside of the vertical diameter, of about 1 in 12, or 1 in 15; the bottom then curves away from that point, concentrically to the wheel, until it meets the vertical diameter line prolonged; and it then falls away with a sudden drop of 4 inches, and every precaution is taken to ensure the rapid withdrawal of the tail-water. The width of the race is made somewhat smaller than that of the floats until a short distance before the position of the wheel; and beyond the centre line it widens out still more than the width of the floats.

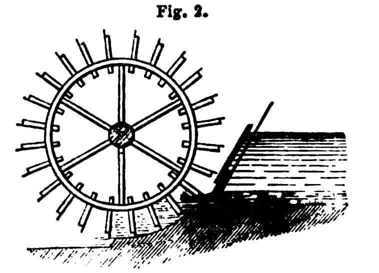
As the water, on escaping from the hatch, heaps up against the float, the latter must be made deeper than the normal thickness of the fluid vein; and generally speaking this is effected by making the floats about three times the depth of the water in the race, provided the width does not exceed 2 feet, or 2 feet 2 inches. The distance from one float to another should be rather less than the depths of the floats, their number being regulated principally by the purposes to which the machinery is to be applied. The diameter of the wheel is fixed in most cases by the number of revolutions it may be required to perform in a given time, in order to drive the connected machinery at the desired speed, and with the intervention of the smallest number of parts; and to a certain extent it is desirable to make the wheel act as a fly-wheel, to regulate the movement of the machinery. In the best wheels, the velocity of the extremity of the floats is made $v = 1{\cdot}7\sqrt{\text{H}}$, in which v = the velocity, and H = the fall of water; and the diameter is made $\text{D} = \frac{32}{\text{N}}\sqrt{\text{H}}$, in which N = the number of revolutions per minute; and D = the diameter sought: it is rarely, however, that the diameter of undershot-wheels varies beyond the respective limits of 13 and 26 feet. The numbers of floats usually adopted are, for the diameters given, as follows: they are multiples of four, because millwrights prefer distributing them equally upon the quadrants of the wheel; but it is to be understood that the number may be increased without inconvenience, if such a course were desired.

Diameter.	13 ft. 6 in.	16 ft. 6 in.	20 feet.	23 feet.	26 feet.
No. of floats .	28	32	36	40	44

It is found theoretically that an undershot water-wheel, in which the water thus acts by its shock upon floats working in a straight mill-race, only yields an efficient power equal to half the dynamical effort exerted upon it, even under the most favourable circumstances. But in practice, Smeaton's experiments appear to show that the useful results rarely attain even that value; and that calling the weight of water P, and the height of the fall H, the real effect does not exceed 0·25P H. The useful effect of these wheels is, therefore, very small; but the facility they present for variations in the diameters of the wheels, and in their velocities, renders them at times advantageous, when an unlimited supply of water is at hand.

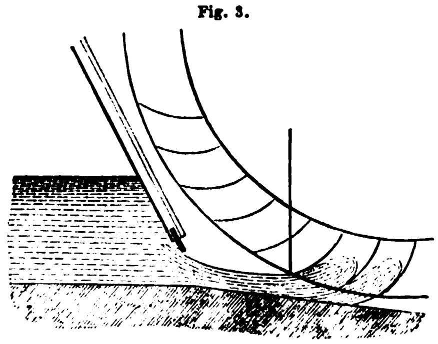
In the previous remarks it was observed, that the useful effect of the undershot-wheel was improved by making the race concentric to the outer circumference of the wheel. The gain thus secured is proportionate to the arc enclosed; and the practice at the present day is, therefore, to make that arc as large as the fall will allow (*fig.* 2), and

Fig. 2.



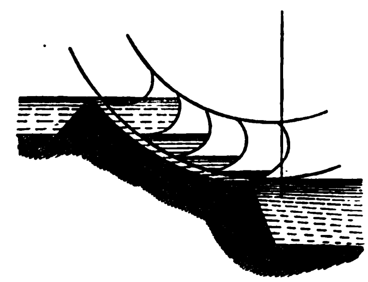
usually it is made equal to ⅔ or ¾ of the available fall. A space of about half an inch is left between the circumference of the wheel and the surface of the enclosing arc of the race; the width of the stream is made such as to allow it to fall on the wheel with a thickness of about 8 inches, and the diameter and number of the floats are calculated as before. The useful effect of these wheels is said to range between 0·60 and 0·65P H. M. Poncelet has, however, increased still more the useful effect of the undershot-wheels by making the floats curved, as shown in *figs.* 3 and 4, and by doubling their number. He confines the

Fig. 3.



water within a close race, and takes more than ordinary precautions to remove the tail-water; he makes the depth of the floats vary between ¼ and ½ of the vertical fall in the inverse proportion to the height of the latter. But with all these improvements, it seems to be very

Fig. 4.

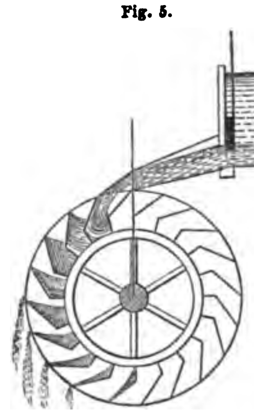


difficult to secure from the best undershot-wheels a greater useful effect than is represented by 0·60 P H.

A species of undershot-wheel is sometimes used upon rivers, which consists of a vertical float-wheel worked by the current of the river, or even occasionally by the tide. The diameters of these wheels are rarely of considerable dimensions, and the proportion of the useful effect to the power actually exerted is but small; nevertheless, these wheels are extremely useful in new countries, and they present one great advantage from the fact of their not interfering in any way with the natural drainage conditions of a locality, as the other classes of mills with heads and dams almost inevitably do, from their upholding the water. [TIDAL WHEEL.]

The vertical *overshot-wheels* with buckets, *fig.* 5, are those in which

Fig. 5.



the water is carried over the top of the wheel, and then made to strike the buckets upon the side of the mill-tail, so that the descent of the wheel is caused by the weight of the water on the unbalanced side; the shock of the falling water adding slightly to the motive power. As in ordinary undershot-wheels, the overshot ones consist of the axle, arms, rim, shrouds, sole, and buckets; which may be of wood or of iron, according to the resources of the locality where the mill is to be erected; the advantage in the use of iron consisting in the facility with which the buckets can be worked to the best theoretical outline, and in its durability; the advantage of wood consisting in its primary economy, and its facility of repair.

The number of buckets on an overshot water-wheel is determined upon the following scale, which is found practically to be the most successful, namely, the diameters being given, the number becomes—

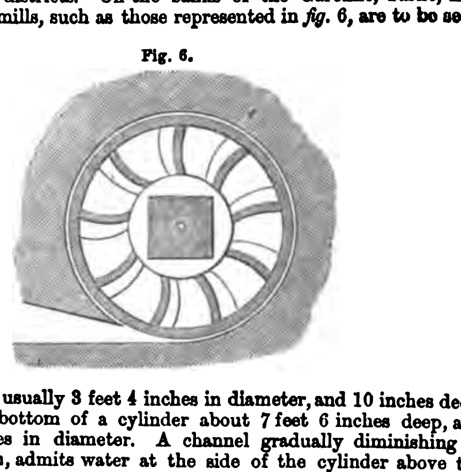
Diameter.	10 ft.	13 ft. 6 in.	16 ft. 6 in.	20 ft.	26 ft.	33 ft.	40 ft.
No. of buckets	24	36	44	56	76	96	108

That is to say, assuming the depth of the shrouds to be, as it usually is, 12 inches, and drawing a circle at one-third of that depth, measuring from the inside, the buckets are spaced upon that circle at distances apart of 13 inches, as nearly as may be. The length between the shrouds will be determined by the quantity of water they have to deliver; and it is desirable not only to make the capacity of the buckets sufficient to receive all the water which may pass into them from the hatch, but also to make their capacity equal to three times that volume, or the water would have a tendency to splash over, and to escape. Generally speaking, the water is carried over the top of the wheel, at a slight distance from it, and is made to strike the second or third bucket beyond the summit, at about 2 feet from the vertical line passing through the centre; because it is considered that the shock thus obtained increases the dynamical force of the water. A more important precaution still than either of those named above, consists in the provision of means of escape for the air contained originally in the bucket, or carried down by the falling water; and one of the greatest improvements effected of late years in the construction of overshot water-wheels consisted in the introduction by Mr. Fairbairn of the ventilating buckets. The diameter of the wheel, of course, should be made as nearly as possible equal to the height of the fall, and the velocity of the wheel kept to about the rate of 3 feet per second, measured on the outer edge. A greater velocity would produce a centrifugal force in the water contained in the buckets, which would to some extent diminish the useful effect of the wheel. The best overshot-wheels, in which the water is conducted upon the wheel carefully, and the tail-bay of the channel built so as not to interfere with the escape of the water, yield an effective result of 0·75 PH; and they are, therefore, constantly used when a sufficient fall can be obtained for their establishment. In some mining districts overshot-wheels of as little as 8 feet in diameter are used; but they do not yield even so good results as the best breast-wheels in close races. A fall of 16 feet seems, in fact, to be about the minimum fall able to produce the full amount of dynamical force an overshot-wheel is able to yield. As to the *backshot-wheels*, they do not involve any other principle than the overshot-wheels; nor, indeed, can they be considered to offer any advantage over the latter, unless in some peculiar cases, wherein the motion of the machinery may require the revolution of the wheel to take place in one particular direction; and wherein the water is required to be brought upon the back part of the wheel. Sometimes, it may also be added, there may be an advantage gained by the use of the backshot-wheel, if the tail-bay should be exposed to be flooded, or to receive backwater; because in such a case the revolution of the wheel would still be in the direction of the natural current, and the backwater would not oppose the passage of the buckets so seriously as would be the case with a true overshot-wheel.

The *breast-wheels* are those in which the water strikes the wheel on the upside, at a point intermediate between the vertical and the horizontal lines passing through its centre; and they are made with buckets of analogous forms to those of overshot-wheels, in order to retain the load on the side receiving the water as long as possible, and having the same provisions for relieving the air, and for obviating the effects of the centrifugal force of the water. In small wheels the water strikes the buckets at an angle of about 40° from the vertical line; in large ones the angle may be 30°, although some constructors make it as much as 52° for wheels of 20 or 30 feet in diameter. Evidently, however, the efficiency of a breast-wheel must depend upon the length of time it can retain the water on the loaded side, and the higher the point of impact, the greater must be the effect; in other words, a wheel receiving the water only a little above the centre line, the loaded arc becomes so small as to produce very trifling results. If then the fall should not exceed 8 feet, it would be preferable to adopt an undershot-wheel working in a close race, rather than a breast-wheel; because it would allow the application of a larger first-motion wheel. With a good fall, and with well proportioned buckets, the useful effect of the breast-wheel is often as high as 0·70 PH.

In some parts of southern Europe, where skilled labour is not easily obtained, and the work required to be performed is of a very simple nature, a number of water-mills exist in which the wheel, instead of being placed vertically, is placed horizontally, and the mill-stones for corn or oil grinding are keyed at once upon the vertical shaft of the mill. Some of these machines have a series of blades so placed upon the shaft, and with respect to the vein of water striking them, (and it is generally the case that the water is conducted for this purpose in a pipe,) that the shock takes effect normally to the plane of the blades. The corn-mills of the Saracens were made in this manner, and the peasants of Galicia retain them to the present day; but the efficiency of these rude machines depends entirely upon the height of the fall disposable, and the useful result obtained is rarely as much as 0·15 PH; so that these mills are never seen in highly civilised districts. On the banks of the Garonne, Tarne, Lot, &c., numerous mills, such as those represented in *fig.* 6, are to be seen.

Fig. 6.



The wheels are usually 3 feet 4 inches in diameter, and 10 inches deep placed at the bottom of a cylinder about 7 feet 6 inches deep, and 3 feet 4¾ inches in diameter. A channel gradually diminishing in width, as shown, admits water at the side of the cylinder above the wheel, and the water escaping from the sluice with violence acquires, in its course round the cylinder, a centrifugal force which acts against the curved blades not only by its impulse, but by its weight. There are many localities where wheels of this description would be of value; but even when the wheels are made of the best form, the useful effect they produce does not exceed 0·25 PH, and it is very rarely that they attain more than 0·16 PH.

The *reaction-wheels* are those in which the water is allowed to escape through apertures upon a vertical shaft, in such a manner as to develope a force in the reverse direction of the outflow, which is capable of being converted into a movement of rotation. Barker's mill, those designed by de la Cour, and by d'Ector, were based upon this principle; but the useful results they have produced have not been such as to lead to their practical application. They are in fact little better than philosophical toys.

It may finally be stated that in the present state of the arts of construction, the undershot-wheels with straight floats working in a close race are those which are the most adapted to falls of between 4 feet, and 8 feet 6 inches; the undershot-wheels with curved floats are the most advantageous when the fall does not exceed 5 feet. Bucket-wheels are desirable when the fall exceeds 10 feet, and is less than 16 feet; and when the supply is variable, it is preferable to use the breast-wheel rather than the overshot one: the breast-wheels at all times suffer less from backwater than any other form of wheel. Overshot-wheels are generally used when the fall ranges between 16 and 40 feet; above the latter fall there are decided advantages in the use of the turbine, which certainly has a remarkable power of adaptation to varying conditions. M. Fourneyron executed one turbine with a head of 9 inches, and another with a head of not less than 354 feet. Mr. G. Rennie states that the coefficients of the useful effects of the various descriptions of wheels are found in practice to differ slightly from those quoted above; and that they cannot with safety be taken at more than, in overshot-wheels, from 0·60 to 0·80; in breast-wheels from 0·45 to 0·50; and in undershot-wheels from 0·27 to 0·30.

WATERING, in Horticulture, the process of applying water artificially to plants. Water in a greater or less quantity is necessary to the existence of the whole vegetable kingdom: not only do the elements of water enter into the composition of the tissues of plants, but by its agency the various saline ingredients, as well as certain gases that enter into the composition of vegetable tissues, are carried into the plant. Water also exerts an influence on the temperature of the soil and of the plants to which it is applied. It is on these accounts that the application of water to plants is an important process in horticulture, more especially in the hothouse and greenhouse. During winter plants require little moisture, as the processes of life are at that period very inactive, but at the same time a small quantity is required in order to meet the demands of approaching activity. If plants are supplied with too much water during winter, their tissues become distended, and the whole plant is enfeebled. The largest supply of water is required when plants are growing rapidly and at the season when they are putting forth their leaves. When plants have ceased to grow, or when the leaves and flowers have ceased to expand, they require less water. When however the object in the culture of plants is to render either their leaves or fruits as succulent as possible, they should be supplied with abundance of water. This is done with spinach, lettuce, and other oleraceous plants, and by this means their tissues are rendered more tender, and their peculiar secretions, which are often disagreeable, are diluted. The same thing is done in the cultivation of the strawberry, where the object is to render the fruit as large as possible. In this case however the large size of the fruit is obtained at the expense of its flavour. Even plants bearing succulent fruits, as the melon, &c., may be over-watered, and the flavour of their fruit destroyed. In supplying water to all plants due regard should be had to temperature, as, *cæteris paribus*, plants require more water in proportion as the temperature is higher.

Although the supply of water artificially to plants cultivated in houses is obviously necessary, there is some doubt as to whether it is required by plants growing in the open air, where they are exposed to natural supplies. Professor Lindley, in his 'Theory of Horticulture,' says, "It is indeed doubtful whether watering plants in the open air is not often more productive of disadvantage than of real service to plants." At the same time the practice is at present very general, and there are some advantages in it, independent of supplying plants with water. It is frequently very effectual for removing insects from the leaves of plants, and also for removing dust and dirt in exposed situations. Mildew is also prevented in annuals by abundant watering. The fungi which produce or are found on mildewed peas, and those which destroy the spinach and onion, may be removed by abundant watering. Where the leaves of plants are watered, this should never be done whilst the sun is shining upon them, as this increases the evaporation. The morning and evening are the best times for watering plants; but where it is necessary to do this in the middle of the day, the roots alone should be watered. After transplanting, whether of young or old plants, in pots or in the open ground, the watering of the plant is always recommended.

In watering plants several instruments are made use of, as the engine, the syringe, and the watering-pot. These are made either to throw water through tubes of various sizes so as to apply the water to a particular point, or by means of a rose which is appended to the tube to distribute the water over a larger surface. The former method is adopted when the roots of a plant are to be watered, and the latter when it is wished to wet the whole surface. Where a stream can be made use of, an effectual way of watering plants is to have a sluice by which the water of the stream may be let on and off as may be thought proper. This is the best mode of watering water-cresses and other plants requiring abundant moisture. Where there are water-works, pipes are sometimes laid for supplying compartments of a garden. Lawns and plots of grass may be watered from the water-butt.

WATERING OF LAND. [IRRIGATION.]

WATERMAN, one who rows a boat on a river for the conveyance of passengers. The only large body of watermen in England are those employed on the river Thames at London. Before the introduction of coaches they were a very essential class for the conveyance of persons not only between London and Southwark, but between London and Westminster, and up and down the river to the various places on each side. The Thames was then the great highway. Stairs and watergates were numerous on the north bank from London to Westminster, where there were many palaces of the nobility, each palace having its landing-place, its barges and wherries, and its private retinue of watermen, or bargemen, as they were then commonly called. Processions on the river, water-tournaments, boat-races, and other aquatic amusements were frequent. In the reign of Richard II. the fare for a passenger, with his truss or farthell, from London to Gravesend or Milton, was 2*d.* Stow computes that there were as many as 2000 boats in his time, that there were 40,000 watermen on the rolls of the Watermen's Company, and that they could furnish 20,000 men for the fleet. No doubt he included in this large number the private watermen of the court and the nobility. John Taylor, the "water-poet," as he styled himself, complains bitterly of the introduction of coaches: "I do not inveigh against any coaches that belong to persons of worth or quality, but only against the caterpillar swarm of hirelings. They have undone my poor trade whereof I am a member." Since that time the increase in the number of bridges and the introduction of steam-boats has reduced the watermen to a comparatively small number.

An apprenticeship of seven years on the Thames constitutes a free waterman. The watermen and lightermen are an incorporated company, founded in 1556, and regulated partly by their own bye-laws and partly by 7 & 8 Geo. IV., c. 75. With the exception of certain flat-bottomed ferry-boats and barges above Kingston, no person can ply in a boat for hire on the Thames who is not a member of the Watermen's Company.

The Trinity House has, however, power to license certain king's seamen, besides pilots, to ply on the river.

WATERS, MINERAL. [AERATED WATERS.]

WAVE. [WAVES AND TIDES.]

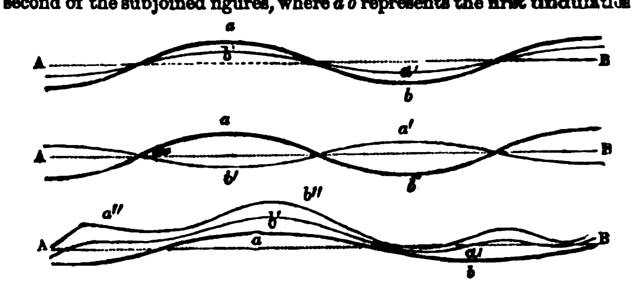
WAVES and TIDES possessing in many respects the same character, it has been thought proper to state in one article the phenomena and the theories of both.

From the earliest times the periodical risings and fallings of the waters on coasts or in rivers have been noticed; and the recurrences of the phenomena depend so obviously on the positions of the moon and sun, that the influences of those celestial bodies in producing them have ever been assigned as their cause. The tide appears as a general wave of water which gradually elevates itself to a certain height, then as gradually sinks till its surface is about as much below the medium level as it was before above it: from that time the wave again begins to rise; and this reciprocating movement of the waters continues constantly, with certain variations in the height (with respect to the mean level), and in the times of attaining the maxima of elevation and depression.

Ordinary waves are produced by any cause which disturbs the equilibrium of the particles of a fluid. Thus, a stone suffered to fall into water at rest gives rise to a series of concentric circular waves extending to a great distance from the place where the stone falls; and in a canal the fall of a body of water from a level above that of the general surface will produce a series of waves advancing along the canal. Waves are also produced by suddenly pressing a solid into water, or by suddenly withdrawing it from thence; and a single wave may be caused by partly immersing a solid body in water and moving it quickly, for a time, in a horizontal direction. The inequalities of the pressure of the air on the surface of water, whether at rest or in motion, when a gentle wind is blowing, will produce ripples; and if the action be continued long, the ripples, at a certain distance from the place of their origin, become considerable waves. In the open seas the heights of the waves depend on the force of the wind; but in confined situations both the heights and forms of the waves are affected by the resistance of the bed, by reflections from the shores, and other circumstances. When waves are formed by wind blowing from the land, each wave-summit preserves constantly the same height; but the heights go on increasing with the distance from the shore.

Wind-waves appear generally to be of a cycloidal form: their summits have a gentle curvature, while the height bears a small proportion to the length in the direction of the motion; but as the height increases, the summit becomes more acute, and assumes the form of a ridge; and when this becomes too sharp for the preservation of equilibrium, the force of the wind acting horizontally near the top breaks it into foam or spray [col. 788 of the present article. The nature of this spray itself has been noticed in WATERFALLS.] As waves advance towards a shore, the water becoming less deep, the resistance of the bed of the sea causes their lengths to diminish, and at the same time their heights to increase, so that the front of the wave becomes steep; and the motion of the upper part, towards the land, being more rapid than that of the lower part, it follows that the summit is carried beyond the base; and, falling forward, there is produced what is called a surf. The breaking of waves over a sunk shoal depends chiefly on a like cause.

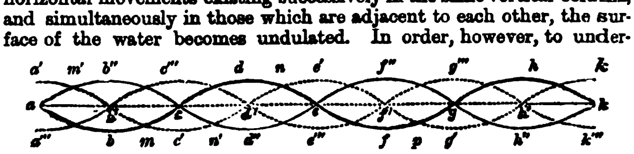
The surface of the sea often presents very complex phenomena. It may happen, for example, that while a long swell resulting from some distant storm is advancing in one direction, a breeze will produce a series of waves moving in the direction of the wind; and a second breeze springing up in another direction will produce a new series, which will become mixed with the former without destroying them. a third gale may also produce a system of waves intersecting the other systems. When a breeze has been blowing for some time from a certain quarter, and afterwards changes to the opposite, two series of waves may be seen moving in contrary directions; and if the waves are nearly of equal lengths, the vertical ordinates at the crest of the compound wave will be equal to the sum or difference of the ordinates of the simple waves, according as the crests are coincident, or fall in each other's intervals. These phenomena are indicated in the first and second of the subjoined figures, where *a b* represents the first undulation



and *a′ b′* the second, the straight line A B being the horizontal surface of the water when at rest. Again, when there exists a third system of waves, caused, for example, by reflection from a coast, so as to be parallel to the two former systems, the combination of the three systems has been observed to produce a compound wave of the form represented in the third figure. ('Report of the Committee of the British Association on Waves.')

The wind-waves of the sea do not extend to considerable depths. From the experiments made by the committee appointed by the British Association in 1836, it was found that with a depth of water equal to 12 feet, waves 9 inches high and 4 or 5 feet long did not sensibly affect the water at the bottom. Waves from 30 to 40 feet long, oscillating at intervals of 6 or 8 seconds, produced some effect, but much less than near the surface: and it was ascertained that, in waves produced by the wind on the surface of a deep sea, the velocities were not a direct function of the depth. In a storm the sea is probably tranquil at the depth of 200 or 300 yards. The most satisfactory measurements, those of the late Rev. Dr. Scoresby ('Report of British Association,' 1850, 'Journal of a Voyage to Australia'), give, for the height of the highest waves, 43 feet, from bottom of trough to crest.

It must not be imagined that when water is agitated by waves, its whole mass has the movement which at first sight appears from the observed progressive motion of the undulation; and, in order to account for the formation and motion of waves, it is sufficient to assume that the particles of water, when disturbed, have merely small oscillatory motions in horizontal and vertical directions. When, from any cause, as the fall of a stone into it, the water becomes agitated, a series of horizontal motions to and fro are produced; and while in a slender vertical column of water these motions are equal and in one direction, the surface neither rises nor falls; but if, in two neighbouring columns, the particles advance to meet each other, the water becoming compressed, the surface rises; if the particles recede from one another, those above descending by gravity, the surface falls. These different horizontal movements existing successively in the same vertical column, and simultaneously in those which are adjacent to each other, the surface of the water becomes undulated. In order, however, to under-



stand the true movements of waves, let the straight line *a k* represent the surface of water when undisturbed, and, disregarding the horizontal oscillations by which the water is alternately compressed and dilated, let the particles be conceived to ascend and descend alternately in vertical lines, that is, in lines parallel to $a' a a'''$, which is supposed to be perpendicular to $a k$. Now, at a given instant let the surface of the water have, in a vertical plane, the form $a b c d$, &c., and let the force of ascent cause the particles in the line $a b m$ to be raised up to the line $a' b' m$ in a portion of time represented by T, that force becoming less as it is farther from a horizontally, and ceasing at m. At this place the force of descent commencing, the particles in the line $m c d n$ fall simultaneously with the rise of the particles in $a b m$, and at the end of the same time T, they occupy the line $m c' d' n$. Here the force of ascent acts, and the particles in $n e f p$ at the end of the same time occupy the line $n e' f' p$, and so on. Thus at the end of the time T the surface of the water has assumed the form $a' b' c' d'$, &c. After this time the force of descent on the particles in the line $a' m'$ causes those particles to fall vertically, during a time equal to T, into the line $a m'$; at m' that force ceases, and the force of ascent raises the particles in $m' b' c' n'$ vertically into the line $m' b'' c n'$, and so on; thus, at the end of the time 2T from the given instant the surface of the water has the form $a b'' c d''$, &c. In like manner, at the end of the time 3T the forces of descent and ascent will have brought the particles into the line $a''' b' c'' d'$, &c.; and at the end of the time 4T the particles will be again in the line $abcd$, &c.: so that in this time every particle of fluid has made one complete vibration vertically, as $a a' a a''' a$, and within the same time the top of the wave has assumed successively the positions d, e', f'', g'', h. The horizontal distance from d to h is called the length of a wave; let it be represented by L, and let τ express the time 4T in which the summit of a wave has passed from d to h; then $\frac{L}{\tau}$ is called the velocity of the wave. On observing the characters of experimental waves in troughs with glass sides, it is found that, by the combinations of the horizontal and vertical vibrations, the particles of water describe the peripheries of circles or ellipses. In the upper parts of the curves, near the tops of the waves, the particles move with their greatest velocities in the direction in which the wave is advancing; in the lower parts, near the bottoms of the waves, they are moving with their greatest velocities backwards; and at the extremities of the horizontal diameters, about the level of the water's surface when at rest, the motion is almost wholly vertical.

The varying attraction of the sun or moon on the particles of water in the ocean is alone sufficient to produce the perturbations by which waves are formed; and if it be assumed that the solid nucleus of the earth is covered entirely with water, both nucleus and water being originally spherical, those perturbations will bring the surface of the water to a spheroidal form, the longer axis being in the direction of a line joining the centres of the earth and luminary; there will consequently exist, at the same instant, two great waves whose summits are at a distance from one another equal to half the circumference of the earth. But the motion of the water in the tide-wave is totally unlike that in an ordinary surface-wave such as the wind produces; and while the latter, even in the most violent storms, agitates the sea to a very trifling depth, the tide-wave affects the whole depth of the ocean equally, from the bottom to the surface.

Very little attention to the phenomena of the tides suffices to show that, in situations where the recurrences of high-water are nearly regular, the greatest elevation of the water takes place at intervals of about 12 hours 25 minutes, and the greatest depressions at the like intervals of time from each other; each greatest depression taking place about 6 hours 12 minutes after the instant of greatest elevation. Now the interval between two successive culminations of the moon on the same side of the geographical meridian of any place varies from about 24 hours 40 minutes to 25 hours; and thus the intervals between the times of high-tide have evidently a connection with the diurnal revolution of the moon; moreover, the occurrence of high-water at any place is observed to have a dependence on the position of the moon with respect to the meridian of the place; at a few ports it coincides with the time that the moon is on meridian, but in general it takes place some time before or after the culmination. The position of the moon at the time is, however, subject to certain variations even at the same port; and it differs considerably at different places. The elevations also of the water with respect to the mean level differ; in some places, during about half the year, the high-tide which occurs when the moon is above the horizon is greater than that which occurs when the moon is below, and during the other half-year the phenomenon is reversed. In every place, at about the times of new and full moon, the high-tides attain their greatest elevation; and at about the times of the quadratures, the least: the former are called *spring-tides*, and the latter *neap-tides*.

In bays and harbours, the time of high-water coincides with that at which the current ceases to flow, but this is not the case with the seas which communicate at both extremities with the ocean. For, if it be imagined that a tide-wave flows in at one of the extremities, this will cause an elevation of the waters; but the waters which are passing off at the opposite extremity cause, at the same time, a depression, or, at least, a diminution of that elevation; the surface, therefore, must be the highest when the current flows with equal rapidity at both extremities, and not at the moment preceding the turn of the tide. When the stream continues to flow up for three hours after it is high-water, it is said to make tide and half-tide; if it continues to flow during one hour and a half, it is said to make tide and quarter-tide, and so on. Near the shores of the British Channel, probably in consequence of the obstructions caused by the land, or the disturbances at the mouths of rivers, the progressive movement of the tide-wave is more retarded than in the middle; and in some places the current has curvilinear motions, which on the French and English sides are in opposite directions. The *race* of Portland is a current produced by the tide-wave, while advancing along the shore; being arrested by the promontory till it attains a height which allows it to flow off obliquely with considerable velocity.

The rise of a tide-wave near the mouth of a river takes place rapidly by the shoaling of the sea and the confinement of the wave between the banks; for the motion of a body of water is capable of raising the particles to the heights through which they must fall to acquire their actual velocities; and if the same motion is employed in raising a smaller quantity of water, it is evidently capable of raising it higher: thus, when the contraction is considerable, as in the Bay of Fundy, the Bristol Channel, and other places, the elevation becomes very great; at Chepstow it amounts to 60 feet. When, at the mouth of a river, the bed has a long and gentle slope on each side, the waves, becoming high and steep, fall over, and flow up rapidly with a surf, constituting what is called a *bore:* the bore-wave which enters the Severn is 9 feet high, and that which occurs in the Amazonas is said to be from 12 to 15 feet in height. [BORE, and col. 784 of the present article.] In flowing up a river the summit of the tide-wave reaches the different stations later as these are farther from the mouth; and in the Thames it advances from Margate to London, a distance of 70 miles, in three hours. It is observed also that the current of a river runs upward during some time after the summit has passed any station, and downwards for some time after the surface of the water is at the lowest; the intervals between the times of low and high water, moreover, gradually diminish as the stations are farther up, while the intervals between high and low water increase.

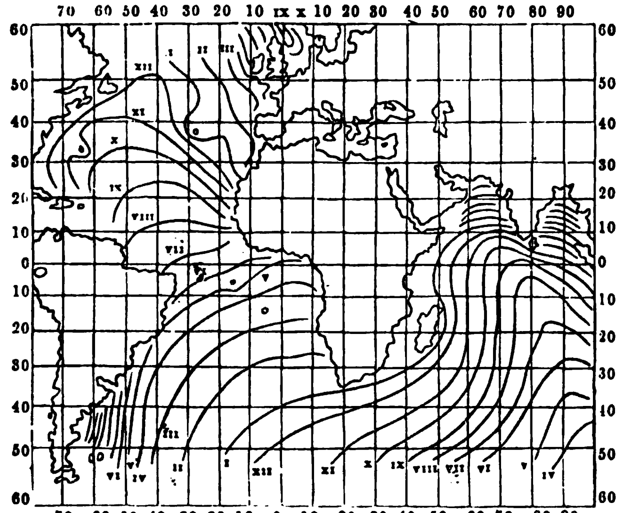
From the observations made by the committee of the British Association in 1836, on the tide-waves of the river Dee in Cheshire, it was found that the first wave of flood-tide advanced 5·275 miles in intervals of time varying from forty-five minutes to one hour, or, at an average, at the rate of 6·4 miles per hour; and that the wave of high-water advanced the same distance with a velocity, by an average of the observations, of 14·6 miles per hour. It is said however to have been impossible to determine whether the wave which carried the flood-tide to the lower station was the same as that which carried it to the higher. It is thought probable that the wave which passed the lower station was diffused in the spaces between certain projections from the bank on one side of the channel, and was overtaken by a subsequent wave from the sea. The wave of high-water, being above those obstructions, flowed up more regularly, and the observed height of the wave approached very nearly to that which is due to its observed velocity: it being understood that the velocity of a wave is that which would be produced by a body falling from rest through half the height of the wave.

In order that the phenomena of the tides at different places may be readily compared together, charts have been constructed, on which are drawn curve-lines joining the points at which high-water takes place at the same times. Now, since the heights of the wave and the times of its greatest elevation vary at every place from day to day, it is necessary to fix on the height attained at a particular time; and on this account, by general agreement, the time of high-water at every seaport on the days of full and change of the moon is chosen. This is called the "Establishment of the Port;" and an extensive table of "Establishments" for the ports of Great Britain and Ireland is given in the 'Nautical Almanac;'* the hours and minutes indicating the time from apparent noon on the days of new and full moon when high-water takes place. Since, on the first of these days, the moon passes the meridian with the sun, the time of high-water on any other day may be found from the table by merely adding the "Establishment" to the time at which the moon comes on the meridian on the given day. Finding upon the surface of the earth and sea any number of points at which the "Establishment," when reckoned according to Greenwich time, is the same, a line drawn through all the points will indicate the summit of a great tide-wave at that time: drawing a curve in like manner through all the points at which the "Establishment" in Greenwich time is an hour later, there is obtained a new position of the summit; and it must then be understood that the wave has travelled, in the sense above explained, from the first line to the next in one hour. These are called "Cotidal lines;" they were first indicated on a chart of the world by Mr. (now Sir John W.) Lubbock, in the 'Philosophical Transactions' for 1831, and an extensive series of such lines is traced on the chart which accompanies Dr. Whewell's 'Essay towards an approximation to a Map of Cotidal Lines,' in the 'Philosophical Transactions' for 1833.

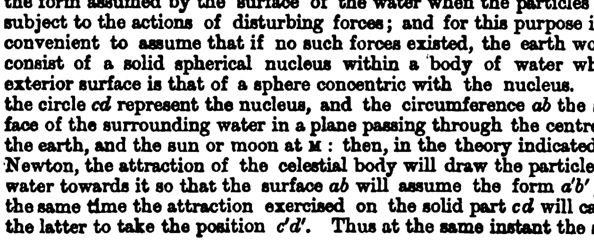
* In the 'Nautical Almanac' this information is now given in tables of the "Time of High Water on the Full and Change of the Moon," not only at ports and places in the British islands, but on the neighbouring shores of foreign countries.

The definition above given of the "Establishment" is only approximatively true: it is observed by Dr. Whewell, in the 'Essay,' that it would be correct if the high-tide always occurred when the moon's hour-circle makes equal angles with the meridian; but in fact the hour of tide on any day is reckoned from the time that the sun is on the meridian; and as the moon changes her right ascension every day by about forty-eight minutes (the observed hour of the tide being given on the day of new or full moon), the moon's hour angle may differ according to the time of the day when the conjunction or opposition takes place, compared with the time of day when the high tide is observed. Therefore an observation of the hour of the tide on the day of new or full moon may leave an uncertainty of about 1h. 8m. in the time of the "Establishment," unless account is taken whether the morning or afternoon tide was observed, and at what hour the syzygy took place.

The subjoined cut, which shows the principal cotidal lines in the Indian and Atlantic oceans, is from Dr. Whewell's chart above mentioned, and contains the modifications introduced in that which is given by Mr. Airy, in his Essay on 'Tides and Waves,' in the 'Encyclopædia Metropolitana.'



In investigations relating to the tides, it is required to determine the form assumed by the surface of the water when the particles are subject to the actions of disturbing forces; and for this purpose it is convenient to assume that if no such forces existed, the earth would consist of a solid spherical nucleus within a body of water whose exterior surface is that of a sphere concentric with the nucleus. Let the circle *cd* represent the nucleus, and the circumference *ab* the surface of the surrounding water in a plane passing through the centre of the earth, and the sun or moon at M: then, in the theory indicated by Newton, the attraction of the celestial body will draw the particles of water towards it so that the surface *ab* will assume the form *a'b'*; at the same time the attraction exercised on the solid part *cd* will cause the latter to take the position *c'd'*. Thus at the same instant the surface of the water at *a'* and *b'* is farther removed from the centre of the earth than it would be if there were no perturbation; while at *e* and *f* it is nearer the centre. If the celestial body were constantly in the plane of the equator, the summit of the elevated water would also be in that plane, and exactly or nearly under the body. A section of the spheroid of water passing through the poles of the equator and the summit just mentioned would be an ellipse, and its periphery would coincide with the direction of a terrestrial meridian. By the diurnal rotation this tide-wave, as it may be called, would appear to move about the earth from east to west at the rate of above 1000 miles per hour at the equator; and its positions at the end of every hour would constitute a series of cotidal lines. Hence, if a small island at the terrestrial equator were to project above the surface of the water, it would arrive successively at the points *a'*, *e*, *b'*, *f*, *a'*, so that in the time of a rotation of the earth on its axis with respect to the celestial body, there would occur at the island two states of high-water and two of



low-water. The arrival of the island at the summit *a'*, which would, if M were the moon, take place at the end of every 24 h. 50 m. nearly, is called the diurnal tide; and that which takes place when the island arrives at the summit *b'*, that is 12 h. 25 m. after the former, is called the semidiurnal tide. By this theory there ought to be scarcely any tides near the poles, the water being always drawn from them towards the tropical regions; and the attractions at *a'* under the celestial body being greater than the attractions at *b'*, it should follow that the diurnal tide is greater than the semidiurnal tide, neither of which circumstances, however, is conformable to observation.

If an island having a great extent from the equator towards the north and south were to intercept the tide-wave, the elevated water, passing round the extremities of the island, would on its western side form two waves, which would advance towards, and meet one another at the equator, making, at different places on the coast, high-water successively later, in the directions of their motions. And it is easy to conceive that the tide-wave of a great ocean will send branches into any seas which it may approach in its movement about the earth: such are called derived tides.

The combined actions of the sun and moon, when those luminaries are in conjunction or opposition, that is, at new or full moon, may be readily conceived to produce what are called spring-tides; and the diminution of each other's attractions when in quadratures, to produce the neap-tides. It may further be understood that, as the distances of the sun and moon from the earth vary by the ellipticity of the orbits, at the times when either of the celestial bodies is in perigee, its attractive power being greater than at other times, the tide-wave raised by it will attain a greater elevation than usual: on the other hand, when in apogee, the high-water elevation must be the least.

The tides are greatly modified at any station or port by the position of the latter with respect to the equator, and by the declination of the sun and moon. The two summits of the great tide-wave are, at the same instant, diametrically opposite to one another; and if the latitude of the station were equal to the moon's declination on a given day, both moon and station being for example north of the equator, the summit of the wave would on that day be at the station when the moon is in or near the zenith; but about twelve hours afterwards, the station, having described half the circumference of a circle about the earth's axis by the diurnal rotation, will be on the opposite of the meridian; and the summit of the wave, being on the southern side of the equator, will be at a distance from the station equal to twice the moon's declination; consequently the height of this tide will be much less than that of the former tide. The contrary phenomenon occurs when the moon and the station are on opposite sides of the equator.

Among the tide-waves with which we are best acquainted are those of the Indian and Atlantic oceans; and from the known times of high-water at different places, it is ascertained that the summit of a wave advances from the seas to the south of Australia into the Bay of Bengal, and towards the Persian Gulf, causing the hour of high-water to be successively later at the ports from Ceylon northwards, on both sides of the western peninsula of India. The summit of a single wave seems to extend from the mouth of the Red Sea, along the eastern coast of Africa, to the Cape of Good Hope, where it joins the tide-waves of the Atlantic. These advancing northwards, cause the time of high-water to be successively later at the different ports on the western coast of Africa and Europe, and on the whole eastern coast of South and North America; so that the wave which at a certain instant is at the Cape, in 15 hours from that time is at the mouth of the English Channel and on the western coast of Ireland. This wave, being apparently checked in its progress by the British Isles, divides itself into two principal branches, of which one flows up the Channel, and passing through the Straits of Dover, is off the mouth of the Thames in 3 hours from the time that it was at Brest. A small branch advances up St. George's Channel; but the second principal branch of the wave flowing round the northern extremity of Scotland, proceeds slowly down the North Sea, and meets the first branch off the mouth of the Thames in 20 hours from the time that it was at the entrance of the Channel.

From Rio Janeiro to the Falkland Islands a wave summit seems to advance directly from east to west; and from the form of the continent of South America, the high tide occurs successively later in going southward from Cape Frio, as if the wave came from the north. The wave from the southern ocean sets northward, from Tierra del Fuego and the Falkland Islands to the coast of Patagonia, and at Port St. Elena on that coast it occurs 12 hours later than at those islands. On the western coast of America the tide travels from north to south, between Acapulco and the Straits of Magelhaens; while from the former place it travels northwards. In the Pacific Ocean the general direction of the tide-wave is from east to west; but the heights of the tides are small, not exceeding 2 feet at the islands of the South Sea. It is observed however by Dr. Whewell ('Phil. Trans.,' 1833), that this must not be understood to be the tide which would be raised if the whole earth were covered with water, on account of the modifications produced by the form of the continent of South America. The most eastern part of New South Wales, between 25° and 30° S. lat., has the high-tide earlier than points which are situated towards the north or south of that tract.

Peculiarities in tides, arising from the interference of tide-waves, occur in many different places. In the middle of the North Sea there is a considerable space within which the tide produced by the tide-waves coming from the north and south takes places at one time. And Dr. Whewell states, on the authority of the late Captain Hewett, that about the Ower Shoal there is no sensible rise of the tide till 3 hours after the time of low-water; but when the ebb stream has nearly ceased, there is a sudden rise of 5 or 6 feet; so that nearly the whole rise of the tide occurs in the last three hours.

In 1740 the Académie des Sciences offered a prize for the best memoir on the theory of tides: and the paper by Daniel Bernoulli on the flux and reflux of the sea shared it with those of Euler and Maclaurin. In that paper it is assumed that the water is kept in equilibrio between the attractions of its particles towards the earth's centre of gravity and the disturbing forces exercised by the sun and moon; and though the results of that theory are found to differ greatly from the observed phenomena, the theory itself is deserving of attention, since the analytical expressions which have been obtained by it first exhibited the several phenomena distinctly from one another: those expressions consequently became guides to the observer or experimenter in his efforts to ascertain the true values of the particular effects which they represented.

The attraction exercised by the solid nucleus of the earth on a particle of water at any distance from its centre, being considered the same as it would be if all the matter of the nucleus existed in that centre, is represented by $\frac{\text{E}}{r^2}$, E being the mass of the earth and r^2 the square of the distance of a particle from the centre. But if x, y, and z are rectangular co-ordinates of a particle, the centre of the earth being the origin, we have $r^2=x^2+y^2+z^2$; and the partial differentials of the expression $\frac{\text{E}}{x^2+y^2+z^2}$, relatively to x, y, and z, represent the effects of that attraction upon a particle in the directions of the three axes. If the attractions of the particles of water for each other are taken into consideration, there must be determined the attraction exercised upon a particle by all the water between the spherical nucleus and the exterior surface (supposed to be spheroidal) of the surrounding fluid, and the expression for this attraction must be added to that for the solid.

The disturbing force of the sun or moon upon a particle of water is represented by $\frac{\text{S}}{\text{R}^2}$, S being the mass of the celestial body and R the distance of the particle of water from it; and the partial differentials of that expression relatively to x, y, and z give the values of the attraction in the direction of the coordinate axes: but the disturbing force exercised by the sun or moon on a particle of water being equal to the difference between its attraction on the particle and its attraction on the centre of the earth—the latter, which is represented by $\frac{\text{S}}{\text{D}^2}$ (D being supposed to be the distance between the centres of the earth and celestial body), is subtracted from the attraction exercised on the particle in the direction of one of the coordinate axes, supposed to be parallel to the line joining those centres, in order to have that difference. The attracting forces of the earth in the directions of the three axes being subtracted from the disturbing forces of the sun or moon in the same directions, there remain three terms which are usually represented by X, Y, and Z. And since it has been demonstrated by mathematicians that when a body is in equilibrio under the action of attracting forces, the expression $\text{X}dx+\text{Y}dy+\text{Z}dz$ is an exact differential; the form of the surface of equilibrium is determined by making the integral of the expression constant.

The resulting equation being found to correspond with the general equation to a spheroid, a comparison of like terms in the two equations gives the values of the constants which enter into the former. If r represent the mean distance of the spheroidal surface of the water from the centre of the earth, and $\pm h$ represent the distance of any point on that surface above or below the mean level; then $x^2+y^2+z^2=(r\pm h)^2$ at the surface; and the determination of h for any place gives at that place the height of the water above, or its depression below the mean level.

Uniting the effects of the solar and lunar disturbances by simply adding them together, since the disturbing forces are very small compared with the force of gravity; and introducing, in place of the rectangular coordinates, angles which depend on the longitude and latitude of a station, with the right ascension and declination of the sun and moon, the value of the term $\pm h$ may be shown to consist of three parts: one of these depends on the variation of the declination of the sun and moon, and indicates a slow tide which goes through its changes in about fourteen days; the second depends on the hour angles both of the sun and moon, and indicates two tides which go through their changes in a solar and a lunar day respectively. These being combined, there is produced a diurnal tide, the highest state of which should precede, at a variable interval, the moon's culmination between the times of passing from syzygy to quadrature, and should follow it between the quadratures and syzygies. It has been found, however, that the observed accelerations and retardations, and also the absolute elevations of the water, in very few cases agree with the results of the theory. [ACCELERATION AND RETARDATION OF TIDES.]

The third part depends upon the doubles of the hour angles just mentioned, and consequently indicates two semi-diurnal tides, which being combined constitute one such tide, whose highest state is variable. The nature of the expression shows that the semi-diurnal tide should be the greatest at the equator, and should diminish till it vanishes at the poles: it denotes also that it is greatest at new or full moon, and least at the quadratures. The theory moreover indicates that the difference between two consecutive tides ought to be very considerable in Europe; whereas they are known to be nearly equal to one another. Both Newton and Bernoulli endeavoured to explain this circumstance by the hypothesis of a general oscillation of the sea, in consequence of which the highest tide gives to the lowest a quantity equal to the difference between them; but the researches of La Place have shown that, even with such oscillations, the two tides could not (according to the theory) be equal unless the sea were everywhere equally deep.

Euler, departing from the hypothesis that the sea is always in equilibrio under the action of the sun and moon, endeavoured to introduce the subject of fluid oscillations in his theory of the tides; but the laws of undulation were not then known, and Euler assumed that a molecule of the sea in motion endeavours to regain the position which, in a state of equilibrium, it would occupy in a vertical line with a force proportional to its vertical distance from that position.

The theory adopted by La Place, in which there are taken into consideration the laws of the motion of fluid molecules when acted on by attracting forces, was a great improvement on that of the mathematicians before mentioned; and it is found to produce a more near agreement with the observed phenomena. The elaborate investigations of La Place will be found in the 'Mémoires de l'Académie des Sciences' for the years 1775, 1776; and in the first and fourth books of the 'Mécanique Céleste.' They are also given, so far as contained in the first book, in the late Dr. Thomas Young's 'Elementary Illustrations of the Celestial Mechanics of Laplace;' Lond., 1821. As in the former theory, the solid nucleus of the earth is supposed to be entirely covered with water of uniform depth; and the investigations commence with the proof ('Méc. Cél.', liv. i., ch. 8) that any portion of the water, however its place may be changed, will always retain the same volume. The equation expressing this law is called the equation of continuity.

A very small parallelopiped of water within that which covers the solid nucleus of the earth is acted upon by accelerative forces arising from pressures estimated in the directions of three rectangular coordinate axes whose origin is at the centre of the earth: the first is supposed to be parallel to the axis of rotation, and the others in the plane of the equator: one being directed to the equinoctial point and the other at right angles to that direction. The pressures are supposed to arise from the attraction of the earth, from the angular velocity of its rotation, and from the disturbing forces, and to tend towards the origin of the coordinates.

These pressures, which are expressed by partial differential coefficients relatively to x, y, and z, in the coordinate axes, are subtracted from the accelerative forces arising from the attraction of the earth, and the perturbations exercised by the sun or moon, by which the molecule would be made to recede from that origin; and the differences in the directions of the axes are represented by $\frac{d^2x}{dt^2}$, $\frac{d^2y}{dt^2}$, and $\frac{d^2z}{dt^2}$.

In these equations of motion the partial differential coefficients representing the pressures are transformed into others depending on the distance of the molecule from the centre of the earth, and on its latitude and longitude; while the perturbations of the sun or moon in the directions of the coordinate axes are expressed in terms of the right ascension and declination of the disturbing body, and also of the distances of the latter from the particle disturbed and from the centre of the earth. The result is that the expression for the altitude of a molecule of water above the mean level, in consequence of the perturbation produced by the sun or moon, consists of three parts ('Méc. Cél.', lib. iv., c. 1); the first does not depend on the rotation of the earth, and indicates a tide which goes through its changes in a long period; it may consequently be disregarded. The second depends on that rotation and on the hour angle of the disturbing body: it indicates the diurnal tides, or those which take place when the celestial bodies are on or near the meridian, above the horizon; and which follow one another at intervals of twenty-four hours for the sun, and about 24h. 50m. for the moon. The third depends on an angle equal to the double of that on which the second depends; and consequently it represents the semi-diurnal tide.

But the subject of waves and tides has been treated in conformity to the theory of undulations by Mr. Airy, the astronomer royal, in a valuable essay originally published in the 'Encyclopædia Metropolitana:' the investigations, though admitting of general application, are particularly adapted to the phenomena of tides in rivers and arms of the sea; and they are conducted by an analysis within the reach of persons acquainted with the ordinary processes of the differential and integral calculus.

As in the theory of La Place, there is formed an "equation of continuity," which is founded on the equality of a rectangular parallelopiped of water at rest, to the oblique parallelopiped formed, when the water is in a state of disturbance, by the new positions of the eight particles constituting the angular points of the former parallelopiped. But, as the water is supposed to be in a rectangular canal, the extent of the parallelopiped in the direction of the breadth of the canal is supposed to be constant; and therefore it is sufficient to assume the equality of the parallelograms which form a side of each in the direction of the length of the canal.

The canal being of uniform depth, the "equation of continuity" is expressed by

$$\text{Y} = -\int \frac{d\text{X}}{dx} \text{ (between 0 and } y)$$

where x and y are respectively the horizontal and vertical coordinates of a particle of fluid, and where X and Y are respectively the horizontal and vertical displacements of the particle by the action of the disturbing forces: the equation expresses a relation between those coordinates and the disturbances or displacements.

An equation of the pressure experienced by any particle from the forces which act upon it is next found in the following manner:—Let p represent the pressure in every direction on the lower part of a disturbed molecule of water in consequence of the height or weight of the filament of particles above it: then, the vertical coordinate of the particle being y' or $y+\text{Y}$, suppose in the element dt of time the vertical coordinate to become $y'+\delta y'$ (the vertical height of the filament above the molecule in that position being increased by the general rising of the wave), the pressure on the upper part of the molecule will be greater than before, and may be represented by $p+\frac{dp}{dy'}\delta y'$; consequently the molecule may be supposed to be pressed downwards by a force represented by $\frac{dp}{dy'}\delta y'$. Now, in order to render the expression for the hydrostatical pressure homologous to that which is employed for the force of gravity, it must be considered as accelerative, or as a motive-power divided by the mass; and therefore the accelerative pressure downwards becomes $\frac{dp}{dy'}$, which being added to g, representing the force of gravity and supposed to be constant, there arises $\frac{dp}{dy'}+g$ for the whole acceleration of the molecule downwards: hence there is obtained the equation

$$-\frac{d^2y}{dt^2} = \frac{dp}{dy} + g.$$

This equation being integrated between the limits for the bottom of the molecule and the top of the wave, gives the hydrostatical force by which a vertical filament of water descends, or that by which it is carried forward horizontally.

Let the slender column of water above the molecule have a horizontal breadth equal to h in the direction of x; then the horizontal pressure in front, by which the column is forced backwards, will exceed the pressure by which it is carried forwards by a force represented by $\frac{dp}{dx}dh$, or by an acceleration represented by $\frac{dp}{dx}$; therefore the horizontal acceleration forwards is $-\frac{dp}{dx}$: if extraneous forces, as the attraction of the sun or moon on the molecule, and the effects of friction, be together represented by F, when estimated in the direction of x, there arises the expression $\text{F}-\frac{dp}{dx}$ for the whole acceleration forwards; then the "equation of motion" becomes

$$\frac{d^2\text{X}}{dt^2} = \text{F} - \frac{dp}{dx},$$

which gives relations between the terms X, Y, x, y, and t. This "equation of equal pressure" and the "equation of continuity" constitute the theory of the motion of fluids in canals of uniform breadth.

The general equation representing the disturbance or displacement of a particle of water is the same as that which expresses the disturbance of a particle of light in the undulatory theory; and, in order to indicate oscillatory motion, both the horizontal and vertical displacements are represented by terms containing the sines or cosines of angles depending on the time t.

If it be assumed that

$$\text{X} = \text{R}\cos(nt-mx) + \text{S}\sin(nt-mx),$$

R and S being functions of y, the above equations of continuity and of equal pressure give, on the supposition that gravity is constant, that no extraneous forces act, and retaining for the present only the first power of $\frac{d\text{X}}{dx}$, or of the horizontal displacement

$$\frac{d^2\text{X}}{dy^2} + \frac{d^2\text{X}}{dx^2} = 0.$$

From these two equations are obtained the values of X and Y in terms of A $\cos(nt-mx)$ and B $\sin(nt-mx)$.

These values will not be altered if mx is increased or diminished by one, two, three, &c. whole circumferences, that is, if x is increased or diminished by $\frac{2\pi}{m}$, $\frac{4\pi}{m}$, &c., while t remains the same; therefore $\frac{2\pi}{m}$ is the value of the increments of x which correspond to points where the particles of water are in the same condition with respect to disturbance, that is, $\frac{2\pi}{m}$ is the length of a wave. Again, the values will not be altered if nt is increased or diminished by whole circumferences, that is, if t is increased or diminished by $\frac{2\pi}{n}$, $\frac{4\pi}{n}$, &c., while x remains the same; therefore $\frac{2\pi}{n}$ is the increment of time which corresponds to the particles of water being successively in the like state of disturbance, that is, $\frac{2\pi}{n}$ is the period of a wave, or the time between two successive formations of a wave-summit at the same place. Therefore $\frac{n}{m}$ is the velocity of the wave; and, from the value found for it by the theory, it follows that the velocity depends on m and on the depth of the water: the latter being constant, the velocity depends on the length of the wave, or it depends on the time in which a particle of water makes a complete vibration. If the length of a wave or the time of its vibration is given, the velocity will vary with the depth of the water.

From a table of the computed velocities of waves of different lengths, and with different depths of water, it is found that when the length of the wave is not greater than the depth of the water, the velocity of the wave is proportional to the square root of its length: also when the length is not less than one thousand times the depth of water, the velocity is proportional to the square root of the depth, and is the same as that which a body would acquire in falling from rest through a height equal to half that depth. The greatest horizontal and vertical displacement of a particle being computed for different values of the length of the wave and the depth of the water, it appears that when the latter is great, compared with the former, as in the open sea, the motion of the water far below the surface is very small compared with the motion at the surface, and at a depth equal to the length of wave it is only about $\frac{1}{533}$ of the motion at the surface. On the same supposition, the greatest horizontal motion is equal to the greatest vertical motion. When the length of the wave is great compared with the depth of the water, as in tide-waves, the horizontal motion of the particles is nearly the same from the surface to the bottom, and the vertical motion varies with the distance from the bottom. On the same supposition, the vertical motion of the superior particles is much less than their horizontal motion.

The movement of a particle of water near the surface may be determined from the values given by the theory to X and Y: if the waves are small, so that A may be considered as equal to B, we have $(\text{X}^2+\text{Y}^2)^{\frac{1}{2}} = \text{C}$, a constant; which, being the equation of a circle, it follows that the particles move in the circumference of a circle whose radius is A; but if the length of the wave is great compared with the depth of water, the equation is that of an ellipse. These last deductions from the theory are conformable to what has been observed in experimental waves, as above mentioned. It follows that, in a long tide-wave flowing up a channel, the horizontal velocity in the direction of the wave's motion is the greatest at the summit of the wave—that is, at high-water: at the place of greatest depression—that is, at low-water—the motion is most rapid downwards; and at the mean level the water is for a time stationary.

In investigating theoretically the phenomena of waves by whatever cause produced, if the lengths of the waves are very great compared with the depth of the canal in which they move, it becomes necessary to retain the second and even higher powers of $\frac{d\text{X}}{dx}$, or of the horizontal displacement, in the equations of continuity and of equal pressure; but the vertical oscillations being then small, the value of $\frac{d^2\text{Y}}{dt^2}$ may be neglected. Then, if the perturbating actions of the sun and moon are not considered, the integration of the differential equation of equal pressure gives a value of the vertical displacement at the surface, or the height of the wave above the mean elevation, in terms which contain $k\sin(nt-mx)$ and $kx\sin(2nt-2mx)$, k being the depth of water in the canal. Tracing an undulating line whose ordinates are the values of that vertical height, corresponding to different values of x, the horizontal distance from the mouth of the canal, which is supposed to open to the sea; it is found that, near the opening, the front and rear slopes of the waves are of equal lengths and of similar forms; but as the distance from the sea becomes greater, the front slope is shorter and steeper, and the rear slope longer and more gentle. At a great distance the latter becomes nearly horizontal in the middle, and at length it divides into two parts, so that the wave becomes double. Near the sea, also, the time occupied by the rise of the wave is equal to the time occupied by its descent: at a certain distance the rise takes place in less time than the descent; and at a still greater distance the descent, after having been rapid, is checked, or changed into a rise, to which another rapid descent succeeds; so that there seem to be two tides, or elevations of the water, in the upper part of the canal, corresponding to one elevation at the mouth.

The value of $\frac{d\text{x}}{dt}$, or the velocity of the particles of water, is found also to contain the sines and cosines of the angles above mentioned; and, substituting in these the greatest positive and the greatest negative values of the elevation, it is found that the velocity corresponding to the first of these values—that is, at the top of the wave—is less than the velocity corresponding to the other; but the motion, in the first case, is up the canal, and in the other down it, and these are nearly the same as the greatest velocities of the water: consequently, the velocity of the flow of the wave in the canal is less than that of the ebb. The preceding conclusions relate to the case in which the water was at rest in the canal previously to the formation of the wave: in the event of the water having a general movement towards the sea, the time in which the wave rises, or the time from low-water to high-water, is still less than the time of the descent; but the difference between the two times is greater than in the former case.

If a section of the bed of the canal, instead of being rectangular, has the form of an isosceles triangle, the investigations show that the velocity of the wave would be equal to that of a wave in a rectangular bed whose depth is equal to half the perpendicular of the triangle. If the section were a parabola, the velocity would be two-thirds of that which the waves would have in a rectangular bed of equal breadth and depth.

When the water, still supposed to be in a canal of uniform breadth and depth, is disturbed by extraneous forces, as the attraction of the sun or moon, the term F in the equation of equal pressure is conceived to consist of two, one represented by H sin. $(it-mx)$ for the horizontal intensity of such force in the direction of x, and the other by G cos. $(it-mx)$ for the vertical intensity; and the equation for $\frac{d^2x}{dt^2}$ being then satisfied by the equation $\text{x}=\phi''(y)$ sin. $(it-mx)$, in which $\phi''(y)$ represents the second differential coefficient of a function of y, there is obtained a value of X at the surface of the fluid in terms of sin. $(it-mx)$, and a value of the height above the level of still water in terms of cos. $(it-mx)$. The wave thus indicated depends upon the continuance of the actions of the extraneous disturbing forces, and is designated by Mr. Airy the *forced* tide-wave. This wave, he observes, would cease to exist if those forces were to cease; but other waves resulting from the previous action would still continue to exist, and these he distinguishes by the name of *free* tide-waves. If the canal be supposed to surround the earth at the equator, the length of the forced tide-wave is equal to half the circumference of that great circle; and from the expressions for X and Y, it appears that the effect of the vertical disturbing forces on the phenomena of the tides is insignificant, almost the whole sensible effect being due to the horizontal force.

Taking into account the effects of friction, which may be considered as a horizontal retarding force proportional to the velocity, and which may consequently be represented by $-f\frac{d\text{x}}{dt}$; the value of X contains terms involving the sines and cosines of angles represented by $it-mx$ and $it \mp qx$, and the expression for the vertical elevation contains the sine and cosine of $it-mx$. The analytical expression arising from the introduction of this additional perturbation indicates the fact that the highest tides take place later than the times at which the disturbing forces arising from the action of the sun or moon are the greatest; and this circumstance gives to the wave theory an important advantage over those of Newton and La Place; for in both these theories the greatest tides take place when the force is the greatest.

In the case of a canal bounded at both extremities, the expression for X, the horizontal disturbance of a particle, is found to consist of two parts, one of which is the horizontal movement due to the disturbing forces, and the other a combination of free tide-waves, probably caused by reflexions of the forced tide-waves from the opposite ends of the canal. When a canal so bounded is of small extent, the horizontal motion of the particles is found to be the greatest in the middle of its length, and to diminish gradually to the ends, where it vanishes. There is proved to be no variation of level in the middle of the length, and the variation in other parts is proportional to the distance from the middle, the elevation at one end taking place at the same time as the depression at the other. It results, also, that the greatest horizontal and vertical displacements of the particles take place at the same time; whereas in other circumstances, from the circular or elliptical motions of the particles, the greatest horizontal displacements take place when the vertical displacements are zero, and *vice versâ*.

In a deep gulf open to the sea at one end and closed at the other, and in which the waters have a tidal fluctuation, the termination of the flow upwards takes place at the mouth a considerable time after high-water; but near the bottom of the gulf the difference between the times is very small. When a tide-wave is propagated up a river, the analysis shows that the vertical elevations of the wave, and also the horizontal motion of the particles of water, diminish continually as the wave advances: also the direction of the tide-current changes sooner after the instant of high-water than it would if friction were not considered. When a river runs on a declivity towards the sea, the latter being affected by tides, it is shown that the low-water at certain points up the river may be higher than the level of high-water on the sea.

The theory, of which a brief outline has just been stated, applies to what are called negative waves by a mere change in the sign of the coefficients of the trigonometrical factors. These waves are depressions below the general surface of the water, and, like the others, they have a progressive motion. Such waves, for example, are those which are formed by the paddles of a steam-boat.

All the theories concur in showing that the difference between the diurnal and semidiurnal tides is great in middle latitudes, and small at the equator and poles; and in this respect they are at variance with the actual phenomena. From observations it is found that this difference is as great at certain places near the equator as near the latitude of either tropic: it has also been found to be great at Petropaulowski and in Norfolk Sound, while in Europe it is small. It has been attempted to account for the latter circumstance by assuming that each tide-wave in this part of the world is composed of two, which flow towards the same place in opposite directions at intervals of about twelve hours. It is supposed that the semidiurnal waves of these tides, being in the same state or phase, produce together a like effect, but that the diurnal waves are in opposite states; so that the superior high tide of one wave coinciding with the inferior high tide of the other, they together produce a mean height of water differing but little from that of the united semidiurnal tides.

We cannot here enter into the details of the investigations relating to the theories of the oscillations of water, or the discussion of the experiments which have been made on waves in artificial canals, the methods of making observations on tides, and accounts of the particular tides in rivers and seas; but the experimental researches of Mr. Scott Russell have made so important an accession to our knowledge of waves, in its relation to practical as well as theoretical science, that this article would be defective without a summary of their results. The details of his experiments will be found chiefly in the 'Transactions of the Royal Society of Edinburgh,' vol. xiv., and in the 'Report of the Seventh Meeting of the British Association for the Advancement of Science.'

At the time when Mr. Russell's hydrodynamical researches were commenced, the celestial mechanics of the tides, as we have seen in the preceding portion of this article, had been analysed and explained in a manner satisfactory both to astronomers and mathematical physicists, but a great variety of considerations relating to the propagation of the tides along the surface of the globe—constituting their terrestrial mechanism—remained without explanation. The solar and lunar attraction having generated the tides, exercise little or no influence over the subsequent propagation of them. It is not until 50 or 60 hours after their creation that the tides reach our shores, having moved in the interval in every possible direction, and with every velocity from 100 down to 10 miles an hour. "This moving elevation of fluid," in the words of the committee on waves, appointed by the British Association in 1836, "may be conveniently designated a *wave*, and its history will be the history of the *tidal wave;* but to confer upon it the name of wave does not imply that its laws are those which belong to any other similar elevation with which we are acquainted. It was necessary to investigate the nature of this tide-wave—to examine the hydrodynamical mechanism by which it is transferred from one place to another—to determine the laws which regulate its form and its velocity—to ascertain if any relations exist between the form and dimensions of its bed, and its own form and rate of transference. These and many similar points," including also the effect of the wind upon the tide-wave, "were still unknown." Laplace, Lubbock, and Whewell had severally pointed out how much was required to be known, and the last had shown that a great number of curious facts in fluid motion had been established by the tide researches, some of which had been discussed and others instituted and pursued by himself, of which he expressed a hope that the theory of hydrodynamics would one day be able to render a reason.

Such having been the condition of science on the subject when Mr. Russell began his inquiries, the following is a condensed statement, but nearly in the words of the Committee, of the "*General Results*" he obtained, and which have eventually been found to possess much more than the value which had been anticipated.

1. The existence of a great primary wave of fluid, differing in its origin, its phenomena, and its laws, from the undulatory and oscillatory waves which alone had been investigated previous to the researches of Mr. Russell, have been confirmed and established. This wave was first observed by him in 1834.

2. The velocity of this wave in channels of uniform depth is independent of the breadth of the fluid, and equal to the velocity acquired by a heavy body falling freely by gravity through a height equal to half the depth of the fluid, reckoned from the top of the wave to the bottom of the channel.

3. The velocity of this primary wave is not affected by the velocity of impulse with which the wave has been originally generated, neither does its form or velocity appear to be derived in any way from the form of the generating body.

4. This wave has been found to differ from every other species of wave in the motion which is given to the individual particles of the

fluid through which the wave is propagated. By the transit of the wave the particles of the fluid are raised from their places, transferred forward in the direction of the motion of the wave, and permanently deposited at rest in a new place at a considerable distance from their original position. There is no retrogradation, no oscillation; the motion is all in the same direction, and the extent of the transference is equal throughout the whole depth. Hence this wave may be descriptively designated the great primary wave of translation. The motion of translation commences when the anterior surface of the wave is vertically over a given series of particles; it increases in velocity until the crest of the wave has come to be vertically above them, and from this moment the motion of translation is retarded, and the particles are left in a condition of perfect rest at the instant when the posterior surface of the wave has terminated its transit through the vertical plane in which they lie. This phenomenon has been verified up to the depth of 5 feet.

5. The elementary form of the wave is cycloidal; when the height of the wave is small in proportion to its length the curve is the prolate cycloid, and as the height of the wave increases the form approaches that of the common cycloid, becoming more and more cusped until at last it becomes exactly that of the common cycloid, with a cusped summit; and if by any means the height be increased beyond this, the curve becomes the curtate cycloid, the summit assumes a form of unstable equilibrium, totters, and falling over on one side forms a crested wave or breaking surge.

6. A wave is possible in forms of channel where the depth is not uniform throughout the whole depth. It appears however that where the difference between the depth of the sides is considerable, one part of the wave will continue during the whole period of propagation in the act of breaking, so as to show that in these circumstances a continuous wave is impossible. In other cases the ridge of the wave rises so much higher on the shallower part of the fluid as to produce a given velocity without exceeding the limits of equilibrium, and in those cases the wave becomes possible, and the velocity appears to coincide closely with that which we obtain by supposing the wave resolved into vertical elements, each having the velocity due to the depth, and then integrating. It results that:—

In the rectangular channel the velocity is that of gravity due to half the depth.

In the sloping or triangular channel the velocity is that due to one-third of the greatest depth.

In a parabolic channel the velocity is that due to three-eighths or three-tenths of the greatest depth, according as the channel is convex or concave.

The velocity of the great primary wave of translation of a fluid is that due to gravity acting through a height equal to the depth of the centre of gravity of the transverse section of the channel below the surface of the fluid.

7. The height of a wave may be indefinitely increased by propagation into a channel which becomes narrower in the form of a wedge, the increased height being nearly in the inverse ratio of the square root of the breadth.

8. If waves be propagated in a channel whose depth diminishes uniformly, the waves will break when their height above the surface of the level fluid becomes equal to the depth at the bottom below the surface.

9. The great waves of translation are reflected from surfaces at right angles to the direction of their motion, without suffering any change but that of direction.

10. The great primary waves of translation cross each other without change of any kind, in the same manner as the small oscillations produced on the surface of a pool by a falling stone.

11. The waves of the sea are not of the first order; they belong to the second or oscillatory order of waves; they are partial displacements at the surface which do not extend to considerable depths, and are therefore totally different in character from the great waves of translation, in which the motion of displacement of the particles of the fluid in the waves of the sea is greatest at the surface and diminishes rapidly. There are generally on the surface of the sea several coexistent classes of oscillations of varying direction and magnitude, which by their union give the surface an appearance of irregularity which does not exist in nature.

12. When waves of the sea approach a shore or come into shallow water, they become waves of translation, and obeying the laws already mentioned, always break when the depth of the water is not greater than their height above the level.

13. Waves at the surface of the sea do not move with the velocity due to the whole depth of the fluid; may they not move with the velocity due to that part which they do agitate, or to some given part of it?

14. A circumstance frequently observed when the waves break on the shore, has been satisfactorily accounted for by the examination of the constitution of the waves of the sea. It has been frequently observed that a certain wave is the largest of a series, and that these large waves occur periodically at equal intervals, so that sometimes every third wave, every seventh, or every ninth wave, is the largest. Now as there are almost always several co-existent series of waves, and as one of these is a long, gentle "under swell," propagated to the shore from the deep sea in the distance, while the others are short and more superficial waves, generated by a temporary breeze of reflections from a neighbouring shore; so it will follow that when the smaller waves are $\frac{1}{3}$rd, or $\frac{1}{4}$th, or $\frac{1}{5}$th, or in any other given ratio to the length of the longer ones, those waves in which the ridges of the two series are coincident will be the periodical large waves; and if there be three systems of coexistent waves, or any greater number, their coincidences will give periodical large recurring waves, having maxima and minima of various orders.

15. The tide-wave appears to be the only wave of the ocean which belongs to the first order, and appears to be identical with the great primary wave of translation; its velocity diminishes and increases with the depth of the fluid, and appears to approximate closely to the velocity due to half the depth of the fluid in the rectangular channel, and to a certain mean depth which is that of the centre of gravity of the section of the channel. It is, however, difficult to determine the limits within which the tide-wave retains its unity; where portions of the same channel differ much in depth at points remote from each other, the tide-waves appear to separate.

16. The tide appears to be a compound wave, one elementary wave bringing the first part of flood tide, another the high water, and as these move with different velocities according to the depth. On approaching shallow shores the anterior tide-waves move more slowly in the shallow water, while the posterior waves moving more rapidly diminish the distance between successive waves. The tide-wave becomes thus dislocated, its anterior surface rising more rapidly and its posterior surface descending more slowly than in deep water.

17. A tidal bore [BORE] is formed when the water is so shallow at low water that the first waves of flood tide move with a velocity much less than that due to the succeeding part of the tidal wave, as to be overtaken by the subsequent waves; or wherever the tide rises rapidly, and the water on the shore or in the river is so shallow that the height of the first wave of the tide is greater than the depth of the fluid at that place. Hence in deep water vessels are safe from the waves of rivers which injure those on the shore.

18. The identity of the tide-wave and the great wave of translation, shows the nature of certain variations in the establishment of ports situated on tidal rivers. Any change in the depth of the river produces a corresponding change between the moon's transit and the high water immediately succeeding. It appears from the observations in this report, that the mean time of high water has been rendered [illegible] minutes earlier than formerly, by deepening a portion of about [illegible] miles in the channel of a tidal river, so that a tide-wave which formerly travelled at the rate of 10 miles an hour, now travels at the rate of nearly 15 miles an hour.

19. It also appears that a large wave, or a wave of high water of spring tides, travels faster than a wave of high water of neap tides, showing that there is a variation on the establishment, or on the interval between the moon's transit and the succeeding high water, due to the depth of the fluid at high water, and which should, of course, enter as an element into the calculation of tide tables for an inland port on the sea shore. The variation of the interval will vary with the square root of mean depth of the channel at high water.

"These results give us principles," the committee on waves conclude, "1, for the construction of canals; 2, for the navigation of canals; 3, for the improvement of tidal rivers; 4, for the navigation of tidal rivers; 5, for the improvement of tide tables." But an equally valuable application, not however foreseen when these results had been obtained and examined, unless by Mr. Russell himself, was to the improvement of naval architecture. Of this, a brief account has already been given in the article SHIP-BUILDING.

After the publication of the report by the committee on waves, which contained the experimental investigation of which we have now given the principal results, the phenomena of waves engaged the attention of eminent mathematicians, who endeavoured to deduce from first principles the curious facts which Mr. Scott Russell and his associates had observed, so as to reconcile theory with experiment. Among these were the Astronomer-Royal (a summary of whose conclusions has been given in this article), Mr. Green, and Professor Kelland, who also succeeded in obtaining from analysis many of the very singular experimental results. Their researches were published in the Transactions of the Cambridge Philosophical Society, and those of the Royal Society of Edinburgh; and Professor Kelland also gave a view of the actual state to which the theory of waves had been brought in the Report of the tenth meeting of the British Association.

The theory of waves, regarded as forming a part of abstract mechanics, as well as in certain applications, has been considered also in the articles ACOUSTICS; INTERFERENCE; VIBRATION; and UNDULATORY THEORY OF LIGHT. An excellent familiar explanation of the subject, especially as regards the coincidence and interference of waves, will be found in Professor Tyndall's 'Glaciers of the Alps,' pp. 230–233.

WAX. There are several varieties of this substance, but the term used by itself means BEES' WAX, under which heading will be found an account of the manner in which it is secreted, its chemical constitution, and the means employed in preparing it for commercial purposes.

Wax is used to a considerable extent in the making of candles, cerates, ointments, and plasters. The so-called *sealing-wax* has no wax in its composition. [SEALING-WAX.] Spurious wax is sometimes made and sold for cheap purposes; consisting of yellow resin, mutton suet, and palm oil, or turmeric instead of palm oil. *Etching-wax* is made of bees'-wax and linseed oil; or white wax, gum benzoin, and linseed oil; or white wax, Burgundy pitch, and powdered asphaltum. *Modelling-wax* is described under WAX-MODELLING.

Vegetable Wax. Various plants yield a substance like wax, which is obtained, like the vegetable butter, by bruising and boiling them in water, when the wax, melting, floats to the surface, and there concretes on cooling. Of these the most remarkable instance is the *Ceroxylon andicola*, the Wax Palm (*Palma de Cera* of the American Spaniards). *Myrica Gale*, Candleberry Myrtle, or Sweet Gale, a native of this country, yields a substance resembling bees'-wax when its catkins or cones are boiled in water. *Myrica cerifera*, a native of North America, yields a similar substance when its berries are thus boiled: candles are made of it also, whence the plant is commonly called Tallow-shrub or Candleberry-tree. *M. quercifolia*, a native of the Cape of Good Hope, is another species which yields a vegetable wax. It grows along the coast, on dry sandy plains exposed to the sea-air, where hardly any other plants will vegetate. The wax invests the berries in the form of a rough crust, which is separated by means of boiling water. It is of a greenish colour, but may be bleached. When made into candles it gives a very fine light. A vegetable wax is also obtained in China from *Ligustrum lucidum*, which is frequently mentioned as the wax-tree in Dr. Abel's and other travels.

Japan is now known to be the chief country whence vegetable wax is imported. Small parcels have been brought to market for many years past; the wax being at first in the form of small thin oval cakes stamped with Japanese characters. Afterwards it came over in cases containing 130lbs. each. In 1859 a cargo arrived direct from Nagasaki, in Japan, of nearly 9000 cases. It commanded a ready sale at the price of the best Russian tallow at that time, (57*s*. per cwt.), but went off slowly at the required price of 70*s*.

Dr. M'Gowan, in a paper read before the Society of Arts in 1860, on the productive industry of Japan, said:—"One of the most remarkable products is the vegetable wax, several cargoes of which have already arrived in this country from Japan. It is said that the first adventurer in this article sold his cargo at 100 per cent. profit. The Japanese, having discovered this wax to be a valuable article of commerce, seemed, when I was in the country, to be making arrangements for cultivating more largely the trees producing the berries from which the wax is expressed; and, with improved machinery, this article could, no doubt, be produced more abundantly and more cheaply. The product requires protracted bleaching before it arrives at the white state in which it is sent to our markets."

Many other plants yield a substance similar to vegetable wax, some from the stem, but mostly from the berries. The *Rhus succedanea*, a plant of the same species as the *sumach*, might (it has been suggested) be profitably cultivated in Australia or at the Cape of Good Hope. It yields a wax residue, in quality between bees'-wax and vegetable tallow, softer and fatter than bees'-wax, and easily kneaded. It has already come into use in England in the candle manufacture. If combined with any cheap tallow or fat, it makes a mixture useful for many purposes.

WAX-MODELLING. Wax has been in all ages an important agent in the art of statuary; and in the formative art generally, whether as a fine art, or for the purposes of science. In statuary it is used in making the models for the metal cast, but more formerly than at present, for now clay is frequently substituted in its place: it is, however, still used by silversmiths in casting cups and other cylindrical or spherical objects, especially such as are required to be kept free from the markings of joints, to avoid injury to the design or embossed work. In fine art it is used in forming images, and iconic portraits, small busts, and bassi-rilievi; and it is also very usefully and largely applied in the preparation of anatomical models, especially in pathology, and in the preparation of fruit, flowers, and many objects of natural history. Wax-modelling, when applied as above described, as a fine art, is frequently termed the *Ceroplastic* art (κηροπλαστική; from κηρός, wax, and πλαστική, the art of fashioning into forms).

Wax was formerly indispensable in metal-casting, though when and how it was first used is wholly unknown. It may have been used for the models of solid casts even in the earliest periods, but was almost certainly used in hollow casting, which was a later invention, and which will presently be described; though of an art so entirely practical, no description can convey more than a general idea.

Different writers of different ages give various directions for the preparation of the wax to be used. Vasari, who doubtless mentions that used in his own time, recommends the admixture of a little tallow, turpentine, and pitch, with the common yellow wax, but he does not specify any particular quantities. The tallow renders it more soluble and fluid, the turpentine more adhesive, and the pitch colours it, and assists it in hardening after the operation is complete: it may also be coloured with a little red ochre in powder, which must be mixed with the wax in its liquid state. It may be made any other colour in the same way. A French mixture is—to one hundred pounds of yellow wax, ten pounds of turpentine, ten of pitch, and ten of hogs'-lard, which probably would be similar in its properties to the mixture described by Vasari. When the wax is melted, great care must be taken that it does not boil, or it cannot be repaired when cold. M. Fiquet, in his 'Art du Mouleur en Plâtre,' gives the following compound for founder's wax—to four of wax, mix one of tallow and two of Burgundy pitch (*poix de Bourgogne*), which when melted together are fluid and manageable. This was probably the composition used by J. B. Keller and Girardon in preparing the mould for Girardon's equestrian statue of Louis XIV., which was cast entire, or in *whole getto*. Several other mixtures were and are probably employed by different sculptors; the above, however, were those employed in France and Italy in the great ages of founding, when the wax method was generally in use. We may now proceed to describe the methods of its application.

Andrea Verrocchio, a celebrated sculptor of the 15th century, is said by Vasari to have been one of the first among the moderns to introduce casting from moulds taken from life, or, in Vasari's words, to bring the practice into general use—"che fu de' primi che cominciasse a metterlo in uso" (ed. 1568). These casts he made in wax and in plaster; and some writers have spoken of him as the inventor of moulding from the human figure, and others even as the inventor of casting in plaster; neither of which is said nor could have been intended to be conveyed by Vasari. Many arts have been known, and occasionally practised, before they have been applied to the ordinary uses to which they were well adapted. There is in Florence still preserved in the cathedral a cast thus formed from the head of Brunelleschi, which, as Bottari has remarked, must have been taken when Verrocchio was only fourteen years of age. And with regard to casting in plaster, if metal casts were made long before the time of Verrocchio, it is more than probable that plaster casts were also made. The first distinguished Italian founder of modern times was Andrea Pisano, who modelled the gates of the Baptistery of St. John at Florence, which were cast by some Venetian founders in 1330. The same sculptor had previously sent by Giotto a present of a bronze crucifix to Pope Clement V. (1305-1314) at Avignon, which must have been about 120 years before Verrochio was born. This crucifix is represented as having been of excellent workmanship; it must have been fashioned consequently by an artist or artists well acquainted both with mould-making and with casting, and the idea, therefore, that either art can have been ever first *practised* at so late a period as Verrocchio is quite untenable. The fact of bringing artists from Venice to cast the gates of the Baptistery of St. John does not so much show that Florence was without good metal-founders, as that Venice had obtained celebrity for its artists of this class. William Austen, a celebrated English founder, was anterior to Verrocchio. [AUSTEN, WILLIAM, in BIOG. DIV.] However, at whatever period and by whatever process the early Italians first prepared their moulds for metal-casting, they most probably in all works of consequence used wax in the preparation of the model for the casting. The ancient Greeks and Romans also most probably used wax for the same purposes. There are few ancient bronzes of a large size now extant; the principal of them is the equestrian statue of Marcus Aurelius before the Capitol at Rome. This monument is hollow, and was cast in two parts; and probably the ancient method was not very different from that described by Vasari; some ancient works were cast solid. The ancients were also in the habit of making plaster moulds of objects; in fact the Greeks and Romans were more or less familiar with almost every method and contrivance known to the modern statuary. (Müller, 'Handbuch der Archäologie der Kunst,' §§ 305, 6.)

It is generally allowed that the triumph of casting in modern times was Girardon's colossal statue of Louis XIV., cast by J. B. Keller; it stood on the Place Vendôme at Paris until 1792, when it was destroyed by the French populace. The weight of the monument is said to have been 60,000 lbs., and its height, including the bronze pedestal, 21 feet. This enormous mass of metal was cast at once, or in a single *getto*. The preparation of the model and mould was on the following plan:—When the model of the statue was finished, a safe mould of plaster and brickdust was made from it in many parts. [MODELLING.] Each of these parts being marked and numbered, and removed from the model, was then oiled, and carefully filled on the inner side to a certain thickness, an inch or two, with the modelling-wax already described; the thickness depending upon the height or position of the part, the lowest parts being the thickest, for the metal is destined to fill exactly the space occupied by the wax. When all the parts of the mould were thus prepared, the whole was again put together in a pit, around a simple framework of iron bars, so as to support it firmly in each direction; the lowest parts of the mould being first placed, and the joints of the wax of the various contiguous parts being filled in, and the pieces carefully united together with melted wax with a brush, as the work proceeded. When the whole was put together, it was bound on the exterior with strong bars of iron attached to the extremities of the bars of the interior framework. The mould is now a hollow shell, with a thick coating of wax all over the interior, the whole being kept together by iron supports, inside and outside. The next step is to fill this hollow shell, through an aperture left at the top, with a composition of plaster and brickdust, which is fire-proof. This fire-proof body is termed in English a *core*, by the French *noyau*, by the Germans *kern*, and by Vasari the *anima*. Air-vents must be made in the shell before the casting of the core.

When the core is fixed, the original mould or shell is taken off, and a wax model of the statue appears to the eye. The sculptor now examines his wax model, and improves it where there is occasion and repairs or makes good all imperfections. When it is perfectly finished, the preparation for the founding commences. Over this wax statue a new fire-proof mould is made of plaster, brickdust or sand, cow-hair, and horse-dung, and sometimes very fine ashes. This composition, used at first as a fine liquid plaster, is put on in many coats with a brush, and care must be taken that every particle of wax is covered with the finer plaster: each coat is allowed to dry before the successive coat is put on, and the composition may be gradually made of a coarser mixture. When this new shell or mould is of a sufficient thickness and is properly strengthened by iron bars, a coal fire must be kindled round it and be allowed to burn until the whole of the wax is burnt out, proper vents being made for its escape. This burning out of the wax is a most tedious and difficult process, lasting sometimes as much as four or even six weeks. (Söltl, 'Bildende Kunst in München,' Stiglmayer, p. 484.) The great difficulty and long process of melting out the wax was the cause of what is called the wax method going comparatively out of use, but it is only recently that the clay and sand modelling as its substitute has been generally established. Until 1824 Stiglmayer, one of the most successful of recent founders, used the wax method; from that time the clay method. The largest single cast by Stiglmayer did not amount to one-half of the given weight of this enormous cast by Keller: it is, however, now no longer considered desirable to cast a monument in a single *getto*. [BRONZE; SCULPTURE.]

When the wax is at length melted out, the mould must be strengthened by brickwork, and the whole pit must be closely filled with sand. A channel is now made from the furnace, and is divided in its course into three smaller channels or ducts which lead to three openings in the now hollow mould, which is buried in the earth a little below the furnace. The vacuum in the mould caused by melting out the wax is to be filled with metal; the original iron framework, which was constructed before the casting of the core, keeps both the core and the mould in their proper places; and air-vents in various parts of the mould preclude any great probability of accident. When all is ready, the furnace is opened at a given signal, the liquid fire runs in the channels simultaneously into the mould, and that part of the work which was previously soft wax becomes perennial bronze. The cast is accomplished when the metal pours out from the vents. When cool, the mould is broken away piecemeal, and the metal is exposed. The core is then removed from the inside through an aperture made on purpose; the whole is then repaired and finished by the bronze-workers. [BRONZE.] Johann Balthasar Keller, who cast in this method the statue of Louis XIV., was a Swiss, and originally a goldsmith. He was born at Zürich, in 1638, and died at Paris, superintendent of the royal foundry, in 1720. There is a print of the statue by C. Simoneau: it was cast in 1699.

Vasari (*Introduzione*, l. c.) describes a very simple method for casting small figures in bronze. When the mould (*cappa*) is made, it must be reversed in water; melted wax is then poured into it, that coming in contact with the cold wet surface of the mould cools immediately, while the interior portion remains liquid; the mould must be again turned over, when the still liquid wax in the centre will immediately run out, leaving in the mould a hollow wax shell. The shell must now be filled with the proper plaster, and this constitutes the core of the object. The wax is then burnt out, and the cast is made as usual.

It remains to treat of that department of wax-modelling termed *Ceroplastic*. Under this term is comprehended modelling and casting in wax, though not in the manner already described. The art of casting in wax from nature was, according to Pliny ('Hist. Nat.' xxxv. 44), invented by Lysistratus, of Sicyon, the brother of Lysippus, about 300 B.C., who, he says, first of all men took plaster moulds from the face and made wax casts from them. These wax portraits became eventually very common, and especially among the Romans. It is however very unlikely that the many treasured wax portraits we read of in ancient writers were made from moulds taken from the face itself. Such would be the mere resemblance of death, for they would be without eyes and otherwise void of expression. They were probably cast from moulds taken from models, though such masks may have been used in the formation of the models.

From Pliny (xxxv. 2), we learn that the Romans were in the habit of having wax images of themselves made, to be handed down to their posterity. Many writers notice and praise the custom. Valerius Maximus (v. 8. 3), alludes to the advantages of the practice by virtue of example. It was indeed a privilege to which only some were entitled. None could make them but those who had themselves, or whose ancestors had, borne some curule magistracy. Cicero speaks of the right of handing down your image to posterity. The number of ancestral images therefore became an object of pride and an evidence of ancient nobility, and the antiquity of a family was sometimes expressed by applying the epithet smoky to its images, "fumosæ imagines." (Cicero in 'Verr' vi. 14.; in 'Pisonem,' 1.; and 'De Leg. Agrar.' ii. 1.)

The most striking passage concerning these images is in Polybius (vi. 52), who as a Greek and a stranger would be more impressed by so peculiar a custom as he describes. He says, "Upon solemn festivals, these images are uncovered, and adorned with the greatest care. And when any other person of the same family dies, they are carried also in the funeral procession, with a body added to the bust, that the representation may be just, even with regard to size. They are dressed likewise in the habits that belong to the ranks which they severally filled when they were alive. If they were consuls or prætors, in a gown bordered with purple; if censors, in a purple robe; and if they triumphed or obtained any similar honour, in a vest embroidered with gold. Thus apparelled they are drawn along in chariots preceded by the rods and axes, and other ensigns of their former dignity. And when they arrive at the forum, they are all seated upon chairs of ivory; and then exhibit the noblest object that can be offered to a youthful mind warmed with the love of virtue and of glory."

This wax-modelling has continued apparently from the time of the Romans until the present day. In the middle ages it was used for the images of saints and votive images. The first modeller however of this class noticed in the history of art is Orsino, the contemporary of Andrea del Verrocchio, in the middle of the 15th century. Vasari represents Orsino as a wax-modeller (ceraiuolo) of good repute in Florence, and that he attained, through the advice of Verrocchio, the highest excellence in his art. Verrocchio and Orsino made some interesting figures together, of which three of Lorenzo de' Medici are worthy of especial notice: they are described by Vasari as something remarkable. The conspiracy of the Pazzi in 1478 was the cause of the production of these figures: they were voted by his friends in commemoration of his escape. Orsino made, under the direction of Verrocchio, three wax images of Lorenzo of the size of life. The framework or skeletons of these figures were made of wood and cane, and the heads, hands, and feet were cast in wax, of considerable thickness, but hollow; they were then furnished with hair and glass eyes, and painted in oil-colours to the exact imitation of life; and were draped in clothes which had been worn by Lorenzo; to give the draperies a fixed character they were waxed. These figures were altogether so successful, says Vasari, that they appeared to be living. One of them was placed in the church of the Monache di Chiarito, in the Via di San Gallo; another in the Servitant church of the Annunciation; and the third in the church of Santa Maria degli Angeli at Assisi. In this Servitant church were many other wax figures by Orsino, all of which were marked with an O, in which was an R, and above it a cross; but they have all long since perished. Vasari adds that few works of later wax-modellers were to be compared with those of Orsino, and complains that the art had declined. A few years however after the death of Vasari, Jacopo Vivio distinguished himself by a model on slate, in coloured wax, of Michel Angelo's Last Judgment in the Sistine Chapel. It was engraved by Ambrosio Brambilla, and a particular description of it was published in Rome in 1590—'Discorso sopra la mirabil opera di Basso-Rilievo di cera stuccata con colori, scolpita in pietra nera, da Jacopo Vivio."

Two centuries after Verrocchio, and one after Vasari, this art was very usefully and with the utmost skill applied by Gaetano Giulio Zummo, born at Syracuse in 1656, to the preparation of anatomical models and pathological examples. Zummo obtained a European celebrity for his two groups of figures representing the various stages of corruption of the human body and the effects of the plague. He modelled also an anatomical head at Paris, which is described in the Mémoires of the French Academy of Sciences, of 1701, the year of his death.

The first collection of anatomical preparations which was made for the purposes of science is that of the Institute of Bologna, established by Benedict XIV. It was commenced under the direction of Ercole Lelli, but the greater part of the preparations were made by Giovanni Manzolini of Bologna and his wife Anna Morandi Manzolini. Manzolini died at Bologna in 1755, aged 55. There are some of his models in London and in many other cities of Europe. Anna Manzolini obtained still greater celebrity than her husband: she executed all or the greater part of the obstetric models in the Stanza Ostetricia of the Institute which were prepared under the direction of Dr. Antonio Galli. She also gave public lectures on anatomy in Bologna, illustrating her discourse by appropriate models. She died in 1774, aged 57. (Crespi, "Felsina Pittrice," where there are portraits of both the Manzolini.)

There is a still more extensive and remarkable collection of wax anatomical models in the Museum of Natural History at Florence: it was established by the Grand-Duke Leopoldo, and occupies fifteen chambers. It contains the works of various artists, but the principal contributors to its treasures were, Felice Fontana and Clemente Susini. The works of the earlier modellers in wax are set apart in a chamber by themselves: here are some of the models of Zummo, among which is one showing the whole anatomy of the human head, similar probably to the one made at Paris.

The Musée Dupuytren at Paris is celebrated for its morbid specimens; it is perhaps the richest pathological collection in the world. It was purchased by the University of Paris, of the heirs of M. Dupuytren, the celebrated anatomist. Most of the principal cities of Europe have now their collections, and some of them very fine ones, and good wax-modellers are numerous.

In this department of modelling none but the purest wax is used, which is the case also in all works where the wax is the final substance of the work. Different modellers use different compositions; and some allowance must be made for hot and cold weather, as what would be well adapted for summer weather might be too brittle for winter use. Some modellers use simply wax and a small proportion of Venetian turpentine; others wax, resin, common turpentine, and a little olive-oil; the wax being at least two-thirds of the whole composition. It is seldom if ever used pure, as in all objects to be modelled whi e or some colour must predominate: for instance in modelling the brain, white in powder must be mixed in the composition, and the same respect must be had with regard to the predominant colour of every object to be modelled.

No strict rules can be given for the process of modelling, as each modeller will soon acquire methods of his own, and generally speaking artists of this class object to disclose their peculiar processes, imagining it to be detrimental to their interests. However, we may speak of general principles. Nearly all wax models are cast from moulds, and the casts only in some cases require the assistance of modelling: these moulds are generally taken from the objects themselves, either in plaster of Paris or in a composition of bees'-wax, Burgundy pitch, and Venice turpentine, with a very small quantity of olive-oil. The advantage of this latter composition is, that even when cold, if properly mixed, the mould is elastic or flexible; and if made thin, when cut on the edges can be peeled off the cast in pieces without any danger to the cast: in taking moulds in plaster of Paris, the object moulded must sometimes be destroyed to render the mould available. Gelatine is now sometimes employed for making elastic moulds. Round objects must be moulded in two or more parts. Sometimes when the object is cast in the mould, the mould must be destroyed before the cast can be removed, and in destroying the mould there is danger of destroying the cast also; the *elastic* mould therefore has great advantages in such cases over the plaster mould. When only one view of an object is presented, and it is only slightly convex, the plaster mould is quite sufficient, except the object itself, as the brain, presents a very uneven and delicate surface. When the cast is to be taken from the plaster mould, the mould must be moist with water, but not absolutely wet, or the water would injure the very delicate surface, which occurs in some pathological cases: the mould may be moistened by allowing it to stand with the interior or face uppermost in a dish of water, when it will soon absorb sufficient moisture for the purpose. The mould must not be oiled when any delicate work is to be done, as the oil will dissolve the surface of the wax, and thus perhaps counteract the principal aim of the cast. The wax composition mould must be slightly touched with a soft hair-tool with oil, to enable it to peel away afterwards without the slightest danger to the cast: being of a perfectly smooth surface, the small quantity of oil it retains is immaterial.

When the cast is made, and what they call *backed up* (that is, strengthened with a coarser composition within), the process of painting commences; but all effects cannot be given by mere colour, some morbid deposits and effects require to be expressed by adding wax of the proper colour with a hair-pencil or other tool. The colouring is done from the natural object represented, with fine hair-pencils and powder colours moistened with turpentine and tempered with a little wax; simple water is also sometimes used as the colouring vehicle. When the colouring is finished, the whole is covered with mastic varnish. In cases where the morbid effects or evidences of disease are of a distinct substance from the healthy texture, different coloured wax should be used in casting the healthy and diseased portions, and the parts may be corrected by modelling. The same process must be employed in modelling fruit and other objects of natural history, as in preparing anatomical models: but fruit, which is generally in full or high relief, will require piece-moulds, that is, to be moulded in several pieces, which is done half or part at a time. Flowers are not all cast; they are prepared from leaves of coloured wax made expressly for the purpose. These leaves are cut the required shape; they then, with the necessary colour and a hair-pencil, receive their local tints; and are finally joined and fashioned into the required flower. Insects are modelled by combining the two processes. In moulding objects with hair or delicate raised parts, a little oil must be carefully put over the parts, unless they are wet. Dry firm objects may be moulded without oil; the plaster must be removed as soon as it is set.

It remains yet to speak of the mode of making images. These likewise are made in various ways; but the essential process is casting. A head may be simply cast, and, when the hair and eyes have been added to it, the local tints be given with turpentine and colour. This method however uses a considerable quantity of wax, and various devices have been had recourse to to save wax. One mode is to cast the pure wax thin, and to back up or fill in to a considerable thickness with a coarse composition of bees'-wax, resin, and cow-hair or tow; in casting images the mould may be oiled. Ordinary heads however may be made in this manner:—Let a thin block head be fashioned in a mould or otherwise, of coarse paper pulp and size; when dry it must be coloured all over with flesh-tint, the local colours being put on, a higher degree than is natural, as also the colours of the cheeks, lips, and eyebrows; the whole may then be covered with wax, which must be poured over it two or three times, until the surface is well covered; its regularity may be secured by retarding the cooling of the wax and assisting it to run, by means of a hot iron or burner (called *cauterium* by the ancients), which must be held near it until the whole has a uniform surface. The colour originally painted on the paper block will show through the wax, and the head will require but the hair, the eyes, and a few local touches to finish it. Masks may be also dipped in wax, or the wax may be put on with a hair-tool, if the mask be kept warm; or a wax cast may be backed up or strengthened with strong paper pulp. There are however other methods of modelling wax figures, but no method can be properly explained by a verbal description; such mechanical processes must be witnessed to be understood: for this reason this article has been limited to mere general principles, which is as much as the general reader can require or understand.

Sculptors are in the habit of making wax models of small objects in the round, or for bassi-rilievi to be cast in metal, in the same manner and with the same tools that common clay models are made of: the same wax is used as is required for casts. [MODELLING.] Medals and small bronzes are generally modelled in wax. Impressions from seals, engraved gems, and cameos are taken with wax. The wax, which is prepared with a little powdered sugar-candy, turpentine, and lamp-black, after being melted, is preserved in small cakes. These cakes when wanted are softened by repeated pressure of the fingers, and are then compressed into or upon the seals or cameos, previously wetted, from which the impressions may be required.

WAX, SEALING. [SEALING-WAX.]

WAY, *Chîmin* (from the French *Chemin*), is a term used to denote either a right, in one person or more, of passing over the land of another, or the space over which such right is exercisable. In the former sense a way is an incorporeal right of the class called EASEMENTS.

There are five kinds of way:—1. A foot-way, for persons passing on foot only; 2. A horse-way, for persons passing on horseback, but including a foot-way; 3. A drift-way, for driving cattle; 4. A carriage-way, for leading or driving carts and other carriages, always including a foot- and horse-way, and usually, but not necessarily, including a drift-way; 5. A water-way for ships and boats. [RIVER.]

All these may be either private or public ways. Private ways are enjoyed by particular persons or classes; public ways are open to all persons; hence such a way is said to be *communis strata*, or *alta via regia*—in the language of pleading, a common and public queen's high-way.

I. The proper origin of a private right of way is, a grant from the owner of the soil.

Such a grant may be made to a party, or to him and his heirs *in gross*; that is, without respect to any land or house of which he may be the owner or occupier: or to the grantee, his heirs, and assigns, *being* owners of such a house or close; in which case the right granted will be *appurtenant* to the house or close to which the grant is annexed, and the right will pass with the house or close.

The grant of a way may be either express or implied; and in the case of an express grant, the grantor may impose such restrictions upon his grant as he thinks proper. If a man at the time when he conveys part of his land to another, has no access to the land conveyed, except over the land which he reserves, the grant of a right of way over the land reserved is implied. If a man conveys part of his land, and has no access to the part reserved, except over the land conveyed, a right of way over the land conveyed is impliedly reserved. The way so impliedly granted or reserved is called a "way of necessity."

Where no deed can be produced whereby a way is expressly or impliedly created, the party who claims the way may, in the case of a long-continued user of the right without evidence of commencement or interruption within the period of legal memory, plead that it has been immemorially enjoyed by him and his ancestors in the case of a way in gross, or by him and all those whose estate he has, in the house or close to which the way is annexed, in the case of a way appendant (that is, immemorially appurtenant).

Until lately also, a lost grant would be presumed in ordinary cases, after an uninterrupted and unexplained user of twenty years. The rule of law as to prescription for ways is settled by 2 & 3 Will. IV. c. 71, s. 2. [PRESCRIPTION.]

A grant of a right of way made by a person who has only a limited estate in the land over which the way passes, is effectual only during the continuance of the estate of the grantor. If a claim to a right of way is set up in respect of the twenty years' or the forty years' enjoyment mentioned in the statute, if it appear that the land over which the right is claimed has, during the whole or part of the twenty or forty years, been in the occupation of a party who had a limited estate in such land, not only is no right of way acquired against the reversioner, but no right whatever is gained by the user.

The party to whom a private road is allotted under the general enclosure act, has a *statutory* right of way.

If the party entitled to a way becomes the owner of the land over which it passes, the right of way is extinguished if the party has the same extent of interest in the land and in the way. But if the one be held for an estate different in extent of duration from the other, the right is only *suspended* during the union of the two interests. Even where a right of way is extinguished by unity of possession, it will, in some cases, revive upon a severance of that unity, as by partition among parceners, &c. A private right of way may also be extinguished by a deed of release executed by the party who is entitled to such way; and such a release may be presumed from a non-user for twenty years or from a declaration made by the party that he has no such right.

A way of necessity is limited by the necessity out of which it has arisen. If the party to whom such a way is impliedly granted, or by whom it is impliedly reserved, becomes entitled to some other access to his land, equally direct, the way of necessity is gone.

The particular rights of the grantee of a private way continue to exist notwithstanding the owner of the land may have dedicated it to the public as a high-way. The grantee cannot throw the burden of repairing the way upon the grantor, unless by the terms of the grant, evidenced by the deed or by user, the grantor has engaged to enable the grantee to use the way.

If the occupier of the land over which a private way passes, or any other person, obstruct the way, the party entitled to the way may remove the obstruction, and he may also bring an action on the case, or, in some cases, an action of covenant against the obstructor. On the other hand, if the occupier of the land resisting the claim of a right of way, bring an action of trespass against the person exercising the alleged right, the defendant may plead in justification a title founded upon prescription, grant, reservation, or statute.

II. Between private ways and public ways stand what may be called *quasi public* ways, which partake of the qualities of both, but differ in some respects from each. By some writers these are classed among private, by others, among public ways; they seem more properly to constitute a distinct intermediate class. Such are ways which the inhabitants of a town, &c., have immemorially used from their town, &c., to a church or market. A right of this description cannot, in modern times, be created. It cannot be the subject of a grant, inasmuch as inhabitants, as such, are not at this day capable of taking any interest by grant; nor can it, like a public way, be created by dedication. as a dedication of a way can only be to the public at large. Such a right therefore can exist only as the consequence of an ancient custom.

III. A highway is created where the owner of the soil has, by express words or by some act done or forborne, declared his intention that the public shall have the use of a way over such soil. The dedication of a way to the public may be by writing or by words; so that it may be inferred from the acts of the party, as the throwing down of fences, or from mere tacit acquiescence where the acquiescing party is in possession of the land, and therefore has the means, if disposed so to do, of preventing the use of the way. In all cases, however, it is necessary that the party dedicating should have a sufficient interest in the land to warrant such dedication. If he has a less estate than a fee-simple, his dedication will not bind the reversioner. But it would also appear that the owner of such a limited estate could not even dedicate a highway to the public for the limited period of his interest in the soil, and that his attempted dedication, however distinctly and formally made, would amount to nothing more than a licence revocable at pleasure.

When there is no express dedication, the presumption of an intention to dedicate, arising out of the conduct of the party, may be rebutted; as by showing that when the public were first admitted a bar or a chain was occasionally placed across the road, whereby passengers might, at times, be excluded; although it should also appear that the bar, &c., had long been omitted to be used, or that it had been suffered to fall into decay, or had been actually broken down, and that no attempt had afterwards been made to restore it.

A highway is frequently created by statute, principally under inclosure acts.

Whatever may have been the origin of a highway, it cannot, at common law, be destroyed or altered, except after an inquisition taken upon a writ of *ad quod damnum*.

By the common law the burden of maintaining highways is thrown upon the occupiers of lands and tenements within the parish, or rather within the township in which the way is situated. But particular persons may be bound to repair a highway. This special liability may exist by reason of enclosure (*ratione coarctationis*), against parties who have enclosed the sides, or one side of the road, and have thereby lessened the facilities for breaking out into the adjoining lands where necessary; or by reason of the possession of lands (*ratione tenuræ terræ suæ*), which have by some means become chargeable with the burden. In the case of a corporation aggregate, a liability to repair may also be established by prescription only, or ancient usage, without enclosure or tenure.

Any obstruction or other nuisance in a highway may be abated or removed by any person who chooses to undertake the task. The wrong-doer may also be proceeded against by indictment as for a misdemeanor; but he is not liable to an action, as he is in the case of nuisance to a private or to a quasi-public way, except in respect of special damage.

The regulation of highways has frequently been made the subject of legislative interference. The general statute now in force is the 5th and 6th Will. IV. c. 50.

In the case of a way over water, either private, quasi-public, or public, if the course of the water alter by sudden or gradual change, the way is continued over the new course. Every navigable river, arm of the sea, or creek, is a highway for ships and boats. [RIVER.]

WAY, MILKY. [MILKY WAY.]

WAYS, ROMAN. Our old chroniclers and writers give this name to four principal ancient highways which they suppose to have been either originally formed by the Romans in Britain during their occupation of the country, or at least to have been completed and perfected by that people upon lines of road for the greater part already traced and used by the former inhabitants. The names however by which the four highways are distinguished appear to be Saxon in form, although they may be Roman or British in etymology: Watling-street, Ikenield-street, Ermine-street, and the Fosse-way. The Saxons no doubt adopted the Roman highways, but probably gave them new, or altered their existing names. Watling-street is held to have extended from Dover to Chester; or, according to another hypothesis, to Chester-le-street, in Durham, passing through Canterbury, London, and Verulam, from which last-mentioned town it had also the name of Werlam-street. Its remains, or supposed remains, are still known in various places by the names of High Dyke, High Ridge, Ridge Way, and Forty-Foot Way. There has indeed been much controversy as to whether Watling-street did actually pass through London; but the received opinion is, that it passed along the line of what is still called Watling-street in the City, meeting the other three great roads or branches from them at the central milliarium in Cannon-street, pointed out by the site of London Stone, and crossing the river at Dowgate to what is still called Stoney-street on the Surrey side. The northward course of Watling-street, after leaving London or its neighbourhood, is supposed to have been over Hampstead Heath, to Edgeware, and hence, through Verulam (or St. Alban's), and Dunstable in Bedfordshire, to Stoney Stratford in Buckinghamshire, whence it skirted Leicestershire on the west to Bosworth, and thence proceeded in a north-western direction to Chester. Ikenield or *Ichenild*-street is said to have been so called from its commencing on the eastern side of the island in the country of the Iceni, mentioned by Tacitus, and supposed to be the same with the Simeni of Ptolemæus, who appear to have occupied Norfolk, Suffolk, and Cambridge. On the supposition however of London Stone having been the central milliarium where all the great roads of the country met, a branch of the *Ikenield* must have extended to this point; it is supposed to have passed through Aldgate, and to have been otherwise known by the name of the Vicinal Way. The course of the Ikenield to the westward is extremely obscure: it appears to have crossed Watling-street at Dunstable, and thence extended first south-by-west to Dorchester, and thence westward through Devonshire and Cornwall. Ermine or Hermin-street, again, is conjectured by some to have extended from St. David's, at the south-western extremity of Wales, to Southampton; by others, to have stretched more directly across the country to London, which it may have entered by what is now called Holborn. From London it proceeded northward by Godmanchester to Lincoln, and thence to Winterton on the Humber, where was a ferry: beyond the Humber, roads proceeded northwards to Whitby, and north-by-west to York; and thence to the border, and later into Scotland. Finally, the Fosse is supposed to have taken its course from south-west to north-east, beginning near Totnes in Devonshire, and passing through Bath, Cirencester, Chipping Norton, Coventry, Leicester, and Newark, to Lincoln, where it united with Ermine-street. The courses of these and the other leading Roman roads through the several counties will generally be found described more particularly under the several counties in the GEOG. DIV. The whole subject of these supposed Roman highways is however obscure and undetermined. Yet it is certain that the entire face of the country was, during the Roman occupation, covered with a network of roads, and these four would seem to have been the main lines, while others branched from them at various points, so as to connect every important military station with London and other principal towns, and with each other. Generally the main or military roads were marked by directness of course; in many cases they are almost coincident with or parallel to the present roads. The branch or cross roads (*viæ vicinales*), the private roads (*viæ privatæ*), and the bye-roads (*deviæ*), were of course less elaborate in construction and less direct in course. Itineraries of the chief Roman roads in Britain have come down to us; that called of Antoninus is probably of the 4th century, that of Richard of Cirencester of the 14th century (of which however there are doubts as to the genuineness), and a less complete one compiled in Ravenna in the 7th century: each is believed to have been compiled from more ancient materials. The four great roads, with one or two more, such as Akeman-street, extending westward from London to Bath, may have been, as commonly supposed, the old British highways; but there can be little doubt that they were re-formed and reconstructed by the Romans. Vitruvius has left a full account of the Roman system of making paved ways [ROADS], and these English roads, though less elaborate in construction than those diverging from Rome itself, seem, from the appearance presented by their foundations wherever they have been dug up, to have been formed on the same substantial principle. Where they remain, they are still often in good order, although they were doubtless adopted by the Saxons, and continued to be used for a long period subsequently.

WAYWODE, or WOYEVODA, is a Slavonian appellation, derived from *voyna*, "war," and *rodit*, "to lead;" and consequently it has the same etymology as the Latin *Dux*, the Saxon *Heretog*, and the modern German *Herzog*.

This name was originally given to military commanders in different

Slavonian countries. In Poland each palatinate or province had its woyevoda, whose duty was to command in time of war the pospolite, or arrière ban of his province. The woyevodes had in time of peace a certain administrative authority, and composed the first class of the senators. By a rather improper comparison with the Comites Palatii of the empire, they were translated in Latin by "palatine."

In the earliest times of Russian history the appellation of woyevoda is given to high military officers. In Muscovy there were military and civil woyevodes: the first were simply generals, and Peter the Great abolished this ancient Slavonian appellation and introduced that of general. The civil woyevodes were divided into provincial and town woyevodes, and they were governors of provinces and towns: and this appellation was changed only under the reign of Catherine II. into that of governors, commanders, &c.

The appellation of waywode was assumed for some time by the rulers of Moldavia and Wallachia, who substituted for it afterwards the Greek title of *despota*, and finally its Slavonian translation, hospodar. The princes of Transylvania had likewise sometimes the title of waiwode, which was also given to some minor Turkish officers.

W is here pronounced as the English V.

WEALTH is the means of obtaining the products of labour. An individual is rich or poor according to the quantity of the necessaries and luxuries of life which he can purchase; and a nation is rich or poor, in the aggregate, according to its means of enjoying such advantages. Labour is the source of wealth, and every addition to its productiveness tends to increase wealth, by lowering the cost of commodities, and rendering them more easy to be obtained. Political economy treats mainly of the means of promoting the increase of national wealth, and of removing obstructions to its development; and it is the purpose of this article very briefly to enumerate and explain some of the chief principles of that science which bear directly upon the production of wealth. The first object is to encourage industry. This is best done by leaving it free to obtain an adequate reward, by protecting all persons in the enjoyment of such reward, and in reducing the amount or value of it as little as possible. These encouragements can only be effectually given in a free state, and under a civilised government, where property is secure, and labour free from restraint. Insecurity of person or property, arbitrary and oppressive taxes, monopolies, restrictions upon the free exercise of skill and enterprise, are all impediments to the increase of wealth: they discourage industry by diminishing the inducement to exert it, and they restrain its productive powers when exerted by thwarting the natural intelligence and activity of man in the pursuit of his own interests.

Whatever gives the best direction to industry, and facilitates its operations, is favourable to the increase of wealth. Thus the separation of men into different employments is highly useful, as it perfects their skill and ingenuity in their respective arts, and causes a general economy of time. Still more useful is capital, without which division of labour cannot be extensively practised. It puts labour in motion; combines the work of many hands; gives means and power to invention; creates mechanical aids to human labour, and finally distributes by degrees what it has assisted in producing. It is capital that incites and utilises improvements in machinery. Without capital, the inventor could not afford to give his time nor produce the improvement he had made. These improvements always occasion the employment of a more skilled, and, therefore, a better paid labour. And if they materially reduce the cost of the article produced, and it is one in large demand, they necessarily tend to the increase of the number of labourers, however much their first introduction may threaten the contrary. Facilities to the ready and effective application of capital obviously add to its utility; as credit, for example, which lends to one man the capital of another when he can employ it more profitably and the various descriptions of money (the representatives of capital) which facilitate and cheapen the exchange of labour and its products between man and man. The higher the *general* rate of profits in a country may be, the more rapidly is capital likely to be accumulated; because the majority of men are usually desirous of accumulating, and the means of doing so are evidently increased by high profits. If a profit of five per cent. upon a man's capital engaged in business enabled him to live in comfort, and to continue his business without any diminution of his capital; a profit of ten per cent. would enable him, at the same time, to add to it five per cent. annually, to be employed in further production and accumulation. It is clear that there can be no increase of capital in any country in which the rate of profits does not leave a surplus beyond the necessary expenses of living. In such a case capital would be stationary, while the population to be supported by it would be on the increase.

The advantages of division of labour have been already noticed. The enriching properties of commerce are of a similar character. By distinct employments labour is made more productive; by commerce, the natural products and the peculiar arts of different countries are exchanged with mutual benefit and economy of labour to all. In France and Spain the grape, grown in the open air, provides delicious wine: in England, to make such wine (if it could be made at all), the grape must be grown in hothouses. In England cotton goods can be manufactured more cheaply than in any country in the world. If France and Spain would buy them, they would save annually whatever excess of price they pay for similar goods made by themselves; while the capital and labour now applied to such manufactures could be added to their means of production. To understand the effects of free commercial intercourse, it is only necessary to keep in view its analogy to the common dealings of life. No man thinks of making anything himself if he can buy it for less than it would cost him to make it. He continues working at his own employment, and buys the article he wants. If he did otherwise, he would lose his own profitable time and labour, and the article made by himself would take still more out of his pocket than if he had bought it; while its quality would most probably be inferior, by reason of his own want of skill and practice in that particular work. The same principle applies to nations. Commerce extends to all countries the happy results of division of labour, instead of confining them to particular communities.

The last circumstance directly favourable to the increase of wealth, which need be noticed, is a cheap and expeditious communication, both in the interior of a country and with all parts of the world, for the transit of merchandise and for the carriage of passengers. Every deduction from the cost of an article is an addition to the national wealth, and the expense of transit forms no inconsiderable part of the ultimate charge upon the consumer. A saving of time also is an addition to the labour and productive energies of a country. The extraordinary resources added to labour by facilities of travelling by the railways in Great Britain is felt by every one. The importance of cheap and rapid modes of commercial intercourse, in other points of view, need not be pointed out.

In conclusion, the advancement of general knowledge and intelligence must be noticed as an agent in the production of wealth. It is the mind and the disciplined will of man which render all the circumstances of the world available for his benefit; and in viewing education chiefly as a social blessing, we should never forget to urge its merits as a producer of wealth, upon those who would regard its other recommendations with less favour.

WEANING, the act of separating a child from the partaking of its mother's milk as food. A few hours after the birth of a child, the breast of the mother secretes milk for its nourishment. The milk that is secreted at first differs in some of its properties from the milk subsequently secreted, and has been called *colostrum*. Healthy milk under the microscope is found to contain globules of various sizes, which are perfectly spherical in form, swimming in a fluid in which are suspended no other particles; whilst the globules of colostrum are irregular and disproportioned, some of them being very large and others very small. There are also in colostrum particles of a yellowish colour, which are very minute, and which consist of fatty matter and a peculiar mucus. The milk retains these characters for several days, and it has been supposed at this period to possess a purgative property, which excites the intestines of the young infant to throw off the accumulated meconium. When the mother is healthy, the secretion of milk goes on abundantly till the ninth or tenth month, at which time the infant is generally able to take some other kind of food, and the process of weaning may commence at this period. It however often happens, from ill health or other causes, that the mother is not able from the first to suckle her child. In this case the child must be either transferred to another nurse or fed artificially. The former, where possible, should always be preferred. In the choice of a nurse care should be taken that the infant is transferred to one whose age, size, and temperament resemble its own mother. There should also be an absence of actual disease or a tendency to hereditary disease, and of all habits likely to interfere with a due secretion of healthy milk. Where children are artificially fed or reared from birth by the hand, the greatest care and attention are required. The first requisite is that the child should have a food as nearly resembling its natural food as possible. For this purpose the milk of various animals has been employed. That of the cow, as being most easily obtained, is most frequently used; but it would appear that the milk of the ass most nearly resembles human milk, and on that account, where it can be obtained, is to be preferred. The following is the latest analysis by Dr. Playfair, of the milk of woman, the cow, and the ass, and may serve as a guide in the preparation of the food of children:—

	Woman.	Cow.	Ass.
Casein	1·5	4·0	1·9
Butter	4·4	4·6	1·3
Sugar	5·7	3·8	6·3
Ashes	0·5	0·6	..
Water	88·0	89·0	90·5

The milk of the cow contains a much larger quantity of the casein, or nitrogenised principle, than that of woman or the ass, and requires dilution previous to its being administered to new-born children. At first two-thirds pure fresh water and one of cows' milk, with a small quantity of sugar, may be employed. As the child grows older, the quantity of water should be gradually decreased till it takes milk alone. This food should be administered to the child at a temperature of about 98°, the heat at which the milk is supplied from the mother. When children are thus fed, a spoon should not be used, but some means should be had recourse to for administering the milk slowly, as the sucking-bottle, artificial nipple, &c. In feeding a child artificially, as in suckling, the first sign of indifference may be regarded as a sign that the child has had enough. On no account should children be fed again immediately after vomiting, a practice that is often extremely injurious.

As a child increases in size and strength, it requires other food in addition to milk, and at last ceases to require supplies from its mother. Although this is a perfectly natural process, it is often, from want of skill, or rather want of knowledge of natural laws, a source of painful disease to the mother, and sometimes even loss of life to the child. As a general rule, it may be stated that a child should never be suddenly weaned, and that the more gradual the separation between mother and child the better will it be for both. The time for weaning must depend in some measure both on the development and health of the child and the state and health of the mother. With regard to the child, one of the first indications that weaning may be commenced is the appearance of teeth. This is indicative of preparation for other kind of food, and generally occurs in healthy children about the sixth or seventh month; and it is at this period that a gradual abstraction of the breast may commence. If this be done, it is seldom that a child will require suckling beyond the first year; although, where no ill consequences result to the mother, there is no objection to the child continuing at the breast till it is eighteen months or two years old. Where children are backward in the development of their teeth, and present other signs of want of strength and delicacy of constitution, it is frequently advisable that they should remain a lengthened period at the breast. It is always necessary to take into consideration the health of the mother during suckling, as children may suffer much more severely from an imperfectly secreted or diseased state of the milk than they would from immediate weaning, and under these circumstances of course the least evil is to be preferred.

In order that the weaning should be gradual, the child should be induced at the fifth or sixth month to take some light food once or twice a day, and its supply from the breast should be proportionately diminished. If such a plan is pursued, the quantity of food administered by hand being increased whilst the supply from the nurse is decreased, it will be generally found that little difficulty will be experienced in entirely weaning the child at ten or twelve months old. After a child has been weaned its food ought principally to consist of liquid or semifluid substances. Asses' and cows' milk alone, or boiled with bread, thickened with barley or baked flour, may be given for the first few months. To these may be added, for the sake of variety, rice, tapioca, sago, and arrow-root, which may be made up with milk or water, or both; and when water alone is used, sugar should be added. Where children cannot take milk, light broths should be administered. As solid food for the first year after weaning, there is nothing better than bread and butter: but in all cases in the diet of children a due regard should be had to the relation between azotised and non-azotised aliments. If the former are given in too great quantity, congestion and inflammation are frequently the result; whilst if the latter prevail in the diet, the child gets fat and loses strength, and becomes subject to diseases of debility. Neither the one kind nor the other should be withheld, and it is only by their judicious combination that the fatal effects of improper diet can be avoided.

WEAR. [WEIR.]

WEARING. [VEERING.]

WEATHER is a term used to denote the state of the earth and of the atmosphere with respect to heat or coldness, dryness or humidity, wind, rain, &c.

In some countries the variations of the atmospherical phenomena occur in an order which is nearly constant; and in those regions, predictions concerning the weather for several days, and even for months to come, may be made with almost a certainty that they will be verified by the event. On the opposite sides of the chain of the Ghauts, which extends along the western peninsula of India nearly from north to south, the phenomena during each half of the year are constantly and exactly reversed: thus, along the Malabar coast there is a clear sky from September to the following April, and on the coast of Coromandel the fair season continues from April to September; while during each following six months, in the two regions, it rains almost incessantly. Alternations of fair weather and rain also take place regularly in the interior of Africa; and, according to Humboldt, it rains constantly during five or six months in every year from the coast of Guiana to the Andes. But in insular situations generally, and in Europe and North America particularly, the winds, varying in direction and intensity according to no constant known law applicable to the purpose, mingle together at intervals of time apparently irregular, the masses of air which abound with vapour raised from the ocean, and thus cause clouds to cover the horizon, and showers of rain, hail, or snow to descend. The wind which is most prevalent at any one place, generally when it begins to blow affords an indication of the kind of weather which may be expected; but, frequently, no circumstance occurs by which a change from a clear to a cloudy sky, or the contrary, can be predicted even a few hours before its occurrence.

The periodical changes of the moon's phases often coinciding with changes in the phenomena of the atmosphere, it was very natural that the latter should, by many persons, be thought to have some dependence on the former [RAIN, col. 929]; an opinion apparently strengthened by the known fact that the tides of the ocean and atmosphere are produced by the attractions which the moon and sun exercise on the particles of water and air. It is certain, however, that the influences of the moon in changing the state of the atmosphere are of short duration, and take place gradually according to constant laws: they are consequently quite incompetent to the production of those sudden and irregular changes to which the atmosphere is subject. There are not, however, wanting men who have formed tables in which the probable state of the weather is stated in connection with the hour of the day or night at which the new and full moons take place; and that which seems to possess most the confidence of persons to whom an anticipation of rain or fair weather is of importance, is one which Dr. Samuel Clarke professed to have formed from a long series of observations. It is sufficient here to mention that in this table rain is predicted when the new or full moon takes place between noon and 2 P.M., or between 4 and 6 A.M.; and fair weather is announced when either takes place between 4 and 6 P.M., or between 10 P.M. and 2 A.M. An opinion has prevailed that seasons of a like character return in like order after each revolution of the moon's nodes; that is, at the end of every 18 or 19 years, at which times the earth and moon are nearly in like situations with respect to the nodes; but though seasons distinguished by more or less than the usual quantities of rain have been observed to return at certain intervals, there appears to be no ground for connecting them with the astronomical period. The existence of a "Cycle of Eighteen Years in the Seasons of Britain," has been maintained by Mr. Luke Howard, in his work having that title; but the validity of the evidence adduced has been subsequently denied by the Rev. L. Jenyns, in a volume on Meteorology.

The only indications of rain or fair weather upon which any reliance may be placed are those which have been noticed by the late Sir Humphrey Davy, in his 'Salmonia;' and as his explanations are founded on physical conditions, a brief statement of them may with propriety be introduced in this place.

One of the speakers in the Dialogue inquiring why the clouds in the west being red, with a tinge of purple, should portend fair weather, is answered that the air, when dry, refracts more of the red and heat-making rays than when moist; and as dry air is not perfectly transparent, those rays are reflected in the horizon. It is added that a coppery or yellow sunset foretells rain; but that, as an indication of approaching wet weather, nothing is more certain than a halo round the moon, since it is produced by precipitated water: the larger the circle is, the nearer are the clouds; consequently the more ready to descend in rain.

In explaining why a rainbow in the morning betokens rain, and one in the evening fair weather, it is stated that the bow can only be seen when the clouds depositing the rain are opposite to the sun; thus in the morning the bow is in the west, and in the evening in the east: and as the rains in this country are usually brought by westerly winds, a bow in the west indicates that the rain is coming towards the spectator; whereas a bow in the east indicates that the rain is passing away from him.

The indications of fine weather from swallows flying high is explained by stating that the insects on which these birds feed delight to fly in a warm stratum of air; but warm air, being lighter than that which is moist, occupies a higher part of the atmosphere, and, therefore the birds then find their prey in the upper regions. On the contrary, when the warm air is near the surface of the earth, the insects and birds are there also; and then, as the cold air from above descends into it, a deposition of water takes place. The opinion that sea-birds come to land in order to avoid an approaching storm is stated to be erroneous; and the cause assigned is that, as the fish upon which the birds prey go deep into the water during storms, the birds come to land merely on account of the greater certainty of finding food there than out at sea.

It may be observed here, that the kind of cloud which is designated cirrostratus [CLOUDS], in which, when the particles of water composing it are in a state of approximate coalescence into drops, the halo is formed, is almost always followed by a depression of temperature in the atmosphere, and by wind or rain. For indications of the weather, which are afforded by the oscillations of a mercurial column, see BAROMETER; and for those which precede cyclones, or revolving storms, see that subject in the article WIND.

The observations of Principal Forbes (stated in the article VAPOUR, OPALESCENT) have shown that the red colour of the clouds is referrible to a different cause from that to which it is ascribed by Davy, in the citations above. But the red evening and gray morning have been regarded as the surest and most consistent signs of fine weather. They would naturally be observed from the earliest periods, and accordingly they appear to be the most ancient of prognostics, having been recorded in the verses of the Greek poet Aratus, who was contemporary with Euclid; in the New Testament (Matt. xvi. 2, 3); and in one of our most familiar proverbs. The purple tinge alluded to, according to Principal Forbes, probably arises from a mixture of the reflected blue of the pure sky, which is always present when purple is seen, with the yellow-orange of the opalescent vapour.

"The modified hues of the sky, and of the sun and moon near the horizon, have, for so many ages and in so many countries, been regarded as the surest indications of atmospheric changes, that we cannot doubt that it is to the variety of conditions in which vapour exists in the air, more or less nearly condensed, that these phenomena are due. Humboldt describes the colour and form of the sun's disc at setting in tropical regions, as the most infallible prognostic, and elsewhere ascribes these variations 'to a particular state of the vesicular vapour.' Since the red steam [opalescent vapour] occurs only during the critical stage of its partial condensation (and perhaps conversely during evaporation), it is evident that it must correspond to a critical state of diffused vapour in the atmosphere. . . . . Every accurate observer of nature in alpine countries will confirm me in stating that fine weather is almost invariably accompanied by the formation of dew on exposed surfaces, and by the progressive depression of the moister strata, until at length visible fogs are formed in the bottom of the valleys, and especially over water. (For the reason why over water, see Davy [MIST]). This is the surest sign of a following fine day in mountainous regions. . . . The inflamed appearance of the morning sky, considered indicative of foul weather, is, I have no doubt, owing to such an excess of humidity being present that clouds are actually being formed by condensation in the upper regions, contrary to the direct tendency of the rising sun to dissipate them, which must therefore be considered as indicating a speedy precipitation of rain." ('Phil. Mag.,' series 2, vol. xv., pp. 34–37.)

Principal Forbes expresses a strong doubt as to the formation of any "vesicular" vapour in the process of the condensation of atmospheric vapour; on which it may be remarked that the existence of such vapour (that is, in fact, of vesicles of water produced by the condensation of vapour) under any circumstances is altogether hypothetical, as noticed in considering the nature of the spray of WATERFALLS. According to observation, when vapours become liquids, minute globules geometrically solid are formed: the globules of dew are such.

Principal Forbes, also, as we have seen, is of opinion that the opalescent vapour occurs "perhaps conversely during evaporation," as well as condensation. This we are able to confirm from our own observations, made long before he had enabled us to understand them. It may be proved by a ready experiment. If a plate or a saucer be plunged into nearly boiling water and withdrawn, it will be covered with a film of water, which the heat acquired by the porcelain will immediately convert into vapour, rendering the plate dry. If, on withdrawing it from the water, it be immediately held up to the light, a pink blush, as it were, will be seen, momentarily, before the steam-cloud resulting from entire condensation. During evaporation in nature the same phenomenon must of course take place: it may readily be observed on Derwentwater, looking northward, on a summer morning, when Skiddaw and the adjacent mountains may be seen through a transparent mist, having a pale pink or rose-coloured hue; the evaporating water below constantly supplying opalescent vapour, the appearance is persistent so long as the sun is acting and the atmospheric circumstances are unaltered, notwithstanding the perpetual resolution of the opalescent into invisible vapour above. This connects the subject with the colours of the sky and the prognostics of the weather derivable from them. A part of this subject, also, is considered in the article just referred to. In the article on OPALESCENT VAPOUR itself we have expressed our dissent from Principal Forbes as to the process by which the colours of the morning sky are produced, deeming it to be merely the reverse of that occurring in the evening. We think it might be shown "that the slowly progressive transition of vast masses of air through the temperature of the dew-point" must occur at sunrise as well as at sunset; of this, the "beautiful rosy tint, shooting far up into the heavens," described as preceding the dawn, when observed from Mont Blanc, is one of many examples that might be mentioned in evidence, according entirely with the facts already noticed, which the distinguished physicist whose views we have been considering first recognised in their due importance. [CLIMATE; METEOROLOGY.]

WEAVING. If we take the term *weaving* in its broadest sense, as applied to the process of combining longitudinal threads into a superficial fabric, it will have relation to the whole series of textile manufactures; not only those which are prepared in the loom, but likewise net-work, lace-work, and hosiery. We shall endeavour therefore in the present article to complete the details of manufacturing many textile fabrics which have been partially described in former articles.

History of Weaving.—From many passages in the Bible, and from the general character of dress, it is apparent that woven fabrics were known in very early times. In all probability weaving was practised before spinning; that is, the combination of reeds, strips of leather, or rude fibres into a material for dress, by a process analogous to that of weaving, preceded the practice of spinning yarn from a congeries of elementary fibres. Sir J. G. Wilkinson ('Manners and Customs of the Ancient Egyptians') observes,—"The Egyptians, from a most remote era, were celebrated for their manufacture of linen and other cloths; and the produce of their looms was exported to, and eagerly purchased by, foreign nations. The fine linen and embroidered work, the yarn and woollen stuffs, of the upper and lower country, are frequently mentioned, and were highly esteemed." The same authority states that the looms, found depicted on the tombs at Thebes, are of an exceedingly rude construction; but he does not think that this circumstance militates against the production of fine fabrics, since it is known at the present day that the Hindu produces exquisite muslins on his rude loom. In a specimen of mummy-cloth, examined by Mr. Thompson of Clitheroe, the texture was close and firm, yet elastic; the yarn of both warp and weft was remarkably even and well spun; the weft was single, while the warp-yarn consisted of two fine threads doubled; and it was observable, in that as well as in other specimens, that the number of threads to an inch in the warp uniformly exceeded that in the weft, a difference not commonly observable in European fabrics. Mr. Thompson examined ancient Egyptian cloths brought to England by Salt and Belzoni, and found that the selvages were well made, that striped goods similar to modern ginghams were often made by the Egyptians, and that indigo was used as one of the dyes. Wilkinson gives copies from some of the pictures at Thebes, Beni Hassan, and Eileithyas, representing weavers at their looms; in one instance the loom appears to be horizontal, while in another it is vertical, with the weft driven upwards; and from representations of five different sorts of shuttles, it would appear that they were generally about half a yard in length.

Weaving appears to have been carried on as a distinct trade in the larger towns of Greece; but every considerable private establishment had also a loom at which the females of the family were employed; the weaving being carried on chiefly by female slaves, while the superintendence rested with the mistress and her daughters. In large houses a particular room was set apart for this occupation.

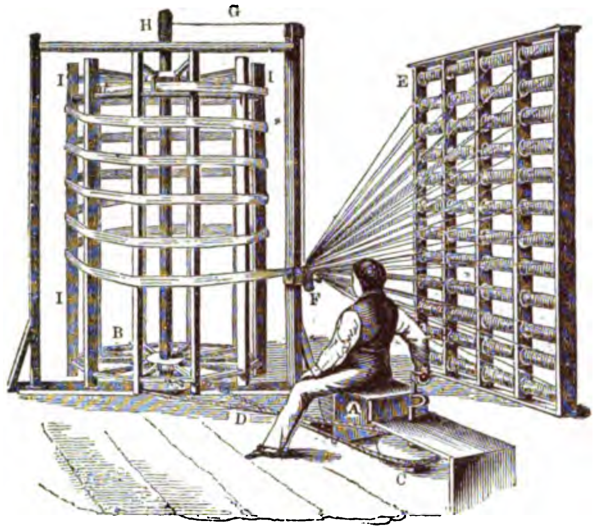
Plato mentions one of the most important differences between the warp and the weft, namely, that the threads of the former are strong and firm in consequence of being more twisted in spinning; whilst those of the latter are comparatively soft and yielding; a comparison which is strictly applicable at the present day. The Greeks evidently understood much of what is now termed "mounting a loom," that is, arranging strings in such a manner as to separate the warp-thread into two or more groups, between which the weft may be introduced: the leash (μίτος) being one such string, and a woven pattern being termed δίμιτος (from which the word *dimity* appears to be derived), τρίμιτος, or πολύμιτος, according as it contained two, three, or more groups of strings, or, as we should now say, leaves of heddles. After the weft was thrown, it was driven up close, either by a kind of bat, called a spatha, or by a kind of comb; both of which appear to be combined in the batten, or lay, of the modern loom. The checks produced by having different coloured warp threads, and stripes, formed of multi-coloured wefts, were known to the Greeks and Romans; as were likewise numerous kinds of fancy weaving derived from these two combined. Among the Romans, as among the Greeks, weaving was a female employment, and, as with them, it was carried on in most towns and in many large private establishments. Weaving, as practised among the ancients, may be illustrated by the proceedings of the weavers among existent imperfectly civilised nations. The Hindu weaver takes his station under the trees, where he stretches his warp-thread between two bamboo rollers, which are fastened to the turf by wooden pins. He digs a hole in the earth large enough to contain his legs when in a sitting posture; and then, suspending to a branch of a tree the cords which are intended to cause the raising and depressing of the warp-threads, he fixes underneath two loops for his toes, by which he produces a substitute for treadles. His shuttle acts also as a batten, or lay, and completes his simple arrangements.

We shall now proceed to describe the weaving processes, classifying them under the names of *Plain-weaving*, *Pattern-weaving*, *Double-weaving*, *Cross-weaving*, *Chain-weaving*, *Pile-weaving*, and *Power-weaving*,—giving cross references to former articles, in which some of these subjects have been treated.

Plain-weaving.—By this term we mean the weaving of all varieties of textile manufacture, in which the weft-threads interlace uniformly among the warp-threads without producing twills, checks, stripes, sprigs, or any variety of figures. Calico, Irish linen, and plain silk are good representatives of this kind of weaving. If we examine any of these, we shall find that the cross threads pass alternately over and under the long threads, no one thread passing over or under two other threads at once. In the language of weavers, the long threads are called *warp*, *twist*, *caine*, or *organzine*; while the cross threads are called *weft*, *woof*, *shoot*, or *tram*. Twist is the general term applied to the kind of yarn used for cotton warp: organzine to that for silk warp; and some of the other terms have in like manner only partial application: if therefore we speak simply of *warp* and *weft*, we shall avoid ambiguity, and be sufficiently correct for the object in view. The warp is always affixed to the loom or weaving-machine; while the weft is contained in the shuttle, a small boat-like instrument.

The first operation consists in laying the requisite number of threads together to form the width of the cloth: this is called *warping*. Supposing there to be 1000 threads in the width of a piece of cloth; then the yarn, wound on the bobbins as it leaves the hand of the spinner, must be so unwound and laid out as to form 1000 lengths, constituting when laid parallel the warp of the intended cloth. The ancient method was to draw out the warp from the bobbins at full length in an open field; and this is still practised in India and China: but the climate of Europe is too uncertain for such a method, and hence the *warping-frame* was devised. This is a large wooden frame fixed up vertically against a wall, the upright sides being pierced with holes to receive wooden pins, which project sufficiently to receive the clue or group of yarns. The warper, having placed the bobbins of yarn in an adjacent frame, ties the ends of all the threads together, and attaches them to one of the pins; then gathering all the threads in his hand into one clue, and permitting them to slip through the fingers, he walks to the other end of the frame, where he passes the yarns over the fixed pin. He walks from end to end of the frame, attaching the clue of yarns to the pins each time, until he has unwound from the bobbins enough yarn to form the warp. But this method, although still followed in some places, has yielded to the use of the *warping-mill*, a much more convenient piece of apparatus. The bobbins are placed in a frame E (*fig.* 1). The

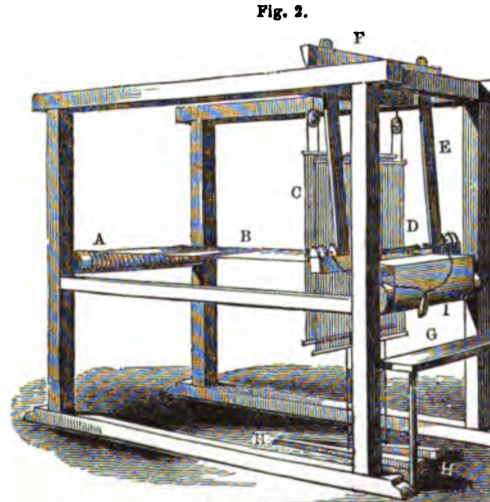
Fig. 1.



warper, sitting at A, rotates the vertical reel or cylinder B, by means of the wheel C and the rope D. The yarns from all the bobbins, collected together in a group at F, there pass through a sliding piece, which through the intervention of the cord G and the revolving shaft H, rises and falls. By this arrangement it is easy to see that when the handle is turned by the warper, the clue becomes wound spirally on the reel. The diameter of the reel is so regulated, that when the spiral equals the intended length of the warp, the clue of yarns is twisted round pins at I I, and then by a reverse motion of the handle is wound spirally down again; and so on up and down alternately until the grouped clues of yarns constitute a sufficient number for the width of the warp. Certain minor adjustments are at the same time made, to facilitate the subsequent operations of the weaver. The more modern warping-machines we shall have to mention when we come to power-weaving.

When the warp is completed on the warping-mill, the warper takes it off and winds it on a stick into a ball, preparatory to the process of *beaming*, or winding it on the beam of the loom. The threads, in this latter process, are wound as evenly as possible on the beam; a separator, ravel, or comb being used to lay them parallel, and to spread them out to about the intended width of the cloth. Arrangements are then made for *drawing*, or attaching the warp-threads individually

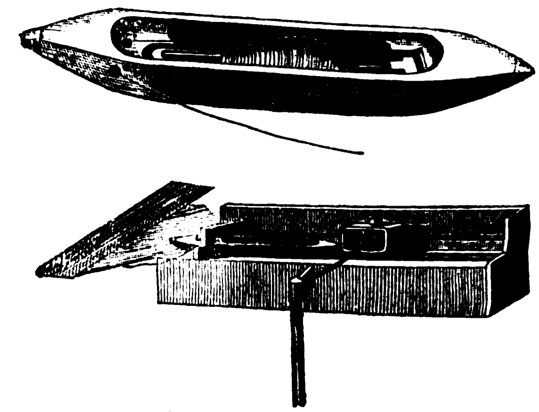
Fig. 2.



to certain mechanism of the loom. This we may illustrate by *fig.* 2, representing the common loom in its simplest state. The yarn-beam is at A, capable of revolving on its axis, and of allowing its threads to be drawn out in a horizontal layer B. At C are two leaves of heddles or healds, each leaf consisting of a number of strings ranged vertically, attached at bottom to two treadles H H, and at top to a cross-bar. At about the middle of every heddle or string is a loop or eye, through which the warp-yarns are drawn, one through each eye; and the passing of the yarns through these loops constitutes the process of *drawing*. Half of the warp-yarns, that is, every alternate yarn, passes through the loops in one leaf of heddles, and the other half through the other leaf; and as the two leaves are so connected by pulleys that one rises when the other sinks, the warp becomes divided into two portions, one above the other, near the anterior end of the loom. The weaver sits at G, drives the shuttle by means of the handle I, and drives up every successive weft-thread by the batten, lay, or lathe I, suspended from F. However complicated the loom, the principle of action is nearly as here described.

There are three movements attending every thread of weft which the weaver throws across the warp. In the first place he presses down one of the two treadles, by which one of the two halves of the warp is depressed, thereby forming a kind of opening called the *shed*. In this shed, at the second movement, he throws the shuttle containing the weft-thread, with sufficient force to drive it across the whole web. Then, at the third movement, he grasps the batten, which is a kind of frame carrying at its lower edge a comb-like piece having as many teeth as there are threads in the warp; and with this he drives up the thread of weft close to those previously thrown. One thread of weft is thus completed, and the weaver proceeds to throw another in a similar way, but in a reverse order, that is, by depressing the left treadle instead of the right, and by throwing the shuttle from left to right, instead of from right to left. In the commonest mode of weaving the shuttle is thrown by both hands alternately; but about a century ago John Kay invented the *fly-shuttle*, in which a string and handle are so placed that the weaver can work the shuttle both ways with one hand. The fly-shuttle is illustrated in CHECK; while *fig.* 3

Fig. 3.



will show more clearly the mode in which the weft is wound round the spindle or pirn of the shuttle, and the arrangement for driving the shuttle into the open shed of the web. The spindle of the shuttle contains enough weft for several shoots or throws; the weft unwinding as the shuttle travels along, and forming the selvage of the cloth when the shuttle returns in the opposite direction.

In cotton and some other fabrics, the warp-yarns must be *dressed* as the weaver proceeds, that is, rubbed over with some kind of vegetable mucilage, such as paste or size, for the purpose of giving them tenacity, of diminishing friction by smoothing down the little hairy *filaments* of the yarn, and of imparting a smoothness or gloss. In hand-weaving, the weaver suspends his operations from time to time, in order to apply dressing to his warp. He first applies a kind of comb to the warp, to clear away knots and burrs; then lays on the paste with a brush; and lastly dries the paste by a current of air excited by a large fan. The more modern and complete *dressing-machine* we shall have to notice in connection with power-weaving.

In weaving plain silks, calicoes, and other webs of moderate width, there are two leaves of heddles and two treadles, for dividing the warp into two parcels. In weaving broader webs, such as floor-cloth canvas, the heddles and treadles are equally simple, but more power and dexterity are necessary in throwing the shuttle, since the width of the web is sometimes as much as eight yards. In weaving very narrow webs, such as ribbons, galloons, &c., there would be a waste of power and of time if only one shuttle were thrown across a distance of two or three inches at each movement; and there has consequently been devised a kind of loom called the *engine-loom*, in which several shuttles work several webs at one time in each machine: this has been explained in RIBBON. Various details concerning plain woven goods will be found under COTTON; LINEN; MUSLIN; SILK; WOOLLEN.

Pattern-weaving.—The number of woven webs which can come under the designation of plain-weaving is much smaller than that of those now to be considered. Whenever the warp and weft are of the same colour, and intersect each other in regular order, so as to produce a uniform surface totally divested of pattern, we may deem that *plain-weaving;* but every day's experience shows that pattern, of some kind or other, is a more prevailing characteristic of woven fabrics.

In the first place we may take the case in which all the threads of the warp are of one colour, and all those of the weft another colour: this produces the peculiar effect called *shot* patterns, but involves no new arrangements as to weaving. Next come the two varieties known respectively as *stripes* and *checks*. A stripe is a pattern in which parallel lines run either along or across the warp; while a check is an alternation of rectangles like a chess-board, or, more properly, like the varieties of Scotch plaid. The production of a stripe depends either upon the warper or the weaver; the production of a check depends upon both. If the stripes are of different colours, and extend lengthwise of the cloth, then the warper so disposes the threads of his warp that the two colours shall succeed each other at regular intervals; but if the stripes are of the same colour, but of different quality as to fineness, then the warper uses two qualities of warp in alternate succession. If the stripes extend across the cloth, the warper arranges his threads as for plain-weaving; but the weaver uses two or more shuttles, carrying two or more coloured wefts, and throws the shuttles at regular intervals in succession. If a check is to be produced, the warper first produces his alternation of colours in the warp, and the weaver then throws in wefts of different colours by using two or more shuttles, so that the interlacing of the long stripes with the cross-stripes produces the check, the pattern of which depends on the comparative width of the various stripes. The manner of using the combined shuttles is described under CHECK.

The next to be noticed is the production of the *twill*, a very extensively adopted variety of woven work, since it comprises satin, bombazeen, kerseymere, and numerous other kinds. In the twill, the weft-threads do not pass over and under the warp-threads in regular succession, but pass over one and under two, over one and under three, or over one and under four, six, &c., according to the kind of twill. The effect of this is to produce a kind of diagonal ribbed appearance, on one side of the cloth, and a smooth and glossy appearance on the other, according as the one thread is crossed above or below by the weft. *Fig.* 4 will assist our comprehension of this point. If we suppose the

Fig. 4.

round dots to be sections of successive warp-threads, and the white double line to be one thread of weft, we shall see that the weft passes over four, under one, over four; then under four, over one, under four; and if the specimen were continued, we should see that these cycles of changes succeed each other in regular order. This arrangement furnishes the *twill* for some particular varieties of cloth; and the weaver has thus a kind of numerical formula for diaper, dimity, dornock, damask, bombazeen, satin, kerseymere, &c.; each one having a certain order of succession in which the weft crosses the warp. [BOMBAZEEN; DAMASK; DIAPER.]

Now in order to allow the weft to pass under four or more threads at once, some mechanism must be devised for elevating all those four at one movement, or keeping them stationary while every fourth thread is depressed. If the weft always passed under the same four threads, no cloth would be produced, for no reticulation would be made; but the groups of four passed under by one weft-shoot are not the same as those crossed at the next following shoot. Hence more than two leaves of heddles are required, and more than two treadles to work them. There must, in such a case as we have above supposed, be five leaves of heddles, to each of which every fifth warp-thread is attached; and to each of these leaves a treadle is appropriated; so that when one treadle is pressed down, one-fifth of the warp-threads becomes drawn out of the horizontal plane; when another treadle is depressed, another fifth is affected; and so on. The weaver, by the management of his treadles, has the power of raising or depressing four-fifths of his warp-threads, in groups of four each, leaving every fifth thread stationary; and in this state of things he throws his shuttle. By various combinations among his five treadles, he can produce many varieties of movement, which give rise to different kinds of twill.

When, instead of, or in addition to, a twill, the weaver has to produce sprigs, flowers, spots, or any kind of figure, a great increase of complexity occurs. The weft may pass over four and under one at one part of the width of the cloth; over two and under two at another; over one and under four at another—according to the part of the figure which may happen to occur at any particular part of the width of the cloth. Hence the order in which the warp-threads must be depressed or elevated varies continually, and the number of leaves of heddles would become so numerous that the loom could not hold them, nor could the feet of the weaver move the requisite treadles. This difficulty gave rise to the invention of the *draw-loom*, in which strings are so arranged that a boy can draw down the requisite warp-threads preparatory to the movement of the shuttle. The warp-threads pass through eyes or loops in vertical strings, each thread having one string; and these strings are so grouped that the attendant boy, by pulling a handle, draws up all those warp-threads which are necessarily elevated for one particular shoot of weft; and when a different order of succession is required, he pulls another handle. Hence it follows that the arrangement of the strings and handles must be preconcerted with especial reference to one particular pattern; and this is called *cording the loom*. The cording would sometimes take one man three or four months, and would then only serve for one particular pattern. Early in the present century two inventions were made with the view of rendering the draw-loom more automatic. One of these, called the *draw-boy*, not only superseded the necessity of employing a boy to pull the handles, but removed, by the unerring certainty of its operation, all possible chance of mistake in pulling the wrong handle. This was a very ingenious arrangement of mechanism by which a treadle, worked by the foot of the weaver, gave a vibratory motion to a curved lever which drew down some of the warp-threads and elevated others; and the skill consisted in so causing the lever to travel along a rack or toothed bar as to act upon different warp-threads in succession. The draw-boy has been very much employed; while another invention, equally ingenious perhaps, has, from various causes, failed to come into use. This latter was the *automatic carpet-loom* of Mr. Duncan. Here the warp-threads, instead of being elevated and depressed by the handles as in a draw-loom, or by the reciprocating lever as in the draw-boy, were moved by pins inserted in a rotating barrel, the pins being placed in an order of succession according to the pattern to be produced, just as those on the barrel of a street-organ or a musical-box are disposed according to the tune to be played. But the draw-loom, the draw-boy, and the barrel-loom have been alike eclipsed by the exquisite apparatus of M. Jacquard, which is very properly named after the inventor. [JACQUARD APPARATUS.]

Double Weaving.—In all the fabrics hitherto noticed, there is but one layer of threads, formed by the intersection of the weft among the warp, both weft and warp being individually single. But there has long been practised the weaving of a kind of double cloth, composed of two webs, each consisting of separate warp and weft, but both sets interwoven at intervals. The junction of the two webs is formed by passing each of them occasionally through the other, so that each particular part of both is sometimes above and sometimes below. Kidderminster or Scotch carpeting is one of the few kinds of double-fabric now woven in this country; and it will therefore be sufficient for us to refer for details to the article CARPET MANUFACTURE.

Cross Weaving. This term may conveniently be applied to those varieties of woven fabric in which the warp-threads, instead of lying constantly parallel, as in all the cases hitherto noticed, cross over or twist around one another, thus forming a plexus or interlacing independent of that produced by the weft. *Gauze* and *bobbin net* are perhaps the most remarkable examples of this kind of fabric. [GAUZE; LACE MANUFACTURE.]

Chain Weaving.—This is a term usefully applied to a mode of using threads in which a series of loops is formed by a continuous thread, each loop or link being so connected with others as to form a kind of chain; and this chain work may either be worked upon a ground woven at the loom, or may constitute the woven material itself. *Sampler work, Berlin work, sewed muslin work, tambouring, embroidery, tapestry, pillow lace,* and *hosiery*, are all examples, more or less varied, of this chain-weaving. [EMBROIDERY; HOSIERY MANUFACTURE; LACE MANUFACTURE; TAPESTRY.]

Pile Weaving.—If we examine a piece of silk velvet, or any kind of fustian, such as velveteen, moleskin, or doeskin, or a Turkey or Wilton carpet, we shall find that in any or all of these fabrics the warp and weft threads are almost concealed by a kind of down, nap, or pile, which imparts a peculiarly soft and smooth texture to them. It may seem strange to class together such very different materials as silk velvet, fustian, and Turkey carpeting; but the classification is strictly correct, because all of them owe their characteristic beauty to the downy surface which they present. Fustians are in fact a kind of cotton velvet, as Turkey carpeting is a woollen velvet. The weaving of these pile-fabrics, so far as regards the decussation of the warp and weft threads by means of the shuttle, resembles that of plain fabrics, or of pattern-fabrics, according to the nature of the design. But there is, besides the warp and weft properly so called, another kind of warp, whose threads are left standing in loops above the general surface till cut, and the cutting of which constitutes the pile. In some kinds of fustians the pile is cut so as to give a smooth velvet surface; while in other kinds it is cut into parallel cords, forming corduroy and such like fabrics. The cutting used formerly to be done by peculiarly shaped knives held in the hand; but some very ingenious machines have been contrived for effecting it more quickly and correctly. For the application of this peculiar manufacture to different fabrics, see CARPET; FUSTIAN; VELVET.

Power-Weaving.—In all the kinds of weaving hitherto noticed, whether of plain goods, figured goods, double cloth, bobbin-net, stockings, or velvet fabrics, we have uniformly spoken of the weaving-machine as being worked by hand, or rather by hand and foot, for the treadle is an almost invariable component of such a machine. We have however now briefly to notice the important steps by which the steam-engine has been brought to bear on this department of industry.

In the 'Philosophical Transactions' for 1678, a loom, invented by

M. de Gennes, is described as "a new engine to make linen cloth without the aid of an artificer," by applying water-power as the moving force. The advantages are thus enumerated: "1, That one mill alone will set ten or twelve of these looms at work; 2, the cloth may be made of what breadth you please, or at least much broader than any which has been hitherto made; 3, there will be fewer knots in the cloth, since the threads will not break so fast as in other looms, because the shuttle that breaks the greater part can never touch them. In short, the work will be carried on quicker and at less expense, since, instead of several workmen, which are required in making up of very large cloths, one boy will serve to tie the threads of several looms as fast as they break, and to order the quills in the shuttle." This description remarkably well expresses the excellences of the power-loom of the present day; but we have no evidence that De Gennes' machine ever came into use. At various times during the last century M. Dolignon, M. Vaucanson, Mr. Austin, and Mr. Miller contrived looms which were to be worked by a winch, by water-power, or by some contrivance more expeditious than the common hand-weaving. The first power-loom for weaving cotton fabrics was put up by Mr. Austin in the factory of Mr. Monteith, near Glasgow, in 1798; but before that time another machine had been invented, whose history is curious and interesting.

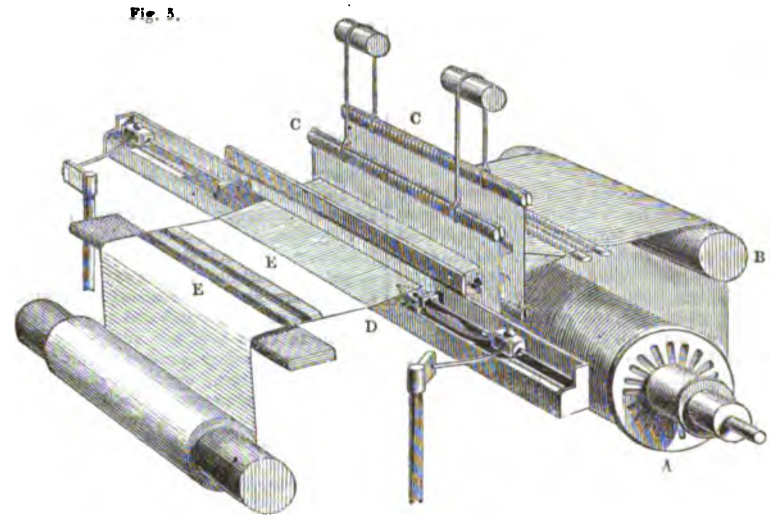
The Rev. Dr. Cartwright, brother of the late Major Cartwright, happened, in 1784, to be in conversation with some gentlemen, concerning Arkwright's spinning machinery. It was observed that, so soon as Arkwright's patent expired, so many mills would be erected, and so much cotton spun, that hands would not be found to weave it. Cartwright remarked that Arkwright must, in that case, invent weaving machinery; and the idea, thus suggested by himself, seems to have taken hold of his mind; for he soon afterwards endeavoured to form a machine which should imitate the three movements in weaving. He succeeded so far as to produce a machine, which he patented in 1785; and another, for which a patent was obtained in 1787. He tried to establish a power-loom weaving factory at Doncaster, but failed: Messrs. Grimshaw also endeavoured to set Cartwright's machines at work at Manchester, but similarly failed from various causes; and, after many years of labour, many patents, and an expenditure of 40,000*l.*, Dr. Cartwright was compelled, in 1808, to ask for a grant from Parliament as a return for his losses and exertions. Parliament awarded him 10,000*l.* One cause which thus delayed the adoption of power-looms was the necessity for stopping the machine frequently, in order to dress the warp as it unrolled from the beam, which operation required a man to be employed for each loom, so that there was no saving of expense. In the year 1802, Mr. Radcliffe, a cotton manufacturer of Stockport, aided by a workman, Thomas Johnson, made many contrivances with a view to remedy this inconvenience, and at length produced the admirable *dressing-machine* of modern factories, by which the warp is dressed before it goes into the loom. At a subsequent period Mr. Horrocks and Mr. Marsland, both of Stockport, made other improvements, which brought the steam-engine fairly into use for weaving operations, and thus power-looms became established. Still more recently, Mr. Roberts, of the firm of Sharp and Roberts, of Manchester, brought the power-loom to a state of high perfection; and every year adds more and more to the number of such looms employed in manufacturing districts.

The application of the power-loom renders necessary the employment of other machines likewise, to effect those preparatory operations which, in hand-loom weaving, are effected by very simple means. If we take a piece of calico as the representative of plain fabrics generally, the mode of proceeding in power-loom factories may be shortly sketched as follows:—

The *warping-frame*, instead of being employed on the same principle as the warping-mill sketched in a former page, is so arranged as to be worked by steam-power. Several bobbins, arranged with their axes parallel and horizontal, in a compartment at one end of the frame, yield the yarn which is to be collected into a warp. The yarns, proceeding from the bobbins, pass under some rollers and over others, until all are brought into a parallel layer, a comb of fine wires being employed to separate the yarns equidistantly. The yarns are then collected and coiled on a cylindrical beam, which is removed from the *warping-frame*, and transferred to the *dressing-machine*. This latter is a large piece of mechanism, by which the contents of eight rollers from the warping-frame are collected on one roller or beam, which is to form the warp-beam of the loom; and in their passage the yarn-threads are coated with the paste or mucilage-dressing, and dried. Four of the rollers are placed at one end of the machine, and four at the other; and the yarns, proceeding from thence, pass between rollers, of which the lowermost dips into the paste, and becomes thus coated with it; they then pass under and over brushes, by which the paste is rubbed into the fibres; then over a steam-heated copper box, by which they are dried; and, lastly, are wound on the warp-beam.

The preparation of the warp in the loom, comprising what are called the *drawing* and *mounting*, is more simple for the power-loom than in the hand-loom, but is still somewhat intricate. When, however, this is effected, steam-power does all the rest: it forms the shed or division of the warp into two parts; it throws the shuttle; it drives up the weft with the batten; it unwinds the warp from the warp-roller; and winds the woven material on the cloth-roller. Part of these operations may be illustrated by *fig.* 6, in which some of the mechanism is omitted to render the rest more clear. The warp, unwinding from the

Fig. 5.



beam A, and bending round the roller B, passes through the two leaves of heddles C C, by which the shed is formed for receiving the shuttle at D; and after the action of the batten (not here shown) the finished cloth E results.

The pressing, finishing, dressing, &c., which the woven goods receive, whether woven by the power-loom or the hand-loom, depend, of course, on the nature of the fabric. One of the most important of these processes, by which the plain goods become diversified with ornament, is described under CALICO PRINTING.

Weaving, like all other parts of textile manufacture, has been marked by the introduction of many new forms of apparatus within the last few years. We will briefly mention the names of a few, as samples of the whole. Messrs. Tatton and Hodgkinson have a new small-ware loom, for weaving all kinds of narrow work, such as ribbons, galloons, chintz-lace, bed-lace, carpet-binding, tapes, &c. Mr. Somerville has introduced a new form of steam-power loom for twill, diaper, and worsted goods, especially intended for varying the effects in the same web by varying the shed-action. Mr. Macfarlane, of Comrie, introduced an arrangement in 1858 for enabling a loom to supply its own shuttle with fresh warp when exhausted or broken, and also to stop itself when any definite number of warp-threads have become broken. Mr. Ingram, of Bradford, patented in 1860 mechanism for obtaining continuous action in looms; that is, a method of supplying the loom with weft without stopping it to change the bobbin or cop; or of giving an additional supply of weft while the loom is in action, and whether the weft be all used up or only broken. Mr. Schwabe has invented an ingenious way of weaving *flounced* dresses. To effect this there is an additional warp-beam laid beside the usual one: the warp from this beam is brought into use in producing the body of the dress; but when a fringe, cording, &c., is wanted for a flounce, a portion of the other warp is brought forward by itself; or else this second warp may only be used in the flounce, and cut off at regular intervals.

Concerning the application of the arts of design to weaving, Professor Willis, in a report on the Paris Exhibition of 1855, gives an interesting account of the duties of a French functionary called the 'Professeur de la Théorie des Fabrications':—"This is a class of instruction which appears to be peculiar to Lyons, and to the want of which our deficiency in that respect may greatly be attributed. Their business is not to teach artistic drawing as a branch of fine art, but to teach the connection of design with the machinery which must be employed to realise it; to explain the entire construction and management of the looms, the mode of mounting and adjusting them, the different tissues or textures of which they are capable; the application of these to the respective parts of a given design, either as grounds or as means of bringing out details with the greatest effect, and at the same time with the necessary economy—seeing that contrast and variety of textures in the different details of a woven picture occupy the place of the painter's *handling* in works of fine art. A design may manifestly be exceedingly beautiful in itself as a work of art, but wholly inapplicable to weaving. No artist, therefore, can be qualified to make a weaver's design which shall combine in itself the beauty of art, applicable to produce effective results when translated from oil-paint or water-colours into silk or worsted, unless he be familiar with the mechanism of the looms in their infinite variety, with their practical adjustment, and with the characteristic surface-effects of the different tissues. Every designer, in short, should be able to put his own designs into the loom. Accordingly, artists, after having studied in the School of Design at Lyons, put themselves in the next place under the instruction of one of these so-called Professors of the Theory of Fabrics, for six months or more, to learn the application of the design to the machine. This is the system which has enabled the manufacturers of that city to produce the magnificent and beautiful specimens which were displayed in the galleries of the French Exhibition."

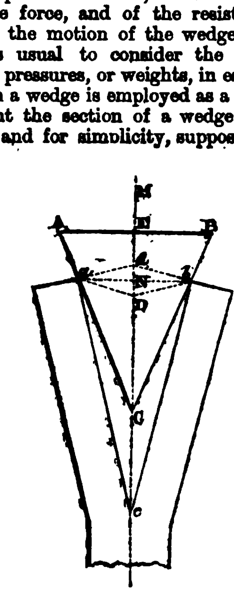
Bonelli's Electric Loom.—There is one modern invention in weaving of so remarkable a character as to deserve special notice. The theory is sound, although there may not at present be obtained a mastery over the mechanical details for carrying it out. M. Bonelli's Electric Loom has been described by Dr. Faraday at the Royal Institution, and by Mr. Le Neve Foster at the Society of Arts. The following is a slight outline of its origin and nature. In 1844 the Society of Arts prize was given to Mr. Riding for certain improvements in the Jacquard Apparatus; he employed an index-machine, something like Duncan's barrel described in an earlier paragraph, with shifting pegs for changing the patterns, the pegs acting in connection with wires in the apparatus. In later years other improvements were introduced, many of which have been noticed in Jacquard Apparatus. This subject attracted the attention of M. Bonelli, an Italian Civil Engineer, and Director General of the Sardinian telegraphs. He employed a long period of time in developing the theory and details of an electric apparatus which might dispense with the cards necessary in the Jacquard looms for weaving figured goods; and brought his machine to England in 1859. Bonelli's apparatus will suit any existing looms. It consists principally of an endless band of paper covered with tinfoil. The design or pattern is painted on the tinfoil with a brush and black varnish. The band passes under a series of thin metal teeth, all in connection with a galvanic battery. Whenever the foil touches a tooth a current passes through it, and thence through coils of wire surrounding small bars of soft iron, making them temporary magnets; but whenever the varnish touches a tooth, no such current is produced. Numerous small rods are placed opposite the ends of the small bar magnets; they pass horizontally to and fro, through a plate in front of a moveable frame. When any of the bars are actively magnetic, they retain or attract the rods when in contact with them. When the frame is swung or moved so as to bring the rods in contact with the bars, some are drawn a little distance through the holes in the plate, while the others are not so affected: according as the particular bars are at that moment in a magnetic state or not. The rods are like pistons, for each exactly fits one hole without tightness; and thus it happens that, when the frame recedes, some of the holes are open, while others are filled with the rods. The plate acts the part of a Jacquard card; each movement of the frame opens a distinct series of holes, and thus changes the pattern. A treadle moves the frame, at each throw of the shuttle. When the design is to be in several colours, it is in like manner painted on the tinfoil; but each separate colour, by removing a very thin strip of foil at the margin, is insulated from its neighbouring colour. All the pieces of foil thus insulated, each representing one colour or shade, are connected by small strips of tinfoil, which pierce through the paper and are fastened at the back, whence they are conducted to another strip of tinfoil which runs along the edge of the band: there being as many such strips of tinfoil as there are colours. Thus each special colour of the design, in all its parts, is connected by a conductor with its own separate strip of tinfoil. By bringing the wire from the galvanic battery successively into contact with the several strips, a current of electricity may be made to pass in succession through the several parts of the design representing the several colours. Thus, assuming four colours; there would be four strips of tinfoil running the length of the band, insulated one from another, each in connection with its own peculiar colour only. At any given moment, thin plates of metal resting on the design would touch it in a line which, as it passes over the *width* of the design, would run through all or any one of the colours; but the current would pass only through those plates which rest on the one colour represented by the strip connected at that moment with the pole of the battery. The shifting of the band does not in this case take place with every throw of the shuttle, but after an interval depending on the number of colours.

Such is Bonelli's electric loom. The inventor states, that two cells of a small Bunsen's battery will suffice, consuming one pennyworth of chemicals per day. The cost of the whole apparatus is about 20*l.* An elaborate damask design will sometimes require, on the Jacquard system 4000 cards and 400 wires, which would cost 24*l.*, and five weeks of a man's labour to set up. On the Bonelli system, we are told, the expense would be 6*l.*, and the time one week. A Jacquard design has been known to take 20,000 cards, costing 150*l.*, and an amount of labour equal to one whole year of one man's time; the figures on the Bonelli system would be 26*l.* and one month. Several advantages are claimed for the system:—1. The great facility with which, in a very short time, and with precision, reductions of the design may be obtained on the fabric by means of the varying velocity with which the design may be passed under the teeth. 2. That without damaging the mounting of the loom or the design, fabrics thinner or thicker may be produced by changing the number of the weft, and making a corresponding change in the movement of the design. 3. The loom and its mounting remaining unchanged, the design may be changed in a few minutes by the substitution of another metallised paper having a different pattern. 4. The power of getting rid of any part of the design, if required, and of modifying it. The validity of these claims remains for the future to show.

WEB. [Weaving.]

WEDGE, in Mechanics, is a prism of wood or metal whose base is a triangle: it is employed to remove two objects from one another laterally, or to rend asunder the parts of a body; an edge which is parallel to the geometrical axis of the prism being introduced between the objects, or parts of the body, and the whole wedge being then driven forward by a percussive force, as the stroke of a hammer. The nature of percussive force, and of the resistance which a yielding material opposes to the motion of the wedge being, however, imperfectly known, it is usual to consider the motive-power and the resistance as simple pressures, or weights, in estimating the conditions of equilibrium when a wedge is employed as a machine.

Let ABC represent the section of a wedge perpendicularly to the mathematical axis; and for simplicity, suppose this section to be an



isosceles triangle. The plane passing though AB, perpendicular to ABC and to the paper, is called the head or back of the wedge: the planes passing through AC and BC perpendicular to the paper are called the sides; and their line of section, passing through C, is called the edge.

The motive-power is applied to the head of the wedge; and may be supposed to act in the direction MC perpendicularly to that plane, and passing through C in the edge. Let the material which is to be rent asunder be in contact with the sides of the wedge in lines passing through *a* and *b* perpendicularly to the paper; and let the two parts yield as if they were capable of turning about some point *c* in the direction of MC, produced if necessary: then it is evident that the effect of the wedge will be the same as if a section of the latter, perpendicularly to the axis, were *abc*. Imagine *ad*, *bd* to be drawn perpendicularly to *ac* and *bc*; then those lines will meet at a certain point, as *d*, in the line MC: imagine also the parallelogram *adb*D of forces to be constructed; then *d*D or 2*d*N will represent the motive force, and *da* or *db* the pressure which that force exerts at *a* or *b* perpendicularly to *ac* and *bc*. Let P represent the motive force, and R the pressure at *a* or *b*; then, in a state of equilibrium, the latter will represent the reaction of the material in the direction *ad* or *bd*; and we have

$$P : R :: 2dN : da.$$

But the triangle aNd is similar to cNa; therefore

$$dN : da :: aN : ac,$$

and consequently $P : R :: 2aN\,(=ab) : ac$.

The position of the point c where the separation of the material is supposed to take place varies for different materials, and can only be estimated, or found from experiment: if it were supposed to coincide with C, we should have

$$P : R :: 2aN : aC;$$

or by similar triangles abC, ABC,

$$P : R :: AB : AC.$$

If the force of the wedge at the points a or b were to be estimated in the direction Na or Nb; as when it is required, neglecting friction, to find the force with which a given pressure P in the direction MC, on the head of the wedge, would make a body at a or b slide in a direction perpendicular to MC: then, R' representing that force, and c coinciding with C, or ad being now perpendicular to AC, we should have

$$P : R' :: 2dN : Na, \text{ or as } 2aN \text{ to } NC, \text{ or as } AB \text{ to } EC.$$

The point c still coinciding with C, let θ represent the angle ACE, or half the angle of the wedge: then

$$\frac{aN}{aC} = \sin\theta, \text{ or } \frac{AB}{AC} = 2\sin\theta;$$

also $\quad AB : EC :: 2\sin\theta : \cos\theta$:

it follows, radius being unity, that

$$P : R :: 2\sin\theta : 1, \text{ or } P = 2R\sin\theta;$$

$$\text{also } P : R' :: 2\sin\theta : \cos\theta, \text{ or } P = 2R'\tan\theta;$$

where R and R' represent the pressures perpendicular to AC and to EC respectively.

If it were required to find an equation for the motion of a wedge when acted upon by a force of percussion, a process corresponding to that which follows must be employed.

Let, as before, ABC be a section of the wedge, which may be supposed of iron: let it be introduced between the parts of a body which can yield only in a lateral direction; and let it be driven by a mass of iron falling upon it from a point at some given height above. Both the wedge and the hammer, or falling body, must be understood to be elastic; and it will be convenient to represent the latter by a parallelopiped of iron whose base is equal to the rectangular head of the wedge: let the height of such solid be represented by P, and let the space through which it is supposed to fall be represented by h; then, by dynamics, $2gh$ will be equal to the square of the velocity of impact. In like manner, let the friction of the wedge, estimated in a direction parallel to CM, be represented by the weight of a parallelopiped of iron whose base is the rectangular head of the wedge; and let the height of such parallelopiped be represented by Q.

When the collision takes place, both the falling body and the wedge will be compressed in the direction of their length. Let the linear contraction of P be represented by p, and that of the wedge, supposed at present immoveable, by q (both p and q coinciding in direction with MC). Then if ϵ represent the modulus of elasticity (or the height of a vertical column of iron, having a base equal to the head of the wedge, whose weight would, by the compression it causes, reduce the height P or Q of the supposed masses of iron to zero) and the forces of compression be assumed proportional to the contractions which they produce, we shall have $\frac{\epsilon p}{P}$ and $\frac{\epsilon q}{Q}$ for the forces by which the falling body and the wedge are respectively compressed in consequence of the collision; or the forces by which they tend to recover their original state: let these be represented by mp and nq respectively; or, in terms of the force of gravity, by mgp and ngq. Then ngq will represent the motive force by which the movement of the falling body is resisted after the impact, or $-\frac{ngp}{P}$ will represent the retardative force against that body.

But from the equality of action and re-action we have $mp = nq$; whence $p = \frac{nq}{m}$, and $p + q$, or the sum of the compressions, is equal to $\frac{n+m}{m}q$: let this be represented by s; then $q = \frac{ms}{n+m}$ and $\frac{ngq}{P} = \frac{mngs}{(n+m)P}$. Now, by dynamics, accelerative or retardative force is represented by $v\,\frac{dv}{ds}$, v here being the velocity of the falling body at any time t between the instant of impact and that at which its motion is extinguished by the resistance: therefore

$$\frac{vdv}{ds} = -\frac{mngs}{(n+m)P},$$

and integrating, V representing the velocity at the instant of impact at which time $s = 0$,

$$v^2 = V^2 - \frac{mng}{(m+n)P}s^2.$$

But when the wedge begins to move, the friction is equal to the force by which the falling body is compressed; therefore, making Q equal to $\frac{mns}{n+m}\ (=nq)$ we have $s = \frac{(n+m)Q}{nm}$; which being substituted in the above equation, we have

$$v^2 = V^2 - \frac{(n+m)gQ^2}{mnP}.$$

Now the wedge being uniformly resisted by friction, while moving in consequence of the impact, the retardative force f, expressed in times of gravity, will be $\frac{gQ}{P+W}$, W representing the weight of the wedge in terms homologous to P. Therefore since, by dynamics, $s = \frac{v^2}{2f}$; if we represent the space through which the wedge moves in the direction MC by z, we have, on substituting for v^2 and f their values, and for V^2 putting its equivalent $2gh$, where h is the height due to the velocity V,

$$z = (P+W).\left(\frac{h}{Q} - \frac{(m+n)Q}{2mngP}\right)$$

The values of m and n, that is, of $\frac{\epsilon}{P}$ and $\frac{\epsilon}{Q}$, may be found, since ϵ, the modulus for iron, is known to be about 10,000,000 feet; and consequently the relation between z and Q can be determined in numbers.

WEDNESDAY. [WEEK.]

WEEDS. Every plant which grows in a field other than that of which the seed has been sown by the husbandman is a weed, and inasmuch as it interferes with the intended crop, should be carefully eradicated. One of the principal uses of summer fallows is to destroy the weeds, which come up in spring, and which would shed their seeds in summer, if they were not destroyed before the seeds ripen. When roots are sown in drills, and carefully hoed, they produce the same cleansing effect, and supersede the fallow; but in heavy loams which have been neglected and overrun with weeds, a clean fallow is sometimes indispensable before any improved method can be adopted. When a farmer enters on lands which are in a foul state, it is the cheapest way, in the end, to sacrifice a crop, and thoroughly purge his fields from weeds, especially those which have vivacious roots, and cannot be extirpated by simple ploughing. The mode of doing this must depend on the nature and duration of the weeds, whether their roots are perennial or die off after the plant has borne seed. Annual weeds are most readily extirpated by repeated harrowings, by which the seeds are brought within the influence of the atmosphere, and when they have fairly vegetated may be buried or rooted out, and by exposing their roots to the influence of a hot sun they are effectually destroyed. The seeds of annual weeds are chiefly brought on the land in the manure which is made in the yards, where the cattle fed on hay or straw swallow the seeds, which pass through them undigested. They are also largely sown by the farmer himself in foul seed which he buys of the seedsman.

One of the great advantages of straw, of artificial manures, and of composts made with human excrements mixed with earths and mineral substances, is that they introduce no weeds into the soil. It is reported that in China, where the dung of cattle is little used, in comparison with human excrements, no weeds are to be found in the fields; and if more attention were paid to the preservation of this highly-enriching manure, and its proper application to the soil, much expense would be saved which is now unavoidably incurred in destroying weeds. Feeding sheep on roots and corn, while they are folded on the land, is another mode of manuring a field without introducing weeds, especially if no hay is given them, except clover-hay of the second crop, which is generally most free from the seeds of weeds.

Perennial weeds, such as various thistles, docks, &c., are very difficult to eradicate, as the roots strike deep in the ground, and throw up fresh shoots every year. The most effectual mode of destroying them is to draw them whenever the stem is grown sufficiently to give a good hold of the crown of the root.

Besides the common couch grass, *Triticum repens*, which is the pest of farmers on light soils, there are a variety of plants which spread both by the roots and by creeping along the surface. Of this kind are the different sorts of *quitches*, as they are provincially called, which grow in wet soils. The only mode of extirpating these last is draining and careful tillage. The most effectual means of destroying common couch is by the fork. If, after the ground has been once ploughed, it be forked up carefully in dry weather, and the tufts of couch with their roots be exposed to the hot sun, they may be raked off and burnt.

There are many other weeds, both in arable and pasture land, which indicate slovenly culture, and which disappear on careful cultivation; such are briars, furze, broom, and rushes; the last being a well-known sign of superabundant moisture, and only to be destroyed by under-draining. The whole process of cultivation is a continual struggle between the farmer and the weeds natural to the soil he cultivates. The sooner he subdues them entirely, the less will be his subsequent trouble; and the perfection of agriculture is to produce crops of such vegetables as are useful and profitable, and are suited to the soil which is cultivated, while all others are excluded which might interfere with the crops to be raised. The almost universal adoption of the system of drilling and hoeing the crops, tends greatly to the destruction of useless plants on arable land; much yet may be done by way of improving the produce of meadows and pastures by the destruction of all noxious and useless plants, and the introduction of those which are nutritious and improve the herbage, whether depastured or made into hay; and nothing is so likely to do so as a good system of alternate husbandry, where the best grasses are cultivated as carefully as the plants which are immediately applied to the food of man.

Annual and biennial weeds are easily got rid of in comparison with those which have perennial roots, and some of which increase the faster the more the roots are divided. It may be proper to observe that too little attention is paid to the weeds in our upland meadows and pastures, many of which are detrimental when they are eaten for want of better food. Of this kind are butter-cups, which, where the cows are forced by hunger to eat them, may be very injurious to their health and to the production of good milk. As these plants have strong perennial roots, they take possession of rich moist soils to the exclusion of good grasses. When not very abundant the plants may be weeded out by means of a sharp spud or hoe, and the expense will be well repaid in the quality of the hay or pasture.

WEEK. This well-known period of seven days, now universally adopted over the Christian and Mohammedan world, appears to be of Hebrew or Chaldæan origin. It has been commonly regarded as a memorial of the creation of the world, according to the Mosaic account, in that space of time; but it is besides the most obvious and convenient division of the lunar or natural month; and it is also more nearly than any other short term would be, an aliquot part of the solar year of 365 days; so that its commodiousness in these two ways would seem to have been sufficient to recommend its adoption.

Dion Cassius attributes the invention of the week to the Egyptians, from whom he seems to say it was borrowed in later times by the Greeks and other nations ('Hist. Rom.,' xxxvii. 18, 19, and the note in Reimar's edition). It is certain that the week was unknown to the Greeks of the classical ages, and also to the Romans, till it was gradually adopted, along with Christianity, under the later emperors.

The curious passage we have referred to in Dion Cassius is the source of all that is known as to the origin of the names that have been given to the days of the week. The Ptolemaic arrangement of the heavenly bodies, according to their distances from the earth, is in this order:—Saturn, Jupiter, Mars, the Sun, Venus, Mercury, the Moon (Saturn being the most distant); and it was a principle of the ancient astrology that these planets presided in this succession over the hours of the day. Upon this notion, if the first hour be assigned to Saturn, it will be found that the 25th (or first hour of the second day) will fall to the Sun; the 49th (or first of the third day) to the Moon; the 73rd (or first of the fourth day) to Mars; the 97th (or first of the fifth day) to Mercury; the 121st (or first of the sixth day) to Jupiter; and the 145th (or first of the seventh day) to Venus. *Dies Saturni* (the day of Saturn), *Dies Solis* (the day of the Sun), &c., are accordingly the Latin designations that have been given to the days of the week; and from these have been formed the modern names used in different countries either by literal translation (in the Italian, Spanish, French, and other languages of the Latin stock), or (in the Teutonic tongues) by the substitution, in some cases, for the classical god of the corresponding deity of northern paganism. Thus, the deity of the Old Saxons most resembling Mars, being held to be Tiw, or Tiu, the day of Mars was called by them, after their conversion to Christianity, Tiwes daeg, whence our Tuesday (and probably also the modern German Dienstag); for a similar reason the day of Mercury received the name of Wodnes daeg (that is, Woden's day), whence our Wednesday (and the old German Odinstag, for which Mittwoche, "Mid-week," is now used); the day of Jupiter, Thunres daeg, or Thor's day (whence our Thursday, and the modern German Donnerstag); and the day of Venus, Frige daeg, or Friga's day (whence our Friday).

Dion Cassius, however, further states that the planetary theory from which the denominations of the days of the week have thus been derived is itself founded upon the doctrine of musical intervals. A highly curious exposition of this idea has been given by the Abbé Roussier, in a Memoir on the Music of the Ancients, printed in the 'Mémoires de Trévoux,' for November and December, 1770, and August, 1771.

It is a remarkable fact that the week of seven days is not only a recognised space of time in the ancient Brahminical astronomy, but that the days (beginning with Soucravaram, "the day of Venus," or our Friday) are named in succession after the same planets or heavenly bodies as among the Greeks and Latins. Upon this subject see Bailly's 'Astronomie Indienne et Orientale," and various papers by Mr. Colebrooke and others in the 'Asiatic Researches.' The subject of the week is also discussed by Bohlen, 'Das Alte Indien,' ii. 214.

WEHRGELD or WEHRE (in Latin "Werigeldum," and in some cases "Compositio"), was a kind of fine for manslaughter, wounds, &c., in use among the ancient Teutonic nations, by paying which the offender, if a freeman, got rid of every further obligation or punishment. The serf or unfree had no right to wehrgeld; but by a law of the emperor Henry II. (1022) the lord of the serf had a claim against the slayer. The punishment of death was almost unknown among the Teutonic nations, and was never inflicted for crimes against individuals, but only for crimes and misdemeanours by which the community as such was injured. Tacitus ('Germania,' 12) says that traitors and deserters were hanged on trees, and that cowards and such as were of infamous lives (*corpore infames*) were smothered in marshes; hurdles were thrown over them, by which their bodies were kept down. Several bodies of Germans who were buried in that way, with the hurdles still over them, have been found in the great marshes of Northern Germany. It is very likely that death inflicted for such crimes was less a punishment than a means of getting rid of persons the sight of whom was a disgrace to the community, and for whom there were no prisons. Crimes committed by one individual against another were considered not directly to concern the community. The wounded man, or the relations of him who had been slain, pursued the culprit till they found him ready to satisfy their vengeance by giving them a certain number of cattle and arms. (Tacitus, *ib.*, 21.) If the parties belonged to different communities, the consequence was a feud between them and their adherents, no community having the slightest authority over another; but if the parties belonged to the same community, the matter was soon settled. The plaintiff called the offender before the community, and if the defendant was found guilty, he was sentenced to pay a certain fine, the wehrgeld or wehre. If the defendant would not or could not pay, his relations were bound to pay for him; the father paid for his children, the master for his serfs, and he who received a stranger in his house was liable for the misconduct of his guest. The plaintiff was not obliged to summon the offender before the meeting: he could pursue his cause with his sword, and thus compel the defender to pay the wehrgeld, which was always proportionate to the offence. If the cause was brought before the community, the plaintiff only received part of the wehrgeld; the community, or the king, when there was any, received the other part. (Tacitus, *ib.*, 12.) The part paid to the community must be considered as a fine for the breach of peace, and the consequence of the reciprocal obligation of the members of the community to maintain order. If the wehrgeld were not paid, the right of taking personal revenge was resumed. Laws therefore were passed enabling the community to enforce a wehrgeld even when the defaulter was unable or refused to pay.

We learn from the written laws of the Teutonic nations that the wehrgeld was for various crimes and misdemeanours, such as murder, manslaughter, infliction of wounds, and grievous bodily harm, robbery, theft, incendiarism, plagiary, rape, sodomy, verbal and real injuries, and several others, such as the violation of a grave ('Lex Salica,' tit. xvii.), by which is understood not only the injury done to the tomb, such as taking the tombstone from one grave and putting it on another, but also stealing a dead body, or its clothes and ornaments. The general Latin name for the fine paid for such crimes is "compositio;" wehrgeld designating merely the fine for a crime committed against the person of a freeman. The amount of the fine was in proportion to the nature of the crime, to the loss of property or damage resulting from it, and it varied according to the rank of the injured person as well as of the offender. In case of theft or damage, the fine did not exclude either the restitution of the stolen object or of the damaged thing, if possible. In England the laws relating to wehrgeld received many modifications from Alfred downward.

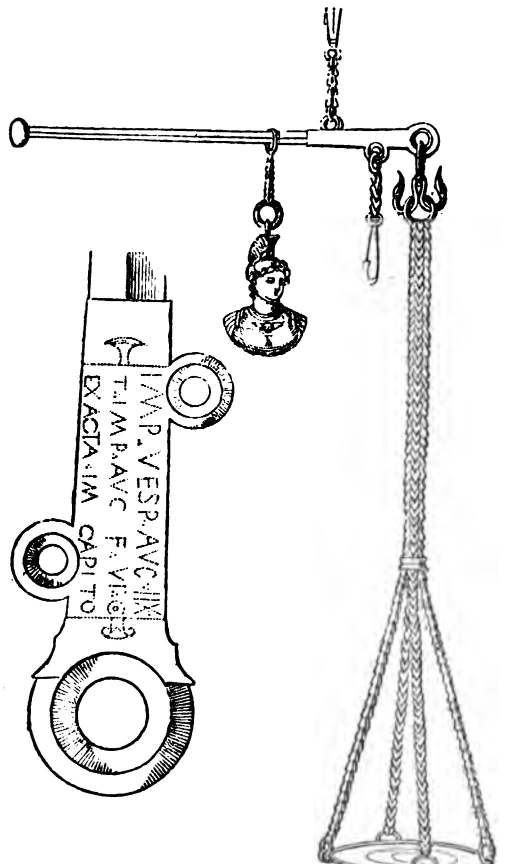
The wehrgeld was not the same among the different Teutonic tribes, as may be seen by a comparison of their laws. The laws of the Anglo-Saxons deserve particular attention. Mr. Kemble calculates that in Kent the wehrgeld of the noble was 360 shillings, and of the freeman (or ceorl) 180 shillings. In Northumberland it seems to have been somewhat higher. In Wessex that of the freeman was 200 shillings and the noble 1200. The clergy were rated high—an archbishop with a prince, a bishop with an ealderman.

(Eichhorn, *Deutsche Staats und Reichts Geschichte;* Kemble, *Saxons in England.*)

WEIGHING-MACHINE is any contrivance by which the weight of an object may be ascertained. Under BALANCE the principles of the machines by which materials of comparatively small magnitude are weighed are explained. The scales with equal arms and equipoised weights require no further elucidation; but a short notice may be given of some others. The *steelyard* is a kind of balance or weighing-machine, consisting of a lever of unequal arms. The most common kind of steelyard, which is often called the Roman balance, is a lever of the first order, and is used by suspending the article to be weighed from the end of the shorter arm, and sliding a determinate weight along the longer arm, to a greater or less distance from the fulcrum, until the instrument remains in equilibrium in an horizontal position; the weight of the substance attached to the short arm of the lever being indicated by observing the position of the moveable balance-weight with respect to a graduated scale marked upon the long arm of the steelyard. In the common steelyard a hook or hooks are usually suspended from the short arm, to hold the article the weight of which is to be ascertained; but sometimes a scale-plate or dish suspended by chains is added. The moveable weight is commonly attached to a ring, the form of which enables it to rest in notches cut on the upper edge of the steelyard, corresponding with the graduations engraved on its side. A ring or hook is also attached to the fulcrum, so that the instrument may be conveniently hung upon a fixed support, or if small, held in the hand; and a vertical index or pointer, similar to that attached to the beam of common scales, is sometimes added. The fulcrum, and the axis from which the weight is suspended, should, when much nicety is required, be provided with knife edges or bearings resembling those used in other lever-balances. Many steelyards are supplied with a second fulcrum; the two being placed at different distances from the point to which the hook or scale is attached, and having their respective pointers and suspending-hooks on opposite sides of the lever, or rather, when held in the position for use, one above and the other below it, as shown in the following cut of an ancient Roman steelyard. In using a steelyard of this kind, capable of weighing from one to sixty pounds, the fulcrum which is nearest to the middle is used if the article be under fifteen pounds; while if it exceed that weight, the instrument must be inverted, and suspended from the fulcrum which divides the lever most unequally.

Several ingenious bent-lever balances have been contrived, some of which, from the circumstance of the levers being of unequal arms, resemble the steelyard in principle; and various modifications of the steelyard have been invented for delicate scientific purposes, or for adapting it to the purpose of weighing very heavy bodies. Of the latter class is that which is employed usually at the toll-gates on roads for the purpose of determining the weights of laden carriages. In order to prevent the roads from being too much cut up, the burdens allowed to be conveyed along them by carts or waggons are made to depend on the breadth of the wheels; and a fine is imposed for any excess above the regulated quantity.

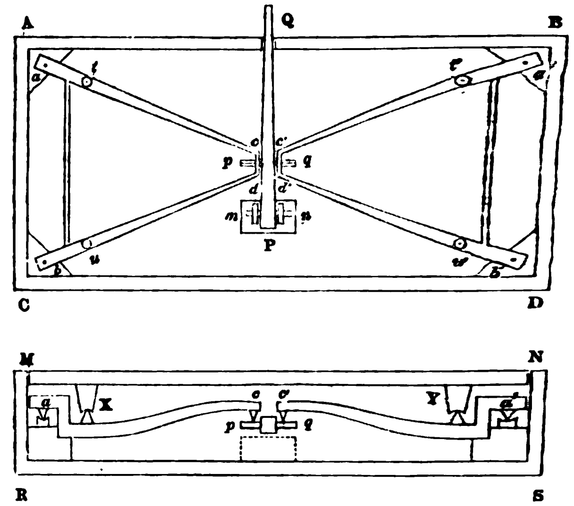
The usual weighing-machine may be described, in a general way, as a platform sunk on a level with the road, and made to rest at four points on a double lever of the second kind. The extremities of the arms of these levers rest upon a third lever, which may be of the first or second kind; and this last lever may either serve as a steelyard, or



Ancient Roman steelyard, found at Pompeii, with part of the beam and inscription on a larger scale.

may be connected with one arm of an ordinary balance, or with the extremity of a steelyard.

But to be more particular, let A B C D be the plan of a rectangular pit sunk in the ground, from 8 to 12 feet long, 6 feet broad, and about 2 feet deep, the sides and bottom being lined with brickwork or iron, and let M N R S represent a longitudinal section of the pit perpendicularly to the ground: $a\,b\,c\,d$, $a'b'c'd'$ are two trapezoidal frames of iron acting as levers; and each of the side bars, as $a\,c$ or $b\,d$, has, in its



vertical position, the form which is represented by $a\,c$, $a'c'$ in the section. At each extremity a, b, a', b', in the plan, the frames have a conical steel point, which appears at a, a' in the section; this rests in a hemispherical cavity made in a die or cylinder of the same metal, which is either attached to the iron-work forming the sides of the pit, or is supported on a block of stone sunk in the ground at each of the four interior angles; and under the shorter side, $c\,d$ or $c'd'$, of each frame there is a wedge-like prism of tempered steel, having its edge parallel to that side. The ends of these prisms appear at c and c' in the section.

The bar P Q is an iron lever, which in the above diagram is of the second kind, having at P a pin, $m\,n$, like that of a balance, turning in two steel rings on a pillar of stone sunk in the ground, or of iron resting on the bottom of the box; a steel pin, $p\,q$, formed also like that of a balance, with its edge upwards, passes through the bar P Q; and upon this rest the edges of the prisms at $c\,d$ and $c'd'$, as shown in the section.

The platform supporting the carriage which is to be weighed, and which is represented at M N in the section, has below it four iron feet, of which two appear at X and Y; and the under surfaces of these feet are formed with hemispherical cavities which rest on the points of four conical steel pins at t, u, t', u', on the two lever-frames; consequently the weight on the platform pressing at these four points, the prisms at $c\,d$, $c'd'$, are forced down upon the pin $p\,q$; and this last then presses down the extremity Q of the lever P Q. This lever itself may be made to act as a steelyard; or, by a rod or chain, the extremity Q may be connected with one arm of a balance or steelyard above the machine; in either case the weight of the carriage may be ascertained.

It is evident, from the nature of the lever, the pressure of the platform itself being balanced by a constant weight at Q, that if W represent the weight of the carriage, $W.\,\frac{at}{ac}.\,\frac{Px}{PQ}$ will express the pressure at Q, or the weight by which that of the carriage is determined; and this is independent of the power obtained by a steelyard which may be connected with Q. If $\frac{at}{ac}=\frac{1}{14}$ and $\frac{Px}{PQ}=\frac{1}{16}$, a weight equal to 10 pounds at Q' will balance a weight equal to 1 ton upon the platform.

The *Spring Balance* is a machine in which the elasticity of a spring of tempered steel is employed as a means of measuring weight or force. The name is most commonly applied to machines for the former purpose; those employed to ascertain the muscular strength of men and animals, the amount of power required to move a carriage or a boat, or any other force applied in the form of a pull, being called dynamometers. [DYNAMOMETER.]

One of the simplest kinds of spring-balance is that which, when employed as a weighing-machine, is known as the spring or pocket steelyard. It consists of a helical spring formed by bending a steel wire spirally round a cylindrical mandril or axis, so as to form an extensive series of convolutions. This spring is placed in the interior of a tube of brass or iron, closed at both ends: one end of the spring abutting against the plate which closes the lower end of the tube. A rod, having a hook or loop at its lower extremity, to hold the article to be weighed, passes through a hole in the bottom of the tube, and up the inside of the spring. At the upper end of this rod is a small plate, which slides up and down like a piston in the tube, and rests upon the upper or free end of the spring; thereby causing it to collapse when a heavy body is attached to the hook at the bottom of the sliding-rod. The machine is supported by means of a hook or ring attached to the upper end of the tube; and the extent of the motion of the spring, and consequently the weight of the body suspended from it, are indicated by the degree to which the rod is drawn out of the tube. For this purpose a graduated scale is engraved upon the rod; the divisions indicating the extent of compression produced in the spring by the application of known weights. Several spring-balances on the same principle are made for various purposes. That known as Salter's balance has a brass plate attached to the tube or cylinder, within which the spring is enclosed, and a vertical slit through the plate and tube. A scale is engraved on the face of the brass plate, and the weight is indicated by a pointer which moves up and down with the spring, with which it is connected through the vertical slit in the tube. Martin's "index weighing-machine" acts upon the same principle, but has a circular dial-plate and a revolving pointer or index, resembling the hand of a clock. On the axis of the index, but at the back of the dial-plate, is a toothed pinion, which is turned by a straight rack attached to the vertical rod, which rises and falls with the spring. The index remains in a vertical position when the balance is unloaded, and deviates more or less from it when a weight is attached to the hook. One advantage of this construction is that the point of the index traverses a much greater space than the spring itself, so that a small movement of the spring becomes readily discernible.

Spring-balances with helical springs are applied to several useful purposes besides that of ascertaining the weight of bodies. A spring of this character is sometimes used to hold down the lever of the safety-valve in a steam-engine boiler, the movement of the index also showing the pressure of the steam. Such an apparatus is useful in a locomotive engine, the shaking motion of which might derange a valve loaded with moveable weights. A helical spring-balance forms also a good cable-stopper. When applied to the measurement of muscular force, the tractive power of a locomotive carriage, &c., one end of the cylinder in which the spring is enclosed is made fast to an immoveable object, and the power to be measured is applied to the sliding-rod. If used to ascertain the force necessary to draw a carriage, the spring is placed between the carriage to be drawn and the power employed to draw it. In using a spring-dynamometer for this purpose, especially when the carriage is moved by animal power, some inconvenience is occasioned by the vibration of the index with every trifling variation in the force applied, to remedy which Mr. H. R. Palmer contrived an apparatus in which the quick vibration of the spring is checked by means of a piston moving in a cylinder filled with oil. A very narrow space is allowed for the oil to pass between the edge of the piston and the cylinder, so that a considerable resistance is opposed to the motion of the piston and the springs, and the index consequently represents the mean amount of force applied without being affected by sudden variations.

The ingenious method adopted by Mr. Martin for transmitting the motion of a spring to an index moving upon a circular dial-plate, is applicable to spring-balances of other than the helical construction. It was used by M. Hanin, a French gentleman, who was rewarded by the Society of Arts, in 1790, for an apparatus for showing at one view the weight of an object according to several different scales or systems of weights. His machine which is described and figured in the ninth volume of the Society's 'Transactions,' consists of a dial-plate, on which are marked several concentric circles, divided according to the systems of weights used in different countries, and an index moved by a rack and pinion, as before described. The spring, instead of being of a helical form, is semicircular; its upper extremity being firmly attached to the back of the dial-plate by means of screws, while its lower end is attached to the hook which carries the weight, and the sliding-rack by which the index is moved. Marriott's patent weighing-machine is similar to that of M. Hanin, but the spring is a perfect ellipsis, with its longer axis laid horizontally. The stem to which the ring for holding the apparatus is attached is fastened by a nut and screw to the middle of the upper side of the spring; and the rack, with the hook which holds the article to be weighed, to the corresponding point on the lower side of the spring. The spring, rack, and pinion are enclosed in a circular box at the back of the dial-plate, the periphery of which serves as a stop to prevent the spring from being overstrained. A similar apparatus, contrived by M. Regnier, has been used as a dynamometer, as well as a weighing-machine.

A scale-plate or dish may be added when necessary to any of the spring weighing-machines which have been described. On account of the absence of weights, and the great simplicity of their application, spring-balances are useful in cases where extreme accuracy is not required, especially when a portable weighing-machine is desirable. Machines for ascertaining the weight of the human body are often made on this principle, a kind of chair being suspended from the spring.

WEIGHT. There is nothing to say on the feeling of weight after what has been said in PRESSURE; nor is it possible to give any idea which will be half so good as that which presents itself in raising a heavy body from the ground. The measure of weight is weight itself [BALANCE], and two weights are equal which counterpoise each other when placed at the ends of equal arms of a self-poising lever.

The weight of a body, that is, of a given bulk of known substance, is referred to that of water by what is called the SPECIFIC GRAVITY of the substance. It is said, for example, that the specific gravity of ivory is 1826, when that of water is 1000. This means that any bulk of ivory is more weighty than the same bulk of water in the proportion of 1826 to 1000. When the specific gravity of water is called 1, that of ivory is 1·826. Since a thousand ounces avoirdupois of water are nearly a cubic foot, a more popular notion of the meaning of specific gravity may be given, in this way :—To say that the specific gravity of a substance is 1·826, that of water being 1, is to say that a cubic foot of it weighs 1·826 × 1000, or 1826 ounces nearly. More correctly, from 1000 times the specific gravity (water being 1), subtract three times that specific gravity, and add its 73rd part: the last step may be left out for common purposes. Thus, the specific gravity being 4·817, 4·817 × 1000 − 4·817 × 3 is 4802·549, the number of ounces in a cubic foot.

But it is to be remembered, when weight is to be very accurately taken, that everybody is buoyed up to a certain extent by the air; and the weight of a body in air is less than it would be in a vacuum by the weight of its own bulk of air. Now the air varies in weight [AIR] in a manner which may be ascertained nearly by the indications of the barometer. Properly speaking, it varies in a manner depending upon the superincumbent pressure, the temperature, and the quantity of moisture contained in it. A hundred cubic inches of dry air, when the barometer is at 30 inches and Fahrenheit's thermometer at 60°, weigh 31·012 grains. In measuring standards of weight, therefore, close attention must be paid to the state of the air at the time of weighing and to the substance weighed. If an iron weight balance a wooden one in a given state of the atmosphere, for that very reason there cannot be strict equilibrium in any other state of the atmosphere; wood being at least seven times as bulky as iron, the effect produced on the weight of the wood by the alteration of the state of the air is at least seven times as much as that produced on the iron.

WEIGHT OF THE AIR. [AIR.]

WEIGHT OF THE EARTH. [EARTH, MEAN DENSITY OF THE.]

WEIGHT OF OBSERVATIONS. This article is only for the reference of the mathematical student; in MEAN will be found as much of it as an arithmetician can use by rule.

This term was first applied in the manner stated in the article MEAN. An observer decided the relative merit of his observations by his unassisted recollection of the impression made by them upon his mind at the time, and affixed *weights* to them; that is, supposing A_1, A_2, &c., to be the n results of observation, he attached numbers c_1, c_2, &c., proportional to their presumed goodness, and used $\Sigma cA \div \Sigma c$ instead of $\Sigma A \div n$, for the average. Instead of c_1, c_2, &c., any numbers proportional to them may obviously be used: and in applying the higher branches of the theory of probabilities, it was found that a certain mode of obtaining c_1, c_2, &c., while it gave the above mode of using these numbers in the formation of an average, made them applicable to other important uses. We here give a sketch of the results of this method in its simplest parts.

1. When a number of discordant observations, made under circumstances in which positive and negative errors are equally likely, do not differ much from each other, and when it is exceedingly unlikely that the truth can differ much from the observations, it may be presumed that the chances of the error of any one of those observations lying between x and $x + dx$, and between a and b, are severally of the forms

$$\sqrt{\frac{c}{\pi}}\,\epsilon^{-cx^2}dx \quad \text{and} \quad \sqrt{\frac{c}{\pi}}\int_a^b \epsilon^{-cx^2}dx,$$

where c is a constant dependent on the goodness of the observations, and $\pi = 3{\cdot}14159\ldots$, $\epsilon = 2{\cdot}71828\ldots$, as usual. Even if this law of error do not exist, it is found that the treatment of *a considerable number of observations*, whatever * may be the law, is reducible to the same rules as those derived from this law, which is now universally assumed by those observers who apply the theory of probabilities to their results.

2. The constant c is called the *weight* of the observations, and depends upon the various circumstances which determine their goodness or badness. The greater it is the better the class of observations to which it applies. It is approximately found, for a given class of observations, as follows :—Subtract each of the observations from their mean, and let e_1, e_2, &c., be the results; then $c = n \div 2\Sigma e^2$. The sum of the squares of the departures from the average may be found by diminishing the sum of the squares of the *observations* by n times the square of the mean; and before doing this any convenient quantity may be struck off from all the observations, provided it be also struck off from the mean.

3. The *probable error* is that within which, taken positively and negatively, there is an even chance an observation shall lie. Thus if there be an even chance (A being the true result) for the result of an observation lying between $A - a$ and $A + a$, then a is the probable error of an observation. To find the probable error, divide ·476936 by the square root of the weight.

* That is, provided the law be such as common sense can admit, as representing what actually takes place in human observations. It would not apply, for example, to a case in which the larger the error the more likely was it to happen.

4. The weight of the average of observations is the sum of the weights of the component observations. If n observations, A_1, A_2, &c., be made, all of the same weight c, the average is $\Sigma A \div n$, the weight of the average is nc, and its probable error is $\cdot 476936 \div \sqrt{(nc)}$. But if the weights be different, say c_1, c_2, &c., then $\Sigma cA \div \Sigma c$ is the average, Σc is its weight, and $\cdot 476936 \div \sqrt{(\Sigma c)}$ its probable error. In the former case the probable error of the average may be directly found from the sum of the squares of the reputed errors,* by the formula

$$\cdot 67449 \sqrt{(\Sigma e^2)} \div n.$$

5. *Cæteris paribus*, the probable error of an average will not be inversely as the number of observations, but as the square root of that number. If p be the probable error of an observation, and P that of the average of n such observations, then $p = \sqrt{n} \cdot P$. An observer who takes such a mode as gives the probable error of an observation *twice* as great as it need be, must not hope to indemnify himself for his carelessness by making *twice* as many observations as would otherwise be necessary, but must make *four times* as many.

6. If p be the probable error of an observation, an average, or other result, the following table will be sufficient to connect the probable error with other errors, for any rough purpose of estimation :—

Odds.	Against.	For.	Odds.	Against.	For.
1½	·79	1·25	7½	·22	2·32
2	·64	1·43	8	·21	2·36
2½	·54	1·58	8½	·20	2·40
3	·47	1·71	9	·19	2·44
3½	·42	1·81	9½	·18	2·47
4	·38	1·90	10	·17	2·50
4½	·34	1·98	20	·09	2·94
5	·31	2·05	30	·06	3·17
5½	·29	2·11	40	·05	3·34
6	·27	2·17	50	·04	3·50
6½	·25	2·22	100	·02	3·90
7	·23	2·27	1000	·002	4·90

This table is to be interpreted as follows :—If p be the probable error above mentioned, it is 1½ to 1, or 3 to 2, against the error turning out less than $\cdot 79 \times p$, and it is 1½ to 1 for the error turning out less than $1\cdot 25 \times p$. It is 8 to 1 against the error being less than $\cdot 21 \times p$, and 8 to 1 for its being less than $2\cdot 36 \times p$. It is 1000 to 1 against the error being less than $\cdot 002 \times p$, and 1000 to 1 for the error being less than $4\cdot 90 \times p$.

WEIGHTS AND MEASURES. The subject of weights and measures is one the actual state of which is prosperous in the inverse ratio of the number of books or the length of articles which are written upon it. There is nothing in it which might not, if the most natural and simple system were adopted, be described in a very few pages. We are speaking of course only with reference to a possible time; for, let that time arrive when it may, the history of the past must be a confused and repulsive subject.

In the article WEIGHT, &c., STANDARD OF, we shall give some idea of the recent history of the attempts which have been made in England to secure a permanent measure of length. These have only succeeded, at least until very recently, somewhat farther than to the extent of making it possible to restore to the merchant a system sufficiently near to that which now exists, if the latter should be lost; but they have all confessedly failed in perpetuating sufficient exactness for scientific purposes. The same may be said of the French endeavour to create a recoverable standard by the measurement of the earth. [TRIGONOMETRICAL SURVEY.] So that in fact we are now come back again to the old notion, that the true way to maintain a measure is to construct accurate copies out of durable material, and to preserve those copies with care.

The measures of time (of which we speak more particularly in YEAR, TIME, PERIODS OF REVOLUTION) are the only usual ones in which a natural standard exists; to which we may add, that in the kindred operation of counting there is something of the same kind. The phenomena of the daily revolution of the earth, and the ten fingers on the two hands, have secured to the whole human race, above the degree of the lowest savages, one mode of assigning periods of duration and large collections of number. But even in these two subjects details have differed considerably in different times and countries; and much more has this happened with respect to measures in which the choice of a standard is purely arbitrary, as in the case of length, surface, capacity, and weight. The angle is another magnitude which has a natural measure [ANGLE]; and, as this has never been out of the hands of geometers, a greater uniformity has prevailed in the measurement of angular magnitude than of any other whatsoever. The measures of length obviously regulate those of surface and capacity. There is no other way of defining an area or a solidity, except by describing, for the area, lengths, and for the solidity, surfaces, by which the area or solid may be bounded in a given manner. Measures of weight may be obtained by defining, as standards, given bulks of given substances; and as water is the most common and most easily purified of all substances, it has been chosen by common consent as the referee for such standards. A measure of length then is all that is wanted in the first instance; and most nations, ancient and modern, have been in the habit of referring all the resulting measures to those of length alone. Nevertheless, there is no small difficulty in obtaining a comparison of a measure of weight deduced from length with one already existing, in such a manner as to perpetuate the latter, if the utmost accuracy be required. (Kater, 'Construction and Adjustment,' &c., 'Phil. Trans. 1826.) So that the commissioners who last reported on the subject advise that the standard of weight shall no longer be deduced from that of length, but shall be simply a piece of metal or other durable substance.

* The departures from the average above mentioned: the average being taken for the truth, these departures are taken for the errors.

It is not our object in this article to consider weights and measures in a scientific point of view, but simply to give some historical account of the measures actually in use, and some tables of the principal ones, ancient and modern. There is no subject whose history is more distinctly divided into three periods, ancient, middle, and modern, than that of weights and measures. The ancient period, ending with the decline of the Roman empire, during which the classical standards were preserved and employed; the middle period, during which, while the names and relations of the classical measures were preserved among the learned, the standards were lost, and the various differences of national measures began to exist among the people; the modern period, which hardly begins before the 17th century, in which the discrepancies of national measures were noted, and the attempts at a system founded upon natural philosophy began to be made.

The origin of measures of length is unquestionably to be found in the parts of the human body; both their usual lengths, roughly speaking, and their names, establish this beyond a doubt. The foot, the digit, the palm, the span, the cubit, &c., are in all languages derived from the same source; nor, in the popular view of measurement, do they materially differ in length: the *yard* is but a variety of the word *rod*, and has no intrinsic meaning. It is also unquestionable that in former times, when authentic measures were not so easily *to be* obtained, the hands, arms, and feet were much more frequently used than they are at present, when every workman, however humble, is in possession of a measure. George Agricola, presently named, says *that* in his time (the beginning of the 16th century) the French workmen commonly measured a foot by joining the extremities of the thumbs, clenching the fingers, and keeping the thumbs as widely *extended as* they could: "vulgo pedem metiuntur opifices manibus in pugnos contractis et porrectis pollicibus altrinsecusque obversis:" nor is this a bad measure of a French foot. At what period the slightly variable measures derived from the living man were first exchanged for a fixed and legal average or other conventional value, whether among the Greeks or Romans, is unknown. All that can be said is, that *none of* the earlier writers enter otherwise than incidentally upon the question, and that the fixed and legal measures were of early date. Most authors give some little information upon the subject; even the poets are frequently cited for their allusions. Fixing the end of the ancient period about the middle of the 6th century (simply because the chain of writers who are cited on ancient weights and measures ends *there*), and omitting names as well known as Homer or Virgil, Hesychius or Suidas, Pliny or Vitruvius, there is direct information on the subject in the works or fragments of Cato, Celsus, Columella, *Dioscorides*, Galen, Hero, Julius Frontinus, Julius Pollux, Martianus Capella, Modestinus, Oribasius, Palladius, Paulus, Pomponius, Priscian (who wrote expressly on the subject), Proclus, Rhemnius Fannius (*who* wrote a poem on the subject, often attributed to Priscian), Scribonius, Boetius, Festus Pompeius, Ulpianus, Volusius Mæcianus, and Varro.

It may be convenient to end the middle period and commence *the* modern with the work of Lucas Pætus (1573), as being the earliest of the writers who are frequently cited for success in their attempts to restore the almost forgotten values of the Roman measures. But *this* middle period may be divided into that which preceded and followed the invention of printing. All that took place in the former part of it is a blank; we know but the result, namely, the (probably gradual) introduction of measures differing from those of Rome in magnitude, though retaining the same names. Nevertheless the writers, as we have seen in MILE, retained, besides a uniformity of expression, an intended uniformity of meaning: if they had not the Roman foot and mile, they thought they had. When the German mile was introduced, which was about four Roman miles, the latter were called Italian miles. An abundance of passages might be cited from writers of different countries about the beginning of the 16th century, when books began to be plentiful, all coinciding in requiring the following explanation, namely, that the learned had among themselves, or believed they had, a system of measures in terms of which they communicated with each other, not recognising nor in any way alluding to the common or vernacular measures. It is our supposition that this system began in ignorance that the national measures really did differ from one another at all, and was continued under the impression that a common system was desirable, attainable, and, by keeping to the Roman measures, attained.

As this point in the history of measures is not alluded to by any metrologist, and as some of its consequences are remarkable, it will be desirable to state some proofs of our assertion. So far as we can find, it was hardly thought necessary, even after the 16th century had commenced, and certainly not before, to mention the scale of measures;

the Roman system was taken for granted. Roger Bacon, when speaking of a foot or a mile, compares statements of Ptolemy, Pliny, and writers of his own time, without a word of suspicion that there could be any difference between the several measures; though his own statements from modern travellers [MILE] prove that they had a mile very different in length from that of the Romans. In the Geography* of Laurentinus Corvinus (Basel, 1496), all that he says on measures is in six words, explaining the single addition which had been made to the Roman system: "Italorum quatuor unicum miliare nostrum mensurant." Lebrixa or Antonius Nebrissensis ('Cosmographiæ Introductio,' Paris, 1533), lays it down that his own foot and his own pace are those of the Romans, he being a man of moderate stature; and having once arrived at a conclusion respecting the Roman pace, he takes it for granted he has the proper foot of his own time: he adds that he has made some verifications on itinerary distances. This idea of the actual use of the human members was a very common one: George Agricola, whose work, 'De Ponderibus et Mensuris,' was much in use, and several times reprinted (Paris, 1533; Venice, 1535; Basel, 1550, and perhaps oftener), would almost seem to hint, in addition to what we have already cited, that the actual measures of his day, as used among merchants, were taken from the body: the measures of length, he says, are "membra humani corporis, perticæ, arundines, funiculi." This can hardly mean that measures, such as the foot, the cubit, &c., were only *originally derived* from the human body; for such an explanation would require us to say that the *arundo* and the *funiculus* were names of measures, which was certainly† not the case. The word pertica is ambiguous; it is both a pole and the measure derived from that pole: had it not been from the double meaning of that word, we should have been quite positive of what we now think by far most probable, namely, that Agricola means to say that people in his time measured by the parts of the body, poles, reeds or canes, and strings. This work of Agricola, though intended to be on the weights and measures of his own time, is in reality wholly occupied by discussions on the Greek and Roman measures. He is the first, he says, who in modern times recovered the distinction between the Greek and Roman measures, which had been entirely lost, or at least never mentioned, by his immediate predecessors. It was not uncommon to illustrate the table of measures by drawings of the human body, with descriptions of the foot, palm, &c., as in the 'Cosmographia' of Peter Apian, reprinted several times in the first half of the 16th century. No other reference to a standard of length is given; and the table and drawings are made in such a manner, that nothing but our habit of using other modes of measurement would make any one doubt for a moment that actual reference to the human body is intended. The complete table of the 16th century is as follows:—the breadth (not the length, as is particularly stated) of four barleycorns makes a digit, or finger-breadth; four digits make a palm (measured across the middle joints of the fingers); four palms are one foot; a foot and a half is a cubit; ten palms, or two feet and a half, are a step (gressus); two steps, or five feet, are a pace (passus); ten feet are a perch; a hundred and twenty-five paces are an Italic stadium; eight stadia, or a thousand paces, are an Italic mile; four Italic miles are a German mile; and five Italic miles are a Swiss mile. It will appear most probable from the preceding statement, that the foot was considerably less even than the ancient Roman foot of 11·6 English inches. The average human foot certainly has not that length; the average foot of an adult Englishman is 10·26 inches. The table just mentioned, derived, as we shall see, from the Romans in most of its parts, is founded upon a notion which is very near the truth in a well-proportioned man, namely, that the breadth of the palm is the 24th part of the height; the length of the foot, the sixth; and the length of the cubit, or from the elbow to the ends of the extended fingers, the fourth.

It was the practice of the 16th century, in which books were written for all Europe, and not for that part of it alone in which the writer lived, to set down on the page printed lines representing the length of a foot, or palm, according to what the page would admit. The term frequently used was "figuratio:" thus a long line extending down the page, marked "figuratio pedis," means that the length of this line at the time it was printed is that of which the author speaks. No instance was ever‡ produced in which such a line was merely a representation, put down for the purpose of showing subdivisions, or in which it was treated by any succeeding writer as other than an absolute facsimile.

The figured foot, or paper-foot as we may call it, requires to be lengthened, as an allowance for the shrinking of the paper. The surest case in which we can accurately ascertain in what proportion this shrinking has taken place, is in the plate of Dr. Bernard's work on English weights and measures, in which a line which is described as 7 English inches has shrunk to 6 inches and $\frac{19}{20}$ths, or in the proportion of 42 to 41. Other instances give smaller* amounts of shrinking: in two different copies of one work we find the difference between two impressions of the same foot agreeing within $\frac{1}{100}$th of an inch in about ten inches. It is very unlikely that, if the shrinking had been perceptible, two copies should have shrunk so equally. We adopt this ratio of 42 to 41, and the more readily, because the larger allowance we make the more is our final conclusion weakened: this final conclusion being, that the geometers of the 16th century used a much shorter foot than the Roman.

That the mathematicians just named did use a set of measures among themselves, in order to avoid the diversities of popular measures, is established by the express assertion of Clavius, who died in 1612, aged 75, and is therefore a contemporary authority. He says, in his commentary on Sacrobosco, "Enumerandæ sunt mensuræ quibus mathematici, maximè geometræ, utuntur. Mathematici enim, ne confusio oriretur ob diversitatem mensurarum in variis regionibus (quælibet namque regio proprias habet propemodum mensuras) utiliter excogitârunt quasdam mensuras, quæ certæ ac ratæ apud omnes nationes haberentur." He then gives the same table as that above. On looking at some of the earlier writers of the 16th century, we find a foot which is figured as ten English inches in length, after the shrinking of the paper is allowed for. First, Fernel,† who measured a degree of the earth, speaks of the foot which he used in two distinct works, the 'Monalosphærium' (Paris, 1526) and the 'Cosmotheoria' (Paris, 1528), in which last the degree is described. In the first work he gives his foot, or "figuratio pedis geometrici," which he says is to be chosen with great care, on account of the great diversity of measures. This paper-foot is now within a sixtieth of an inch of nine inches and two-thirds (English), which, increased in the proportion of 41 to 42, is nine inches and nine-tenths. In the second work, he says, that five of his own paces, or those of ordinary men, make six geometrical paces. Now the pace of an ordinary man, or two steps, is almost exactly five English feet, which is the double of the regulation step of the army in England. Paucton (p. 187), from actual experiment, gives what amounts to 59 inches and 7-tenths English. At sixty inches per pace, Fernel's foot is then ten inches (English) exactly; at 59·7 inches it is 9·95 inches. The two descriptions agree so well, that Fernel's foot may be considered as very well determined; nevertheless, Picard, Cassini, Montucla, Lalande, and Delambre have all taken it for granted that by a foot Fernel could have meant nothing but the Parisian foot (12·8 English inches), and have therefore considered him as having (by accident, they suppose), measured his degree with very great correctness, whereas, in fact, he is fifteen miles wrong. Budæus (followed by Glareanus and others) had, a few years before (1515), in his treatise, 'De Asse,' the earliest work on Roman measures, &c., declared that the Roman foot was the same as the Parisian; and Picard, &c. seem to have taken it for granted that Fernel followed Budæus. They might have learnt from Lucas Pætus that this foot of Budæus was "reprobated by all as having nothing in common with the Roman foot." The treatise of Stöffler, 'Elucidatio Fabricæ Ususque Astrolabii' (Oppenheim, 1524), contains his configuration of the digit, palm, and foot, separately, the foot being also divided into palms. These agree exceedingly well with one another, and the foot on the paper is precisely nine inches and three-quarters (English). This increased in the ratio of 41 to 42, gives 9·98 inches. The author speaks of the digit, &c. as being the celebrated measures which are used by all or most, and gives no hint whatever of his having made a measure for himself. It may here be noted that the English writers of the period make little mention of this book-system, and, when they do mention it, sometimes confound it with the common and popular system. Thus Blundevil, in his 'Exercises,' tells us that the *German foot*, according to Stöffler, is two inches and a half less than ours; alluding, no doubt, to the foot we have just cited.

Since the 'Penny Cyclopædia' appeared, we have examined several other figured feet; for some of which see De Morgan, 'Arithmetical Books,' pp. 8, 9. The results accord very well with those given above; and the mean of the whole gives a foot of 9·85 inches. But Fernel and Stöffler are the best authorities, because they are the best names, have given the whole foot, and have taken the greatest pains with the subdivisions. The mean of their results, before allowance for shrinking, is 9·7 inches: that of the barley, presently mentioned, is 9·8 inches. The allowance for shrinking is, as above given, perhaps too great; and 9·8 inches is, it may be, as good an estimate as can be given of this once well-known measure.

There is little reliance to be placed on the barley standard; nevertheless, this addition to the Roman system of measures must have been made by some who had tried it: we can hardly suppose that writers

* Remarkable as being probably the last work in which America is not mentioned.

† We do not forget the *canna*, but this was only an isolated Italian measure, not likely to be named as a technical term by Agricola, writing in France, and putting all measures under four heads.

‡ We have found *one*, in the work of Neander (1555), in which the ratios of the measures are represented by arbitrary lines. But as if to show what was intended, the words next following the figured measures are "Hactenus persecuti sumus *nomina* mensurarum," &c.

* We have taken the one which is most against us: in the 'Pathway to Knowledge,' (1596; not the work of Recorde under that name, but a translation from the Dutch, of which we can find no mention in bibliographers) a line of six English inches, figured in the translator's preface, has shrunk only by one part out of sixty. With reference to our frequent subsequent citations from this 'Pathway,' we may observe that Jeake, whose ample and laborious accounts of weights and measures (in his 'Λογιστικηλογία, or Arithmetick, Surveighed and Reviewed,' London, 1696, but finished in 1674) makes him a very respectable witness, considers it as a first-rate authority.

† See a discussion on this case in various numbers of the 'Philosophical Magazine' for 1841 and 1842.

would in all cases carefully state that four grains of barley placed side by side give their first and lowest measure, unless they were at least repeating a well-established tradition, founded upon an actual mode of measurement. According to this mode, 64 grains, placed side by side, ought to give their foot: we believe it will be found very difficult to make any barley of our day give more than 10 inches. On trying the first grains we obtained, we found that, by picking out the largest grains, 33 of them just gave more, and 32 less, than five inches: but that, taking the grains as they came, 38 gave only five inches. Not wishing however to trust to one trial, we procured the largest specimens of barley which could be got from two different and distant parts of England, and from these specimens, already selected as choice samples, we picked out the largest grains. In a first sample, 33 grains placed side by side gave five inches; in a second, 33 grains gave five inches and one-tenth; in a third, 33 grains gave also 5 inches and one-tenth. And yet these samples differed apparently in bulk; but on examination we found that the *lengths* of the grains differed materially, their breadths very little. So that the ancient English standard which depended, or was said to have depended, upon the lengths of barley-corns placed end to end, was not founded upon so sure a method as that above described, which depended upon the breadths. The foot of 64 barley-corns derived from the average of the preceding (rejecting that from the smaller grains of the London sample) is 9 inches and eight-tenths of an inch, rather smaller than might be supposed from the other methods of judging, which, however, it must be remembered, have been pushed to their utmost.

We feel persuaded from all that precedes, not only that at the beginning of the 16th century there was no distinction made between the measures of the learned and the Roman measures, but that the Roman foot, the foundation of all, was taken to be considerably shorter than the truth, having been probably recovered from the human body. Long after the introduction of sounder notions, we see traces of the same sort of thing. For instance, in the second edition of the mathematical Lexicon of Vitalis (1690), the first edition (1668) being silent on the matter, an article on measures is introduced in which the only authorities alluded to are the 'Dies Geniales' of Alexander ab Alexandro, in which there is nothing but description of ancient measures, and the work of George Agricola already cited. The Roman foot was recovered with tolerable ease as soon as it was looked for. Leonard di Portis, an Italian lawyer, gave its length from the Colotian foot hereafter noticed; and Lucas Pætus, another lawyer, wrote elaborately on the ancient weights and measures in 1573. Those who would see more of this subject in the 16th century must search for the writings of Alciatus, Alcasar, Geo. Agricola, Budæus, Budelius, Capellus, Montanus, Mariana, Lebrixa (Nebrissensis), Neander, Pasi, Pætus, Portius, Villalpandus, &c.

As soon as the middle period is past, the history of weights and measures down to our own time ceases to be European, and, with the exception of those of England and France, we need not, in so short a sketch as the present, give any very close account of the various national measures.

In England, it seems as if the standards were tolerably well settled and widely diffused at so early a period that the writers of this country took comparatively little notice of the system which the continental mathematicians used for their own communications. That the ear of barley and of wheat were actually used in determining the standards, seems * to admit of no doubt. The statute 51 Henry III. (A.D. 1266) enacts, "that an English penny,† called the sterling, round, without clipping, should weigh 32 grains of wheat, well dried and gathered out of the middle of the ear; and twenty pence to make an ounce, twelve ounces a pound, eight pounds a gallon of wine, and eight gallons of wine a bushel of London, which is the eighth part of a quarter." Again, 17 Edward II. (A.D. 1324) provides that three barley-corns, round and dry, make an inch, 12 inches a foot, &c. And the interpretation of the older scientific writers on measures is agreeable to the common meaning of the words. "Look to the first grounde," says Oughtred, "and principle of our English measuring, from Barley-cornes." But it is so difficult to know how much of the sharp end of a barley-corn must be cut or worn away before it becomes what was called "round," that this mode of measuring by the *lengths* of barley-corns is very indefinite. Standards were made at early periods and enforced by various statutes; one of the earliest is one of Edward I. of uncertain date, which directs that a standard of bushels, gallons, and ells, shall be kept in every town, agreeing with the king's measure. With regard to the measure of length, this country has been fortunate, and its standards have, for commercial purposes, fully deserved the name. But the measure of capacity [GALLON] remained various in spite of all acts of Parliament. In the year 1650 there were three distinct modes of determining a wine gallon: 1, From general opinion, which gave 231 cubic inches, and with which, in fact, the gallons in common use agreed, as was proved by the measurements of Oughtred, Gunter, Briggs, and others. 2, The customary standard at the Guildhall, which, though not a legal standard, was considered as such, even by the law-officers of the crown, and which, though in reality only 224 cubic inches, was always taken to be 231 inches. 3, The real legal standard, preserved at the Treasury, containing 282 cubic inches. Oughtred says that the difference between the ale and wine gallons is, "that because of the frothing of the ale or beer, the quantity becometh lesse, and therefore such liquors as did not so yield froth, as wine, perry, and the like, should in reason have a lesser measure." The Report of one of the Committees states that the wine gallon had been gradually shrinking in capacity, until it was arrested at 231 cubic inches by a fiscal * definition. That this value was laid down by the statute [illegible] Anne, cap. 27, is certain; and the origin of this definition (which is inserted into a statute having nothing to do with weights and measures) seems to have been as follows:—A little after 1700, an information was tried in the Exchequer against one Barker, for having imported more of Alicant wine than he had paid duty for. On the part of the crown it was contended that the sealed gallon at Guildhall (said to contain 231 cubic inches) was the standard. But the defendants appealed to the law which required that a standard gallon should be kept at the Treasury, proved that there was such a gallon at the Treasury containing 282 cubic inches, and established, by the evidence of the oldest persons in the trade, that the butts and hogsheads which came from Spain had always contained the proper number of these standard gallons. A juror was withdrawn, and the law-officers of the crown took no further proceedings except procuring the above act. A better instance of confusion could hardly be imagined: the legal gallon had gradually been diminished more than 50 cubic inches; the merchants in one particular trade continued to import and to pay duty by the real gallon, and were finally called to account by the attorney-general, who, in common with the rest of the world, had forgotten what the real gallon was, and sued for penalties upon appeal to what was no more a legal standard than the measure in a private shop.

There is something curious about the history of the experiment [GALLON] mentioned by Ward, who was an eye-witness, and wrote just after the statute of Anne, when his account could do no harm. The gallon was found to be 224 (Wollaston afterwards found it to be 224) cubic inches, that is, the sealed gallon at Guildhall: but, "for several reasons, it was at that time thought convenient to continue the former supposed content of 231 cubic inches." This means, as explained by the Committee of 1758, that the Lords of the Treasury direct an authority to be drawn for gauging according to the Guildhall gallon: the merchants immediately petition to be allowed to sell as they were gauged; the commissioners of customs do not follow the order (which however it does not appear was ever signed); and when the Lords of the Treasury take the attorney-general's opinion upon it, they are recommended to make no change: "For if the usage of gauging is departed from, he knows not where we shall be, because resort cannot be had to the Exchequer for a standard to which almost all the statutes refer; *for* there is none there but what the king will be vastly a loser by."

The old division of the gallon into that of wine measure, ale and beer measure, and dry † measure, was not only unknown to the law, but even to the writers on arithmetic, till the beginning of the 17th century. Nor when Briggs, Oughtred, &c. measured the gallons, did they divide them into more than two kinds—for ale and wine. Oughtred, who measured pecks, bushels, &c., and thence found $272\frac{1}{4}$ cubic inches for the deduced gallon, imagines this to be the ale gallon. It was undoubtedly the old Winchester gallon, before its content was a little reduced by the statute of 1697; this gallon still continued in use in Ireland up to the introduction of the imperial measures; and even in England, as late as 1727, Arbuthnot takes it for the existing dry measure. Perhaps we have the first time in which, and the first person by whom, the distinction of the corn and ale gallon was made, in the following citation from Wyberd ('Tactometria,' 1650, p. 266):—"Now as to Mr. Oughtred's ale gallon of $272\frac{1}{4}$ inches, the said Mr. Reynolds" (John Reynolds, a clerk in the Mint, often referred to by Wyberd as a mathematician and experimenter) "indeed alloweth of such a Gallon measure, but not for any liquid thing, but for drie things, as Corne, Coals, Salt, and other dry things measurable by this kind of Measure, and so calleth it the drie Gallon measure: and thereupon he wil have to be 3 severall Gallons (or other like Measures), one for *Wines* (which also serveth for oiles, strong-waters, and the like), another for *Ale* and *Beer*, and a third for *Corne, Coales*, and the like." Wyberd, rejecting the distinction of the dry and ale gallons, made his wine and ale gallons to be 224 and 266 cubic inches, by a series of carefully conducted experiments: it is singular that a good experimenter, with access to existing standards, and as good an experimenter

* We do not believe the story of Henry I. ordering that the yard should be of the length of his arm.

† A silver penny.

* We were wrong, we believe, in stating in GALLON that the *wine* gallon was determined by statutes of 1689 and 1697: these related to the other gallons. But there is singular confusion in the Reports of the Committee, which nothing but a new search into the actual statutes will remove.

† We do not mean that there was no distinction between liquid and dry measure, but that there was no distinction between the gallons of those measures. Thus Mellis, in the arithmetic appended to his treatise on book-keeping (1588), very distinctly separates the liquid and dry measures, but uses only one gallon, namely that of which the pint is one pound. It may be worth while to add that the mile of 1760 yards is mentioned by this writer four years before it became the *statute* mile.

The preface to the 'Pathway of Knowledge,' already cited, makes no distinction between the ale and wine gallon; it says that the wine gallon is the same as that of ale, and contains eight pounds of wine; it also makes the corn gallon contain eight pounds of wheat.

to suggest something like the actual truth, should not have been able to find out the mere existence of the largest or ale gallon, and it shows the extreme confusion in which the subject was then enveloped.

There has been in various quarters a disposition to suppose that the varieties of gallons arose from the varieties of pounds, since the original definition of the gallon depended upon the pound. This we think exceedingly likely: we do not imagine that it was done of set purpose, but only by confounding one species of pound with the other, in the way of common mistake. There is among most antiquarians a perverse unwillingness to admit human frailty among the explanations of the phenomena of former times, which has caused many an hour to be thrown away in trying to reconcile the Greek musical scales [TETRACHORD], and many more in finding out for the rude forefathers of all kinds of nations an accurate and self-consistent system of weights and measures. Though even in our day, a learned body,* legislating for educated men, after declaring in one paragraph that none but troy weight is to be used, has introduced averdupois weight in the very next paragraph,—we never permit ourselves to suppose that such a thing could have taken place in the reign of Henry VIII. or Elizabeth. Now it certainly does happen that there is a close relation not only between the old gallons and the weights, but even between the different versions of the old gallons and the weights. There was a gallon of 282 cubic inches, in the Exchequer as a standard; there was one of $272\frac{1}{4}$ inches, in common use; there was one of 281 inches, in common use; and there was one of 224 inches, in the Guildhall. Now 282 and 232 are, as near as integers will show it, in the proportion of the pound averdupois to the pound troy, and $272\frac{1}{4}$ and 224 are as nearly in the same proportion. It is unlikely that this should have been accidental.

Common usage, in the 16th century, made more distinctions of measures than have lasted. The editor of the 'Pathway of Knowledge' gives four sorts of pounds as in use: the Tower pound (already mentioned in TROY), the troy and "haberdepoys," the subtill, and the foyle. The word *subtill* was not the one mentioned in TARE, at least one would suppose so; let the reader try to understand it himself:—"The poundes subtill, so tearmed for that in in small quantitie it may bee made ratable to represent anye other greater waight whatsoever, as foure penny waight troy, or less to answere in due proportion unto the whole pound Troye, with all his parts, every parte sensible and severally to be handled. This waight is private, to assaye Maisters and such as can make triall of minerals, and not knowne to many other, neither is there any use thereof, in ordinarie accompts." This seems to mean that any small piece, such as an assayer would cut off for trial, was made to represent a pound, and the fineness expressed in ounces of that small pound would of course represent that of the actual pound. The pound foyle was less than the pound troy by its fifth part, and was used for gold foil and for wire, and for pearls. In the two former cases it obviously means that the workman paid himself for labour and loss by selling four-fifths of a pound of wire or foil at the price of a pound of bullion. And many varieties of measure arise in this way, namely, by varying, not the price of a given amount, but the amount of a given name at a given price. A wholesale bookseller now says that he sells 25 *as* 24, meaning that he who buys two dozen shall have one more; but in the 16th century, had this usage existed, it would have been put down that two dozen of books *are* twenty-five.

It is needless to give an account of the old standards of weight mentioned by the committee of 1758, as many of them are lost; a much greater agreement was found to exist between those made at various times than was observed in regard to the standards of capacity. The origin and history of the different weights is alluded to in AVERDUPOIS and TROY; of the standards of length in WEIGHTS AND MEASURES, STANDARD, in which last article will be found an account of the transition to the now established *imperial measures*. The day is probably distant when the English public shall enjoy the advantages of a uniform decimal system of weights and measures—the only one which is sure of stability. An opinion is gaining ground that the best method of ultimately attaining this end is by beginning with the coinage, and this was recommended by the commissioners who reported on the subject. [WEIGHTS AND MEASURES, STANDARD.] Nothing, as it fortunately happens, can be easier than this change: the introduction of coins of two shillings each, in place of the half-crown, might be followed by that of coins of twopence-halfpenny each, without requiring any alteration in the habits or calculations of any one. It is the advantage of this proposition that the two new coins might be learnt as parts of the old system, before the subsequent alteration of the copper is made. As soon as these coins are well established, an alteration of four per cent. in the copper coinage, or the enactment that *twelvepence-halfpenny* shall pass for the silver shilling, is the whole step requisite to complete the process; and the pound will then consist of ten *two-shilling* coins (under their proper name), the two-shilling coin of ten *twopence-halfpenny* coins (also under their proper name), and the twopence-halfpenny of ten farthings as at present. As soon as this change is made, and the convenience of its arithmetic found by experience, it will not be long before there is a demand for the extension of the principle to weights and measures. And it would be well if those who endeavour to bring about a reform in this matter would remember that change of coinage is the only change which a government can immediately command—that for one calculation which is made upon goods, hundreds are made upon money—and that, if the small alteration which is required to make the coinage* purely decimal cannot be attained, there is little chance of the more extensive changes which the weights and measures will require.

* We allude to the College of Physicians, in the matter of the fluid apothecaries' measure, presently mentioned. The mistake was exceedingly natural, almost inevitable, but it shows what extreme care is necessary.

We now describe the English weights and measures as they stood on the last day of the year 1825, immediately before the introduction by law of the imperial measures, with some remarks on their states at different times. As it is not to such an article as the present that the young arithmetician will refer, it will not be necessary to give more than a condensed set of tables. For the modern continental measures which follow, we have to acknowledge great assistance from Dr. Kelly's 'Cambist,' the standard work on the subject.

Troy Weight.—This weight is said to have always been the standard weight of the country: on this assertion we have some doubts; but this is not the place to enter on them at length. The pound is 12 ounces; the ounce is 20 pennyweights; the pennyweight is 24 grains. The pound is 5760 grains. There is but one grain in use, whether troy or averdupois, and a cubic inch of pure water is 252·458 grains (barometer 30 inches, thermometer 62° Fahr.). A cubic foot of water is 75·7374 pounds troy. Wheat and bread were once measured by this weight, but latterly only gold and silver. It is usual to say that precious stones are also measured by troy weight; but, as may be supposed, the measure of these is the grain. The diamond is measured by carats of $151\frac{1}{2}$ to the ounce troy; so that the carat is $3\frac{1}{6}$ grains, very nearly. In pearls, the old foil measure already noticed still exists; for the pearl grain is one-fifth less than the troy grain. In the 17th century the goldsmiths divided the ounce troy into 24 carats of four grains each for gold and silver: so that the pound troy contained 1152 gold-carat grains. They also divided the ounce into 150 carats of four grains each, for diamonds: so the pound troy contained 7200 diamond-carat grains. But now the CARAT has only the sense noted under that word, for gold and silver; and is altered as above for diamonds.

According to the old statutes, the pound troy is 7680 grains; for 32 grains are to make a pennyweight, 20 pennyweights an ounce, 12 ounces a pound. It is not known when or why the pennyweight was first† made 24 grains. In some old books a grain is 20 mites, a mite 24 droites, a droite 20 peroites, and a peroite 24 blanks. This division of the grain into 230,400 parts must of course have been book-learning: it is said to have been confined to the *moneyers*.

In Swallow's Almanac for 1673, we find the troy weight given as for "pearls, precious stones, gold, silver, bread, and all manner of corn and grain; and this weight the apothecaries ought to use."

Apothecaries' Weight.—In *dispensing* medicines, the pound troy (Does that weight ever occur in prescriptions?) is divided into 12 ounces, the ounce into 8 drams, the dram into 3 scruples; consequently each scruple is 20 grains. But in buying and selling medicines wholesale, averdupois weight is and always has been used. The 'Pathway,' so often cited (1596), says, "all physicall drugges" were weighed by averdupois, and Jeake (1674) says that "many" (only many) of the "physical doses" are weighed by what we now call apothecaries' weight. The fact seems to be that in the first instance the more precious drugs, as musk, were weighed by troy weight, in the same manner as the more precious metals; and that the common medicines were dispensed by fractions of what was then the common pound, as we shall see under the next head.

Apothecaries' fluid measure.—In 1836, in the new edition of the 'Pharmacopœia,' the College of Physicians prescribed the use of the following measure:—60 minims make a fluid dram; 8 fluid drams a fluid ounce; 20 fluid ounces a pint. For water this is actual weight as well as measure, since the imperial pint‡ is 20 ounces averdupois of water; but for other liquids the fluid ounce§ must merely be considered as a name given to the 20th part of a pint. The minim of water is as nearly as possible the natural drop; but not of other substances, the drops of which vary with their several tenacities.

According to Dr. Young (who has reduced them from Vega), the apothecaries' grains used in different countries are as follows:—1000 English grains make 1125 Austrian, 956 Bernese, 981 French, 850 Genoese, 958 German, 978 Hanoverian, 989 Dutch, 860 Neapolitan,

* We leave these remarks as they stood in the 'Penny Cyclopædia,' without any allusion to recent discussions.

† Cocker, Wingate, &c., say that a pennyweight is 32 *real* grains, and 2 *artificial* grains.

‡ The old pint was more nearly a pound, and some of our readers will remember the old saying,—

"A pint's a pound
All the world round."

The second line of this was certainly not true, and the first only approximately. But under the imperial system the following, which is literally true, may be substituted,—

"A pint of pure water
Weighs a pound and a quarter."

§ It is not noted in the 'Pharmacopœia' that the fluid ounce, when it *is* an ounce, is an ounce averdupois: a preceding sentence in that work implies that medical men are never to use anything but troy weight.

824 Piedmontese, 864 Portuguese, 909 Roman, 925 Spanish, 955 Swedish, 809 Venetian.

The recent alterations in the government of the medical profession have produced proposals to alter the method of weighing medicines. A committee of the General Council of Medical Education has given a recommendation to the following effect. The pound averdupois is to have its ounce divided into drachms, scruples, and grains, as in the present troy ounce. To effect this, a new grain is invented, being ·91145 of the present grain: and the pound is to be 7680 grains, as of old. What purpose this change can answer, or, supposing a purpose, how it can bring benefit enough to counterbalance the alteration of the grain in which all doses are now remembered, and all prescriptions written, we cannot imagine.

Averdupois weight.—The pound is 16 ounces, and the ounce 16 drams: the modern pound is 7000 grains (the same as the troy grains); whence the dram is 27 grains and 11-32nds of a grain. The hundredweight is 112 pounds, and the ton 20 hundredweight. The cubic foot of water is 62·3210606 pounds averdupois. The stone * is the 8th part of the hundredweight, or 14 pounds. The ton of shipping is not a weight, but a measure, 42 cubic feet, holding 24 hundredweight of sea-water. In the oldest mentions which are made of *haberdupois* or *averdupois*, the word is not applied to weight, but to goods weighed. A charter of Edward I. speaks, "de averis ponderis, et de aliis rebus subtilibus;" and no mention is made of averdupois *weight* before the time of Henry VIII. Wingate (quoting Gerard Malynes, whose 'Lex Mercatoria' was published in 1636) says that it serves to weigh "all kind of grocery ware, as also butter, cheese, flesh, tallow, wax, and every other thing which beareth the name of *garbel*, and whereof issueth a refuse or waste." To which the almanac of 1673, already quoted, adds, "and therefore 112 lbs. averd. is called a hundredweight."

The old merchants' pound, which was 15 ounces [Troy], may have been the origin of the modern averdupois pound. Fleta says everything was weighed by it except gold, silver, and drugs; but it is to be remembered that this does not mean that gold and silver were weighed by troy weight; for it is well known that, until a change was made by Henry VIII. in 1527, gold and silver were weighed by the Tower pound of 11¼ ounces. The modern averdupois pound is 14 ounces, 12 pennyweights, all but 8 grains troy. The standards of Elizabeth agree tolerably well with this; but it is to be noticed that, unless we suppose two averdupois pounds, one ancient and one modern, there is much reason to doubt whether the averdupois pound was uniform. Dr. Kelly says, "The old commercial weight of England, which is still retained in Scotland, is about one-twelfth heavier than averdupois, the pound being 7600 grains troy .... this has been long the weight in England by which the assize † of bread is fixed." Our suspicion is this, that the old commercial pound, probably differing in different places, though supposed to be uniform, gradually gained the name of averdupois; and that the standards deposited in the Exchequer in the time of Elizabeth, which certainly do not agree with the arithmetical writers of the same date, were probably derived either from this old merchants' pound of 15 ounces troy, or from a selection out of the varying specimens of a pound derived from it. In the 'Pathway' the "pound haberdupois is parted into 16 ounces, every ounce 8 dragmes, every dragme 3 scruples, every scruple 20 grains;" giving 7680 grains to the pound. This is the probable origin of the old pound which Dr. Kelly mentions, and it happens to contain precisely the same number of grains as the old statute ‡ pound before 32 grains took the place of 24 in the pennyweight. And this shows the origin of apothecaries' weight: medicines were dispensed by this old subdivision of the pound, and continued to be so after the pound of Elizabeth's standard had supplanted the old one. It was then natural that this ounce, drachm, and scruple, which were no aliquot parts of the new averdupois pound, but which were aliquot parts of the pound troy, should be referred by arithmeticians to the latter. § Sir Jonas Moore, who had been surveyor-general of the Ordnance, and could hardly have failed to be correctly informed, gives the same pound and subdivisions. Moore's 'Arithmetic' was first published in 1650. Jeake, as late as 1674, gives the same division and the same pound of 7680 grains; and Harris, as late as 1716, does the same in the third edition of the 'Lexicon Technicum.' Jeake gives several citations tending to show that there was no universal agreement about the pound averdupois. Dalton (the lawyer) and Malynes, he says, agree in making 56 lbs. averd. equal to 67½ lbs. troy (or 6942$\frac{6}{7}$ grains to the pound averd.), but *both* afterwards put 68 for 67½ (which gives 6994$\frac{2}{7}$ grains). Others, he continues, affirm the pound averdupois to be 14 ounces 12 pennyweights troy (giving 7008 grains). The older writers hardly mention averdupois we[ight]: Recorde not at all; Mellis slightly, not subdividing the ounce. [Hart]well, an editor of Recorde (1648), mentions this pound of 16 o[unces] and 7680 grains, divided as above, and says it is used by apothec[aries]. Oughtred, mentioning Ghetaldi's pound of 6912 grains, compare[s it] only with the English troy pound, without mention of any other. A[ll] this shows that, at the beginning of the 17th century, there wa[s a] complete want of agreement as to what constituted averdupois we[ight], which continued in some degree till the end. Nevertheless in [the] middle of the century, Wyberd, who measured for himself, and [his] friend Reynolds (before mentioned), assert that the averdupois p[ound] is to the troy as 17 to 14 (which gives 6994$\frac{2}{7}$ grains, agreeing w[ith] Dalton and Malynes), though they say that the then common n[otion] was that the ratio was 73 to 60 (which gives 7008 grains). M[oore] (1679) gives as much as 7680 grains. Ward says that, by a very [ex]experiment, he found 6999¼ grains. Arbuthnot, apparently mea[ning] to cite Greaves, but we cannot find the place, gives the ratio 17[5 to] 144, or 6890$\frac{5}{8}$ grains. Down to the statute of Geo. IV., the aver[dupois] pound varied a little, according to the notion of the writer: Dilw[orth] makes it 6999¼ grains; Dr. Robert Smith, 7000 grains; Bonny[castle], 6999$\frac{23}{24}$ grains. And even since that act came into operation, wh[ich] declares "that seven thousand such grains shall be, and they ar[e] hereby declared to be, a pound avoirdupois," an editor of the last-nam[ed] writer will not obey the statute, but adds the 123rd part of a grain.

Long measure.—Three barleycorns make an inch, 12 inches a f[oot], 3 feet a yard, 5½ yards a pole, perch,* or gad, 40 poles a furlong, [8] furlongs (1760 yards) a mile. Also 2¼ inches are a nail, 3 quarters [of] a yard a Flemish ell, 5 quarters an English ell, 6 quarters a Fren[ch] ell. A pace is 2 steps, or 5 feet; a fathom is 6 feet. The chain is [22] yards, or 100 links: 10 chains make a furlong, and 80 chains a mi[le]. The barleycorn is now disused, and the inch is sometimes divided in[to] 12 lines (as in France), but oftener into tenths or eighths. On our older itinerary measures, see League and Mile. The yard is frequently called an ell in old books; *commonly,* Recorde says. Mellis says that both the yard and the ell were divided each into 16 nails. A goad is an old name for a yard and a half. The band (anciently handful), used in measuring the height of horses, is fixed at 4 inches by 27 Henry VIII., cap. 6. The furlong is probably a corruption of forty-long, from its forty poles: the old derivation, furrowlong, as long as a furrow, seems to us to carry absurdity on the face of it. The etymologists of measures are not always fortunate; Verstegan derives Troy weight from Troynovant,† the mythological name for London; and Jeake will have averdupois to be overdupois, because the pound is greater than in troy weight; while Moxon says the word means "Have your weight."

Square Measure.—A square perch is 30¼ square yards; 40 square perches are a rood (formerly also farthendele), 4 roods are an acre. The acre is also ten square chains, or 4840 square yards. Four square perches were anciently called a day's work. The rood ‡ is the same word as rod: Mellis says four *rods* make an acre. The old terms which have come down from 'Domesday Book' at latest, the hide, plow-land, carucate, and oxgang, are wholly unsettled as to what magnitudes they meant.

The cubic measures, or measures of capacity, do not immediately depend upon the cubic foot, except in the case of timber. Forty cubic feet of rough timber, or fifty feet of hewn timber, make a load.

The preceding measures have been untouched by the act which introduced the imperial measures. The old measures of capacity, the wine measure, ale and beer measure, and the dry measure, are now replaced by the imperial measure.

Old Dry or Corn Measure.—The gallon is 268·6 cubic inches. Two pints make a quart, 2 quarts a pottle, 2 pottles a gallon, 2 gallons a peck, 4 pecks a bushel, 2 bushels a strike, 2 strikes a comb or coomb, 2 coombs a quarter (eight bushels), 5 quarters a wey or load, and 2 weys a last. In measuring grain, the bushel is struck, that is, the part which more than fills the measure is scraped off. Most other goods were sold by heaped measure, or as much as could be laid on the top of the measure was added. This heaped measure (which was supposed to give about a third more than the other) was at first allowed in the imperial system, but has since been abolished. Coals, which must now be sold by weight, were sold by the chaldron. Three bushels make a sack,§ three sacks a vat, and four vats a chaldron.

There was anciently a *dell,* or half-bushel (also called a *torit*), which makes the binary character of this measure almost complete. In the 'Pathway' we do not find the load or wey,‖ and the coomb is

* There were a great many different stone weights: every one but that of 14 pounds is now illegal.

† Abolished in 1815.

‡ This circumstance and others may lead to the suspicion that the pound of which we now speak (being that which was called averdupois in the 16th century) was in reality the old standard. In 1750 Mr. Reynardson published a pamphlet, asserting that the common averdupois pound was the ancient standard, on other grounds.

§ The writers of books might invent a pound for this measure, because medicines are not dispensed by pounds, just as they might coin billions, trillions, &c. [Numeration], those numbers being never used. But the druggists continued to buy and sell wholesale by averdupois weight.

* In recent times the word perch has been almost confined to the square perch.

† Mr. Davies Gilbert, in his evidence before the committee on weights and measures, declared for this derivation. Lord Swinton derives it from *trois,* three; observing that the money and the money weight have three denominations each—penny, shilling, pound; and pennyweight, ounce, pound.

‡ Rod or rood merely means a piece of wood much longer than it is broad or thick. So the word rood was frequently used for the cross; and when Milton says that Satan "lay floating many a rood," he is taking the length of his hero, and not the ground which he covered.

§ In 1596 the sack was four bushels.

‖ Moore makes six quarters, and Ward ten, in a wey.

lso called a *cornook* (by Jonas Moore, *canock*), and the quarter also seam.* The 'Pathway,' Mellis, and Moore, &c., mention the *water measure* of five pecks to a bushel (11 Henry VII., cap. 4.), and lways in conjunction with dry measure: it means a dry measure in use at the waterside, and lime, sea-coal, and salt were measured by t. The common dry bushel was called the Winchester bushel; this name is a remnant of the laws of King Edgar, who ordained that specimens kept at Winchester should be legal standards.

Old Wine† Measure.—The gallon contains 231 cubic inches. Four gills make a pint, 2 pints a quart, 4 quarts a gallon, 18 gallons a rundlet, 31½ gallons a barrel, 42 gallons a tierce, 63 gallons a hogshead, 2 tierces a puncheon, 2 hogsheads a pipe or butt,‡ 2 pipes a tun. But the pipes of foreign wine depend more on the measures of their different countries than on the above. The rundlet and barrel are generally omitted, but they are both found in writers of the 16th century. Mellis gives 18½ gallons, and the 'Pathway' 18 gallons, to the rundlet. Tierce merely means the third part of a pipe, and the puncheon was anciently called the tercian (of a tun). The pottle (of two quarts) formerly existed. The anker of brandy, a foreign measure of comparatively recent introduction into England, is ten gallons.

Old Ale and Beer Measure.—One gallon contains 282 cubic inches. Two pints make a quart, 4 quarts a gallon, 9 gallons a firkin, 2 firkins a kilderkin, 2 kilderkins a barrel, 1½ barrel a hogshead, 2 hogsheads a butt, 2 butts a tun. Up to the year 1803, when the two measures were assimilated§ by statute, this was the beer measure, and the ale measure only differed from it in that 8 gallons made a firkin. Nothing above a barrel is mentioned in the oldest tables, and the pottle (two quarts) is introduced. Two tuns were sometimes called a last.

Imperial Measure.—This measure supersedes the old corn, wine, and beer measures. The gallon contains 277·274 cubic inches, and is 10 pounds averdupois of water. Four gills are a pint, 2 pints a quart, 4 quarts a gallon, 2 gallons a peck, 4 pecks a bushel, 8 bushels a quarter, 5 quarters a load. Of these the gill and load are not named in the statute, but are derived from common usage. When heaped measure was allowed, 3 bushels made a sack, and 12 sacks a chaldron. This heaped measure was abolished‖ by 4 & 5 Will. IV., c. 49, and the abolition was re-enacted by 5 & 6 Will. IV., c. 63, which repealed the former. These acts leave the higher measures of wine, &c., to custom, considering them apparently as merely names of casks, which in fact they are, and leaving them to be gauged in gallons. It must be remembered that in former times any usual vessel which was generally made of one size came in time to the dignity of a place among the national measures.

Wool Measure.—Seven pounds make a clove, 2 cloves a stone, 2 stones a tod, 6½ tods a wey, 2 weys a sack, 12 sacks a last. The 'Pathway' points out the etymology of the word cloves: it calls them '*claves* or *nails*." It is to be observed here that a sack is 13 tods, and a tod 28 pounds, so that the sack is 364 pounds. Jeake says this was arranged (31 Edward III., cap. 8) according to the lunar year of 13 months of 28 days each. The reason, no doubt, was, that the multitudes of whose occupation the spinning of wool formed a part might instantly be able to calculate the supply for the year or month from the amount of the day's work; a pound a day being a tod a month and a sack a year. But it would seem as if Sundays and holidays had to be made up on other days.

Tale or Reckoning.—If we were to collect every mode of counting, this would be the largest head of all. The dozen, the gross of 12 dozen, and the score, are the only denominations not immediately contained in the common system of numeration, which are universally received; and in all cases, by a dozen, a score, a hundred, a thousand, &c., were signified different numbers, composed of the arithmetical dozen, score, &c., together with the allowances usually made upon taking quantities of different goods. The "baker's dozen," for instance, which has passed into a proverb, arose from its being usual in many places to give 13 penny loaves for a shilling. The increased dozen, hundred, &c., were sometimes called the long dozen, long hundred, &c.; and this phrase is sometimes heard in our own day, when a dear price is called a "long price." The 12 dozen was formerly called the *small* gross, and 12 small gross made the great gross. The hundred was more frequently ¶ 120 than 100, the thousand generally ten hundred. Ten thousand was frequently called a last; and it is to be observed that the word last was frequently (almost usually) applied to the highest measure of one given kind. The *shock* was always 60; the dicar, or dicker, always 10, as the name imports. In measuring paper (1594), the quire was 25 sheets, the ream 20 quires, and the bale 10 reams. By 1650 the practice of reckoning 24 sheets to the quire (now universal) had been introduced as to some sorts of paper. The memory may be assisted by the phrase that a quire is the shilling of a ream, and a sheet is its halfpenny. Tale-fish, as those were called which were allowed to be sold by tale, were (22 Edw. IV., cap. 2) such as measured from the bone of the fin to the third joint of the tail 16 inches at least.

It is impossible for us to describe the various weights, measures, &c., which have found their way into use in the various counties. Dr. Young collected a list, which is printed in the second Report of the Commissioners on Weights and Measures (1820), to which we must refer for the various local barrels, bushels, hundreds, &c., and also for the awm, bag, bale, basket, bat, bay, beatment, billet, bind, bing, boll, bolt, bolting, bottle, bout, box, bucket, bunch, bundle, burden, cabot, cade, canter, caroteel, carriage, cart, cartload, case, cast, cheef, chest, clue, cord, corf, cran, cranock, cut, cyvar, cyvelin, daugh, dish, dole, drop, dupper, erw, faggot, fall, fan, flask, fodder, fotmal, frazil, garb, gaun, glean, gunny, gwaith-gwr, hank, head, heap, hide, hobed, hoop, hutch, hyle, incast, ingrain, jar, jug, keel, kemple, kenning, kibin, kishon, kiver, knot, lay, leap, lispound, llath, llathen gyvelin, llestraid, lug, maen, maise, mark, mast, math, measure, meer, meiliaid, merk, mount, mug, oxland, pack, packet, paladr, pared, peccaid, peget, piece, pig, plough land, pocket, poke, pot, pwys, quintal, reel, rees, rhaw, ridge, role, rope, roul, sack, saume, sester, sieve, skain, skin, skron, sleek, spindle, square, stacca, stack, staff, stang, stick, stimpart, stook, stored, sum, table, talshide, tankard, teal, thrave, thread, threave, timber, topston, truss, tub, tunnell, vergée, vragina, waggon-load, wain, warp, web, weight, and windle.

The old Scottish measures vary even more in the different counties than the English. The standard foot was 12·0194 English inches, 3 feet 1 inch make an ell, 6 ells a fall, 40 falls a furlong, and 8 furlongs a mile (1976¼ yards). Again, 40 square falls make a rood, and 4 roods an acre. Hence the measures of length and surface are so connected that the Scottish land-chain is the 80th part of a mile, and its square the 10th part of an acre.

In Scotland, the English troy and averdupois weight obtained an early introduction, and were used with the Scottish troy weight, called also Dutch weight, and with the tron weight. The Dutch weight is as follows:—A drop is 29·722 English troy grains, 16 drops are an ounce, 16 ounces a pound (7608·95 grains), and 16 pounds a stone. This pound coincides with the old English pound already mentioned, very nearly. In the tron weight the divisions are as before; but the drop is 37·588 English troy grains, and the pound 9622·67 of the same.

The Scottish liquid gallon was 833·6272 English cubic inches. Four gills made a mutchkin, 2 mutchkins a chopin, 2 chopins a pint, and 8 pints a gallon. The Scottish pint was therefore 3 English pints very nearly. They had only one liquid measure, but they had two dry measures; the first for wheat, peas, beans, &c.; the second for barley and oats. In the first the peck contained 553·581 English cubic inches. Four lippies made a peck, 4 pecks a firlot, 4 firlots a boll, and 16 bolls a chalder. The second measure was divided in the same way, but the peck was 807·576 English cubic inches.*

On the Irish measures, previous to the introduction of the imperial system, there is nothing to remark, except that the coal bushel contained 10 English corn gallons, the lime bushel 8, the malt† gallon 272¼ cubic inches, and the liquid gallon 217·6 cubic inches. The pole was 7 yards, which made the mile equal to an English mile and three-elevenths, and the acre greater than the English acre in the proportion of 121 to 196.

We have not space to enter into the ancient history of French measures, for which the reader‡ may consult Paucton's 'Métrologie,'

* This word has been preserved as a measure of glass.

† For wine and spirits, cider, mead, oil, honey, vinegar.

‡ According to Mellis, the butt was a name applied only to half-tuns of malmsey or sack.

§ The reader would look in vain for any notice of this in books of arithmetic. Perhaps the statute was not attended to. The distinction of the ale and beer firkin is said by Ward to have existed only in London, an average firkin of 8½ gallons having been enacted for all other parts of England by the statute of Excise of 1689. But it does not follow, in matters of weight and measure, that any change was actually produced merely because there was an Act of Parliament for it.

‖ It was abolished in Scotland two centuries ago, and re-enacted by neglect in the act of 1825. But the re-enactment did not obtain for it the slightest introduction, according to M'Culloch.

¶ According to the old adage, the hundred was—

"Five score of men, money, and pins,
Six score of all other things."

And the real hundred, ten tens, was the *little* hundred; as in the old rhyme—

"One's none,
Two's some,
Three's a many,
Four's a penny,
Five's a little hundred" [*score* understood].

* Our authority for the Scottish measures is 'Tables for converting the weights and measures hitherto in use in Great Britain into those of the Imperial Standards, &c., also abstracts of the jury verdicts throughout Scotland,' &c., by George Buchanan, Civil Engineer, Edinburgh, 1829. This work is as complete as a work can be: the reader may compare it with 'A proposal for the Uniformity of Weights and Measures in Scotland,' &c., second edition, Edinburgh, 1789.

† This was the old Winchester gallon, already mentioned.

‡ On this work, that of Romé de L'Isle (1789) and the anonymous 'Métrologies Constitutionelles et Primitives' (1801), it may be observed that they are all vitiated by the assumption that a very accurate knowledge of the earth's diameter anciently existed, from which all weights and measures, even those anterior to Greek and Roman times, were derived. Greaves had led the way by finding out English weights and measures from the Egyptian pyramid. All particular pursuits have their peculiarities: that of the metrologists has been to imagine some grand and mysterious connection between existing measures

Paris, 1780. On the measurement of the earth on which the metre depends, see TRIGONOMETRICAL SURVEY. The system of measures derived from this great operation was introduced in 1795 (by the law of 18 Germinal, An III., or, to speak intelligibly, March, 1795): not that the survey was then completed, but because, in the hurry to get rid of the old system, it was decided to introduce a "mètre provisoire" obtained from the existing surveys. The definitive metrical system was introduced in 1799, but it was found impossible to drive out the old subdivisions; accordingly, in 1812, the "système usuel." as it was called, was allowed* to be engrafted upon the metrical system; in which the measures, &c., were taken from the metrical system, but with the ancient subdivisions adapted to them. Even this was very far from entirely driving out the old system. In 1837 a law was passed ordaining that from and after the 1st of January, 1840, no other weights nor measures should be used except those of the pure metrical system, and this law seems to have been effective. In the ancient French system the *pied de Roi* was 12·7892 English inches, the aune (at Paris) 46·85 of the same. The toise was 6 feet. For the itinerary measures see MILE. The *arpent d'ordonnance* was 1 acre, 1 rood, 2 perches (English); the *arpent commun* 1 acre, 7 perches, the *arpent de Paris* 3 roods, 15 perches, English. The *acre de Normandie* was 2 acres, 2 perches, English. For measuring liquids, the pinte was less than the English quart by its 61st part. Two boissons made a demi-setier, 2 demisetiers a chopine, 2 chopines a pinte, 2 pintes a quarte, 4 quartes a setier, 36 setiers a muid (70·8 English gallons). For grain, 16 litrons made a boisseau, 3 boisseaux a minot, 2 minots a mine, 2 mines a setier, 12 setiers a muid. The minot was 1·108 English bushels. The principal weight, called *poids de marc*, was the livre of 9216 French grains, or 7555 English grains; 72 grains made one gros, 8 gros an ounce, 8 ounces a marc, 2 marcs a livre. The apothecaries divided the ounce into 2 duelles, the duelle into 4 sciliques, and also into 6 sextules and into 8 drachms, the drachm into 3 scruples, and therefore the scruple into 12 grains.

The new system is called metrical, as derived from the measurement of the earth. Its first measure, the metre, is presumed to be the ten-millionth part of a line drawn from the pole to the equator, and is 39·37079 English inches. All the multiples and subdivisions of every measure are decimal, and are formed by the same prefixes. For 10, 100, 1000, and 10,000, the syllables *Deca*, *Hecto*, *Kilo*, and *Myria* are prefixed; and for tenths, hundredths, thousandths, the syllables *Deci*, *Centi*, *Milli*. Latin† prefixes indicate division, Greek prefixes multiplication. Thus the hectometre is 100 metres, and the centimetre the hundredth part of a metre. The metre being thus settled, the other fundamental measures are formed as follows:—For surface or area, the *Are*, which is a decametre square, or 100 square metres, or ·02471143 of an English acre, or 3·9538 English perches.

For solidity, the *stere*, or cubic meter, 35·32 cubic feet English, or 220·09687 imperial gallons English.

For liquid measures, the *litre*, or cubic decimetre, ·22009687 of an imperial gallon, or a very little more than a pint and three-quarters English.

For weight, the *gramme*, a cubic centimetre of distilled water at the freezing-point, ·00220606 of an English pound averdupois, or 15·442 grains‡ English. The kilogramme is threfore 2·2 pounds averdupois, or, roughly, 50 kilogrammes make a hundredweight. The franc, the unit of money, is divided into 10 decimes, and each decime into 10 centimes. The sous is therefore 5 centimes. The advantage of the whole system, *when established*, is so great, that all who are fully aware of it, long for the introduction of a similar one into our own country. A Frenchman, when told that a kilogramme costs 253 francs 74 centimes, sees at once that a gramme costs 25 centimes and $\frac{374}{1000}$ths of a centime. An Englishman, wanting to know the price of an ounce when a hundredweight costs 253*l.* 14*s.* 10*d.*, must go through the whole of the following process:—

```
 112              253l. 14s. 10d.
   8                 20
 ---
 896        1792)5074(2
   2             3584
 ----            ----
1792             1490
                   12
            1792)17890(10
```

to get 2*s.* 10*d.* the answer.

The *système usuel*, now abolished, was as follows, the divisions being those of the old system. The toise was 2 metres, and the foot its sixth part. The aune was 3 feet 11¼ inches English. The boisseau was one-eighth of the hectolitre: the litron was 1·074 Paris pintes. The livre was 500 grammes. The arpent was that of the old system.

It is not in our limits to give a complete list of the weights and measures of foreign* countries. We have selected accordingly a num- ber of places from the smaller works on exchange operations, pre- that the best choice we can make is that which includes the important countries or spots which have large money-dealings with own country. All the weights, &c. named have been taken† i places from Kelly's 'Cambist.' All the English measures are imperial (the gallons being reduced by ourselves into imperial g and each measure is given in English measures.

Austria.—The metrical system is introduced in the Itali minions. In Austria Proper, gold and silver are weighed Vienna marc of 4333 grains. The pfund is 1·235 pounds aver the metzen is 1·691 bushels. The eimer is 12·444 gallons. is 12·45 inches: the ell, 30·66 inches. The joch is 1 acre, 1 perches.

Bavaria.—The Augsburg marc is 3643 grains; 24 lb. com weight is 25 lb. averdupois; and 24 lb. carriers' weight is dupois, nearly. The metzen is 1·515 bushels; the fuder (16 31·24 bushels. The foot (half the short ell) is 11·667 inches long ell is 24 inches.

Bremen.—For gold and silver, as at Hamburg. The com pound is 1·098 pounds averdupois. The last is 78·217 bushels ohm is 31·562 gallons. The foot, or half-ell, is 11·38 inches.

Colonies.—Follow in general the weights and measures of the country, except where they have passed under other governme which case there is usually a mixture of the two.

Constantinople.—The chequee is 4957 grains. The oke is pounds averdupois. The killow (dry) is 7·296 gallons. The 1·150 gallons. The pike is 27 inches. The measures of Tur very imperfectly known.

Denmark.—The pound for gold and silver is 7266 grains. commercial pound is 1·1028 pounds averdupois. The barrel is bushels. The viertel is 1·701 gallons. The foot, or half-ell Rhineland foot of 12·356 English inches. The toende of 5⅓ acres.

Florence and Leghorn.—The cantaro is 150 pounds of ·74864 p averdupois each. The stajo is ·6702 bushel. The barile is gallons. The braccio is 22·98 English inches. The saccata is 1 36 perches.

Frankfort.—For gold and silver, the Cologne marc. The com pound is 1·03 pounds averdupois. The centner is 112·25 pounds dupois. The malter is 2·9705 bushels. The ohm is 32·454 g The foot is 11·27 inches; the ell, 21·24 inches.

Geneva.—The mark is 3785 grains. The *poids fort* is 1·214 averdupois; the *poids foible* one-sixth less. The coupe is bushels. The setier is 99·53 gallons. The foot is 19·2 inches. acre is 1 acre, 1 rood, 4 perches.

Genoa.—The pound *sottile* for gold and silver is 4891·5 grains. pound *grosso* is ·76875 pounds averdupois. The mina is 3·321 bus The mezzarola is 32·57 gallons. The palmo is 9·725 inches.

Hamburg.—The Cologne marc is 3608 grains. The pound two marcs. The commercial pound is 1·068 pounds averdupois. last of wheat (30 scheffels) is 10·9 quarters; the ahm is 31·85 g The foot is 11·289 inches. The scheffel (quantity usually sown a scheffel) of land is 1 acre 6 perches.

Holland.—The marc is 3798 grains. The pound is two marcs; the commercial pound is 1·0893 pounds averdupois. The last (vari divided) is 10·231 quarters. The aam (256 pints) is 34·16 gall The Rhineland foot is 12·36 inches. There are several ells of 27 inches. The Rhineland perch is 12 Rhineland feet, and the Rhine land morgen or acre is 2 acres 16 perches.

Ionian Islands.—The weights and measures are mostly Venetian and Turkish.

Lübeck.—For gold and silver, as at Hamburg. The commercial pound is 1·0685 pounds averdupois. The scheffel is ·92 bushels. The ahm is 31·85 gallons. The foot, or half-ell, is 11·346 inches.

Malta.—The pound for gold and silver is 4886 grains. The commer- cial pound is 1·745 pounds averdupois. The salma is 7·968 bushels The foot is 11·167 inches. The canna (8 palmi) is 81·9 inches.

Milan.—The mark is 3627 grains. The pound *sottile* is ·7206 pounds averdupois; the pound *grosso* is 1·682 pounds averdupois. The mo (32 quartari) is 4·0234 bushels. The brenta (12 quartari) is 15 gallons. The braccio is 23·42 inches. The metrical system is als introduced, with Italian names.

Naples.—The pound for gold and silver is 4950 grains. The cantaro *grosso* is 196·5 pounds averdupois, the cantaro *piccolo* 106 pounds aver- dupois. The tomolo is 1·407 bushels. The barile is 9·172 gallons The palmo is 10·38 inches. The moggio is 3 roods 12 perches.

Netherlands.—Since 1820 the French metrical system has been in use, with Flemish names.

Portugal.—The marc is 3541·5 grains. The commercial pound is

and a body of science which they say has been forgotten, but which they have never shown to have had existence.

* In 1816 it was enforced, decimal division being prohibited in retail business.

† The Latin prefixes suit the French language well enough: the Greek ones are incongruous and unsightly. Nor has the system been kept to entirely; the centigrade thermometer ought to have been *hectograde*.

‡ Dr. Kelly ('Cambist,' i. 141) makes it 15·434 grains, for which he gives reasons.

* There is a large list of the fundamental measures of length, which are those most wanted, in 'Table of Continental Lineal and Square Measures,' by W. Woolhouse (London, Weale, 1836).

† We find the weights, &c., in the works from which the list of places was taken, rather different from those in Dr. Kelly's work. But the latter work is the best authority, and nothing but evidence can alter any weight or measure given in it. When a standard work exists in any language, it is absurd in any second-rate writer to differ from it without stating why.

1·0119 pounds averdupois. The moyo is 22·39 bushels. The almude is 3·6407 gallons. The foot is 12·944 inches.

Prussia.—(New system, established 1816.) The Cologne* marc is 3609 grains. Two marcs are a commercial pound, or 1·0811 pounds averdupois. The scheffel is 1·5116 bushels. The eimer is 15·11 gallons. The foot is 12·356 inches; the ell, two-thirds of a metre. The morgen, or acre, is 2 roods 21 perches.

Rome.—The pound is 5234 grains, or ·7477 pound averdupois. The rubbio (4 quarte) is 8·1012 bushels. The barile (32 boccali) is 12·841 gallons. The foot is 11·72 inches. The builders' canna, of 10 palms, is 87·96 inches.

Russia.—There is but one pound, ·9026 of a pound averdupois. The pood is 36 lb. averdupois. The chertwert is 5·7698 bushels. The vedro is 2·7048 gallons. The inch is the English one; the arshine is 28 inches; the foot is 13¾ inches; but the English foot is in common use. The dessetina is 2 acres, 2 roods, 32 perches.

Saxony.—For gold and silver, the Cologne marc. The commercial pound is 1·0294 lb. averdupois. The Dresden wispel (24 scheffels) is 69·85 bushels; the Leipzic wispel, 91·747 bushels. The Dresden eimer is 14·89 gallons; the Leipzic eimer 16·75 gallons. The Dresden foot is 11·14 inches; the Leipzic foot is 11·13 inches. The acre is 1 acre, 1 rood, 18 perches.

Sicily.—The pound is 7 pounds averdupois. The cantaro grosso is 192·5 pounds averdupois; the cantaro sottile is 175 lb. averdupois. The salma grossa is 9·46 bushels; the salma generale 7·59 bushels. The salma of wine is 19·23 litres. The palmo is 9·5 inches.

Smyrna.—The chequee is 4958 grains. The rottolo is 1·2748 pounds averdupois. The killow is 11·3 gallons. The pike is 27 inches.

Spain.—The Castilian marc for gold and silver is 4800 grains. The commercial pound is 1·0144 pounds averdupois. The fanega is 1·55 bushels. The arroba of wine is 3·538 gallons. The foot is 11·128 inches: the vara is 33·384 inches. The fanegada (for corn-land) is 1 acre, 21 perches.

Sweden.—The Mint marc is 3252 grains. The commercial pound is ·9376 lb. averdupois. The dry tunna is 4·028 bushels; the liquid tunna is 48 kanns of ·5756 gallons each. The foot, or half-ell, is 11·684 inches. The tunneland is 1 acre, 35 perches.

United States.—The weights and measures are those of England before the late alterations.

Venice—The marc for gold and silver is 3681·5 grains. The pound *peso grosso* is 1·0518 lb. averdupois. The pound *peso sottile* is ·664 pound averdupois. The stajo is 2·2 bushels. The anfora is 114·1 gallons. The braccio for woollen is 26·61 inches; for silk, 24·8 inches. The foot is 13·68 inches.

We now proceed to the weights and measures of the ancients, taking first the relations of the various denominations to one another, and afterwards the fundamental comparisons of their values with the modern weights and measures.

The Romans had a mode of dividing the as or libra which they transferred upon occasion to any unit. The whole, whether an as or anything else, consisted of twelve unciæ, so that the uncia became little more than a name for the twelfth part. The division stood thus—

1½	unciæ was	Sescuncia, or Sescunx.
2	„	Sextans (a sixth).
3	„	Quadrans (a fourth), or Teruncius.
4	„	Triens (a third).
5	„	Quincunx.
6	„	Semis, or Semissis (a half).
7	„	Septunx.
8	„	Bes, or Bessis.
9	„	Dodrans.
10	„	Dextans, or Decuncis.
11	„	Deunx.

The libra of weight was thus subdivided:—3 siliquæ, one obolus; 2 oboli, one scrupulum; 4 scrupula, one sextula; 6 scrupula, one sicilicus; 8 scrupula, one duella; 3 duellæ, one uncia; 12 unciæ, one libra. In later times the uncia was divided into 8 drachmæ of 3 scrupula each. This mode of dividing an integer into 288 scrupula runs through other branches of their system, and is also used in subdivision of a unit. The obolus in the preceding system rather belongs to a later period in which the Greek divisions were introduced, the ounce being made 8 drachmæ of 3 scrupula or 6 oboli each. The uncia appears (as *οὐγγία*) in the later Greek writers.

In the measures of length the pes, or foot, was divided not only into 12 unciæ, but also into 16 digiti. In such Roman foot-rules as have been found, all have the digital division, some both, but none the uncial without the digital. And 4 digiti are one palmus; 4 palmi, one pes; 1¼ pedes, one palmipes; 1½ pedes, one cubitus; 2½ pedes, one gradus; 2 gradus, or 5 pedes, one passus; 2 passus, one decempeda; 12 decempedæ, one actus;† 1000 passus, one milliare.

. The jugerum was an area of which the scrupulum (or 288th part) was the square decempeda, or 100 square feet. It was frequently divided uncially, and also as follows:—36 scrupula made 1 clima, 4 climata, 1 actus quadratus; 2 actus quadrati, 1 jugerum; 2 jugera, 1 heredium; 100 heredia, 1 centuria; 4 centuriæ, 1 saltus. The actus minimus was 480 square feet. The versus was 10,000 square feet. The aripennis (whence *arpent*) was a Gallic measure which Columella defines as semi-jugerum, but whether of Romans or Gauls is not clear.

The amphora, or quadrantal,* for liquid measure, was a cubic foot: 4 ligulæ made 1 cyathus; 6 ligulæ, 1 acetabulum; 2 acetabula, 1 quartarius; 2 quartarii, 1 hemina; 2 heminæ, 1 sextarius; 6 sextarii, 1 congius; 4 congii, 1 urna; 2 urnæ, 1 amphora; 20 amphoræ, 1 culeus. In Galen the cochleare is the tenth of a ligula.

The modius, or modium, of dry measure, was 16 sextarii, or the third part of the amphora, or cubic foot. The sextarius was divided in the same manner as in liquid measure. The concha is mentioned as a smaller measure than the ligula.

The Greek weights have been discussed in the article TALENT. Six *ὀβολοι* make one *δραχμη*; 100 *δραχμαι*, one *μνα* (mina); 60 *μναι*, one *ταλαντον*. The *χαλκος* and the *λεπτον* are mentioned as subdivisions of the *ὀβολος*, but are not generally recognised.

As to length, the *πους*, or foot, was thus divided:—4 *δακτυλοι* make one *παλαιστη*; 12 *δακτυλοι*, one *σπιθαμη*; 4 *παλαισται*, one *πους*; 1½ *ποδες*, one *πηχυς*; 4 *πηχεις*, one *ὀργυια*; 100 *ποδες*, one *πλεθρον*; 6 *πλεθρα*, or 600 *ποδες*, one *σταδιον*. [STADIUM.] The *δοχμη* is the *παλαιστη* in some writers, the *σπιθαμη* in others. The *παλαιστη* is also called *δακτυλοδοχμη* and *δωρον*. The *λιχας* is 10 *δακτυλοι*, the *ὀρθοδωρον* is 11 *δακτυλοι*, the *πυγμη* 18, and the *πυγων* 20 *δακτυλοι*. The *διχας* is half a *πους*, the *βημα* is 2½ *ποδες*. The *ξυλον* is 4½ *ποδες*, and the *καλαμος* 10 *ποδες*. The *σταδιον* was once called *αὐλος*, and the *διαυλος* is 2 *σταδια*. The *σταδιον ἱππικον* is 4 *σταδια*, and the *δολιχος* is 12 *σταδια* generally, but is variously used. We must also mention the *κονδυλος* of 2 *δακτυλοι*, and the *ἁμμα* of 60 *ποδες*. The Greeks have taken the *σχοινος* (variously described) from the Egyptians, the *μιλιον* from the Romans, and the *παρυσαγγης*, which is 30 stadia, according to Herodotus and Xenophon, from the Persians. The *πους φιλεταιριος*, or Philetærian foot, though used by Greek writers, is not originally Greek, and is said to be longer by a fifth than the Roman foot. All writers agree that the common Greek *πους* is longer than the Roman foot by the 24th part of the latter.

The *πλεθρον* in square measure was a square of the side of a *πλεθρον* in length, or 10,000 square *ποδες*. The *ἀρουρα* was the fourth part of the *πλεθρον*; but the Egyptian *ἄρουρα* mentioned by Herodotus is the square of 100 Egyptian cubits.

In liquid measure, 2 *κοχλιαρια* make one *χημη*; 2½ *κοχλιαρια*, one *μυστρον*; 2 *μυστρα*, one *κογχη*; 2 *κογχαι*, one *κυαθος*; 3 *κογχαι*, one *ὀξυβαφον*; 2 *ὀξυβαφα*, one *τεταρτον*; 2 *τεταρτα*, one *κοτυλη*; 2 *κοτυλαι*, one *ξεστης*; 6 *ξεσται*, one *χους*; 12 *χοες*, one *μετρητης*. The *μετρητης* is said to have been an amphora and a half, and the *κυαθος* to have contained 10 drachms of wine. The *λαγυνος*, or *λαγηνος*, was the same as the *χους*. There were also the *χημη γεωργικη* and the *μυστρον γεωργικον*, rural measures. The *μετρητης* was also called *ἀμφορευς* and *καδος*.

In dry measures, the *μεδιμνος* was one-third larger than the *μετρητης* (or was two Roman amphoræ), and was thus divided:—Ten *κοχλιαρια* made one *κυαθος*; 15 *κοχλιαρια*, one *ὀξυβαφον*; 4 *ὀξυβαφα*, one *κοτυλη*; 2 *κοτυλαι*, one *ξεστης*; 2 *ξεσται*, one *χοινιξ*; 4 *χοινικες*, one *ἡμιεκτον*; 2 *ἡμιεκτα*, one *ἑκτος*; 6 *ἑκτοι*, one *μεδιμνος*. There are various descriptions of the *χοινιξ*, from which it may be that there are several measures of the name. The Greeks mention the Persian *ἀχανη* of 45 *μεδιμνοι*, the *ἀρταβη*, of one *μεδιμνος*, and the *καπιθη* of 2 *χοινικες*. The Bœotian *κοφινος* is 3 *χοες*: the Homeric *ἀδδιξ* is 4 *χοινικες*; the *μαρις* is 6 *κοτυλαι*; the *ἀλαβαστρον*† is the *κοτυλη*.

The following measures are identical in pairs, if the *μεδιμνος* be two amphoræ:—The *χους* and the congius; the *ξεστης* and the sextarius; the *κοτυλη* and the hemina; the *τεταρτον* and the quartarius; the *ὀξυβαφον* and the acetabulum; the *κυαθος* and the cyathus.

All the Greek measures above given are Attic: there are some variations of description which, if not erroneous, probably belong to other parts of Greece. It is customary to give the Greek and Roman measures in two collections, without any attempt to distinguish the times at which they were in use; so that Homer and Athenæus, or Herodotus and Galen, may appear as authorities in the same set. There are many other names of measures noted by different writers, some of which are but synonymes of some of those above mentioned, and of others it may be doubted whether they were really names of recognised measures. If the writers of our day were compared in isolated passages as closely as those of the ancients, we might probably have a great many measures made for us of which we know nothing: the shells which the grocers use would have good chance of a permanent establishment, and their paper bags could not possibly escape.

The Hebrew measures, though tolerably well settled in their proportions, are very imperfectly known as to their absolute magnitudes.

* This weight, established by Charles V. as the standard of the precious metals throughout Germany, has varied in different places from 3606 to 3612 grains.

† The actus is described as the length of a furrow. If our furlong had been (as some would suppose) a furrow long, it would have been nearer to the Roman actus, not one-eighth of a mile.

* The term quadratus seems to have applied to cubes as well as squares among the Romans.

† This word is translated in two of the gospels (Mark xiv. 3; Luke vii. 37) *an alabaster box*; Epiphanius is the authority for the measure, which there is no doubt took its rise from the circumstance of perfumes being commonly inclosed in alabaster boxes of one size.

We shall only give here the usual summary, and shall then give some account of the mode of determining the actual magnitude of the Greek and Roman measures. With regard to these Hebrew measures, much uncertainty prevails; the authorities are by no means so numerous as those for the other ancient measures, nor has the subject received so much discussion.

The cubic was about 22 inches; 4 digits make 1 palm; 3 palms, 1 span; 2 spans, 1 cubit; 4 cubits, 1 fathom; 6 cubits, 1 reed (Kaneh); 8 cubits, 1 pole (Arabian); 80 cubits, 1 measuring-line;* 400 cubits 1 stadium; 5 stadia, a Sabbath-day's journey; 10 stadia, a mile; 24 miles, a day's journey.

In liquid measures, the bath, or ephah, of about 6¼ imperial gallons, is thus divided:—Four logs make 1 cab, 3 cabs, 1 hin; 2 hins, 1 seah; 3 seahs, 1 ephah. The caph is three-fourths of the log. For dry measures, besides the cab, seah, and ephah, 5 ephahs make 1 letech; 2 letech, 1 Chomer, or Homer. The gomer is the tenth of the seah.

For weight, 60 shekels make one maneh; 50 maneh, 1 talent of 93·75 pounds averdupois.

We now come to the comparison of the Greek and Roman measures with our own. The Roman foot, the most important of all, has been determined in the following † ways:—1. By feet laid down on sepulchral monuments. 2. By foot-rules obtained in the ruins of Rome and elsewhere. 3. By the distance of mile-stones. 4. By the distance of places. 5. By specimens of the congius. 6. By some obelisks. 7. By the dimensions of buildings. The results are given in lines of 144 to the Parisian foot, and as many dissertations on this subject make great use of the line, it will be convenient to give a table of its multiples in terms of the English inch.

One line ($\frac{1}{12}$ inch French) is	·08881378	English inch.
2 lines are	·17762756	"
3 "	·26644134	"
4 "	·35525512	"
5 "	·44406890	"
6 "	·53288268	"
7 "	·62169646	"
8 "	·71051024	"
9 "	·79932402	"

129·484 lines are 11½ English inches.

The *sepulchral* feet are:—1. That marked on the tomb of one Statilius,‡ found in the Vatican garden in the 16th century; 2. That found on the tomb of Cneius Cossutius (Vitruvius mentions an architect of that name), dug up in the garden of Angelo Colozzi § before 1516; 3. That on the tomb of M. Æbutius; 4. That on a monument without inscription, given by the Marquis Capponi to the Capitoline Museum at Rome. Taking the means of such trustworthy measures as have been made of these different feet, it appears that the Statilian foot is 131·17 Paris lines; the Cossutian, or Colotian, 130·59 lines; the Æbutian 131·14 lines; and the Capponian 130·80 lines.

The first foot-rule was measured by Lucas Pætus, 'De Mensuris et Ponderibus Romanis et Græcis,' Venice, 1573, who found three of them agreeing with each other so far as his means of comparing them went, a copy of which he caused to be engraved on stone and placed in the Capitoline Museum. This was called the *Capitoline foot*, and was frequently regarded as conclusive. Pætus himself makes the foot amount to 128·7 lines; but there is reason to suppose either that his measures are too short or that the standard to which he referred them has been mistaken; for others make his own Capitoline foot to be 130·5 lines. Two other foot-rules give 128·75 and 130·03 lines. There was a porphyry column at Rome (now lost) marked *ποδ. θ*, which was certainly meant for nine Roman feet. An editor of Vitruvius, Philander (1552), makes the Roman foot to be, from this column, 131·63 lines; but Pætus makes it only 130·03. Other foot-rules have been made to give 130·5, 130·93, 132·89, 130·56, 129·24, 131·16, 130·66. Some of these are different measures of the same rule.

Very few consecutive milestones have been found from which to deduce the foot. From one mile in the Appian way, and from two different ones between Nismes and Beaucaire, the foot has been deduced to be 130·60, 130·29, and 130·51 lines. From various recorded distances between towns, subject to the difficulty of knowing precisely from what parts of them the miles were measured, the foot has been found to be 132·34, 128·42, 130·99, 129·31, 132·55 lines. D'Anville, from a collection of such measures, fixes it at 130·8 lines.

A specimen of the congius is yet remaining, which, by an inscription, is declared to have been placed in the Capitol by Vespasian as a standard. The congius is the eighth part of the amphora, or cubic foot. By ascertaining the weight of water which this contains, the foot was estimated by various observers at 131·15, 133·21, and 132·44 lines. From the length of the foot drawn upon the congius [illegible] been obtained 132·8, 133·5 lines. From another congius [illegible] Paris, Auzout found 134·18 lines for the Roman foot.

There are two obelisks at Rome, which were brought by [illegible] from Heliopolis. Pliny gives the height of these in feet, or [illegible] the height of the higher and the defect of the lower from it. [illegible] ment proves that, with respect to the higher, the number [illegible] must be corrupt; but from his difference between the two, [illegible] pared with the measured difference, the Roman foot is 137·19 lines.

The method of ascertaining the foot by buildings is as [illegible] Any remarkable length, such as that of the whole front of a [illegible] being known nearly in Roman feet, is presumed to be exactly [illegible] number of feet which it must be nearly. This supposes the Roman architects were in the habit of choosing exact numbers [illegible] when there was no particular reason for breaking a foot. [illegible] ('Phil. Trans.,' 1760) proceeds in the manner of which the [illegible] is an instance:—He finds the distances between the columns [illegible] the temple of *Fortuna virilis* to be 9·7106 English feet. If [illegible] an exact number of Roman feet, it must be 10; we know [illegible] beforehand of the Roman foot to say it cannot be 9 or 11. [illegible] quently, if the distance between these columns be a whole number [illegible] feet, the foot must be ·97106 of the English foot. By [illegible] this sort, Greaves found 131·50 lines, La Hire 131·0 and [illegible] Condamine 130·9, Jacquier 131·08 and 131·14. Raper, who went [illegible] into this subject than the others, found by different buildings [illegible] 131·60, 131·62, 131·11, 131·16, 131·05, 131·16, 131·05, and 131[illegible] the mean. Wurm, from the Verona amphitheatre, adds [illegible] Raper thought he observed that the buildings subsequent to the [illegible] of Titus give a shorter foot than their predecessors: from instances [illegible] gets 130·75, 130·33, 130·34, with a mean of 130·34. He refers [illegible] change to the destruction of the Capitol (where the standards were kept) in the time of Vitellius.

From all these data Raper's average, adopted by Wurm, is [illegible] French lines for the ancient foot, or 11·648 English inches or [illegible] English feet. But Sir G. Shuckburgh made a careful review of [illegible] three best modes of obtaining the required result, namely, rules, buildings, and tombs, and obtained ·9672, ·9681, ·9696 of a foot English (Young's 'Lectures,' ii. 153.) The mean of these is ·9683 feet, or 11·6196 inches. Again, if we take a mean of the results given [illegible] others, namely, Bernard ·970, Picard and Greaves ·967, Folkes [illegible] Raper ·970, we have also ·9683. We take then the Roman foot at 11·62 English inches, which is represented far within the probable limits of error by the following:—61 English feet make 63 Roman feet. We are well aware that eminent authorities of late years prefer 11·65 inches for the Roman foot, but we like to keep as near to the foot-rules as we can, consistently with giving due weight to other modes. Indeed, the question between 11·62 and 11·65 cannot be settled by authority, but must be decided by closer appreciation than has yet been made of the probabilities of the different methods.

The Roman measures of length may thus be considered, we fully believe, to be as well known to us as they were to themselves. The same cannot be said of the measures of weight. All writers agree that the amphora, or cubic foot, weighs 80 pounds of wine; but it is also said that they considered wine to be of the same weight as water. We have no means of ascertaining the specific gravities of their wines; those of our own vary from ·99 to 1·04, water being taken as 1. But there is one very obvious consideration which, we believe, has escaped notice. No metrologist has given the Romans credit for seeing that water would do just as well to make comparisons and adjust standards by, as wine, believing, as they did, that both are of the same weight. If we suppose then that they preferred to spill water rather than wine, and assume 11·62 inches for the foot, we have 1568·984 cubic inches* English, in the amphora, or 5·6586 imperial gallons, or 56·586 pounds averdupois of water. If the Roman pound be the 80th part of this, it is ·7073 pounds averdupois, or ·8595 pounds troy. This is 4951 grains, or 6039¼ French grains. Now, according to Wurm, Budæus made it 7200 French grains, Capellus and Romé de L'Isle 6048, Auzout 6226, Eisenschmid 6216, Dupuis 6300, Leblanc and De la Nauze 6144, Paucton 6312, Arbuthnot 6395. Of these, those of Romé de L'Isle and La Nauze, which come the nearest to 6039¼, were determined from weighing coins: but the most modern valuations deduced from coins give 5040 grains. On coins however we do not much rely. The congius of Vespasian, already mentioned, gave to different experimenters 6094, 6386, and 6276 Paris grains; but it is most probable that the capacity of this vessel has been somewhat increased by rust. There are also some ancient weights in stone or metal, preserved in different places, from which De L'Isle brings out 6071 and 6042 grains. But others make different results, whether from the coins or the weights; and the result of the whole seems to be, that the Roman pound cannot be more accurately stated than in the following words: "something more than seven-tenths of a pound averdupois." The Attic TALENT is said by many writers to be 80 Roman pounds. Now this being taken, as in the article cited, at 56·953 pounds averdupois, gives ·7119 of a pound averdupois. Between ·707 and ·712, or very

* Pathil, or Chebel; σχοινος in the Septuagint.

† In the historical account of the Roman foot we have followed J. P. Wurm, 'De Ponderum, &c. Rationibus apud Romanos et Græcos,' Stutgard, 1821, as to method, verifying several of his statements.

‡ We enumerate these, not for their importance, but because they are so frequently referred to.

§ The foot is figured in the work of Leonardus Portius, the first in which any attempt was made to restore the real Roman measures. It has no place nor date; but being printed by Joh. Frobenius, must be of Basel before 1527.

* To turn cubic inches into imperial gallons, multiply by 11 and by 2, divide by 6100, and, if worth while, from the result subtract its two hundred thousandth part.

near to one of these extremes, we have little doubt the truth really lies. Accordingly, the Roman uncia is much nearer to our ounce averdupois than to our ounce troy; and many metrologists have supposed that the former was originally the uncia.

We have never had any means of knowing whether the fundamental points of connection between the Greek and Roman measures are exact or only approximate. These are, that the foot is longer than the Roman by one twenty-fourth, and the Philetærian foot by one-fifth; that the μετρητης is an amphora and a half, and that the amphora of water or wine weighs an attic talent. Taking these relations for granted, we have for the Greek foot 12·10 English inches or 1·008 feet, for the Philetærian foot 13·94 inches, for the metretes 8·4879 gallons, and for the attic talent 56·586 pounds averdupois. There is one stadium left at Athens [STADIUM] which is 630 English feet, giving for the Greek foot 1·05 feet English; but there is not much dependence to be placed on the measure. Such buildings as have been examined at Athens, in the manner already described, give as a mean 136·69 Paris lines, or 12·14 English inches. We may therefore say that the Greek foot was longer than the English one by the tenth part of an inch. The statements then as to the relations between the Greek and Roman measures appear to have been tolerably exact, and our knowledge of the relations between our measures and theirs, though not sufficient for scientific comparison, is abundantly exact for the purposes of the classical student, far more so than could have been expected to have been attainable by those who remember that for a long period all means of comparison were lost.*

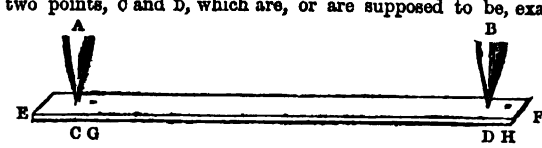
WEIGHTS AND MEASURES, STANDARD. In this article we separate from the general subject of WEIGHTS AND MEASURES those preliminary considerations which refer to the manner in which weights and measures are verified and preserved, so far as they can be entered upon in a work partly of reference, partly of general information. We do not pretend to complete a scientific account, but shall be satisfied with preparing the unpractised reader to look with some degree of interest on the sources of more elaborate information to which we shall refer.

Measures are wanted for two distinct objects, the commercial and the scientific. The wants of natural philosophy have grown up within the last two centuries; while so early as Magna Charta it was one of the concessions to the grievances of the subject that there should be one weight and one measure throughout the land. But though a few acts of parliament were sufficient, in process of time, substantially to establish the political rights which that charter was intended to grant, hundreds of them, down to the present time, have been ineffectual in producing the use of one weight and one measure. Some of these we shall afterwards refer to [WEIGHTS, &c.]; in the meanwhile we have here only to state that, as may be supposed, this unity was for commercial, not scientific purposes; and that the resemblance of natural objects was supposed to be a sufficient reliance for obtaining it. Some of the old statutes expressly make the inch to be the length of three barleycorns, placed end to end, round and dry, from the middle of the ear. Standards were made, no doubt, from this definition; or at least it was supposed that if the existing standard should be lost, the barleycorns would enable its restoration to be effected. Our readers may smile at what they think so rude a contrivance; but the same principle, carried a little further, might be made very efficient in preserving a measure. Suppose for example, that the government were now to think it desirable to recover the three-barleycorn inch, or at least to invent one which should be capable of being recovered. They would put together not three barleycorns, but three thousand, or thirty thousand; or many different collections of three thousand or more. The average inch deduced from these would be capable of being recovered at any time from the same grain grown in the same soil. A commercial standard might be easily recovered from many different modes of proceeding: for example, the *average* height of the barometer at a given place throughout any period of five years is so nearly the same from one five years to another, that a commercial standard might be sufficiently well obtained from it. It would be of little consequence if the yard were wrongly recovered by one-hundredth or even one-tenth of an inch, in any matter of buying and selling.

It is the *scientific* standard at which the government has been aiming during the last century. The object here is, first, to measure the old standards to the utmost accuracy of which our senses, assisted by microscopes, are capable; secondly, to discover the means of reconstructing a lost standard. In the more delicate operations of natural philosophy and astronomy, our knowledge cannot go down to posterity, unless they know within the thousandth of an inch what it is that we call a yard. The public at large has never understood the reason why so much trouble has been taken; and perhaps the members of different administrations, while trusting such investigations to men of science, and relying on them for the whole conduct of the matter, may have wondered at the great difficulty which there seemed to be in the way of furnishing the shopkeepers of all generations with the yard measures and pound weights of the same values. It is our principal object in this article to endeavour to point out the nature of these difficulties, and the extent to which they have been overcome: it being remembered however that the object is scientific, not commercial, and that the standard of length is chosen as the most important illustration.

To elucidate the *principle* merely of the manner in which scales are compared, we must first show how it is that very small lengths can be measured. A screw can be very accurately constructed, say with threads one-twentieth of an inch apart: if this screw be the axis of a circular plate, which turns with it, and the edge of the plate be divided into 100 parts, each of these parts will be very perceptible, if the plate be three-quarters of an inch or more in diameter, and it will not be difficult to estimate the half or quarter of one of the divisions. Let there be an index attached to the frame, which does not move with the screw, by which it may be seen, when the plate (and with it the screw) is turned, how many divisions it is turned through. Now since a whole turn of the screw moves the end of it forward through one-twentieth of an inch, a motion of the plate which passes one of the divisions over the index, or the hundredth part of a turn, sends the end of the screw forward through only one two-thousandth of an inch, and a quarter of a division answers to one eight-thousandth of an inch. Suppose a couple of such screws, each of which is attached to a pointer, as in the following diagram, in which the pointers only are inserted, and one of the scales which are to be compared; the screws which move the pointers, and all the frame-work, being omitted. Observe also that this is not the apparatus employed, but only a convenient illustration of it.

It is supposed that A and B can be moved, by the screw motion, in such a manner that a motion so small as the eight-thousandth of an inch may be given to either. The scale at present used is E F, on which are two points, C and D, which are, or are supposed to be, exactly a



yard asunder. Let the screws be moved until the ends of the pointers, which all but touch the scale, are exactly over C and D; then if the scale be removed, the length C D is retained in the distance between the points of the pointers. Now let another scale be introduced, and let its points be brought as near as may be, conveniently, to the pointers: it is supposed that the distances C D and G H are very nearly equal, for workmen used to the construction of mathematical instruments never fail in making two yard measures agree within a fiftieth of an inch. Perhaps the reader will say the point G might be brought *exactly* under the pointer A, and then the pointer B alone would show whether the present scale is shorter or longer than its predecessor: but as the pointer is much less cumbrous than the scale, it is easier and safer to put the scale in a convenient position than to attempt to place it in one exactly given. This being done, move the pointer A from C to G, and observe how many turns, or how much of a turn, of the screw, is required to do it: say it makes 87½ divisions of the plate pass the index. Also move the pointer B from D to H, which makes, say, 97¾ divisions of the plate pass the index. Now we obviously have

$$GH = CD + DH - CG;$$

and since D H is longer than C G, it appears that G H exceeds C D by the excess of D H over C G, answering to 97¾ – 87½, or 10¼ divisions of the plate, being 10¼ times the two-thousandth of an inch, or ·005125 of an inch. This experiment may be repeated any number of times, and as may be expected, the results will not agree, since it is not to be supposed that any two persons, or the same person at two different times, will agree in their estimation of exact coincidence between the pointers and the ends of the scales. As in other cases, the averaging of the discordant results will bring out the truth very nearly.

The difference between the apparatus which was actually used in the next experiments and that above described was as follows. The pointers were MICROMETER* microscopes, in which the intersection of two fine spider-threads, placed at the focus, was the point which was made, by a slow screw motion, to coincide with the centre of the (magnified) dot (or line) which formed the extremity of the scale. The micrometer head (the circular plate of the preceding illustration) was divided into 100 parts, each of which was found to be equivalent to one 20,000th of an inch; or a whole turn of the screw altered the position of the intersection of the spider's webs by one 200th of an inch. The magnifying power used was about 27 times in linear dimension. It was attempted, in each experiment, to estimate tenths of the divisions of the micrometer-head, or to attain† the 200,000th

* For further information on ancient weights, coins, and measures, the reader is referred to the following work, 'Metrologische Untersuchungen über Gewichte, Münzfüsse, und Masse des Alterthums in ihrem Zusammenhange, von August Boeckh,' Berlin, 1838; and to a review of this work in the 'Classical Museum,' No. 1, by Mr. Grote.

* The principle is the same as that of the beam compasses, and the apparatus might be called microscopic beam-compasses, or beam-microscopes.

† Every attempt at measurement strives to be ready for more than there is any reasonable hope of attaining. It is certainly not likely, at present, that even the mean of a large number of measures would settle the question within so small a quantity; but if ever the day shall arrive when the 200,000th of an inch is attainable, the previous attempts to obtain it will point out the cause of their own failure, and probably be a source of information.

part of an inch. The apparatus is described in Mr. Baily's 'Report to the Royal Astronomical Society on their Standard Scale' (published in the ninth volume of their Memoirs), from which much of the present article is taken.

The first attempts to be scientific in matters of measurement made in this country date from the beginning of the 17th century. Previously to this time men of information probably believed that the Roman and English foot were the same, and that the pound troy was deducible from the Roman Libra. Bishop Tonstal, in his Arithmetic (1522), where he only treats what is necessary for common life, "ad vitam communem transigendam necessaria," cites Columella on measures of length, and deduces the system of coinage from Budæus on the Roman As. The other writers of the same century pass over the mode of obtaining measures, as if it were perfectly fixed, and generally refer to the three-barleycorn inch as a standard. In the early part of the 17th century we find Oughtred ('Circles of Proportion,' pp. 55-57) referring to actual measures of the contents of the gallon made by the celebrated Briggs, and also by one William Twine, but taking the Roman foot as "very little less, if not exactly the same," as the English foot. Later in the century, Dr. Wybard ('Tactometria,' p. 268, published in 1650) gives an account of experiments, at which he was present, for the determination of the same gallon; and later still, in 1688, we have the experiment with the same object [GALLON], at which Flamsteed and Halley were present, which is referred to in the Report of the Committee of the House of Commons in 1758. As far as measurements are concerned, had it not been for Greaves [GREAVES, JOHN, in BIOG. DIV.], we might have summed up the efforts of the 17th century by saying they were mostly directed to finding, within one, how many cubic inches there were in the several gallons. Greaves first directed attention to the difference between the Roman foot and the English, by tolerably accurate determinations of the former. [WEIGHTS AND MEASURES.] He also attempted the investigation of the Roman weights, and must be considered as the earliest of the scientific metrologists. He was followed by Dr. Bernard [BERNARD, EDWARD, in BIOG. DIV.], whose treatise on ancient weights and measures (1685 and 1688) must have given a great impetus to the spirit of comparison. A work of this kind soon shows its consequences: Jeake's 'Arithmetic' (folio, 1696) contains a hundred pages on the subject. Towards the end of the century the measures of Auzout and Picard awakened attention to the comparison of standards in France. Both countries were thus prepared to desire some information from each other on the subject of their measures; and a communication took place in 1742 between the Royal Society and the Academy of Sciences for an interchange of standards. Then, for the first time, as far as we can learn, a yard was taken off on a brass rod from a standard kept in the Tower of London (which we believe is not now in existence). But the legal standard, usually so considered, was one which was kept at the Exchequer; there was another at the Guildhall, and another in the possession of the Clockmakers' Company. When these came to be compared with one another and with the Exchequer standard by Graham (who also laid down an Exchequer yard on the same brass rod), it appeared that the shortest and the longest differed by seven-hundredths of an inch, a little more than the height of an *o* or an *a* in this work. But had the difference been greater, it would not have mattered much, considering the way in which standards were to be used. In our own day, after nearly a century of communication between statesmen and philosophers on the subject of a uniform measure, Mr. Baily visited the Exchequer standard (from which the copies we shall presently mention were made), and his account (Report above cited, p. 146) is as follows:—"Since the preceding sheets were printed, I have had an opportunity of seeing this curious instrument, of which it is impossible at the present day to speak too much in derision or contempt. A common kitchen poker, filed at the ends in the rudest manner by the most bungling workman, would make as good a standard. It has been broken asunder, and the two pieces have been dovetailed together, but so badly that the joint is nearly as loose as that of a pair of tongs. The date of this fracture I could not ascertain, it having occurred beyond the memory or knowledge of any of the officers at the Exchequer. And yet, till within the last ten years, to the disgrace of this country, copies of this measure have been circulated all over Europe and America, with a parchment document accompanying them (charged with a stamp that costs 3*l.* 10*s.*, exclusive of official fees), certifying that they are true copies of the English *standard*."

In 1758, a committee of the House of Commons began to investigate this subject, and was followed by another in 1759: both committees made full Reports. Both committees caused to be made, by Bird, a copy of the Royal Society's (or Graham's) copy of the Exchequer standard, and these copies, which remained in the official possession of the Speaker of the House of Commons, were called Bird's parliamentary standards of 1758 and 1760: it should be stated, however, that the latter was only a copy of the former. The Reports were agreed to by the House: a bill was brought in, according to their recommendation, namely, that Bird's standard of 1758 should be the national standard; but it was not carried through. A committee, appointed in 1790, did nothing, and the matter was thus abandoned. Private individuals and scientific societies began to provide themselves with standards: Sir G. Shuckburgh ('Phil. Trans.,' 1798) had one made by Troughton, which he compared with the parliamentary standards and others. Troughton made one for himself, and first introduced the micrometer microscopes into the comparisons; this last was made from one which Bird had made for the then assay-master of the Mint. Another was made for General Roy, and was used by him in the great survey; and this, Bird's own private property, was in existence. Thus matters were until the year 1814, when the House of Commons again appointed a committee to consider the subject.

In the meanwhile however experimental philosophy had made great advances, and investigators began to look more at the successes of the past than at the new difficulties which those very successes had opened into view. As soon as the measurements of the earth began to be attended with some success, the French proposed a standard measure which should be the ten-millionth part of a quarter of the meridian, which last they hoped, by their great survey, to ascertain so exactly that no future measurement should make even a microscopic alteration of their new *metre*. In England the pendulum began to be considered a perfect instrument; and the second being determined invariably by the motion of the earth, it was thought that the length of the seconds' pendulum in a given latitude would be an invariable quantity which could always be recovered. The committee of 1814, on the evidence of Playfair and Wollaston, recommended that Bird's standard of 1760 should be the one adopted, and gave it as their opinion that the length of a seconds' pendulum in the latitude of London is 39·13047 inches, of which the above-named standard yard contains 36. Playfair and Wollaston hinted at the necessity of verifying this number, but the committee take it for granted, and assert that any expert watchmaker can make a seconds' pendulum, without stating how that pendulum is afterwards to be measured, nor at what temperature, pressure, &c. it is to be swung. They also state that a cubic foot of pure water at 56½ Fahr. weighs exactly 1000 ounces avoirdupois, as the connecting link between measures of weight and capacity. No bill was brought in in consequence of this Report.

In 1819 the Prince Regent appointed a commission composed of Sir J. Banks, Sir G. Clerk, Davies Gilbert, Wollaston, Young, and Kater. This commission made three Reports, dated June 24, 1819, July 13, 1820, and March 31, 1821. In the first (we confine ourselves to matters affecting the standards) the standard yard recommended is that on the scale used by General Roy in the measurement of the Hounslow Heath base, and it was the opinion of the reporters that the mean solar seconds' pendulum in London, at the level of the sea, in a vacuum, and at 62° of Fahr., was 39·1372 inches of this scale. They also take 19 cubic inches of distilled water at 50° to be exactly 10 ounces troy. In the Second Report, they announce that an error has been discovered in their standard, and they propose that Bird's parliamentary scale of 1760 shall be the standard, the seconds' pendulum being 39·13929 inches. In the Third Report, they announce, by new experiments, that a cubic inch of distilled water at 62° is 252·72 grains of the standard pound of 1758, when weighed in a vacuum. The House of Commons again appointed a committee in 1821, to which these Reports were submitted: this committee agreed with the commissioners, and a bill was introduced in 1823. A petition from the Chamber of Commerce at Glasgow to the House of Lords occasioned an investigation in that House also; Dr. Kelly, one of the witnesses before the committee, called attention to the known effects of variety of attraction on the pendulum, as shown by Captain Kater's own observations, and to the insufficient manner in which the level of the sea was known: and his opinion was that of few others at the time, though now nearly universally received, namely, that "nature seems to refuse invariable standards; for, as science advances, difficulties are found to multiply, or at least they become more perceptible, and some appear insuperable." The House of Lords adjourned the question over till 1824; when the act 5 Geo. IV. c. 74, was passed, from which extracts will presently be made. This act was to take effect May 1, 1825, but in the March of that year 6 Geo. IV. c. 12, was passed, deferring the operation of the preceding act till January 1, 1826. There was an inquiry before the House of Commons in 1834, which ended in the statute of 4 & 5 Will. IV. c. 49, and another inquiry before the same House in 1835, which ended in 5 & 6 Will. IV. c. 63, repealing the former act and substituting new provisions. These last acts however contain nothing with reference to the standards, except the following excellent wind-up of the chequered and ill understood legislation upon weights and measures. The Houses of Parliament were burnt in 1834, and with them Bird's standards of 1758 and 1760 (the last *the* standard). Nevertheless 5 & 6 Will. IV. c. 63, passed after the fire, takes no notice of the destruction of the standard, but refers to it as still in existence. Seven years * have since elapsed, but we are not aware of the legislature having yet swung the pendulum to recover the lost measure.

As to the standards, the act prescribes as follows:—

1. The straight line or distance between the centres of the two points in the gold studs in the straight brass rod now in the custody of the clerk of the House of Commons, whereon the words and figures "Standard yard, 1760" are engraved, shall be the original and genuine standard of that measure of length or lineal extension called a yard... the brass being at the temperature of sixty-two degrees of Fahrenheit's

* This was written by Mr. Sheepshanks in 1841.

thermometer. . . . . The act goes on in many words to say that the pendulum vibrating seconds of mean time in the latitude of London * in a vacuum at the level of the sea is 39·1393 inches of the said standard.

2. The standard brass weight of one pound troy weight, made in the year 1758, now in the custody of the clerk of the House of Commons, shall be the original and genuine standard measure of weight. . . . The act goes on to say that the cubic inch of distilled water, weighed in air by brass weights, at 62° of Fahr., the barometer being at 30 inches, is equal to 252·458 grains.

It happened fortunately for the scientific standard, that about the year 1832 the council of the Royal Astronomical Society caused a scale to be constructed for themselves, and obtained permission of the Speaker of the House of Commons to compare it with Bird's two standards, which was done in the beginning of 1834, by a much more extensive set of experiments than had ever been made before for a like purpose, conducted chiefly by Mr. Baily and the late Lieutenant Murphy. This is now, in fact, the standard scale of the country; or, at least, the only measure from which the standard scale can be deduced. The manner of conducting the comparisons has already been slightly described; we shall now proceed (from the Report already quoted) to give some account of the difficulties which were found in the way of measurement, and of the results.

This scale is a cylindrical tube of brass 63 inches long, 1·12 inches and ·74 inches in exterior and interior diameter. Three thermometers are immoveably inserted into its length, and the ends are stopped by brass plugs. Two parallel lines (·09 of an inch apart) are drawn in the upper surface; and, commencing 1¼ inches from one end, at the distance of every foot, a palladium pin is inserted in the tube, between those lines; on each of which pins, at proper distances, a fine line is cut to designate the length of a foot. The first foot is similarly divided into inches and tenths; and the middle foot (there being five in all) is bisected. The three middle feet constituted the yard which was used in the comparisons. It was found that any constraint, however slight, affected the expansion and contraction of the bar; even the friction arising from its first supports, which were lined with baize: it was therefore found necessary to support it, when under the microscopes, on friction-rollers: and care was taken that these should always be placed under the same points of the tube. To give an idea of the power of the mode of comparison, it was found, by fourteen experiments agreeing very well with each other, that the middle yard was shortened ·48 of one of the divisions of the micrometer-head (described at the beginning of the article), or ·000024 of an inch, by nothing but removing the plugs from the end of the tube.

Nothing can be known of such a bar as a scientific standard until the rate at which it expands by the action of heat is determined. By a mean of six experiments, taken with the tube at the freezing and boiling temperatures, it was found that every addition of 1° of Fahr. to the temperature lengthened the centre yard by ·000377 of an inch, or 7·6 divisions of the micrometer-head.

The instrument being placed ready for observation, and two scales being put down for comparison, one observer may bring both the micrometers to the ends of one scale, or one observer may be placed at one end, and another at the other. In the latter case, a new cause of error enters, of which it is impossible to give any account, though a remedy may be provided. It is not true that two persons, though using exactly the same instrument, and noting the same phenomenon under the same circumstances, will note it exactly in the same way. When one observer made (as he thought) the coincidence of the intersection of the micrometer-wires with the dot or line at the end of a scale, another, looking into the microscope, would seldom or never agree with the former that the coincidence was exactly made, but would turn the micrometer-head three or four divisions, one way or the other, before he (the second) could be satisfied that the coincidence was perfect. This difference of the manner of observing, arising from the peculiar habits of vision and judgment of the observers themselves, has received the name of the *personal equation*, and its amount, as between any pair of observers, can be ascertained by experiment. If one observer made the coincidences at both ends, it would matter nothing what his manner of observing was, since, however much he might differ from absolute correctness (be that what it may), he would differ by the same amount at both ends, and the length of the scale would not be affected. If, when two observers are employed, they make a given number of comparisons, and then change places and make the same number, the mean of all their observations will be unaffected by their mode of observing, since, if the scale be made too long in the first set, it will be made as much too short in the other, and vice versâ. [EQUATION, PERSONAL.] Some of the personal equation might arise from the curious figures which the dots of the old scales (into which beam-compasses had been inserted) presented when viewed under the microscope. Bird's standard of 1758, for instance, had pear-shaped holes at its extremities, the centres of which no two persons could agree upon.

The following results will give a notion of the degree of accuracy obtained in the workmanship of scales. The Astronomical Society's scale was compared with the imperial standard (Bird's of 1760): the Royal Society's scale of 1742, having two scales in it marked E and Exch.; a scale called Aubert's, the prototype of one which was used in the Indian survey by Lambton; one which had been used by Sir G. Shuckburgh; one belonging to the town of Aberdeen; one belonging to Mr. T. Jones; and four new ones made after the model of the Society's scale, one for the Danish government, one for the Russian government, one retained for himself by Mr. Simms the constructor, and one for Mr. Baily. Calling the middle yard of the Astronomical Society's scale 36 inches, the different scales are as follows, each from the mean of many observations :—

Scale.	Standard portion.	Mean inches of Ast. Soc. scale.
Astron. Soc.	centre yard.	36·000000
Danish	,,	35·999758
Russian	,,	36·000050
Simms's	,,	35·999903
Baily's	,,	35·999949
Aberdeen	,,	35·998615
Jones's	,,	35·999802
Aubert's	0 in.—36 in.	35·998447
Shuckburgh	0 in.—36 in.	36·000185

,, ...	line Exch.	35·993684
Imperial standard of Bird's of 1760	. . .	35·999624

Temperature is not here alluded to, it being presumed, of course, that the effect of temperature upon the *difference* of two scales is inappreciable: thus the Astronomical Society's standard being ·000376 longer than the imperial standard, and the standard temperature being 62°, the length of the former standard, observed at 62°, and diminished by ·000376 of an inch, will give the true standard of the law.

It is believed, after all, that the imperial standard is about 1-140th of an inch longer than the old standard of the country; but this matters nothing to the scientific part of the question, for all the scales which have been used in trigonometrical surveys have now been diligently compared with the Astronomical Society's scale, and are therefore known, independently of the national standard, as long as the latter scale exists. The only thing to be feared is the loss of this last-mentioned standard; the government might keep it, but cannot be trusted to use it; the Society, which knows how to use it, has no place of perfect security in which to keep it.

We shall not here enter into the various modes used by Sir G. Shuckburgh, and subsequently by Captain Kater, for the determination of the standard of weight. An old standard pound exists in the Exchequer, from which in 1758 a copy was made for the committee of the House of Commons. This last, as we have seen, has been declared the standard, and was never recovered from the ruins of the late House of Commons. The original standard of weight, as prescribed in a statute of 51 Hen. III., called *Assiza Panis et Cervisiæ*, was that an English penny called the sterling, round without clipping, should weigh 32 grains of wheat, well dried and gathered out of the middle of the ear; and that 20 pence should make an ounce, and 12 ounces a pound.*

In 1838 a Treasury Commission was appointed to consider the best mode of replacing the ruined standards of weight and measure. The report of the commission was presented to the government on the 21st of December, 1841. The opinion was expressed therein that the definition contained in the act 5 Geo. IV. cap. 74, by which the standard yard was declared to be a certain brass rod was the best which could possibly be adopted. With regard to the restoration of the standard the commissioners were not prepared to recommend, conformably to the said act, that it should be effected by taking the length which shall bear a certain proportion to the length of the pendulum vibrating seconds of mean time, in the latitude of London, in a vacuum, at the level of the sea. They remarked that since the passing of the act above mentioned, it had been ascertained that several elements of reduction of the pendulum experiments referred to therein, were doubtful or erroneous. Dr. Young had shown that the reduction to the level of the sea was doubtful. Bessel and Baily had proved that the reduction for the weight of the air was erroneous: Baily had pointed out that the specific gravity of the pendulum was erroneously estimated, and that the defects of the agate planes introduced some degree of doubt. Finally, Kater had shown that very sensible errors were introduced in the operation of comparing the length of the pendulum with Shuckburgh's scale used as the representative of the legal standard. On these grounds it appeared evident to the commissioners that the course prescribed by the act would not necessarily reproduce the length of the original yard. They remarked, however, that several measures were in existence which had been accurately compared with the former

* The latitude of London was rather a vague phrase for legislation which could not let "length" pass without the explanation "lineal extension."

* Here ends the article on Standard Weights and Measures as it originally appeared in the 'Penny Cyclopædia' from the pen of the late Mr. Sheepshanks. The continuation is mainly derived from a paper by Mr. Airy, published in the 'Philosophical Transactions' of the Royal Society for 1857—'Account of the Construction of the New National Standard of Length, and of its principal Copies,' vol. clxvii., pp. 621–702.

standard, more especially the Royal Astronomical Society's scale, and the iron bars belonging to the Board of Ordnance, and they asserted that by the aid of these the values of the original standard might be restored without sensible error. They further expressed their firm belief that by employing due care it will always be possible to effect the restoration of a standard by the aid of material copies which have been accurately compared with them, more securely than by experiments having reference to any natural constants. They accordingly offered a series of suggestions, of which the following are the most important:—

1. That so much of the act 5 Geo. IV. c. 74 as provides for the restoration of the standards in the manner therein mentioned, be repealed; and that the standard of length be defined in subsequent enactments of the legislature, either by the whole length of a certain piece of metal or other durable substance, supported in a certain manner, at a certain temperature; or by the distance between two points or lines engraved on the surface of a certain piece of metal or other durable substance, supported in a certain manner, at a certain temperature; but that the standard be in no way defined by reference to any natural basis, such as the length of a degree of meridian on the earth's surface in an assigned latitude, or the length of a pendulum vibrating seconds in a specified place.

5. That four sets of copies (to be denominated the parliamentary copies) of the standards of length and weight be made, in all respects similar to the legal standards of length and weight (which are hereinafter denominated the parliamentary standards), and as nearly as possible equivalent to them; their difference from the parliamentary standards, if appreciable, being carefully ascertained; and that the several parliamentary copies be distinguished by proper marks.

6. That one set of the parliamentary copies be enclosed in a case hermetically sealed and embedded within the masonry of some public building; and that the place in which it is enclosed be pointed out by a conspicuous inscription on the outside; and that this set of copies be not disturbed without the sanction of an act of parliament.

17. That the superintendence of the construction of the new parliamentary standards be intrusted to a committee of scientific men, to be named by her Majesty, subject to the general instructions which follow.

18. That the superintending committee be instructed to combine, in the way which may appear most advantageous, the evidence afforded by the Royal Astronomical Society's scale No. 46, and by the 3 feet bars of the Ordnance Survey; and by the use of these to construct a new standard of length, representing as nearly as possible the same measure as the lost standard.

The government, acting upon this report, appointed a committee of scientific men to superintend the carrying into effect of the operations recommended by the commissioners. The committee thus formed consisted in fact of the commissioners themselves, who were requested by the government to continue their services. The following is a list of the individuals of which it was composed:—The Astronomer Royal, the Marquis of Northampton, the Lord Wrottesley, F. Baily, J. E. D. Bethune, J. G. S. Lefevre, Sir J. W. Lubbock, the Rev. G. Peacock, Rev. R. Sheepshanks, Sir John Herschel, and Professor Miller.

The Earl of Rosse was subsequently appointed a member of the committee. Mr. Baily undertook to execute the operations for restoring the standard of length. The work relating to the standards of weight was undertaken by Professor Miller of Cambridge. [MILLER, WILLIAM HALLOWS, in BIOG. DIV.]

The committee having carefully considered the advantages and disadvantages of line measures, as compared with end measures, decided upon making the standard of length a line measure.

The next point to be considered was the material of which the new standard was to be composed. A series of interesting experiments was made by Mr. Baily, with a view to this object. The committee finally decided upon adopting for the material of the standard of length, an alloy of copper, tin, and zinc, in the following proportions:—

Copper	16
Tin	2½
Zinc	1

Mr. Baily next made a series of valuable experiments on the circumstances which exercise a disturbing influence on the length of a bar. Captain Kater had found that the length of the bar is sensibly affected by small inequalities of the surface on which it rests. It resulted from this circumstance, that the same bar, when compared with other bars at different times, might not indicate the same length. This was fully verified by the experiments of Mr. Baily. It followed as a necessary consequence of this circumstance, that no reliance could be placed on the existing copies of Shuckburgh's scale as representatives of the scientific standard of length, since we possessed no security that we were thereby referring to a consistent system.

Besides Shuckburgh's scale, which was found to be unworthy of confidence, there existed five other standards, which had been carefully compared with the imperial standard. Mr. Baily having obtained temporary possession of four of these, the Royal Society's 3-foot brass scale, the Astronomical Society's tubular scale, and the two 3-foot iron bars of the Ordnance Survey, instituted a series of careful comparisons of their lengths under different conditions. The results of these experiments were by no means satisfactory as regards the degree of reliance to be placed on these bars, as representatives of the imperial standard.

Mr. Baily died in the autumn of 1844. At the request of the committee, Mr. Sheepshanks undertook to continue the operations.

It appeared to the committee that no reliance could be placed either on Shuckburgh's scale, or on any other existing copy of the imperial standard, the experiments of Mr. Baily having shown that the comparisons of those measures could not fail to have been sensibly affected by errors of different kinds. "It was plain therefore that either in the scientific or the legal sense, the restoration of the standard was indeterminate. The formation of a new standard must be an operation *de novo;* the length must be confined within certain limits (wide in the scientific, narrow in the commercial sense), but within these it might have any definite value, and when that definite value was fixed, it must in no way be again referred to the old standards or scales, whether original or intermediary. The principal object now was to ensure constancy and definiteness to the new standard and its copies, and means of reducing without sensible error the comparisons which might be made with them. As far as depended on the standard itself, it was hoped that the construction adopted gave sufficient security. As regarded the means of making comparisons, a far firmer apparatus than had hitherto been used was requisite. As regards the effects of temperature, it was necessary to create an entirely new system of thermometers, founded upon the natural constants, to be determined by appropriate physical experiments; and to use them in new determinations of thermometric expansion."*

It was found in the course of the experiments that a change of 0°·01 Fahr. produces a sensible effect in the measure of a bar. It was therefore necessary to employ thermometers which would serve to indicate variations of temperature of no greater magnitude than this. At the time when Mr. Sheepshanks commenced his experiments there were not to be found in England any thermometers of such delicacy. He was consequently induced to undertake the construction of an original system of thermometers adapted to the important object of his labours. He then proceeded to determine the thermometric expansion of a great number of bars of different metals.† This object being accomplished, the next step was, by means of the existing standards, to determine the relation of the length of one of the new bars to the lost imperial standard. After many comparisons, he finally decided upon adopting a bar designated by him bronze 28, as a suitable representative of the imperial standard. He remarked, with reference to the circumstances which led him to adopt this resolution, that bronze 28 was as nearly as possible equal in length to the imperial standard, measuring in fact 35·999992 in., that it floated evenly in quicksilver, and that it was nicely divided.

Having now obtained a satisfactory representative of the imperial standard, Mr. Sheepshanks made a great number of comparisons of the length of the new standard with other bars, in order to select from them four Parliamentary copies of the standard, to be disposed of in the way recommended by the committee to the government. He also made careful comparisons of these with a great number of other bars, which were intended for distribution throughout the empire and in foreign countries. It would be out of place here to enter into the details of his arduous and persevering labours in connection with this great national work. It may give the reader some idea of their magnitude when we state, upon the authority of Mr. Airy, that in the course of them he executed about two hundred thousand micrometric measures. He still continued to labour at his task when, in the summer of 1855, symptoms of a serious nature affecting his health began to manifest themselves. On the 28th of July in that year he was engaged on the comparing apparatus, and returned in the evening to his residence at Reading. On the following day he was struck with apoplexy, and died on the 4th of August. We quote the following tribute to his character by Mr. Airy:—

"Thus died—almost in the scene of his labours, and with his thoughts still intent on them—a man whose equal in talent and perseverance, in disinterestedness, in love of justice and truth, I have scarcely known.‡ He had, however, brought to a satisfactory termination the great division of the standard-work which best suited his taste, having well overcome the last of the difficulties which had presented themselves, and leaving the work in such a state that not a single additional comparison of line-measures was compared. All that was necessary was to collect and arrange the papers, to complete some few means and abstracts which he had been unable to finish, and to draw up such an account as I have attempted here." ('Phil. Trans.,' 1857, p. 684.)

The form adopted for the standard, and for all its copies, is that of a solid square bar, 38 inches long and 1 inch square in transverse section. Near to each end a cylindrical hole is sunk (the distance between the centres of the two holes being 36 inches) to the depth of 0·5 inch. At the bottom of this hole is inserted in a smaller hole a gold plug or pin about 0·1 inch diameter, and upon the surface of this pin there are cut three fine lines at intervals of about 0·01 inch trans-

* 'Phil. Trans.,' 1857, p. 646.

† They were chiefly of gun-metal, as recommended by the committee; but there were also several of cast-iron and steel.

‡ Mr. Sheepshanks' public services, in connection with the restoration of the national standard of length, were wholly gratuitous.

verse to the axis of the bar, and two lines at nearly the same interval parallel to the axis of the bar. The measure of length is given by the interval between the middle transversal line at one end and the middle transversal line at the other end, the part of each line which is employed being the point midway between the longitudinal lines. The other transversal lines were used in the operations of comparison only for assigning the scales of the micrometers.

The committee having carefully examined the numerous bars placed at their disposal by Mr. Sheepshanks, agreed in considering the bars denominated by him bronze 19 and bronze 28, as exact copies of the imperial standard, and they resolved that bronze 19 should henceforward be regarded as the new national standard.

The final report of the committee addressed to the Lords Commissioners of her Majesty's Treasury was signed on the 28th of March, 1854. The following are a few extracts from this important document:

19. "The report of 1841 recommended (article 5) that, besides the legal standard, there should be prepared four copies, to be deposited in places to be afterwards determined.

20. "The expansions of these bars corresponding to a given change of temperature had been sufficiently determined in the course of the experiments; and it was then judged expedient, instead of stating the difference in length of the selected bars at the same temperature, to infer the difference of temperature which would cause all to represent the same length, by the application of which it would be possible to assign the specific temperature at which each bar represents precisely the length of one yard. Thus it was found that the length of one yard as given by the lost imperial standard, is represented with no sensible uncertainty, except in the measures of the imperial standard itself, by the following bars, at the temperatures placed opposite to them.

Bronze 19 or No. 1, at 62°·00 Fahrenheit.
Bronze 20 or No. 2, at 61°·94 Fahrenheit.
Bronze 2 or No. 3, at 62°·10 Fahrenheit.
Bronze 7 or No. 4, at 61°·98 Fahrenheit.
Bronze 10 or No. 5, at 62°·16 Fahrenheit.
Bronze 28 or No. 6, at 62°·00 Fahrenheit.

21. "The degrees of temperature for the use of these standards are defined as proportional to the corresponding apparent increase of volume of quicksilver in the thermometer tube; the degree 32° representing the freezing point of water; and the degree 212° representing the temperature of steam under Laplace's standard atmospheric pressure, or the atmospheric pressure corresponding to the following number of inches in the barometric reading reduced to 32° Fahr.:— $29{\cdot}9218 + 0{\cdot}0766 \times \text{cosine } (2 \text{ latitude}) + 0{\cdot}00000179 \times \text{height}$ in feet above the sea; and the degree 62° denoting the temperature which produces in quicksilver an apparent expansion equal to $\frac{30}{180}$ of the expansion between 32° and 212°; and so in proportion for other degrees.

23. "We propose that the bar No. 1 be adopted by the legislature as the *parliamentary standard of one yard;* that Nos. 2, 3, 4, 5 be adopted as parliamentary copies; and that No. 6 be retained by some officer of the government for the comparison of other bars, or for other scientific purposes in which reference to the standard may seem to be required.

35. "After careful consideration we recommend:—

"That the copy of length standard, No. 2, and the copy of weight standard P.C., No. 1, be deposited in the Royal Mint.

"That the copy of length standard, No. 3, and the copy of weight standard, P.C., No. 2, be transferred to the Royal Society.

"That the copy of length standard, No. 5, and the copy of weight standard, P.C., No. 3, be deposited in the Royal Observatory of Greenwich.

"That the copy of length standard, No. 4, and the copy of weight standard, P.C., No. 4, be immured in the cill of the recess on the east side of the lower waiting hall in the New Palace at Westminster.

40. "After due consideration of this question, referring to the reasons explained in Chapter II., of the report of 1841, December 21, we adhere to the recommendation contained in that chapter, and embodied in Articles 1 and 2 of the same report, that no reference be made to natural elements for the values represented by the standards.

41. "We consider the ascertaining of the earth's dimensions and of the length of the seconds pendulum in terms of the standard length, and of the weight of a certain volume of water in terms of the standard weight, as philosophical determinations of the highest importance, to the prosecution of which we trust that her Majesty's Government will always give their most liberal assistance; but we do not urge them on the government at present as connected with the conservation of standards."

The Lords Commissioners of the Treasury adopted the report of the committee, and a bill was introduced into parliament relative to the new standard weights and measures. This bill received the royal assent on the 30th of July, 1855. It is styled an Act for legalising and preserving the restored standards of weights and measures. In the preamble of the bill allusion is made to the provisions in the act 5 Geo. IV. c. 74, for legalising and ensuring the restoration of the standards. After referring to the destruction of the standards by the fire of the Houses of Parliament, and to the doubts entertained by scientific men respecting the adequacy of the methods provided by the said act for their restoration, it then announces the labours of the committee of weights and measures, describing the construction of the new standards of weights and measures, and their parliamentary copies, and specifies the places in which they have been respectively deposited. It then proceeds thus:—

"And whereas it is expedient to legalise the standards so constructed, and to provide for the preservation thereof: Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the lords spiritual and temporal and commons in this present parliament assembled, and by the authority of the same as follows:—

"I. So much of the said act of the fifth year of king George the Fourth, as relates to the restoration of the imperial standard yard, and of the standard troy pound respectively, in case of loss, destruction, defacement, or other injury, shall be repealed.

"II. The straight line or distance between the centres of the two gold plugs or pins in the bronze bar deposited in the office of the Exchequer, as aforesaid, shall be the genuine standard of the measure of length called a yard, and the said straight line or distance between the centres of the said gold plugs or pins in the said bronze bar (the bronze being at the temperature of sixty-two degrees by Fahrenheit's thermometer), shall be and be deemed to be the imperial standard yard.

"VII. If at any time hereafter, the said imperial standard yard and standard pound avoirdupois respectively, or either of them, be lost, or in any manner destroyed, defaced, or otherwise injured, the commissioners of her Majesty's Treasury may cause the same to be restored, by reference to, or adoption of, any of the copies so deposited as aforesaid, or such of them as may remain available for that purpose."

For an account of the restoration of the standard of weight, we must refer the reader to a paper by Professor Miller, printed in the 'Transactions of the Royal Society,' for 1856 ('On the construction of the New Imperial Standard Pound, and its Copies of Platinum;' and 'On the Comparison of the Imperial Standard Pound with the Kilogramme des Archives,' 'Phil. Trans.,' vol. cxlvi., pp. 753-946). We shall merely quote from the new act the following extracts relating to the standard of weight:—

"I. So much of the said act of the fifth year of king George the Fourth, as relates to the restoration of the standard troy pound, in case of loss, destruction, defacement, or other injury, shall be repealed.

"III. The said weight of platinum marked P.S., 1844, 1 lb., deposited in the office of the Exchequer, as aforesaid, shall be the legal and genuine standard measure of weight, and shall be and be denominated the imperial standard pound avoirdupois, and shall be deemed to be the only standard measure of weight from which all other weights and other measures having reference to weights shall be derived, computed, and ascertained, and one equal seven-thousandth part of such pound avoirdupois shall be a grain, and five thousand seven hundred and sixty such grains shall be, and be deemed to be, a pound troy.

"VII. If at any time hereafter the said imperial standard pound avoirdupois be lost, or in any manner destroyed, defaced, or otherwise injured, the commissioners of her Majesty's Treasury may cause the same to be restored by reference to, or adoption of, any of the copies so deposited as aforesaid, or such of them as may remain available for that purpose."

WEIR, or WEAR, is a dam erected across a river, either for the purpose of taking fish, of conveying a stream to a mill, or of maintaining the water at the level required for the navigation of it.

The erection of weirs across public rivers has always been considered a public nuisance. Magna Charta (c. 23) directs that all weirs for the taking of fish should be put down except on the sea-coast. By the 12 Edw. IV. c. 7, and other subsequent acts, weirs were treated as public nuisances, and it was forbidden to erect new weirs, or to enhance, straighten, or enlarge those which had aforetime existed. Hence in a case where a brushwood weir across a river had been converted into a stone one, whereby the fish were prevented from passing except in flood-time, and the plaintiff's fishery was injured, this was considered to be a public nuisance, although two-thirds of the weir had been so converted without interruption for upwards of forty years. And it was laid down that though a twenty years' acquiescence might bind parties whose private rights only were affected, yet that no length of time can legitimate a public nuisance.

The provision of the Roman law as to the maintenance of public rivers (flumina publica) against any impediment to navigation, or against any act by which the course of the water is changed, are contained in the Digest (43 tit. 12, 13).

WEIRS. The constructions, whether of stonework, timber, or earth, by means of which the waters of a river are retained to a given height, or are diverted in any required direction, are known in the arts by the name of *weirs*, or *dams;* and they are principally used for the purposes of creating mill-heads, artificial navigations, or head-waters for irrigations. They may either be placed directly across a stream, or in the line of its flow; and when placed in the latter direction, they may be made to regulate the height of the stream by the level of their crown, in which case the weirs are called *waste weirs*, or tumbling bays, because the excess of the waters, beyond the quantity necessary to keep the surface up to the level of the crown, falls over the weir, and escapes through the byewash, without producing any useful effect.

The height of a weir is, of course, regulated by the depth of the water required to be upheld, and in many cases they are made in such a manner that the upper portion may be raised or lowered at will. In river navigations this variable height is often of great importance on account of the great differences which occur in the volume of the stream; but in millworks the waste weirs are usually made to perform the function of regulators, thus leaving the water line near the shuttle at a constant level. Weirs across rivers are always accompanied by lock-chambers, or by flushing sluices, according to the nature of the traffic, in order to facilitate the passage from the level of the upper to the lower reach of the stream; and whenever lock chambers are formed, it is important that their tail bays should fall again into the main stream at a point beyond the influence of the water falling over the crown of the weir. In forming these structures it is necessary to guard against the syphonic action of the water ponded up in the head bay, which has a great tendency to penetrate the materials composing the weir, and to blow them up, should their specific gravity not be such as to ensure the stability of the structure; and also to guard against the undermining action of the water falling over the crown of the weir. On the former account it is desirable that the height of the head waters should be kept as low as possible, with regard to the convenience of the peculiar service considered; on account of the latter it is desirable that the down side of the weir should present a gradually inclined slope, so as to obviate the effects of the cataract, which would exist if the lower face wall were vertical. In many cases the weirs, which are placed across rivers, are made to present an angle to the course of the stream, in order to offer a greater length, and consequently a smaller depth of water, on the crown; but there can be no absolute rule in this matter, as in so many of the other practical details of hydraulic engineering.

The thickness of water falling over a weir is calculated by the formula $x = 0{\cdot}64 \sqrt[3]{\left(\frac{Q}{L}\right)^2}$, in which x = the thickness sought; Q = the discharge per second; and L = the length of the weir. It is, however, important to observe that although the effect of these weirs is to cause an accumulation of waters on their upper sides, the greatest depth is not found immediately upon them, but at a certain distance above them in the line of the stream. The surface of the fluid, in fact, assumes a convex form before arriving at the weir, the curve of which commences at a point on the up-stream dependent upon the velocity of arrival. It is considered that the outline of the curve is a portion of an hyperbola, whose summit is above the weir before the waters begin to fall, and whose asymptote is the line of the natural mean fall of the waters before the establishment of the weir. According to d'Aubuisson and Guilhem, the equation to this curve is $\left(\frac{y+px}{H}\right)^2 - \frac{px}{H} = \frac{1}{1+\frac{4H}{g}\left(\frac{px}{H}\right)6}$; in which x = the horizontal distance from any point in the curve to the weir; y = the height to which the waters are heaped up at that point above the original level; H = the greatest height to which they are raised; and p = the fall of the river, in this case supposed to have a straight course. As a general rule, the crown of a weir across a stream is kept at about 8 inches, or a foot, below the height calculated for the augmented depth.

Very good models of leading weirs have been executed by Smeaton, on the river Carron; by Telford, on the Weaver; and by Stevenson, on the Ribble and on the Dee. The American engineers have introduced a very economical form of weir, consisting of what is called cribwork of timber filled in with loose rubble; and the Dutch engineers execute with surprising skill weirs or dams of earthwork, bundles of reeds, and fascines. A very ingenious description of moveable weirs is used upon the Seine, in order to close the passage of the subsidiary channels in the dry season; it was invented by M. Poirée, and has been described by him in a pamphlet upon the subject. The waste weirs, and the head weirs of the majority of English mill streams, are rudely constructed earthen banks, which are too often undermined, and left in a very unsatisfactory state of repair: our canal weirs are, however, skilfully formed, as a general rule. Upon the great Indian irrigation canals the most extraordinary works of this description are to be found; and the reader is referred, for a description of them, to General Baird Smith's, 'Indian Irrigation,' and to his 'Irrigation of the Madras Provinces.'

Upon some of our rivers, structures composed of basket-work are placed for the purpose of arresting the progress of fish in their migrations up or down the stream, which are known by the name of fish weirs. These structures do not interfere with the conditions of flow of the rivers, and as their efficiency for the desired end must be regulated by the habits of the fish they are designed to catch, the mode of their construction must be regulated by local conditions.

WELD. [COLOURING MATTERS.]

WELDING is the process of uniting pieces of metal by hammering when hot. It depends on properties chiefly possessed by iron and the allied group of metals; and is illustrated by the details given under CUTLERY; IRON; STEEL; &c.

WELLS. The term Well is, generally speaking, applied to any excavation sunk in the ground, for the purpose of obtaining, or of getting rid of water; the technical distinction between the two kinds of wells being that the former are known by the simple name of *well*, the latter by the names of *dead wells*, or of *absorbing wells*, accordingly as the water escapes by deep seated, or by superficial permeable beds. The distinction between Artesian and common wells has already been referred to under ARTESIAN WELLS; and that between a *shaft* and a *well* consists in the fact that shafts are generally dry, and are intended to give access to galleries, tunnels, or subterranean workings, whereas wells are intended to act as reservoirs of water.

Common wells are made by sinking an excavation through an upper permeable, or partially permeable, stratum, which lies upon an impermeable one, in such a manner as to allow the water falling upon the surface to percolate through, and to accumulate in, the upper stratum. The depth to which it may be necessary to sink a well will then depend on 1, the permeability of the water-bearing stratum; 2, on its area; 3, on its thickness; 4, on the relief of the upholding stratum; and 5, on the existence of other wells, or places of draught upon the source of supply. The diameter of the well will depend upon the rapidity with which the water will enter from the sides, or bottom, to replace the consumption; it being always observed that there are *à priori* advantages in making the well of large dimensions, in order to obviate the effects of the stagnation of the water, which affects small quantities more rapidly than it does larger ones. The construction of the sides, and of the margins of the wells, must depend entirely upon the nature of the ground traversed, and upon its greater or less tendency to cave in.

Generally speaking, the margin of a well intended to supply water for domestic use is executed of watertight masonry, and the well itself is lined with masonry of the same description to some considerable depth, in order to shut out from the well the infiltrations from land-drains, and from surface waters. In England this part of the work is done in brickwork and cement, or in cast iron; abroad it is commonly done in ashlar masonry. Below the level to which these waters may reach, the sides of the wells only require to be lined in such a manner as to resist the tendency of the sides to collapse; and this object may in many cases be effected by what is called *dry steining*, or brickwork laid without mortar. It is customary in modern well-sinking to execute the steining by sinking the ground to the full diameter of the outside of the work to depths of about 6 feet each, and then inserting what is called a *wooden curb*, or a frame circular in plan, of from 3 to 6 inches in thickness, at the level of the floor; upon this curb the steining is then built regularly, as close to the side of the well as possible. The ground is excavated from under the upper curbs, which are maintained in their positions either by the friction upon the side of the steining, or by means of shores, struts, &c. In traversing running sands, or formations containing much water, close tubes must be used; and great precautions are required to prevent such sands from *blowing*, that is to say, from rising in the excavation. In the lower parts of all wells, whatever may be the nature of the material used for lining the sides, means must be provided for the ingress of the water; when iron cylinders are used, or close planking of wood is introduced, a series of holes in the circumference will effect this object. Great care must also be taken that the materials employed be of such nature as not to act upon the quality of the waters; and whilst every precaution must be taken to protect the waters from the light, and from atmospheric impurities, it is desirable that an efficient ventilation should take place in the well. Local considerations of economy must, of course, regulate to a great extent the selection of the materials to be used in steining a well; but theoretically it would be preferable to employ none but the hardest fire bricks and Roman cement, or cast-iron. Copper tubes are sometimes used in Artesian wells; but in ordinary wells the cost of copper pipes of the size required would render the use of that material impossible. Wrought-iron tubes are far too liable to rust, to allow of their being used in wells, without their being galvanised; cast-iron pipes are therefore most generally used.

In such formations as the gravels when they hold much water, it usually is sufficient to sink a well in a vertical direction so far as to maintain a good depth of water at all times of the year, provided there be not many wells drawing their supply from the same bed. It rarely happens that the permeable gravel strata of large towns are able to supply the demand made upon them, and it is therefore almost always the case that after the wells have been gradually deepened, their use is forcedly abandoned in such places: the area of supply is in fact limited; the demands of a large population practically are unbounded. But there is another reason of far more serious importance why the ordinary wells of towns are at the present day being gradually abandoned, in the contamination to which they are exposed from the infiltrations from drains, sewers, cesspools, and dead wells, which eventually introduce so large a proportion of organic matters (in the form of the nitrates) into the waters, as to render them unfit for human consumption. The infiltrations from the sewers, or the leakage from the water pipes of a town distribution may, it is true, provide an unexpected quantity of water in the superficial wells; but the earth traversed by it is so charged with organic matters, under all towns, that the quality of the water must be of the most objectionable nature. In towns situated upon the chalk even it has been found that unless the wells are sunk to a great depth, they are subject to contamination from the causes referred to; and it therefore becomes more than usually important to form an impermeable brick steining round those portions of the wells which are within the range of the effects of surface waters.

The gravel, or sand beds, hitherto considered, are penetrated by water in the whole of their thickness able to yield a supply; and the chalk marl, the green sand, the new red sandstone in some of its beds, present the same hydroscopic conditions. But such formations as the upper chalk, the oolites, the slate rocks, &c., do not allow the water to pervade the whole mass; on the contrary, the water only passes through them freely upon their great planes of stratification, or by following the joints of cleavage, or the vertical fissures which so commonly occur in those rocks. If then, wells sunk in the former class of materials should not contain much water (always assuming them to be sunk of the ordinary dimensions, that is to say of about 4 feet clear internal diameter), there is little probability of obtaining an increased supply by domeing out the bottom of the well, or by driving headings or lateral adits. In the latter class of materials, however, it frequently happens that very beneficial results are obtained by thus increasing the contributing area; for it is by no means rare to encounter springs of considerable volume by thus opening up successively the edges of the divisional planes. It is advisable in forming headings, in the strata referred to, to drive them at a slight inclination horizontally to the axis of upheaval of the strata, and vertically to follow their dip, making the height of the heading as great as possible, in order to lay bare the edges of a great number of the beds.

The water obtained from superficial wells is raised to the surface by some one or other of the ordinary machines. Where the consumption is small and the depth inconsiderable, the bucket and windlass will be found generally speaking to be sufficient; where the consumption is large, pumps must be used; common suction pumps will suffice when the lift does not exceed 28 feet; beyond that depth force pumps must be used, and they may be driven by hand, by wind, animal, or steam-power, as may be most advisable. All wells are improved by frequent and hard pumping; for not only does the water they contain undergo a species of unsatisfactory chemical action whilst standing in them, but it is also found that by relieving the pressure upon the edges of the water-bearing strata the water passages become increased.

Dead wells and absorbing wells depend for their action upon the hydrostatical law that water will, when left to itself, attain a uniform level over the whole of the surface. If then a column of water be made to stand upon a water-bearing stratum, the level of the former will subside to that of the normal water-line in the latter; and the excess of the column will be dispersed throughout the stratum. Advantage was formerly taken of this law, in such towns as Southampton, to get rid of the liquid matters of cesspools by sinking them into the permeable water stratum of the district, and leaving the bottom of the excavation open; the liquid matters thus diffused themselves throughout the superficial water-bearing stratum to the ultimate destruction of the wells fed by the latter. Of late years an attempt has also been made at Paris to get rid of the foul waters of the Voirie of that town, by sinking a boring of large diameter to the permeable strata between the chalk and the upper tertiary beds of that locality; but not only has it been found that serious injury was thus done to the neighbouring wells, but that the bore holes very soon became choked up. The fact is that dead wells and absorbing wells are public nuisances of a very serious nature, and their formation ought to be rigorously forbidden and carefully prevented. Unfortunately there is no legislation on any part of the natural conditions of flow of underground waters; nor do any legal means exist by which a landed proprietor could be prevented from contaminating the wells of a large district around him.

(See Swindell, *On Well Boring and Sinking*; Degoussée, *Guide du Sondeur*; Burat, *La Géologie appliquée aux Arts*.)

WELSH LANGUAGE AND LITERATURE.—Language. The Welsh language is that which is now spoken, and has been so far back as historical records extend, in the principality of Wales. The name of "Welsh" was first given to the people who speak it by the Anglo-Saxons, and the same term or a similar one seems to have been used in many of the Germanic and even of the Slavonic languages to denote the Italians, or other nations whose languages resembled the Latin. "Welschland" was the name for Italy in German of the middle ages, and is not yet entirely superseded in the language of the common people; the name of that country in Polish is "Wlochy," and the appellations of the Walloons and the Wallachians appear to be derived from the same root. Singularly enough, the word has a strong correspondence with the appellation given by the Romans themselves to the kindred nation of Gaul, who, as Cæsar tells us, called themselves Celts ("qui ipsorum linguâ Celtæ, nostrâ Galli appellantur"). Wallia and Gallia differ only by a letter, and Gallic and Gaelic have as close a resemblance.

The name which the Welsh give to themselves is "Cymry," and to their language "Cymreig," the obvious resemblance of the sound of which to "Cimbri" has led many to suppose them identical with the Cimbri of Roman history. The meaning now assigned to the word "Cymry" is "primitive," but this meaning does not seem to have occurred to any Welsh scholar before the Rev. John Walters, who first published it about the middle of the 18th century. The Welsh is one of a family of languages generally denominated the Celtic languages, and described as six in number, which were all spoken in the 18th century, and five of which are still spoken in the 19th, four of them within the British islands. These are 1, the Irish, which prevails in different parts of Ireland: 2, the Gaelic of the Highlands of Scotland: 3, the Manks, which is decaying and appears to be dying in the Isle of Man: 4, the Welsh, or language of Wales: 5, the Cornish, formerly spoken in Cornwall, but now extinct, and 6, the Armoric or "Bas-Breton," prevalent in some departments in the ancient province of Lower Brittany in France. All of these languages which still survive have occupied for centuries a subordinate position to some other language, the first five to English and the sixth to French. They have thus been precluded from the advantage of being spoken by the higher classes of society, and have in many cases for want of a standard of phraseology and pronunciation separated into dialects, some of which in process of time have been considered as distinct languages.

The degree of affinity between the different Celtic languages is a point of considerable interest. A controversy was carried on in 1839 on the question whether the Gaelic and Welsh, two languages in common use in different parts of our own island, are, or are not connected. The prevalent opinion for a long time had been that they were dialects bearing a close resemblance to each other: Schlözer and Adelung hinted suspicions of the correctness of this view; and Sir William Betham, in his 'Gael and Cymri,' published in 1834, asserted that they were wholly dissimilar. Professor Forbes, the learned Orientalist, whose native tongue is Gaelic, maintained the same views as Sir William, in an animated correspondence on the subject, which appeared in the 'Gentleman's Magazine' for 1836 and 1838. The main fact which he announced, that the most intimate knowledge of the Gaelic language would not enable a person to master a single verse of the Bible in Welsh, was certainly new to the world in general, and would never have been suspected from the tone in which most Celtic scholars were accustomed to speak of the affinity of the languages; but the inference which he drew from it, of a total want of connection between the two, was satisfactorily refuted by other facts. The Rev. Richard Garnett, of the British Museum, who was induced to search into the question by the statements of Professor Forbes, reported in the 'Gentleman's Magazine' for May, 1839, that on examining the monosyllabic words in the introductory portion of Neilson's Irish Grammar, about 270 in all, he found of

Words perfectly identical with corresponding Welsh terms in sense and origin	140
Clearly cognate	40
Derived from the Latin, Saxon, &c., repetitions and compound terms	40
Peculiar to the Gaelic	50

"In the Grammar," he added, "prefixed to Armstrong's Gaelic Dictionary there is a list of about two hundred verbs in common use. Seventy, or more than one-third of the whole, are unequivocally cognate with Welsh and Armoric, and twenty more probably so." "In 'Stewart's Gaelic Grammar' we have a list of twenty-four simple prepositions (omitting mere varieties of form), and about forty improper, or compound. Of the former, fourteen are Welsh, and three Cornish; and of the latter, eighteen, or nearly one-half, radically Welsh." Mr. Garnett remarked with justice, that "the amount of resemblance is hardly so great between Icelandic and German," and these are unquestionably kindred languages.

The Celtic languages must, therefore, be divided into two great branches, one of which comprises the Irish, the Gaelic, and the Manks, and the other, the Welsh, the Cornish, and the Armorican. The Irish and Gaelic have a very close resemblance, and in fact, their separation from each other appears to have been remarkably recent. The book that is generally cited as the earliest printed in Gaelic, is a translation of John Knox's 'Liturgy, or Forms of Prayer,' by John Carsewell, Bishop of the Isles, which was issued at Edinburgh in 1567, four years before anything whatever in Irish was printed in Ireland. The Rev. Thomas Maclauchlan, a Gaelic scholar, in his 'Celtic Gleanings,' a course of lectures delivered at Edinburgh in 1857, informs us that "the dialect of Gaelic used by Carsewell is that commonly known as the Irish, but which was common to the writers of both countries. It is manifest," he adds, "that Carsewell did not acquire this dialect in Ireland, for we have no reason to believe that he ever visited Ireland, and his saying that he knew nothing of the dialect but what was current in the country, shows that the possession of this dialect was not in itself an evidence of very high scholarship, but was somewhat common among the people." The close resemblance of Irish and Gaelic for some time after is shown by the circumstance that about 1690, three thousand copies of Bishop Bedell's Irish version of the Bible were printed for the benefit of the Scottish Highlanders, and Mr. Maclauchlan states, that a gentleman who was living about 1807, remembered hearing the Irish Bible used in the services at the parish church of Kirkhill, near Inverness. It was not till about 1760, soon after the appearance of Macpherson's first 'Specimens of Erse poetry,' that the Society for Propagating Christian Knowledge in Scotland, resolved on encouraging a translation of the Scriptures into Scottish Gaelic, and it was not till 1801, that a complete version existed in print. It would appear, therefore, that while in the reign of Queen Elizabeth, the Lowlands of Scotland spoke a language distinct from English as evidenced in the printed works of Knox, the Highlands spoke a language identical with Irish, as evidenced by the translation of Knox's Liturgy, and that while the language of the Lowlands has gradually assimilated to that of England, the language of the Highlands has gradually separated from that of Ireland. A similar process of disintegration appears to be still going on with the Irish language in Ireland itself—a separate version of the New Testament in the dialect of Munster was issued in 1858, and it is not improbable, therefore, that in the 20th century, there may be a larger number of Celtic languages stated to be in existence than in the 19th. The dialects of Irish vary so much, that it is said that Irishmen from different provinces who are acquainted even imperfectly with English, often make use of English in conversation with each other. An Irish clergyman, who had been a missionary to Shang Haé, informed us that he had been a witness to the use of English as the most convenient medium of intercourse by the natives of different provinces in Ireland, and the natives of different provinces in China. Campion, an English writer of the year 1571, says, that "the true Irish indeede differeth so much from that they commonly speake, that scarce one among five-score can either write, read, or understand it." The Gaelic is now itself divided into two dialects, which seem to have a tendency to diverge more and more. Forms of speech which are frequent in the version of the Scriptures printed in 1801, are not found in the curious collection of Gaelic stories taken down from the lips of Highland narrators, and published by Mr. Campbell of Islay in 1861, one of the most careful records of oral language in existence. The so-called Manks language is a kind of corrupted Gaelic, more different to the eye than the ear, from being written in a less artificial system of spelling. The system of "orthography" of Irish and Gaelic is so excessively complex and difficult, that those who speak them are often unable to read them even when they have learned to read English.

The three forms of the Gaelic branch of the Celtic family of languages are thus intelligible with a little trouble to any person who is a thorough master of one; but this is not the case with the three forms of the other branch. The affinity between Welsh and Bas-Breton is much less than has been sometimes asserted. The best evidence on this point is that of the Rev. Thomas Price, a distinguished Welsh scholar, who made a tour through Brittany in the summer of 1829. "I may," he says ('Cambrian Quarterly Magazine,' vol. ii. p. 197), "be asked a question which I should myself have proposed to another upon a similar occasion, had I never visited Brittany, and that is, if the Welsh and Breton languages bear so near a resemblance to each other as is generally understood, where was the necessity of having recourse to the French as a medium of communication? Why not converse with the Bretons in the Welsh at once? To this I answer that, notwithstanding the many assertions which have been made respecting the natives of Wales and Brittany being mutually intelligible through the medium of their respective languages, I do not hesitate to say that the thing is utterly impossible; single words in either language will frequently be found to have corresponding terms of a similar sound in the other, and occasionally a short sentence deliberately pronounced may be partially intelligible, but as to holding a conversation, that is totally out of the question."

One of the earliest and most valuable books of research and information on the Celtic languages in general is the 'Archæologia Britannica, giving some account additional to what has been hitherto published of the languages, histories, and customs of the original inhabitants of Great Britain, from collections and observations in travels through Wales, Cornwall, Bas-Bretagne, Ireland, and Scotland, by Edward Lhuyd, M.A., of Jesus College, Keeper of the Ashmolean Museum at Oxford.' The first volume, a closely printed folio on 'Glossography' appeared in 1707, and was never followed by a second, the continuation of the work being prevented by the death of the author in 1709. Lhuyd had travelled in all the Celtic countries to collect materials, and was only driven from Brittany by the outbreak of Marlborough's war. He unfortunately adopted a peculiar system of orthography for the Welsh, and took a singular whim of displaying his knowledge of Irish and Cornish, by writing prefaces in Irish and Cornish to parts of his book; the first of which is censured by Irish scholars as full of solecisms, and the second was a 'sealed book,' till portions of it were lately translated into English by Mr. Edwin Norris. But his work comprises a valuable comparative collection of vocabularies, and a large body of miscellaneous information on the manuscript literature of the Celtic languages, similar to the information on the northern languages which was brought together by his friend Dr. Hickes in 1705, in the celebrated 'Linguarum Septentrionalium Thesaurus.' Lhuyd left behind him a large collection of manuscript materials for the continuation of his work, which have unfortunately perished—by three separate accidental fires in London and Wales. The next student of Celtic on an equally extensive scale appears to have been the famous and infamous Eugene Aram, who refers to the subject in an autobiographical letter written in 1759, while he was in confinement in York Castle, not long before his trial and execution. "I investigated the Celtic," says Aram, "as far as possible in all its dialects; begun collections, and made comparisons between that, the English, the Latin, the Greek, and even the Hebrew. I had made notes and compared above three thousand of these together, and found such a surprising affinity,

even beyond my expectation or conception, that I was determined to proceed through the whole of all these languages and form a comparative lexicon, which I hoped would account for numberless vocables in use with us, the Latins, and Greeks, before concealed and unobserved. This, or something like it, was the design of a clergyman of great erudition in Scotland, but it must prove abortive, for he died before he executed it, and most of my books and papers are now scattered and lost." This laurel was not destined for a British head. Nearly a hundred years later, in 1853, appeared at Leipsic the most important contribution yet made to Celtic philology, the 'Grammatica Celtica' of Professor Johann Caspar Zeuss of Bamberg, who had devoted thirteen years to the necessary preliminary studies. The book, which extends to two volumes, comprising more than eleven hundred pages, embraces a grammar of the Celtic languages in a mass, the Irish, Welsh, Cornish, Armorican, and ancient Gaulish, constructed on an unusual plan. The author takes the parts of speech separately, and the languages one after the other, treating, for instance, the article in Irish, in Welsh, in Cornish, &c., before he proceeds to examine the substantive in any one of those languages. As in some other German works on philology, the method of treatment is laborious and unattractive, wanting in generalisation, and calculated to repel all but the determined student. The author adopted the medium of Latin as the general language of the learned, but his Latin is unfortunately the reverse of elegant. The value of the work, which is great, consists in the minute and careful scrutiny to which Zeuss has subjected the manuscript materials for a knowledge of the early state of the Celtic languages, which are scattered in the libraries of England and the continent, and which he for the first time brought together. These materials mostly consist of 'Glosses,' or translations of single words or passages in the margins, or between the lines of old Latin copies of the classics. Specimens of interlineary Welsh of this kind are to be found in a manuscript of Eutychius and Ovid in the Bodleian Library at Oxford, of the conclusion of the 8th or commencement of the 9th century, while the 'Black Book of Caernarvon,' and the 'Red Book of Hergest,' the oldest manuscripts of unbroken Welsh, are ascribed by the best judges to the 12th and the 14th centuries, and are thus later in date by no less than four and six hundred years. A steady light was also thrown by Zeuss on the ancient Irish from study of the 'Glosses' in manuscript, which lay unnoticed in the libraries of Germany and Italy; in some cases, as in the library of St. Gall in Switzerland, founded by the Irish monks who converted the Swiss to Christianity, buried and forgotten for a thousand years. The suggestion which he threw out that a minute examination of the manuscripts in English and Irish libraries might probably lead to the discovery of further stores of the same kind has already borne its fruits in the discoveries made by Stokes at Dublin, and Bradshaw at Cambridge, and in all probability much still remains to be dug out. Zeuss himself was unfortunately lost to science by his premature death in 1856, at the age of fifty. In an interesting biographical sketch of him by his learned countryman, Dr. Siegfried, now of Dublin, in the 'Ulster Journal of Archæology,' for 1859, his illness is ascribed to over study.

A great and striking merit of Zeuss's laborious work, and one which makes its publication an epoch in Celtic studies is, that it presents a total contrast in its tone and spirit to that which had too long prevailed in this branch of investigation. The students who follow the track opened in the 'Grammatica Celtica' have no pleasant path before them—it leads amid "Glosses," and other such literature as only the severest philologists can tolerate and none can relish—but their footing is on firm dry ground. Zeuss is not indeed averse to speculation any more than his German colleagues in general, one of his views being that Irish and Welsh were identical not long before the invasion of Cæsar, as Irish and Gaelic were identical a few hundred years ago. But there is a wide difference between such views as these, open to discussion as they are, and the wild hallucinations to which Celtic scholars have been too often subject. Pezron, the Breton investigator, maintained in 1703, in perfect good faith, that Welsh and Breton, which he considered the same language, had been "the language of the Titans, that is, the language of Saturn, Jupiter, and the other principal gods of heathen antiquity." The Rev. Joseph Harris, a respectable Baptist minister of Swansea, editor of the 'Seren Gomer,' observed in 1814, very gravely, that "it is supposed by some, and no one can disprove it, that Welsh was the language spoken by Adam and Eve in Paradise; and if so, what can be more natural than to suppose that it will be the language of the celestial Paradise where all the nations of the earth shall be of one tongue." Unluckily for the force of his observation, not only has the honour of being the language of Paradise been positively claimed for other languages—for Basque by several authors, for Dutch by Goropius Becanus, for Gaelic by Mr. Maclean, author of a 'History of the Celtic Language,' in 1840—but there is a Welsh tradition, unknown to Mr. Harris, which expressly states that Welsh was not the language of Paradise, but the first language spoken out of it. The Rev. John Williams ab Ithel, editor of the 'Cambrian Journal' for the Cambrian Institute, in his preface to an ancient grammar of Edeyrn, which he edited in 1856 for the Welsh Manuscript Society, speaks in a tone of assent of the assertion that there are only three languages of divine origin, that of Adam, that of Moses, and the Welsh; and also of an assertion grounded on bardic tradition respecting the word by which the world was created, and its embodiment in the first letter of the ancient Welsh alphabet. Passages like these, which are but too common in the works of some Celtic scholars, have had the effect of disgusting many with the study of Celtic antiquities.

Some of the more important conclusions to which Zeuss's researches conduct, are embodied by Mr. Edwin Norris, of the Foreign Office, in the valuable observations on the Cornish language, appended to his edition of the remains of the 'Ancient Cornish Drama,' printed at the University Press at Oxford in 1859. "The superior antiquity of the Irish over the British language is now," says Mr. Norris, "scarcely doubted; it is seen as well in their grammatical as in their glossarial relations. The declension of the Irish noun is even yet in existence, and it is shown with much probability to have been closely allied to that of the oldest Indo-European forms at an early period; of the British, the only remnant left is a Cornish genitive, and a scarcely discernible trace in Welsh." He then produces several instances in which, as in *teagh* and *ti*, Irish and Welsh for "a house," and *nochd* and *nos*, Irish and Welsh for "night," letters are dropped in Welsh that remain in Irish, and argues for the greater antiquity of the fuller form. "It may look like the partiality of an editor," he continues, "to ascribe a greater antiquity to Cornish than to Welsh, in the face of the universally adverse opinion, but the writer confesses that he is inclined to consider the Cornish the older of the two;" and he gives his grounds for so doing, principally founded on the fact that it is shown by the glosses produced by Zeuss, that "in the 8th century Welsh had Cornish forms and words which were lost or altered in the 12th." From these premises Mr. Norris infers that "Cornish is the representative of a language once current over South Britain at least." If these views be correct, the Welsh will lose their claim to the honour they have so long retained of being considered the representatives of the "Ancient Britons."

A good comparative dictionary of the Celtic languages would be an acquisition to philology, and is much required. The Rev. Robert Williams, of Llangadwaladr, author of the 'Lives of Eminent Welshmen,' announced in 1860 that he had completed a labour of the kind, the publication of which would be commenced as soon as a sufficient number of subscribers could be obtained. One of the publications of Prince Louis Lucien Bonaparte supplies material for a comparison of the different dialects not otherwise attainable. It is entitled 'The Celtic Hexapla' (London, 1858, 4to), and comprises the Song of Solomon in eight languages, which are all presented to view at the opening of any page—French and English, Irish and Welsh, Gaelic and Manx, Breton of the ordinary form, and Breton of the dialect of Vannes. The two latter translations were first printed in this volume; the others are taken from the authorised versions.

The degree of prevalence of the ancient Celtic element in Europe,—the area over which the various dialects were spoken, and the remains of them which may be still traced out,—is a subject upon which much has been written, but which still awaits its Zeuss. It is however an antiquarian subject alone; it is certain that no Celtic language is now spoken on the continent beyond the limits of Brittany. The Basque of the Pyrenees, so often asserted to belong to the Celtic family, is as distinct, both in words and construction, as can well be imagined. The notion of Dr. Owen Pughe that the Wendish of Lusatia was a language akin to Welsh, is as wide of the mark as the strange notion which found its way by a series of blunders into Adelung's 'Mithridates,' that a Celtic dialect was spoken at Maldon in Essex. The small value of Dr. Owen's statements on such a subject is shown by his declaration in the preface to the edition of Llywarch Hen, published in 1792, that he had "a collection of evidence sufficient to convince as great sceptics as any that will see this" that "the Nadowesses, a people west of the Mississippi in America, known to the Indian traders by the name of the civilised Indians and the Welsh Indians, do now actually speak the Welsh language." "These people," he confidently added, "are the descendants of the emigration under the conduct of Madog ab Owain Gwynedd in the year 1170." The remains of the extinct Celtic languages of the continent are singularly scanty. A few scattered words are all that is preserved of the speech of ancient Gaul—the language that prevailed in France at the time that Cicero wrote in Italy. These words bear so close a resemblance to those of the same meaning in Welsh, as to justify the assumption that there was little distinction between the dialects of France and England at the earliest dawn of history. Whether we ought to believe that the "Celts" who are mentioned by different writers of antiquity in different parts of Europe were all closely connected with one another, or all even rightly named, is a perplexing question. The most reliable evidence now attainable on the subject appears to be that of the names of places, and these must be very cautiously sifted. Dr. R. G. Latham reminds philologists that there is no connection beyond a mere resemblance in name between Gallicia in Spain and Galicia in Poland. A large collection of materials of this kind has been amassed by Dieffenbach in his 'Celtica,' and a work on the subject by Contzen, 'Die Wanderung der Kelten,' which received a prize from the Academy of Munich in 1856, has (in 1861) just issued from the press.

The question of the affinity of the Celtic languages to the other languages of the world is one that has given rise to considerable debate since the epoch that was made in comparative philology by the introduction of the study of Sanskrit, about the commencement of the 19th century. In preceding centuries Welsh had been often compared with Hebrew. "It is commonly observed," says Llewellyn in his 'Historical and Critical Remarks on the British Tongue,' "that the British and the Hebrew are similar languages," on the ground of their being alike in many peculiarities of construction, especially in permutation or the change incident to several letters in the beginning of words, and also in the paucity and confusion of tenses in the conjugation of verbs, and in the binding together in one word of some prepositions and pronouns. This degree of resemblance is certainly not sufficient to place the Welsh and the other Celtic languages in the Semitic family, but in these respects it does resemble the Hebrew and differ from the Greek and Latin, which form a portion of the Indo-European family to which it is now adjudged to belong. The Indo-European family, or rather tribe, is now so extended that it comprises many languages formerly regarded as entirely disjoined, such as Greek and Persian, Russian and English,—while the Semitic only comprises a very small circle of languages bearing a close resemblance to each other—a circle, in fact, no larger than that of the Celtic family alone.

The history of the controversy is an instructive one. For the first thirty years of the 19th century the Celtic languages were supposed, to quote the words of the Rev. Richard Garnett, "to form a class apart, and to have no connection whatever with the great Indo-European stock. This was strongly asserted by Colonel Vans Kennedy, and also maintained, though in more guarded terms, by Bopp, Pott, and Schlegel. The researches of Dr. Prichard in his 'Eastern Origin of the Celtic Nations,' and of Professor Pictet of Geneva, in his truly able work, 'Sur l'Affinité des langues Celtiques avec le Sanscrit,' may be considered as having settled the question the other way. The demonstration of Pictet is so complete, that the German scholars who had previously denied the connection, now fully admit it, and several of them have written elaborate treatises, showing more affinities between Celtic and Sanscrit than perhaps really exist." The work of Dr. Prichard, himself a Welshman, is entitled 'The Eastern Origin of the Celtic Nations proved by a comparison of their dialects with the Sanskrit, Greek, Latin, and Teutonic Languages.' The first edition appeared in 1831; a second, with extensive and important additions by Dr. R. G. Latham, in 1857. On the subject of the Celtic languages in the British Islands, there are some valuable and really instructive papers by the Rev. R. Garnett, in the 'Quarterly Review,' and the 'Transactions of the Philological Society,' which are collected in the posthumous volume of his 'Philological Essays,' edited in 1859 by his son.

The Welsh language is one of the oldest in Europe: the Irish and Welsh are in fact among spoken languages the most ancient of which any written monuments are preserved, unless we regard the modern as identical with the ancient Greek. The Welsh has poems now in existence, the origin of which is believed by the best critics to date back to the 6th century, to a period little after the time when the Romans left the country, in which of course, while they held it, the dominant language was Latin. It is true that Zeuss has shown that the language of these poems, when originally composed, must have differed in a considerable degree from that of the form in which they are preserved to us, and that one of the most learned Welshmen of a century ago, the Rev. Evan Evans, says in his 'Specimens of the Bards,' published in 1763, that he had shown the most genuine remains of Taliesin to the best Welsh antiquaries and scholars then living, and that "they all confessed they did not understand one half of any of his pieces." It is true also that Price, in his 'Hanes Cymru,' a book intended for ordinary readers, found it necessary to give a modern Welsh version of an ancient Welsh poem, which he quoted from Gwalchmai, a bard of the 12th century, who is said to have accompanied Cœur de Lion to the Crusades. Still from about the Norman conquest downwards, there exists a mass of literary matter in a language which is readily intelligible to those who are acquainted with the modern Welsh after a slight degree of study. A similar observation is perhaps applicable to no other living European language except the Icelandic. The language of the Saxon contemporaries of Taliesin has been a dead language for centuries, and even in the time of Gwalchmai the present English was as yet unborn.

The Welsh has long been an object of study to those who speak it. "There are," says Owen Pughe ('Archæologia,' xiv. 220), "about thirty different old treatises on Welsh grammar and prosody preserved. Of these, one is particularly deserving of notice as a curious relic: it was composed by Geraint about 880, revised by Einion about 1200, and again by Edeyrn about the year 1270, and regularly privileged by the different sovereigns who then exercised authority in Wales." This work was first printed by the Welsh Manuscript Society in 1856, under the editorship of the Rev. John Williams ab Ithel. A portion of a grammar which appeared in 1567, from the pen of Griffith Roberts, and of which mention will be made hereafter as remarkable on other accounts, is remarkable also as containing some proposals on the subject of Welsh orthography of an ingenious character, which were not however adopted. Two Latin grammars of the language followed, the 'Cambrobrytannicæ Linguæ Rudimenta' of Dr. David Rhys, in 1592, and the 'Antiquæ Linguæ Britannicæ nunc communiter dictæ Cambro-Britannicæ Rudimenta' of Dr. John Davies, in 1621, both of them much esteemed. There are now several grammars of the Welsh language in English, of which that by the Rev. Thomas Rowland, the second edition of which was published in 1857, may be recommended as the most satisfactory. Dictionaries are less numerous. Dr. John Davies, the author of the grammar, published in London in 1632 a Welsh and Latin dictionary, 'Antiquæ Linguæ Britannicæ Dictionarium Duplex,' which continued in repute for a century and a half, till superseded by that of Dr. Owen Pughe. This work, 'Geiriadur Cymraeg a Saesoneg, a Welsh and English Dictionary,' with a grammar prefixed, published in two closely-printed octavo volumes in 1793, and again in 1829, is still the only Welsh dictionary on a sufficiently extensive scale, and is a work of great labour and merit, but it is open to serious objections. The number of words it contains is nearly 100,000; but many of these are compounds, formed on regular principles, which only serve to swell the book, and many of them are only words which ought to exist in Welsh, according to the lexicographer's opinion, rather than words which actually exist in it. A third edition is now (1861) in course of publication, under the editorship of R. J. Pryse, who promises that the work shall contain "scores of thousands" of words not in the previous editions. As Owen's comprises Welsh and English only, not English and Welsh, the want of the latter was formerly supplied by the excellent English-Welsh dictionary of the Rev. John Walters, of which a new and improved edition was published about 1825. The 'English and Welsh Dictionary' by Daniel Silvan Evans, in two thick volumes (Denbigh, 1852–1858), is however still superior to that of Walters. There are a compendious grammar and dictionary by Mr. Spurrell of Carmarthen, both of which will be found useful. Some information on the Welsh dialects is given in the 'Essay on the Ancient and Present State of the Welsh Language,' by Mr. John Hughes, published about 1820. There are differences in pronunciation and idiom sufficiently marked to render it difficult for persons from remote districts to converse with each other; and North Wales is more pure and correct in its language than South Wales.

The system of spelling in Welsh corresponds with and represents the pronunciation, and in that respect it has a marked superiority not only over its kindred Celtic languages, the Irish and Gaelic, but, as we daily feel to our cost, over the English. There are at the same time some peculiarities in Welsh spelling, the motive of which is not very plain, and the effect of which is often ludicrous. The sound which is generally represented by the letter *v* is in Welsh represented by *f*, even in proper names, so that pronouncing Calvin and Virgil not unlike ourselves, a Welshman writes "Calfin" and "Firgil." The sound represented in the English alphabet by *f* is represented in Welsh by *ff*; and thus Fox and Franklin must be written Ffox and Ffranklin, as, if spelt in the ordinary manner, a Welsh reader might pronounce them Vox and Vranklin. Some efforts have been made by Owen Pughe and others to introduce the missing *v* into the Welsh alphabet; and it is usual for English writers to follow his system in spelling Welsh names—to write Merthyr-Tydvil, for instance, instead of Merthyr-Tydfil. But the advantage of uniformity is so great, that though the present system scarcely dates further back than the 16th century, and though there are several eccentricities like that with the *v*, resistance to innovation has hitherto triumphed.

It has been said, that in English the grammar is excellent and the dictionary is execrable. The grammar of English is, in fact, distinguished by its great comparative freedom from needless complexities, while its list of words comprises thousands that a careful writer will carefully avoid. In Welsh, almost the converse is the case. For useless intricacy its grammar has a bad pre-eminence. It is pervaded from first to last by a certain law of "permutations," the nature of which will best be understood by an instance. The word for "father" in Welsh is *tad*; the word for "my" is *fy*: but to say *Fy tad* for "my father" would be an unpardonable solecism. After *fy*, every word beginning with a *t* must change the *t* to *nh*, and the correct phrase is therefore *fy nhad*. The word for "thy" is *dy*; but after this a different change is required: "thy father" is *dy dad*. The word *ei* in Welsh means "his" or "her," but according to the sense requires a different mutation to follow: "his father" is expressed by *ei dad*, and "her father" by *ei thad*. Some of the letters, as *t*, have three of these mutations to undergo, some only two, some only one, and some none at all. There is a multitude of intricate rules to determine in what circumstances the different mutations are to be used, and at the same time the existence of letters which undergo no mutations whatever, and the words beginning with which are just as elegant and forcible without them, proves to demonstration the utter uselessness of the whole. In the other Celtic languages there is a similar system, but not carried quite so far as in the Welsh. The principle has been generally considered to be peculiar to that family of languages in Europe; but Prince Louis Lucien Bonaparte, in his extensive researches among the obscurer tongues, has discovered slight traces of mutation in some of the dialects of Sardinia. In the complexity caused by an intricate system of declensions and conjugations there is generally some compensation obtained in a superior precision and force; but there is nothing of the kind in mutation. Its origin was long a subject of debate. In some compounds of words it was plain that attention to euphony had given rise to it. The opposite to "possible," in English, is "impossible": both words are taken from the Latin, and the "in" privative, as it is called, is altered to "im" in this and other cases before the letter *p*, to avoid unpleasantness of sound. The Welsh have also borrowed the word *posibl* from the Latin, and for "impossible" they say *anmhosibl*. The Welsh particle answering to our "un" is an: the collision of *n* and *p* was also to be avoided; but instead of altering the last letter of the *an*, they altered the first letter of *posibl*. It has lately been pointed out by Zeuss and his school, that in other cases where *p* is altered to *mh*, it was in the old forms of the language preceded by an *n* which no longer exists. Hence it may be inferred that the whole system of mutations was originally founded on the euphonic principle. While the effect remains, however, the reason for it has disappeared in the actual state of the language. The rules for mutations are at the present day mere arbitrary rules, the motive for which is as unknown to those who practise them as the reason for spelling "wright" with *w* and *gh* is unknown to the schoolboy who is being taught to spell. After all these sacrifices to harmony, the Welsh has never been considered harmonious by those of whom it was not the mother-tongue, though a writer in the 'Cambrian Register' for 1[illegible], affirms that "strangers to both languages frequently mistake the Welsh for Italian."

The principal beauty of Welsh as a language consists in the facility which it possesses of forming derivatives and compounds, and the completeness with which that power has been exercised, making full and ingenious use of every root, and thus avoiding that useless borrowing of terms from other languages which has been carried to such an absurd extent in English. Many foreign words have indeed been introduced into Welsh, but they have been so assimilated to those of native origin as often not to be easily detected. The whole language seems of a piece. But there is this advantage in a language in which the grammar is superior to the dictionary: that by a skilful choice of words, by limiting himself, like Metastasio, to a certain select vocabulary, an author may exclude from his writings all but the beauties of the language; while in the opposite case, the defects—as in Welsh, the rules for mutation—are necessarily involved in every sentence and intrude at every turn. These rules alone make it much more difficult for an Englishman to learn to speak Welsh than for a Welshman to learn to speak English.

The general character of the Welsh language in composition is that of a certain stateliness, and even grandiloquence, the reverse of what would probably be expected by strangers who know for how long it has been the language of the peasantry alone and discountenanced by the higher classes. In its effect, it reminds a reader more of the Spanish than the German. It has been sometimes praised for its conciseness, but in its present state it may be much more justly characterised as diffuse. The words in the first paragraph of the 'Pilgrim's Progress,' "I looked and saw him open the book and read therein, and as he read he wept and trembled," are thus rendered in the Welsh translation by Thomas Jones, published at Shrewsbury in 1699, "Edrychais a gwelais ef yn egor y Llyfr ac yn darllain ynddo; a phan ddarllenodd ef wŷlodd a chrynnodd." In this there are exactly as many words as in the original, namely, nineteen; but in the translation published at Caermarthen in 1771, and reprinted in 1854, the passage stands thus, "Mi a edrychais ac a'i gwelais ef yn agor y llyfr ac yn darllen ynddo, ac fel yr oedd efe yn darllen fe wylodd ac a grynodd," and the number of words is twenty-eight. The same proportions seem to prevail between the language of the two translations in general.

The Welsh are strongly attached to their language. The Irish, so vehemently opposed to the Saxon in religion and politics, are in the matter of language far from obstinate. Daniel O'Connell, the patriotic orator, and Moore, the patriotic poet, were ignorant and careless of the Celtic tongue. It is said that the peasantry are so anxious to secure to their children that mastery of English of which they feel the want themselves, that they have a forfeit for speaking Irish, and enforce it on the children in their cabins with as much severity as a forfeit of a similar kind is enforced on the pupils in an English boarding-school. Under the influence of this feeling the Celtic language of Ireland appears to be slowly but surely losing ground, while the English language is indebted to Ireland for some of its finest poets and novelists, and most brilliant orators, with a long array of literary labourers of a less ambitious class. With Wales all this is different. The Commissioners of Inquiry into the state of Education in Wales, give it as their opinion in their official report, that "the Welshman possesses a mastery over his own language far beyond that which the Englishman of the same degree has over his;" and that "readiness and propriety of expression to an extent more than merely colloquial, is a feature in the intellectual character of the Welsh." But the Welsh are eloquent and poetical in their own language only. They have contributed no bard, no orator, no historian, no dramatist, no preacher, of the first, or the second, or even the third rank, to the literature of England.

The use of two languages in the same country cannot but be considered as an evil, for it is an element not of concord but of discord. The experience of the continent, in the case of German and Danish, and of German and Hungarian, shows that under certain circumstances it may even become a source of civil war. It is an admitted fact that antipathy and animosity towards the Saxon still lurk among that portion of the Welsh population to whom English is a language either entirely unknown, or known but imperfectly. There is a well-authenticated story that in the time of the Commonwealth, Sir Edward Stradling, of St. Donat's Castle, flying from the victorious Roundheads after a lost battle, came to the river Taff, and finding the bridge broken down, asked in the English language of a Welsh peasant who was standing near, where he might safely ford the stream. He was told in reply, "Keep straight on, for that is the shortest and best way to thy home." Sir Edward rode on to the bank, and chanced before entering the water to speak a few words to his soldiers in Welsh, on which the peasant, perceiving he was not an Englishman, called out in haste to him not to enter the stream at that point, for if so he would lose his life. There was a whirlpool on the spot, to which the malignant peasant, when he thought Sir Edward a Saxon, had directed the stranger with a view to drown him. Such feelings are far from extinct, even in modern times, unless those who are well acquainted with Wales are much mistaken.

The Welsh language is now in a very flourishing state. The fate of its neighbour, the Cornish, which gradually perished of mere neglect, led to the supposition that the Welsh would also disappear from the same cause; and indeed Mr. Wynne, the president of the Asiatic Society, himself a Welshman, referred to the decline of Welsh as a proof of the efficacy of the non-interference system in such cases, in a discussion on the subject of endeavouring to introduce the English in the place of some of the native languages of India. More than a century ago, Goronwy Owen, the Welsh poet, related in one of his letters (printed in the 'Cambrian Register'), that in a discussion on the Welsh language with another Welshman, Owen, the translator of Juvenal into English, "the wicked imp, with an air of complacency and satisfaction, said there was nothing in it worth reading, and that to his certain knowledge the English daily got ground of it, and he doubted not but in a hundred years it would be quite lost." The experience of the time that has since elapsed has shown that Mr. Owen was mistaken. "For upwards of ten centuries," says the Rev. W. J. Rees, in an address delivered in 1821 on the formation of the Cambrian Society in Gwent, "since the reign of Offa, who made his celebrated dyke to prevent incursions of the Welsh into his territories, the Welsh language has receded comparatively but little within the boundary, especially in some parts of North Wales; and in other districts, when the long lapse of time since the conquest by Edward I., and the intimate incorporation by Henry VIII., and the great encouragement given for the attainment of the English language are considered, it has gained less ground than could be expected. An Englishman travelling the public roads of the principality often meets with persons who speak English, and those whom he has occasion to address at the inns are able to accommodate themselves to his language: the gentry he may visit speak English, and those who call upon them probably use the same language in his hearing; and from these slight facts which come to his knowledge, he erroneously concludes that the English is the prevailing language of the country. It is only one who has resided a long time in the interior, having intercourse with the common people, that can form a true estimate of the extent of the Welsh language; and most persons will readily assent to the truth of the assertion, that the Welsh is the sole living speech not only of thousands, but of tens of thousands, and even of some hundreds of thousands of the inhabitants of the principality." ('Cambro-Briton,' vol. iii., p. 229.) It not only holds its ground in the Old World, but has emigrated to the New. While Dr. Macleod, in the preface to his 'Leabhar nan Cnoc,' exulted in the hope that if Gaelic is destined to perish in the Highlands, it will survive beyond the Atlantic in the living speech of numbers greater than ever spoke it in Europe, the Rev. T. Price, in his 'Hanes Cymru,' related with similar exultation that he had received from America some numbers of a Welsh periodical, the 'Cyfaill yr Hen Wlad,' or 'Friend of the Old Country,' which was publishing at New York. This progress continues. In an account of the press in the United States in 1861 it is mentioned that five Welsh newspapers are printed in that country, a circumstance which may probably lead some future Celtic historian to infer the truth of the belief, so firmly entertained by some Welshmen, that the language has flourished on the American continent since the days of Madoc. At the same time the periodical press of Wales itself is increasing yearly, while in the first number which ever appeared of a Welsh newspaper, not fifty years ago, a notion was stated that the language would hardly survive that generation. Eisteddvods or Bardic meetings, formerly rare, are now frequent and more and more popular. The call for bishops who understand the Welsh language has been loud enough to compel the attention of the English cabinet. At the present moment the patriotic aspiration so often on the lips of Welshmen, "Oes y byd i'r iaith Gymreig,"—"May the Welsh language last as long as the world,"—appears in small danger of non-fulfilment.

If it be really decided that the language of "some hundreds of thousands" is to continue to be cultivated amidst its native mountains, side by side with the language of sixty millions, to which fresh millions are added every year, care should be taken to avoid the disadvantages that might arise from such a state of things. The preservation of the old language ought to be combined with the cultivation of that which has grown up beside it,—of the great English language that has put a girdle round the earth, and is now spoken by mighty communities in each quarter of the world, and on the shores of every ocean. The "Cymro uniaith" "the Welshman of one language,"—a phrase in common use—is not necessarily more patriotic than the Welshman of two languages; but he is, by a great deal, a member of society less capable of aiding others and of aiding himself. Were the English language introduced into every school, and were the youth of Wales induced to make themselves thoroughly familiar with it, much good would undoubtedly be the result. The acquisition of the general language of the empire, of the language of great cities and high civilisation, and ample stores of learning, would open a new field to the abilities of many a young Welshman, whose ignorance of any but his native language confines him to a small circle and a narrow career—the general diffusion of English would invite more frequent visitors from England to the lovely and romantic scenery of the principality, and a new era of more cheerful prosperity might dawn upon Wales.

Literature.—The quotation is peculiarly happy which was prefixed to a magazine entitled 'The Cambro-Briton,' devoted to the cultivation of Welsh literature: "Nulli quidem mihi satis eruditi videntur quibus nostra ignota sunt."

The history of the literature of Wales is as peculiar as that of its language. It commences with poems ascribed to the 6th century, a period of almost classical antiquity, to which no living language of the Teutonic or Sclavonic families can be traced. It flourished undoubtedly in the 12th century, and its "golden age" is referred to a date at which no English literature could be in existence, because the English language was as yet unborn. For the last six or seven hundred years its course may be distinctly traced, almost the "solitary pride" of a nation, that, amidst all obstacles and struggles, has been remarkably constant in its attachment to letters. It is true that the value of this literature is not to be compared for an instant with the value of our own, but it is a literature eminently curious and eminently British; and the apathy can hardly be explained with credit to English scholars that has allowed the subject to remain as it has, in almost total obscurity and neglect.

Perhaps the most valid excuse that can be pleaded is that obstacles to investigation were offered in the very quarter from which assistance might be looked for. A mass of unfounded and uncritical statement on the subject of Welsh antiquities is in existence and in print, which obstructs in the most annoying way the endeavour to arrive at a clear view of the subject. "A Scotsman," says Dr. Johnson, "must be a sturdy moralist indeed if he loves not Scotland better than truth." "How justly," says Edward Williams, or Iolo Morganwg, the most eminent Welsh antiquary of the 19th century, "might he have said the same thing of every Welsh antiquary that has hitherto appeared in the world." ('Cambrian Journal,' for 1860, page 18.) "How many truly learned and ingenious literary gentlemen," says the same writer in another place, "applied to Mr. Evans and his *fib-monger*, Lewis Morris, for information relating to Welsh literature and Welsh antiquities, and how many of the most glaring falsehoods have they had in return from these fellows," whose alleged ignorance and bad faith he proceeds to expose. But the very Iolo Morganwg whose words we have quoted, and who up to his death, in 1826, was, and is even now regarded by many as the chief authority on Welsh literature, is pointed out by others as absolutely still less worthy of confidence than any Welsh antiquary who preceded him. Not only therefore is the entrance into the cavern of Welsh antiquities dark and difficult, but the guides are not to be trusted. The national practice has not been in accordance with the national motto of Wales, "Y Gwir yn erbyn y Byd," "Truth against the world."

Another obstacle, though an inferior one, has been the difficulty of arriving at the materials for forming a judgment. The Welsh, as has been said, claim to be in possession of a body of poetical compositions extending over a period of thirteen hundred years. Till the commencement of the 19th century almost all the compositions for which this antiquity is claimed remained buried in the libraries of colleges and of private individuals, some so difficult of access, that Lhuyd, the author of the 'Archæologia Britannica,' who spent his life in researches into Celtic literature, was never able to obtain a sight of some of the most interesting. This reproach was removed, after ineffectual appeals to the patriotism of the gentry of Wales, by the liberality of Owen Jones, a furrier in Thames Street, father of Owen Jones, the architect, so well-known by his publications on the 'Alhambra,' and his restoration of it at the Crystal Palace of Sydenham. At the expense of more than a thousand pounds Mr. Jones, the elder, collected and published, in 1801 and subsequent years, in three volumes, under the title of 'The Myvyrian Archaiology of Wales,' the chief productions of Welsh literature for nearly nine hundred years, from about 500 to 1400. In this task he was assisted by Edward Williams, better known by the name of Iolo Morganwg, or Edward of Glamorgan, already mentioned, and by Dr. Owen, afterwards Dr. Owen Pughe. The enterprise was by no means undertaken too soon. "A number of manuscripts equal to what now remains," says Owen in the fourteenth volume of the 'Archæologia' of the Antiquarian Society, "hath perished through neglect within the last two hundred years, that is to say, since the higher ranks of Welshmen have withdrawn their patronage from the cultivation of the literature of their native country. We have still upwards of two thousand manuscript books of various ages, from the beginning of the 9th to the close of the 16th century." By the publication of the 'Myvyrian Archaiology' a vast mass of materials was placed out of danger, but it did not comprise the whole of what Jones intended to publish,—in the library of the British Museum, no less than eighty volumes of transcripts are now deposited which were intended for a continuation of the work. After the cessation of Jones's exertions, the old apathy returned, and more than thirty years elapsed before, in 1837, an association was set on foot on the model of the Camden and similar societies, and under the name of the Welsh Manuscript Society, for the purpose of publishing manuscripts, whether in Welsh or other languages, connected with Wales. The important provision was made in the rules, that the works in Welsh were to be accompanied with translations. The Society has not been so active as it promised. Since its foundation, it has scarcely issued five volumes, and some of them are of a mere antiquarian and genealogical cast. The most important is that entitled 'The Iolo MSS.,' a volume of selections from the materials collected by Iolo Morganwg for the continuation of the 'Myvyrian Archaiology.' At present (in 1861) it is said in the 'Cambrian Journal' that measures have been taken for "re-invigorating" the society, and we heartily wish them success.

In the publications of this society the second step was begun to be taken of the three which are requisite to bring the literature of Wales fairly before the world. The first is, the publication of its monuments, as indispensable materials for all that is to follow; the second, the rendering of them accessible, by translations, to those who have not the opportunity of acquiring, in addition to the knowledge of the Welsh language as it now is, that of all its variations from the time of King Arthur. The third will be, that of applying a judicious criticism to these materials; of comparing, elucidating, and investigating; separating the genuine from the spurious; and deciding their value. When all this has been done, and not before, it will be possible to take a satisfactory survey of the history of early Welsh literature, in which is involved the history of two of the most interesting points of modern literature in general, the origin of rhyme and the origin of romantic fiction. Under present circumstances many questions of interest must be left doubtful.

The history of Welsh literature may be divided into four periods: from the earliest times to the Norman conquest of England in 1066,—from the Norman conquest to the Reformation, which nearly coincides with the incorporation of Wales with England in the reign of Henry VIII., in 1536,—from the Reformation to the commencement of the reign of George III., in 1760,—and from 1760 to the present time.

The First Period, 1066.—The Welsh, it has been already stated, claim to be in possession of several poetic compositions of the date of the 6th century, and these compositions are in rhyme, which would be, as far as is at present known, the earliest instances of that kind of composition in Europe. The whole of them were printed in the 'Myvyrian Archaiology,' in which they occupy one hundred and eighty-eight pages of double columns, nothing of which beyond a few specimens had appeared in print before. The authors to whom they are attributed are:—Aneurin, who is supposed to have lived from 510 to 560; Taliesin, the Chief of Bards, from 520 to 570; Llywarch Hen, or Llywarch the Old, from 550 to 640; and Myrddin, or Merlin, from 530 to 600; besides Gwyddno, Gwilym ab Don, Golyddan, and others of minor importance.

The authenticity of these poems having been impugned by two celebrated antagonists of the Celts, by Pinkerton, in his preface to Barbour, and by Laing, in a note to his 'Dissertation on Ossian,' it was maintained by Sharon Turner, the Anglo-Saxon scholar, in his 'Vindication of the Genuineness of the Antient British Poems of Aneurin, Taliesin, Llywarch Hen, and Merddin,' first published separately in 1803, and since appended to the successive editions of his 'History of the Anglo-Saxons.'

In this treatise Mr. Turner asserted the genuineness of the ancient poems on both internal and external evidence. The oldest copy of any of them extant occurs in an ancient manuscript called 'The Black-Book of Carmarthen,' formerly preserved in the library of the Vaughans at Hengwrt in Merionethshire, which was brought together by Robert Vaughan, who died in 1666. This book is believed, by competent judges, to be of the 12th century; so that if forged at all the poems must have been forged as far back as that period, while in fact they are alluded to as ancient by writers of the centuries immediately following. If fabricated at that time, it is probable that they would have contained allusions to the popular legends respecting King Arthur, whose name had then become known throughout Europe as that of the hero of romantic tradition; while these compositions, professing to be written by contemporaries of Arthur, and frequently referring to his life and actions, always mention him in a sober, unexaggerated, strain, perfectly consistent with the light in which he is presented by authentic history. Finally the language is of an extremely antiquated cast, often obscure, and sometimes unintelligible, and altogether different from that of compositions known to be of the 12th century.

The weak point in Mr. Turner's argument is that it proves, or assumes to prove, too much. If all that he advances were valid, the whole of the poems ascribed to the primitive bards would be genuine, but in fact some are demonstrably otherwise. There is a remarkable passage in Evans's 'Specimens of the British Bards,' published in 1763, every word of which has been confirmed by the most recent investigations. Speaking of Taliesin, Evans says, "There are many spurious pieces fathered on this bard in a great many hands in North Wales, but these are all forged, either by the monks to answer the purpose of

WELSH LANGUAGE AND LITERATURE.

the Church of Rome, or by the British bards in the time of the late princes of Wales to spirit up their countrymen against the English, which any body versed in the language may easily find by the style and matter." These pieces are those made public in the 'Myvyrian Archaiology,' on the judicious principle laid down by its editors, of putting in print and on record whatever was asserted to be of a certain degree of antiquity, without any preliminary inquiry into the justice of its claims. The opportunity thus afforded of subjecting them to criticism has been taken.

The two works in which the subject has been treated with the greatest care since Mr. Turner's time, are 'The Literature of the Kymry,' by Mr. Thomas Stephens, of Merthyr-Tydvil, published in 1849, and 'Taliesin, or the Bards and Druids of Britain,' by Mr. D. W. Nash, of the Royal Society of Literature, published in 1858. Mr. Stephens is a Welshman of learning and of a critical habit of mind and a candour not always met with among his countrymen. Mr. Nash is an Englishman who has studied Welsh literature with peculiar attention and success. The conclusions at which they arrive are almost the same. Of the seventy-seven poems ascribed to Taliesin, and printed in the 'Myvyrian Archaiology,' Mr. Stephens considers fifty-seven to be demonstrably spurious, and of the remaining twenty there are only twelve that he assigns with confidence to the time of Taliesin. Mr. Nash gives translations of more than fifty of these poems, many of which had never appeared before in any other language than Welsh; and the mere perusal of them is sufficient to show that the notion of their belonging to the 6th century is absurd. Poems which had been represented by some Welsh writers as full of allusions to the rites of Druidism are full of allusions to Roman Catholic theology, partly couched in mediæval Latin. One instance will be sufficient to show the nature of the arguments. There is a poem, ascribed to Taliesin, prophetic of the fall of his country, in which occur the lines which are on the lips of every Welshman, and have been cited oftener than any other lines in the language:—

> "Eu Ner a molant,
> Eu hiaith a gadwant,
> Eu tir a gollant
> Ond gwyllt Walia."

> "Their God they shall adore,
> Their language they shall keep,
> Their country they shall lose
> Except wild Wales."

Such a prophecy made in the 6th century, when the Saxons were contending with King Arthur, and the struggle between the races was still going on in Cumberland and elsewhere, would indeed be remarkable, while in the 12th century it would be that not unusual phenomenon, a prophecy after the event. The language of the poem is so free from obscurity, that it is said, in the periodical entitled 'Taliesin,' for 1861, to be "intelligible this day to the children of Aberystwith." Many of the proper names which occur in the poem have a very peculiar character. They are in a Latinised form, "Troia" for Troy, "Germania" for Germany, "Saxonia" for Saxony, "Sabrina" for the Severn, and, in the passage quoted, "Walia" for Wales. Can it be supposed that the Saxon term for Wales was in common use in the 6th century? that it had been already Latinised? and, lastly, that a Welsh bard of the court of King Arthur borrowed the Latinised form of the name of his country from his country's foes to introduce in his patriotic poem? All these circumstances appear to indicate the composition of the lines by a mediæval monk, and the supposition is strengthened by the mention of Troy as the land of the origin of the Britons, a prevalent belief after the time of Geoffrey of Monmouth, who flourished under Henry I.

While the authenticity of some of the most interesting supposed relics of Taliesin must therefore be given up, the critics who impugn them concur in believing that other portions are really genuine. The Rev. Evan Evans in his 'Specimens,' Mr. Stephens, Mr. Nash, and others, are all of this opinion. Unfortunately, those of the seventy-seven which they respect are of a very small degree of interest Taliesin, as he has descended to us, is certainly no Ossian—taking as the proper representative of the Gaelic bard the Ossian of Macpherson—nor is he even equal to Aneurin, still less to Llywarch Hen.

Many of the fictitious poems ascribed to Taliesin occur in a strange legend of his life, which is itself a singular relic of literature. The traditions of the great bard, relied on by Williams in his 'Lives of Eminent Welshmen,' represent him as the son of a saint, a certain St. Henwg, and educated at the College of St. Cadog. Much of his time was spent at the court of Urien Rheged, a chieftain to whom many of his poems are addressed, but being once fishing at sea in a skin coracle he was seized by Irish pirates, who bore away with him towards Ireland. Escaping from them in his coracle, while they were engaged in drunken revelry, he was tossed about at the mercy of the waves till the coracle stuck to the point of a pole in the weir of Gwyddno, prince of Cardigan at Aberdyvi. At the court of Gwyddno, who was himself a poet, he remained till the memorable event of the destruction of Gwyddno's country, in the beginning of the 6th century, by an inundation of the sea, which converted what was dry land into the present Cardigan Bay. After this time Taliesin went to the court of King Arthur at Caerleon on Usk, and on his death was interred at the spot near Aberystwith which still goes by the name of Bedd Taliesin (Taliesin's grave).

The chief incident in this life appears in an altered form in the legend or romance which is printed in Welsh in the 'Myvyrian Archaiology,' and in Welsh, with an English translation, in the fifth volume of the 'Cambrian Quarterly Magazine,' and in Lady Charlotte Guest's 'Mabinogion.' According to this story, Gwion the Little, a boy who was employed by Keridwen, a witch of Meirion, or Merionethshire, to watch a magic cauldron in which she was preparing a concoction that was to bestow knowledge and genius on her son, incurred the vengeance of his mistress by involuntarily drinking the three blessed drops which were to produce these wonderful effects. Of course he became endowed with sudden wisdom, and fled from the wrath of Keridwen, who at once pursued him. He fled in the form of a hare, she pursued in that of a hound; when nearly overtaken, he turned to a fish, and she to an otter; then he to a sparrow, and she to a hawk; and he was finally swallowed in the form of a grain of wheat by Keridwen, in the form of a hen. After nine months she was delivered of him again, and he was so handsome that, unwilling directly to take his life, she tied him up in a leathern bag and threw him into the sea, from which he was rescued by Prince Elphin, the son of Gwyddno, who, fishing for salmon at the weir of Aberdyvi, caught a child instead. The prince looked disappointed in consequence, and was addressed in consolation by the miraculous infant in a strain of poetry, the merits of which are anything but miraculous. This infant had such a splendid forehead that he received the name of Taliesin, which bears that meaning in Welsh. The narrative proceeds with a medley of incidents, interspersed with poems of little or no merit put into the mouth of Taliesin, and inextricably connected with the circumstances of the tale. The whole story appears to be of the same character with those which were told of Virgil in the middle ages,—a wildly fictitious narrative fastened on a distinguished name, from the wish to give it an air of authenticity in the eyes of ignorance. It may be taken therefore as a proof that, at the time of its invention, the name of Taliesin was current in popular tradition as that of the great poet of Wales; while the fact that the poems ascribed to him in it are as spurious as the adventures are impossible, is no stronger proof against the existence of the real works of a real Taliesin, than the stories about Virgil's feats of necromancy are proof of the spuriousness of the Georgics and the Æneid. Some of the incidents regarding the magic cauldron are traced by Mr. Nash to Irish and Icelandic fiction, and some, as the pursuit of Keridwen, bear a striking resemblance to passages in the 'Arabian Nights.' The tale of Taliesin, and of course the poetry inserted in it, are traced with tolerable certainty to one Thomas ab Einion, a priest who flourished in the 12th century.

Many of the poems ascribed to Aneurin are shown to be spurious by modern criticism, but that entitled 'The Gododin,' bears very strong marks of authenticity. Aneurin was one of the northern Britons of Strath Clyde, who have left to that part of the district they inhabited the name of Cumberland, in token that it was once in possession of a section of the Cymry. In this poem he laments the defeat of his countrymen by the Saxons at the battle of Cattraeth, in consequence of their having partaken too freely of the mead before joining in combat. He commemorates many obscure chieftains who fell on the occasion in language which seems dictated by the freshness of grief. A portion of this poem has been translated by Gray; a version of the whole was inserted by the Rev. Edward Davies in his 'Mythology of the Druids;' and a translation of the whole works of Aneurin, 'The Gododin' and the 'Odes of the Months,' was published in 1820 by Mr. Probert. A fresh translation of 'The Gododin' was published in 1858, by the Rev. John Williams ap Ithel, the editor of the 'Cambrian Journal.' It may be taken as a proof of the authenticity of the original that the translators have had an opportunity of disputing, not only about the meaning of several of the passages, but even of the whole poem. The Rev. Edward Davies maintains that it relates not to the battle of Cattraeth, but to the massacre of the Welsh chieftains by order of Hengist at a banquet at Stonehenge.

'The Heroic Elegies and other Pieces of Llywarch Hen, Prince of the Cumbrian Britons, with a literal translation by William Owen,' were published in 1792. Llywarch Hen, like Aneurin, was one of the warriors of Strath Clyde, and, like him, was driven to Wales by the successes of the Saxons. His poems are by far the finest of those ascribed to the primitive bards. Southey, who remarks that "their authenticity has been proved by Mr. Turner; and they are exceedingly curious, and some of the oldest remains of Celtic poetry," observes, in the notes to his 'Sir Thomas More,' that their "general strain is as melancholy as it is rude." According to Welsh tradition Llywarch Hen, or Llywarch the Old, lived to the age of a hundred and fifty. His four-and-twenty sons and three daughters all died before him, as was natural in that case, but in his 'Elegy on Old Age and the Loss of his Sons,' he enumerates many who had perished in war, and accuses himself of having caused their destruction. The staple of his poetry is bitter complaint of the woes of age. "Those that loved me once now love me not," he exclaims. "Ah death, why will he not befriend me? I am outrageous! I am loathsome! I am old." Some 'Lines to the Cuckoo in the Vale of Cuawg' which are now ascribed to a certain Mabclaf ap Llywarch, who lived towards the close of the 14th century, are in precisely the same impressive strain.

Some of the remaining poems in the 'Myvyrian Archaiology,' are ascribed to two Merddyns, who have been amalgamated and made into the Merlin of romance. The same work contains a considerable number of anonymous pieces ascribed to the earliest bards; but the language is sufficient to show that their genuineness is more than doubtful.

Strange to say, the only collection that has yet been published of the primitive bards of Britain, with a translation and explanatory and critical notes, is that by a Frenchman, the Count Hersart de la Villemarqué, 'Poëmes des Bardes Bretons du VIième siècle, traduits pour la première fois avec le texte en régard,' Paris, 1850. The ingenious critic, himself a Breton, and the first collector of the ballads of Brittany, has unfortunately adopted the singular idea of printing his Welsh text neither according to the ancient nor the modern Welsh spelling, but according to the system proposed for the Breton by Legonidec, and the result is that it requires a separate study to decipher a line of his text. His prefaces and notes are written in a strain of hyperbolic enthusiasm, but have a foundation of good sense. He omits almost all of the poems of Taliesin as spurious, and he quotes the names of the French critics Fauriel, Ampère, and Magnin as concurring in the opinion that those which he gives are authentic.

The earliest monument of Welsh prose would, if it were genuine, be the "Wisdom of Cadog the Wise," a collection of proverbs ascribed to St. Cadog, who is said to have lived in the 6th century, and to have been the friend and instructor of Taliesin, and one of the ornaments of the court of King Arthur. They are printed in the 'Myvyrian Archaiology,' and in the Iolo MSS. there is a collection of fables and tales ascribed to the same St. Cadog. One of the tales is the story of the man who hastily slew his faithful dog from the erroneous supposition that it had killed his child, whom it had in reality defended from a serpent. This story, which is told by St. Cadog, without name of person or place, is now the most popular legend of Wales, and sheds an additional charm over the scenery of Bedd Gelert, but the Gelert of the modern tradition, and of Spencer's ballad, is 'The gift of royal John' to Llewelyn ab Jorwerth, who married a daughter of King John of England. There can be no doubt that the language of the narrative in the Iolo MSS. is nearer to the time of Llewelyn ab Jorwerth than to that of St. Cadog, but unfortunately the original of the story is to be found in Sanskrit.

The earliest Welsh prose of which the authenticity is unquestioned, is the collection of the laws of King Hywel Dda, or Howel the Good, who died in 748, after a reign of forty years, during the last seven of which he was monarch of all Wales. This code is divided into the laws of the court and the laws of the country, and under both heads it comprises a quantity of matter curiously illustrative of the manners of the times; it is assumed, for instance, that there is one cat in each village, and it is estimated as of precisely the same value as a sheep. The bards are endowed with many privileges, extending to receiving dues on marriages, to exemption from bearing arms, and to various other sources of emolument and honour. The leading feature of the legislation is that every crime is punishable by a fine, even that of the murder of the king himself, which is to be atoned for, among other things, by "three golden cups, with covers each as broad as the offender's face," and as "thick as the thumb of a ploughman who has been nine years in that employment, three silver rods of the same height as the king, and as thick as his thumb," &c. &c. These laws were first published in a somewhat uncritical fashion in 1730, in Wotton's 'Leges Wallicæ;' the last edition, in Welsh and English, is comprised in the 'Ancient Laws and Institutes of Wales,' issued in 1841 by the Record Commission, and edited by Aneurin Owen, the son of Owen Pughe, a much severer and more acute critic than his father. The earliest manuscript is of the 12th century; and Owen cautiously describes his text as the "Laws, *supposed* to be enacted by Howel the Good, modified by subsequent regulations under the native princes prior to the conquest by Edward I." "References are made," he adds, "to laws ordained by Dyvnwal Moelmud, an ancient Regulus in the west, and some triads are ascribed to him; but these, although they contain ordinances likely to obtain in a primitive state of society, have no warrant of authenticity. We find mention of laws by Marsia, of an equally apocryphal origin." The laws of Dyvnwal are supposed by some Welsh writers to have been prevalent in Britain 400 years *before* Christ. The triads here mentioned belong to the historical triads, of which a portion is admitted on all hands to be of at least as late a date as the reign of King Edward I., and they will therefore be treated of in our notice of the second era of Welsh literature, commencing from the date of the Norman Conquest.

Second Period—1066-1536. The epoch of the Norman Conquest of England is one strongly marked in the literature as well as the history of Wales. Harold, the last of the Saxons, had overrun the country, and reduced it under princes subordinate to himself, in 1063, only three years prior to his own overthrow at Hastings. Two of the native princes, who were re-established on their thrones before the close of the 11th century, Gruffydd ab Cynan, prince of North Wales, and Rhys ab Tewdwr, prince of South Wales, came from abroad, the one from Ireland, and the other from Brittany, where two kindred Celtic nations were at that time in close intercourse with the Danes and the Normans. Gruffydd ab Cynan gave birth to a new era in Welsh poetry, and Rhys ab Tewdwr may have had some influence in the production of the most interesting monument of Welsh prose—the stories of King Arthur, whose name was for so many centuries a household word on the lips of the English as well as the Welsh.

The name of Arthur is first mentioned in the Latin chronicle of Nennius, who also mentions the name of the earliest bards, Taliesin, Talhaiarn, and others. The oldest manuscript of Nennius, which is in the Vatican, is assigned by its editor and translator, the Rev. William Gunn, to the 10th century. But the Arthur of Nennius is very different from the Arthur of romance, who first appears in the pages of Geoffrey of Monmouth. Before proceeding, however, to Geoffrey, who wrote in Latin, some mention should be made of the earliest of Welsh chroniclers, Caradoc of Llancarvan.

The history of the monk of Llancarvan contains the annals of Wales from the death of Cadwallader, A. D. 682 or 689, to the times of Caradoc himself, about the middle of the 12th century. It was continued, as was the custom with monkish chronicles, by other hands, and a good deal more was added in the English translation made about 1557 by the Welsh antiquary, Humphrey Llwyd, and published by Dr. Powell in 1584. The original Welsh remained in manuscript till included in the second volume of the 'Myvyrian Archaiology.' A different "recension" of it is known under the name of 'Brut y Tywysogion' or 'Chronicle of the Princes,' and was printed in Welsh and English in 1860 in the collection issued under the authority of the Master of the Rolls. The chronicle of Caradoc is one of the less attractive kind of monkish histories, dry and jejune like the 'Anglo-Saxon Chronicle,' which goes over much of the same period, but affording a useful skeleton and ground-work for less succinct historians. It has never emerged into much notice.

Far different was the character and the fate of the 'History of the Britons,' by Geoffrey of Monmouth, archdeacon of Monmouth, and bishop of St. Asaph, who was consecrated to his bishopric in 1152, and died in 1154. Geoffrey closes his narrative by the death of Cadwallader, at which Caradoc begins, and tells us that he left the story there on purpose for his friend Caradoc to continue. His 'History of the Britons' opens with the destruction of Troy, and the coming of Brutus, the coloniser of England, from Troy to Britain; and goes on, through the stories of Locrine and Lear, and Cymbeline and Gorboduc, to the legends of King Arthur and his conquests, and the prophecies of the enchanter Merlin. The work had a wonderful and a sudden success. As it is dedicated to Robert of Gloucester, the illegitimate son of Henry I., it must have been issued before 1147, the date of his death; and Alanus de Insulis, a Breton writer, who died in 1187, speaks of Arthur as then universally known. "Whither," he exclaims, "has not the name of Arthur the Briton been carried by Fame? What region of Christendom has it not reached? Arthur is almost better known to the Oriental nations than to the Britons themselves, as our pilgrims returning from the East declare." There was, doubtless, exaggeration in this, but there was doubtless also some foundation in truth; and the work of Geoffrey of Monmouth is the main source of the fame of Arthur. Translated and versified by Wace and Layamon, it became popular in French and English. For many centuries the story of Brutus, whose name is first mentioned by Nennius, passed for authentic history: in the pedigree of Henry VII., drawn up for him by Welsh heralds, the line of the Tudors is traced to Brutus as its founder; and even so far onward as in the time of Milton, the great poet gave way to his inclination to insert, though with an apology, these poetic stories in his history of England. With the poets, indeed, the success of the story of Geoffrey of Monmouth is still prolonged, and has burst out into fresh brilliancy in our own generation. The greatest work of Shakspere is founded on the legend of King Lear. Both Milton and Dryden projected an epic on the story of King Arthur, and Pope an epic on the story of Brutus. Walter Scott, who lamented that the court of Charles had

"The world defrauded of the high design"

of Dryden, himself paid tribute to Arthurian fiction in his 'Bridal of Triermain.' In our own days Bulwer Lytton has given us his finest poetry in his epic of 'King Arthur,' and Alfred Tennyson has achieved one of his brightest triumphs in his 'Idylls of the King.'

Geoffrey of Monmouth was attacked with singular vigour by a contemporary antagonist—the chronicler, William of Newburgh. "In our days," says the critic, "a writer has emerged, who strings together the most ridiculous figments about the Britons, raising them, with impudent vanity, above the Macedonians and Romans. Geoffrey is the name of this man, who is now called 'Arthur's Geoffrey' (Galfridus hic dictus est, agnomen habens Arthuri), because taking some fables of Arthur from the original figments of the Britons, and adding others of his own, he has coloured them up in the Latin language, and decked them with the name of a genuine history." It will be noticed that the worthy chronicler, who adds more to the same purpose, admits in this passage that the object of his indignation did not entirely invent his narrative, substance, details, and all, but that some "ridiculous figments" about King Arthur were current before he took pen in hand. There must therefore have been Welsh traditions on the subject.

The account which Geoffrey himself gives of the origin of his history is this: that Walter Calenius, archdeacon of Oxford, finding a book in Brittany on the deeds of King Arthur, gave it to him to translate, having a favourable opinion of his Latin style, and that his work is neither more nor less than a version of this original. It is so evident that if he wished his production to pass for a history, it was advisable to say something of this kind, and it has been so customary for writers of fiction to do so, from before Tirant the White down to after Don Quixote, that this statement carries no great weight in itself. At first sight it seems confirmed by the fact that there is a book in Welsh passing by the name of the 'Chronicle of Tysilio,' which corresponds exactly with Geoffrey of Monmouth. Unluckily, however, it is evidently translated from the Latin, and at the end of the manuscript containing it is this singular note: "I, Walter, archdeacon of Oxford, turned this book from Welsh into Latin, and in my old age I turned it again from Latin into Welsh." The perplexity is therefore only increased by a statement which introduces the name of Walter, the archdeacon, not merely as the patron of Geoffrey, but as himself the translator. There is fresh material for controversy in the question whether the book said to have been found in Brittany may not have been in Breton, instead of Welsh, and both Mr. Thomas Wright, and Mr. Stephens, of Merthyr Tydvil, have arguments in favour of the Armorican origin of the legends of Arthur, but no such book is to be found in the one language any more than in the other. George Ellis, the friend of Sir Walter Scott, in the introduction to his 'Specimens of the early English Romances,' in which there is an admirable analysis of Geoffrey of Monmouth, gives reasons for believing that his history was really translated from a Welsh original.

There are still extant in Welsh a series of chivalric legends relating to the time of King Arthur and the Round Table, which may possibly have existed in a rude shape before the time of Geoffrey of Monmouth, and furnished him with some of his materials. In their present form they are much more elegant and finished than in his history, and embrace stories and particulars that he would hardly have passed over had he known them. These narratives now go by the general name of the 'Mabinogion,' or Children's Tales, the name which may be appropriate to some being applied to all. They are contained in a splendid manuscript volume of more than 700 pages, in double columns, preserved in the library of Jesus College, at Oxford, and known by the name of the 'Red Book of Hergest,' from the place in which it was originally discovered. The date of its transcription has been assigned by antiquaries to about 1370, or the close of the 14th century; but towards the end of the volume there are inserted, it is supposed in his own handwriting, many of the poems of Lewis Glyn Cothi, who flourished in the 15th, after the invention of printing. Were the date of the composition of the tales no earlier than that of their transcription, they would not be original. The stories of the 'Knight of the Lion,' the 'Knight of the Sword,' 'Lancelot of the Lake,' and others which occur in Welsh prose in the 'Red Book of Hergest,' were extant in French verse from the pen of Chrétien de Troyes before 1200, and as early as 1225 the Arthurian tales had been translated from French verse into Icelandic prose, at the instance of King Hakon Hakonsson of Norway. It is to be observed also that the manuscript volume contains other tales than those belonging to the Arthurian cycle, 'Sir Bevis of Hampton,' the 'Seven Wise Masters of Rome,' and the 'History of Charlemagne.' This is pointed out in the valuable preface and notes appended to the edition of the 'Mabinogion' in Welsh and English, published in the years between 1838 and 1849, in three large volumes, by Lady Charlotte Guest, now Lady Charlotte Schreiber. The 'Mabinogion,' the most attractive lady's book in the Welsh language, has appropriately been edited by a lady, and the volumes are in typography and embellishment by far the handsomest that have ever issued from the Cambrian press.

On the whole, though there are arguments against it into which our limits will not permit us to enter, the preponderance of evidence seems to be in favour of the Welsh origin of the romantic fictions connected with the Round Table of King Arthur, and thus of the Welsh origin of chivalric fiction in general. The reasons in support have been ably summed up in an 'Essay on the influence of Welsh Tradition upon European Literature,' by Mr. J. D. Harding, who also refers to the high authority of a scholar whose view of the subject was taken from a different point—Mr. Panizzi, of the British Museum. In the celebrated 'Essay on the Narrative Poetry of the Italians,' prefixed to his edition of Boiardo and Ariosto. Mr. Panizzi states, as the result of his researches, that "All the chivalrous fictions since spread through Europe appear to have had their birth in Wales."

The narrative of Brutus and his expedition from Troy, given by Geoffrey of Monmouth, was, as we have seen, adopted for some centuries, in spite of the energetic protest of William of Newburgh, as the basis of popular English history. Yet it was totally inconsistent with another history of the colonisation of Britain, which, if we are to believe its supporters, was current long before Geoffrey of Monmouth, in the so-called Triads. These constitute the most peculiar feature in the whole of Welsh literature. A 'Triad' is the enumeration of three persons, or events, or observations, strung together in one short sentence by some thread of connection. This form of composition has been so popular among the Welsh that, brief as most of the Triads are, the collection of them occupies more than 170 pages in double columns in the 'Myvyrian Archaiology.' A few instances of Triads of different kinds and different ages, taken from the preface to Owen

Pughe's translation of Llywarch Hen, and other sources will show of what elegance they are susceptible.

"The three foundations of genius—the gift of God, man's exertion, and the events of life.

"The three primary requisites of genius—an eye that can see nature, a heart that can feel nature, and boldness that dares follow nature.

"The three supports of genius—strong mental endowment, memory, and learning.

"The three supports of genius—prosperity, social acquaintance, and praise.

"The three foundations of judgment—bold design, frequent practice, and frequent mistakes.

"The three fountains of knowledge—invention, study, and experience.

"The three indispensables of language—purity, copiousness, and aptness."

Other Triads are of a less general and more patriotic kind:—

"There are three things for which a Cymro should be willing to die—his country, his good name, and the truth, wherever it be.

"There are three things highly disgraceful to a Cymro—to look with one eye, to listen with one ear, and to defend with one hand.

"Three persons it especially behoves a Cymro to choose from his own country—his king, his wife, and his friend.

"Three things a Cymro ought to love beyond everything—the nation of the Cymry, the manners and customs of the Cymry, and the language of the Cymry."

The Triads are of all ages. There are instances of the throwing of ideas into threes in some of the poems of Llywarch Hen, and it is probable that some of the Triads of Proverbs attributed to St. Cadog are as ancient as anything in the language. But the oldest record of them is, we believe, in the Red Book of Hergest, supposed to be of the date of 1370, and the greater part are only extant in transcripts and books of miscellanies of the 16th and 17th centuries. They are peculiarly a class of composition to which any ingenious transcriber would be tempted to add something of his own. But with regard to the 'Triads,' which stand only on their merits, and of which some are as pointless as those we have quoted are pointed, the fact of their antiquity is of much less interest than with regard to the 'Historical Triads,' which form part of the class. The main value of these, of course, depends on their authenticity.

"The 'Historical Triads,'" says the Rev. T. Price, author of the 'History of Wales," are extremely perplexing to the historian, as it is difficult to decide whether they are to be considered as authentic records, or merely as ingenious fabrications. The collection in which they were found was made by Thomas Jones, of Tregaron, about the close of the 16th century, a time when the Trojan origin of the Britons had scarcely been called in question, and yet the Triads gave a totally different and more rational account of the colonisation of Britain. The character of this Jones as an antiquary and genealogist scarcely admits a suspicion of forgery on his part; and the statement of Jones, respecting his being merely a transcriber, is also supported by certain indications of their being positively corrupted when he found them." The character of Jones was, however, one that was peculiarly liable to suspicion, if not to something worse. Mr. Thomas Jones of Tregaron was, according to Williams in his 'Lives of Eminent Welshmen,' an eminent robber on the highway, who later in life reformed, married a rich heiress, and became an exemplary justice of the peace for the county of Brecon. His life seems to have resembled that of his countryman, Sir Henry Morgan, the famous buccaneer, who closed his career in the reign of Charles II. as governor of Jamaica. Dr. Rhys, the Welsh lexicographer, pays a compliment to Jones in the preface to his dictionary as an eminent antiquarian and genealogist; but what his humbler neighbours thought of him may be inferred from the fact that his name still survives in popular tradition as that of a bandit and a conjuror. Mr. Thomas Jones of Tregaron is, in fact, no other than Twm Sion Catti, or Tom Jones Catty, who has been often denominated in recent times "the Welsh Rob Roy."

The statements of the 'Historical Triads' are the sole authority for much that has found its way into the works of recent writers on Wales, as if it were of the most unquestioned truth. According to these statements, Hu Gadarn, or Hu the Mighty, an ancient patriarch of the Cymry, was the first who brought the nation to the shores of Britain from a country called the Summer Land, and over a sea called the Hazy Sea. The Summer Land is decided by some to have been Constantinople, and by others the Crimea. In a speech by the Rev. R. W. Morgan at the Eisteddvod of Llangollen, in 1858, on presenting to the meeting a Corporal of the Welsh Fusiliers, who had served in the Crimean war, the orator remarked, "Very singular and instructive is the reflection that to the Crimea, whence our forefathers first under Hu Gadarn emigrated and colonised Britain, their children should from their British home return, a living nation and an imperishable tongue, to combat the gigantic oppressor of the North on his own soil, and to lay their ashes by the side of the tumuli of their ancestors." In short, there are modern Welsh scholars who believe in Hu Gadarn quite as firmly as their forefathers did in Brutus.

The statements of the Triads are, it is evident, directly at issue with those of Geoffrey of Monmouth, and if they were really in being during the centuries that elapsed between the reign of Henry I., which is the time of Geoffrey, and the reign of James I., which is the time of Twm Sion Catty, it seems hard to imagine why all Welsh antiquaries, heralds, and genealogists should have preserved so deep a silence on the subject. If, on the other hand, we suppose that Thomas Jones of Tregaron was a person of the same turn of mind as Thomas Chatterton of Bristol,—that he had a lively imagination, and a strong desire to impose the fruits of that imagination upon others for fact; if we suppose that a man of his far from strait-laced character was one of those "fib-mongers" who are denounced by Edward Williams as so abundant in Welsh literature, the mystery is at once explained. To support the authority of the Triads, however, a new authority has in the course of the last seventy years been brought forward in the shape of "Bardic Tradition," to which, however, it will be unnecessary to advert, till the fourth stage in the history of Welsh literature is reached.

In following the different ways in which the history of Wales has been treated, almost every important specimen of the prose literature of the second period has been already mentioned, with the exception of a remarkable piece of biography, the life of Gruffydd ab Cynan, the Welsh prince who revived Welsh poetry after the Norman Conquest. Gruffydd was Irish by birth, and by descent partly Scandinavian, having been born to his father during his exile in Ireland, where Cynan married the daughter of Anlaf or Olaf, the Dano-Irish king of Dublin. Gruffydd recovered the dominions of his ancestors in North Wales, in 1079, and, after various vicissitudes, in the course of which he was held for twelve years in captivity by the Norman Earl of Chester, died in possession of his princedom in 1137. In 1100 he held, at Caerwys, in North Wales, a famous Eisteddvod, or meeting of the bards, which forms an epoch in the history of Welsh literature. It was attended by numerous Irish bards and musicians, whom Gruffydd had invited; and he introduced, by the influence of these foreigners, the use of bag-pipes into Wales, where, however, after languishing for some centuries, they finally gave way before their constant competitor, the national harp. The influence of his Scandinavian mother, and the Scandinavian court he had seen at Dublin, may be traced in the love of war and the love of alliteration which became more conspicuous than ever in Welsh poetry after the Eisteddvod of Gruffydd ab Cynan.

From the time of Gruffydd commences, in the opinion of many Welsh critics, the "golden age" of their poetry, which lasts for about a hundred and fifty years, nearly to the extinction of the independence of Wales by the conquest of Edward I. After the 6th century there had been a long interval of all but silence to the 12th. The 'Myvyrian Archaiology' contains the poems of fifty-nine bards, from the time of Meilyr, who flourished between 1120 and 1160, to Tudor Ddalt, between 1340 and 1380; but it must be remarked that the dates of many of these are very unsettled, and that Mr. Stephens of Merthyr-Tydvil, in his work on the 'Literature of the Cymry,' especially devoted to this era, has rectified many oversights on this point committed by Owen Pughe and others. The first bard on the list is Meilyr, whose early poems are very inferior to his later ones, and whose finest is undoubtedly that entitled 'The Death-Bed of the Bard.' His son, Gwalchmai ab Meilyr (1150-90), who was a much superior poet to his father, is reported to have accompanied Richard Cœur de Lion to the Crusades. Fourteen compositions by him are still extant, one of which, in praise of Owen Gwynedd, on the occasion of the battle of Tal-y-Voel, in 1158 is the original of the imitation by Gray:—

"Owen's praise demands my song."

The "Awen," as the Welsh term poetical genius, seems to have been hereditary in this family, for Einion, the son of Gwalchmai (1170-1220), was also a bard, but rather to be compared to his grandfather than his father. Forty pieces by Cynddelw (1150-1200), a contemporary of Gwalchmai, are printed in the 'Myvyrian Archaiology,' of which the most interesting is his poem 'The Death-Bed of Cynddelw.' Some of his verses are addressed to the famous Madog, or Madoc, prince of Powys, one of the sons of Owain Gwynedd, and maintained by many Welsh writers to have been a discoverer of America before Columbus. Some verses of another bard, Llywarch ab Llewellyn (1160-1220), are an invocation composed by him when subjected to the fiery ordeal to ascertain if he possessed any knowledge of the fate of Madoc, whose absence seems, before it was known that he had gone on a voyage, to have been attributed to murder. One of the bards of that period was Madoc's brother, Hywel (1140-1169 or 1172), whose poems are chiefly love-odes, but who fell in a fierce struggle to obtain his father's throne. Another princely bard, and the most gifted of all the competitors of Gwalchmai, was Owain Cyveilioc (1150-97), whose poem of the 'Hirlas,' or the 'Long Blue Horn,' has been much admired by foreign critics since its first introduction to their notice in Evans's 'Specimens of the Bards.' The thought on which it is founded is very pleasing:—Owain supposes himself to be directing the horn to be offered in succession to his warrior-friends at a banquet, and, as it passes, he describes the character of each; but forgetting himself on one occasion, he names the name of a chief who had fallen in battle, and then a burst of grief as the remembrance comes across him preludes a warmer eulogy than usual. The names of Elidyr Sais, or

Elidyr the Saxon (1160-1220), of Philip Brydydd (1200-50), and Prydydd Bychan (1210-60), are three of the most conspicuous of the period they belong to. Their poems are chiefly eulogies on the princes and great men with whom they were connected.

The next generation of bards was that which witnessed the conquest of Wales by the English. According to a current story which has been made universally known by 'The Bard' of Gray, they must have perished by the sword of the invader; but the notion of the massacre of the bards appears to rest on no adequate authority. There is no memorial or tradition of it in the country which is said to have been its scene, and no allusion to it in the productions of bards of the time immediately following. In the 'Myvyrian Archaiology' there appears no greater falling off in the number of poetical productions than might naturally be expected as the result of a foreign conquest, of however mild a character; and the next century was destined to produce a bard who in national popularity surpassed all who preceded him.

The representatives of the Scandinavian Scalds in Cambrian poetry gave way to a Troubadour. Davydd ab Gwilym has sometimes been called the Welsh Ovid, and sometimes the Welsh Petrarch, but is said by his English translator to "approach more nearly to Burns than to any other poet, whether of his own or other countries." His poems are of a character almost entirely new in the literature of Wales; the subjects of them are chiefly themes of love and social festivity, instead of valour and heroism. The exact dates of Davydd's birth and death are unknown, but he is supposed to have been born about 1340, and to have died about 1400, the year of the death of our Chaucer. The incidents of his life, which have been related at some length by Owen Jones and Owen Pughe, are chiefly connected with his success in love and in satire. On one occasion he eloped with a married woman who had been his paramour; but the fugitives were overtaken and separated, and Davydd was condemned to pay a heavy fine, from which the men of Glamorgan, who had elected him their chief bard, and who looked more to his genius than his morality, released him by discharging it. In satire his powers were so tremendous that when Rhys Meigan, another bard, incensed him by a poem reflecting on the illegitimacy of his birth, he replied in another of such pungency that Rhys, on hearing it recited, fell down and expired. Later in life another contest of satire with Gruffydd Gryg, an ancient bard of Anglesea, was brought to a more agreeable close by a good-natured stratagem of Bola Bauol, a mutual friend. He contrived that a report of the death of each should reach the ears of the other; and, as he expected, on receipt of the sad intelligence animosity was forgotten. Davydd composed a panegyrical elegy on Gruffydd, and Gruffydd one on Davydd; and when the trick was discovered the friendship was renewed with more warmth than ever. The chief object of his satire was, however, the "Little Hunchback," Bwa Bach, the husband of the Morvydd, to whom a hundred and forty of the love-poems of Ab Gwilym are addressed. The religious orders of the time are also taken to task by a poet whose right to criticise them is not very clearly made out. Towards the close of his life, Davydd ab Gwilym, surviving his friends, became of a melancholy and religious turn, and some verses composed on his death-bed are said to breathe a strain of genuine piety.

The poems of Davydd ab Gwilym were first published in Welsh only, with an English biographical notice, by Owen Jones and Owen Pughe, in 1789. An English translation of several of the best, by Mr. Arthur Johnes, under the assumed name of Maelog, appeared in 1834. Mr. Borrow gives us to understand in his 'Lavengro' that he has completed a translation of the works of Ab Gwilym with notes, critical, historical, and explanatory, but nothing of this version has been made public. Mr. Borrow is a warm admirer of the Welsh poet. "I have no hesitation in saying," he observes, "that he makes one of the some half-dozen really great poets whose verses, in whatever language they write, exist at the present day and are more or less known."

Contemporary with Davydd ab Gwilym during the whole course of his career, and flourishing long before and after it, was Iolo Goch, the friend and domestic bard of Owain Glyndwr, or Owen Glendower, who wrote verses on the death of Tudyr ab Gronw in 1315, and on the comet of 1402, and who died about 1420, at the age, it is supposed, of nearly a century and a quarter. If the dates be correct, he must have been about 118 at the time that he spoke of Owain, who died at 67, as "old." One of his most interesting pieces, composed two years before the insurrection of Glyndwr, is a description of Owain's house at Sycharth, which the poet somewhat hyperbolically compares to Westminster Abbey, and which he describes its master as keeping almost literally an "open house," there being neither bolts, bars, nor door-keeper. Iolo Goch wrote several poems to inflame his countrymen in their rising, and lamented the death of Owain in a patriotic elegy.

Some uncertainty seems to prevail as to the date of Sion Cent, or John of Kent, a poet and religious writer, who is stated by Owen Pughe to have lived between 1410 and 1470, and by Williams to have flourished from 1380 to 1410. The latter date is probably the correct one, if Sion Cent was, as he appears to have been, a Lollard. His name was derived not from the county of Kent, but from Kentchurch, or Kentchester, in Herefordshire, where he resided. His poems, which are of interest in an historical point of view, as illustrating, like our Piers Plowman, the dawn of the Reformation, are the subject of a series of articles in the 'Cambrian Journal' for 1860. His name is

still current in popular tradition as that of a conjuror, probably owin[g] to his having been a heretic.

The last of our list of bards of the second period of Welsh poetry [is] Lewis Glyn Cothi, who flourished during the wars of the Roses, which terminated in the accession of a Tudor to the English throne. He was the bard to Jasper, earl of Pembroke, son of Owen Tudor and the widow of Henry V., and fought with his patron at the battle of Mortimer's Cross in 1461. His works are of less poetical than historical value, throwing a considerable light on the history of Wales during his period. They were first published, in the original Welsh, with English notes, chiefly of explanatory historical matter, by the Cymmrodorion, or Royal Cambrian Institution, in the year 1837, under the editorship of the Rev. John Jones, of Christchurch, known by the name of Tegid.

The bards we have mentioned are but a small proportion of those who flourished, and some of whose compositions have been preserved. Mr. Stephens, in his 'Literature of the Kymry during the Twelfth and Two Succeeding Centuries,' mentions six-and-twenty poets whose names we have not enumerated, between 1350 and 1400; and at or subsequent to the year 1400, during the revolt of Glyndwr and the wars of the Roses, the bards amounted, he states, to "several hundreds."

It is stated by Owen Pughe, in the 'Archæologia' (vol. xiv., p. 216), that the principal heads under which ancient Welsh literature may be classed are—poetry, bardic institutes, laws, history, theology, ethics, proverbs, dramatic tales, and grammars; and that "the first of these classes, poetry, is by far the most extensive, for it may be computed to fill about eight parts out of the ten of our old writings, omitting to take into account the heraldic collections altogether; but with respect to the quantity that is printed, such a proportion may be reversed." "On this subject," he adds, "I have made a calculation so as to enable me to infer that I have perused upwards of 13,000 poetical pieces of various denominations for the purpose of collecting words in the course of about eighteen years that I have been compiling the dictionary of the Welsh language."

Towards the conclusion of the second period of Welsh literature some alterations of consequence took place in the laws of metrical composition. Certain changes appear to have been proposed and adopted at a congress of bards held in 1350, under the presidency of Ivor Hael, or Ivor the Generous, the constant patron and friend of Davydd ab Gwilym; but it was a hundred and one years later, in 1451, that at the Eisteddvod of Caermarthen, held under the influence of Gruffydd ab Nicolas, a powerful nobleman, a system was adopted which prevailed for nearly four hundred succeeding years. Davydd ab Edmwnd, a bard now of no great note, who was president of the Eisteddvod, succeeded in obtaining the assent of his colleagues to four-and-twenty new canons of poetry, which he had compiled with the assistance of other bards of North Wales, and though the men of Glamorgan protested against the decision, their protest seems to have had but little effect.

The most prominent feature in the new canons is the more definite establishment of laws of "Cynghanedd," or consonancy—a species of alliteration which was thenceforth considered as essential to verse as metre and rhyme. It had much analogy to the alliteration employed in Anglo-Saxon, Icelandic, and occasionally in earlier English poetry; but while other nations became more lax in applying it, the Welsh became more stringent. A specimen of English verse, composed about the middle of the 15th century, by a Welsh student at Oxford, to exhibit the advantages of the "cross consonancy," is printed in the second volume of the 'Cambrian Register.' A more recent example, given in Walters's 'Dissertation on the Welsh Language,' will perhaps convey a clearer notion of it than a lengthened description. The lines are on Envy:—

> "A fiend in Phœbus' fane he found,
> That yonder grew yet underground,
> Sprung from the spawn of Spite;
> The Elf his spleen durst not display,
> Nor act the devil in the day,
> But at the noon of night."

A happier instance occurs in a song by John Parry, the Welsh song-writer and composer, known as 'Bardd Alaw:'—

> "God grant that Great Britain for ever may be
> The terror of tyrants, the friend of the free."

Alliteration is appropriately introduced by Gray in the first line of his Bard:—

> "Ruin seize thee, ruthless king,"

and by Mason in his Caractacus:—

> "I marked his mail, I marked his shield,
> I spied the sparkling of his spear,
> I saw his giant arm the falchion wield,
> Wide waved the bickering blade and fired the angry air."

The lines of Mason also exemplify how easily the search after this ornament may lead to the neglect of the much more essential beauty of appropriate diction. A spear would not have been "spied," nor would a blade have "bickered," but for the attraction of alliteration. In the third stage of Welsh literature on which we are now about to enter, it was a frequent complaint that in poetry the sense was almost constantly sacrificed to the sound; but the legal restrictions on Welsh freedom in poetry could apparently only be legally removed. The laws of the Eisteddvod of Caermarthen, in 1451, were at last repealed by an Eisteddvod of Caermarthen, in 1819, and Welsh poetry has materially benefited by this Reform Act.

Third Period—1536-1760. The next period of Welsh literature commences with the Reformation and with the incorporation of Wales with England by the Act of Parliament of King Henry VIII., in 1536, two events which changed both the religious and the political aspect of the country. In Wales the Reformation, introduced by a Tudor monarch, took from the first a much firmer root than in other Celtic countries; but there, as elsewhere, some of the learned adhered to the ancient faith, and in the reigns of the early Protestant sovereigns were compelled to carry their dissent abroad.

The first book printed in the Welsh language, which was also the first book printed in any Celtic language, was a species of Almanac, by William Salesbury, with a translation of the Lord's Prayer, the Ten Commandments, &c., issued at London in 1546, in a quarto volume. Salesbury, who was an eminently learned man and the master of nine languages, was a master also of his mother-tongue. He published the first Dictionary of English and Welsh, in 1547. He wrote on orthography and kindred subjects, and appears to have had it at heart to make both the Welsh and English nations better acquainted with each other. He was also a zealous Protestant, and wrote the greater part of the first translation of the New Testament into Welsh—a translation so excellent that it forms the groundwork of that still in use. It was first published at London, in 1567, in a quarto volume, a copy of which is one of the choicest treasures in Welsh libraries.

The history of the Welsh translation of the Bible is curious. In the year 1562 or 1563 it was enacted by Parliament that "the Bible, Testament, and Common Prayer should be translated into the British or Welsh tongue; should be viewed, perused, and allowed by the bishops of St. Asaph, Bangor, St. David's, Llandaff, and Hereford; and should be printed and used in the churches by the 1st of March in the year 1566, under a penalty in case of failure of forty pounds on each of the bishops." Salesbury was engaged by the bishops to carry out this important commission; his friend Dr. Richard Davies, bishop of St. David's, assisted him by translating a portion; and in 1567, a year after the term fixed by the Act of Parliament, the Testament made its appearance. After this came a long pause. Salesbury was residing, for the purpose of carrying on the translation, with the Bishop of St. David's, when a dispute arose between them on the meaning and etymology of one word, and ran to such a length that the two friends parted for ever. The consequence of this not very Christian outbreak was, that the Welsh were left without a Bible for more than twenty years. The penalty provided by the Act was too small to enforce it; for the bishops, who seem to have had to defray the expense of the translation, would have had to pay more than the forfeit to carry it out. In 1588 the difficulty was solved by the appearance at London of a translation executed by Dr. William Morgan, vicar of Llanrhaiadr, in Denbighshire, not in consequence of the Act of Parliament, but because he felt the necessity of the work for his countrymen. Morgan received a bishopric in recompense: he was promoted in 1595 to the see of Llandaff, and "translated," says Llewellyn, the historian of the Welsh Bible, "to St. Asaph in 1601, and in 1604 to a better place." His successor at St. Asaph, Dr. Parry, published in 1620 a revised edition of this Bible, with considerable alterations; and in the Scriptures of both editions, Salesbury's translation of 1567 affords the groundwork of the Testament. The Welsh have, like the English, been remarkably fortunate in their translation of the Bible. It is with both nations the acknowledged standard of the language, and equally a favourite with the learned and the people. It is now in Wales the book of every household; but this state of affairs has only been attained by degrees. In Prichard's 'Canwyll y Cymry,' the date of which is that of the triumph of English Puritanism in the time of the Commonwealth, are some lines thus translated by Evans:—

"Women and men of low degree,
The very abjects of the land,
You always may in England see
Each with the Bible in his hand.

"With us, 'mongst those who most abound,
And sumptuously their tables spread,
Scarce can a prayer-book be found,
Or one who can his Bible read.

"'Tis to the Welsh a foul disgrace
They're in religion still so young,
That not a tithe of all the race
The Scriptures read in their own tongue."

In 1802 Owen Pughe stated that nineteen editions of the Bible, amounting to upwards of 130,000 copies, had circulated in Wales; and yet it was the demand for more copies at that very time which led the Rev. Thomas Charles, of Bala, to propose the establishment of a benevolent religious society for printing and distributing Bibles in Wales—a notion which expanded and developed under the guidance of Welshmen till it led to the foundation of the great British and Foreign Bible Society. One of the first publications which the Society took in hand was naturally the issue of the Welsh Bible; and a vivacious account is given in the 'Christian Observer,' by an eye-witness, of its reception in Wales:—"When the arrival of the cart was announced which carried the first sacred load, the Welsh peasants went out in crowds to meet it, welcomed it as the Israelites did the Ark of old, drew it into the town, and eagerly bore off every copy as rapidly as they could be distributed. Labourers carried it with them to the fields, &c." The number of copies issued by the Bible Society in Wales between 1806 and 1849 was, of Bibles, 329,131, and Testaments, 384,209, while of "Diglotts, Welsh and English, there were 1986."

While the Protestant Salesbury had the honour of publishing the first Welsh book in England, a zealous Catholic, Dr. Griffith Roberts, issued the first that was printed abroad, both of them anticipating by more than a century and a half the first Welsh book printed in Wales. In the celebrated letter addressed by Dr. Johnson to the King's Librarian on the purchase of books during a foreign tour, he made the remark: "In every place things often occur where they are least expected. I was shown a Welsh grammar, written in Welsh and printed at Milan, I believe, before any grammar of that language had been printed here." The book which had attracted Dr. Johnson's observation was only the first part of a treatise on grammar, 'Dosparth byrr ar y rhan gyntaf i Ramadeg'—a treatise on orthography embodying suggestions of some value for the improvement of the Welsh alphabet, illustrated with peculiar types. The volume bears the date of 1567, but no indication of its place of imprint; and the authority for the usual assertion on that score was that David Rhys, in the Latin preface to his 'Cambro-Britannicæ Linguæ Institutiones,' said that the book of his predecessor was printed at "Mediolanum." A few years ago the old tradition on the subject was combated by the ingenious argument that as there is more than one place in Wales itself the name of which is Latinised into Mediolanum, the book might have been printed at, for instance, Llanvyllin. Unluckily for the new view, a decisive confirmation of the old one has since been discovered in another book, by Griffith Roberts, a religious treatise entitled the 'Drych,' or 'Mirror,' containing a fervent exhortation to his countrymen in behalf of the Roman Catholic faith. In this book, which was printed at Rouen about 1585, the exhortation is signed "G. R.," and dated "O Fulan" ("From Milan"); while in a preface by Dr. Roger Smith the author is styled "the great teacher of the city of Milan, in the land of Italy" ("yr Athro mawr o Dhinas Fulan yngwlad yr Idal"), where it is moreover added that some of his books have been printed. Griffith Roberts also left behind him some imperfect books on grammar, which he had commenced to print, but never completed, and of which it is said that only three copies are at present known: that presented by the Welsh School, formerly of Gray's Inn Lane, to the British Museum; that in the library of Wynnstay, which fortunately escaped the conflagration of 1858; and that in the library of Mr. Wynne of Peniarth. The works of Roberts are well deserving of republication.

Another Welsh scholar who spent some time in Italy, but who returned to die in a cottage in Breconshire, was Dr. John David Rhys, already mentioned. He left the University of Oxford in 1555 without taking a degree, and resided for some time at Sienna and Padua, where he practised as a doctor of physic, and published a book in Italian on the study of Latin, and a book in Latin on the pronunciation of Italian. His principal work is his grammar of Welsh, 'Cambrobrytannicæ Cymrææcæve Linguæ Institutiones et Rudimenta,' in which he enters at great length and with much learning on the subject of Cambrian prosody, on which he is still consulted. The book was published in London in 1592, at the expense of Sir Edward Stradling, of St. Donat's Castle, a munificent patron of Welsh literature, and a cousin of that Sir Edward who was so near losing his life on suspicion of being a Saxon. Rhys, who was born in 1534 in Anglesey, died in 1609 in Brecon, and is said by Anthony a Wood to have died as he had lived, a Roman Catholic; but in the title page to his 'Institutiones' he lays especial claim to the merit of facilitating the study of the Holy Scriptures, "lately so elegantly and chastely translated into Welsh," a circumstance which, with some others, favours the supposition of his having become a Protestant.

One of Rhys's friends, to whom he refers in his works as an excellent genealogist and antiquary, was Thomas Jones, of Tregaron, or Twm Sion Catti, whose remarkable career has already been noticed in connection with his transcript of the 'Triads.' Jones was a poet as well as an antiquary, but while his reputation as a robber and magician still survives, that as a poet has passed into oblivion. He died about 1620.

A metrical version of the Psalms, which was written about this period, is still in high esteem. It was produced by a captain in Queen Elizabeth's fleet—William Myddelton, the elder brother of Sir Hugh Myddelton, the projector of the New River, and himself remarked for having been one of the first three who smoked tobacco in England, when crowds gathered round to witness the phenomenon. He did warlike service in America and the Azores, and records in a Latin note to his last Welsh Psalm that he finished it on the 24th of January, 1595, at "Scutum," one of the West Indian Islands. The Psalms, which appeared in 1603, were a posthumous publication, but Captain Myddelton had issued in his lifetime, in 1593, the first part of a treatise on the art of Welsh versification, 'Barddoniaeth,' which was never completed. The Psalms were reprinted in 1827.

The most popular poem, not only of that period, but of any period in the history of Welsh literature, was produced, it is said, by the simple process of turning into verse a series of sermons. The Rev. Rees Prichard, known as the Vicar of Llandovery, was as popular a preacher in his lifetime as after his death he became a popular poet. When he preached at St. David's the cathedral was too small to hold his congregation, and he was cited in the ecclesiastical courts for having set up a movable pulpit in the churchyard. Perceiving the partiality of his flock for verse he turned his homilies into rhymes, and the collection was first published in 1646—two years after his death. "The work," says Williams, in his 'Lives of Eminent Welshmen,' "was no sooner printed than it appeared in almost every hand, and was heard from almost every mouth throughout the principality, and it is scarcely credible with what uncommon avidity and pleasure it was received, read, and repeated by the people." The Italian student is reminded by this account of the passage in Bernardo Tasso's letters, in which he speaks of the first appearance of Ariosto's epic and its overwhelming success. The secret of the popularity of Prichard's volume, the 'Canwyll y Cymry,' or 'Candle of the Cambrians,' as it is called, appears to have lain in its combined religious and homely character—it did not fly one inch above common apprehension. A passage has been already quoted from an English translation of it by the Rev. William Evans, which was published in 1771, and this passage may be taken as an average specimen. The 'Candle of the Cambrians' is not yet extinguished, for the last edition, about the twentieth, appeared with notes, &c., in 1858. Its author was born at Llandovery in 1579, became vicar of the parish in 1602, and died at Llandovery in 1644, and the two last and best editions of his work are from the Llandovery press.

The next bard who deserves attention in a general survey of Welsh literature is Huw Morus, or Hugh Morris, who was born in 1622, and survived till 1709. "He is to be ranked," we are told in the 'Cambrian Register,' "among the first of the Welsh poets. He eminently excelled in that talent which we call humour, and was equally master of the pathetic and the sublime." The same writer states that his 'Elegy on the Death of Mrs. Middleton,' is equal or superior to "the two most beautiful compositions in the English language on the same subject, the 'Monody' on the death of his lady, by Lord Lyttelton, and that 'To the Memory of a Young Lady,' by Mr. Shaw." The works of Huw Morus were published in two duodecimo volumes, at Wrexham, in 1823, under the title of 'Eos Ceiriog,' or 'The Nightingale of Ceiriog.'

The most distinguished bard of the 18th century was Goronwy Owen, who is styled by Owen Pughe "one of the greatest poets that appeared among the Welsh." He was the son of a peasant in Anglesey, where he was born on the 1st of January, 1722, and was indebted for his education to Mr. Lewis Morris, a distinguished antiquary, who had him brought up for the church. He married in Oswestry, where he was curate, and says in one of his letters, "My wife speaks very little Welsh, yet she understands some; so that I fear that if I go not to Wales, my boys will be Saxons, for by the life of me I cannot teach the eldest one word of Welsh." He was curate to Dr. Douglas, afterwards bishop of Salisbury, "the person," he says, in one of his letters, "who defended the poet Milton against the insidious defamation of Lauder. Be it as it may, he is sufficiently severe and hard towards me. I hold some little land of him appertaining to the school, and though it was set too high before, yet he has sent down this year orders to raise the rent, lest a poor wretched curate should gain anything in his service, or obtain too good a bargain at his hand." His career appears to have been a very unfortunate one; but it must not be forgotten that he was an incorrigible drunkard. His poverty led him to petition the Cymmrodorion Society, in 1757, for assistance towards paying his passage for America, where he settled at Williamsburg in Virginia; and after the year 1767 nothing further was heard of him. "About the year 1798," says Owen Pughe, in the 'Cambrian Biography,' "some persons who revered his memory tried to obtain information if he were alive or dead, and with that view sent a letter over to his son. Him they found perfectly Americanised; before any answer was sent, he must first know who would pay him for his trouble." In a life of Goronwy Owen by Mr. Borrow, first printed in the 'Quarterly Review' for 1861, it is stated that he died about 1780. The principal poems of Goronwy Owen are to be found in the first volume of a book called 'Diddanwch Teuluaidd,' or 'Domestic Amusement,' printed at London in 1763. In a curious preface the printer states that the work was 'put into his hands by the editor, Hugh Jones,' who "owned himself incapable of writing an English preface to it, and therefore desired me to do that office for him." "The editor," he adds, "being an itinerary bard in the manner of the ancients, hath given me leave to tell his readers that he pretends to neither learning nor languages; he despises them all except his own, as the chief Greek poets did, calling other languages barbarous. He can hardly be persuaded that the English or French nations have anything that may properly be called poetry; such is man's partiality towards his own country and people."

The prose literature of the third period is remarkably poor. Its most popular production is itself only an adaptation or imitation of a foreign original, the 'Bardd Cwsg,' or 'Sleeping Bard,' of Ellis Wynne, first published in 1703, and since frequently reprinted, the last time in 1861, with notes by Silvan Evans. It consists of a series of visions of hell and the invisible world, chiefly taken from the visions of Quevedo, the Spanish humourist, which were translated into English, and for a time enjoyed considerable popularity. Wynne had prepared a second work, 'Gweledigaeth y Nev,' or 'A Vision of Heaven,' but was so mortified at being spoken of as a plagiarist from Quevedo, that he threw the manuscript into the fire. The plan of the "Bardd Cwsg" is a singularly gloomy and repulsive one for a satire; but the beauty of the style is so striking, that the book remains popular in Welsh; and, strange to say, a translation of it into English was published in 1861 by Mr. George Borrow, the author of 'The Gipsies,' and 'The Bible in Spain.' Ellis Wynne also translated into Welsh, Jeremy Taylor's 'Holy Living,' and revised the version of the Common Prayer, and though most celebrated for his prose, enjoyed some reputation as a poet. He was induced to take holy orders, though he had no inclination for the ministry, and held the rectory of Llanvair. He was born in 1670 and died in 1734.

A vigorous attempt to call attention to the study of the ancient literature was made towards the end of this period by the Rev. Moses Williams, an antiquary and author, who was in advance of his age, and has not yet received his due share of fame. There are in the British Museum printed 'Proposals for printing by subscription a Collection of Writings in the Welsh Tongue to the beginning of the Sixteenth Century,' dated July 31st, 1719. "This design," it is said, "hath been approved of by such gentlemen as have been made acquainted therewith, who have promised to encourage it as well by subscribing to it as by communicating their manuscripts, some whereof are already put into the publisher's hands. . . . Subscriptions for the first volume are taken in by Mr. Alban Thomas, at the Royal Society's House in Crane Court, Fleet Street; Messrs. William and John Innys, booksellers in St. Paul's Churchyard, London; and by the editor, Moses Williams." A specimen is subjoined of two pages of the 'Liber Triadum,' or Book of Triads, in Welsh only. Bound up in the same volume with it in the Museum is a manuscript portion of the intended preface, in Latin, apologising for publishing the documents in the original language without a translation, which is excused on the ground of the extreme difficulty of arriving at a certain knowledge of the meaning of every sentence in the then state of the study of the language. The writer, Moses Williams, was, however, at that time one of the best Welsh scholars living, and the glossary which he supplied to Wotton's 'Leges Wallicæ' is a proof of his erudition. The library of the Earl of Macclesfield contains a number of transcripts which he had made, doubtless for the purposes of this intended work, and which are likely to be of great critical value. Had his proposals been received with favour, he might have had the glory of anticipating the 'Myvyrian Archaiology.' Williams was a singularly diligent and accurate scholar, and published a 'Repertorium Poeticum,' or list of Welsh poems, and a general catalogue of Welsh books, which will be mentioned more particularly hereafter. Two Welsh sermons, preached and printed by him in London, in 1717 and 1719, are in the British Museum, and are of considerable interest from the information they contain on the state of the Welsh church, and of the Welsh language at that period. They are not mentioned, so far as we are aware, in any of the notices on Williams's biography, of which the most ample that we have seen is in Williams of Llangadwaladr's 'Lives of Eminent Welshmen.' He was born in Cardiganshire in 1685, and died as vicar of St. Mary's, Bridgewater, in 1742.

It has been mentioned that the early editions of the Welsh Bible were printed in London, and the introduction of typography into the Principality was exceedingly slow. Cotton, in the 'Typographical Gazetteer,' states that the earliest information he possesses on the subject is from one of the Martin Mar-Prelate tracts in Queen Elizabeth's reign, in which mention is made of 'knave Thackwell the printer, which printed popyshe and traiterous Welshe books in Wales,' and nothing more has ever been discovered of the printer or his books. Penry, who was hanged as the author of the Mar-Prelate tracts, was by birth a Welshman. In the 'Gentleman's Magazine' for August, 1821, it is observed by a correspondent, that "from the invention of printing downwards, so adverse were the circumstances attending the diffusion of Welsh literature, that there was not a printing-press in the principality until the year 1734, or thereabouts, when a temporary one was set up by Mr. Lewis Morris, of Bod-Edeyrn, in Anglesey. This identical press," the correspondent adds, "is still in being at Trevriw, near Llanrwst."

Fourth Period—1760-1861. A new period in the history of Welsh literature may be said to commence with the reign of George III., a hundred years ago, soon after the middle of the 18th century. The remarkable increase of activity which is observable in that literature during these hundred years, and especially during the last forty, seems to be attributable to the spontaneous impulse given by a few distinguished men; to the spread of Methodism in Wales; to the establishment, for the first time, of periodical publications; and to the institution or revival of patriotic societies.

One of the first signs of a new era in the literature of Wales was given by the publication in 1764 of a thin but important quarto volume. "Some Specimens of the Poetry of the ancient Welsh Bards translated into English, with explanatory notes on the historical passages and a short account of the men and places mentioned by the Bards, by the Rev. Mr. Evan Evans, curate of Llanvair Talyhaern, in Denbighshire," (London, 1764). It was the first book in which the claims of the Welsh bards were brought under the notice of the English public. Evans says in his preface that it "was first thought of and encouraged some years before the name of Ossian was heard of in England," but it was evidently the success of Macpherson's Ossian which had brought the project to maturity. "Certainly," says the author in a Welsh address to Mr. Richard Morris, printed in the volume, "I would not have taken this labour upon me except to put a stop to the reproaches of the English, who say that we have nothing of poetry to show the world, while one of the Scotch Highlanders has translated portions of their ancient bard, or rather has dressed up and adorned some recent production and put it forth in his name." He is not sparing of his insinuations against the genuineness of Ossian, and his critical remarks on the ancient bards of Wales are marked by acuteness. His greatest mistake is that he does not question the truth of the massacre of the bards, of which he remarks that it "gave occasion to a very fine ode by Mr. Grey." Evans's own prose translation of pieces by Gwalchmai and others also gave occasion to some imitations by Gray, which, though of no great merit, are of all translations from the Welsh by far the most extensively known. His volume concludes with an excellent proposal to send a literary traveller through Wales to examine and transcribe the remains of ancient poetry; but it appears to have met with cold neglect. Evan Evans was born in 1731, and died in 1789. He entered the church, but rose to no higher position than that of a curate in a parish said to derive its name from the ancient bard, Talhaiarn, and which also gave birth to the living bard, Talhaiarn. As a Welsh poet his reputation is now even higher than during his lifetime. Theophilus Jones, the historian of Brecknockshire, says in a letter written in 1797, "I did not think Evan Prydydd Hir (the bardic name of Evans) the poet he was. I knew him well, but I suppose the *cwrw* had expelled the *awen* before I became acquainted with him." Despair appears to have driven the disappointed man of talent to drink, and at the time of his death, in 1789, he was reported to have perished in a state of intoxication on a mountain, a report which happily appears to be unfounded. He left behind him a good collection of transcribed manuscripts, which passed on his death to Mr. Panton, of Anglesey, who had allowed him an annuity on that condition. Two volumes of Welsh sermons published by him contained an English preface so caustic as to be said to have stood in the way of his preferment.

Of the distinguished men of this period none seems to have acted more entirely from internal impulse and to have had a stronger influence on others than Owen Jones. Owen Jones was born at Llanvihangel Glyn y Myvyr, in Denbighshire, in 1741. "In early life," says the Rev. Robert Williams, "he was sent to London, where he was taken into the employ of Messrs. Kidney and Nutt, furriers in Thames Street, to whose business he eventually succeeded, and he continued to carry it on with credit until his decease," which took place at his house in Thames Street, in 1814, at the age of seventy-three. Count Villemarqué, in the preface to his translation of the ancient bards, gives a very poetical sketch of the biography of Owen Jones. "While still a child," he says, "and engaged in herding cows, he could see at a distance rising through the air the snow-covered peak of Snowdon, the Celtic Parnassus, on whose summit whoever slumbers awakes inspired. He ascended it more than once, and his happy inspiration might make us believe that there he must have slept. When he was older, he often witnessed on this mountain the poetical contests of the bards and harpers of the different cantons of the country, and passing at the foot of the ancient castles which held the poetic treasures of his race he formed the daring project of bringing them to the knowledge of the world."

There are here some palpable mistakes, as in attributing to Snowdon the properties of Cader Idris, on whose summit it is the popular belief that whoever sleeps awakes either crazy or a poet, and it is not probable that Snowdon was often ascended by a Denbighshire boy. But however hyperbolically expressed, the sentiment is correct. In the midst of his prosperous business in London, Owen Jones was still a warm-hearted Welshman, far more munificent in the promotion of his country's literature than all the magnates of the country combined. In 1771 he founded the society of Gwyneddigion (or Men of Gwynedd, a portion of North Wales), which revived in a manner the ancient congresses of the bards, and distributed prizes among the best performers on the Welsh harp and the writers of the best Welsh poems. In 1789 he published with Owen Pughe the poems of Ab Gwilym, and in 1801 and the subsequent years up to 1807 he issued at his expense three volumes of the 'Myvyrian Archaiology,' so called in his honour from Myvyr, the bardic name which he had assumed in remembrance of his native vale of Myvyr, in Denbighshire. Owen Pughe and Edward Williams were, as has been already mentioned, the editors of the work. The chief connection of Jones with the Archaiology was in supplying the funds, and it is said that he thus expended upwards of 1000*l.*—a sum, large as it was, by which he cheaply earned the gratitude and respect of all lovers of literature of his own times and all to come. His last literary enterprise was the publication of a periodical, 'Y Greal,' which appeared in 1805 and advanced no further than one volume. In this too, Owen Pughe was the editor and Owen Jones only the Mæcenas. The triad of his labours was thus formed by the Gwyneddigion Society, the 'Myvyrian Archaiology,' and the 'Greal.'

William Owen or William Owen Pughe, as he was called in later life after he had inherited some property in Wales, was an antiquary, a lexicographer, and a poet. He was born in 1759, in a primitive part of Merionethshire, close to Cader Idris, from which he assumed the bardic name of Idrison, and he closed a long life in 1835, at the foot of the same mountain, to the vicinity of which he happened to be on a visit. Till he was seven years old he heard not a word of English, and though he went to school at Altringham, near Manchester, and at the age of seventeen was sent up to London to earn his living, he never seems to have acquired a thorough mastery of the English language. His English has always a taint of Welsh in it, while, on the other hand, his colleague, Edward Williams, says that his Welsh writings "may be said to be English written in Welsh words." In the great city he remained for six years without knowing that any other person in it ever thought of the Welsh language and literature, till an accidental meeting with another Welshman, who introduced him to Owen Jones, brought into connection two men who scarcely seem to have passed a day without doing something for both. The largest Welsh and English dictionary in existence, published in two large volumes between 1793 and 1803, was the work of eighteen years of Owen Pughe's life. It is said in regard to it, by the Rev. R. Williams, that "while Johnson's Dictionary of English, as enlarged by Todd, comprises only 58,000 words and Webster's about 70,000, Owen Pughe's Dictionary of Welsh contains more than 100,000 words, illustrated by 12,000 quotations." The dictionary would be much improved by striking out many of these words which appear to exist only in its pages. In it Owen introduced a new system of Welsh orthography, and his friend, the Rev. T. Charles, of Bala, who was appointed at the same time to superintend through the press the edition of the Welsh Bible, the agitation for which had given rise to the British and Foreign Bible Society, took the opportunity of introducing it there; but the Society interfered and, the system was obliged to be dropped. In the second edition of his dictionary, issued at Denbigh, in 1832, the customary spelling is used. There is an abridgment of the work by Owen himself in 1806, which is much too compendious. In 1806 Owen came into possession of some property by inheritance, which enabled him to take up his residence in Wales, at Tros-y-Parc, near Denbigh, and to have the command of his time, which he devoted as usual to Welsh literature. His most important work of this period is a translation of 'Paradise Lost' into Welsh, which has a peculiar importance from his having thrown off in it the shackles of "Cynghanedd" or alliteration, which had fettered the movements of Welsh poetry for centuries. The innovation was a most happy one: it was adopted by the Eisteddvod of Caermarthen in the same year, and has been followed by many succeeding bards with great advantage. Owen Pughe was known to Southey the poet, and is frequently mentioned in his correspondence, but not always in terms of respect. On one occasion Southey expresses his surprise that Pughe should have translated 'Paradise Lost,' of which, in Southey's opinion, he could hardly understand a sentence; and on another Southey says of him, in a letter to Wynne, "full of Welsh information he certainly was, but a muddier-minded man I never met with." That there was some foundation for this opinion may be inferred from the fact that Pughe was a follower of Joanna Southcott, and was one of her twenty-four elders. Edward Williams, who quarrelled with him in the latter part of his life, said in a letter, in 1813, that Owen "with his *hobbyhorsisms* absolutely ruined everything he ever took in hand."

Edward Williams, still better known by his bardic name of Iolo Morganwg, is the third of the three associates of the "Myvyrian Archaiology," and undoubtedly the most gifted of the three. Less fortunate than his companions, he was born in so low a sphere of life that at the age of nine he began to assist his father at his trade of a stonemason, and with all his endowments he worked through life at the trade, though never in strong health, and in his old age was in need of the assistance of a public subscription. He was born in 1745, in the parish of Llancarvan, in Glamorganshire, and was noted in youth for absence of mind and literary enthusiasm. On a quarrel with his father he left him abruptly for London, and worked as a stonemason at Blackfriars Bridge. An interview which he sought with Dr. Johnson in a bookseller's shop only left a painful impression of the great lexicographer's rudeness; and though he saw Cowper, the poet, he only saw him in his decline. With Robert Southey he appears to have been intimate, at a time when Southey, like himself, was full of republican ideas, and the English poet drew from him much of the Welsh lore of his 'Madoc,' and introduces him as a character in the poem under the name of Iolo. Of all English authors of celebrity, Southey took the greatest interest in Welsh history and literature; and if he had carried out his purpose of fixing his residence in the Vale of Neath, which was only prevented by a trifle, the literary consequences might have been important. He had a high opinion both of the talents and the character of Iolo. "Bard Williams is in town," he wrote once to his wife, when on a visit to London, "and so I shall shake one honest man by the hand whom I did not expect to see." Both the bards had a thorough abhorrence of the great metropolis; and Williams, who at one time proposed to emigrate to America, not, like Southey, to found a Pantisocracy, but to search for the descendants of Madoc and his men, finally returned to Flemingstone, in Glamorganshire, within about two miles of his birthplace, and there continued till his death. Iolo, like his friend, was a great pedestrian, so much so, that when his son Taliesin bought him a horse, he could not be prevailed upon to ride, and carried his eccentricity so far as to lead the animal about the country on his journeys without ever mounting it. He had a personal triad of his own: "There are three things I do not want: a horse, for I have a good pair of legs; a cellar, for I drink no beer; and a purse, for I have no money." It is painful to record that he quarrelled with his friends of the 'Myvyrian Archaiology,' and complained that Owen Jones had not paid him some money which was due to him; while at the same time his principles were so high that he refused to take possession of an estate in Jamaica, which had been left him by his brothers, because it was cultivated by slaves. He wrote between two and three thousand Welsh hymns, some of which are highly esteemed, and were published under the title of 'Salmau yr Eglwys yn yr Anialwch' ('Psalms of the Church in the Desert'); but, as his friend Waring tells us, "his creed appeared to be so whimsical a compound of Christianity and Druidism, Philosophy and Mysticism, that the 'History of all Religions,' copious as it is in variety, furnishes no definition of it." He was surrounded, in spite of his eccentricities, by general respect, which was strikingly manifested at the great Eisteddvod of Caermarthen, in 1819. His death took place in 1826, at the age of eighty-one. He appears, from some letters published in the 'Cambrian Register' for 1818, to have written his autobiography, with a survey of Welsh literature during his time, but this work, which would certainly have been of value, has disappeared. His son, Taliesin Williams, was to have written an extended biography of his father, but the project was never put in execution. A life of him, which appeared in 1850, from the pen of an English friend, Elijah Waring, who was unacquainted with the Welsh language, is an amusing volume of light reading, but not the sort of biography required; for though in all his letters and writings which remain, Iolo Morganwg appears the frankest of the frank, there are several points in his literary career which require elucidation, and on which depend important questions with regard to Welsh literature.

Edward Williams was an English as well as a Welsh poet. His 'English Poems, Lyrical and Pastoral,' published in two volumes with the date of 1794, present perhaps the most curious list of subscribers that was ever attached to any publication. It begins with the name of the Prince of Wales; it contains those of Mrs. Barbauld and Miss Burney, of William Lisle Bowles the poet, and William Bowles, "Generalissimo of the Creek nation," Miss Hannah More and Mrs. Yearsley the milkmaid, Cowper, the poet of the 'Task,' and Rogers, the poet of the 'Pleasures of Memory,' Cyril Jackson, Dean of Christ Church, and Dr. Priestley of Birmingham, Mr. Raikes of Gloucester, the founder of Sunday Schools, and Mr. Thomas Paine, Dr. Parr and Mr. Horne Tooke, Citizen Brissot, Wilberforce and General Washington. The poems are of some merit, but the chief point of interest that now attaches to the volumes centres in the notes. One of the pieces is an 'Ode on the Mythology of the Ancient British Bards in the manner of Taliesin, recited on Primrose Hill at a meeting of British Bards in the summer solstice of 1792, and ratified at the subsequent autumnal equinox and winter solstice.' Primrose Hill was then a comparatively unfrequented green height in the fields between London and Hampstead, distinguished by a grove of trees which was barbarously cut down about 1828, and being in view of Owen Pughe's residence at Pentonville, may have been selected as a more convenient place for a meeting of bards than the summit of Plinlimmon originally named. Edward Williams, who was then an ardent republican, seems to have been at the same time an equally ardent defender of the privileges of the British bards. These, he maintained, were a regular corporate body, traceable from the earliest times to his own, in which there was only one legitimate board of bards remaining, the "Chair of Glamorgan," and only two members of that, himself and the Rev. Evan Evans of Aberdare.

In the notes to his 'Ode,' he gives a number of Triads in Welsh and English, containing the doctrines of "the Bards," and embracing a system of theology which is declaredt o be anterior to Christianity, but no more adverse to it than the religion of Enoch, Noah, and Abraham. "There are three circles or states of existence," according to one of these Triads: "the Circle of Infinity, where there is nothing but God of living or dead, and none but God can traverse it; the Circle of Inchoation, where all things are by nature derived from death—this circle has been traversed by man; and the Circle of Felicity, where all things spring from life—this man shall traverse in heaven." "Animated beings have three states of existence," says another Triad; "that of Inchoation in the great deep or lowest point of existence, that of Liberty in the state of Humanity, and that of Love which is felicity in Heaven." The system is further explained as one of metempsychosis, and there is a larger development of it contributed by Williams to the preface to his friend Owen Pughe's edition of Llywarch Hen. In this it is said, among other things, "No finite beings can possibly bear the infinite tedium of eternity. They will be relieved from it by continual renovations at proper periods, by passing into new modes of existence and which will not, like death, be dreaded, but be eagerly looked for and approached with joy. Every existence will impart its peculiar epoch of knowledge, for consciousness and memory will remain, or there would be no such thing as endless life."

These doctrines, first put in print at the time of the French Revolution, certainly bear a close resemblance to many of those which had their origin at that period, and it was a point of some interest to know how far back they could in reality be traced. Williams informed the readers of his 'Poems' that the Triads he had given were "from a manuscript collection by Llewelyn Sion, a bard of Glamorgan, about the year 1560. Of this manuscript" he added, "I have a transcript; the original is in the possession of Mr. Richard Bradford, of [illegible] near Bridgend, in Glamorgan. This collection was made from various manuscripts of considerable, and some of very great, antiquity—these and their authors are mentioned, and most or all of them still extant." It is not surprising that they were not received with unlimited confidence in their authenticity, but it is very surprising that Iolo did not take the best method of silencing doubts by printing the manuscript in the Myvyrian Archaiology, which a few years after he was engaged in editing. Far from this, he did not even show it to his friend who published the extracts. The manuscript in which they were contained bore the title of 'Cyvrinach y Beirdd' or the 'Secret of the Bards,' and was in two parts. "Edward Williams had only the first part with him in London," says Owen Pughe in a letter to his son in 1819, first printed by his grandson (in the 'Cambrian Journal' for 1857, p. [illegible]) "at least he said he had not the second, which by his description is the most curious, and the real Cyvrinach," and this Owen Pughe never saw. The association of the Myvyrian Archaiology finally broke up without its appearing. "In my collection," says Iolo, in a document printed by Waring, "I strenuously opposed the absurd fables of the darker ages, which are most obviously falsehoods of the darkest hue. This gave offence to my coadjutors, who charged me with rejecting supposititious documents which never existed, which I with diligence could never find, and which they cannot but know do not exist elsewhere. Such are the fictions of Geoffrey of Monmouth, that of King Arthur and his Knights of the Round Table, and many things more of the same character." It would seem from this that Williams quarrelled with Owen Pughe on the question of the insertion of the Mabinogion, which never appeared in the Archaiology, but it is strange that under the circumstances he should talk in this strain respecting "supposititious documents." The Rev. Edward Davies, in his 'Mythology of the Druids,' published in 1809, very plainly intimated that he considered the 'Bardic Triads,' with their theophilanthropic ideas, as supposititious. Doubts on the same score were freely expressed by many, but in 1819, Iolo Morganwg had a distinguished triumph at the Eisteddvod of Caermarthen, where he invested Dr. Burgess, the Bishop of St. David's, with the insignia of a Bard. From that time Bards, Druids, and Ovates, once reduced to two in number, have become numerous and in vogue, and Bardism has held a position in Wales analogous to that of Freemasonry in England. The call naturally became louder for the publication of the documents on which the institution was supposed to rest; and finally, in 1822, *Iolo Morganwg*, then a man of seventy-seven, issued a prospectus to publish a work in Welsh to contain the 'Esoteric Literature of the British Bards.' He died four years after without having published it. It was *only* in 1829 that his son brought out the long-expected 'Cyvrinach y Beirdd,' and in it, to the surprise of all, though the work was published as complete, no 'Triads of Bardism' were to be found. The '*Cyvrinach*' *of* 1829 was simply an excellent treatise on Welsh versification by Llewelyn Sion, of Llangewyd, interspersed with some very absurd statements respecting the Welsh language before the Flood, which *of course* derived no authority from having been made by a man of the age of Elizabeth. According to the 'Cyvrinach' there are but three proper languages—that spoken by Adam before the Fall, which is now *the* language of God, the angels, and the saints in Heaven; that written by Moses, which is the language of the Scriptures (a statement showing that the writer did not know that the Testament is in Greek); and *that* first spoken by Enoch, the son of Seth, and now spoken by the Welsh in Wales. Welsh is thus the only living language of divine origin; and the Awen or poetic genius of the Welsh is due to divine inspiration, *while* the poetry of the Saxon, English, and other corrupted languages, is inspired by their inventor—the devil.

Some disappointment was naturally felt at the non-appearance of the 'Bardic Triads' in the book, the chief interest of which consisted in its being supposed to contain them, but no explanation could be obtained further than that, of the two parts of the '*Cyvrinach*,' Taliesin Williams had only printed the first. No public information was vouchsafed as to why he had not printed the second, or what had become of it. The admirers of the Bardic Triads were *reduced to* look forward to the publication of them in a volume on the Iolo Manuscripts, a large collection of transcripts made by Iolo Morganwg, and from which Taliesin was engaged by the Welsh Manuscript Society to make and publish a selection. By a second misfortune, Taliesin Williams died in 1847, before the publication of the Iolo Manuscripts, as his father had died before the publication of the 'Cyvrinach.' So much, however, had been printed before his decease, as to render it certain that the Bardic Triads would have formed no portion of the volume. The Iolo Manuscripts, published by the Welsh Manuscript Society in 1849, contain a variety of pieces of very different value, respecting the origin of which we only learn that they were taken from transcripts made by Iolo Morganwg from other transcripts of which he mentions the possessors, adding in some cases from what originals they were transcribed. One of these pieces, called the 'Voice Conventional of the Bards of Britain,' contains an account of the origin of the ancient Welsh alphabet at the time of the Creation, taken also from a manuscript by Llewelyn Sion of Llangewyd. But again, as has been said, the 'Bardic Triads' are missing, and in 1861 the 'Secret of the Bards' is still a secret.

Taliesin Williams appears to have told the Rev. Thomas Price, after the death of Iolo ('Cambrian Journal' for 1857, p. 224), that "he himself had been for twenty years under a sort of druidical training with his father, and that the system was of so sublime and intellectual a nature, that unless he could find some one qualified in such a way as to be a worthy member of the order the secret should die with him." The hope, therefore, of developing the mystery, such as it is, might be abandoned, but for the declaration of the Rev. John Williams ab Ithel, in the 'Cambrian Journal,' of which he is the editor (1857, p. 57): "Much of the real Cyvrinach alluded to is still extant, as we ourselves can testify, and we sincerely trust that measures will be adopted by the Welsh Manuscript Society for the speedy publication of the whole. Until this is done, the early literature and history of our country can never be properly understood."

Much doubt was also thrown on the discovery of the 'Coelbren y Beirdd," or Alphabet of the Bards, an alphabet resembling the Runic, which was also brought forward by Iolo Morganwg, and an essay on its genuineness was proposed as the subject of a prize at an Eisteddvod in 1840. When the author of the successful essay was sought for by opening the envelope containing his name, it was found to be Taliesin Williams, or, as he was proud to call himself, Ab Iolo, who thus strove to vindicate the fair fame of his father. The dissertation is pronounced by impartial critics, Dr. Williams of Llangadwaladr, and Dr. Tregelles, to be a masterpiece, and the author is said to have shown satisfactorily that there were traces of the alphabet in Welsh literature long before his father's time. Since then, it has apparently been assumed by some Welsh writers, not only that the history of this alphabet, tracing it back to the Creation, was shown to be Elizabethan, or mediæval, but was also shown to be druidical, and—strangest of all—authentic. There are many illiterate persons who suppose that a statement must necessarily be true because it has appeared in print, but some of the Welsh critics carry the point still farther, and apparently believe everything they find in manuscript.

The three associates of the 'Myvyrian Archaiology' had each but one son, and in each case the son became an eminent man. Taliesin Williams, or Ab Iolo, the son of Edward Williams, or Iolo Morganwg, who has been already so frequently mentioned, was for the greater part of his life a schoolmaster at Merthyr-Tydvil. He was born in 1787, and died in 1847. Like his father, he wrote both Welsh and English poetry. Aneurin Owen, the son of William Owen Pughe, never took the name of Pughe, assumed by his father. His edition of the 'Laws of Wales,' already mentioned, is a lasting title to remembrance. He was born in 1792, and died in 1851. The son of Owen Jones, still living, is Owen Jones the eminent architect, who produced, in conjunction with Goury and Gayangos, the finest work on the Alhambra of Granada; and afterwards reproduced, with signal magnificence, the Alhambra itself at Sydenham, where he employed, in the decoration of a second Crystal Palace, the talents which had largely contributed to the success of the first.

One of the most eminent writers on Welsh antiquities of the commencement of the century, was the Rev. Edward Davies, born in Radnorshire in 1756, who died, after a long illness, on the first day of the year 1831. He first essayed his powers in works of imagination—'Aphtharte,' a poem, and 'Eliza Powell, or the Trials of Sensibility,' a novel; but his chief productions were 'Celtic Researches,' published in 1804, and the 'Mythology of the Druids,' published in 1809, two volumes of no inconsiderable ingenuity and learning, employed in the support of a singular theory. According to Davies the druidical superstition was preserved and patronised in Wales, in an esoteric fashion, down to the time of Edward I., and was a form of worship in which the bull, the horse, and the element of fire were prominent emblems. "If this be genuine British heathenism," he remarks, "it will be expected that vestiges of it should be discovered in the oldest bards now extant, and here, in fact, they present themselves in horrid profusion." The translations of Davies are made in so peculiar a fashion, that he turns the Gododin of Aneurin into a description, not of a battle at Cattraeth, but of the massacre at Stonehenge; and indeed in his hands, it is difficult to see what any passage may not prove. He is, as might be expected, severe in his criticism on Iolo Morganwg and his 'Bardic Triads,' of the genuineness of which he distinctly intimated his disbelief in 1809; but his own views are in many cases evidently fanciful, though they have been supported, even in later years, by writers of learning. Davies, towards the close of his life, received one of the literary pensions of 100 guineas, paid by George IV. to the nominees of the Royal Society of Literature.

The Rev. Thomas Price, another eminent Welsh antiquary, was a much safer and more candid guide than most of those who have been equally enthusiastic in the cause of his country's language and literature. He observed, in his 'Hanes Cymru,' while praising the care which had been taken to collect and print all the alleged productions of the primitive bards in the Myvyrian Archaiology, that it was only necessary to turn over the pages to see that some of the pieces did not, and could not, belong to the names they were ascribed to, and he acknowledged the difficulties with regard to the 'Historic Triads' and other documents, which are often quoted by others without a hint of unsoundness. Thomas Price was, like Edward Williams, the son of a stonemason, but of a stonemason who, having formed an attachment to a clergyman's daughter, had qualified himself to become a clergyman, and died a Welsh pluralist with a salary of fifty pounds a year. Mr. Price himself, who was born in 1787, and died in 1848, at the age of sixty-one, rose no higher in the church than to the vicarage of Cwmdu. He was so indefatigable a writer in Welsh periodicals, chiefly under the signature of "Carnhuanawc," that he contributed to fifteen, and wrote an article for one or the other of them every month. His chief production in Welsh is the 'Hanes Cymru a chenedl y Cymry' (published in numbers between 1836 and 1842), a 'History of Wales and the Welsh nation from the earliest times to the death of Llewellyn,' after which it is indeed continued, but on a very meagre scale. It is the only history of Wales in Welsh at all commensurate in size and importance with the histories of Wales in English by Warrington and Woodward. It comprises not only a political, but a literary history of the country during most of the period that it embraces, and well merits a translation. The best of his English works are collected in the 'Literary Remains of the Rev. Thomas Price, with a Memoir of his Life by Jane Williams,' in two volumes (1854-55), the correspondence in which presents, it has been remarked, the fullest picture yet drawn of a Welsh literary life.

One of the few instances of Welsh scholars who have obtained distinction in some other walk is afforded by the Rev. John Williams, archdeacon of Cardigan, author of 'Homer' and 'Gomer,' the former a treatise on the Greek poet, and the latter on the Welsh language. Born in 1792, and sent from the school at Ludlow to Balliol College, Oxford, Williams was fortunate enough to meet with Lockhart as a fellow-student, and to form a friendship with him which influenced his whole future career. Recommended by Lockhart as tutor to the second son of Sir Walter Scott, he obtained, by Sir Walter's support, in 1824, the rectorship of the new Edinburgh Academy, a sort of rival to the old High School and formed one of the circle of the great poet and romancer, over whose remains he finally read the funeral service in Dryburgh Abbey. His success as a teacher was marked, and the first 'Dux' in his school was Archibald Tait, the present bishop of London. After twenty years of life in Scotland, he returned to Wales, to the vicarage of Lampeter and the archdeaconry of Cardigan, and continued a career of authorship till his death at Bushey Heath in December, 1858. His best known work was a life of Alexander the Great, and as archdeacon of Cardigan, his ecclesiastical superior was the Bishop of St. David's, Dr. Connop Thirlwall, author of the celebrated 'History of Greece.' Both bishop and archdeacon were also Welsh scholars; but Thirlwall acquired the language after his accession to the bishopric; Williams had always been noted for his attachment to his country's language and literature, and was zealous in Scotland for the honour of Wales. His writings on Welsh subjects, however, did not raise his reputation. In 'Gomer,' a dissertation on the early forms and history of the language, he expressed himself with such positiveness on doubtful subjects, and such vehemence on unimportant ones, as to weaken his authority. He had announced a translation of the poems of Aneurin, Taliesin, and the other primitive bards, with a critical revision and re-establishment of the text, which was looked for with much interest; but though the announcement was made in 1841, nothing had been done towards carrying it out at his death in 1858.

Among the most eminent of living Welsh antiquaries is another John Williams, the Rev. John Williams ab Ithel, rector of Llanymowddwy, Merionethshire, and editor of the 'Cambrian Journal,' gainer of the prizes at numerous Eisteddvods, and author of numerous works on Cambrian subjects. Ab Ithel is an ardent believer in the discoveries and disclosures of the last seventy years, with regard to Cambrian history. In the year 1856 he edited, for the Welsh Manuscript Society, the 'Grammar of Edeyrn the Golden Tongued,' said to be composed about the year 1270, and to which Mr. Williams added a translation and copious notes. The first note is as follows:—"The British alphabet is said to be of divine origin. God in the beginning announced His name, and said /|\, whereupon all things sprang simultaneously into life and being, and responded in a shout of extatic joy, /|\. At the same time there appeared three rays of light, forming the divine name and the three first letters, which were also the source of all letters and sciences. Einigan Gawr, who was favoured with this sight, took three rods of mountain ash, and inscribed upon them the name of the Deity, but the people that saw them mistook the rods, thus bearing His name, for God himself, which caused Einigan to die of grief. (See Coelbren y Beirdd, pp. 6, 7, Iolo Manuscripts, p. 424.) After his decease, Menw ap y Teirgwaedd received a knowledge of the primary alphabet, and developed it, as it would seem, to the extent of ten letters. These letters, or, as they were originally termed, awgrymmau (signs), coelbrai (omen-marks), or ystorrynau (cuttings), were kept a secret by the Bards until the time of Beli Mawr, or, as Llywelyn Sion says, even unto his own day. (Iolo Manuscripts, pp. 617, 618, 623.)" As Llewelyn Sion, of Llangewyd, of whom we have so often had occasion to speak, died about the year 1616, it must be acknowledged that this was the best kept secret on record. Mr. Williams, it will be observed, speaks of these statements, in regard to the British alphabet, not as the dreams of insanity, but as disclosures to be received with respect. He adopts the same serious tone in the preface to the 'Brut y Tywysogion, or the Chronicle of the Princes,' edited by him in 1860, and 'published by the authority of the Lords Commissioners of Her Majesty's Treasury, under the direction of the Master of the Rolls.' "The voice of tradition," he begins, "would not lead us to suppose that the ancient Britons paid any very particular attention to the study of chronology previous to the era of Prydain, son of Aedd the Great, which is variously dated from the year 1780 to 480 before the nativity of Christ." The remarks which follow are of a similar character. Ab Ithel is now (1861) publishing 'The Traditionary Annals of the Cymry; reprinted from the Cambrian Journal,' in which many of the statements are based on the manuscript of Llewelyn Sion, and many others on what are simply quoted as "unpublished manuscripts."

A more complete contrast to Ab Ithel, in the character of his criticism, can hardly be imagined than Mr. Thomas Stephens, of Merthyr-Tydvil, acknowledged even by his opponents to be one of the first of living Welsh scholars. In his 'Studies on British Biography,' printed in the 'Cambrian Journal' in which the editor is in the habit of speaking of Prydain ab Aedd Mawr as a personage as historical as Llewelyn ab Jorwerth, or William the Conqueror, Mr. Stephens remarks that "it is seldom that a name can be clearly demonstrated to be a myth, and the stages of its growth fully and satisfactorily unfolded, but we are enabled to do this in the case of Prydain ab Aedd Mawr, and to show that the name is one of the best specimens of a myth in all literature." "On me be the shame," he adds, "if the statement is not borne out by the facts and reasons here following: on those who have deluded their countrymen with dreamy speculations and hardy mis-statements, if the proof should be conclusive." Mr. Stephens forcibly describes himself at the end of his article, as one "who honestly endeavours to unfold the real history of his country and countrymen, and who aspires to teach them that that can be no true patriotism which upholds as veritable history a tissue of demonstrable fictions, which fears to realise its own boast of 'Truth against the world,' and dreads nothing so much as to see its 'traditions' subjected to a rigorous examination 'in the face of the sun and in the eye of light.'" The most important work hitherto published by Mr. Stephens is his valuable volume on the 'Literature of the Cymry in the Twelfth and following Centuries.' The reader, even where he cannot agree with the author's opinions, feels assured that they are those, not only of a man of learning, but of sincerity and judgment. A complete history of Welsh literature from the same pen would be a boon, not only to the literature of England, but of Europe, and the gratitude of men of letters would make amends to Mr. Stephens for the virulence with which he has been sometimes assailed by the mistaken patriotism of ill-judging countrymen, who do not perceive that he is one of the best friends and supporters of the real honour of Wales.

It has been already mentioned that Mr. Stephens's general views have found a powerful supporter, and in some cases extender, in Mr. Nash of Cheltenham. They are also substantially those adopted in the able 'History of Wales' from the earliest times to the incorporation with England, by Mr. Bernard Woodward, librarian to the Queen. Much excellent criticism on Welsh Druidism, Bardism, and literature may be found embodied to the greatest advantage in a volume which is distinguished for the vivacity, as well as the general soundness of its views.

The music of Wales was first brought before the English public, in connection with its poetry, in the 'Relics of the Welsh Bards,' published in 1784, by Edward Jones, "Bard to the Prince of Wales," a native of Merionethshire, who died at London in 1824. The work is valuable from the specimens it contains of both poetry and music, but the poetry is too paraphrastically rendered, and the accompanying notices are little to be relied on. A similar collection of Welsh tunes was made by John Parry (born at Denbigh in 1776, died at London in 1851), a self-taught musician, who became composer to Vauxhall Gardens, and was moreover honoured with the degree of "Bardd Alaw," or Bard of Music, at a congress of Bards, in 1821. Mr. Parry had the good fortune to engage Mrs. Hemans to write the verses to his collection of melodies; but Mrs. Hemans, though she spent part of her childhood and much of her life in Wales, and was attached to the country, was unacquainted with the language. Another collection of Welsh tunes is now announced as in preparation, with Welsh words, by "Talhaiarn," one of the first of living Welsh poets, and translations into English verse by Mr. Thomas Oliphant, of the Madrigal Society, author of the 'Musa Madrigalesca.'

The quantity of Welsh poetry, or verse, that has been written during the last hundred years is very remarkable, and not the less remarkable is the general uniformity of its character. It is almost exclusively lyrical. In the whole range of Welsh literature for many centuries there was nothing of the epic or narrative kind, not even so much as a ballad, while the most popular volume of Breton poetry that has been published, the 'Barzas Breiz,' consists of a collection of ballads gathered among the peasantry. An absence of fiction in prose, of that class which the Germans consider a branch of poetry, is also very striking in Welsh literature. It might be brought as an argument against the originality of the Mabinogion, that the only other fictitious narratives that have been popular in Wales, even down to our own times, have certainly been imported. The 'Pilgrim's Progress' is simply a translation of Bunyan; the 'Sleeping Bard' of Ellis Wynne [illegible] founded on Quevedo; and the only book of the kind that has [illegible] the mind of the Welsh in our days is 'Uncle Tom's Cabin,' [illegible] received the extraordinary honour of four different translations [illegible] adaptations. All these works, it may be remarked, partake of a religious character. We have never heard of a Welsh translation [illegible] 'Robinson Crusoe,' or of a novel by Sir Walter Scott. Some 'Temperance Tales' have lately been produced in answer to prizes, and [illegible] observe that with the present year (1861) a serial was commenced [illegible] Llanerchymedd under the title of 'Y Nofelydd,' 'The Novelist' [illegible] well conducted, we heartily wish it success. The "Cymro uniaith"—the Welshman who knows no language but Welsh, has been left [illegible]gularly deficient in means of literary recreation. The Saxon [illegible] hardly be more ignorant of the literature of Wales than [illegible] "Cymro uniaith" necessarily was, till very recently, of the literature of England.

Some of the poets of the more recent period have already been mentioned in giving an account of the antiquaries,—Owen Pughe, Edward Williams, and his son Taliesin; of the others, the only dramatic one [illegible] take precedence. "Twm o'r Nant," says Williams, or Iolo Morganwg, in one of his letters, "has been called the Shakspere of Wales. [illegible] blasphemy to name him with the Shakspere of England! You [illegible] most probably seen a foolish crambo sometimes put into the hands [illegible] little children beginning to read, 'This is the House that Jack built.' It is much fairer to compare this to the writings of Shakspere than anything that was ever written by Twm o'r Nant, whose interludes consist of nothing but the lowest and frequently the most indecent buffoonery that can be imagined." "Twm o'r Nant," or "Tom of the Valley," was the bardic name of Thomas Edwards, who was the originator and chief of a band of strolling players who went about [illegible] the Welsh villages. His interludes, "Enterlutes," as he calls them [illegible] Welsh, resemble, if we may judge by their titles, which are given [illegible] a correspondent in the 'Gwladgarwr' (vol. vi., p. 144), the Mysteries or Moralities, which preceded the establishment of the regular theatre in most countries of Europe. One of them is a dialogue between [illegible] Protestant and a Dissenter; another between Pleasure and Misery. The dates of these are 1783 and 1787. He afterwards advanced nearer to the regular drama, for in 1812 we have the 'Ystori Richard Whittington yr hwn a fu dair gwaith yn Arglwydd Maer Llundain;' the story of Whittington thrice lord mayor of London. Their merit, we may charitably suppose, was greater than Williams allows them, since some who deny him the name of the Welsh Shakspere call him the Welsh Aristophanes. Edwards was born in Denbighshire in 173[illegible], and died, apparently, before 1820. Before his time the only existing specimens of the Welsh drama, that we are aware of, are a volume of "interludes" of the 17th century, among the manuscripts of the British Museum. Since his time we have heard of no attempt to revive the acted drama in Wales; but in a recent number of 'Y Beirniad,' a periodical, there is an adaptation of David and Goliath from the original of Hannah More; and Talhaiarn gives in his poems a translation of a scene or two from Shakspere's 'King Lear.'

The poetry of the fourth period in Wales is generally of a serious character. Three Davids are mentioned as distinguished among the bards—David Richards of Dolgelly (1751–1827), known as Davydd Ionawr; David Thomas of Caernarvon (1769–1822), known as Davydd Ddu Eryri; and David Owen of Eivion (1784–1841), by his bardic name Dewi Wyn. Davydd Ionawr is sometimes called "the Christian poet of Wales," his chief productions being a sort of epic on the Trinity, and a paraphrase of the history of Joseph. Davydd Ddu Eryri was one of the companions of Iolo Morganwg in the bardic meeting held in 1792 on the summit of Primrose Hill, and in 1793 and 1794 he was with his rival, Walter Davies, or Gwallter Mechain, prohibited from contending at Eisteddvods for a time, because, when they did so, their competitors had no chance of success. Dewi Wyn spent his life in rural pursuits, and his poems were collected in a volume under the title of 'Blodau Arfon,' or 'Flowers of Arvon.' Mr. Thomas Lloyd Jones (Gwenffrwd), of Holywell, in Flintshire, who emigrated to America, and died in Alabama in 1834, in his twenty-fourth year, published a small but useful volume, 'Ceinion Awen y Cymry,' 'the Beauties of Welsh Poetry,' an acceptable guide both to the stranger and native. A larger volume of this description, with biographical notices of the poets, on the plan of Mackenzie's 'Specimens of Gaelic Poetry,' is much required in Welsh literature. Lloyd Jones had also translated into Welsh, Thomson's 'Seasons,' and the 'Deserted Village,' and thus set an example, which has been followed by Daniel Silvan Evans and by —— Jones (Talhaiarn), of enabling the Welsh reader to taste some of the beauties of the bards of England. Merthyr-Tydvil at one time boasted of three poets—Taliesin Williams, already repeatedly mentioned; Edward Williams, an innkeeper, who, to distinguish him from the more famous Edward Williams, or Iolo Morganwg, was called Iolo Mynwy; and John Thomas, said by his admirers to be the best minstrel in South Wales. Two eminent Welsh bards were resident at Oxford together—the Rev. Daniel Evans, of Jesus College, who assumed the name of Daniel Ddu o Geredigion, from his native Cardigan, and the Rev. John Jones, of Christ Church, who took that of Tegid, from having been born near Llyn Tegid. A collection of poems by the former was published at Llandovery in 1831, under the name of 'Gwinllan y Bardd,' 'The Poet's Vineyard.' The productions of the other have not yet, that we are aware, been collected, though the death of Tegid took place some years ago, and his poems are such as his countrymen would not willingly let die. The Rev. Walter Davies, called Gwallter Mechain, from his birthplace, Llanvechain, in Montgomeryshire, was born in 1761, and died in 1849, in his eighty-ninth year, still an active contributor to Welsh periodicals, for which he had then been in the habit of writing for more than half a century. As a Welsh poet he was more remarkable than his friend Iolo Morganwg, and his influence at the Eisteddvod of 1819 was strong against Cyngha-nedd. The Rev. James Hughes, born in 1779, at first a peasant in Cardiganshire, then a workman in Deptford dockyard from his twenty-first to his forty-fifth year, became, in 1810, a Calvinistic Methodist preacher, was for many years minister in Jewin Crescent Chapel, and died in 1846. His Welsh commentary on the New Testament is in high esteem, and he was also considered a good poet and critic. Among his productions is a translation of Gray's 'Bard.' Some Welsh verses are inscribed on his tombstone in Bunhill Fields burying-ground, in full view of the passengers along the busy City Road, whose eye they often catch. The Rev. William Rees, of Liverpool (Gwilym Hiraethog), is a poet of high reputation, who generally exercises his pen on serious subjects, and the chief production in whose volume of poems is a paraphrase on the Book of Job. The Rev. William Williams, of Caernarvon (Gwilym Caledfryn), author of 'Grawn Awen' ('The Treasure of the Muse'), and other volumes of poetry, has been for the last forty years one of the leaders of the poetical choir. It is somewhat remarkable that we hear of no "tenth Muse," no poetess whatever in the Welsh Parnassus, though of late even female preachers and female lecturers have been numerous in the country, and its history and literature owe permanent obligations to the Englishwoman Mrs. Hemans and the Scotchwoman Lady Charlotte Guest. A poem entitled 'Wales,' which has appeared in America, is a tribute to her native country by Miss Maria James, who, when she left the Old World at the age of eight, was acquainted with no language but Welsh, and whose first lesson in English was to learn on board the vessel the meaning of "Get out of the way." But even in her tribute to Wales she adopted the English language. One good effect of the prizes proposed by the Welsh societies has been that of late some versified narrative has been introduced to give a little more variety to Welsh poetry. It is singular to observe with what undeviating constancy the national mind has run for centuries in the track of funeral elegies and eulogies, so that, even in modern times, scarcely any respectable clergyman is lost to his congregation without being celebrated in verse. The poet whose Bardic name is Talhairn, but whose real name is —— Jones, seems to offer an exception in many respects to the general course of his countrymen. He writes poetry in English as well as Welsh; he appears to appreciate and enjoy English literature; and his productions are of a lighter and more amusing kind than usual. A long residence abroad, not only in England, but in France, in pursuit of his profession as an architect, appears to have emancipated him from many of the narrow ideas which are still found in the glens of Wales.

The cultivation of Welsh prose has lately taken a much wider range than formerly, owing to the great spread of periodical publications. Of separate works there are few, except of a purely theological cast, and these are generally commentaries on the Scriptures, in which the matter is taken from English commentators, and only arranged in a new manner. The Rev. Thomas Price's 'Hanes Cymru,' a history of Wales which has been already noticed, is almost the only volume of original research. A volume entitled 'Brutusiana sef Casgliad Detholedig o'i Cyfansoddiadau' ('Brutusiana, or a Select Collection of his Compositions'), by David Owen, who writes under the signature of Brutus, is considered to contain some of the best specimens of modern Welsh prose, which are chiefly reprinted from the periodical entitled 'Yr Haul,' of which Mr. Owen was editor. The subjects are mostly religious. Mr. Hugh Williams, known under the bardic name of Cadvan, and formerly editor of the 'Cymro,' a newspaper published at Bangor, is also celebrated as a writer of elegant and idiomatic Welsh prose, and was presented with a testimonial on that account by his countrymen in London, in May, 1860. Mr. Williams is one of the translators into Welsh of 'Uncle Tom's Cabin.'

The spread of Methodism in Wales has been referred to as one of the causes of the revival and extension of its literature, and the proof is at hand in the fact, that no other literature whatever is so eminently sectarian. Methodism in Wales, as elsewhere, has found its chief acceptance among the lower classes. In England the Methodists have a literature of their own, but it is couched in the common language of the country; in Wales that literature is in the peculiar language of the peasantry. The peasantry are delighted beyond measure to hear themselves addressed from the pulpit in their native tongue. The two popular preachers of Anglesey, Christmas Evans (1766-1838) and John Elias (1774-1841), produced wonderful effects on their Welsh congregations. Christmas Evans, so baptised because he was born on Christmas-day, was noted for his fine voice and his theatrical action. John Elias, who paid a visit to London every three years, and also took tours through England, preaching in Welsh in towns where no other Welsh sermon had ever been heard, was a sort of apostle to his countrymen. The great body of modern Welsh literature is thus of a theological and sectarian cast, and it is supported by many to whom nationality and national traditions are a matter of comparative indifference. There are also many, to whom theological disputes are matters of less interest, but who are enthusiastic for their nationality and their language. Between the two are all shades of combinations of the two feelings—theological and national; and the progress of both is more faithfully delineated than anywhere else in the Welsh periodical press. In almost every country the periodical portion of its literature has now assumed an importance unknown to previous stages of its history, but in no country is it so predominant as in Wales.

The first Welsh periodical of any kind appeared about 1770: its title was 'Yr Eurgrawn Cymraeg,' or the 'Welsh Treasure,' and it was edited by the Rev. Peter Williams, of Caermarthen, and Evan Thomas, a Welsh poet, from Montgomeryshire, then resident in that town. Allusion has already been made to 'Y Greal,' or 'The Miscellany,' which was set on foot by Owen Jones, under the editorship of Owen Pughe, in 1805, and did not proceed further than one volume. The 'Seren Gomer,' or 'Star of Gomer,' was the first periodical that achieved a decided success in Wales. There are three different stages of its career,—as a weekly newspaper, a monthly magazine, and a quarterly miscellany. The first number of it appeared at Swansea, on Saturday, the 1st of January, 1814, and was the first Welsh newspaper ever printed. Its object was stated by the editor, in his opening address, to be to arrest or prevent the extinction of the language, which it appears was then expected by many not to survive that generation. The editor, the Rev. Joseph Harris, a Baptist minister of Swansea, was a self-taught man, who carried his admiration of his native language to a fanatical extent. The 'Seren Gomer' newspaper was at first very successful, but its supporters soon began to cool and fall off, and it came to a close with No. 85, in 1815, the proprietors, six in number, suffering it is said a loss of 1000*l.* by the enterprise. In 1818, it was resumed as a monthly magazine at Caermarthen, under the same title and with the same editor; but this time it had more of a sectarian character, and it struck deep root. Even the loss of its editor, Harris, did not check its success: he died in 1825, of a broken heart at the loss of his only son, who had died the year before at the age of twenty-one, and was already known, under the name of Jeuan Glan Tawy, as a poet of merit. The 'Seren Gomer' continued to be for many years the most popular magazine in Wales, though its success gave birth to several rivals. Its general character was that of the English magazines of the early part of the 19th century, the contents consisting mainly of articles from chance contributors, and every number comprising a digest of foreign and domestic news, with the state of the markets, so as to give the reader the advantage of a monthly newspaper. Questions of theology and church government took however such a prominence in its columns, as would have caused it to be classed in England among the religious magazines, such as the 'Evangelical,' or the 'Baptist.' Its price as a monthly magazine was sixpence; it is now raised to a shilling, and the 'Seren Gomer' of 1861 is a quarterly publication.

Several of the other periodicals which arose in consequence of its success were connected with religious bodies. 'Y Drysorfa,' or 'The Treasury,' edited by John Parry, and commenced in 1831, was under the superintendence of the Calvinists. 'Y Diwygiwr,' or 'The Reformer,' commenced at Llanelly in 1836, was conducted by a committee of the Independents; and 'Y Dysgedydd,' or 'The Teacher, published for the last thirty years at Dolgelly, is edited by six or seven Congregational ministers. Most of the other magazines are organs of Wesleyans, Independents, Baptists, or Universalists. The 'Cylchgrawn,' or 'Circulator,' consisting principally of translations from the publications of the Society for the Diffusion of Useful Knowledge, in particular the 'Penny Magazine,' and 'Penny Cyclopædia,' had a very short career, in consequence of the distaste of the Welsh public for all but religious publications. It was commenced in 1834, and discontinued in 1835. Its editor was the Rev. John Blackwell, of Mold, in Flintshire, who had raised himself from the position of a shoemaker to that of rector of Meinordeifi, in Cardiganshire, and had some poetical reputation. Other publications were more successful, which, though not excluding sectarian matter, had a strong tincture of literature. 'Y Gwladgarwr,' or 'The Patriot,' published at Chester and Liverpool from 1833 to 1841, under the editorship originally of the Rev. Evan Evans (Jeuan Glan Geirionydd), contains amusing and instructive biographical articles. 'Yr Haul,' or 'The Sun,' published by Rees of Llandovery, though espousing the interests of the Established Church, was edited by a layman, David Owen, and contained some valuable and non-ecclesiastical matter. But the leading literary organ of Wales for some years has been a quarterly periodical entitled 'Y Traethodydd,' or 'The Essayist,' commenced in 1845 at Denbigh. This is a production of a class answering to the English quarterly reviews, the articles in it being all of a superior character, and supplied by paid contributors. It takes a wider and freer range than its predecessors, and is the only Welsh periodical which contains, for instance, an "essay" on Goethe's 'Faust,' and another on Kant's 'Philosophy.' Many of its articles well merit translation: we may cite, as an instance, a curious account of the French invasion at Fishguard, much fuller, we believe, than any that has yet appeared in English. Since 1859 a companion has arisen to the 'Traethodydd' in 'Talicsin,' a quarterly magazine issued at Ruthyn, which publishes the productions, both poetical and in prose, which have received the prizes at the Eisteddvods, in addition to reviews of new books and miscellaneous articles. The Welsh periodicals form altogether the most striking and attractive feature in their modern literature. Their number is astonishing, and they are issued even in secluded towns and villages. In the catalogue of the periodical publications in the Library of the British Museum, we find two Welsh magazines published at Llangollen, three at Llanidloes, and four at Llanelly. An interesting notice of them was given in some articles of the 'Athenæum' (8th and 15th November, 1856), which enumerated sixteen magazines and six newspapers. The leading newspaper is the 'Amserau' (the 'Times'), published at Liverpool, whose circulation was computed in the 'Athenæum,' but no doubt very erroneously, at 100,000. Penny newspapers are now numerous and well conducted. 'Yr Herald Cymraeg,' published at Caernarvon, and 'Yr Udgorn y Bobl' ('The People's Trumpet'), published at Denbigh, contain letters from correspondents at London, Liverpool, Dublin, Hirwaun, &c., &c., which though not remarkable for purity of language, furnish much more amusing reading than was formerly within reach of the Welsh reader. It was mentioned in the 'Athenæum' that a selection of extracts from the Welsh periodicals was issued at New York, under the title of 'Y Detholydd,' or 'The Selector,' and that there were also original Welsh periodicals in America: 'Y Cenhadwr' ('The Messenger'), 'Y Seren' ('The Star'), 'Y Cyfaill o'r Hen Wlad' ('The Friend from the Old Country'), "and many others." Samuel Jenkins, of Philadelphia, who contributes a letter on eminent Welshmen to a book by Alexander Jones on the Welsh in America, entitled 'The Cymry of '76,' published at New York in 1855, mentions that of four Welsh magazines then published in the United States, one was issued in the city of New York, two in towns in Oneida county, and the other in Pottsville, Pennsylvania. We have also seen mentioned a newspaper at New York, 'Y Cymro Americanaidd' ('The American Welshman'), which is said to have 5000 subscribers. In an enumeration of the newspapers published in America in 1861, it is stated that there are five in the Welsh language,—and, we believe, exactly four thousand in the English.

One of the greatest enterprises of Welsh publishing is the Welsh Encyclopædia, commenced by Mr. Gee, of Denbigh, in the year 1856, under the editorship of the Rev. John Parry, of Bala. Its title is 'Encyclopædia Cambrensis-Y Gwyddoniadur Cymreig.' It is divided, on the plan of the 'English Cyclopædia,' into several sections, of which the first, which is now publishing, is that of Divinity, Philosophy, and Antiquities. The first number of the fourth volume, just issued (in August, 1861), carries it to the article *Dyfnwal Moelmud*, in which, as in the article on *Bardd*, which occupies 36 closely-printed pages, a full and impartial account is given of the views of both of the parties in Welsh antiquities, but in a manner which leaves no doubt that the writer's judgment is adverse to the supporters of Bardic tradition. The Encyclopædia is a work which in its literary character does honour to Welsh literature, and in its typographical execution does honour to the Welsh press.

This is perhaps the most appropriate place to mention that some of the most valuable information in print with regard to the literature of Wales is comprised in five periodicals in the English language, devoted exclusively to Welsh subjects. The earliest of these, 'The Cambrian Register,' extends to three volumes, the first of which was published in 1796, the second in 1799, and the third in 1818. It would be difficult to name three volumes of a periodical publication more rich in original information of interest. The letters of distinguished Welsh antiquaries, which form a portion of its contents, are particularly entertaining; and a history of Welsh poetry, which appears in the first volume, contains more information on the subject of its recent authors than will be found elsewhere. Dr. Owen Pughe was one of its principal contributors, and is said to have been its editor. 'The Cambro-Briton and General Celtic Repository,' also in three volumes, published in the years 1819—1822, is an excellent periodical, replete with information of every kind, and remarkably free from frivolous or unimportant matter. Its editor was Mr. John Humffreys Parry, secretary to the Cymmrodorion Society, author of the 'Cambrian Plutarch' and other works of reputation. The 'Cambrian Quarterly Magazine,' in five volumes, published from 1829 to 1833, is unfavourably distinguished from its predecessors by the admission of articles of mere light reading: but some of these are extremely well written. The present successor to these works is the 'Cambrian Journal, published under the auspices of the Cambrian Institute,' and edited by the Rev. John Williams ab Ithel. It was commenced in 1854, and the four quarterly numbers form a volume each year. The articles are of a very varied kind, and of extremely different degrees of merit, and opinions of the most opposite character are freely and strongly expressed. The 'Archæologia Cambrensis,' or 'Journal of the Cambrian Archæological Association,' though of course less devoted to literary subjects than the other periodicals, contains a good deal that bears upon them. It has produced an annual volume of four quarterly numbers, with occasional supplements, since its commencement in 1846. The editor is the secretary of the society, the Rev. Longueville Jones. The volumes of these periodicals, now about thirty in number, should find a place in every public library in England, where the literature of ancient Britain and the [illegible] literature of a considerable portion of it, are not objects of [illegible]ence. They comprise almost all the information on the [illegible] present accessible to the English reader—defective in many [illegible] it is true, and scattered over many volumes; but we can scarcely [illegible] plain of the deficiency of a general and satisfactory survey [illegible] literature of Wales, while as yet we have nothing of a similar [illegible] our own.

In speaking of the periodicals we have anticipated some of our [illegible]mation with regard to societies. The literary associations of W[illegible], though not very successful at first, have been in the long run [illegible] effectual in reviving the taste for its literature. The earliest of [illegible] seems to have been the Cymmrodorion (Associates) or Metropolitan [illegible]brian Institution, which was originally established in London in 17[illegible] immediate purpose was to cultivate the language and literature of W[illegible] and its members were also to "contribute their endeavours toward[illegible] instruction of the ignorant and the relief of the distressed part of [illegible] countrymen." It collected some scarce books and manuscripts re[illegible] to Wales, which were afterwards deposited in the library of [illegible] Welsh school in Gray's Inn Lane, but did little else in a literary [illegible] of view, and after an existence of thirty years appears to [illegible] gradually expired of inaction. Its place was more vigorously [illegible] by the Gwyneddigion, or Society of the Men of Gwynedd, or N[illegible] Wales, which was established in London in 1771, by that indefatiga[illegible] patriot Owen Jones of Myvyr. This association at different [illegible] patronised various literary works connected with the principality [illegible] its chief aim was to keep alive the attachment to the national [illegible] and poetry. With this view it revived the ancient congresses of [illegible] bards, and distributed medals among the best performers on [illegible] national instrument, the harp, and the writers of the best W[illegible] poems on subjects selected annually for the occasion. In 17[illegible] "Eisteddvod" was held under the auspices of Owen Jones, at Caerw[illegible] in Flintshire, which prepared the way for the "Eisteddvods" of [illegible] recent times. The London Cymreigyddion Society, founded in [illegible] was intended to place the natives of Wales on something of [illegible] equality with the natives of Great Britain, in respect of the oppor[illegible]tunities of acquiring useful knowledge; and for this purpose [illegible] meetings once a month were to be devoted to the *delivery* of lectures [illegible] in the Welsh language on scientific and useful subjects, many of wh[illegible] were printed and published. This society now appears to be ex[illegible] and one of its last public acts was to reward in *1840*, the Rev. [illegible] Bray for his 'Essay on the Means of Promoting the Literature [illegible] Wales,' in which he recommended the systematic discouragement [illegible] the Welsh language. The second "Cymmrodorion" Society w[illegible] formed in 1820, at a meeting held at the Freemasons' Tavern, [illegible] has similar objects with the first. It commenced the publicati[illegible] of its 'Transactions' in 1822, and completed a *second* volume [illegible] 1843, after which it appears to have come to a stand-still. Th[illegible] "Society for the Publication of Ancient Welsh Manuscripts," w[illegible] founded at Abergavenny in 1837, and was announced *in its* prospect[illegible] to be acting in conjunction with the "Cymmrodorion Society, founde[illegible] at London in 1750," by which the second Cymmrodorion Society wa[illegible] probably meant, though the date given is anterior *even to* the fo[illegible]mation of the first. The Manuscript Society after issuing the 'Liber Landavensis,' or the 'Ancient Register of the Cathedral Church of Llandaff,' in Latin and English, under the editorship *of the* Rev. W. J. Rees, the 'Heraldic Visitation of Wales,' the 'Lives of the Welsh Saints,' and other valuable publications, the Iolo Manuscripts, and the 'Grammar of Edeyrn,' appears to have fallen into a *state of* languor. It was recently announced, however, as already stated, that measures are about to be taken for restoring its vigour.

The Cambrian Institute, founded in 1853, has *held a few* occasional meetings in London, and has a number of sectional committees and local secretaries, but its activity is chiefly displayed in the publication of the 'Cambrian Journal,' which is circulated *among its* subscribers. It is remarkable that one of its earliest patrons and its present president is Prince Louis Lucien Bonaparte, nephew of Napoleon I., and cousin of the present Emperor of the French, who *has in* many ways distinguished himself as a cultivator and student of the Celtic languages as well as of others of the less known tongues of Europe. The Prince was born in England, and on the Welsh border, at the time that his father, Lucien Bonaparte, was resident in this country, during the reign of the first Napoleon. Another distinguished name in the list of the Institute is that of the poet-laureate, *Alfred* Tennyson—a peculiarly appropriate one, not only because Tennyson has given fresh brilliancy in our time to the legends of King Arthur, but because the office he holds is one peculiarly in keeping with Cambrian notions of privileged bards and poets named by authority. The first poet-laureate of the English court was appointed in the reign of Edward IV., who is said in some Welsh Guide-Books to have been born *in* Wales.

While the Societies have, as a general rule, been somewhat inert, a brilliant success has attended the revival of the Eisteddvodau (literally 'sessions'), or meetings for poetry and music, such as were first re-inaugurated in 1798 by Owen Jones, who seems to have had a happy tact in discovering what was likely to succeed, though he was himself in advance of his time. Their progress was obscure *till* 1819, when one was held at Caermarthen, under the presidency of Dr. Burgess, then bishop of St. David's, but in reality prompted and supported by Dr. Joseph Harris, the Baptist editor of the 'Seren Gomer,' and conducted and enlivened by Iolo Morganwg, who completely took the lead and put in practice many of the ideas which appear in the notes to his 'Ode on Primrose Hill.' This Eisteddvod was so successful as to form an epoch in their history, and ever since they have been becoming more frequent and more popular. The idea at the basis of such meetings, that of holding a sort of Fair for poetry and music, is one that was practised in the "singer's festivals" of the Minne-singers and the floral games of the Troubadours, and even among the Arabs before Mohammed, whose poetical rivalries at the fair of Ocadh gave rise to the 'Moallakat,' which are some of the most classical compositions of Arabic literature. The same principle received a new application in the Fairs for Science introduced by Oken in Germany in 1822, on the model of a meeting of naturalists in Switzerland in 1815, and the idea was imported from Germany to England by the foundation of the British Association in 1831. Meetings of agriculturists, archæologists, orientalists, men of science, and others, are now held in many parts of Europe, but fairs for poetry and authorship appear to be still peculiar in modern times to Wales and Provence. A distinct idea of the nature of an Eisteddvod may be most readily obtained by observing the proceedings at one of the most successful of them—that held at Llangollen in the autumnal equinox of 1858. The meeting took place at the equinox, in obedience to alleged bardic custom, and was consequently rather too late in the year, so that there were several days of rain. A pavilion was erected on the bowling-green adjacent to the Ponsonby Arms Hotel, at Llangollen, so spacious as to be capable of containing five thousand persons; and at the last meeting it is stated that this pavilion was "literally crammed, with such an assembly as was scarcely, if ever, witnessed in the Principality." On the first day the proceedings commenced with a procession of Bards, Druids, Ovates, and others, with the members of the three orders attired in their distinctive costumes—the bards in a loose habit of blue, the druids in snowy white, and the ovates in green. The procession led to a spot where three hugh stones were placed in the order /|\. "These lines, or pencils of light, as they are termed, form," we are told in the Report, "the mystic symbol known amongst the bards and druids as the name of God—the 'Word' or attribute of creation—it being held by the bards that God created the universe by showing and pronouncing His own name." It will be remembered that seventy years ago this tradition, such as it is, was unheard-of in Wales, and only existed in an unpublished manuscript. The Rev. John Williams ab Ithel, presiding bard of the Eisteddvod, stood on the central stone within a circle, and delivered an address, received with "frequent marks of applause," to the effect that the Cymry succeeded beyond all other nations in keeping the ancient religion of Noah uncorrupted till the coming of the Messiah, when "they received the Gospel as the superstructure or completion of Druidism, and their ancient system was clothed with Christianity." A ceremony then took place of receiving and admitting candidates for the orders of bards, druids, and ovates. In the course of the day, speeches were delivered, and various essays were read which had been determined to be the best sent in to compete for prizes. One of these prizes was of twenty-five pounds, offered by the young men of Llangollen, for the best treatise on the mineral resources of Wales, with the stipulation that if the successful composition should be in English, it should be translated into Welsh at the author's expense. The prize was adjudged to an essay signed "Didascalos;" and the author being called for, appeared in the person of the Rev. John Jones, Baptist minister of Llangollen, who was publicly presented with the prize by Miss Williams ab Ithel. The proceedings of the day terminated with a concert, at which about three thousand persons attended, to admire Mr. Ellis Roberts's performance on the harp, laugh at Owen Alaw's comic song of "Hen Forgan a' i Wraig" (Old Morgan and his Wife), and enjoy similar festivities. On the second day, an English gentleman, Mr. Kenward, recited some lines of a poem on 'English Sympathy with Wales;' but, say the reporters, "a feeling of impatience being manifested by the Welsh portion of the audience who did not understand English, Mr. Kenward, felt reluctant to read the whole, and retired from the platform." Another English gentleman remonstrated, and Ab Ithel came forward to inform the meeting that Mr. Kenward was a person who pre-eminently "loved our nation," and had been most indefatigable in collecting subscriptions for the Eisteddvod, on which he was allowed to proceed through about twenty stanzas. More speeches and Pennillion singing followed, and an adjudication of the prize of 30*l.* for an Ode in Welsh on "the Battle of Bosworth Field, by which the Cymry recovered the monarchy of the isle of Britain." On another day the main feature was the presentation of a "Cambrian gold torque of valour" to Corporal Shields, of the Welsh Fusileers, who had fought in the Crimea. Close to Llangollen, on the summit of a hill, are the ruins of Dinas Bran, a name sometimes translated "Crow's Castle," Bran being the Welsh word for "crow," but supposed to take its origin from the mountain-torrent, Bran, which runs beneath. Some antiquaries have absurdly supposed the castle to be named after Brennus, king of the Gauls, and the Rev. R. W. Morgan, in presenting the torque, took occasion to mention it thus: "Corporal Shields is a Cymro, the representative of a race that from the earliest ages has been distinguished by two grand characteristics—profound religious feeling, and chivalry in the field. Towering above us, frown the ruins of the castle of one of the earliest of the great conquerors of mankind, Brân or Brennus, the captor of the Eternal City, the founder of the Cisalpine empire and its civilisation, the first general that, long antecedent to Hannibal, crossed the glaciers and snows of the Alps, and vanquished the opposing bulwarks of Nature herself. (Loud cheers.)" Choral singing, contentions with the harp, impromptu poetical contests, recitations of the speech of Caractacus by boys, competitions of the best female singers to the harp, and the best female harpists, filled up the remainder of the four days during which the Eisteddvod lasted, each day concluding with a concert. The devotion to the charms of poetry and music, which was shown by so large a population, many of the peasant class, was certainly a high mark of civilisation and refinement of character; but the patriotism of many of the speeches was of the spurious kind, which is as ready to boast of the false as the true, and the semi-religious character of many of the proceedings presented still graver matter of objection. There seems too much resemblance between the adherents of the Book of Llewelyn Sion of Llangewyd and the believers in the Book of Mormon, who are unhappily numerous in Wales.

One speech at an Eisteddvod, of a different character from those usually delivered, contains some remarks which, though expressed in rough and homely terms, it would be well for Cymric patriots to consider. They occur in the Welsh portion of the works of the modern Talhaiarn, in the report of a speech delivered at an Eisteddvod at Llanfairtalhaiarn:—"It is the greatest folly in us to shout out that we are at the head of the world in poetry and prose. It is a very great mistake; for the fact is the Saxons beat us all to pieces in poetry, philosophy, and all kinds of learning. Do you think I say this to hurt or insult my country or my nation? Nothing of the kind. I reverence and love them both, nor will I ever go about to seek to find fault with either. Neither will I soil my lips with an untruth to please any man, nor will I do an injustice to my neighbour by boasting of what is really nothing to boast of. If you could all read Shakspeare, Milton, Byron, and Burns, the 'Times,' and 'Blackwood's Magazine,' and some other authors, magazines, and newspapers, you would all believe with me that the Saxons are much our superiors. Well, you will say, and have not we a literature? Yes, most certainly, and an excellent literature too, considering that Wales is but a little corner of the world. My only purpose was to wean you from the silly boast that we are at the head of the world in literature; there never was such nonsense."

The formation of a library of ancient Welsh manuscripts on a liberal and extensive scale in the possession of a public establishment appears an object greatly to be desired. The history of the fate of Welsh manuscripts during the last two centuries affords ample proof of the danger to collections of this kind in private hands, to say nothing of the fact that in many cases all access to the manuscripts has been denied to the very men, such as Lhuyd, who would have made the best use of them, and that in all cases there is necessarily a delicacy of intruding on the courtesy of a private proprietor. The number of libraries destroyed by fire has been unusually large in the case of the country gentlemen of Wales. The collection of transcripts by Lhuyd, which, after his death, was unfortunately declined both by the University of Oxford and by Jesus College, passed into the hands of Sir Thomas Sebright, by purchase, and was long afterwards divided by sale between the libraries of Hafod and Wynnstay. The portion in the splendid collection of Colonel Johnes, at Hafod, perished with that collection in the fire of 1807. The portion belonging to the Wynnes was almost entirely destroyed by a fire at a bookbinder's in London, and the conflagration of Wynnstay itself, in 1858, probably consumed the remainder, as on that occasion only the books that had been casually sent to a bookbinder's in London were saved. In the preface to the 'Myvyrian Archaiology' is given a list of the libraries public and private in Wales, London, and Oxford, in which valuable Welsh collections were preserved, amounting to twenty-five in number. Four of these libraries were in London, that of the British Museum, of the Welsh School, in Gray's Inn Lane, of Mr. Owen Jones, the originator of the 'Myvyrian Archaiology,' and of Mr. Edward Jones, author of the 'Relics of British Bards.' Three of these are now united, the collections of the Welsh School and Owen Jones having been presented to the British Museum in 1843. These books are thus preserved in one collection under public care, and it would be most conducive to the interests of literature if others were to follow. Some of the perpetual disputes about the accuracy of the transcripts of Iolo Morganwg which agitate Welsh literature might be settled at once if the 'Book of Aberpergwm' were in a collection where any one might examine it. It is stated in the 'Myvyrian Archaiology,' in 1801, that the editors had some hope that the Earl of Macclesfield would deposit in the Museum the collection of manuscripts made by the learned Moses Williams, and which Williams had bequeathed to Mr. Jones, father of the celebrated Sir William Jones, who bequeathed them to the then Earl of Macclesfield, with the singular injunction not to show them to any person whatever. These manuscripts however are still in the possession of the noble family of Macclesfield. The famous library of the Vaughans, at Hengwrt, in Merionethshire, is now united with the collection of Mr. W. E. Wynne, of Peniarth, M.P., for Merioneth, to whom it was bequeathed by his friend the late Sir R. W. Vaughan.

There is no collection of Welsh printed books approaching to completeness, the best in existence being probably that in the British Museum, which contains an assemblage of magazines and newspapers in that language, to which, though far from perfect, it would be difficult to find a rival. Welsh books were first collected at the Museum, about the year 1838, and the presentation of the libraries of the Welsh School, and the Cymmrodorion in 1843 made some augmentation to the stock. Another Welsh collection of some extent is to be found where it would scarcely be looked for, in the library of Brown University, at Providence, in Rhode Island, to which it was bequeathed in 1818 by the Rev. William Richards, of Lynn, in Norfolk. The books are enumerated in the excellent catalogue of that library published by Professor Jewett.

The bibliography of Wales was first cultivated by the Rev. Moses Williams, the able and indefatigable antiquary, who has been mentioned as having nearly anticipated the 'Myvyrian Archaiology.' Owen says of him, in his 'Cambrian Biography,' that "he published nothing of consequence besides an index to the Welsh poets," but in this he is mistaken. In addition to the 'Repertorium Poeticum, sive Poematum Wallicorum, quotquot hactenus videre contigit Index Alphabeticus' (London, 1726, 8vo), which contains an index of pieces of Welsh poetry, according to their first lines, and the fullest catalogue of poets we have seen, Williams issued a 'Cofrestr o'r holl Lyfrau Printiedig gan mwyaf a gyfansoddwyd yn y Jaith Gymraeg, neu a gyfjeithwyd iddi, hyd y Flwyddyn 1717' (London, 1717, 8vo)—'A catalogue of all the books that have been printed, and several that have been composed, in the Welsh Language, or translated into it, up to the year 1717.' This catalogue does not extend to more than a single sheet, but it is very closely printed. The original edition is now very scarce, but the whole of it was reprinted in the periodical entitled 'Y Gwyliedydd,' for 1832. In the 'Gwladgarwr' for 1840 a list of Welsh publications is given, from the earliest time to the year 1799; but, though valuable, it is probably very imperfect, as it omits even some of the works inserted in Williams's catalogue. The number of articles it enumerates is 620, but these include a few works relating to Wales in other languages than the Welsh. In the volume of the 'Traethodydd' for 1852, was commenced a valuable series of articles on Welsh bibliography, 'Llyfryddiaeth y Cymry,' containing not only the titles of the books but bibliographical notes and observations, but it was not continued so long as bibliographers would have desired. A work of the same kind in English, from the pen of the Rev. Robert Jones, of Rotherhithe, a scholar eminently qualified for the task, was spoken of some time ago, but has not yet appeared. A very useful bibliographical list of works on Wales and its literature is to be found in the German work, 'Das alte Wales,' (Bonn, 1859) by Ferdinand Walter, a continental scholar who has lately studied the subject with German diligence. A bibliographical periodical intended to be quarterly, 'The Cambrian Book Register,' was commenced in June, 1857, by Mr. Pryse, a bookseller of Llanidloes and Rhayader, but never advanced we believe beyond the first number.

The earliest attempt at a collection of Welsh lives is Owen Pughe's 'Cambrian Biography, or Historical Notices of celebrated men among the Ancient Britons' (London, 1803, 12mo), but the notices are so extremely brief, averaging four or five to a page, that the book can hardly be regarded in any other light than an index. The dates are also very far from accurate. The 'Cambrian Plutarch' of John Humffreys Parry (London, 1824, 8vo), is much more satisfactory, but embraces only twenty-two lives. A biographical dictionary under the name of 'Lives of Eminent Welshmen,' was commenced in numbers in 1843 and completed in 1852, by the Rev. Robert Williams of Llangadwaladr. The articles are too brief, and not so entertaining as they might have been made by the use of the materials existing in Welsh; but the volume is indispensable in every Welsh library, and one to which we have been much indebted in this general summary of the history of Welsh literature.

WEN, the name of those tumours occurring on the human body which assume the form of a bag or cyst, and contain a variety of contents. These cysts have been named according to the character of their contents. When the contained matter resembles fat or suet, the tumor is called *Steatoma;* when it resembles honey in consistence, *Meliceris;* and when it is like a poultice or pap, it is called *Atheroma*. These however are mere artificial distinctions, and can seldom be satisfactorily applied. These tumours consist essentially of a serous or mucous bag varying in size, and the contents are of an exceedingly varying and sometimes anomalous character. Those which are commonly called wens, and which are usually situated immediately under the skin, are mostly enlargements of the sebaceous follicles which naturally exist in the skin. Sir Astley Cooper says that in wens a dark-coloured spot may be often seen on the skin in the centre of the tumour, and such spot, he says, is caused by the construction of the orifice of one of the sebaceous glands of the skin. Such also is the origin of many of the cysts of the mammæ, which consist of dilated lactiferous ducts. But this is not the origin of many of the larger forms of encysted tumours, as those of the ovary, &c. There are many forms of encysted tumour occurring in the internal viscera, in which the lining membrane is composed of serous tissue, as those of the liver, lungs, &c. Those tumours also called ganglions, which occur within the sheaths of tendons, have a serous lining, but ought not to be referred to under the character of wens.

The cysts of wens, especially those of the atheromatous kind, vary much in thickness. When situated on the head, back, and trunk, they are very dense; but when on the face, often very thin. Sometimes the cysts become hardened by the deposition of cartilaginous and even ossific matter. It is from this process that many of these cysts have a tendency to assume the hardness and even the form of horns. These horny formations are however the result of the ulceration of the cyst, and the horny matter is produced by the secretion from the walls of the cyst. These horns mostly grow on the forehead or some part of the scalp. They are generally small, but instances are on record of their being eight or nine inches long and two or three in circumference.

In ordinary cases the cyst has only one cavity, but it not unfrequently happens that there are partitions in it, dividing its interior into cells of different sizes. The contents of the cysts are, as before stated, frequently very anomalous. Some are filled with a thin, fetid brown fluid, mixed with flakes of the fibrinous parts of the blood; some contain serum; some a matter of gelatinous consistence; some a calcareous matter; some a black fluid; and others hair, teeth, and other organic substances. Those containing hair are mostly found in the neighbourhood of the eyebrows or eyelids.

On dissecting these tumours, some part of their surface is found firmly adhering to the skin, while other parts are connected with it by cellular membrane. The cyst is always more or less embedded in cellular membrane. In some cases these cysts are congenital and persons who have them are frequently troubled with a great number in various parts of their body.

In the treatment of wens two modes may be had recourse to; the one by puncture, the other by removal. When the cyst is small and presents a small black point on its centre, it may be opened and the contents pressed out, when it will sometimes get well. But it frequently happens when these tumours are punctured, that severe inflammatory action is the result, so that painful suppuration occurs, and life is put in danger, and sometimes a bleeding fungus has protruded itself through the aperture. The safest mode of treatment in the whole is to remove them with the knife, where their situation will permit of it. When this is done, the cyst may either be dissected out entire, or it may be cut into two halves, and each half may be dissected out separately. In both cases great care should be taken to remove the whole of the cyst.

WERST, or VERST, the Russian itinerary measure, being 3500 English feet, or nearly two-thirds of a mile. From the number of wersts subtract its third, and also one for every 250 wersts, and the result will be near enough to the answer in English miles.

WESTMINSTER ASSEMBLY OF DIVINES. One of five bills to which it was proposed by the Parliamentary Commissioners that the King (Charles I.) should give his consent in the negotiations at Oxford (from 30th January to 17th April, 1643) was entitled 'A Bill for calling an Assembly of learned and godly Divines and others to be consulted with by the Parliament for the settling of the government and liturgy of the Church of England, and for the vindication and clearing of the doctrine of the said church from false aspersions and interpretations.' This bill was afterwards converted into 'An Ordinance of the Lords and Commons in Parliament,' and passed 12th June, 1643.

The persons nominated in the ordinance to constitute the assembly consisted of a hundred and twenty-one clergymen, together with ten lords and twenty commoners as lay assessors. Among the commoners were John Selden, Francis Rouse, Sir Henry Vane, senior and junior, John Glynn (the recorder of London), John Whyte, Bulstrode Whitelock, Sergeant Wild, Oliver St. John, John Pym, and John Maynard. Among the most distinguished of the clerical members were, Dr. Ralph Brownrigge, bishop of Exeter; Mr. Anthony Burges (considered the head of the Puritans), Edmund Calamy, Dr. Francis Cheynel, Thomas Coleman, Thomas Gataker (the editor of 'Marcus Antoninus'), Dr. Thomas Goodwin, Dr. John Hacket (afterwards bishop of Lichfield), Dr. John Lightfoot, Dr. George Morley (afterwards bishop of Winchester), Dr. William Nicholson (afterwards bishop of Gloucester), Philip Nye, Dr. John Prideaux (bishop of Worcester), Dr. Edward Reynolds (afterwards bishop of Norwich), Dr. Robert Saunderson (afterwards bishop of Lincoln), Dr. James Usher (archbishop of Armagh), George Walker, Dr. Samuel Ward, and John Wallis (the mathematician). Several other persons (about twenty in all) were appointed by the Parliament from time to time to supply vacancies occasioned by death, secession, or otherwise, who were called superadded divines. Finally, two lay assessors, John Lord Maitland and Sir Archibald Johnson of Warriston, and four ministers, Alexander Henderson and George Gillespie of Edinburgh, Samuel Rutherford of St. Andrews, and Robert Baillie of Glasgow, were, on the 15th of September, 1643, admitted to seats and votes in the assembly by a warrant from the Parliament as commissioners from the Church of Scotland. They had been deputed by the General Assembly, to which body, and to the Scottish Convention of Estates, commissioners had been sent from the two houses of the English Parliament, and also from the Assembly of Divines, soliciting a union in the circumstances in which they were placed. This negotiation between the supreme civil and ecclesiastical authorities of the two countries gave rise to the Solemn League and Covenant, which was drawn up by Henderson, moderator (or president) of the General Assembly, and, having been adopted by a unanimous vote of that body on the 17th of August, was then forwarded to the English Parliament and the Assembly of Divines at Westminster for their consideration.

The meeting of the Assembly of Divines had been forbidden by the king in a proclamation dated the 22nd of June. The only effect however of that prohibition had been to induce the greater number of the members of episcopalian principles to refrain from attending. On Saturday, the 1st of July, the day named in the ordinance, sixty-nine clerical members assembled in Henry the Seventh's chapel, in Westminster Abbey. They appeared, it is recorded, not in their canonical habits, but mostly, after the fashion of foreign Protestant clergymen, in black coats and bands. At subsequent sittings the attendance appears to have ranged between sixty and eighty. About twenty-five of the persons who had been nominated members of the Assembly (including one or two who had died) never took their seats; and even of the sixty or seventy who attended pretty regularly, only from twelve to twenty were frequent speakers.

In theological doctrine the divines of the Westminster Assembly were almost to a man of one mind. They were all, or nearly all, Calvinistic or anti-Arminian. But upon the subject of church government they were divided into several violently hostile sections. Episcopacy, even of the most mitigated kind, could scarcely be said to have any representative in the synod as actually constituted; the great majority were Presbyterians; but there was a small party who passed under the name of Erastians; and there was a more numerous and also a more active body of Independents, or, as they called themselves, Congregationalists, who, formidable from the perseverance and ability of their leaders, were still more so from the ascendancy which their principles were fast acquiring in the Parliament, in the army, and throughout the nation. The chiefs of the Independent party in the Assembly were Dr. Thomas Goodwin, Philip Nye, Jeremiah Burroughs, William Bridge, and Sidrach Simpson, often spoken of as the Five Dissenting Brethren: their followers might amount to about as many more. The heads of the Erastian party were Selden, and the two divines, Lightfoot and Thomas Coleman; the only other steady members of the sect being the laymen Whitelock and St. John. In the Parliament however Erastianism was nearly as strong as Independency: indeed, however much the two systems might differ in the grounds on which they professed to stand, they came practically to very nearly the same thing, or at least were easily reconcileable; and some persons were probably to be classed as adherents of both.

This position of parties explains and makes intelligible the history of the proceedings of the Westminster Assembly, and the results of its deliberations. The ordinance of the Lords and Commons by which the Assembly was constituted only authorised the members, until further order should be taken by the two houses, "to confer and treat among themselves of such matters and things touching and concerning the Liturgy, discipline, and government of the Church of England, or the vindicating and clearing of the doctrine of the same," &c. as should be "proposed to them by both or either of the said houses of Parliament, and no other," and to deliver their opinions and advices to the said houses from time to time in such manner and sort as by the said houses should be required. They were not empowered to enact or settle anything. It was expressly provided that the Assembly should not assume to exercise any jurisdiction, power, or authority ecclesiastical whatsoever, or any other power except merely this right of delivering their opinion and advice upon the matters submitted to it. As its discussions proceeded, a discordance of principles and views upon various points between the ruling Presbyterian party in the Assembly and the growing Independent or Erastian majority in the Parliament became more and more evident; while the progress of events also tended to separate the two bodies more widely every day, and at last to place them almost in opposition and hostility to each other. The Assembly of Divines continued to sit under that name till the 22nd of February, 1649, having existed five years, six months, and twenty-two days, during which time it had met 1163 times. The Scottish commissioners had left above a year and a half before. Those of the members who remained in town were then changed by an ordinance of the Parliament into a committee for trying and examining ministers, and continued to hold meetings for this purpose every Thursday morning till Cromwell's dissolution of the Long Parliament, 25th of March, 1652, after which they never met again.

All the important work of the Assembly was performed in the first three or four years of its existence. On the 12th of October, 1643, the Parliament sent them an order directing that they should "forthwith confer and treat among themselves of such a discipline and government as may be most agreeable to God's holy word, and most apt to procure and preserve the peace of the church at home, and nearer agreement with the Church of Scotland and other Reformed churches abroad, to be settled in this church in stead and place of the present church government by archbishops, bishops, &c., which is resolved to be taken away; and touching and concerning the directory of worship or Liturgy hereafter to be in the church." This order produced the Assembly's Directory for Public Worship, which was submitted to parliament on the 20th of April, 1644; and their Confession of Faith, the first part of which was laid before Parliament in the beginning of October, 1646, and the remainder on the 26th of November in the same year. Their Shorter Catechism was presented to the House of Commons on the 5th of November, 1647; their Larger Catechism on the 15th of September, 1648. The other publications of the Assembly were only of temporary importance, such as admonitory addresses to the Parliament and the nation, letters to foreign churches, and some controversial tracts. What are called their Annotations on the Bible did not proceed from the Assembly at all, but from several members of the Assembly and other clergymen nominated by a committee of Parliament, to whom the business had been entrusted.

The Directory of Public Worship was approved of and ratified by the General Assembly of the Church of Scotland held at Edinburgh in February, 1645; the Confession of Faith, by that held in August, 1647; the Larger and Shorter Catechisms, by that held in July, 1648; and these formularies still continue to constitute the authorised standards of that establishment. The Directory of Public Worship was also ratified by both houses of the English Parliament on the 2nd of October, 1644; and so was the doctrinal part of the Confession of Faith, with some slight verbal alterations, in March, 1648. On the 13th of October, 1647, the House of Commons passed an order that the Presbyterian form of church government should be tried for a year; but it was never conclusively established in England by legislative authority; and even what was done by the parliament in partial confirmation of the proposals of the Westminster Assembly of Divines, having been done without the royal assent, was all regarded as of no validity at the Restoration, upon which event episcopacy resumed its authority without any act being passed to that effect.

It is remarkable that there is not in existence, as far as is known, any complete account of the proceedings of the Westminster Assembly of Divines, either printed or in manuscript. The official record is commonly supposed to have perished in the fire of London. Three volumes of notes by Dr. Thomas Goodwin are preserved in Dr. Williams's Library, London; and two volumes by George Gillespie in the Advocates' Library, Edinburgh. Baillie's Letters, however, contain very full details of what was done during the period of his attendance; and a Journal kept by Lightfoot has also been printed. Much information is to be found scattered in various works, such as Reid's 'Memoirs of the Westminster Divines;' Orme's 'Life of Owen;' and especially Neal's 'History of the Puritans.'

WESTPHALIA, TREATY OF. [TREATIES, CHRONOLOGICAL TABLE OF.]

WEY. [WEIGHTS AND MEASURES.]

WHALE FISHING. [FISHERIES.]

WHALEBONE is the horny laminated substance found in the mouth of the whale. It is not really whale-*bone*, but bears a nearer resemblance to horn in its structure: in commerce it is usually termed *whale-fin*. There are in the mouth of a whale two extensive rows, each consisting of upwards of 300 blades or plates; and each of these blades is a piece of whalebone. The blades are on an average about 10 feet long, but some attain a length of 15 feet. The substance is naturally of a bluish or brownish-black; but in some animals it is striped longitudinally with white. Three principal kinds are known in commerce—the Greenland whalebone, from the North Atlantic and Icy Seas; the South Sea, or black fish; and the North-West, from the North Pacific and Behring's Straits. [CETACEA, cols. 895-98, in NAT. HIST. DIV.] Sometimes as much as 5,000,000 lbs. have been imported in one year; but the supply is generally from 2,000,000 to 3,000,000 lbs. All the kinds of whalebone are nearly alike in constitution. It consists chiefly of albumen hardened by a small proportion of phosphate of lime. The surface of each blade is compact, and takes a high polish. The texture is lamellar or fibrous in the direction of its length, so that the substance easily splits and divides. The middle of each blade is of looser texture than the ends, presenting the appearance of coarse bristly hairs. When whalebone has been boiled, it takes a harder texture and deeper colour than before.

The peculiar structure of whalebone renders it applicable to many useful purposes. It is cut into quadrangular sticks for the ribs or stretchers of umbrellas and parasols, ranging in length from 20 to 40 inches. It is made into stay-bones, from $\frac{3}{8}$ths to $1\frac{1}{4}$ inch in width, and from 12 to 16 inches long. It is cut into lengths of what is called bristle-bone, of different thicknesses, for making brushes and brooms, chimney-sweeping machines, and road-sweeping machines. It is used in thin strips for covering whip-handles, walking-sticks, telescopes, and other articles. In thinner shavings it is plaited like straw into light hats and bonnets; while the waste shavings are employed by upholsterers as a stuffing for cushions, for filling fire-grates in summer, and for other purposes. Occasionally solid pieces of mixed tints are twisted into walking-sticks. And when all the useful fragments have been rendered available, the refuse sells as manure.

The nature of whalebone, something midway between horn and hair, points to the mode in which it is worked. It cannot be soldered or joined like tortoiseshell, but must be used in distinct pieces. When boiled in water for several hours, it becomes soft enough to be cut up into pieces of various sizes and shapes. Without being heated and softened, it is easily cut into strips and fibres by means of a compound guarded knife. The different qualities in different parts of each blade are closely examined by the workmen, in order to apply each part to the best use. Whalebone takes a very good jet-black dye, but is not well fitted for dyeing in bright colours. It is generally polished by being scraped with a steel edge or a piece of glass, rubbed with emery-paper, and finally rubbed with a woollen cloth dipped in tripoli powder; or by a polishing-wheel, as in the case of horn or tortoiseshell.

Common horn, if steeped for several days in a solution of gelatine, and then in a liquid containing several ingredients, acquires properties which enable it to be used for some purposes as a cheap substitute for whalebone.

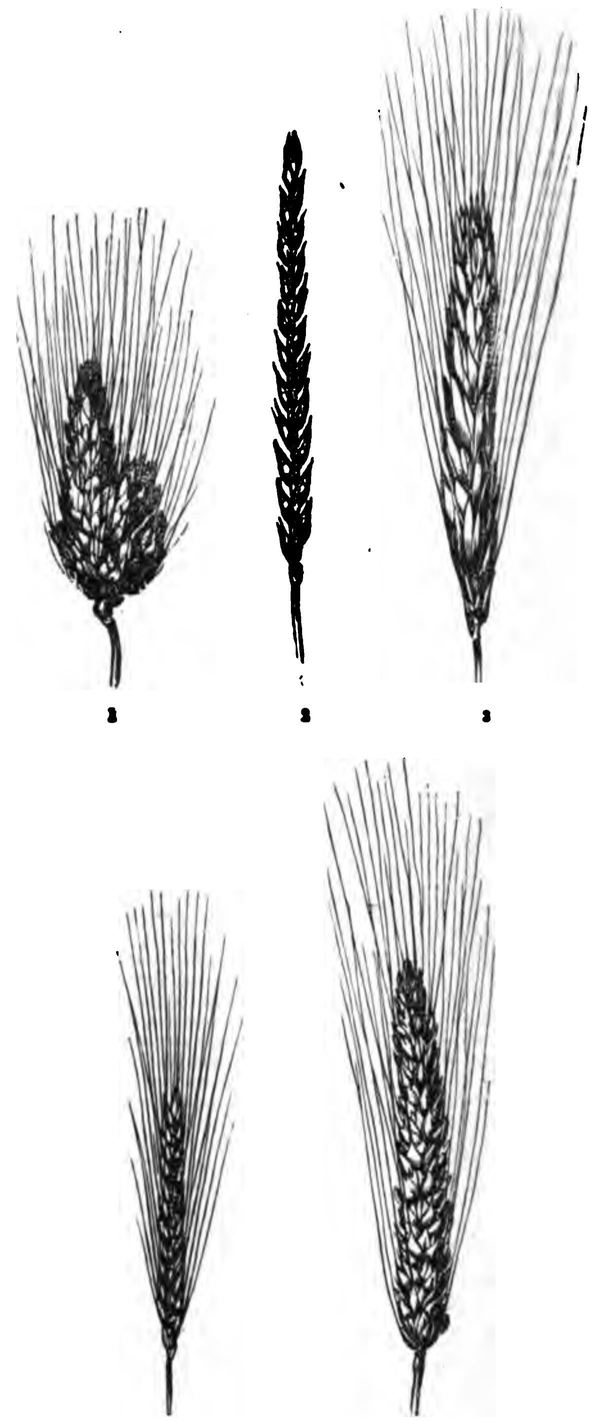
WHARF, a place constructed or set apart for the loading and unloading of goods. In this sense the word includes the quays of all sea-ports at which goods are required to be shipped or landed. The sea-beach, or natural ground on the banks of a river or canal, is not a wharf. Wharfs in docks and similar situations are made legal by special acts of parliament, as the London Docks, &c.; and there are some places which are deemed wharfs from immemorial usage, as at Chepstow. For the use of a wharf certain rates of compensation are usually charged, which are called *wharfage;* and the act 22 Car. II., c. 11, allows any one to load or unload goods on paying wharfage at the rates appointed. The wharfs of the port of London were established in 1558, in the first year of the reign of Queen Elizabeth. Several *sufferance wharfs* have been since added to these, under the authority of the Commissioners of Customs, and other sufferance wharfs are occasionally authorised for the landing and keeping of goods by the Custom-House till the duties are paid or the goods bonded.

No goods except diamonds and bullion, fresh fish of British taking, and turbots and lobsters fresh, however taken or imported, are allowed to be unshipped from any ship arriving from foreign parts beyond seas, or landed or put on shore, except at legal quays appointed by her Majesty for landing of goods, or at some wharf appointed by the Commissioners of Customs. Goods entitled to drawback or bounty are only to be shipped in Great Britain by wharfingers appointed by the Commissioners of Customs.

WHEAT. The botanical characters of wheat will be found under the word TRITICUM, in NAT. HIST. DIV. Some botanists have divided wheats into different species, from some marked peculiarity in their formation. Others, considering that they mostly form hybrids when mixed in the sowing, and that their peculiarities vary with the soil and climate, have looked upon all the cultivated wheats as mere varieties. There are, however, three principal varieties, so different in appearance that they claim peculiar attention. These are the hard wheats, the soft wheats, and the Polish wheats. The hard wheats are the produce of warm climates, such as Italy, Sicily, and Barbary. The soft wheats grow in the northern parts of Europe, as in Belgium, England, Denmark, and Sweden. The Polish wheats grow in the country from which they derive their name, and are also hard wheats. It is from their external form that they are distinguished from other wheats. The hard wheats have a compact seed nearly transparent, which, when bitten through, breaks short, and shows a very white flour within. The soft wheats are those usually cultivated in Britain: they have an opaque coat or skin, which, when first reaped, gives way readily to the pressure of the finger and thumb. These wheats require to be well dried and hardened before they can be conveniently ground into flour. The Polish wheat has a long chaff which is much longer than the seed, a large oblong hard seed, and an ear cylindrical in appearance. It is a delicate spring wheat, and not very productive in the climate of England: hence it has only been occasionally cultivated by way of experiment.

The following cuts represent some peculiar varieties of wheat. The first is a compound ear, common in Egypt. The second is the spelter wheat, of which the chaff is so strongly attached to the grain as to be separated only by passing through a mill. It is an inferior variety, but grows in less fertile soils. The third is the Polish wheat, with very long chaff and hard grains. The fourth is a variety which only ripens one seed in each spikelet, and is not much cultivated. The fifth is common soft bearded wheat. If the awns of this kind are obliterated, it forms our common soft wheat. The circumstance of awns seems not to affect the nature of the wheat, and they differ so much in length that the varieties of smooth-eared and bearded wheats run insensibly into each other.

The distinction between the winter and summer wheats is one which arises entirely from the season in which they have been usually sown; for they can readily be converted into each other by sowing earlier or later, and gradually accelerating or retarding their growths. The original difference in colour between red and white wheats is owing chiefly to the soil: white wheats gradually become darker and ultimately red in some stiff wet soils, and the red wheats lose their colour and become first yellow and then white on rich, light, and mellow soils. It is remarkable that the grain sooner changes colour than the chaff and straw. Hence we have red wheats with white chaff, and white wheats with red chaff, which on the foregoing principle is readily accounted for. The chaff retains the original colour when the skin of the grain has already changed to another. We state this on our own experience. The soil best adapted to the growth of wheat is a deep loam inclined to clay, with a dry subsoil. If this is not dry naturally, it must be drained artificially, to ensure good crops of wheat. In such a soil wheat may be sown every third year, with proper intermediate crops. Formerly the preparation for a wheat crop was generally by a clean naked fallow, with a certain addition of manure, the remains of which were thought sufficient for a crop of barley or oats, after which the fallow recurred. It was soon found out that by this means a crop



1. Egyptian Wheat (Triticum Egyptiacum); 2, Spelter Wheat (Triticum Spelta); 3, Long-chaffed Polish Wheat (Triticum Polonicum); 4, Single-grained Wheat (Triticum monococcum); 5, Common Bearded Wheat (Triticum turgidum).

of wheat could never be forced beyond a certain average; for if more than the usual portion of manure was carried on the land the wheat failed, by being laid before it arrived at maturity. Thus a limit appeared to have been set to its increase. New modes of cultivation have shown that this was not without its remedy, and that it was recent manuring which caused the wheat to lodge: but that an increased fertility, produced by judicious preparation, enabled the land to bear crops of wheat far superior to what it ever could before. Wheat requires a soil in which the organic matter is intimately mixed with the earthy ingredients; where it can have a firm hold by its roots, and can at the same time strike the fibres of them downwards, as well as around, in search of food. When it meets with such a soil and is deposited at a proper depth, it vegetates slowly, pushing to the surface one cylindrical filament, while numerous fibres strike into the soil from the seed. These supply the plant with regular nourishment, and in due time a knot is formed at the surface of the soil, from which several roots and stems branch out. This is called the tillering of the wheat. The new roots near the surface soon become the chief source of nourishment, and in a rich compact soil, where there is room, numerous stems arise, forming a tuft, and each of these in time bears a large ear well filled with seeds; so that from a very moderate quantity of seed a great return is produced. The strong stems supporting each other are well able to resist the effect of storms and rains, which would lay weaker plants level with the ground. The effect of surface manuring immediately before the seed is sown is to produce too rapid a growth, weakening the straw, and increasing its quantity often at the expense of the ear, which does not attain its proper development. This is called running to straw. Ammoniacal and nitrogenous manures have this effect; which is corroborated by late experiments with sulphate of ammonia, saltpetre, and nitrate of soda.

Lime has been often considered as the most efficacious manure for wheat, even more than dung. As long as there is organic matter in the soil, lime acts beneficially, and the richer the land, which does not contain carbonate of lime already, the more powerful the effect of liming. But experience has proved that lime has little effect on poor soils, until they are first manured with animal and vegetable substances. To produce good wheat then, the land should be gradually brought to the proper degree of fertility, by abundant manuring for preparatory crops, which will not suffer from an over-dose of dung, and will leave in the soil a sufficient quantity of humus, intimately blended with it, for a crop of wheat. Clover is a plant which will bear a considerable forcing, and so are beans, and both are an excellent preparation for wheat. The roots left in the ground from a good crop of either, decay slowly, and thus furnish a regular supply of food for the wheat sown in the next season. Potatoes also admit of much forcing, but the necessary loosening of the soil for this crop renders it less fit as a preparation for wheat. Experience has fully proved that, as a general rule, it is better to sow barley and clover after potatoes, and let them be succeeded by wheat.

Although wheat thrives best on heavy soils, and without due preparation produces only scanty and uncertain crops in those which are naturally light and loose, it may be made to give a very good return in soils which would once have been thought fitted only for the growth of rye and oats. But then the texture and composition of these soils must have been greatly improved by judicious tillage and manuring. While the heavy soils are repeatedly ploughed and pulverised to render them mellow, the lighter are rendered more compact by marling, where this can be readily done, by adding composts in which the principal earth is clay, and especially by such plants as have substantial and long roots, by which the soil is kept together, such as clover, lucern, sainfoin, and other grasses. If these plants have been well manured, and cover the ground well, keeping in the moisture, the soil will have become sufficiently compact to bear wheat. One ploughing is then quite sufficient, and if a heavy land-presser is made to follow two ploughs and press in the furrows, so as to leave deep smooth drills eight or nine inches apart, in which seed can find a solid bed, there will be every probability of a good crop, of wheat, which will come up in regular rows, the roots being at such a depth as to run no risk of wanting moisture till the stem has arisen to its full height, and the ear is formed: a few showers at that critical time will make the grain swell, and insure a good crop.

On some soils it may not be judicious to attempt to sow wheat; but these are the poorest loose sands, which naturally would bear only oats and buckwheat; on these, unless they can be abundantly marled, it is much better to sow rye. When wheat is sown on light soils in good heart, it grows vigorously in spring, if it has not been injured by the frost, which is very apt to raise up the roots and throw them out of the ground. The driving of sheep over the field presses the roots into the ground, and prevents this throwing out; but a vigorous growth of straw is not always a sure sign of a good crop at harvest, as many farmers know by sad experience: what would be advisable in heavy soils is not always so in lighter. A heavy rolling in spring after a light harrowing is very useful at a time when the surface is moist. It closes the pores and checks the evaporation: and the tighter the surface can be made the better the chance there is of a fair crop. The Norfolk rotation, as it is generally called, in which wheat is sown after clover, is the only one well adapted for wheat on light soils. The manure having been put abundantly for the turnips, and the land being freed from weeds, the barley which follows is generally a good crop; the clover, which is sown in this, is trodden in the reaping and carrying of the barley: and there is only one ploughing from the time the barley is sown to the sowing of the wheat. If this be dibbled on the turned sward of the clover, the land will receive another treading by the dibblers, the seed will be regularly deposited at a proper depth, and no preparation of light land can be more likely to produce good wheat. On heavy soils the process must be varied; the surface, instead of being rendered more compact, will often be so bound as to require to be stirred by harrowing or hoeing before the wheat plant can properly tiller. If a farmer is anxious to have good crops of wheat, he must not rest satisfied after he has ploughed, manured, and sown: he must watch the growth of this important crop daily, and use the means which experience and observation have suggested to assist the growth and to remove the causes of failure.

In either case it is of importance to sow the proper quantity of seed per acre in rows far enough apart. One bushel per acre is enough on well-cultivated soils—two bushels are not too much where there is liability to loss by water, wireworm, and weather. If sown by drill from 10 to 12 inches is a proper interval between the rows.

In heavy soils nothing is more detrimental than excess of moisture. Even in well-drained fields the water will stand too long in the furrows if there is not a proper outlet for it. The furrows should be well cleared out with the spade as soon as the seed is sown, drilled, or dibbled, the earth being thrown evenly over the surface of the stitches, and not left in an unsightly ridge, which crumbles down with the furrow at the first frost. In proper places and at regular distances deeper water furrows should be dug out after the plough has ploughed a deep furrow in the intended line; and this should then be finished as is said above: so that if a heavy fall of rain should come suddenly, the water would have a regular course and outlet into the ditches which lie in the lowest part of the land, without soaking into the soil, which is already too retentive of moisture. It is chiefly in spring and when snow melts that there should be a daily inspection of the wheat-field. An experienced eye going along the bottom of the ridges of a large field will discover at once whether there is any stoppage of the water; and by means of a spade or shovel it will be remedied with little trouble. When the surface binds, as it does in some soils, and prevents the access of air to the roots, the land is harrowed or hoed, and in a few days the effect will be apparent.

It is a very common notion that good wheat and bean land is not well adapted to the growth of roots, especially of such as are usually fed off the land by sheep, because the treading of animals is injurious in winter and spring, when these crops are usually wanted; and if they are carted off, the wheels and the horses make such impressions as are equally detrimental or more so. But all roots, even the white turnip, will grow luxuriantly on heavy soils well prepared and manured; and they may be so managed as to be taken off before the winter. The land being ploughed immediately on the removal of the roots, will be well prepared for wheat, or, when mellowed by the winter's frost, may be sown in spring with beans, barley, or oats. The manure will be incorporated with the soil, even if it has been put on in a very fresh state for the roots, which can only be recommended on very compact soils. If the root crops are well cleaned, fallows may be avoided, or at least recur very seldom, and then only when root weeds have accumulated from neglect.

When the wheat has blossomed, and the grain in the ear is fully formed, it should be watched, and as soon as the seed feels of the consistence of tough dough, and the straw is dry and yellow below the ear, it should be reaped. The skin of the grain will be thinner, and its substance will harden readily by mere drying, while the straw is better fodder for the cattle. It is found by experience that the increase of flour by adopting this method is very considerable. The operation of reaping is now best done by the reaping machine.

The choosing of wheat for seed is a matter of great importance. Some farmers like to change their seed often; others sow the produce of their own land continually, and both seem persuaded that their method is the best. The fact is, that it is not always the finest wheat which makes the best seed; but it depends on the nature of the land on which it grew. Some soils are renowned far and wide for producing good seed, and it is well known that this seed degenerates in other soils, so that the original soil is resorted to for fresh seed.

While the wheat is growing it is exposed to various accidents, which it is often difficult to foresee, and more difficult to guard against. The smut and burnt-ear are diseases which may be generally prevented by a proper preparation of the seed before it is sown. Many corrosive substances have been recommended to steep the seed in, such as blue vitriol, one pound to a quarter of a grain, dissolved in water enough to wet every seed. It seems, however, that washing the seed well with plain water, or with salt and water, and afterwards drying it with quick-lime, sufficiently destroys the germ of the smut to prevent its propagation. The most common steep is water in which so much salt has been dissolved as will enable it to float an egg. In this the seed may be left for twelve hours or more, and then spread on a floor and mixed with as much quicklime as will absorb the moisture, and allow it to be sown or drilled, without the grains adhering to one another.

In the second volume of the 'Journal of the Royal Society of Agriculture of England,' Part I., is a valuable paper, by the Rev. T. S. Henslow, on the diseases of wheat. He describes the different *fungi* which produce the various diseases of pepper-brand, dust-brand, rust, and mildew. The ergot in wheat is an excrescence from the ear, like a small horn, into which the seed is transformed. It has a poisonous quality and a medicinal one. The cause of this monstrosity in the seed is not fully known. It is supposed to be caused by the puncture of some insect, introducing a virus which has entirely altered the functions of the germ, and made it produce this ergot, instead of a healthy seed. Another disease of the seed is called ear-cockles, and is caused by extremely minute insects like eels, which fill the skin of the seeds, instead of flour. This insect, which is called *Vibrio tritici*, is described by Mr. Bauer in the 'Philosophical Transactions' for 1823. This disease is not so common as the smut and the pepper-brand. It is probable, according to Mr. Henslow, that the animalcula may be killed by exposing the grain to a certain heat, so as not to destroy its power of vegetation, but sufficient to kill the vibrio. The wheat-midge (*Cecidomyia tritici*) is another external enemy, which does more harm to the crop than is generally known. It deposits its eggs at the root of the germ in the ear, and prevents the filling of the grain, the maggot living on the nutritive juices which should produce the farina. The Hessian fly, which caused such depredations in America and Canada at one time, is a different species of the same fly. This deposits its eggs in the straw near the root, and thus destroys the whole plant. We must refer the reader for further particulars to the paper above mentioned.

Great attention has been lately paid to the introduction of the best and most prolific varieties of wheat, and by merely observing what ears appear much superior to others in a field of ripe wheat, and collecting these to be sown separately in a garden or portion of a field, the variety, which may have been produced by some fortuitous impregnation, or some peculiarity in the spot where it grew, is perpetuated. By carefully selecting the seed which is best adapted to the soil, by a more careful and garden-like cultivation, and by adding those manures which are found most adapted to favour its perfect vegetation, crops of wheat have been raised, which, at one time, would have been thought marvellous; and the average produce of this important grain has been increased on all soils.

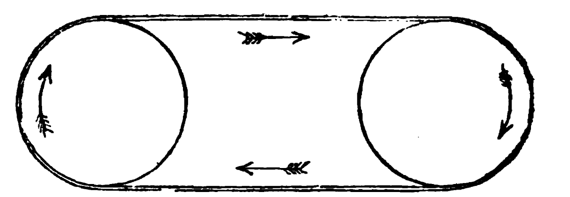
WHEEL. A mechanical contrivance, by means of which the intermittent and limited action of the lever is extended to any distance, and made to act continuously and uniformly. The direction and the velocity of movement of a machine are commonly regulated by the disposition and character of the wheelwork which enters into its composition; but the principle upon which all wheels really act, consists in the application, in a continuous manner, and in a circular direction, of the power obtained by leverage.

Wheels are either of the kind known as *carriage* wheels, or *friction* wheels, or *teethed* wheels; including under the second division *band* wheels, and under the third the various kinds of *cog*, *trundle*, *spur*, *crown*, and *bevilled* wheels. In a system of wheelwork the wheels may be either *multiplying* or *diminishing*, according to their relative sizes; they may either perform complete revolutions, or, as in the case of *balance* wheels, only revolve over small arcs; they may revolve either horizontally or vertically; they may be used to produce motion or to communicate it; or, finally, they may be used for the purpose of regulating the velocity of the machinery to which they are annexed, as in the case of *fly* wheels. Water-wheels constitute a separate class of machinery, known under the same generic name of wheels, in which the power is produced by the direct action upon the wheel itself. [WATER-WHEELS.] In ordinary wheels the power is applied originally to the shaft bearing them, by the intervention of cranks, handles, winches, or levers.

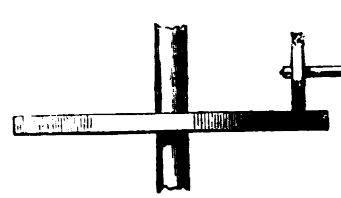
In carriage wheels the object sought to be attained is to convert a sliding friction into a rolling one, in order to facilitate the horizontal movement of heavy loads. The efficiency of a carriage wheel, therefore, consists in the length of the lever it offers (or, in other words, upon its diameter); upon the direction in which the power is applied to it; and upon the small extent of surface producing friction; always provided that the surface should be sufficient to prevent the load from forcing the wheels into the materials over which they run. It is for the avowed object of insuring the application of the power exercised by a horse, in drawing a cart or carriage, *above* the horizontal line passing through the centre of the fore wheels, that they are made smaller than the hind wheels; but, as an abstract proposition, it may be stated that the larger a wheel is, the greater is the useful effect it produces, provided the line of draught pass horizontally through its centre. Another abstract proposition with respect to carriage wheels is, that the narrower their surfaces, the less friction they must develope; but evidently the character of the roadway over which the load travels must re-act upon this condition, for upon a soft surface a narrow wheel, heavily laden, would compress the road materials, and thus create a continually occurring series of obstacles to its own progress. Upon soft roadways, under heavy loads, carriage wheels must therefore be made wide upon the face of the felloes; for quick traffic, on hard roads, when the carriages do not convey heavy loads, narrow wheels are generally resorted to.

In the earliest wheeled carriages, the wheels were made of solid planks, and the axles were fastened to them, so that wheel and axle turned together; the load in such cases being borne upon collars worked upon the axles. Rude carts of this description have been used in England within a very short period, and they may still be seen upon the provincial roads of such countries as Spain or southern Italy. When the roads are habitually of a superior character, however, carriage wheels are made as lightly as the work they are required to perform will admit of; and they consist usually of a *nave*, or centre boss, into which the *spokes* or radiating arms are fastened at one end, whilst the spokes at their other ends bear the *felloes*; the whole assemblage being bound together by an iron *tire*, nailed to the felloes whilst it is hot, in order that the shrinkage of the iron in cooling may "force the various joints home," as workmen say. The nave is usually bored out to receive a *box* of iron (or of gun metal in some cases), in which the collar of the axle is inserted, so that the wheels on the respective sides of the carriage can revolve independently of one another in their horizontal positions, but are maintained at fixed distances apart horizontally. In wheeled carriages the bodies are attached to the axles, either with, or without, the intervention of springs; in four-wheeled carriages the front pair of wheels is usually made to revolve on a pivot fixed under the fore part of the body. Of course the dimensions of all the details of carriage wheels must depend upon the weights they are intended to transport, and upon the velocity at which they are intended to travel; in railway carriages the naves, spokes, felloes, and tires of the wheels are executed of iron, or of steel; in common carriages, wood is the material principally used.

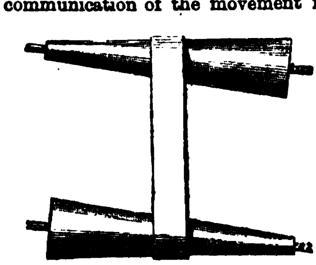
The friction wheels of mill-work are introduced for the same purpose that wheels are adapted to ordinary carriages; that is to say, for the purpose of converting sliding friction into rolling friction. They are used to facilitate the horizontal or vertical movement of traversing beds, of guide rods, &c., and therefore the only conditions they are required to fulfil are, that they should revolve freely on their own axles, and present smooth surfaces (able to retain a lubricating fluid) to the bodies moving over them, or over which they may move. Driving band-wheels, on the contrary, are fixed on their bearing shafts, and have their surfaces formed in such a manner as to cause the straps, or bands, to adhere to them by their mere friction upon the asperities, and thus to produce motion in the secondary band-wheels of the machinery to which they are applied, by the rotation of the first wheels. In some cases also, motion is communicated by means of



wheels whose surfaces are in contact, and which act upon one another by the mere unevenness of those surfaces; if, however, any serious resistance should be encountered, the wheels would be likely to slide over one another, and they are therefore only used in light and delicate

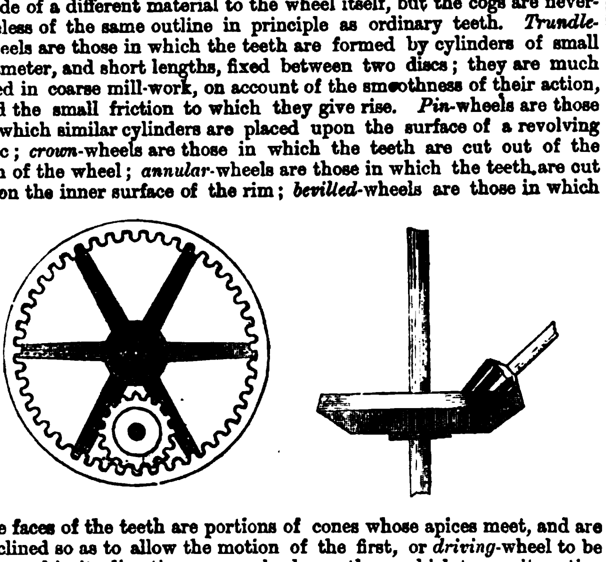


machinery. Indeed all descriptions of band-wheels are exposed to the same objection, because they only communicate motion by the friction of the bands upon the respective surfaces, and when the resistance exceeds that friction, the bands must slide over the wheels; but they present so many facilities for the introduction of *speed* pulleys, (that is to say, of pulleys by means of which the rate of revolution may be modified at will) that they are constantly resorted to in machinery, especially when it is desirable to avoid making a noise. Band-wheels are commonly arranged so as to present on the same axle, and in immediate proximity to one another, what are called *fast* and *loose* pulleys; the fast pulleys being fixed upon the axle, so that the two must turn together, whilst the loose pulley turns freely upon the axle, and does not communicate any motion to the latter. When, therefore, it is desired to put band-wheels with fast and loose pulleys out of gear, all that is required to be done is to pass the band upon the loose pulley, and the communication of the movement immediately ceases



Band-wheels also present great advantages from the ease with which they admit of the change in the direction of the motion. If, for instance, it be desired to reverse the motion, the band is simply crossed, and endless bands may be made to communicate motion in every possible direction with respect to the driving pulley. Long bands are, however, objectionable, as they have a tendency to stretch; and it must also be observed that the circumferences of band-wheels should be made slightly rounded, because there is a tendency in bands running over pulleys to work towards the portions of those pulleys which are of the largest diameter; and thus, perhaps, to "cast off." The friction cones, used by rope-spinners, may be cited as amongst the most valuable illustrations of the use of these modifications of wheel-work; as may also be cited the speed pulleys of lathes, the carrying-bands of printing machinery, the friction-rollers upon which the endless sieves of paper-making machines traverse, &c.

In *teethed* wheels, a series of projections, or *teeth*, are formed on the outer rim of one wheel, which work into corresponding projections upon the outer rim of the wheel connected with it, in such a manner as to allow the teeth of the former to communicate their motion by the sliding or rubbing of their surfaces upon the surfaces of the teeth of the second wheel. *Cog*-wheels are those in which the teeth are made of a different material to the wheel itself, but the cogs are nevertheless of the same outline in principle as ordinary teeth. *Trundle*-wheels are those in which the teeth are formed by cylinders of small diameter, and short lengths, fixed between two discs; they are much used in coarse mill-work, on account of the smoothness of their action, and the small friction to which they give rise. *Pin*-wheels are those in which similar cylinders are placed upon the surface of a revolving disc; *crown*-wheels are those in which the teeth are cut out of the rim of the wheel; *annular*-wheels are those in which the teeth are cut upon the inner surface of the rim; *bevilled*-wheels are those in which



the faces of the teeth are portions of cones whose apices meet, and are inclined so as to allow the motion of the first, or *driving*-wheel to be changed in its direction; *spur*-wheels are those which transmit motion in directions parallel to that of the revolution of the driving-wheel. The first wheel in all these instances bears the name of the *first motion* or *driving*-wheel; the secondary wheel is called the *follower*, or the *pinion* in the case of cog-wheels, but sometimes it is called the *wallower*, in the case of trundle-wheels. The wheels themselves are composed of the central boss, the arms, and the rim, bearing the teeth; sometimes, however, in small pinions the arms are replaced by a solid plate, and then they are known by the name of *plate*-wheels; the inner rim of a first motion annular-wheel is known by the name of the *annulus*. When it is essential that no sliding should take place on the surfaces of wheels the faces are broken into what are called *compound* or *combined* wheels, which consist of a series of parallel concentric ranges of teeth, so placed that the contact of any pair of teeth should only be momentary. Dr. Hooke introduced this kind of wheel, and indeed it is at times known by his name; but it is too complicated, and too liable to fracture, for ordinary work.

In setting out a wheel, the basis of the operation is the *pitch circle*, or the working circumference; the term *pitch* itself means the distance apart of the centres of the teeth upon that circle. The only condition which regulates the pitch is, that the material should be strong enough to bear the effort to which it is to be exposed; and in practice it is found that cast-iron wheels work satisfactorily with pitches varying between 1 and 3 inches in large wheels, and between a quarter of an inch and three quarters of an inch in very small ones. The number of teeth depends upon the circumference, and upon the pitch; or calling the number of teeth n, the circumference c, and the pitch p; then $n=\frac{c}{p}$, all the dimensions being in inches; or the diameter d will be found by making $d=\frac{p\,n}{3 \cdot 1416}$. The velocities at which the various wheels of a piece of machinery are required to revolve determines their respective diameters, and they are calculated upon the principles to be described in the sequel; but it is to be observed that the *true* radii are always rather larger than the *primitive* radii, which latter serve to define the pitch circle; the true radii, on the contrary, define the extremities of the teeth. Another general law is that the number of teeth in the *spur*- (or driving-) wheel is to the number of teeth in the *pinion* (or follower) in the ratio of their respective radii; or calling the diameter of the spur-wheel A B; the diameter of the pinion C D; and the number of teeth on the former N; then the number of teeth on the pinion will be found thus:—A B : C D :: N : n. The outlines of the teeth are ascertained by dividing the pitch circle into equal parts corresponding with the proposed number of teeth; the pitch is then subdivided into four parts, to obtain the centres of the intervals, and also the flanks of the teeth within the line of the pitch circle. Beyond that line the flanks of the spur teeth are formed by portions of an epicycloid generated by the revolution of a circle, whose diameter is equal to the radius of the pinion pitch circle around the pitch circle of the spur; and the flanks of the extremity of the teeth of the pinion are formed by portions of a hypocycloid generated by the revolution of the circle before named on the interior of the pitch circle of the pinion itself. The projection of the teeth beyond their respective pitch circles is regulated by the condition that the epicycloidal and hypocycloidal curves shall be sufficiently long to cause the latter to bear upon the side of the teeth, through an extent of circumferential movement equal to the length of the pitch. Practically this length may be found by describing a circle of a diameter equal to the radius of the pinion upon the line of centres, and at the point where it intersects the radial line forming the flank of the second tooth, describing the true radius of the spur. The depth of the intervals is made so as to leave a small space between the extremity of the teeth and the rim, and it is customary to leave a little play between the teeth, equal to about $\frac{1}{15}$th or $\frac{1}{20}$th of the pitch; the interior angles of the teeth are rounded off in order to increase their strength. In setting out a pinion intended to drive a lantern-wheel, the teeth must still be made portions of epicycloids; but in the case of racks driven by teethed pinions the curves must be involutes of the pitch circle, and in annular wheels the teeth of the annulus must be portions of a hypocycloid. The portion of the tooth beyond the pitch circle, to which the above peculiar forms are given, is occasionally known by the name of the *addendum*, and it is usually about $\frac{3}{10}$ths of the pitch employed. In common construction the proportions of the various parts of a pair of teethed wheels gearing into one another are as follows:—

Depth of addendum	$\frac{3}{10}$	of pitch.
Working depth, from addendum to flank . .	$\frac{6}{10}$	"
Whole depth	$\frac{7}{10}$	"
Thickness of tooth on pitch line	$\frac{5}{11}$	"
Breadth of space on ditto	$\frac{6}{11}$	"

In small wheels with few teeth the depth of the addendum must be increased above the proportion above-mentioned.

Bevilled gearing consists of frustra of cones, which are supposed to roll upon one another, and whose apices are supposed to meet in one point; and in this case the form of the addenda ought to be a portion of a spherical epicycloid, according to strict theory, but in practice a much more simple form, devised by Telford, and described in Buchanan's 'Treatise on Mill-work,' p. 58 (1841), is used. Indeed, it is very rarely that the faces of wheels are made with cycloidal forms of any description; and practical men adopt, instead of them, simpler circular forms. Professor Willis, in his 'Principles of Mechanism,' has described an instrument of his own invention, for drawing the teeth of wheels by arcs of circles; and has accompanied the description by tables illustrating its use. The reader is referred to the various books above mentioned, and to Warr's 'Construction of Machinery,' Camus 'On the Teeth of Wheels,' Hachette's 'Traité des Machines,' Armengaud's 'Dessin Industriel,' and W. Johnston's 'Practical Mechanic,' for more specific details with respect to the principles upon which teethed wheels of the various kinds enumerated are designed. Professor Willis's 'Principles of Mechanism' may, perhaps, be cited as containing the most valuable information on the subject.

It is necessary here to add that in some cases it is desirable to produce in machinery an intermittence in its action, or a certain alternation of motion and of rest, in the wheels gearing into one another. This is effected by leaving a portion of the circumference of the driving-wheel without teeth for a length corresponding with the desired period of repose; precautions, however, must be taken to insure that the teeth should fall into their proper places when contact is restored, for which purpose pins and guides on the face of the wheel are commonly introduced. *Ratchet*-wheels, or those which only revolve in one direction, and have a species of alternate reciprocating action on the driver (in this sense, that they are raised gradually for a certain portion of the revolution, and are then suddenly released), are introduced for the purposes either of preventing the wheel-work from revolving in more than in the direction originally selected, or for obtaining alternate vertical or horizontal motion in the shafts of a piece of machinery. The pin which prevents the alteration of the rotation of a ratchet-wheel, is usually placed on a pivot, and is able to be thrown out of gear at will: it is commonly known by the name of a *paull*. Mill work of all kinds may either be kept permanently in gear, or it may be constructed so as to allow any of its parts to work, or to rest, independently of the general combination, by means of couplings, clutch-boxes, friction, or reversing-gear. In the construction of machinery, wheels play very important parts by the action of drivers upon the various combinations for producing change of motion, such as racks, endless screws, cams, eccentrics, teethed arcs, &c.; but the consideration of these functions of wheels, as also of those by which they are made to regulate the motion of the machinery to which they are attached, by reason of their power of retaining momentum, belongs especially to the province of applied mechanics. Before closing this article, however, it is essential to allude cursorily to some of the mechanical conditions involved in the application of wheels.

The simplest manner in which those contrivances for the transmission of power are used, is the one known by the term of the wheel and axle. [WHEEL-AND-AXLE.] In the *windlass* the power is applied to the axle by means of a cranked lever revolving in a circular path, instead of by a wheel; but the principle of the action of this form of lever is precisely the same as that of the wheel, with only the difference that the moments of inertia of the moving machinery are slightly changed. [WINDLASS.] In *tread-wheels* the power is obtained by causing the men or animals who act upon the machinery to exercise their effect, by the application of their weight, upon the periphery of the wheel. When equable motion is required to be produced by a wheel animated by a variable power, it is obtained by the interposition of a cone, or of some such contrivance for increasing the leverage of the power in proportion as the power itself diminishes; as, for instance, in the spiral springs and fusees of watch-work.

The power of a combination of two cog-wheels is ascertained by multiplying the distance at which the power is applied from the centre of the first wheel, by the radius of the second wheel; and dividing that sum by the sum of the distance at which the resistance acts from the centre of the second wheel, multiplied by the radius of the first: the quotient will represent the ratio of the power to the resistance it is able to overcome. In a combination of any number of teethed wheels the power of the system may be ascertained by taking the radii of the wheels as the even terms of a series, and the distances at which the power and resistance act from the centres of their respective wheels as the odd terms (or the intermediate ones) of the series; then the product of the odd terms, divided by the product of the even terms, will represent the ratio of the power to the resistance. The even terms will in this case represent the flyers or *drivers*, and the odd ones the *followers*, and the product of the former will give the velocity of the power, whilst that of the latter will give the velocity of the weight or resistance.

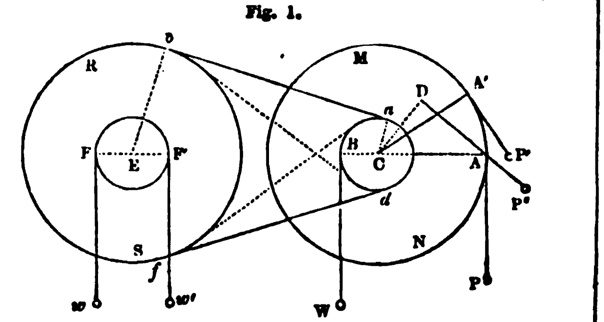
Very good practical rules, and examples for their application, of the relations of the various parts of a system of wheel-work are to be found in the Memorandum-book of Mr. Telford, inserted in his 'Biography,' and reprinted in the 'Engineer's Pocket Book;' but none of these easy practical solutions of the mechanical problems involved in this branch of applied mechanics, can dispense the engineer from the study of their principles. These are discussed at considerable length in such works as those previously mentioned, and in Moseley's 'Mechanics applied to the Arts;' his work on 'Engineering and Architecture;' in Warr's 'Dynamics;' Weisbach's 'Mechanics of Machinery;' Borgnis, 'Traité complet de Mécanique appliquée aux Arts;' Dupin's 'Géometrie et Mécanique des Arts;' Lanz et Bétancourt, 'Essai sur la Composition des Machines,' &c.; and to them the student is earnestly referred.

WHEEL-AND-AXLE, is a machine consisting usually of a cylinder to which a wheel is firmly united, so that the mathematical axes of both are coincident. The wheel and cylinder are of wood or metal, and the diameter of the former is greater than that of the latter.

A cylinder on the circumference of which are fixed exteriorly boards whose planes, if produced, would pass through the axis, and which (being turned by the force of running water, or by the weight of men in the act of stepping from one board to the next above it) is employed to raise a heavy body by means of a rope passing over a smaller cylinder on the same axis, as in the treadmill, is a simple machine of this kind: the same may be said of a hollow cylinder which, with its axle, is made to revolve by men or animals walking in the direction of its circumference, in its interior surface. The capstan, the windlass, and the helm-wheel of a ship are only so many different forms of the same class of machines. Frequently also the axle is made to carry a wheel with teeth on its circumference, in order that, by revolving, motion may be communicated to machinery: such are the wind and water mills which are employed for grinding corn.

When it is required to exhibit the mechanical properties of the

Fig. 1.



wheel-and-axle, a weight representing the moving power is applied at one extremity of a string which at the other extremity is attached to and passes round the circumference of the wheel; and a weight, representing the resistance to be overcome, is applied in like manner at one end of a string which passes round the axle or cylinder. Let MN (in *fig.* 1) be a section passing through the wheel and cylinder perpendicularly to their common axis, and let CA, or CA′, and CB be the semi-diameters of the circles in that section: let P represent the moving power and W a weight to be raised, or held in equilibrio; AP or A′P′, and BW, being the directions of the strings to which those weights are attached; and for simplicity, let these lines be in one plane and coincident with tangents to the circles at A, or A′, and at B. Here it is evident that the mechanical power of the wheel-and-axle is the same as that of a lever of the first kind; for (the thickness of the ropes and the weight and inertia of the materials being disregarded) the forces P and W acting perpendicularly to the arms CA and CB, the effect is the same as if those forces were applied immediately at the extremities of the straight line AB, or of the bent line A′CB, and C being the fulcrum or point of support, we have, by the nature of the lever, in the case of equilibrium,

$$P : W :: BC : AC\ (=A'C), \text{ or } P = W \cdot \frac{BC}{AC}.$$

The wheel-and-axle has manifestly however a great advantage over the simple lever, since the weight W may be raised to any height which is consistent with the lengths of the ropes, by winding the rope round the axle.

If the power P or P′ do not act in the direction of a tangent to the circle, but in some other, as AP″; then letting fall CD perpendicularly on P″A, produced if necessary, we have, by the lever,

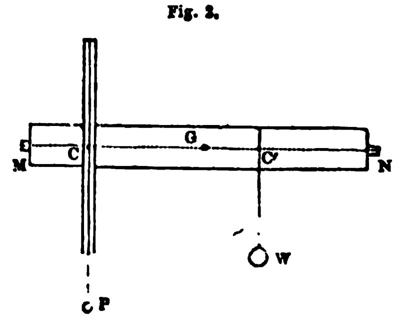
$$P'' : W :: BC : CD.$$

If the ropes to which the weights are attached have sensible thicknesses, and it is thought proper to take those thicknesses into consideration, the ropes may be conceived to be reduced to their mathematical axes, and these to pass over the circumferences of the wheel and cylinder at distances equal to the semidiameters: thus, if r and R be the semidiameters of the ropes passing over those circumferences, respectively, we obtain, in the case first supposed,

$$P : W :: BC + R : AC + r.$$

If it be required to determine the pressures on the supports of a wheel-and-axle when the weights applied to it are in equilibrio, and the whole machine is at rest, the investigation may be conducted in the following manner:—Let the weight of the wheel be represented by A and that of the cylinder by B; also let M and N (in *fig.* 2) be the

Fig. 2.



points on which the two pivots rest; then ½B is evidently the pressure supported on each of the points M and N, arising from the weight of the cylinder *alone*. Let the weight A be supposed to act at C, the centre of the wheel, and let CM = m, CN = n; then, by mechanics,

$$m + n : m :: A : \text{pressure at } N, = \frac{m}{m+n} A :$$

in like manner, $\frac{n}{m+n}$ A expresses the pressure at M; each of these pressures arising from the weight of the wheel *alone*.

In order to find the pressures arising from the weights P and W, the sum of those weights must be considered as applied at a point G in the axis of the machine, where that axis would be cut by a vertical plane passing through the common centre of gravity of the two weights: let C and C′ be points in which the axis is cut by vertical planes passing through the respective centres of gravity of P and W; then, in order to find G, we have, by mechanics,

$$P + W : CC' :: P : CG \left(= \frac{P \cdot CC'}{P+W} \right);$$

$$\text{hence } \frac{P \cdot CC'}{P+W} + m, \text{ or } \frac{P \cdot CC' + m(P+W)}{P+W}, = MG,$$

$$\text{and } n - \frac{P \cdot CC'}{P+W}, \text{ or } \frac{n(P+W) - P \cdot CC'}{P+W}, = GN:$$

therefore, again by mechanics,

$$m+n : \frac{\text{P}.\text{CC}'+m(\text{P}+\text{W})}{\text{P}+\text{W}} :: \text{P}+\text{W} : \text{pressure on}$$

$$\text{N}\left(=\frac{\text{P}.\text{CC}'+m(\text{P}+\text{W})}{m+n}\right),$$

and, in like manner, $\frac{n(\text{P}+\text{W})-\text{P}.\text{CC}'}{m+n}$ expresses the pressure on M.

Consequently the whole pressure on M is

$$\tfrac{1}{2}\text{B}+\frac{n\text{A}+n(\text{P}+\text{W})-\text{P}.\text{CC}'}{m+n},$$

and on N, is $\tfrac{1}{2}\text{B}+\frac{m\text{A}+m(\text{P}+\text{W})+\text{P}.\text{CC}'}{m+n}$.

If the wheel and cylinder are in a state of motion about their mathematical axis, the pressure on the supports will evidently be diminished by the force with which the common centre of gravity of the weights P and W tends to descend; the value of this force is investigated in treatises on dynamics.

If two wheels and cylinders are connected together by a string *b a d f* (in *fig.* 1), or by teeth in the circumferences, as in most forms of rack-work, the ratio between the power P and the resistance *w*, in the case of equilibrium, may be determined by the same rule as would be employed if those weights were at the opposite extremities of a double lever of the first or second kind. For the power P may be conceived to be applied at A perpendicularly to the semidiameter CA, and it will be in equilibrio with a resistance at *a*, perpendicular to C*a*, which may be expressed by $\text{P}.\frac{\text{CA}}{\text{C}a}$: let this be represented by *p*. Now this force at *a* may, in consequence of the string passing round the axle CB and the circumference of the wheel RS, be conceived to be a moving power applied at *b* perpendicularly to E*b*; and this will be in equilibrio with a resistance *w* at F, acting perpendicularly to FE, which may be expressed by $p\,\frac{\text{E}b}{\text{EF}}$; therefore, substituting in it the above value of *p*, we have $w=\text{P}.\frac{\text{CA}}{\text{C}a}.\frac{\text{E}b}{\text{EF}}$. And in like manner may the relation between the power and resistance be found, in the case of equilibrium, whatever be the number of wheels and axles.

It is to be understood, in the above description, that the axles of the two wheels MN and RS are supposed to be parallel to one another and to the horizon; and that the parts of the string *b a d f* are in a vertical plane perpendicular to those axes, in order to avoid the reductions which would be necessary on account of a loss of power resulting from an oblique action of the forces at *a* and *b*. The forces acting in AP and BW, or F*w*, are also supposed to be exactly or very nearly in one vertical plane, in order to avoid the strain on the axle which would otherwise take place. [MATERIALS, STRENGTH OF.]

If the string passing over the circumference of the wheel RS and the axle CB were to cross itself, as represented by the lines *b d a f*, the relation between the powers would be the same as before, but the weight *w'* would be raised in the direction *w'* F' instead of *w*F.

It is easy to perceive that (as in the lever and other mechanical powers) the spaces described by the weights B and W, in a given time, when in motion, are to one another in the inverse ratio of those weights; for the spaces described are respectively equal to the lengths of the strings which pass over the circumferences of the wheel-and-axle in the given time; and these lengths are proportional to the circumferences, or radii, that is, inversely as the weights acting at the circumferences.

Hence the advantage in the wheel-and-axle may be increased either by increasing the radius of the wheel, or by diminishing that of the axle. In the latter case, of course, the axle would soon become too weak to sustain the weight. This is beautifully avoided by the use of a *compound* axle, one part of which is of smaller radius than the other. One end of the cord carrying W is wound round the *thicker*, and the other, in a contrary direction, round the *thinner* part. As P descends, some of the cord unwinds from the thinner axle, while another part is wound up round the thicker; but as the latter part, of course, exceeds the former in length, the weight is raised in this proportion. Thus we may have an axle of virtually vanishing radius, and may, consequently, almost indefinitely increase the power, but, of course, only at the expense of time.

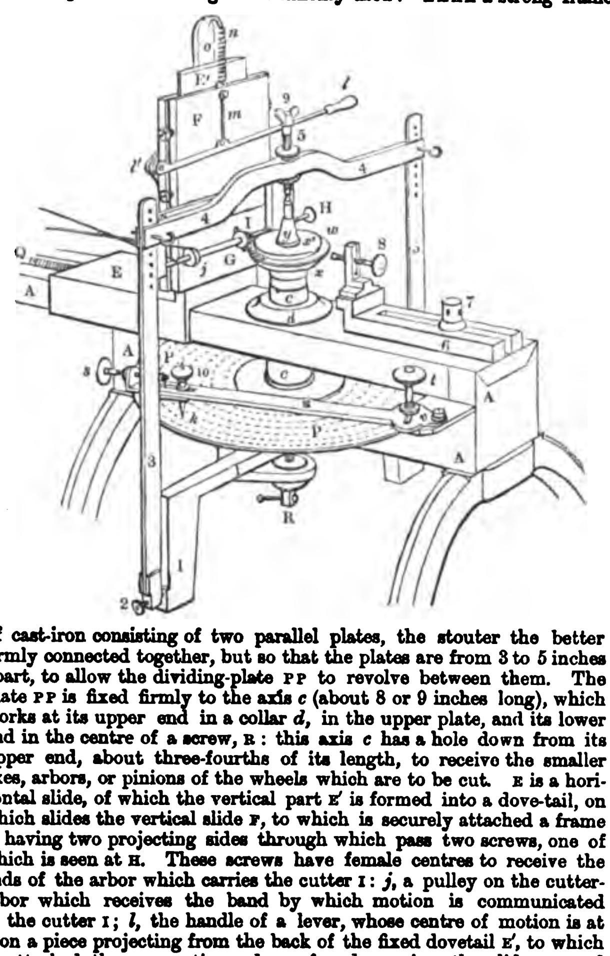
Taking the measurements as in *fig.* 1, and representing the radius of the *thicker* axle by BC, and that of the *thinner* by a quantity *a*, less than BC; since the whole weight W is supported by the *two* parts of the cord, the tension of the cord $=\tfrac{1}{2}$W.

Hence, by mechanics, taking moments about C, we get,

$$\text{P}.\text{CA}+\tfrac{1}{2}\text{W}a=\tfrac{1}{2}\text{W}.\text{CB}$$
$$\therefore \text{P}.\text{CA}=\tfrac{1}{2}\text{W}(\text{CB}-a)$$
$$\therefore \text{P}:\text{W}::\tfrac{1}{2}(\text{CB}-a):\text{CA}.$$

WHEEL-CUTTING, a term applied to a particular branch of practical mechanics, which comprehends the modes of cutting the teeth in the wheels used by watch and clock makers and for other mechanical purposes. The engines used for this purpose vary in their construction according to the wants or caprice of the artists who use them. We shall content ourselves with giving a description of the engine commonly employed, with a few remarks on the kind of tools used for cutting the spaces between the teeth, which operation is usually termed cutting the teeth of a wheel, although in reality the teeth are those portions of the metal which are left standing. We shall, however, employ the common phrase, as it will perhaps be best understood by all who feel an interest in the art.

Description of the engine commonly used:—AAAA a strong frame



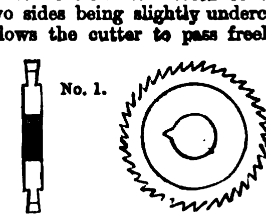
of cast-iron consisting of two parallel plates, the stouter the better firmly connected together, but so that the plates are from 3 to 5 inches apart, to allow the dividing-plate PP to revolve between them. The plate PP is fixed firmly to the axis *c* (about 8 or 9 inches long), which works at its upper end in a collar *d*, in the upper plate, and its lower end in the centre of a screw, R: this axis *c* has a hole down from its upper end, about three-fourths of its length, to receive the smaller axes, arbors, or pinions of the wheels which are to be cut. E is a horizontal slide, of which the vertical part E' is formed into a dove-tail, on which slides the vertical slide F, to which is securely attached a frame G, having two projecting sides through which pass two screws, one of which is seen at H. These screws have female centres to receive the ends of the arbor which carries the cutter I: *j*, a pulley on the cutter-arbor which receives the band by which motion is communicated to the cutter I; *l*, the handle of a lever, whose centre of motion is at *l'* on a piece projecting from the back of the fixed dovetail E', to which is attached the connecting-rod *m*, for depressing the slide F, and thereby passing the cutter through the wheel; *o*, a piece attached to the back of the dovetail E', for the purpose of fixing the spring *n*, one end of which is attached to the slide F, and operates to bring up the slide after the cutter has passed through the wheel. The slide E is for the purpose of bringing the cutter to the requisite distance from the centre of the wheel to be cut, and has a screw, not seen in the drawing, for the purpose of setting it fast when brought by the screw Q to its proper place. The dividing-plate PP has on its surface a number of concentric circles, which occupy that portion of the plate nearest its circumference: these circles are each accurately divided into such a number of equal parts as are likely to be suitable for the wheels required to be cut; the outer circles, being the largest, generally contain high numbers, such as 400, 360, 192, 168, 160, 150, 140, 136, 130, &c., and with these almost any common number of teeth can be cut. Firmly fixed on a moveable centre or joint attached to the frame of the engine is an index *u*, capable of a motion on its joint parallel to the plate PP, and having at its end a pin *k*, with a rather long conical point. On the plate PP, at the intersection of each division with its corresponding circle, is drilled a hole; and if these holes are drilled quite through the plate all the better. The pin *k* is attached to the index *u* by a moveable piece which is acted upon by the screw *s*, and serves the purpose of shifting the plate PP any small quantity less than the distance of a single division on the plate; and 10 is a nut to set the pin *k* fast in any required position.

The index, being placed with its conical point *k* in one of the holes in any circle by means of slit *v* (say that of 360 divisions), is screwed fast by the screw *t*, and the elasticity of the index keeps it sufficiently tight in the hole to prevent the plate and arbor from moving round: if the end of the spring or index be now lifted up by the hand, and the plate be moved round till the next division or hole in the same circle comes under the conical point, and the point k be then dropped into it, the distance moved over by the plate, and also by the wheel which is screwed or otherwise fixed on to the end of the arbor c, will be $\frac{1}{360}$th part of a circle. The cutter having been adjusted to such a distance from the centre of the arbor c as is required to cut a proper depth into the wheel, the operation of cutting is performed by bringing down the slide F which carries the cutter-arbor by the lever l, the arbor being carried round by the band which passes round the pulley j, and a wheel similar to a lathe-wheel, which the operator keeps in motion by the foot acting on a treadle in the same way as in a common lathe. As soon as the cutter has passed through the thickness of the wheel, the pressure is taken off the lever by which the cutting-frame or slide has been depressed, and it is brought back to the position it had before by the spring n, the plate is shifted one division, and the operation of cutting is repeated. It will be perceived that any number can be cut from each circle, provided the required number is an aliquot part of the divisions in the circle used: thus, on the circle of 360, by passing over two divisions between each cutting, 180 will be cut; three divisions, 120; four divisions, 90; and so on.

In some engines the edge of the dividing-plate, or rather a rim just within the edge on the under side of the plate, has a screw cut upon it, into which a tangent-screw is made to act; and the head of this screw consists of a small wheel, or dividing-plate, removeable at pleasure, in order to substitute another of a different number. By such an arrangement as this just described, not only may any number (even prime numbers) be cut, but the plate itself may be divided. The cutting of wheels, or rather shifting the plate by the screw, would take too much time for ordinary wheel-cutting; hence the numbers most in use are drilled in the plate as above described. A great many ingenious methods are resorted to in wheel-cutting for the purpose of cutting odd numbers, for moving the plate over any number of divisions rapidly without the possibility of making a mistake, the details of which our limits will not allow us to go into: what we have said above we deem sufficient to illustrate the principle. It is necessary here to observe that the cutter, previous to commencing to operate, should be adjusted so that a plane passing through the centre of its cutting-edge, and parallel with its sides, should pass also through the centre of the arbor on which the wheel is fixed; otherwise the teeth will not be cut in straight to the centre, and will have the appearance of being bent on one side. It is also necessary that the downward motion of the slide containing the cutter-arbor should be perfectly at right angles with the plane of the wheel. We have hitherto spoken of the wheels as being screwed to the arbor c, but we have also said the arbor c is hollow, for the purpose of receiving the axes of the wheels to be cut. This hollow arbor is, in fact, capable of receiving end-pieces, which are firmly fixed therein; and it is on these latter pieces that the wheels which have no axes of their own, but simply a hole through them, are screwed. But when the wheel to be cut is already fixed on an axis, the hollow arbor is used with an apparatus shown in the figure, which we shall now describe:—1, 1, part of a very firm bar attached to the lower frame, and extending horizontally across the centre of the engine-plate, the extremities of which bar terminate in two pins or pivots; 2, 2, one of which is not seen, extending a short distance beyond the edge of the dividing-plate; on to these pins are hooked two pieces, 3, 3, which, at their upper ends, pass through slits in the piece of iron, 4, 4, which has a screw, 5, passing through its centre. (In all this apparatus, except the screw, 5, there must be no nice fitting, but perfect freedom.) The screw 5 has a centre, either male or female, by which it presses down the hollow cone y; but the foregoing apparatus, called the gallows, will be best understood by describing the mode of putting on a wheel having an arbor in it:—Remove the gallows; on to the end of axis c drop a flange x, a little less in diameter than the circle which corresponds with the bottom of the teeth to be cut: through the centre of this flange drop the longer part of the arbor of the wheel w, to be cut, so that the wheel rests on the flange x; then over the wheel drop the flange or collar x' (of the same diameter as x); over the shorter part of the axis of wheel w place the hollow cone y: bring the gallows over the cone; screw down screw 5 just sufficiently tight to hold the gallows in its position, but not to set the wheel w fast; remove the pin k from the plate P P, and cause the latter to revolve rapidly by the hand or otherwise; the wheel w will in all probability be far from concentric with the plate, as will also the centre of cone y. With the hand slip the wheel w or cone y, or both, as may be required, together with the upper flange x', as nearly concentric with the plate P P as the hand and eye will enable you in one or two seconds to do; next slide the piece 6 so as to bring the screw 8 to a convenient distance from the wheel w, and set fast by screw 7; then by revolving the plate rapidly, and gradually bringing the end of 8 to the edge of wheel w, it will be got perfectly concentric; next screw down 5 sufficiently tight to prevent the wheel from moving, and set fast screw 5 by tightening nut 9: the cutter being then adjusted so as to cut the teeth a proper depth, the cutting proceeds as before described. This operation of setting the wheel perfectly concentric will not occupy an experienced hand more than fifteen seconds.

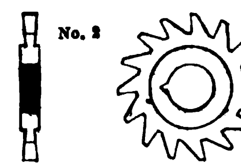
Of the Cutters, and the mode of making and using them.—The cutters vary with the nature of the work to be done, and much depends upon having good ones and well adapted for the purpose. The first kind we shall describe is used for the commonest work, that is, merely for cutting spaces whose sides are parallel through their whole length (in which case the teeth have to be rounded up afterwards), and the cutter is merely a circular disc of steel with teeth on its edge, similar to a circular saw, the two sides being slightly undercut, as seen in the section No. 1: this allows the cutter to pass freely through the metal

No. 1.



without clogging, which it would do were the sides parallel. These teeth in the cutter are sometimes made with a file by hand, but they are much better made in the engine. Cutters of this description are generally tempered so low, after having been hardened, as to allow of the teeth being renovated with a 3-square file when they become dull, and answer the purpose well enough for common purposes. A better sort of cutter, and more lasting, is made with from six to sixteen or eighteen teeth, as in No. 2, which gives a side-view and section: these

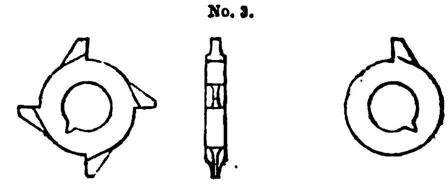
No. 2



are left very hard, being tempered only to a light straw-colour, and are sharpened with emery and oil on a metal mill or lap; these take much longer making than those first described. When these consist of not more than six teeth, each tooth is generally relieved in direction shown in section No. 3, but not on the sides, by which means the cutter frees itself better, and cuts on its sides to the very root of its tooth, which can be kept sharper and in much better working condition than the foregoing.

Cutters are also made having but one tooth, others with two, three, and four; but these are more frequently used when the teeth are to be cut and rounded up at one operation, in which case the side view and section No. 3 will represent the form in which they require to be

No. 3.



made to produce the necessary curve for the wheel-teeth; and great nicety is required to produce two curves on each side of the cutting-tooth exactly similar, for unless they are so, the teeth in the wheel cut therewith will have a very unsightly appearance.

It will be necessary to say a few words on the different kinds of work to which the various cutters above described are applicable. No. 1 is used, when tempered low, for soft metal, such as gold and brass and gun-metal; if left hard, they should be sharpened with oilstone dust or very fine emery, and they can then be used for harder metals, such as iron and steel. No. 2 may also be used for the same purposes, but when used for the harder metals should have a greater number of teeth, from 20 to 30 not being too many in a cutter of three-quarters of an inch in diameter. In general, the harder the metal to be cut the greater the number of teeth required in the cutter; and with some metals, such as steel and bell-metal, it is requisite to keep the cutter well supplied with oil, and in all cases where hard metals are under operation the cutter should have a slow motion. Cutters with from one to six teeth may revolve from 10,000 to 20,000 times in a minute in cutting the softer metals, and those with 10 to 20 teeth from 5000 to 8000 or 10,000; in fact, cutters with few teeth cannot be used for the harder metals with advantage, and the others should not have more than from 60 to 100 revolutions in a minute. These observations apply to cutters whose diameter is about three-quarters of an inch; if the cutters are larger, they must have a proportionably less number of revolutions. Cutters are sometimes made for cutting steel, and indeed for all the metals, having very fine teeth, from 200 to 300 in the inch; but the use of them is now almost obsolete: in fact, the process approximates very closely to filing, and such cutters may be regarded as circular files. One great disadvantage is that the keen edges are soon lost, and they cannot be renovated without softening.

Wheel-cutting is one of those operations in which much depends upon the manual dexterity and judgment of the operator; for it sometimes happens that steel, one of the hardest metals, may be cut with a more rapid motion, and a less number of teeth in the cutter, than is stated above; but it is only when the metal is of a particularly mild quality, or has been prepared especially for the purpose by softening. The following mode of softening the steel to be cut is a very good one, and may be frequently adopted with great advantage:—Envelope the articles in a mass of loam, clay, or lime, with sufficient moisture to make it adhesive, taking care that the articles to be softened have a considerable thickness of the material all round them. Heat the mass gradually to a blood-red heat; keep it at this heat as long as convenient, and let it remain in the fire to cool gradually as the fire goes out, after which the articles may be removed, and will be found more uniform in texture and easier to be cut than before being subjected to the operation. In making cutters, as well indeed as any other edge-tools, the susceptibility of receiving and retaining a keen edge will be considerably increased by subjecting the steel to great condensation, by cold hammering, previous to the process of hardening, and more especially if the scale left after forging be first removed with a file. Harden in water, but do not heat your steel too hot; for every degree that steel is heated above its hardening point deteriorates its quality.

WHEEL MANUFACTURE. The simplest form of wheel that can be used for any purpose is that of a plain circular disc, such as might be procured by a transverse section of the trunk of a tree of tolerably regular form. Solid wooden wheels are still occasionally used in machinery, but if large they are usually formed of two or three thicknesses of planking fastened together, with the grain crossing in various directions. Wooden wheels for millwork, when not required to be solid, usually have the periphery formed of segments, the inner sides or edges of which are left straight. The periphery may consist of three thicknesses of planking, each composed of six or eight such segments; and if the three thicknesses are properly break-jointed, a wheel of considerable strength may be thus produced. The arms, or radii, of the wheel are fitted to the inner or straight sides of the segments by bolting or other modes of fastening. Wooden wheels are occasionally morticed into their shafts or axes; but a preferable plan is to use four arms, arranged in two pairs crossing at right angles, and halved into each other in the centre, where their intersection leaves a square opening for the shaft. This opening should be somewhat larger than the shaft itself, and the difference of size should be made up by the insertion of wedges, which afford the means of adjusting the wheel perfectly true upon the axis. In very large wheels, such as water-wheels, two complete sets of clasp arms, one on each side of the wheel, are used. In mounting face-wheels it is not unusual to add stays or braces from the back of the wheel to a point at some distance along the shaft, to resist the tendency of the trundle or pinion to force the wheel out of its true position at right angles with the shaft. Hornbeam is considered to be the best kind of wood for the cogs or teeth of wheels.

In modern machinery cast-iron has almost entirely superseded the use of wood for cog-wheels of every description. If they do not exceed eight or ten feet in diameter, they may be cast in one piece; but if above that size it is desirable to form them into two or more parts, because of the difficulty of cooling a very large casting without unequal contraction. Where the diameter does not exceed twelve or fourteen feet, the rim may still be formed in one piece, and the centre and arms in another, the two to be united by bolts; but when those dimensions are exceeded, a further subdivision is necessary. The rim may then be cast in three segments, the box or centre in one piece, and the arms in several pieces, each terminating in a rib forming half the thickness of an arm, for convenience of bolting together. Large iron wheels are adjusted accurately on their axes by wedges or keys; but small ones may, in many cases, be adjusted by turning the periphery in a lathe after mounting.

Carriage-wheels are those in which the greatest ingenuity of construction is called for, as they are exposed to strains far greater for their size and weight than almost any others. The peculiar nature of these strains requires not only that the wheels be made exceedingly strong, but also that they possess a degree of elasticity sufficient to enable them to bear the violent concussions to which they are continually exposed, without risk of fracture or without the starting of any of their numerous joints. An ordinary carriage-wheel consists of the *nave*, a cylindrical block of wood, usually elm, which forms the centre of the wheel, and is pierced longitudinally with a hole to receive the axle; the *spokes*, which are radiating arms framed into the nave at equal distances; and the *felloes*, which are circular segments framed on to the outer extremities of the spokes, and forming collectively the periphery or rim of the wheel. The external surface of the felloes is usually protected by a covering of iron, called the *tire*, which may either be put on in several pieces, or *strakes*, the joints of which are made to alternate with those of the felloes, or in a single piece, forming a *hoop-tire*. The simplest form in which such a wheel as here alluded to could be formed, would be that in which the spokes would stand at right angles with the axis, and would form a flat or plane figure when the wheel is viewed edgewise; but such a wheel would be ill adapted to meet the lateral shocks to which a carriage-wheel is exposed. The more common form is that called the *dished*-wheel, in which the centre or nave is made to fall back a little from the plane of the felloes, so that the face of the wheel is not flat, but slightly concave. The elasticity of this form is a very great recommendation. It possesses also this advantage: that if the axle be slightly bent downwards towards its extremity, so as to bring the spokes of the lower half of the wheel into a nearly vertical position, which will enable them to bear the greatest possible weight, the upper half of the wheel will have such an inclination outwards as to leave more room for the body of the carriage, and to throw particles of dirt, caught up in its revolution, away from it. Very strong wheels are occasionally made in a double-dished form, or with the spokes alternately inclining outwards and inwards from the felloes, so that the centre or nave of the wheel forms the base of a pyramid of which the felloe forms the apex; but such wheels are very deficient in elasticity, and consequently will not bear much concussion. In ordinary dished wheels the spokes are arranged in two sets, being alternately more and less inclined or dished; and in some cases every alternate spoke is set absolutely straight or square with the nave. The dished form of wheel, together with the bending of the axle, involves some increase of axle friction, and also, if the wheel be wide, the use of a conical tire, which cannot possibly roll in a straight line without a degree of rubbing friction most injurious to the road, and which also increases the draught. Some years ago the use of conical wheels for waggons, combined with the inordinate breadth of tire encouraged by injudicious legislation, was carried to a most absurd extent, and broad-wheeled waggons were used which were far better adapted for grinding stones into dust and mud than for the purpose of locomotion. This extravagance, however, is now seldom seen.

The ordinary mode of making a coach-wheel is as follows. The piece of elm for the nave is turned in a lathe to the proper size and shape, and is hollowed within to receive the axle. It is then fixed in a groove, and holes are chiselled out for the reception of the ends of the spokes. There is nothing but the practised eye of the workman to guide him in making these holes in the proper position for producing the *dishing* of the wheels;—half of the spokes are near one end of the nave, and half near the other, and the holes have to be regulated accordingly. The pieces of oak for the spokes are shaped by hand: a small cutting tool, called a *spoke-shave*, being the chief instrument employed. One end of each spoke is formed into a tenon to fit the mortice-hole in the nave. The spokes are fixed into the holes by driving with a mallet, and are finally shaped after fixing. The rim being formed of several *felloes*, and each felloe being large enough to receive the ends of two spokes, the pieces of ash to form them require to be wrought into segments of curves; this is done by means of pattern-boards and various cutting tools. The felloes are drilled with holes to join them together by means of dowels, with other holes to receive the ends of the spokes.

Few mechanical operations of equal complexity, and requiring an equal amount of precision, have received so little aid from machinery as the manufacture of carriage-wheels; though wheels made by machinery are said to be superior in truth, firmness, and durability to any others. In ordinary wheels the neatness and strength are increased by the application of a hoop of iron to each end of the nave, to enable it the better to resist the strain of the spokes. The spokes, which are usually formed of oak saplings, are wrought into the proper form after being driven into the nave, and are usually cut to a narrow edge in front to lighten their appearance. Wheels have been made with the periphery in one or two pieces, bent into the required form after being softened by boiling and steaming; but the plan has not been found successful, because, among other disadvantages, the wood is injured by the long boiling required. In ordinary coach-wheels, from 4 feet 3 inches to 4 feet 8 inches high, there are fourteen spokes; and in fore-wheels, which are about a foot lower, there are commonly twelve spokes; and the usual arrangement is to have half as many felloes as there are spokes. The introduction of solid or hoop tires is a great improvement upon the former system of wheel-making, as it affords the means of binding the whole of the wheel together with irresistible force. The tire is made very hot, and the wheel is made of such a size as only just to receive it when it is thus expanded; but so soon as the hoop is brought into its proper place, water is thrown upon the wheel to cool the tire, and to prevent the wood-work from catching fire, and the result of the sudden contraction of the hoop is to compress the felloes, and to force each spoke into a slightly curved form, so that when complete the wheel forms a flat dome-shaped figure, admirably adapted, by its combined strength and elasticity, for the purpose for which it is designed. The tire is further secured, after cooling, by a few pins driven through it and the felloes, and riveted inside the latter.

Having found, during his experiments on steam locomotion upon common roads, that wheels of the ordinary construction were not strong enough for his purpose, Mr. Hancock contrived and patented a wheel in which the nave is abandoned altogether, and the inner ends of the spokes are formed into wedges which abut against each other, and form a kind of arch surrounding the axle-box. They are firmly secured in their places by an iron plate on each side of the wheel, and a bolt passing through each spoke. Though too rigid for very rapid motion, this wheel is exceedingly strong, and its simplicity of construction forms a great recommendation.

The rapid motion of railway carriages, coupled with their great weight, so greatly increases the effect of such concussions as must occur on even the smoothest road, that wooden wheels have been fonud utterly unsuitable for them. Cast-iron wheels have been much used on colliery railways, and in some cases where rapid motion is required; but while they may be made abundantly strong, as far as direct pressure is concerned, their brittleness renders them very unsuitable for passenger carriages. Many ingenious plans for the combination of wrought-iron and cast-iron in the same wheel have been devised; but whil some of these have been brought into operation, wheels entirely composed of wrought-iron have been by far the most generally adopted. The facility with which that material may be worked into form has led to endless variety of plans, some of which are highly ingenious, for combining the requisite degrees of strength and elasticity. In some wheels the annular space between the central boss or nave and the rim is filled up by a series of elliptical loops, formed of thin bars of iron, abutting against each other; in others there are spokes, but instead of consisting of single rigid bars, each consists of two halves, having a slight degree of curvature. By these and similar contrivances elasticity is insured without dishing the wheels, which would, for railway carriages, be inconvenient. In some cases a portion of the annular space above described is filled with segmental blocks of wood, resembling the felloes of a common wheel; but while this arrangement claims some advantages, its appearance is very inferior to that of the light and often elegant wheels formed entirely of wrought-iron. One kind of iron wheel which claims notice is that patented by Mr. Theodore Jones. These wheels may be compared to double-dished wheels in general appearance, but their principle is very different. They consist of an iron rim pierced at intervals with conical holes, the largest apertures of which are on the outside; two sets of round rods or spokes, with pyramidal heads to fit in the conical holes of the rim, the two sets radiating or inclining alternately inwards and outwards, like the spokes of a double-dished wheel; and a cast-iron nave, which is formed hollow, with holes to receive the inner ends of the spokes, which are secured by nuts screwed on to them within the nave. The peculiarity of this construction is, that instead of the weight resting almost entirely, as in a common wheel, upon those spokes which happen to be below the nave, it is, as it were, suspended by means of the rods or spokes which are above the nave, from the top of the wheel, the rim of which is considered as an inflexible arch. On this account the wheels are called *suspension-wheels*; and as the strength of wrought-iron to resist tension is far greater than its strength to resist compression, a wheel on this principle may be made to bear a much greater load in proportion to its bulk and weight than any other.

As an example of railway-wheels, we may advert to that of Messrs. Hollis & Lee. It is built together in four parts, of which each comprises two spokes, a quadrant of rim, and one fourth part of the nave. The nave thus formed is square. The rim-pieces are a continuation of the spokes, bent round to a curve, and fastened at the spoke ends by tenon and mortice joints.

Patent *noiseless* wheels have been made with tires of india-rubber, and with various contrivances for ensuring durability while obtaining elasticity and noiselessness; but they have not come extensively into use.

The wheels used by cutlers, lapidaries, seal-engravers, and glass engravers, under the names of brush-wheels, buff-wheels, cloth-wheels, composition-wheels, crocus-wheels, emery-wheels, lap-wheels, &c., are mostly made of metal or wood, coated with some other substance at the edge. Their manufacture needs no description.

WHETSTONE, a smooth flat stone used for *whetting* or sharpening edged instruments by friction. Whetstones, which are sometimes called *hones*, are made of various kinds of hard close-grained stone, and are moistened, when in use, with either oil or water. The latter is preferred by some, for giving a keener edge to cutting instruments; but as it allows closer contact between the stone and the metal, it does not appear so well adapted for producing a very smooth surface. The proper use of a whetstone involves a degree of skill and dexterity which can only be obtained by much practice.

WHEY. [Cheese.]

WHIG. This term, like that of Tory, was adopted as a term of reproach, although its origin is by no means certain. North, in his 'Examen,' says it "was very significative as well as ready, being vernacular in Scotland (from whence it was borrowed) for corrupt and sour whey." In point of fact, *whig*, according to the Scottish lexicographers, is not whey, but the slightly acidulated serum of butter-milk.

Quite a different account from this, however, is given by Burnet, in his 'History of his Own Time,' under the year 1648. That writer says, "The south-west counties of Scotland have seldom corn enough to serve them round the year; and the northern parts producing more than they need, those in the west came in the summer to buy at Leith the stores that come from the north; and from a word *whiggam*, used in driving their horses, all that drove were called *whiggamors* and, shorter, the *whiggs*. Now, in that year, after the news came down of Duke Hamilton's defeat, the ministers animated their people to rise and march to Edinburgh; and they came up marching on the head of their parishes, with an unheard-of fury, praying and preaching all the way as they came. The Marquis of Argyle and his party came and bearded them, they being about 6000. This was called the whiggamors' inroad; and ever after that all that opposed the court came in contempt to be called *whiggs*; and from Scotland the word was brought into England, where it is now one of our unhappy terms of distinction."

Probably this is the true origin of the name Whig, and that it was really its previous application to the Scotch Covenanters which led to its revival as a designation for the opponents of the court in England in 1679. Kirkton, in his 'History of the Church of Scotland from the Restoration to 1678' (edited by C. K. Sharpe, Esq., 4to., Edinb., 1817), says, under the year 1667, "The poor people, who were in contempt called Whiggs, became name-fathers to all that owned one honest interest in Britain, who were called Whiggs, after them, even at the court of England: so strangely doth providence improve man's mistakes for the furthering of the Lord's purposes."

With regard to the party opinions of the Whigs, it is scarcely necessary to add anything to what has been stated under the word Tory. The Whigs of the last century and a half are generally viewed as the representatives of the friends of reform or change in the ancient constitution of the country, ever since the popular element became active in the legislature, whether they were called puritans, nonconformists, round-heads, covenanters, or by any other name. Down to the Revolution of 1688 the object of this reform party was to make such change; since that event, at least till recently, it has principally been to maintain the principles of the change then made. Of course, however, this party, like all other parties, has both shifted or modified its professions, principles, and modes of action within certain limits from time to time, in conformity with the continual variations of circumstances, and has seldom been without several shades of opinion among the persons belonging to it in the same age. These differences have been sometimes less, sometimes more distinctive; at one time referring to matters of apparently mere temporary policy, as was thought to be the case when the Whigs of the last age, soon after the breaking out of the French Revolution, split into two sections, which came to be known as the Old and New Whigs; at another, seeming to involve so fundamental a discordance of ultimate views and objects, if not of first principles, as perhaps to make it expedient for one extreme of the party to drop the name of Whig altogether and to call itself something else, as we have seen the Radicals do in our own day. All parties in politics indeed are liable to be thus drawn or forced to shift their ground from time to time; even that party whose general object is to resist change and to preserve what exists, although it has no doubt a more definite course marked out for it than the opposite party, must still often, as Burke expresses it, vary its means to secure the unity of its end; besides, upon no principles will precisely the same objects seem the most desirable or important at all times. But the innovating party, or party of the movement, is more especially subject to this change of views, aims, and character: it can, properly speaking, have no fixed principles; as soon as it begins to assume or profess such, it loses its true character and really passes into its opposite. Accordingly, in point of fact, much of what was once Whiggism has now become Toryism or Conservatism, the changes in the constitution which were formerly sought for being now attained; and, on the other hand, as new objects have presented themselves to it, Whiggism has, in so far as it retains its proper character, put on new aspects, and even taken to itself new names.

WHIRLING-MACHINE is an apparatus invented by Mr. Robins for the purpose of determining the resistance of the air against bodies moving with velocities less than those for which the resistance can be determined by the Ballistic pendulum.

It consists of a brass cylinder, 2 inches in diameter and about 6 inches long, which is fitted in a frame so as to be capable of turning freely with its axis in a vertical position between the base of the frame and a horizontal plate of wood or metal which is supported above the base by four small pillars. The axle of the cylinder, which is of steel, passes through that plate, and terminates about 4 inches above it. To this is attached horizontally, and immediately upon the plate, a thin arm of wood or metal about 4 feet long, and formed with what is called a feather edge on each side: to the extremity of this arm is affixed the object which is to be used in the experiment, and a wire proceeding from the top of the steel axle to the extremity of the arm serves to prevent the latter from bending by its weight.

A silk line made fast at one end to the surface of the cylinder is in part wound round the latter; the line then passes over a pulley fixed in a vertical position at the opposite extremity of the machine, and to its lower end is attached some given weight: the descent of the weight causes the cylinder, and consequently the object at the extremity of the arm above mentioned, to revolve about the vertical axis during the experiment. The weight at the end of the line being acted on by gravity descends at first with an accelerated motion, and consequently the circular movement of the object at the extremity of the bar is also accelerated; but after a few revolutions the resistance of the air against the object becomes very nearly equal to the weight of the descending body, and from that time the descent of the weight and the revolving motion of the object become, as to sense, uniform. When this uniform or terminal velocity is obtained in any experiment, the descending weight evidently expresses the amount of the air's resistance together with the inertia of the machine.

An instrument of this kind was much used by Dr. Hutton, of Woolwich, during the years 1786 and 1787, in his researches concerning the resistance experienced by military projectiles in passing through the air; and the objects which this mathematician applied at the extremity of the revolving arm were hemispheres of pasteboard. Any one of these he could at pleasure dispose so that either its convex or plane surface might be resisted by the air: there was also provided a flat plate of lead equal in weight to the hemisphere employed, which could be fixed to the arm when the hemisphere was removed, for the purpose of ascertaining the resistance opposed by the air to the motion of the arm itself.

The radius of the circle described by each hemisphere in its revolution is measured from the axis of the cylinder to the centre of the sphere, of which the revolving object is the half, and the radius of the cylinder is measured from the same axis to the middle of the silk line passing round the surface: let the latter radius be represented by r, and the former, when any one of the hemispheres is applied, by R. The time is marked by a stop-watch at the end of each revolution, and the differences between them are taken for the times of the revolutions. After a few revolutions the differences are very nearly constant; and a mean of ten or twelve of these nearly constant differences may be considered as the time of revolution, when the motion is uniform in consequence of the equality of the resistance and inertia to the weight of the descending body; let this weight be represented by W.

In order to discover the resistance due to the inertia of the machine and the action of the air upon the arm (the plate of lead, with its plane in a horizontal position, being fixed at the end of the arm), different weights are attached to the silk line, till some one is found which causes the arm to revolve uniformly in the same time as the hemisphere may have been observed to revolve when its motion was uniform. This weight, which may be represented by w, is evidently the equivalent of that resistance and inertia; and the difference $W-w$ is the value of the air's resistance against the anterior surface of the revolving hemisphere only. The velocity of the latter is measured by the length, in feet, of the arc described by its centre in one second, and the weight or resistance $W-w$ is supposed to be applied at the circumference of the cylinder, to which the silk line is a tangent. This term must consequently be multiplied by $\frac{r}{R}$, in order to reduce it to the value of that which would be equivalent to it if applied at the centre of the revolving object.

From a mean of numerous experiments with a hemisphere whose diameter was 6·375 inches, and which revolved with velocities varying from 3 feet to 20 feet per second, Dr. Hutton found that the resistance of the air against the flat side was to the resistance against the convex side as 2·48 to 1: by theory it should be as 2 to 1 only. From experiments made with hemispheres of different magnitudes, also with a whole sphere, a cone, and a very short cylinder, it was found that the resistance experienced by similar surfaces (the velocities varying from 10 feet to 20 feet per second) were nearly proportional to the surfaces, increasing a little above that proportion with the greater surfaces; and that the resistances on the same surface varied, at a mean, with the 2·04 power of the velocity, gradually increasing with the increasing velocities. When a hemispherical or conical surface was acted on by the air, the resistance was less than that which was experienced by a plane surface of equal diameter; but the sharper surface had not always less resistance than one which was round: the convex surface of a hemisphere, for example, experienced less resistance than that of a cone, contrary to the result of theory. The resistance on the base of a cone was to the resistance on the convex surface as 2·3 to 1: by theory it should be as 4 to 1. The resistance on the base of a short cylinder was less than that on the base of a cone, though the areas were equal; also, on account of the different manner in which air acts on the posterior surfaces, the base of a hemisphere experienced less resistance than that of a cone, and the convex surface of a hemisphere less than that of a whole sphere of equal diameter.

The whirling-machine invented by Ferguson is a frame or box of wood, containing a wheel about 2 feet in diameter, on each side of which is a pulley about 6 inches in diameter; the axes of all are in vertical positions, and, by strings passing over the wheel and pulleys, the latter are made to revolve on turning the wheel by means of a handle. The machine was intended to exhibit, in a popular manner, the principal effects of centripetal or centrifugal forces, when bodies revolve in the circumferences of circles.

On the axle of each pulley there is fixed, at its middle point, a bar of wood in a horizontal position, and on this a small plate or carriage of brass is made to slide easily along two horizontal wires extending from the centre to one extremity of the bar: a silk line attached to this plate passes under a small brass pulley near the centre of the bar, and over a similar pulley fixed in a brass frame, about 6 inches above the first pulley; the line is afterwards attached to a brass plate or carriage, which is capable of sliding up or down in the brass frame, according as the first plate moves from or towards the centre, along the wires on the horizontal bar. A given weight is placed on this first carriage at any distance from the centre, and the pulley, to whose axle the bar is fixed, is made to revolve by turning the handle on the axle of the wheel: then, on placing such a weight on the carriage in the brass frame as will just allow the former weight to recede in consequence of the centrifugal force which that weight with its carriage acquires by the revolution, the weight in the frame, including that of its carriage, is to be considered as the equivalent of the centrifugal force.

For example, let the two pulleys be of equal diameters, and let each be made to carry on its axle a horizontal bar with a sliding plate or carriage: then, if a weight of 6 ounces, including the carriage, be placed at 3 inches from the centre of motion on one bar, and 2 ounces, including the carriage, on the other bar, at 9 inches from its centre of motion; upon making the two bars revolve rapidly, the centrifugal forces will cause any equal weights on the carriages in the two brass frames to rise to the tops of those frames at the same instant. Here the velocities of rotation are represented by 3 and 9, and the weights by 6 and 2, so that the ratio compounded of the velocities and masses is one of equality; and this is considered as verifying the proposition that if bodies revolve in circular orbits, the centrifugal forces are equal when the products of the masses and velocities are equal. Again, let the diameter of one of the pulleys be twice as great as that of the other, so that when the bars are placed on the axles and are made to revolve by turning the wheel, the angular velocity of one may be half the angular velocity of the other: then, if any equal weights, for example, be fixed on the carriages which slide on the two bars, at equal distances from the centres of motion, and if there be placed on the carriages in the brass frames above those centres, weights, including those of the carriages, such that the weight above the larger pulley may be one-fourth of that which is above the smaller pulley; the centrifugal forces arising from the revolutions will allow these weights to be raised at the same instant, proving that both the revolving bodies are retained in circular orbits. Here the angular velocities of the revolving bodies are as 1 to 2, and the weights in the frames, which represent the centrifugal forces, are as 1 to 4; and the experiment shows that when equal bodies revolve in equal circular orbits, the centrifugal or centripetal forces are to one another as the squares of the angular velocities.

It is easy to understand that such experiments may be varied so as to exhibit all the phenomena of circular movements.

WHIRLPOOL, a place in a river, or in the sea, where in consequence of obstructions from banks, rocks, or islands, or the opposition of winds and currents, the waters acquire a revolving motion.

The agitation of the waters which is constantly observed near Messina, and which is usually designated the whirlpool of Charybdis, is now well known to be unaccompanied by any vortiginous motion by which vessels might be absorbed, and is, rather, an incessant undulation of the water. The agitation is said to exist in several different places at the same time, within the circumferences of circles whose diameters, when the wind is moderate, do not exceed 100 feet, and is caused by the wind acting obliquely on the rapid current which sets towards the faro, or lighthouse, from the north during six hours, and from the south during the next six hours, and so on alternately; the changes taking place respectively with the rising and setting of the moon. Spallanzani, who was rowed over the spot when the wind was light, experienced no danger, though the boat was much tossed by the waves: he was informed however that when the wind is high, the swelling of the waves is more violent and extensive, so that small vessels which are driven within the limits of the agitation may be sunk by the waves breaking over them, and large ones may be driven on the Italian shore, where they are sometimes wrecked on the rock of Scylla. The dashing of the waves on the hollow rocks about Cape Peloro produces a noise which is said to resemble the barking of dogs; and it is probable that these sounds gave rise to the fable that a female monster surrounded by ferocious dogs and wolves lay there in wait to devour the mariners who might be wrecked on the coast.

Some of the descriptive particulars of the Galofaro, the supposed Charybdis [CALABRIA, col. 236, in GEOG. DIV.], just given, are derived from Captain (now Admiral) W. H. Smyth's account of Sicily and its islands. We now add the following, as given, from that work, in the author's subsequent memoir on the Mediterranean, pp. 181, 182:—

"To the undecked boats of the Rhegians, Locrians, Zanoleans, and Greeks it must have been formidable; for even in the present day small craft are sometimes endangered by it, and I have seen several men-of-war, and even a 74-gun ship (*the Queen, bearing the flag of Rear-Admiral Sir Charles Penrose*), whirled round on its surface; but by using due caution there is generally very little danger or inconvenience to be apprehended. The Galofaro appears to be an agitated water, of from 70 to 90 fathoms in depth. . . . . . It is owing probably to the meeting of the harbour and lateral currents with the main one, the latter being forced over in this direction by the opposite point of Pezzo. This agrees in some measure with the relation of Thucydides, who calls it a violent reciprocation of the Tyrrhene and Sicilian seas; and he is the only writer of remote antiquity I remember to have read who has assigned this danger its true situation and not exaggerated its effects. Many wonderful stories are told respecting this vortex, particularly some said to have been related by the celebrated diver, Colas, who at last lost his life here. I have never found reason, however, during my examination of this spot, to believe one of them. The formation of the Tangdora shoals, stretching out on each side of the little kind of bay off which the Galofaro is situated, is probably owing to the eddies of Charybdis."

The Maelstrom, between the islands of Mosker and Waroe on the coast of Norway, appears to be of a similar nature: the tide there forms a current which runs with violence alternately from north to south, and in a contrary direction; and when this is opposed by the winds, there is created an agitation of the water, the sound of which is heard at sea to the distance of many leagues. At high and at low water, in moderate weather, ships pass through the strait without danger; but during strong gales they keep at a considerable distance in order to avoid being drawn into the current, in consequence of which they might founder among the waves, or be otherwise destroyed. Whales and fish, it is said, are often found dead on the shores, against which they have been dashed by the violence with which the waters rush through the channel.

Whirlpools are produced among the Orkney Islands by the actions of winds and currents; but boats, it is said, pass over the spots in safety, a log of wood or a bundle of straw previously thrown into the water being sufficient to arrest its revolving motion.

The circular or spiral motion of the water, which constitutes a whirlpool or eddy in a river, is produced by flexures of the banks or contractions of the bed; in consequence of which the current, instead of continuing parallel to the general direction of the river, is turned obliquely towards the middle: the particles of water between this oblique current and the bank by which the waters from the upper part of the river are reflected, are acted upon by forces in different directions; and the centrifugal force resulting from the curvilinear motion causes the centres of the whirlpools to be on a lower level than the general surface of the water in the river.

Let A B be the distance between the two banks of a river at a part where a contraction of the bed begins to take place, and let *a b* be the narrowest part of the channel, in the vicinity: the water in part arrested by the bank A *a*, rises above the general level of the water in the river at that place, and being reflected, will be made to take an oblique direction, as *a c*; at the same time, the velocity in the contracted section becomes, by the laws of hydrodynamics, greater than that

of the river above A B. Then the particles of water within the space *a* C *c*, rushing towards *a c*, the surface within that space becomes depressed, and the particles about D descend into the space by their gravity. It follows that there is a constant tendency of the waters from D towards C *a*, and from C towards *a c*, besides the current in the direction *a c*; and by the action of the forces in these directions the revolving motion takes place. Whirlpools are continually being formed in this manner, and are carried to some distance down the river by the general current.

Whirlpools may in like manner be formed at the same time, below *b*, on the opposite bank of the river, if this should have a similar form to the bank between A and C; or the stream *a c* may be reflected from E, should there be a contraction at that place, and whirlpools may be formed in the enlargement beyond, as shown in the diagram. Precisely in like manner are formed the whirlpools or eddies at the shoulders of the piers of a bridge, when the breadth of the river is so much contracted as to cause its surface above the bridge to be considerably higher than the surface below. Under these whirlpools the bed of the river must evidently sustain less pressure than takes place on the parts about them: consequently, the water under the bed, acting hydrostatically upwards, may lift up the earth and stones, and thus undermine the piers; or it may blow up the piles driven for the formation of dams. By this cause the accidents which occur in hydraulic operations are frequently produced.

Inequalities in the depth of the bed of a river must evidently give rise to vertical whirlpools by the reflexion of the water from the ascending slopes; the particles then take an oblique direction upwards, so as to rise like a wave above the general surface: also, a sudden depression of the bed will produce a vertical whirlpool in the lower part, nearly as the horizontal whirlpools before mentioned are supposed to have been formed.

WHIRLWIND. [WIND.]

WHISKEY. The preparation of this spirit is sufficiently described under DISTILLERY; while the trade and the taxation connected with it are noticed under WINE AND SPIRIT TRADE. The name is derived from the Irish word *uisgue*, 'water;' and *usquebaugh*, the name of a cordial at one time in much request, is derived from the Irish *uisgue beatha*, 'water of life.' We may here remark, among the discoveries of the rectifiers, that a few drops of creasote and fusel oil will give a whiskey flavour to two or three gallons of good London gin, if long kept.

WHISPERING PLACES are vaults or galleries in which the sound of words uttered with a low voice is augmented, so as to become audible at a considerable distance from the speaker.

When the air is agitated by any impulse, as the utterance of a word at some spot, the undulations extend spherically in every direction, and thus give rise to perceptions of sound which diminish rapidly in intensity as the distance of the auditor increases; but if the impulse be given at one of the extremities of a tube, it is evident that the undulations will be prevented from spreading laterally, and the whole effect, augmented in consequence of the condensation of the particles of air in the tube, will be experienced: in this manner may be explained the increase of the intensity of sound in a trumpet or a speaking-pipe. [PIPE.] A like effect takes place in a less degree when sound ascends from the bottom of a deep well, or when words are uttered at one extremity of a long corridor or passage in a building. It is said that if a pin be dropped into the well in Carisbrooke Castle, in the Isle of Wight, the sound produced when it strikes the water is distinctly heard at the mouth: the well is above 200 feet deep. The sound of words spoken near the surface of any long wall is similarly augmented in the direction of the length of the wall; the latter, in some measure preventing the undulation from being diffused in the atmosphere. The effect in a corridor is frequently increased when the corridor has bends in its length, or when it is smaller at one extremity than at the other.

When the place is in the form of a dome, the undulations of the air, which are produced by a sound emitted near the concave surface, at any part of the base of the dome, are, by continual deflections from every part of the concave surface, transmitted to a point in the base diametrically opposite to that from whence the sound proceeded; and there the waves are concentrated so as to cause the perception of a sound many times louder than that which was emitted.

The whispering gallery in Gloucester Cathedral, which is described in Birch's 'History of the Royal Society,' vol. i., is a passage leading from one aisle to the opposite, behind the east window of the choir: it is 3 feet wide, and about 6½ feet high; its whole length is about 75 feet, and its form on the plan is half an irregular octagon: the walls and ceiling are of freestone, and the latter, which is flat, is unevenly wrought. If two persons are placed, one at each end, near either wall, and one converses with the other in the lowest whisper, the words are as distinctly heard as if the persons were close together. The whispering gallery in St. Paul's Cathedral, London, is that which surrounds the base in the concave surface of the interior dome: here a person speaking in a whisper near the surface of the vault is heard distinctly by a person also near the surface and at the opposite extremity of a diameter, persons in any other part not being able to hear the sound.

WHITE ARSENIC. A popular name for arsenious acid. [ARSENIC. *Arsenious Acid.*]

WHITE CANONS, so called from their habit, which was a white cassock with a rochet over it, a long white cloak, and white caps, belonged to the Premonstratensian Order of the Augustine Monks. They were brought into England shortly after 1140, and settled first at Newhouse in Lincolnshire. They had in England a conservator of their privileges, but were nevertheless often visited by their superiors of Premonstre, who raised great contributions out of them, as the generals or foreign heads of the Cluniacs or Cistercians also did from their order, till restrained from it by the parliament of Carlisle, in the last year of Edward I., 1307. They, however, continued under the jurisdiction of the Abbot of Premonstre and the general chapter of the order till 1512, when they were exempted from it by a bull of Pope Julius II., confirmed by King Henry VIII., when the superiority of all the houses of this order in England and Wales was given to the Abbot of Welbeck, in Nottinghamshire. Tanner reckoned about thirty-five houses of this order in England. (Tanner, *Notit. Monast.*; Dugd., *Mon. Angl.*)

WHITE FLUX. A substance used in metallurgical operations on a small scale. It consists chiefly of carbonate of potash, and is prepared by calcining bitartrate of potash (*cream of tartar*) with twice its weight of nitrate of potash.

WHITE GUNPOWDER. A composition consisting of three parts of chlorate of potash, one part of white sugar, and one of ferrocyanide of potassium. The ingredients must be *separately* reduced to fine powder and then intimately mixed in a wooden mortar with a wooden pestle. Its explosive force is much greater than ordinary gunpowder, and the ingredients may be kept separate until the powder is wanted, which would prevent all danger of the accidental explosion of large quantities. Its manufacture is, however, attended with considerable risk, as it explodes by friction and percussion, and several serious accidents have already resulted even from its preparation on a small scale. Contact with a minute drop of sulphuric acid causes it instantly to explode.

WHITE LEAD. [LEAD.]

WHITE PRECIPITATE. [MERCURY. *White precipitate.*]

WHITE SWELLING, a disease of the joints, so called on account of the unaltered colour of the skin. Under this term are included nearly all those diseases of the joints which are the result of chronic inflammation in the bones, cartilages, or membranes constituting the joint. These inflammations are constantly attended with swelling, which is circumscribed; the part is sometimes hard, resisting the pressure of the fingers, and thus leading to the impression that the bone is swollen and diseased; or it may be elastic, and yielding to pressure; or so soft as to produce the impression of the presence of fluid. Sometimes these swellings are attended with no pain; at other times pain is one of the earliest symptoms, and is constantly present, and greatly aggravated by the motion of the limb. In some cases the motions of the joint are but little impeded, whilst in others they are entirely destroyed. These general symptoms however admit of distinction, and several forms of white swelling can now be traced to different parts of the joint as their seat.

Amongst old writers these diseases have been described under the names of *spina ventosa*, *fungus articuli*, lymphatic tumour, and other names. A common division of these diseases is also into rheumatic and scrofulous, according as they were supposed to have their origin in a rheumatic or scrofulous state of the system. The more active were referred to the former and the chronic to the latter. Many other distinctions are founded more upon the age, temperament, and constitution of the patient, than upon essential differences of the disease. The following are the diseases of the joints which are generally denominated white swellings.

1. *Inflammation of the Synovial Membranes.*—This disease may be either acute or chronic. When acute, the skin is generally red, and the joint very painful and tender. It commences with pain at one particular spot, and in a day or two after, swelling takes place. The swelling may be felt at first to undulate, from the effusion of fluid into the membrane; but this becomes less evident as the disease advances, from the thickening of the membranes and also from the effusion of lymph. The swelling always assumes the form and direction of the synovial membranes. In a few days the disease subsides altogether or assumes the chronic form. When the inflammation is chronic from the beginning, the pain and tenderness are much less, so that the patient is able to walk about without much difficulty. There is little or no fever, the skin retains its natural colour, the swelling increases only slowly, and the symptoms are rendered worse by exposure to cold and exertion. In these cases, although the effused fluid may at length become absorbed, the synovial membrane remains thickened, and swelling and stiffness of the joint are the consequence, constituting a very common form of white swelling. The causes of this disease are both constitutional and local. It may arise as an effect of phlebitis, gout, rheumatism, syphilis, or mercury; or it may be produced by sprains, contusions, wounds, dislocations, or fractures of the heads of the bones.

The treatment of this disease must vary according as it is acute or chronic, or dependent on local or constitutional causes. In the acute and local form of the disease perfect quietude must be insisted on, cupping and leeches to the part should be had recourse to, with saline purgatives and diaphoretics. When the skin is tense, fomentations and poultices may be used; but where not, cold lotions will be best. In the early stage of the chronic form, leeches and cold lotions to the part may be applied and perfect quietude enjoined. In the latter stages, counter-irritants may be used, such as blisters, the savine cerate, ointment of tartarised antimony, &c. When persons are well enough to move about, the joint should be kept from movement by strapping it with soap-plaster, or covering it with a bandage or a cap of leather or other material made to fit tight. Bathing with cold salt water, or pouring on the part cold water may be recommended. For the removal of the stiffness, shampooing, the vapour-bath, or friction with the hand, may be employed. When the inflammation arises from rheumatism or syphilis, the treatment should be the same as for those diseases.

2. *Pulpy Thickening of the Synovial Membrane.*—This disease generally occurs in young persons between the ages of sixteen and twenty-five, and is mostly confined to the knee-joint. There is not much pain in the joint, but swelling and rigidity come on slowly. The joint on being touched appears to have fluid in it. This disease goes on sometimes for years, till at last it destroys the joint; and unless the limb is amputated, hectic symptoms ensue and destroy the patient. This disease consists in a total disorganisation of the synovial membrane, which is converted into a brownish or lightish brown pulpy substance, varying from a quarter of an inch to half an inch in thickness. In its advanced stages the cartilages, bones, and ligaments of the joint become implicated in the disease.

The well-marked cases of this disease must be looked upon as incurable, and only amputation will give a chance of relief. In mild or doubtful cases the only plan that seems to offer success is perfect quietude of the joint, which may be secured by pasteboard or other splints, or by soap-plaster. The general health should be attended to, and local applications made according to the symptoms. Inflammation should be subdued by leeches, and gentle counter-irritants may be kept constantly applied.

3. *Ulceration of the Cartilages.*—This disease occurs chiefly in children or adults under the middle age. It is frequently a consequence of the preceding diseases, but often occurs alone, although in its progress it may involve the whole joint. The joint in which it is most frequently seen is the hip, producing the greater amount of the diseases known by the name of hip-joint disease. When it occurs in the knee, it differs from inflammation of the synovial membrane by the pain at the commencement of the disease being slight, and its going on increasing in intensity. The pain is also present sometimes four or five weeks before any swelling is perceived. The swelling, when it does occur, arises from inflammation of the cellular tissue outside the joint, and often appears much larger than it really is, from the previous wasting of the leg from want of use. In many cases an effusion takes place into the synovial membrane and increases the swelling. In the progress of the disease abscesses form, having fistulous connections with the synovial membrane and the surrounding inflamed tissue. As the cartilaginous tissue is renewed with difficulty, the most favourable termination of this disease is generally attended with anchylosis of the joint.

In the treatment of this disease rest is essential; whatever moves the limb, affects the diseased cartilage. The limb may be placed in splints, or bandaged up with soap-plaster, or perfect quietude of the joint may be secured by M'Intyre's fracture-splint, which has the advantage of being easily removed for the purpose of making applications to the part affected. Where the joint is hot, cold lotions and leeches may be applied; but where it is cool, counter-irritants, blisters, issues, moxas, antimonial ointment, or croton oil. On the continent the actual cautery is recommended. For the swelling and rigidity which so constantly remain, relief may be sought in the cold douche, shampooing, or friction with the hand.

4. *Scrofulous Disease of the Joints, beginning in the Bones.*—At one time all white swellings were supposed to involve the bones, and this on account of the apparent enlargement of the bones of the affected joint. That this is not the case the existence of the above forms of disease proves, but even the fact on which the supposition was founded is not correct. So far from the bones being always enlarged in these cases, there are only a very few on record in which dissection has shown the bones to be enlarged. The bone has been supposed to be swelled from the hardness of the part and its size: but the former arises from the natural texture of the parts, and the latter is made to appear greater by contrast with the wasting diseased limb. But the bones are subject to disease which begins in their cancellous texture. The phosphate of lime is removed from them or deposited in less quantity, and a yellow caseous substance is secreted in its place. The heads of the bones are altogether weakened and softened, and deposits of bony matter of an irregular form are found on their outside. Whilst this change is going on the patient experiences pain; the knee, which is the joint it most commonly attacks, swells; the motions of the joint are affected, and it becomes more or less contracted, so as to prevent it being straightened. In the course of time matter is formed in the cavity, and makes its way out by ulceration through the synovial membrane, or abscesses form on the outside of the joint. Sometimes sinuses occur, and run to a considerable extent from the joint under the fascia, or between it and the skin.

This condition of a limb is generally connected with a scrofulous constitution, and the more decided the scrofulous disposition, the more difficult will the disease be to treat. However, whatever may be the state of the constitution, this must be attended to primarily in the treatment of these cases. [SCROFULA.] The local treatment must be the same as for other cases of white swelling. Quietude of the joint should be secured on some of the plans previously proposed; and as there is a constant tendency to anchylosis, care should be taken if possible that the anchylosis occurs in a position most convenient for using the limb. Counter-irritants will be found of great utility in these cases, such as blisters, antimonial ointment, and croton oil. Care, however, must be taken that they are not employed whilst there is a tendency to inflammatory action; and, on the other hand, the means that are employed, such as leeches, cold lotions, &c., for an increased activity of the part, should be immediately abandoned when that activity ceases. When the morbid process has been arrested, shampooing, friction, and pouring water on the part from a height, should be had recourse to for the purpose of strengthening it. The abscesses which form in these cases should be opened early; if left to themselves, they often leave ulcerations which are difficult to heal.

(Cooper, *First Lines of Surgery*; *Surgical Dictionary*; Brodie, *Pathological and Surgical Observations on Diseases of the Joints.*)

WHITE VITRIOL. [VITRIOL.]

WHITING. An impure carbonate of lime, prepared by grinding and then washing chalk, so as to separate the coarser and heavier particles from the lighter and finer ones, which latter are then collected into masses and dried.

WHITLOW is an inflammation affecting the phalanges of the fingers, and generally proceeding to suppuration. The part attacked, however, is not confined to the fingers; the same disease may also appear in the toes. *Paronychia* and *Onychia* are terms which are used to express the same disease. Surgical authors describe several forms of whitlow, or paronychia, according to the textures which the inflammation attacks. Thus it may be situated in the skin, the cellular tissue under the skin, the tendons or theca of the fingers or toes, in the periosteum, or it may be seated in the cellular tissue under the nail. When the inflammation is confined to the skin, vesicles appear, which quickly advance to suppuration, and the case requires little attention. When the subcutaneous cellular tissue is affected, the case is more serious, though it seldom extends: there is throbbing pain of the part, and there may be severe constitutional disturbance, and suppuration is a less or greater length of time in taking place. The whitlow under the nail differs from this form only in situation. In these cases only the cellular tissue under the cutis is affected, and no great danger or mischief is to be apprehended from the whitlow. When, however, the inflammation extends to the tendons, periosteum, and bone, then the symptoms are very severe; and by extending from the finger affected, up the arm, and involving a large extent of surface, fatal consequences have sometimes been the result. The commencement of this form of whitlow is indicated by a burning, shooting, throbbing pain of the finger, with a varying degree of constitutional disturbance. Sometimes the febrile symptoms are very violent; and when the arm is involved, delirium and other alarming symptoms come on. At first there is no perceptible change in the part affected: at length, however, slight swelling comes on, which may extend up the arm, even to the axilla. In these cases a small quantity of matter is collected under the flexor tendon of the finger, or under the periosteum, in which latter case the bone is mostly affected with caries.

Whitlows may be caused by some external injury, such as a prick from a needle, pin, thorn, or other pointed object, or they may arise spontaneously. The latter not unfrequently occurs in young persons who are apparently in a good state of health.

In the treatment of whitlow the inflammation can rarely be subdued before it proceeds to suppuration. It may however be tried, and cold lotions and local bleeding, with general antiphlogistic treatment, will sometimes subdue the inflammation. When matter is formed, the best thing that can be done is to get rid of it as soon as possible, and this must be done by cutting down quite upon the seat of inflammation and pain. When matter is formed, ease is immediately given by its being discharged; and even should an incision be made before suppuration has taken place, it will alleviate the symptoms. Where matter is formed extensively under the tendons, free incisions should be made wherever it is collected. Where caries of the bone exists in whitlows, it may be sometimes a question as to whether amputation is not the most effectual treatment. Where whitlow occurs under the nail, the matter may be discharged either by an incision under the nail from the side, or by scraping the nail and making the incision from above.

WHITSUNTIDE is probably a contracted form of White Sunday tide or time. In the early ages of Christianity the favourite seasons for administering the rite of baptism were Easter Sunday, the anniversary of the resurrection of Christ, and Whitsunday, that of the Jewish feast of Pentecost, when the apostles were "baptised with the Holy Ghost and with fire," and they themselves commenced their public ministry by baptising three thousand persons. As emblematic of the spiritual purity which the rite of baptism is supposed to confer, those who received it were clothed in white, and the day is hence conjectured to have received its name of White Sunday (*Dominica alba*). Other etymologies more remote and less probable have been given. The rite of baptism was performed in early times on Easter Sunday eve and Whit Sunday eve, that is, on the preceding Saturday evening, when there was a special ceremony of hallowing the font. In a volume of manuscript homilies in the Harleian Library, in the British Museum, No. 2371, it is stated, that "in the begynnyng of holy chirch, all the children weren kept to be crystened on thys even, at the font hallowyng; but now, for enchesone that in so long abydynge they might dye without crystendome, therefore holy church ordeyneth to crysten at all times of the yeare; save, eyght dayes before these evenyns, the chylde shalle abyde till the font hallowing, if it may savely for perrill of death, or ells not."

Our ancestors seem to have indulged to excess in the season of Whitsuntide in all kinds of exercises and amusements, for which many of the parishes provided the needful stimulus, and out of which they claimed their due share of profit: for this purpose a house or barn, which was called the church-house, was set apart, and a quantity of ale was brewed, which was called Whitsun Ale, or Church Ale, and was sold to the parishioners who came there to feast and drink, and gamble, and the profits were applied to the repairs of the church, and sometimes to charitable and other purposes.

(Brady's *Clavis Calendaria*; Strutt's *Sports and Pastimes* by Hone; Brand's *Popular Antiquities*, by Ellis.)

WIFE; HUSBAND and WIFE. Many of the legal incidents attached to the relation of husband and wife, or, as they are called in our law books, *Baron* and *Feme*, have been already noticed under their several heads: the mode of contracting the connection may be found under MARRIAGE, and of dissolving it, under DIVORCE; the provision for the wife out of her husband's real estates, made by the common law and modified by statutes, is treated of under DOWER; and the right derived from the same source by the husband to a life interest in his wife's real estate if he survives her and has had a child capable of inheriting, under COURTESY OF ENGLAND; the voluntary provision which may be made for the husband, the wife, and the offspring of the marriage, is discussed under SETTLEMENT and JOINTURE; and the nature of the property which the wife has, if not independently of her husband, concurrently with him, is described under PARAPHERNALIA and SEPARATE PROPERTY. The article PARENT AND CHILD shows what little right the law has conceded to the wife with regard to the children of the marriage. It is, therefore, only necessary now to give a general sketch of the subject, so as to bring the separate parts under one view, and to supply such information as may not yet have been given.

The common law treats the wife (whom it calls a feme covert, and her condition coverture) as subject to the husband, and gives him leave to exercise over her reasonable restraint, and it has been said to inflict on her moderate chastisement. The wife may now, however, obtain security that the husband shall keep the peace towards her. It looks on the husband and wife in most respects as one person, having only one mind or will, which is exercised by the husband. Hence a wife cannot sue separately from her husband for injuries done to her or to her property, or be sued alone for debts, unless her husband shall have abjured or been banished the realm; or she has obtained a judicial separation, or protection for her earnings, in consequence of his having deserted her; or unless where, by particular customs, she is permitted to trade alone, as in London; but even here the husband should be joined as defendant by way of conformity, though execution will issue against the wife alone. For injuries to the wife's person or property the remedy is by a joint action, or sometimes by the separate action of the husband. Hence again not only can they not in any case, by the common law, contract with or sue one another; but compacts made between them and all debts contracted towards each other when single (unless those made in consideration or at least in contemplation of marriage) are made void at the common law by their union. This rule does not, however, apply to debts due from the husband to the wife in a representative character, as administratrix or executrix, for instance. They cannot make grants one to another to take effect during the joint lives; nor can the wife, excepting in the exercise of a power, devise lands to her husband or to any other person; but the husband may devise to his wife property to be enjoyed by her after his death. They can give evidence, however, touching one another, except in criminal cases, or proceedings arising out of or relating to adultery. In criminal prosecutions, however, founded on injuries committed by either party on the person of the other, the injured party may (*ex necessitate rei*) be a witness. Neither can rob the other in the contemplation of law. The property of both is, with some modifications, liable to the debts of either, and with the person of his wife the husband takes the liability to her debts contracted before marriage; but those debts are only recoverable during the wife's life. If she dies before him, he is relieved from that responsibility, whatsoever fortune he may have had with her, excepting that he must apply to the discharge of such debts any assets which are received by him as his wife's administrator. As the law considers the wife to be under the perpetual control of her husband, it relieves her from responsibility for offences short of murder and high treason committed at his instigation—the evidence of that instigation being his presence during the commission of the offence. For the same reason all deeds executed by her are void; unless in fulfilment of powers vested in her or under the guarantee of certain solemnities to ensure her free agency. A disposition by a woman of her property after the commencement of a treaty for marriage, without the privity and concurrence of her intended husband, is deemed by courts of equity to be fraudulent, and will be set aside after the marriage as an injury to her husband; a will made before marriage is also revoked by the subsequent marriage of the party making it. [WILL AND TESTAMENT.]

This legal identity cannot be dissolved, whether in the eyes of the civil or ecclesiastical courts, by any voluntary act of the parties. Thus no deed of separation, unless it contains an immediate and certain provision for the wife, and no advertisement or other public notification will relieve a husband from the liability to provide his wife with necessaries fitting to her rank in life (the question of fitness being decided by a jury), or consequently from the duty of paying the debts contracted for such necessaries, if she has been driven from his house by his misconduct. On the other hand, a wife cannot recover at law from her husband from whom she lives apart any allowance which he has contracted with herself to pay her in consideration of the separation, if he desires that their union should be renewed. Nor again is a deed of separation a sufficient answer to a suit promoted by either party for restitution of conjugal rights; far less is it an answer to the charge of adultery committed either before or after separation. (Haggard's 'Consistory Reports,' i. 143.)

But this union may be dissolved, when sought for, *bonâ fide*, by either party without collusion with the other, as a remedy for that other's conjugal offences [DIVORCE]; and the dissolution relieves the husband of his responsibility for his wife's debts contracted after the decree is pronounced, or, in case of his wife's adultery, contracted after the discovery of the adultery and the consequent separation; for if no separation takes place, or if the husband abandons his usual residence to his wife and her paramour, he will be liable to debts contracted by her with tradesmen who are ignorant of the facts. So too, by the common law, a husband is not liable for the debts of his wife contracted after she has quitted his house without sufficient cause, and he has given particular notice to the tradesmen that he will not pay her debts. Still less is he liable for debts contracted while she is living in open adultery. On the other hand, where the separation or divorce is obtained by the wife on account of the cruelty or adultery of her husband, the court continues on him the duty of maintaining her (if her separate property will not enable her to live according to her rank in life) by requiring him to make her an allowance proportionate to his means. [ALIMONY.] The common law recognises this right of the wife in such circumstances to an allowance under the name of her estovers; and grants her a writ for the recovery of them; but this remedy is now never resorted to.

Such is the general and leading principle of the common law; but this supposed identity of person, of interest, and of property by no means involves equal rights.

The theory of the law is, that the husband has over his wife's personal property absolute control, and over real property a control modified partly by the general rules of descent, partly by statute, partly by the decisions of courts of equity, which always lean to the protection of the wife's property and the maintenance of any contract or provision made, whether by her husband or others, for her benefit, even so far as to admit a suit of the wife in the name of her next friend against the husband for injuries done by the latter to her property or for the recovery of rights withheld by him. To this end they interpret the Statute of Uses, as giving the wife, by the interposition of trustees, independent rights to property and control over it. Thus although she cannot take by direct grant from her husband, she may avail herself of such a grant by him to trustees for her benefit, and generally she may take by devise and by descent directly; and by settlement, or by grant through the intervention of trustees; she may herself be a trustee, and (although that position has been controverted) she may devise her trusts. Again, the common law vests in her husband not only her personal property (excepting her paraphernalia), but her chattels, real or leasehold interests; yet if a settlement has not been made on her expressly in consideration of her fortune, those portions of her personal property which consist of securities for money or beneficial contracts, and her chattels real, survive to herself, provided the securities have not been realised, and the chattels real have not been aliened, during his life by her husband; to arrears of rent due on the wife's separate estate, the husband is, however, entitled by statute 32 Henry VIII. c. 37. [CHOSES IN ACTION.] Nor does the settlement deprive her of this right with regard to things in action acquired subsequently to the execution of the settlement, unless it expressly reserves to the husband future as well as present personalty. If a husband requires the intervention of a court of equity for the purpose of reducing into possession his wife's property, the court will require him to make on her a settlement proportionate to the benefit which he derives. Usually one-half of the fund is settled upon the wife and children, but the court takes all the circumstances into consideration, especially whether any settlement already exists. The adultery of the wife deprives her of her equity (unless she has been a ward of court married without the consent of the court); but her delinquency will not induce the court to vest the whole of her property in her husband, because he does not maintain her. The court will secure the property for the benefit of the survivor and the children. On the other hand, in case of the cruelty of the husband or his desertion of his wife, the court will award to her and her children not only the whole principal, but the interest of the property in question. On the same principle, if the husband is insolvent, the court will grant to the wife out of her trust property an allowance usually equal to half the proceeds of that property. The interest which the husband takes in his wife's real estate of which she is seised in fee vests the profits in him during her life, but it gives him no power over the inheritance. By the common law a husband might alien his wife's real estate, or lease it for her life or that of the tenant, and she was left to her remedy if she survived him, or her heir at law had his remedy if the husband survived: if they neglected that remedy, the alienation by the husband was good; but by the 32 Henry VIII., c. 28, the wife or her heir may enter and defeat the husband's act. By that statute the lease of lands held by a man in right of his wife, or jointly with her, is good against husband and wife if executed by both; the lease may be for years or for life, but it must relate to land usually leased, it must not be by anticipation or in consideration of a fine; it must reserve a fair yearly rent to the husband and wife; and the husband is restricted from aliening or discharging the rent for a longer term than his own life. If, however, the wife receives rent after her husband's death upon any lease of her estate improperly granted by him, she confirms that lease. A wife's copyhold estates are forfeited to the lord by any such acts of her husband as are ruinous to the estate (for example, waste), as destroy the tenure (for example, an attempt to convert it into a freehold), or otherwise deprive the lord of his rights, as a positive refusal to pay rent or perform service. But courts of equity will relieve the tenant when the forfeiture is not wilful or can be compensated.

The husband may mortgage his wife's real property during their joint lives and during his life in addition, if he survives her, and become tenant by the courtesy; if the wife joins in that mortgage, and recognises it after her husband's death, she will be bound by it; but she may, if she thinks fit, repudiate it. Before fines were abolished, her levying a fine rendered a mortgage a good security against her and her heirs; and since the act abolishing that form of assurance, a deed acknowledged by her as the act prescribes effects the same object. [FINE OF LANDS.] A mortgage made by a wife of her estate for the sole benefit of her husband, and not to discharge a debt of her own, gives her a right at equity to compensation out of his assets.

Such are the principal rights which a husband acquires in his wife's property, and the limitations of those rights. On the other hand, the common law gives to her if she survives him an estate for life in a third part of all such estates of inheritance as he was *solely seised of during* the marriage, and as any children of the marriage might possibly have inherited. [DOWER.] That right of dower may be forfeited in various ways, and it may be defeated by a provision for her, made before marriage, in the shape of jointure. [JOINTURE.] Since the stat. 3 & 4 Wm. IV. c. 105, in marriages subsequent to 1st January, 1834, dower does not attach unless the *husband died possessed*; and it does accrue on estates disposed of by the husband during his life or by will, while it may be defeated by a declaration of the husband by deed or will, that his estates are not to be subject to dower.

The Statute of Distributions (22 & 23 Car. II. c. 10) gives to the widow of an intestate husband (if her claim has not been barred by settlement) one-third of his personal property where there is issue of the marriage living, and one-half where there is none. Marriage revokes powers of attorney previously granted by the wife, and disables her from granting them; but it does not disable her from accepting such a power, or from acting on one granted to her before coverture. She may too be attorney for her husband. She cannot bequeath her personal estate by will unless under a power, or with the consent of her husband.

The separate property of the wife has been already treated under that head. [SEPARATE PROPERTY; PIN-MONEY.]

There remains only the separation of husband and wife; which may be by deed or by decree of the Court for Divorce and Matrimonial Causes. The ecclesiastical courts considered all deeds of separation and all covenants in the nature of such deeds to be void. The courts of law, however, not only have supported such deeds against the husband, but have enforced a covenant made by him with his wife's trustees to pay her an annuity as a separate maintenance in the event of their future separation, with the approbation of the trustees. But courts of equity will not interfere to enforce such deeds, though by a strange inconsistency they will enforce the husband's covenant for a separate maintenance if made through the intervention of trustees, and indeed in certain rare cases if made between the husband and wife alone. Nor is the adultery of the wife a sufficient answer to her claim to the separate maintenance. The separation by decree is either a judicial separation or a divorce. A wife when deserted by her husband may obtain an order to protect her earnings from him or his creditors, and she will then be able to contract as if she were a *feme sole*. But when the desertion of the husband extends over a period of two years, or when he treats her with cruelty, or commits adultery, the wife may obtain a judicial separation. [SEPARATION.] When, again, the husband commits incestuous adultery, or to adultery adds the crimes of bigamy or rape, cruelty or desertion for two years, or is guilty besides the adultery of an unnatural offence, the wife may obtain a dissolution of the marriage. [DIVORCE.]

WIFE. (*Scotland.*) The moveable or personal estate of a husband and wife is under the administration of the husband; according to the phraseology of the law it is called "the goods in communion," because on the dissolution of the marriage by the death of either party it falls to be so divided that if there be issue of the marriage a third, and if there be no issue a half, goes to the nearest of kin or to the legatees of the deceased, whether husband or wife, the remainder being the property of the survivor. During the continuance of the marriage the husband's right as administrator is in all respects equivalent to the right of a proprietor, and whether the common property has been acquired by himself or by the wife, it is entirely at his disposal, in so far as that disposal is intended to have effect during his lifetime. His right of bequeathing it is limited by the Scottish law of succession. [WILL.] As the husband has the administration of the wife's property, he is responsible not only to the extent of the goods in communion, but personally, for the wife's obligations, whether contracted before or after marriage. No suit can be brought against a married woman unless the husband be made a party. The wife cannot of herself enter into a contract exigible by execution against the goods in communion and the person of her husband, unless in certain cases in which by general law or by practice she holds an agency. To this effect she is *præposita negotiis domesticis*, and whatever debts she incurs for household purposes are debts against the husband; but the husband may discharge himself from responsibility for debts so incurred by obtaining an "inhibition" against her. A wife's agency may be extended like that of any other agent; but it does not extend, without special authority, to the borrowing of money.

Heritable property (a term nearly equivalent to that of real property in England) belonging to either party is in the administration of the husband. He can however grant no lease of his wife's heritable property, to last beyond his own life, without her concurrence. On the other hand, from the date of the proclamation of the banns all deeds granted by the wife are null if they do not bear the husband's concurrence. His right of administration, including the necessity for his concurrence in the wife's deeds, may be excluded by his resigning his *jus mariti* in an antenuptial contract of marriage, or by the special exclusion of the *jus mariti* in the title of any estate conveyed to the wife. Every deed executed by a wife is presumed to have been executed under the coercion of her husband, and may be set aside unless the wife ratify it by oath before a magistrate.

A separation of married parties may take place either by judicial interference or voluntary contract. Personal violence or acts physically or morally injurious on the part of the husband, will justify a judicial separation at the suit of the wife, in which an alimentary allowance is awarded to her proportioned to his means. A voluntary separation may take place by mutual agreement, but in such a case an alimentary allowance will not be awarded unless it has been stipulated for. The husband whose wife is either judicially or voluntarily separated from him ceases to be responsible for the debts incurred by her after the date of the separation. Her own property is liable to execution for her obligations, but not her person, unless her husband be living out of Scotland, in which case it has been decided that a wife transacting business on her own account is liable to diligence against her person, or arrest and imprisonment. The husband has the uncontrolled custody of the children of the marriage during pupillarity. The court of session will interfere for their protection in the case of their personal ill-usage, or of danger of contamination, but not on the ground of a special estate being settled on a child by a third party.

On the dissolution of a marriage by the death of either party, an anterior question to that of the distribution of the property is, whether the marriage was permanent. A permanent marriage is one which has lasted for a year and part of a day, or of which a living child has been born. In the case of dissolution by death of a marriage not permanent, there is a question of accounting, and the property of the parties is, as nearly as circumstances will permit, so distributed as it would have been had no marriage between them been solemnised. In the case of a permanent marriage, the moveable property is divided as above stated, the survivor getting a half, if there is no issue, and a third if there is issue. Of any real property in which a wife dies infeft, if there have been a living child born of the marriage, and if there is no surviving issue of the wife by a former marriage, the widower enjoys the life-rent use; this is called "the courtesy of Scotland." A widow enjoys the life-rent of one-third part of the lands over which her husband has died infeft, by way of "Terce." The distribution of the property, personal or heritable, may be otherwise arranged by antenuptial contract, or equivalents to the property to which a party would succeed may be made by the settlements of the deceased.

On the dissolution of marriage by divorce, the offending party forfeits whatever provisions, legal or conventional, he or she might be entitled to from the marriage; and the innocent party, at whose instance the suit of divorce is brought, retains whatever benefits, legal or conventional, he or she may have become entitled to by the marriage. It follows that when the divorce proceeds at the suit of the wife, she obtains, at the date of the decree of divorce, the provisions which, as above, she would be entitled to on the death of her husband; and that, on the other hand, if the suit be at the instance of the husband, the wife not only loses her right to such provisions, but forfeits to the husband whatever property she may have brought into the goods in communion.

WIFE, ROMAN. [MARRIAGE, ROMAN.]

WILL. [FREE-WILL.]

WILL AND TESTAMENT. Before the passing of the 32 Hen. VIII. c. 7, commonly called the Statute of Wills, and the 34 & 35 Hen. VIII. c. 5, there was no general testamentary power of freehold land in England, but the power of making a will of personal property appears to have existed from the earliest period. Yet this power did not originally extend to the whole of a man's personal estate; but a man's goods, after paying his debts and funeral expenses, were divisible into three equal parts, one of which went to his children, another to his wife, and the third was at his own disposal. If he had no wife or no children, he might bequeath one half, and if he had neither wife nor children, the whole was disposable by will (2 Bl. 'Comm.,' 522, Mr. Kerr's edit.; Fitzherbert, 'Nat. Brev.,' 122). The law, however, was gradually altered in other parts of England, and in the province of York, the principality of Wales, and in the city of London more lately by statute, so as to give a man the power of bequeathing the whole of his personal property. At present by the 1 Vict. c. 26, for the amendment of the law with respect to wills (whereby the former statutes there enumerated, with respect to wills are repealed, except so far as the same acts or any of them respectively relate to any wills of estates *pur autre vie* to which this act does not extend), it is enacted that it shall be lawful for every person to devise, bequeath, and dispose of, by his will, executed as required by that act, all real and personal estate which he shall be entitled to either at law or in equity at the time of his death. Great alterations have been introduced into the law of wills by this statute; but as it does not extend to any will made before the 1st of January, 1838, it is necessary to consider the law as it stood previous to the act.

In general all persons are capable of disposing by will of both real and personal estate who have sufficient understanding. The power of the king to make a will is defined by the 39 & 40 Geo. III. c. 88, s. 10. By the former Statute of Wills, married women, persons within the age of twenty-one years, idiots and persons of non sane memory, were declared incapable of making wills of real estate. These disabilities also applied to a bequest of personal estate, except that infants of a certain age, namely, males of fourteen and females of twelve, might dispose, by will, of personalty; and that by the 12 Car. II. c. 21, s. 8, a father under twenty-one might, by a will attested by two witnesses, appoint guardians to his children. But, by the second section of the Wills Act, no will made by any person under the age of twenty-one years is valid; and no will made by any married woman is valid, except such a will as might have been made by a married woman before the passing of the new act. The disability of a married woman is not absolute. She may make a will of her personal property if her husband consents to that particular will, and it will be operative if he survive her. The validity of a lunatic's will depends upon the state of his mind at the time of making it. Persons born deaf and dumb are presumed to be incapable of making a will, but the presumption may be rebutted by evidence. Blindness and deafness alone do not produce incapacity. Devises of lands by aliens are at least voidable, the crown being entitled, after office found, to seize them in the hands of the devisee, as it might have done in those of the alien during his life.

Previously to the act 1 Vict. c. 26, the general power of testators was subject to exceptions. Customary freeholds and copyholds were not within the Statute of Wills, and therefore, unless where devisable by special custom, could in general be passed only by means of a surrender to the use of a will. By the 55 Geo. III. c. 192, the want of a surrender was supplied in cases where it was a mere form, but the act did not apply to cases where there was no custom to surrender to the use of a will, nor to what are called customary freeholds. A devisee or surrenderee of copyholds could not devise before admittance, though an heir-at-law might. Conditions were not devisable, nor were rights of entry or action, nor contingent interests when the person to be entitled was not ascertained: lands acquired after the execution of the will also did not pass by it; but by section 3 of 1 Vict. c. 26, the power of disposition by will extends to all real and personal estate, and to all estates, interests, and rights to which the testator may be entitled at the time of his death, though acquired subsequently to the execution of his will. There is no restriction as to the persons to whom devises or bequests may be made, except under the 34 & 35 Hen. VIII. c. 5, which forbids devises of lands to bodies politic and corporate. Exceptions to this statute have been introduced by the 43 Geo. III. c. 107, and 43 Geo. III. c. 108, which authorise devises of lands to the governors of Queen Anne's Bounty, and for the erection or repair of churches or chapels, the enlargement of churchyards or of the residence or glebe for ministers of the Church of England. Alienage cannot be properly called an incapacity to take by devise, as the devised lands remain in the alien till office found, when they vest in the crown. By the 9 Geo. II. c. 36, no lands or personal estate to be laid out in the purchase of or charged on land can be given to any charitable use by way of devise. [MORTMAIN.] By the 40 Geo. III. c. 98, no disposition of property can be made by will or otherwise, so as to accumulate the income for a longer period than for twenty-one years after the death of the settlor, or during certain minorities [ACCUMULATION]; and by what is called the rule against perpetuities, no property can be settled by deed or will so as to be inalienable for more than a life or lives in being, and twenty-one years afterwards.

Before the 1 Vict. c. 26, wills of personal estate might even be nuncupative, that is to say, might be declared by the testator without writing before witnesses, provided they were made in conformity with the directions contained in the 19th section of the Statute of Frauds (29 Car. II. c. 3). A will of freehold lands of inheritance was required to be executed in the manner prescribed by the 5th section of the Statute of Frauds, which required it to be signed by the party devising, or by some other person in his presence and by his express direction, and to be attested and subscribed in the presence of the devisor by three or more credible witnesses. The term "credible," which gave rise to much discussion under the old law, is omitted in the 1 Vict. c. 26, and it is enacted in the 14th section that no will is to be void on account of the incompetency of any attesting witness. By the 15th section gifts to attesting witnesses or their wives or husbands are declared void. This is an extension of the 25 Geo. II. c. 26, which related only to wills which at that time required the attestation of witnesses, that is to say, to wills of real estate. The words as to wives or husbands are new. The signature of the testator was not required for the validity of a will of personalty or of copyholds, whether the instrument was in his own hand-writing or in that of another. But by the 9th section of 1 Vict. c. 26, no will, whether of real or personal estate, is to be valid unless it be in writing, and signed at the foot or end by the testator or by some person in his presence and by his direction; and such signature must be made or acknowledged by the testator in the presence of two or more witnesses present at the same time, and such witnesses must attest and subscribe the will in the presence of the testator, but no particular form of attestation is necessary. Section 10 enacts that all appointments made by will are to be executed in the manner above prescribed, and are to be valid when so executed notwithstanding the non-observance of any other ceremonies required by the power under which the appointment is made. By the 11th and 12th sections, it is declared that the act is not to affect the wills of soldiers on actual service, or of mariners at sea, which are to remain subject to the particular provisions made respecting them by the 11 Geo. IV. and 1 Will. IV. c. 20. Questions formerly arose as to what was a publication of a will, but section 13 of 1 Vict. c. 26 enacts that no other publication shall be requisite than execution in the manner prescribed.

It is the rule in England, that a will of lands is regulated by the law of the country in which the lands are. The place where and the language in which such a will is written are unimportant: the locality of the lands is the only point to be considered. A will made in France and written in French, of lands in England, must contain expressions which when translated into English would properly designate the lands in question, and must be executed according to the forms required by the English law. Lands in England which belong to an

English subject domiciled abroad and dying intestate, will descend according to the English law. With respect to personalty, on the other hand, in cases both of testacy and intestacy, the law is different. If a British subject becomes domiciled abroad, the law of his domicile at the time of his death is the rule which the English courts follow in determining the validity of his will and administering his personal property in England, and *vice versâ* in the case of a foreigner dying domiciled in England. Cases sometimes arise in which it is difficult to determine what was the domicile at the time of the death of the party, and consequently what rule is to be followed in the distribution of his personal estate. If an Englishman domiciled abroad has real property in England, he ought on account of the difference of the doctrine with respect to real and personal property, to make two wills, one duly executed according to the English law for devising his real estate, and another framed according to the law of his domicile for the disposal of his personal property.

A will is a revocable instrument. It was an established rule of law that the will of a *feme sole* was revoked by her marriage, but marriage alone was not considered a revocation of the will of a man; though marriage and the birth of a child, whom the will would disinherit, conjointly were admitted by the courts to have that effect, on the ground that these circumstances together produced such a change in the testator's situation, that it could not be presumed he could intend any previous disposition of his property to continue unchanged. By section 18 of the act 1 Vict. c. 26, every will made by a man or woman is revoked by marriage, except a will made in exercise of a power of appointment when the real or personal estate thereby appointed would not, in default of appointment, pass to the heir, personal representative, or next of kin of the appointor. And by the 19th section no will is to be considered as revoked by any presumption of intention on the ground of an alteration in circumstances. By the 20th section no will or codicil is revocable except as above mentioned, or by another will or codicil executed in the manner required by the act, or by a writing declaring an intention to revoke, executed in the same manner, or by burning, tearing, or otherwise destroying the will by the testator himself, or by some other person in his presence, and by his direction, with intent to revoke. By the 21st section no obliteration, interlineation, or other alteration made in any will after execution is to have any effect, except in so far as the words or effect of the will previous to the alteration cannot be made out, unless the alteration be executed as a will, such execution to be in the margin opposite or near to the alteration, or to a memorandum referring to the alteration. By the Statute of Frauds witnesses to a will were required to sign in the testator's presence, but it was not necessary that he should sign in their presence, whereas by section 6 of that act, a mere revocation in writing must have been signed by the testator in presence of the witnesses, but they were not required to sign in his presence. This inconsistency is now removed. The 21st section alters the law as to the effect of obliterations where the words remain legible, and of cancellation by drawing lines across the whole or any part of the will. These acts will now be of no effect unless properly executed and attested. By the 23rd section no conveyance or other act made or done subsequently to the execution of a will of real or personal estate, except an act of revocation, is to prevent the operation of the will upon such estate or interest as the testator has power to dispose of at the time of his death: and by the 24th section every will is to be construed with reference to the real and personal estate comprised in it, so as to take effect as if it had been executed immediately before the death of the testator, unless a contrary intention appear on the will.

Republication of a will is in fact a re-execution of it, being a repetition of the ceremonies required for its original validity: before the act 1 Vict. c. 26, a devise of lands could only be republished by signature and attestation by three witnesses, while with respect to copyholds and personalty a will might be republished without any formal execution, and even by the mere parol acts and declarations of the testator.

The 22nd section of the act provides that no will or codicil, or any part thereof, which shall have been in any manner revoked, shall be revived otherwise than by the re-execution thereof, or by a codicil executed in manner required by the act, and showing an intention to revive the same; and when any will or codicil which shall be partly and afterwards wholly revoked, shall be revived, the revival is not to extend to such parts as had been revoked before the revocation of the whole, unless a contrary intention appear. Under the old law, if a second will or codicil which revoked a former will was afterwards cancelled, the first, if it had been kept undestroyed, was held to be revived. It had previously been determined (4 Ves., 610) that a subsequent codicil, merely for a particular purpose and confirming the will in other respects, did not amount to a republication of parts of the will revoked by a former codicil. This section extends the doctrine to the case where a will had been first partially and afterwards wholly revoked.

Estates or interests in property created by way of executory devise or bequest, that is to say, such as are made expectant on the determination of prior estates in the same property, may be, like estates created by way of remainder in a deed, either vested or contingent. So far as depends upon the nature of the limitations themselves, the same rules are in general applicable to executory devises or bequests as to remainders; but testamentary instruments are not construed with the same strictness as deeds, and in determining the question of vesting or contingency, many considerations, depending on expressions in the will or other circumstances appearing upon the face of it, are admitted as affording presumptions of the intention of the testator. It is impossible here to give any enumeration of the numerous rules which have been laid down on this subject, and which are of course liable to be modified according to the circumstances of each particular case. It may however be observed generally that when a future gift is preceded by a gift of the immediate interest, it is to be presumed that the enjoyment only is postponed, and that the future gift is vested in interest; whereas when there is no gift of the immediate interest, the contrary presumption obtains: and again, that when the enjoyment of a gift is postponed, not on account of circumstances personal to the object of the gift, but with a view to the circumstances of the estate, the gift is to be presumed vested. With respect to pecuniary legacies, some distinctions, borrowed from the civil law, are admitted which have no place as to real estate. One of these distinctions is that where futurity is annexed to the *substance* of the gift, the vesting is in the mean time suspended: but where the *time of payment* only is future, the legacy vests immediately. If however the only gift is contained in the direction to pay, this case is to be regarded as one in which time is annexed to the substance of the gift. When a future gift of a principal sum is coupled with a gift of the interest in the mean time, a strong presumption exists in favour of vesting. It is generally considered that a very clear expression of intention must exist in order to postpone the vesting of residuary bequests, on the ground that intestacy may often be the consequence of holding them to be contingent.

Great changes have been introduced in the law, as to the interpretation of wills by the above-mentioned 24th section of the act, which declares that wills are to be construed to speak as if they were executed immediately before the death of the testator, and by the six following clauses. The 25th section enacts that, unless a contrary intention appear on the will, a residuary devise shall include all estates comprised in lapsed and void devises. This alters the former law, whereby such estates devolved on the heir. The 26th clause enacts that a general devise of the testator's lands shall include copyhold and leasehold as well as freehold lands, unless a contrary intention appear. This also effects a considerable alteration in the law of devises. Formerly neither copyholds (unless surrendered to the use of the will) nor leaseholds would pass by a general devise of lands or other general words descriptive of real estate, unless the testator had no freehold lands on which the devise might operate. Since the statute of the 55 Geo. III. c. 192, which dispenses with the necessity of surrenders in certain cases, copyholds stood upon nearly the same footing as freeholds, in respect to a general devise; but leaseholds still continued subject to the old rule of law. By the 27th section, unless a contrary intention appear, a general devise of real estate and a general bequest of personal estate are respectively to include estates and property over which the testator has a general power of appointment. It was never considered necessary in the execution of a power of appointing real estate, whether general or special, to refer expressly to the power. It was sufficient if the intention to exercise it appeared from a description of the property in the will or by other means. If the testator had no other lands which answered the description, a general devise would have been a good execution of the power; but it was otherwise if he had any other lands which would satisfy the terms of the devise. The enactment applies only when the testator has a general power of appointment. Where the power is limited or special, it seems that the old rule of construction will still hold. As to personal property the rule was, that there must be some reference to the power, on the somewhat unsatisfactory ground that as any person must be supposed possessed of some personalty, there was enough to make a general bequest operative without reference to the property comprised in the power. With respect to devises, it seems that the old rule must still prevail where the power is special or limited. By the 28th section a devise of real estate without words of limitation is, unless a contrary intention appear by the will, to be construed to pass the fee. This clause introduces a very considerable alteration of the old law, under which, in accordance with the doctrine that the heir was not to be disinherited by implication, it was settled that a devise of lands without words of limitation conferred on the devisee an estate for life only, notwithstanding the appearance of a contrary intention in other parts of the will. The 29th section enacts, that in any devise or bequest of real or personal estate the words "die without issue," "die without leaving issue," or "have no issue," or any other words of the like import, shall be construed to mean a want or failure of issue at the time of the death, and not an indefinite failure of issue, unless a contrary intention appear; except in cases where such words mean, if no issue described in a preceding gift shall be born, or if there shall be no issue who shall live to attain the age or otherwise answer the description required for obtaining a vested estate by a preceding gift to such issue. Under the old law, when a testator gave an estate to A and his heirs, and directed that if A died without issue it should go to B, though his meaning in most cases was that B should have it unless A had issue living at the time of his death, the word "issue" was held to comprise descendants of every degree existing at any distance of time, and the consequence was, that where the subject of the devise was real estate, A took an estate tail and acquired the absolute dominion over the property, and where it was personalty the ulterior disposition to B was void for remoteness.

By the 30th section every devise of real estate (not being a right of presentation to a church) to a trustee or executor is to be construed to pass a fee simple, unless where a definite term of years or an estate of freehold less than the fee simple is expressly given to him. And by the 31st section trustees under an unlimited devise to them, when the trust may endure beyond the life of a person beneficially entitled for life, are to take the fee. When the limitation in a will was made to a trustee by way of use, he took the legal estate by the operation of the Statute of Uses, without reference to the nature of the trust. But in other cases the question was determined by the intention of the testator, as collected from the nature of the trust; and the trustee was considered to take only that quantity of estate which the exigencies of the trust required. Such a rule of construction was obviously of very difficult operation, and it was often not easy to determine in whom the fee was vested at any given period, and therefore who were the proper parties to deal with the property and to join in a conveyance of it. The enactments contained in the two last-mentioned sections will in a great measure remedy this inconvenience.

It follows from the nature of wills that the devises and bequests contained in them are liable to failure from the death of the devisee or legatee before the testator. This is called the doctrine of lapse. It applies equally to devises of real estate and to bequests of personalty. It is a general rule that words of limitation to heirs or executors superadded to a gift have no effect in preventing lapse in case of the devisee or legatee dying before the testator, for they are considered not as words of gift, but merely as indicating the legal devolution of the property. When the gift is to several persons as joint tenants, unless all the objects die before the testator, there can be no lapse; for as joint tenants are each takers of the whole, any one existing at the death of the testator will be entitled to the whole. The same is the case where the gift is to a class, unless where the individuals of the class were ascertained before the lapse. Two changes have been introduced into the law of lapse by the new act. The 32nd section enacts that devises of estates tail shall not lapse, but that where the devisee in tail dies during the life-time of the testator, leaving issue, the devise shall take effect as if he had died immediately after the testator, unless a contrary intention appear by the will: and, by the 33rd section, gifts to children or other issue who shall die before the testator, having issue living at the testator's death are not to lapse, but, if no contrary intention appear by the will, are to take effect as if the persons had died immediately after the testator. As a will of personalty operated upon all the property of that kind belonging to the testator at the time of his decease, there could obviously be no intestacy with regard to any part of the personal estate while there was a valid residuary bequest. The same is now true of wills of real estate in which there is a valid residuary devise, so that there is no longer room for many of the questions that arose as to whether the residuary devisee took beneficially or as a trustee, and as to the devolution of real estate directed to be sold.

If an ambiguity exists on the face of a will, or, as it is technically termed, is patent, parol evidence cannot be admitted to remove it, because to admit evidence to explain what the will has left uncertain would be in effect to make a new will by parol. If the ambiguity is not apparent on the face of the will, but arises from circumstances disclosed when an attempt is made to carry the will into effect, it may be removed by evidence of the same nature.

(Jarman, *On Wills*, and Jarman and Sweet's *Notes* to Bythewood's *Precedents, Wills*.)

WILL. (*Scotland*.) The right of bequest in Scotland is confined to moveable or personal property. It does not extend to heritable or real property—which comprehends lands and tenements, fixtures, those appurtenances of a family mansion (such as the pictures, plate, and library) which are called "heirship moveables," the machinery in mines and manufactories, the stock on farms, and every description of security or other right over any of these kinds of property. Settlements may be made of heritable property in the manner which will be described below, but it is a principle of the greatest importance, and one the neglect of which is often productive of the most serious consequences, hat no such settlement can be made in the form of a will. All persons of sound mind above the age of puberty (fourteen in males, and twelve in females) may execute wills; and persons under guardianship, as wives and minors who have curators, may do so without the consent of their guardians. The will of a bastard was formerly ineffectual, and the moveable goods of such a person, lapsing to the crown on his death, were distributed by a gift in exchequer; but this peculiarity was abolished by 6 & 7 Will. IV. c. 22. A verbal or "nuncupative" will, if uttered in the presence of two witnesses who bear testimony to it, is valid to the extent of a hundred pounds Scots, or 8*l.* 6*s.* 8*d.* sterling. A will, sufficiently formal in all points to prove its terms and its date, must be executed in the presence of witnesses and attested.

Where the will is holograph, or written by the granter himself, it does not require to be attested. If the party cannot write, he can execute a will through a notary, who receives authority in presence of two subscribing witnesses to sign for the testator, and describes the transaction in his notarial docquet. A clergyman of the Established Church of Scotland may act as a notary for the signing of a will. It is usual to nominate an executor of the will, but it is not essential to do so; and if there be no one named, an executor is supplied by operation of law. Wills executed by persons domiciled out of Scotland, if they be according to the form which would carry such property in the place where they were executed, will be effectual to convey moveable property in Scotland; but no will, whatever be the law of the place where it is made, can dispose of heritable property in Scotland. The last dated will is the effectual one, and all others are considered as revoked by it in so far as they are inconsistent with it.

The peculiar feature of the law of Scotland out of which arises the circumstance that heritable or real property cannot be bequeathed is, that no deed conveying such property is effectual unless it be expressed in what are called "dispositive terms," or terms making over the property at the moment of the signing of the deed. The peculiarity arose during the time when the holder of a fief could not part with it to another person, unless that person were accepted as a vassal by the feudal superior. But to accomplish the purposes of a virtual bequest, the party grants a conveyance, reserving power to alter, and dispenses with delivery of the deed. The formalities necessary to the execution of wills carrying moveables are necessary to settlements conveying heritable property, but with this difference, that in the settlement of heritable property, if the party cannot write, the deed must be executed by two notaries before four witnesses; and in this case a clergyman cannot act as notary.

No settlement of heritable property to the prejudice of the heir-at-law can be validly granted on a death-bed. Three elements are necessary to constitute the legal exception of death-bed: 1st, that the granter was ill of the disease of which he died when he granted the deed; 2nd, that he died within sixty days after executing it; and, 3rd, that he did not go to church, or to a market, unsupported, during the sixty days.

WILL, ROMAN. A Roman will—called Testamentum, was defined by the jurists of the Imperial period to be "a legal mode of a man's declaring his intention in due form, to take effect after his death."

The power of making a Roman testament only belonged to Roman citizens who were sui juris, a rule which excluded a great number of persons: those who were in the power of another, as sons not emancipated, and daughters; impuberes; dumb persons, deaf persons, insane persons, and others; and, as a general rule, all women. The circumstances under which a woman could make a will were peculiar; and they would require a very particular statement. A male of the age of fourteen years complete, unless under some special incapacity, could make a valid will. A female, so far as respected age only, acquired this capacity on the completion of her twelfth year.

Originally Roman citizens made their wills at Calata Comitia, which were held twice a year for this purpose. It is not said that these wills were made in writing; and it is here assumed that they were made at the Calata Comitia only for the purpose of securing the proper evidence of the testator's intention. If a man died in the interval between two such Comitia without having made his will, he must have died intestate. But wills could also be made in Procinctu, that is, by a soldier under arms and in presence of the enemy. Another mode of testamentary disposition was introduced, apparently for the purpose of preventing intestacy. If a man, says Gaius (ii. 102), had neither made his will at the Calata Comitia nor in Procinctu, and was threatened with sudden death, he transferred, by the form of mancipatio, his familia, that is, his patrimonium, to a friend, and told him what to give to each person after his death: this was called the testamentum per æs et libram, because the transfer was effected by mancipatio. Thus it appears that the testamentum per æs et libram was a formal transfer of the property during the lifetime of the owner to a person who undertook to dispose of it as he was directed. As it was a substitute for the testament made at the Calata Comitia, it is a probable inference that it only differed from the testament made at the Comitia in wanting that publicity. The two old forms of testamentary disposition, adds Gaius, fell into disuse, and that per æs et libram became the common form. Originally the formal purchaser of the testator's estate (familiæ emptor) occupied the place of the heres at a later time; when Gaius wrote, and long before his time, the old form of testamentary disposition was retained as to the familiæ emptor, but a heres was appointed by the will to carry into effect the testator's intention. The formal purchaser was only retained out of regard to ancient custom, and the institution of a heres became necessary to the validity of a will.

The form of testamentary transfer per æs et libram is described by Gaius (ii. 104). Written wills, as already observed, were not necessary, for neither mancipation nor the institution of a heres require a writing. But written wills were the common form during the later republican and the imperial period. Wills were written on tablets of wood or wax; hence the word "cera" (wax) is often used as equivalent to tabula. A Roman will was required to be in the Latin language until A.D. 439, when it was enacted that wills might be written in Greek. A Roman will in the later periods was sealed and signed by the witnesses. The sealing consisted in making a mark with a ring or something else on the wax, and the names were added. The seals and names were on the outside, for, according to the old law, there was no occasion for the witnesses to know the contents of the will. The old practice was for the testator to show the will to the witnesses, and to call on them to witness that what he so presented to them was his will. It was not unusual for a man to make several copies of his will, and to deposit them in some safe keeping. At the opening of the will the witnesses or the greater part, if alive and on the spot, were present, and after acknowledging their signatures the will was opened.

It has been mentioned that, in order to make a Roman will valid, it must appoint or institute a heres. The heres was a person who represented the testator, and who paid the legacies which were left by the will. He stood in the place of the familiæ emptor, or formal purchaser of the property in the old form of will. A heres might be appointed in such words as follow:—"Titius heres esto" ("let Titius be my heres"), or "Titium heredem esse jubeo" ("I will Titius to be my heres"). Generally, all Roman citizens who could make a will could be heredes; but persons could be heredes who could not make a will—slaves, for instance, and others who were not sui juris.

Fraud in the case of wills and other instruments was punished by severe penalties under a Lex Cornelia.

The development of the Edictal or Prætorian law at Rome introduced a less formal kind of will. If there were seven proper witnesses and seven seals, and if the testator had the power of disposition both at the time of making his will and at the time of his death, the edict dispensed with the ceremony of mancipation and gave to the heres or heredes the bonorum possessio. This mode of testamentary disposition existed under the Republic, and, accordingly, a man could either make his will by the civil form of mancipatio, or he might make it after the prætorian form, with seven seals and seven witnesses, without any mancipatio. The form of testamentary disposition by mancipatio was ultimately superseded by the more convenient prætorian form. The legislation of Justinian required several male witnesses of proper age and due legal capacity; and it was sufficient if the testator declared his will orally before these witnesses.

A Roman will, as already observed, was valid if the testator had a disposing power at the time of making his will and at the time of his death. It follows that his will, though made at any time before his death, was sufficient to dispose of all the property that he had at the time of his death. In order to render a Roman will valid, it was necessary that the heredes sui of a man (his sons and daughters were in the class of heredes sui) should either be appointed heredes or should be expressly excluded from the inheritance. A will which was illegal at the time of being made was testamentum injustum; that is, "non jure factum" (not made in due legal form). A will which was justum might become invalid; it might become ruptum (broken) or irritum (ineffectual).

A second will duly (jure) made rendered a former will invalid (ruptum); and it was immaterial whether the second will took effect or not. If it was duly made, it rendered a former will of no effect, and the testator died intestate.

If a testator sustained a capitis diminutio after making his will,—that is, if he lost any part of his status of a Roman citizen which was essential to give him a full testamentary power,—the will became irritum (ineffectual). A prior will might become ruptum by the making of a subsequent will; and such subsequent will might become irritum in various ways; for instance, if there was no heres to take under the second will.

Though a will had become ruptum or irritum, and consequently lost all its effect by the Jus Civile, it might not be entirely without effect. The Bonorum Possessio might be granted by the Prætorian law, if the will was attested by seven witnesses, and if the testator had a disposing power, though the proper forms required by the Jus Civile had not been observed.

The rule of Roman law which required heredes sui to be expressly exheredated applied to posthumous children. If a suus heres was born after the making of the will, and was not recognised as heres or exheredated in due form, the will became ruptum. This rule of law was thus expressed: "adgnascendo rumpitur testamentum." There were also cases in which a will might become ruptum by a quasiadgnatio.

A testament was called Inofficiosum when it was made in due legal form, but not "ex officio pietatis." Thus, when a man did not give the hereditas, or a portion of it, to his own children or to others who were in a near relation to him; and when there was no sufficient reason for passing them by, the person so injured might have an action, called Inofficiosi Querela. The persons who could maintain this action were particularly defined by the legislation of Justinian. If the testamentum was declared by the competent authorities to be inofficiosum, it was rescinded to the amount of one-fourth of the hereditas, which was distributed among the claimants.

The ground of the Inofficiosi Querela is explained by Savigny. ('System des Heutiges Röm. Rechts,' ii. 127, &c.) When the testator in his will passed by persons who were his nearest kin, it was presumed that such persons had merited the testator's disapprobation. If this was not so, it was considered that the testator had by his will done them a wrong, and the object of the action was to get redress by setting the will aside. The main object, however, was the establishment of the complainant's character, to which the obtaining of part of the testator's property was a subsidiary means. The expression Testamentum Inofficiosum occurs in Cicero and in Quintilian; but it is not known when the Inofficiosi Querela was introduced.

A Roman codicil (Codicili, for the word is not used in the singular number till a late period under the Empire) was a testamentary disposition, but it had not the full effect of a will. Codicils were, in fact, useless unless there was a will prior or subsequent, which confirmed them either retrospectively or prospectively. (Gaius, ii. 270; 'Dig.,' 29, 7, 8.)

The subject of Roman wills is of great extent, and it involves questions of considerable difficulty. The principal authorities have been mentioned in this article, to which may be added Ulpian, 'Fragmenta,' tit. 20; 'Dig.,' 28, tit. 1, &c.; 29, tit. 1, &c.; 'Cod.,' 6, tit. 23.)

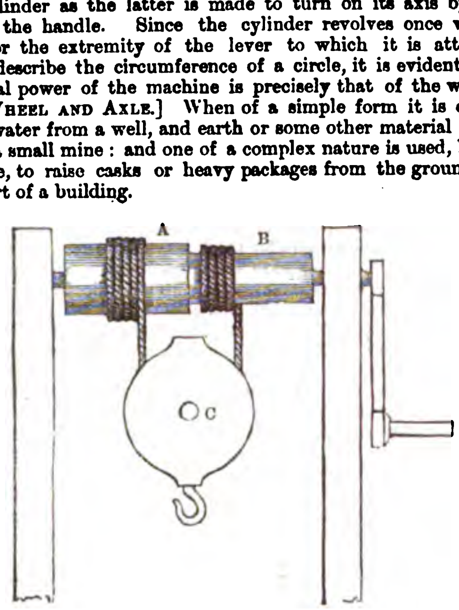
WILLOW, ECONOMICAL USES OF THE. The willow is applied to a very large number of useful purposes. The *white* willow, the *weeping* willow, and the *osier* willow, may be regarded as the types of three great classes, marking out three different kinds of applications. Taking them one with another, almost every part of the plant, in each of the three classes, is made available. The leaves of the growing tree furnish food for insects; the flowers for the honey-bee; the young leaves and shoots for cattle, horses, and goats. Sometimes they are dried and stored for this last-named purpose. In the north of Europe the inner bark is dried, ground, and mixed with oatmeal for peasants' food in years of scarcity. Willow twigs are much used in rude states of society for bridles, boat-cables, fishing-tackle, and various household implements. The bark of the young shoots is woven by the Russians for the upper parts of their shoes; while the outer bark serves for the soles. The outer bark as a material, and strips of the inner bark as a fastening, are much used for making baskets and boxes, and roofing houses. The bark, when steeped in water, may easily be stripped into fibres, and spun to make thread for cloth. The bark also yields a black dye, or tanning ingredient, and a medicinal agent. The wood of the willow is applied to many useful purposes. The timber of the larger trees is soft, smooth, and light. Its lightness led to its employment by the ancients in making shields. It has qualities which render it fitted to be used in making cutting boards for tailors and shoemakers; sharpening boards for fine steel instruments, such as cork-cutting knives; many kinds of turnery articles; shoemakers' lasts, &c. It is durable enough to form a good material for rafters in dry buildings, on account of its lightness. Its softness renders it applicable as a lining for waggons and carts intended to contain coal or stone, as it will not splinter from blows of hard angular materials. Being durable in water, it is much employed for water-wheels, floats of paddle-wheels, &c. Before the invention of iron hoops for cart-wheels, felloes were often made of red-willow wood, which speedily shod itself with small angular fragments of durable stone and gravel. The smaller portions of the wood of the trees are applied to an almost infinite variety of purposes. In some cases the straight stems of young trees, either split or whole; in some, the more vigorous shoots cut in two; and in some, the smaller shoots—are thus employed. Styles for ladders, fencing-poles, hop-poles, vine-props, clothes-props, rake-handles, handles of various tools and implements, hurdles, crates, hampers, hay and straw ricks, barrel hoops, binders for brocoli and other vegetables when sent to market, binders for standard trees and shrubs, skeleton frames for plants, are all made in large quantities from the parts of the willow now under notice. Many ornamental articles are made from strips or shavings of the wood of the white willow. Such shavings are first obtained in thin layers by a cutting instrument, and then separated into strips by a kind of steel comb having sharp teeth. The strips or ribbons are woven into a framework for bonnets and for light silk hats, and into a substitute for straw hats.

The downy substance which encloses the seed is in some countries used for wadding, and as a stuffing for cushions, beds, pillows, &c.

Some varieties of the tree are valuable when planted on the banks of rivers and canals, to retain the soil against the encroaching action of the water. Some kinds furnish good coppice, to be cut down every six or eight years for hoops, poles, and faggot-wood. The shrubby species make good hedges. The loppings, branches, and old trunks, when used as fuel, produce when dry a clear fire with little smoke. The wood produces excellent charcoal, especially for gunpowder.

Especially useful is one large group of willows, in furnishing the *osiers* for basket-making. The Dutch were the first to use osiers extensively for this purpose; the English imported the twigs from that country; but early in the present century, chiefly through the encouragement afforded by the Society of Arts, osier culture became extensive at home, and has ever since been continued. The osiers are cut in the form of rods. For coarse work they are used with the bark on; but for finer work the rods are peeled before being made up into bundles. For some work, again, the rods are used whole; while for others they are split or bisected. Some particular kinds only are known in the market as *osiers;* all the rest receive the general name of willows. For the mode of use, see Baskets.

WINCH AND AXLE is a machine constituting a small windlass, and consisting of a cylinder of wood which is capable of turning on its axis between two upright posts of the same material, or between the ends of a cast-iron frame: a lever at one or at each extremity of the cylinder, is attached to an iron axle passing through the latter at right angles to its direction, and is furnished with a handle, which is parallel to that axle. The name winch is given to a lever or handle of this kind, and the word is supposed to be derived from the verb *guincher*, signifying, in old French, to turn or bend in a curvilinear manner. The machine is used to raise a weight vertically, or to draw an object towards it; for which purposes the object is connected with it by a rope or chain which continually passes over the curve surface of the cylinder as the latter is made to turn on its axis by a man acting at the handle. Since the cylinder revolves once while the handle, or the extremity of the lever to which it is attached, is made to describe the circumference of a circle, it is evident that the mechanical power of the machine is precisely that of the wheel and axle. [WHEEL AND AXLE.] When of a simple form it is employed to raise water from a well, and earth or some other material from the shaft of a small mine: and one of a complex nature is used, by means of a crane, to raise casks or heavy packages from the ground to the upper part of a building.



When great weights are to be raised, the machine is usually fixed in a frame of cast-iron, which is rectangular on the plan, but its extremities or faces have the form of a triangle, or of the letter A. The axle of the cylinder is supported on a horizontal bar at the middle of each end of the frame, and to the cylinder is attached a toothed-wheel which turns with it on the common axis: above this wheel and parallel to the cylinder is an iron axle which carries a pinion with teeth working in those of the wheel, and causing the latter to revolve, the pinion itself being turned by means of the lever and handle at one or at each extremity of the frame. A machine of this kind is called a *crab;* and when a weight is to be drawn horizontally, or raised above the cylinder, the machine must of course be bolted to the floor or firmly fixed in the ground, in order to prevent it from being moved from its place. In such machines there is generally, at one extremity of the cylinder a wheel, having on its circumference teeth like those of a saw; and a *click* or catch, which turns freely on a pin, is attached by that pin to the side of the frame in such a manner that it may fall between the teeth. By this contrivance, if the handle should break, or the moving power be taken off while the weight is suspended in the air, the latter is prevented from descending.

Machines of this kind are occasionally constructed which have the power of holding the weight in any part of its ascent or descent without a ratchet-wheel and catch. Such a machine consists of a barrel formed in two cylindrical portions, A and B, of different diameters, but having a common axle: the rope passes under a pulley in the block C, to which the weight is attached, and over the two cylinders, in such a manner that when the handle is turned it uncoils from the smaller and coils upon the larger portion. Thus every revolution of the barrel causes the larger cylinder to take up a quantity of rope equal in length to its circumference, while there is uncoiled from the smaller a quantity equal to the circumference of the latter: consequently, after each revolution, the quantity of rope between the axis of the cylinder and the pulley is diminished by the difference between the two circumferences, and the weight is raised up through a height equal to half that difference. Hence by mechanics, if $2R\pi$ represent the circumference of the circle described by the handle of the winch in one revolution, $(r'-r)\pi$ half the difference between the circumferences of the two cylinders, W the weight to be raised, and P the power applied to the handle, we shall have, in the state of equilibrium, $\frac{r'-r}{2R}\,W = P$.

The weight which may be balanced by a given power P will evidently be greater as $r'-r$, or the difference between the radii of the cylinder, is less; and the difference may be made very small without much increasing the friction. The only disadvantage attending the machine, when compared with an ordinary winch or capstan, is that it requires a much greater quantity of rope to raise or move the object through any given distance. It was first proposed in Europe by Mr. George Eckhardt, but machines of a like kind have, it is said, been long in use in the East.

The winch is employed with the common jack, which is used to lift great weights, or to move them through small distances. The handle turns a pinion with teeth, which act on others at the circumference of a small wheel; and on the axle of this is a pinion with teeth which work in those of a rack-rod. The axles of the wheel and pinions being let into the sides of a case of wood or iron, the revolution of the wheel produces a rectilinear motion of the rack; and one end of the case being fixed to the ground, or against an immoveable object, the extremity of the rack at the opposite end forces forward the body which is to be displaced. Sometimes, instead of a rack, the machine is furnished with a wheel whose axle is hollow, and cut in the form of a concave screw; within this screw is one of the convex kind, which by the revolution of the wheel and its axle is made to move in the direction of the latter, and thus to press before it the object which is to be removed. This machine has however considerable friction.

The force exerted by a man in turning a winch vertically varies according to the position of the lever with respect to the horizon. When the lever, or that part which is perpendicular to the axle, is perpendicular to the ground, and the handle is at the highest or lowest part of the circle described by the end of the lever, the man either pushes the handle directly from him, or pulls it directly towards him; and in each case he exerts a power which is estimated at 27 or 30 lbs.; but when the lever is in a horizontal position, the man either throws a great portion of his weight on the handle to press it down, or he exerts his muscular force in a direct manner to pull it upwards; and the force exerted in these positions is estimated at 140 or 160 lbs. The force exerted must evidently have different values between these quantities in other positions of the winch; and the practice is to cause two men to work at the same time to turn the machine, one being at each extremity of the axle of the cylinder. The levers of the two winches are placed at right angles to one another; consequently when one man is pushing or pulling horizontally, the other is pressing or pulling vertically, and thus the operation of turning goes on with nearly uniform intensity; the first man working in the least favourable position when the other is working in that which is most so. [WINDLASS.]

WIND is a motion of the atmosphere independent of that which it has in consequence of the diurnal and annual movements of the earth. The latter motion being performed in a part of space which may be considered as devoid of any resisting medium, the particles of air suffer no partial displacements on that account; and the friction of the particles against each other, and against the earth which they surround, must have long since brought the diurnal movements of the atmosphere and earth to a state of equality: thus, the angular velocity of the air on any parallel of terrestrial latitude being the same as that of an observer on the same parallel, the air would seem to be at rest about him. But if, from any disturbance of the equilibrium of the atmosphere, the particles should move less rapidly than the observer from west to east, or should acquire movements in some other direction, then the sensation of a wind would be experienced. The tides which take place in the atmosphere by the attractions of the sun, moon, and planets on the particles of air giving rise to differences in the heights of the vertical columns, they must necessarily cause inequalities of pressure in horizontal directions, and thus produce winds or currents of air; but it has been shown by La Place that these currents are scarcely sensible; and such attractions are by no means adequate to the production of the winds which are observed on the earth's surface. [ATMOSPHERE, col. 692.]

The immediate effect of the solar radiation, communicating heat to any region of the earth's surface, is to generate an ascensional movement in the incumbent atmosphere, a bodily overflowing of its material above, and a relief of barometrical pressure below. The air of the cooler surrounding region, not being so relieved, will be driven in by the difference of hydrostatic—in this case of atmospheric—pressure, so arising, and thus originate two distinct winds: an upper one setting outward from the heated region; a lower inward, or towards it. "If the region heated be a limited one, these currents will radiate from and to it as a centre; if a linear belt, or a whole zone of the globe intervene, such as the generally heated intertropical region, they will assume the character of two sheets of air setting inwards on both sides below, uniting and flowing vertically upwards along the medial line, and again separating aloft and taking on a reversed movement."

These effects of heat upon the atmosphere, together with the rotatory motion of the earth, are the primary causes of all the phenomena of the winds, the latter having been found by modern meteorologists to have a much more extensive influence than was supposed when its part in the production of the trade-winds was first duly recognised. On this account, and because the consequences of these united actions impart to us a key to the whole subject,—including even that part of it which relates to revolving storms, or cyclones,—we shall now proceed to consider the trade-winds, both with respect to their theory and to their facts, in some adequate detail.

Trade-Winds is the term used by seamen to indicate the perpetual or constant winds, because they promote more than any other circumstance navigation and trade. These perpetual or trade-winds occur in all open seas on both sides of the equator, and to the distance of about 30 degrees north and south of it. They were not known to the ancients, and seem to have been unknown even to modern seamen up to the time of Columbus. Though before his time Portuguese navigators had proceeded as far as the Cape of Good Hope, they had not ventured to any great distance from the coast of Africa, and consequently they had not entered the regions where the trade-winds blow. Columbus, however, who had passed some time at the Canaries, to which the trade-winds extend in summer, seems to have conceived a just idea of their extent. On his first voyage, after leaving the Canaries, his crew were greatly alarmed at finding that the wind always blew from the north-east and east, and feared that they would be prevented by it from returning to their native country. Columbus did not participate in their fears; and on his return from the newly-discovered islands his track was north of the trade-winds, in the region of the variable winds. After the time of Columbus, European navigation extended rapidly in the Atlantic and Indian oceans, and the trade-winds became generally known. It does not, however, appear that any attempt to explain this phenomenon was made before the time of Galileo, who, in adopting the astronomical system of Copernicus and the revolution of the earth round its axis, thought he found some confirmation of this opinion in the trade-winds, which, as he conjectured, owed their origin to the revolution of the earth and to the circumstance that the atmosphere, though it participated in that motion, could not follow with equal speed the motion of the dense parts of our planet, and that a motion in the air was thus produced which was contrary to that of the earth round its axis, or from east to west. The strongest fact in favour of this hypothesis was the circumstance that the trade-winds occur only in the lower latitudes, where the surface of the earth, in its revolution round its axis, has to make a large circle in twenty-four hours, and consequently must move with a greater degree of rapidity than in the higher latitudes. Galileo's theory was relinquished about the end of the 17th century, in favour of a not less fallacious one proposed by Dr. Edmund Halley, who, however, had collected extensive information respecting these winds, and had indeed discovered several facts which were incompatible with the opinion of Galileo. The two most decisive were, that there are no trade-winds near the equator, where the diurnal motion of the earth is greatest, and that the trade-winds change their position according to the seasons, which could not take place if they were only the effect of the rotation of the earth. Galileo, however, appears to have had a true, though obscure, perception that the rotatory motion of the earth must be somehow concerned in the production of the trade-winds, though he singularly omitted to consider the operation of the sun's heat.

The trade-winds are met with on both sides of the equator. The mean boundary-line of the region in which they blow, and beyond which variable winds prevail, is about 28° lat. in the eastern parts of the ocean, but in the western parts this line is generally two or three degrees farther north and south. To the north of the equator they blow in the eastern parts of the ocean from the north-east, seldom from the eastward of east-north-east, or from the northward of north-north-east. In proceeding farther west they become more easterly, and often they blow from due east, and sometimes from the south of east, but generally they are one or two points north of east. To the south of the equator the trade-winds in the eastern parts of the ocean blow from south-east, and usually between south-east and east, but they also decline more to due east in reaching the western portion of the ocean. They do not occur in the vicinity of the continents, but are chiefly separated from them by a tract of sea in which either periodical or variable winds prevail. The trade-winds therefore are only experienced when we are well out from the land in the open sea. The wind blows with less force and steadiness in the eastern than in the western portion of the ocean. It is also stronger and more constant in the hemisphere where the sun is not, than in that which is exposed to its perpendicular rays; in the latter, however, it is more easterly than in the former. The region in which the trade-winds occur is distinguished by an almost continual serenity and fair weather. Though the trade-winds of the northern and southern hemisphere blow in an oblique direction towards one another, they do not meet in general, but are divided by a tract of sea in which calms frequently prevail, and also variable light winds, mostly from the west, are met with. This region of the calms is distinguished by a thick foggy air, and frequent rains of short duration attended by thunder and lightning. The region of calms which separates the north-east trade-winds from the south-eastern, and which usually occupies a width of four or five degrees of latitude, is not always found at the same part of the ocean, but advances farther north when the sun has a northern declination, and farther south when it is in the southern hemisphere. [CALMS.] The same is observed respecting the winds themselves. Though the mean boundary-line of the trade-winds is 28° of lat. in the eastern parts of the ocean, it extends two, three, and even four degrees farther north when the sun approaches the northern tropic, and about the same distance farther southward when the sun is near its greatest southern declination. It sometimes happens that a north-eastern wind occurs as far north as 40° in the Atlantic, along the southern coasts of Spain and Portugal, but as this is seldom the case, it is supposed that such a wind cannot be considered as a trade-wind, but only as one of the variable winds which prevail to the north and south of the trade-winds. There are also a few instances on record in which the north-east and south-east trade-winds have not been found separated by a region of calms, but in which a vessel, with the intervention of a calm of short duration, has passed from one trade-wind into the other.

The true explanation of these "magnificent phenomena," as they have justly been called, according to Dove and Herschel, was first delivered in the 'Philosophical Transactions' for 1735, by George Hadley. It has often been erroneously attributed to Dr. Edmund Halley, in part, doubtless, from the similarity of his name, and partly on account of a theory of these winds, now long proved to be fallacious, having been actually proposed by him, as already noticed. The true theory was also divined by the sagacity of John Dalton, who, not knowing what Hadley had done, printed it in his 'Meteorological Observations and Essays' in the year 1793, but discovered Hadley's priority in time to acknowledge it in his preface.

The astronomical point of view from which the objects of meteorology have always been viewed by Sir John F. W. Herschel, has given to his treatment of atmospheric phenomena, a breadth and perspicuity scarcely to be found in the writings of other meteorologists. His view of the theory of the trade-winds presents a remarkable example of this, and, as a whole, is, we think, unequalled. In what follows we give an epitome of it, condensed from two works—his 'Outlines of Astronomy,' and 'Treatise on Meteorology,' with some adaptations of our own.

It is a matter of observed fact that the sun is constantly vertical over some one or other part of the earth between the tropics, and that the whole of the zone or belt so included between the tropics, and equally divided by the equator, is, in consequence of the great altitude attained by the sun in its diurnal course, maintained at a much higher temperature than those regions to the north and south which lie nearer the poles. The heat thus acquired by the earth's surface, agreeably to the principles explained above, is communicated to the incumbent air, and becomes the universal primary cause of the phenomena of the winds, in conjunction with the earth's rotation. The colder and heavier air glides in on both sides, along the surface, from the regions beyond the tropics; while the displaced air, thus raised above its due level, and unsustained by any lateral pressure, flows over, as it were, and forms an upper current in the contrary direction, or towards the poles; which being cooled in its course, and also pressed down by the mass of the atmosphere above to supply the deficiency in the extra-tropical regions, thus keeps up a continual circulation. "That this is a real cause (*vera causa*) is placed in complete evidence by the general fact that the atmospheric pressure at the surface of the sea diminishes regularly from either tropic to the equator, where the barometer stands habitually about 0·2 in. lower than in the temperate zones."

The principle whose action was made known and applied by Hadley now comes into play. The equatorial portion of the earth's surface has the greatest velocity of rotation, and all other parts less in the proportion of the radii of the circles of latitude to which they correspond. But as the air, when relatively and apparently at rest on any part of the earth's surface, is only so, because in reality it participates in the motion of rotation proper to that part, as indicated at the beginning of this article, it follows that when a mass of air near the poles is transferred to the region near the equator by any impulse urging it directly towards that circle, in every point of its progress towards its new situation it must be found deficient in rotatory velocity, and therefore unable to keep up with the speed of the new surface over which it is brought. Hence, the currents of air which set in towards the equator from the north and south, must, as they glide along the surface, at the same time lag, or hang back, and *drag upon* it in the direction opposite to the earth's rotation, that is, from east to west. Thus these currents, which but for the rotation would be simply northerly and southerly winds, acquire, from this cause, a *relative* direction towards the west, and assume the character of permanent north-easterly and south-easterly winds.

It follows from this, then, that as the winds from both sides approach the equator, their easterly tendency must diminish; a fact which though inevitably resulting from the principle maintained by Hadley, was reserved for the late Captain Basil Hall to reason out, and, though thus for the first time, in a very distinct manner, in his 'Fragments of Voyages and Travels.' The lengths of the diurnal circles increase very slowly in the immediate vicinity of the equator, and for several degrees on either side of it hardly change at all. Thus the friction of the surface has more time to act in accelerating the velocity of the air, bringing it towards a state of *relative* rest, and diminishing thereby the relative set of the currents from east to west, which, on the other hand, is feebly, and, at length, not at all, reinforced by the cause which originally produced it. Arrived, then, at the equator, the trade winds must be expected to lose their easterly character altogether. And not only this, but the northern and southern currents here meeting and opposing, will mutually destroy each other, leaving only such preponderancy as may be due to a difference of local causes acting in the two hemispheres—which in some regions around the equator may lie one way, in some another—as will presently be seen. "The result, then," says Sir John Herschel, "must be the production of two great tropical belts, in the northern of which a constant north-easterly, and in the southern a south-easterly, wind must prevail, while the winds in the equatorial belt, which separates the two former, should be comparatively calm, and free from any steady prevalence of easterly character. All these consequences are agreeable to observed fact, and the system of aërial currents above described constitutes in reality what is understood by the regular *trade winds*."

On the subject of the region of calms, intervening between the trade-winds, Kämtz, in his 'Manual of Meteorology,' remarks, "In the space between the two trade-winds the air is heated to the highest degree. There the ascending currents of air are the most rapid; and by this quick ascent the velocity of the wind blowing along the surface of the sea is greatly diminished. Besides it would seem that the upper and lower current of the air come into contact with one another at a comparatively small elevation above the surface of the globe. These two circumstances appear to be the reason why no regular winds are met with within the region of the calms."

We now proceed to review the actual and local phenomena of these winds. Two currents of air are found within their limits, of which the lower runs to the south-west, north of the equator, and to the north-west, south of it, and the upper in the opposite direction. In this manner a kind of atmospherical circulation is formed, which is admirably adapted for the preservation of animal life. The existence of this counter-current of air in the upper regions had only been inferred from the theory, and nothing could be adduced to prove it, except that within the trade-winds the clouds, which rarely make their appearance in this region, generally take a direction which corresponds to that of the supposed current of air. But in 1812 an event took place which was rather more decisive in favour of the theory. In the eruption of the volcano of St. Vincent, considerable quantities of ashes and other volcanic matter descended on and spread over the island of Barbadoes. This event certainly excited a high degree of surprise, as in this part of the Caribbean Sea the trade-wind always blows with a considerable force, so that vessels sailing from St. Vincent to Barbadoes are obliged to make a circuitous course of some hundred miles to reach the place of their destination. It can hardly be questioned that the volcanic matter was raised, by the eruption of the volcano, to such an elevation that it reached the counter-current, which, blowing from the west, carried it to Barbadoes. Humboldt adduces also, in support of the theory, the strong south-western wind which he experienced at the top of the Peak of Teneriffe, whilst all the other parts of the islands were under the sway of the trade-wind; and this observation is also confirmed by Glass, who, in his 'History of the Canary Islands,' states that during the trade-winds the most elevated parts of those islands experience a continual westerly wind, which blows with considerable force. Confirmatory facts on this point, as observed by Professor C. Piazzi Smyth, will be found at the end of the article CLOUD. Lastly, we may adduce, in corroboration of the theory, the instantaneous change of wind which is frequently experienced when the limits of the trade-winds are passed.

It has been already observed that the boundary of the trade-winds towards the nearest pole does not always occur in the same part of the ocean, but changes with the seasons. The difference is considerable. At the greatest southern declination of the sun, in December and January, the northern boundary of the north-east trade-wind of the Atlantic occurs to the south of 25° N. lat., whilst in the opposite season, from June to September, it occurs about 32° N. lat. Thus we find a tract of sea, seven degrees of latitude in width, which is alternately exposed to the sway of the trade-winds and of variable winds, and nearly in the middle of this tract the Canaries are situated. These islands, therefore, are within the trade-winds for six months, and for the remainder of the year without them. Von Buch, in his description of these islands, has given an account of the regular manner in which the trade-wind advances towards the north, with the progress of the sun in the northern hemisphere, and in which it recedes when the sun passes the equator on his return to the southern hemisphere, observing that the south-western wind, which is always found in the upper regions of the atmosphere above the trade-winds, does not make its appearance on the south, as may be inferred from the direction in which it blows, but is first experienced at Madeira, whence it gradually advances to Teneriffe and the other Canaries. Whilst this south-western wind advances from north to south, it also descends by degrees from the upper to the lower regions, and to the surface of the globe. On Teneriffe this takes place in October, when the south-west wind is experienced on all mountains 6000 feet high, but generally one week passes, and sometimes several weeks, before the south-western wind sinks to the level of the sea.

The trade-winds are only met with on the sea; but in some countries of the globe between the tropics, or near them, regular and constant easterly winds occur, which may owe their origin to the same cause. These winds only occur in extensive level plains, where there is nothing to break their force or to change their direction; for if the wind comes in contact with high land or mountains, its regular progress is obstructed. But over a considerable tract of low level land the wind passes without being much changed in its direction and velocity, particularly if the land be barren and destitute of moisture. In the Sahel, or western part of the Sahara, an easterly wind blows all the year round with great force, but in the eastern district of the Great Desert it is less constant and less violent, so that in all respects it may be compared with a trade-wind. An easterly wind is also always found on the plain drained by the Amazonas; and by its assistance the voyage against the strong current of the river may be accomplished nearly in the same time as the voyage downwards by means of the current. Humboldt found that this easterly wind, which, near the mouth of the Amazonas is moderate, has acquired such a force at the base of the Andes, that it is almost impossible to keep one's footing against it. A similar easterly wind, though of less strength, is found in the great plain which is traversed by the lower course of the Orinoco.

The countries just mentioned, in which these easterly winds blow constantly, are contiguous to those parts of the Atlantic Ocean where trade-winds in general are regular all the year round. But the trade-winds of the ocean and the land-winds of the plains do not come into contact with one another. They are separated by a tract of the globe in which other winds prevail. This tract lies within the ocean, and extends along the coasts of the continents; its width varies greatly. Where it lies east of the trade-wind it is usually a hundred miles wide, but it is of inconsiderable breadth when the land lies to the west of the trade-winds. The continuity of the easterly winds is evidently interrupted by the difference of the temperature of the air incumbent on the sea and on the land. This difference changes with the seasons, the air over the land being hotter than that of the sea when the sun is near, and colder when it is far off. Hence it follows that during the first period the wind blows from the sea to the land, and in the second from the land to the sea. Thus a kind of monsoon is produced along the coasts of the continents, even within the region of the trade-winds. A large island in such a situation is therefore surrounded by winds blowing from all quarters. When the land of Australia is heated by the presence of the sun in the southern hemisphere, the wind generally blows from the westward upon the north-western coast, and from the south-west upon the western coast; from the south-west, south, and south-east on the southern coast; and from the south-east and east upon the east coast. In the opposite season, however, the winds are less regular, because the greatest part of the island is then without the reach of the trade-winds.

The trade-winds occur on both sides of the equator in the Atlantic and Pacific oceans, but they vary considerably in extent and force in both oceans. Some account of this difference is given under the heads of ATLANTIC OCEAN and PACIFIC OCEAN, in GEOG. DIV. We shall here add, respecting the last-mentioned sea, that the trade-winds in the southern parts appear to be subject to great changes in direction and force, and that they properly occur only along the coasts of South America, where a constant south-easterly wind is met with at the distance of 500 to 600 miles from the coast: but in the middle of the Southern Pacific the trade-wind seems by no means regular and constant. Admiral Fitzroy, in speaking of the Paamuto Islands, or the Dangerous Archipelago of the Low Islands, says that among them a steady south-easterly trade-wind prevails from March to October, but that in the rainy season, from October to March, westerly winds, squalls, and rains are frequent; and in the abstract of his meteorological journal we find that in running from the Galapagos to Otaheite he experienced only south-eastern winds near the equator; and that in the remainder of his voyage the wind blew almost constantly from the north-east, north-north-east, or north-east by east. Kotzebue, on his first voyage, observed it as a remarkable circumstance, that between Easter Island and 14° 51′ S. lat. he met only with winds blowing from north, north-east, and east-north-east. This anomaly in the trade-winds of the Southern Pacific is probably produced by the innumerable islands and coral rocks which cover that ocean between the equator and the southern tropic, and extend from 130° W. long. to the coast of Australia. Horsburgh says, probably from his own observation, that "where shoal coral-banks shoot up out of the deep water in many places between the tropics, a decrease of the prevailing wind is frequently experienced; for when a steady wind is blowing over the surface of the deep water, no sooner does a ship get upon the verge of a shoal coral-bank than a sudden decrease of the wind is often perceived. This is, in his opinion, occasioned by the atmosphere over these banks being less rarefied by the increased evaporation than that over the deep water, and consequently not requiring so great a supply of air to restore the equilibrium as the circumjacent parts, which are more rarefied and heated." When such effects, according to the statement of this intelligent hydrographer, are produced by single coral-banks in the midst of the ocean, we may easily comprehend that their number and immense extent in the Southern Pacific not only diminish their force, but change the direction of the trade-winds, and that these reefs and islands affect them nearly to the same extent as a large continent. It appears that in the Southern Pacific the trade-winds are replaced by the north-eastern, northern, and western winds only during the period when the sun is in the southern hemisphere. A south-eastern trade-wind prevails also in the Indian Ocean from within a few degrees of the eastern side of Madagascar nearly to the coasts of Australia, between the parallels of 10° and 28° S. lat.; but in this ocean from 10° S. lat. to the coasts of Hindostan the winds are periodical; the influence of the land issuing in a complete reversal of the north-east trade during a considerable portion of the year, and the production of MONSOONS, that is of winds which blow half the year in one, and the other half in the contrary direction, as explained at length in the article devoted to them.

Even very limited local movements of the atmosphere are modified by the same cause. It is a remark as old as Bacon, and afterwards confirmed by Mariotte in France, Sturm in Germany, and Toaldo in Italy, and since by "many other writers both in Europe and North America, that the wind has a decidedly preponderating tendency to veer round the compass according to the sun's motion, that is, to pass from north through north-east, east, south-east, to south, and so on round in the same direction through west to north; that it often makes a complete circuit in that direction, or more than one in succession (occupying sometimes many days in so doing); but that it rarely veers, and very rarely or never makes a complete circuit, in the contrary direction." According to Sir John Herschel, Professor Dove was the first to show that this tendency is a direct consequence of the rotatory motion of the earth; it has therefore been denominated "Dove's law of rotation of the wind," to which we shall shortly return.

The heated equatorial air, while it rises and flows over towards the poles, carries with it the rotatory velocity due to its equatorial situation into a higher latitude, where the earth's surface has less motion. Hence, as it travels northward or southward, it will *gain* continually more and more on the surface of the earth in its diurnal motion, and assume constantly more and more a *westerly* relative direction; and when at length it returns to the surface, in its circulation, which it must do more or less in all the interval between the tropics and the poles, it will act on it by its friction as a powerful south-west wind in the northern hemisphere, and a north-west in the southern, and restore to it the impulse taken up from it at the equator. "We have here the origin of the south-west and westerly gales so prevalent in our latitudes, and of the almost universal westerly winds in the North Atlantic, which are, in fact, nothing else than a part of the general system of the re-action of the trades, and of the process by which the equilibrium of the earth's motion is maintained under their action." The only winds of a regular character which remain to be noticed are the land and sea breezes which occur diurnally on the coasts and in the islands of the tropical regions, and the periodical winds which are observed to prevail in some parts of Europe. The first are probably caused by the inequality of the sun's action on the land and water; and both, by the tendency of the atmosphere to preserve a state of nearly uniform density. During the day the land acquires a temperature higher than that of the neighbouring ocean: the atmosphere above it consequently becomes rarefied, and from about 9 A.M. the air from the sea flows towards the land, to occupy the partial vacuum there produced. In proportion as the heat of the land goes on increasing, the force of the sea-breeze also increases, and this continues till 2 or 3 P.M. After that time the temperature over the land diminishes more rapidly than over the sea, as the heat more readily escapes by radiation from the land than from the water, and about sunset the breeze from the sea ceases. During the night, the land continuing to cool, the air over the sea becomes comparatively warmer and more rarefied, and a breeze from the land takes place: this wind augments in force till near sunrise, when the temperature of the earth begins to increase, and about 9 A.M. the wind blows from the sea as at first. These land-breezes diverge in every direction towards the coasts of the tropical islands from the high lands in their interior. Mr. Redfield modifies the hypothesis above stated by assuming that when the stratum of air lying on the surface of land which ascends towards the interior of a country becomes rarefied by the sun's heat, it is forced by an excess of pressure at its lowest part to move up the slope; and during the night the stratum of air on this inclining surface acquiring greater density, its gravity causes it to descend towards the sea. ('Amer. Journal of Science,' vol. xxxiii., No. 1.)

The Etesian winds (so called from ἐτησίαι, "annual") is a designation formerly given only to those which every summer blow during six weeks over the countries bordering the Mediterranean; but it has since been applied to other periodical winds, as those which blow on the coast of Holland. They commence in the Levant about the middle of July, rising at 9 A.M., and continuing during the day-time only: the direction of the current of air is from north-east to south-west; and it is probably caused by the rarefaction of the atmosphere nearly under the tropic of Cancer, in consequence of the heat of the sun at that season. Pliny states that, in Spain and Asia, the etesian winds blow from the east; and he adds that they also take place in winter, when they are called Ornithian winds: these are, however, said to be more gentle than the others, and to continue during nine days only. (Smyth's 'Mediterranean,' p. 270.)

It may be observed, in addition to what has been said respecting the trade and other regular winds, that those which prevail in the temperate zones are probably the results of currents proceeding about the earth from the tropical regions. Professor Dove suggests (in a paper published in Poggendorff's 'Annalen,' of which a translation appeared in the 'Philosophical Magazine' for September, 1837) that when the sun is on the meridian of any place, as London, situated beyond those regions, the currents of heated air which proceed from the point vertically under him must arrive at that place from the south earlier than at any other place eastward or westward of it on the same parallel of latitude. But in proportion as the sun becomes successively vertical at different points westward of the meridian of London, the currents of air, in describing great circles of the sphere, arrive later, and in a direction from the westward of south; and when, during the summer, he is vertically over a point about 60 degrees west of London (that is, in the evening), they arrive nearly from the west. At midnight, when the sun is on the meridian under the horizon, the current of air passing over the north pole is felt as a north wind; and after this time the currents coming from points having less than 180 degrees of longitude eastward are felt as easterly winds, which become due east in the morning when the sun is about 60 degrees eastward of the meridian. In this order the movements take place daily, except when the currents are disturbed by accidental circumstances or by the influence of currents which proceed from the pole to the equator in order to supply the place of the heated air which ascends from the surface of the earth between the tropics.

The sun is not the sole cause of the currents which are observed in the atmosphere, for they often arise from the condensation of the aqueous vapours which are constantly rising from the surfaces of seas and rivers. Such vapours, being lighter than air, ascend in the atmosphere, carrying with them a quantity of heat, which escapes on arriving in a region where there is less heat than at the surface of the earth; and the vapour being then reduced to a state of water, a partial vacuum is produced, into which the neighbouring air rushes. The heat is at the same time conveyed by the wind with the drops of water, and thus the region in which the rain is falling is sometimes warmer than those which surround it. Rain-winds are produced by the air which descends to the ground with the globules of water; the particles of air being disengaged from the globules on the latter striking the ground, are then driven off, with considerable force, in every direction from the place where the rain is falling.

All mountain districts are subject to sudden and violent gusts of wind from the interruptions which the ridges of high land create to the general currents of the air; but that which is called the Helm-wind, at Crossfell, in Cumberland, is one of the most remarkable of these phenomena. It occurs at uncertain times between the end of September and the month of May, and occasionally, though rarely, in summer. It is stated that, when not a breath of wind is stirring, and scarcely a cloud is to be seen, there is suddenly formed a line of clouds, called the "Helm," extending nearly north and south along the top ridge of the mountains; and nearly parallel to this, another line of clouds, called the "Bar," forms itself: the first of these lines of clouds is well defined at its western and the other at its eastern edge; and the lines unite together at their northern and southern extremities so as to contain between them an elliptical space whose length, in the north and south direction, varies from 8 to 30 miles, and its breadth, in an east and west direction, from half a mile to 4 or 5 miles; the highest point of the ridge of mountains being about the middle of the first line of clouds. In a few minutes after the formation of the Helm a violent wind begins, within the space between the clouds, to blow from some eastern point of the compass, but generally from due east to due west: its force is such as to break trees, disperse the grain in stacks, and overturn a cart with its horse. It continues frequently for nine successive days, and its noise is said to resemble that of the sea in a violent storm; but it is seldom accompanied by rain. No satisfactory hypothesis has yet been offered to account for the phenomenon; but that which seems most probable is, that the air from the coast of Northumberland, being cooled as it rises to the summit of the mountain, and there condensed, descends from thence with great force, by its gravity, into the district at the foot of the western escarpment. (Rev. J. Watson, in the 'Reports of the British Association,' vol. vii.)

If we contemplate the influence of the winds in the economy of human life, we shall find them highly beneficial. Though storms are often destructive to life and property, both at sea and land, yet they contribute greatly to preserve the health of animated beings by the dissipation of noxious exhalations: the winds impel the clouds from place to place, and thus diffuse over great tracts of country the rains which contribute so much to fertilise the ground. Wind is extensively employed in giving motion to machinery; and, till the recent application of steam, it was the only power by which ships were transported across the ocean between different regions of the earth.

Whirlwind is a violent movement of the atmosphere in a circular or spiral direction apparently about a mathematical axis, the latter having at the same time a progressive motion, rectilinear or curvilinear, on the surface of the land or sea.

The tornados of North America and the coasts of Africa, as well as the typhoons in the sea of China, have long been known as violent tempests in which the wind has a revolving motion of this kind, but these terms are commonly applied to such storms as are of short duration and comparatively of small extent, the diameters of the vortices varying from a few hundred yards to one or two miles. It is now ascertained, by such evidence as leaves scarcely any doubt of the fact, that in all or most of the great storms which agitate the atmosphere the wind has a rotatory movement, and that the diameter of the circle within which the gyration is performed is sometimes equal in extent to several hundred miles: in great whirlwinds the axis appears to be either vertical or nearly so, but in those of small extent its inclination is often inconsiderable, and it is sometimes parallel to the horizon.

As early as the middle of the 17th century the revolving motion of the wind, during the great hurricanes which take place in the West Indies, appears to have been noticed; and in a description of them, which was given at that time in the 'Philosophical Transactions,' it is stated that, after a cessation of the trade-winds, the storm begins from the north; that the wind afterwards goes round to the north-west and then to the south, the storm subsiding when the wind comes to the south-east: and in Colonel Capper's work on the 'Winds and Monsoons,' which was published in 1801, the gyratory nature of the storms in the East Indian seas is inferred from the recorded changes in the directions of the wind during the storms of 1760 and 1770. Whirlwind storms appear however to have been then considered as local and temporary; and we owe to the late Mr. Redfield, of New York, the discovery that they have a progressive as well as a revolving motion. Dr. Franklin ascertained that the storm which he witnessed at Philadelphia in 1748, took a certain time to arrive at Boston, but he did not pursue the subject, and, from a mistaken estimate of the distance between those cities, his opinion of the rate of movement is now known to be erroneous.

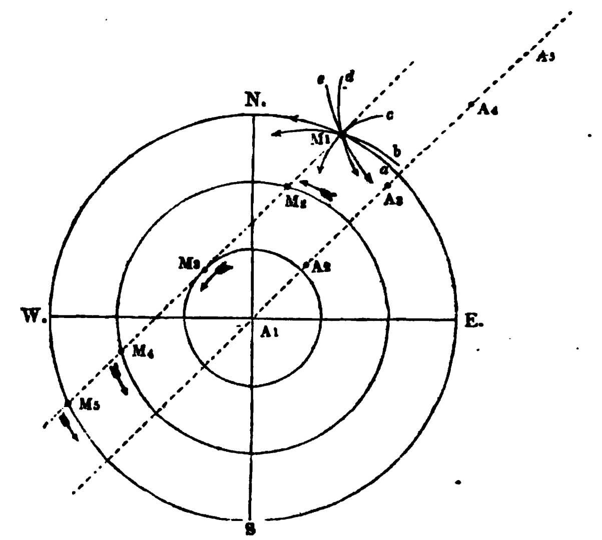
Currents of air are frequently, as at the changes of the monsoons in the East Indian seas, impelled obliquely against each other, and thus rotatory motions in the atmosphere may be produced, exactly as eddies or whirlpools are formed in currents of water. [WHIRLPOOL.]

Mr. Redfield, in his 'Observations on Storms,' in the 'Transactions of the American Philosophical Society,' 1841, offers an opinion that generally during a gale there is, in the lower part of the atmosphere, a spiral motion inclining downwards and towards the centre; and in the higher regions a like spiral motion inclining upwards and towards the exterior. He adds that, in storms of great extent, there is sometimes found a considerable area within which the winds are moderate and blow in various directions. These characters of a revolving storm appear to be verified by the manner in which trees were prostrated during the hurricane which occurred in New Brunswick in June, 1835; when, about the centre, bodies of great weight were carried spirally upwards, and, on opposite sides of the storm's path, the trees were thrown in contrary directions. It is observed that when a storm rages violently, the doors and windows of houses are often forced outwards, either from the centrifugal force caused by the revolving motion, or from the expansion of the air within, when a temporary rarefaction takes place on the exterior; and from the movements of the clouds it appears often that a storm, in passing over a place, is in activity at a considerable altitude before it descends to the earth's surface.

That a whirlwind may have a progressive as well as a revolving motion may be easily understood if it be observed that, as the atmosphere in the tropical regions moves from east to west with respect to the surface of the land or sea, it may, after crossing the Atlantic and Pacific oceans, be arrested in its progress westward by the continents of America and Asia, and deflected from thence towards the poles: the whirlwinds formed by electricity or otherwise in the general current of air will consequently be carried with the deflected branches into high northern and southern latitudes; and it may occasionally happen that, from the nature of the deflecting forces, the path of the axis of a revolving storm in either branch is a curve line like a segment of a circle or a parabola. Sir John F. W. Herschel, at the meeting of the British Association in 1838, suggested that the Gulf-Stream may be the cause of the nearly parabolic curves assumed by the paths of the storms on the coast of North America: the paths nearly coincide with the course of this stream; and the warmth of the water, by increasing the temperature of the air above it, must disturb the equilibrium of the atmosphere, and maintain the storms which had their origin in a lower latitude.

It is evident that the velocity of the wind in a revolving storm must be the greatest and the least respectively on opposite sides of the axis of rotation, in a diameter which is perpendicular to the path of that axis; for on one side the direction of the revolving current conspires with that of the progressive motion of the storm, and on the other it is contrary to it. In other parts within the limits of the storm the direction and velocity of the wind must be compounded of the rotative and progressive motions; and it will happen frequently that a temporary calm is experienced at each point on the earth's surface at which the axis of the storm successively arrives.

The phenomena of tropical storms are not precisely such as they would be if the air had a simple movement of rotation; the particles of air, while revolving, are probably subject to undulatory motions in spiral curves, and the wind appears sometimes to shift to different points all round the compass. Mr. Redfield states that, in small whirlwinds, the axis of rotation appears at times to describe gyrations in looped curves about its mean place in the line of progressive motion; and the like gyrations probably take place in those of an extensive kind; indeed in some voyages under the influence of revolving storms they have been actually observed: but in order to simplify the explanation of the phenomena of whirlwinds, it is usual to assume that the particles of air revolve in the circumferences of circles whose centres are in the axis; the latter having at the same time a movement of progression in a rectilinear or curvilinear direction. Now, if the plane of the paper represent the surface of the sea, and a line through A_1, perpendicular to it, represent the axis of a whirlwind whose north and south diameter is N., S., and in which the particles of air are supposed to revolve (for example) in the direction indicated by the order of the letters N., W., S., E.; the progressive movement of the axis being also supposed to be from A_1 through N., or from south to north: then, since at N. a tangent to the circle lies due east and west, it is evident that a ship at that point would experience a wind blowing from the east when the centre of the storm is at A_1; and if the ship remain stationary, the wind will continue to blow from the same quarter till A_1 arrives at N., the tangents to the concentric circles supposed to be described by the particles being due east and west at the northern points of the circumferences as they successively arrive at N., and the wind in all the northern half of the storm revolving in the direction E., N., W.: but after this time, the wind blowing in the



direction W., S., E., must be felt at N. as a west wind till the remaining half of the storm has passed over that point. In like manner, if the axis of the storm were to move from A_1 towards W., a ship supposed to be stationary at the latter point would feel the gale from the north till A_1 arrives at W.; after which, as the eastern semicircle passes over that point, the ship would experience a wind from the south.

Again, if the axis were to move from A_1 towards A_5, that is, from south-west to north-east, for example, the direction of the whirlwind being, as before, according to the order of the letters N., W., S., E., and the ship being supposed to remain stationary at some point, as M, till the storm has passed over it, then the line of direction in which the points of the whirlwind successively overtake the ship being $M_1 M_5$, parallel to $A_1 A_5$, the arcs aM_1, bM_1, &c., will represent the several directions in which the wind will successively be felt at the ship during the continuance of the storm. Thus, the axis of the whirlwind being at A_1, the convex surface of the storm has just reached the ship, and the wind blows in the direction aM_1, or in the circumference of the circle whose centre is A_1, that is, nearly from the east-south-east; next, the axis being at A_2, the point M_2 in the circumference of the circle whose radius is $A_1 M_2$, is at M_1; and then, at the ship the wind is felt in the direction bM_1, or in the circumference whose radius is $A_2 M_1$, or its equal $A_1 M_2$, that is, nearly from the east-by-south. Again, the axis being at A_3, the point M_3 in the circumference whose radius is $A_1 M_3$, is at M_1; and then at the ship the wind is felt in the direction cM_1, or in the circumference whose radius is $A_3 M_1$, or its equal $A_1 M_3$, that is, from the north-east. When the axis is at A_4 and A_5 the points M_4 and M_5 arrive at M_1, and the wind there is felt successively in the directions dM_1 and eM_1, that is, nearly from the north-by-west, and from the north-north-west. When the axis has advanced beyond A_5, it is evident that the whirlwind ceases to have any effect on a ship at M_1. If tangents were drawn at M_1 to the arcs bM_1, cM_1, &c., they would evidently be parallel to tangents at the corresponding points M_2, M_3, &c.; therefore the directions in which the circumference of the concentric circles meet the line of direction $M_1 M_5$ will be those in which the wind is felt at the ship during the storm. In like manner, the successive directions in which the wind blows in a revolving storm may be exhibited, whatever be the situation of the ship and the movement of the axis of rotation.

The diagram, therefore, may be regarded as a plan or a horizontal section, or, more accurately, a section at right angles to the axis, of a revolving storm. In the sequel of this article another diagram will be found, presenting vertical sections of such storms, or sections parallel to their axis, and at right angles to their greatest diameter.

The hurricanes or whirlwinds of the Atlantic commence in a part of the ocean which is frequently designated the region of variable winds, and is situated between 10° and 20° N. lat., and between 55° and 60° W. long., and their progress along the coast of the United States is marked by the devastation they so often produce. They are felt between July and October, but they are most frequent and violent in August and September; and being on the great line of communication between Europe and the West, the phenomena which they present have been more attentively observed than those of the storms in any other region of the earth. The valuable publications of Mr. Redfield contain nearly all the details which have yet been collected concerning them; while the works of the late Sir W. Reid [REID, SIR WILLIAM, in BIOG. DIV.], especially that entitled 'An Attempt to develope the Law of Storms,' contain almost all that is known of the whirlwinds in the southern hemisphere.

In the 'American Journal of Science,' vol. xx., it is shown that the storm which took place in September, 1821, began in the West Indies, and arrived off the coast of the United States, in lat. 35° N., at daylight, September 3rd, when the wind blew from E.S.E. On the same day, at 11 A.M., the storm commenced at Cape Henlopen, with the wind in the same quarter, but it afterwards shifted to E.N.E., and blew during nearly an hour: a calm of half an hour succeeded, when the wind shifted to W.N.W., and blew with great violence. At New York the storm commenced at 5 P.M., from E. and N.E., the wind blowing with fury for three hours, and then it changed to W. At Boston the hurricane commenced at 10 P.M., but beyond this city it was not traced. All the phenomena just mentioned indicate, agreeably to the principles above explained, a revolving hurricane in which the direction of the rotation was according to the order of the cardinal points, N., W., S., E., while the progressive movement of the axis was about N. by E. The temporary calm at Cape Henlopen seems to show that the centre of the vortex was then near that place.

In the same work it is stated that, during the hurricane of 1830, at the Bahama Islands, the wind veered almost round the compass in the night of August 14. The storm appears to have passed from the island of St. Thomas, near Porto Rico, to the south-east coast of Nova Scotia, in about six days, consequently it must have moved at the rate of about 17 miles per hour; and by the positions of the different points at which its effects were at the same time felt, its diameter must have been about 150 or 200 miles.

A movement of progression combined with a movement of rotation in the direction of the points N., W., S., E., is also indicated by the phenomena of the Barbadoes hurricane in August, 1831, in July, 1837, and of the hurricane at Antigua, August 2 of the latter year. But of the North Atlantic storms, that which presents the most remarkable phenomena is one which raged between the 12th and 23rd of August, 1837. Details of the circumstances attending it have been given at length, with a chart of its course, by Sir W. Reid, in his work on storms; and it appears that it was first felt in lat. 17° 30′ N., about 400 miles eastward of Antigua, though it may have had its origin still farther eastward.

By the effects experienced at different points on the ocean, Sir W. Reid concludes that the centre or axis of the storm advanced at first from east to west nearly; and after moving in that direction about two days, it turned towards the north-west, as if the storm had been abruptly deflected from the land; and when the whirlwind ceased to be noticed, it was passing eastward across the Atlantic to the south of Newfoundland. On the 18th of August, 1837, a ship, named the Rawlins, was becalmed for an hour in lat. 30° 30′ N. nearly; at that time another, named the Calypso, above three degrees northward of the Rawlins, was thrown on her beam-ends with the wind successively at N.W., W., and S.W.; and a ship, named the Sophia, situated about as far towards the north-east of the Rawlins, evidently eastward of the storm's centre, experienced the hurricane from the E.N.E., E., and E.S.E. Previously to the temporary calm, the wind at the place of the Rawlins had been N.E. by E. and N., and afterwards it suddenly changed to the S.W. These circumstances sufficiently indicate that the whirlwind had then a progressive motion towards the north-west, and at the same time a rotation in the direction of the points N., W., S., E. On the 20th of August the wind at the point occupied by the Sophia appeared to veer back, first to the east, and subsequently to the north; and since at this time the progressive movement of the hurricane had changed from a south-west to a north-east direction, the veering of the wind admits of being explained on the supposition that the Sophia had then fallen into the western semicircle of the whirlwind, while the latter, still revolving in the same direction, passed over her.

That independent whirlwinds occasionally interfere with each other may be inferred from the circumstances attending the voyage of the Castries from St. Lucia to England in the same year (1837). This ship, between the 14th and 25th of August, sailed nearly from south to north on the chord of the arc described by the centre of the great hurricane just mentioned. On the 14th and 15th, in about the 18th degree of north latitude, where the wind usually blows from the east, she felt a gale, which at first came from S.S.W., and afterwards changed to S.E., as if she had crossed the eastern side of a storm revolving in the direction N., W., S., E., and whose centre was moving nearly from east to west: this was in fact the said hurricane near the place where it was first observed. The Castries then sailed northward with fair weather till August 24th, when, in lat. 35° 46′ N. and in long. 57° 40′ W. nearly, she was overtaken by a whirlwind which passed over her. Now this could not have been the great hurricane before mentioned, since at that time the latter had passed beyond the spot towards the N.E., and the rotation at its southern extremity must have caused at the place a west wind to be felt; whereas the direction of the wind at the ship was at first from E.S.E., subsequently changing to N.E., N., and N.W.: the ship must evidently therefore have been then in the north-eastern side of a whirlwind coming up from the S.E., and revolving, like the others, in the direction N., W., S., E. This whirlwind must have fallen into the track pursued by the former, and probably both became afterwards blended together.

Mr. Redfield, Professor Dove, and Sir W. Reid, independently of each other, and nearly at the same time, ascertained, from the accounts of persons who had navigated the southern hemisphere, that in the whirlwind storms of those regions the rotation takes place in the order of the cardinal points N., E., S., W., or contrary to that in which the rotations are made in the North Atlantic, the axis of the storm having also a progressive motion from the equator obliquely towards the south pole. Such appears to have been the nature of the storm near the isle of Rodrigues, February, 1807, in which the Blenheim, the flag-ship of Sir Thomas Troubridge, foundered; for it is observed by Sir W. Reid, that the Harrier, brig of war (one of the squadron), by scudding before the wind from the 1st to the 4th of February, described about three-quarters of the circumference of a circle in the order just mentioned. And since the ships first received the wind from the north-east, it may be inferred that, by sailing south-westward faster than the storm advanced, they actually overtook it at its south-east side. A like circumstance occurred to the ship Neptune, during its voyage from Calcutta to the Cape, in 1835. From a French account of the hurricane which was felt at Mauritius in March, 1818, it appears that the wind began early in the morning to blow from S.S.E. and S.; but in about an hour it changed to E.; and at daybreak it became N.N.E. and N., and when the storm ceased it blew from N.W. These circumstances indicate a rotation in the order N., E., S., W., about an axis passing a little way to the north of the island, from nearly east to south-west.

But the most remarkable storm which Sir W. Reid has investigated is that which occurred in the Indian Ocean, in March, 1809, when the fleet, under the convoy of the Culloden and Terpsichore, suffered severely. The fleet, homeward bound from India, had got in lat. 21° S., when, on March 14, the hurricane became so violent that the ships were dispersed. By tracing the courses which they pursued, and also those of four ships which had sailed from the Cape to cruise near Mauritius, Colonel Reid found that the general movement of the storm from long. 80° E., where it was first felt, to long. 55° E., was from N.E. to S.W. nearly: from thence the path turned abruptly, and its direction afterwards was from N.W. to S.E. It therefore described a curve-line similar to that of the North Atlantic storm in August, 1837, but in a direction tending towards the south pole; and the manner in which the wind veered at each of the ships whose logs have been examined is capable of being represented by assuming that the rotation was, as in the preceding cases, according to the order of the points N., E., S., W.

From the 12th to the 15th of March the whole fleet appears to have been near the southern extremity of the vortex, and to have sailed in a direction parallel to the path of the axis. Seven of the ships, by *lying to* and falling to the southward, got out of the hurricane on the 15th; but on the 18th, one of them, the Huddart, fell into the southern branch of the line described by the axis, and crossed the northern extremity of the vortex as that axis moved south-eastward.

The Culloden, with part of the fleet, by sailing eastward, got, on the 15th, nearly to the centre of the vortex in the northern branch; on the 15th and 16th this ship scudded before the wind; but it afterwards changed its course to S.E., and on the 19th it got out of the storm. The ships which followed her probably continued to go before the wind; they thus kept near the centre of the storm, where they must have foundered.

In November of the same year, a hurricane which commenced in lat. 5° S. and long. 90° E., appears to have had little progressive motion; all the ships which were exposed to it experienced a temporary calm in the midst of the storm, and on the afternoon of one day, November 21, the wind veered rapidly quite round the horizon in the order N., E., S., W.

The whirlwinds in the Sea of China appear to differ in no respect from those which take place on the coast of North America. During a hurricane on the coast near Canton, August, 1829, when the East India Company's ship Bridgewater was driven on shore, the changes of the wind were successively from N. to E., and to E.S.E., ending at S.E.; therefore, if it be supposed that the course of the storm was nearly from E. to W., and that the ship was to the north of its centre, the rotation must have been in the order N., W., S., E. It has been ascertained that the rotations took place in the same order during the hurricanes of 1832 and 1835.

Little, comparatively, is known of the storms in the Pacific Ocean; but they also are of a rotatory character.

In higher latitudes the storms are irregular, probably because the vortices follow each other in the same direction and interfere with each other's gyrations. The great storm which, in 1838, was felt on the south coast of Ireland, and proceeded from thence along the west coast of Scotland, had all the characters of a whirlwind. It is stated by Sir W. Reid, that on the 14th of February, while at Cape Clear, the wind blew from S.E.; off Oporto the gale was from S.W.; at the same time, at the bottom of the Bay of Biscay, it was felt from S. and S.W.; and at the Shetland Islands, from the 16th to the 20th of February, the wind blew successively from S.E., S., and S.W. At Cadiz, between the 7th and 12th of February, the wind blew from S.W. and W.; and on the 16th, off Lisbon, there were heavy gales from S.W. to W.N.W. All these circumstances indicate a storm revolving in the order N., W., S., E., while its centre advanced in a line nearly from south to north. Professor Dove has remarked, in his paper already referred to, that in Prussia all storms are great whirlwinds, which continue during one or several days, sometimes as many as twenty, the rotation of the wind being generally in one direction.

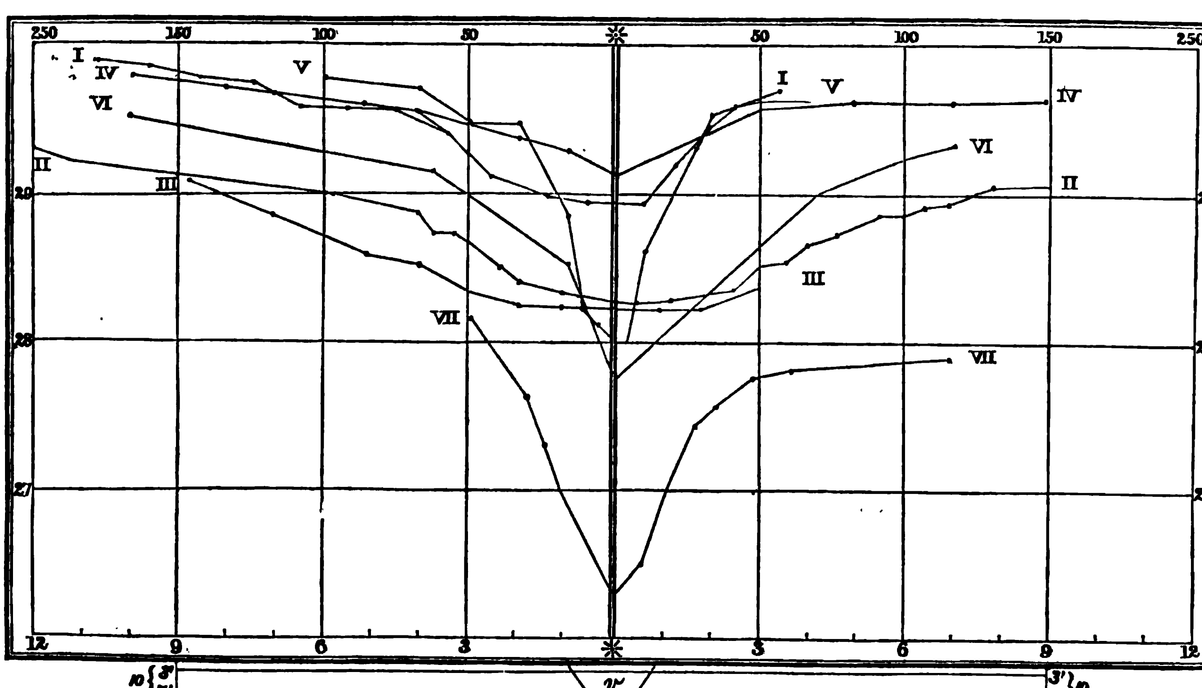
It resulted from the investigation and comparison of these and other facts by Mr. Redfield and Sir W. Reid, that a revolving storm, or Cyclone, as it is called, rotates, in the Northern hemisphere, from the east, or the right hand, by the north, towards the west, or *contrary* to the hands of a watch; and, in the Southern hemisphere, from the west, or the left hand, by the south, towards the east, or *with* the hands of a watch. Professor Dove expresses the same fact, beginning in both cases with the right hand, or the east side of the cyclone, by S., E., N., W. for the Northern hemisphere, and N., E., S., W. for the Southern.

The variations in the height of the column of mercury in a barometer afford, within the tropics, indications of the approach and the state of a whirlwind; the column is observed to fall gradually during part of the time that the storm continues at a place, apparently till the centre of the vortex has passed over, and then to rise as gradually. The depression of the column continues also during the movement of a storm from one region to another; the centrifugal tendency of the revolving particles probably opposing that of gravity, by which the particles would otherwise move towards the axis of rotation. Proofs of these circumstances are given by Sir W. Reid from observations made at Mauritius, during the hurricanes in March, 1819, and in February, 1824.

As the investigation of the subject has proceeded, the observation of the depression of the barometer during a revolving storm has been found to be of the utmost importance, as well in a philosophical as in a practical point of view. The fact is connected inseparably with the general history of the atmosphere. That a considerable decrease of pressure should be an effect of any unusual disturbance in it is a supposition so natural, that it at once occurred to those who first remarked that the weight of air surrounding us is not always the same. For the purpose of measuring these changes, the inventor of the air-pump, Otto Von Guerike attached a scale to the water barometer, which he also invented, and he records an observation that in the year 1660, the index pointed below the lowest mark on the glass tube, on which he had confidently affirmed that there was a great storm somewhere, and that, two hours afterwards a tempest was raging in the district of Magdeburg. As a more recent example, Dove mentions the great storm of January 17, 1818, which extended from the shores of England to Memel, and was felt throughout a region 240 German miles in length, and during which the barometer fell eight lines in as many hours, having also fallen between the 3rd and the 17th of January in all twenty-one lines, or an inch and three-quarters. The experience of the last two centuries indeed has so far confirmed the remark of Von Guerike, that the scales attached to our common barometers usually terminate with "very stormy." But its applicability is not confined to the temperate zone: in lat. 70° N., long. 70° W., the warning afforded by a considerable fall in the marine barometer, enabled the celebrated navigator Scoresby to avoid the dangers of a tempest which lasted two days uninterruptedly. Sir W. Reid, as we have just seen, established corresponding facts in relation to the revolving storms of the Indian Ocean; and in the regions of the trade winds, and of the monsoons, the numerous examples of greatly diminished pressure ushering in the typhoons and West India hurricanes are now well known.

The 'Law of Storms,' principally by the skilfully conducted and continued researches of Mr. Redfield and Sir W. Reid, having been brought into the condition explained in the preceding columns, and the latter, especially, having indicated to the seaman not only how he might, by applying the acquired knowledge of that law, avoid the dangers of hurricanes, but even profit by their intervention in his voyage, a new advance was given to the subject; a new explorer being added to those by whom it had been investigated, and who, indeed, had been pursuing his own researches contemporaneously with some of theirs. The late Mr. Henry Piddington, President of Marine Courts, Calcutta, communicated to the Asiatic Society of Bengal, in 1839, the first of an extensive series of memoirs, in which he discussed the phenomena of revolving storms in the Indian and Chinese Seas, as recorded in the log-books of the ships which had experienced them, and in various other documents. These having been first printed in the 'Journal' of the Society, Mr. Piddington published a valuable digest of their results, and of those obtained by his contemporaries, in a work entitled 'The Sailor's Horn-Book for the Law of Storms,' of which several editions appeared, the first in 1848 and the second in 1851. In the first edition of this work, the author proposed the designation of *Cyclone*, from the Greek Κυκλος, a circle, also the coil of a snake, for hurricanes, typhoons, revolving storms, and circular blowing gales in general, superseding, for nautical as well as scientific purposes, all the terms previously in use. This designation having been universally adopted, we shall employ it in the remainder of this article, premising, however, that the term 'whirlstorm' has been recommended by some as an apt English emphatic synonyme when required.

Mr. Piddington constructed, and published in his work, what he termed a barometrical chart, exhibiting certain numerical phenomena of seven cyclones, which, as being one of the most instructive graphical representations of physical facts we have ever seen, and as giving what may be called vertical sections of the cyclones, we have copied in the diagram annexed.



A few words in explanation are required. The double set of numbers and spaces at the top line of the diagram, forms a general scale of distances in miles from the centre of each cyclone. The double set at the bottom forms a scale of hours before and after the passage of the centre. The numbers and spaces at each side denote the heights of the barometer in inches. The Roman numerals refer to the cyclones enumerated in the following list, the barometrical observations taken as standards being such as were made on shore, which alone could be used in a construction of this description—a circumstance enhancing the value of the chart; few observations of the phenomena of cyclones, as may be supposed, having been made on the land.

The diagram thus comprises—

	Authority.

V. Duke of York, Kedgeree, mouth of the Hooghly . . .	1833, Mr. James Prinsep, 'Jour. As. Soc.,' vol. iv., Reid, p. 291.
VI. Havanah	1846, 'Bermuda Royal Gazette.'
VII. Madras	1841, Observatory Reports, 5th Memoir, 'Jour. As. Soc.,' vol. vii.

The principle on which the diagram is constructed, is to take without reference to the hour of the day or night at which it occurs, the lowest point of the barometrical depression in a cyclone, as the centre or axis of that storm. This is placed on double, or axis lines in the middle, and the fall and rise, and the time in which these occur are shown on a scale of hours below, and of inches to the right and left. We have thus the cyclones brought together and placed upon each other, as it were, for comparison, under exactly equal conditions as to time, and as to the fall of the mercury in that time. The scale of miles above will be presently explained.

And we are immediately struck with the fact, that there are evidently two distinct classes of cyclones, compared by Dove to deep ravines with precipitous sides, and to extensive valleys with gentle declivities, in one of which the fall and rise are more or less gradual, forming an easy curve, while in the others it forms not so much a curve but almost an angle, or rather the figures called by opticians caustic curves, and in these last cyclones the fall has been excessive and the fury of the tempest far beyond the average of such visitations. We may thus divide the storms into a first and second class; the first class being those of the greatest (excessive), and sudden falls near the centre.

There is also evidently another peculiarity, that is, that all the rapid part of the fall seems to begin at from three to six hours before the passage of the centre, and that before that time the fall even of the violent cyclones is comparatively gradual, and in fact approaches closely to the second class.

The scale which Mr. Piddington, after much consideration, found the nearest to the probable truth, is that marked in miles on the upper part of the diagram, though this is to be considered as by no means strictly a limit; for, as regards limits, he says it may possibly be found in the end that there are no strict ones at all, and that even the various extremes may be wider apart than the following table will indicate:—

An average fall of the barometer per hour of		Shows the distance of the centre from the ship to be in miles,	
From.	To.	From.	To.
0·020 . . .	0·060	250 . . .	150
0·060 . . .	0·080	150 . . .	100
0·080 . . .	0·120	100 . . .	80
0·120 . . .	0·150	80 . . .	50

The third decimal of the barometer heights is replaced by a cypher.

"I have not set down anything," Mr. Piddington remarks, in continuation, "for the centre division of our table, that is, from the centre to $3h$ before its passage, for it will be seen that the rate of fall per hour doubles after the cyclone has fairly begun and lasted six hours; and that then (from $3h$ to ‖, or from nine hours after the commencement up to the centre) it may either continue to fall at the same rate of about 0·1 per hour, or a little more, or that its rate of fall per hour may be, if it should be a cyclone of the first class, as 100 to 400, when compared with that of the former three hours; or, in other words, that it will now begin to fall four times as fast, or 0·40 per hour! We have plenty of instances of this, and even of a fall of more than 0·5 or 0·75 (half or three-quarters of an inch) in the hour! I doubt not that this peculiarity will fully account to the seaman for, and I hope put him well on his guard against, cases of sudden falls, which, if they occur at the beginning of cyclones, as they sometimes do, are warning enough, of course; but which may also advise him of his too near approach to danger of such imminence that we may at least say that no ship can hope to escape from it with her masts standing; and he should in such cases have the axes upon deck—a precaution too often neglected by young commanders and officers, who are apt to suppose that caution indicates fear, and they are sometimes afraid of being thought afraid of the storm. It will be remembered, also, that it is quite impossible by any previous rates of fall to estimate, when so near the centre, which of the classes of storms we have to deal with; and I repeat that what we have to do with our ship must all be done before this time."

Below the framing-line, at the bottom of the diagram, is represented in section, on a very small scale, the entire form of cyclones, as from Mr. Piddington's discussion of his own and other results it would appear to be—a disc, the thickness or height of which measures a very small fraction only of its diameter. The lines indicate the discs of cyclones of 300 miles in diameter, and of 10, 7, and 3 miles in height respectively, with a supposed vortex (v) at the centre, which has a calm of 10 miles at its base. "The reader," Mr. Piddington remarks, "may from this estimate what it would be if 5 or even 15 miles high, and how fallacious all our notions are apt to become when we consider these storms as whirling *columns*, and insensibly go on to liken them to waterspouts as to height, which it is evident they cannot at all resemble, since their size (diameter) may be said to have been in many cases estimated to a few miles with tolerable correctness; and in frequent instances the next stratum of clouds above the storm, either at rest or moving altogether differently, has also been clearly distinguished and noted: so that we may boldly affirm that at most the height (thickness is the more correct word) of the disc never exceeds 10 miles, and usually falls far short of it." The cyclone-disc, indeed, is sometimes so thin, that at or near the centre, whether calm or not, it has often been seen through, of which the following, in Mr. Piddington's opinion, are instances:—Dr. Malcomson, in describing a cyclone in the Arabian Sea, in which a ship was dismasted and in great danger, after alluding to the intensely dark masses of clouds that pressed down, as it were, on the troubled sea, states that, "In the zenith there was visibly an obscure circle of imperfect light of 10 or 12 degrees." In another storm, which was a true cyclone by its veering, and a tornado as to duration and violence, while all round the horizon was a thick dark bank of clouds, the sky above was so perfectly clear that the stars were seen. In the cyclone, one of the number investigated by Mr. Piddington, of October, 1849, in the Bay of Bengal, at the time of the passage of the centre over the lighthouse at False Point, Palmiras, or for about two hours of calm, the stars were seen very clear overhead, with a thick bank of haze all round. In this instance, also, the observers in several ships speak of a circle of light, or of its being much clearer overhead at the centre; "and this is exactly the appearance which should occur to an observer situated at the centre of a thin disc, as well as to one in the focus of a thick vortex." The phenomenon, in fact, is so constant, as to have received a name from the Spanish navigators, who call it "the eye of the storm."

We proceed to explain some popular designations connected with the subject, and the phenomena to which they more specifically relate:—

Tornado, a whirlwind, from the Spanish *tornar*, to turn, is the term given to a sudden and violent cyclonal storm, accompanied by lightning and thunder and heavy torrents of rain, as observed originally on the coast of Africa, and in the Spanish West Indies. Terrestrial bodies within its influence are violently displaced, or the ocean is strongly agitated: on land, forests, plantations, and buildings are destroyed; and at sea, ships are engulfed or driven on shore: the effects are of course the greatest near the circumference of the vortex, and the space within which they are felt varies in extent; sometimes the diameter of the area is several miles, and at other times it does not exceed one hundred yards. The approach of the storm is foreboded in the morning by the appearance, over the land, of dark clouds which move towards the sea, while a gentle breeze is blowing towards the shore: soon afterwards the rain comes down in torrents, and the lightning darting from the clouds resembles showers of electric matter. While the tornado is passing over a ship, which may be four or five hours from the first appearance of the clouds, the flashes cease, but the rain continues, and a loud crackling noise, occasioned by the electric fluid descending along the masts, is distinctly heard among the rigging. After the squall has passed beyond the ship, the lightnings again appear to descend in sheets as they did on its approach.

A less extensive whirlwind is frequently preceded by a remarkable tranquillity of the atmosphere and a sultry heat; when suddenly, within a circle of one or two hundred yards only in diameter, a revolving motion of the air commences, and is accompanied by thunder and rain: the velocity of the rotation gradually increases, and at length its violence is such as to tear up trees and destroy buildings which may be within the vortex. It may not continue longer than half an hour, but in that short time the damage is immense, and the loss of life is frequently considerable.

Typhoon (Greek τυφῶν, a whirlwind) is a name frequently applied to a tropical storm: it is also given to the hot winds which occasionally blow with great violence in Africa, Syria, Arabia, and Persia; and which are felt, though rarely and with much-diminished force, in the southern parts of Italy and Spain. It has been supposed that the Chinese designation for a cyclone, *Tyfoon*, was also originally derived from the Greek, but Mr. Piddington has shown, after the celebrated sinologist Dr. Morrison, that it is indubitably a Chinese word. The latter relates that there are in China "temples dedicated to the Tyfoon, the god (goddess?) of which they call *Keu woo*, 'the tyfoon mother,' in allusion to its producing a gale from every point of the compass, and this mother-gale, with her numerous offspring, or a union of gales from the four quarters of heaven, make conjointly a *taefung*, or tyfoon." The sirocco of Egypt and the coasts of the Mediterranean, the simoom of Arabia, and the harmattan of the coast of Guinea, are understood to be so many designations of the typhoon; all of them being supposed to originate in the same cause.

Frequently when the winds have a whirling as well as a progressive motion, columns of sand are raised and driven about with great rapidity; and Burckhardt observes that in Africa and the East the dust obscures the face of the sun, giving to the atmosphere a blue, a yellow, or a reddish tint. [DUST, ATMOSPHERIC.] M. de Humboldt occasionally observed columns of sand in motion in the interior of South America.

The fatal effects which have been said to result both from the masses of moving sand and from the supposed deleterious quality of the winds, are now considered as exaggerations: the inconveniences felt by men and animals during the continuance of the hurricane are chiefly such as arise from the heat and dryness of the air, and from the quantity of sand which is blown into the eyes. [SAMIELI; SIROCCO.]

Some short notices on the theory of cyclones, and probably allied phenomena, must conclude this article. In Sir J. Herschel's 'Report on the Reduction of Meteorological Observations,' presented to the thirteenth meeting of the British Association, 1843, after discussing the philosophy of what he calls winds of barometrical oscillations, arising from local and temporary causes prevailing over great areas simultaneously, and occasioning, eventually, an extensive atmospheric undulation, he applies the subject to the theory of cyclones in the following manner:—"Some of the principal of the phenomena of revolving storms would seem capable of explanation in this way of conceiving winds of oscillation, and in which they would become traced up, not to funnel-shaped revolving depressions in the nature of waterspouts, but simply to the crossing of two large long [atmospheric barometrical] waves running in different directions. The way in which a rotary movement in an ellipse or circle, or in in some other partly oval and partly rectilinear figure, may result from the combination of two rectilinear movements of advance and recess, will easily be understood by the analogy of the circular and elliptic polarisation of light, where rectilinear movements of the ethereal molecules are conceived to be similarly combined. [ELLIPTIC POLARISATION.] Some features in such storms are strongly in harmony with this view, namely, the fact that in them the direction of the wind at a given locality never makes more than one rotation, and not always that; and that in the central line of the storm's progress there is a simple and sudden reversal of direction. On the other hand, it must not be concealed that some features militate against it; for instance, the fact that such gales are stated always 'to revolve' in one direction, whereas, on this view of their origin, the changes of wind ought to be in opposite directions on opposite sides of the medial line."

M. Lartigue, in a paper on the storms of the Pyrenees, communicated to the French Academy of Sciences on the 3rd of December, 1855, and of which an abstract appears in the 'Comptes Rendus,' has some remarks on their analogy to the hurricanes of the intertropical regions, and of the seas adjacent to the coasts of the United States of America. In these he announces an explanation of cyclones substantially identical with that of Sir J. Herschel here given. Two illustrative diagrams represent a storm determined by winds the direction of which are perpendicular to each other, and another produced by winds having diametrically opposite directions.

The following important suggestion on the immediate cause of hurricanes, has been made by Sir J. Herschel in several of his works, both anteriorly and subsequently to the preceding: it is now extracted from 'Outlines of Astronomy,' 1849, par. (245), note:—"It seems worth inquiry, whether hurricanes in tropical climates may not arise from portions of the upper currents [of heated equatorial air] prematurely diverted downwards before their relative velocity has been sufficiently reduced by friction on, and gradual mixing with, the lower strata, and so dashing upon the earth with that tremendous velocity which gives them their destructive character, and of which hardly any rational account has yet been given. But it by no means follows that this must always be the case. In general, a rapid transfer, either way, in latitude, of any mass of air which local or temporary causes might carry *above the immediate reach of the friction of the earth's surface*, would give a fearful exaggeration to its velocity. Wherever such a mass should strike the earth, a hurricane might arise; and should two such masses encounter in mid-air, a tornado of any degree of intensity on record might easily result from their combination."

The manner in which this is related to the principle enunciated by Hadley to account for the trade-winds (col. 926), and developed by Dove in his Law of Rotation, will readily occur to the reader. Sir J. Herschel, when last noticing the subject, in his 'Treatise on Meteorology,' alludes to that principle and its development, as applied to this specific class of aërial movements by Professor Taylor, as affording "a complete account of all the characters of cyclones."

In the article WATERSPOUTS, the opinion has been expressed, that probably phenomena of several distinct classes are at present confounded together under that appellation. Sir J. Herschel, contravening, as it would appear, his former opinion, now regards them as of the nature of cyclones. Mr. Piddington, as we have seen, carefully discriminates between them, at least as to form, on account of the discoidal character of the one set of phenomena and the columnar figure of the other; notwithstanding his admissions that waterspouts have the characters of whirlwinds, and exhibit them manifestly when they advance upon the land. It seems difficult to refer to the same causes a disc of which the thickness or height is a very small fraction of its diameter, as in cyclones, and a slender column of which the diameter is an equally small fraction of the length or height, as in the waterspouts observed on land by Major Sherwill, and at sea by the Rev. Dr. Scoresby. The former describes the powerful attraction, which he naturally attributes to electricity of the summit of the mountain Tonglo, for certain waterspouts. This is strongly corroborated by some facts stated by another Indian observer, Captain Montgomerie, B.E., of the Trigonometrical Survey of India, who found, on the Pir Punjal peaks of the Himalaya, south of Cashmere, at elevations of from 13,000 to 15,000 feet, the electricity to be so troublesome, even when there was no storm, that it was necessary to carry a portable lightning conductor for the protection of the theodolite. Still, however, waterspouts, if of mere mechanical origin,—if merely excessively rapid gyrations of condensing vapour or closely approximated globules of water,—might, and in all probability would, exhibit powerful electric action. If their form be so sustained, enormous friction of the particles must ensue, and a corresponding amount of electricity be developed; the entire column would be strongly charged, and would eventually attract and be attracted by the ground. The sudden precipitation of the water may be the united effect of the electrical discharge and of the destruction of the sustaining gyration by contact and friction with the fixed mass of the land. But everything tends to show that our ideas of waterspouts are inexact, and that the subject of their origin and nature and relation to mere gyrations of the air, is in need of that critical discussion which all the complex phenomena of nature require, and but few of them have received.

The force of the winds has been noticed under AËRODYNAMICS, and the means of measuring it described under ANEMOMETER. In Mr. Piddington's *Sailor's Horn Book*, a catalogue of other works on the Law of Storms will be found, and on that subject, and that of the winds in general, may be consulted (in addition to the works and memoirs which have been cited in this article), Admiral Beaufort's *Remarks on Revolving Storms*; and also Mr. W. R. Birt's *Hurricane Guide*; and his article on Atmospheric Waves in the *Admiralty Manual of Scientific Enquiry*.

WINDAGE is the quantity by which the bore of a gun, mortar, or howitzer exceeds that of the shot or shell which is to be discharged from it.

The deviations of shot and shells from a truly spherical figure, and the inequalities in the bore of the ordnance, were formerly considerable; and on these accounts it was necessary to have a sufficient difference between the presumed diameters of the ball and bore, in order to ensure the possibility of making the former enter into the latter: it followed, from the greatness of this difference, which in the British service was about one-twentieth of the diameter of the bore, that much of the fired gunpowder escaped without producing any impulse on the shot, and that the latter was driven from one part of the surface of the bore to another; so that, on being expelled from the gun, it deviated widely from the intended direction of its flight.

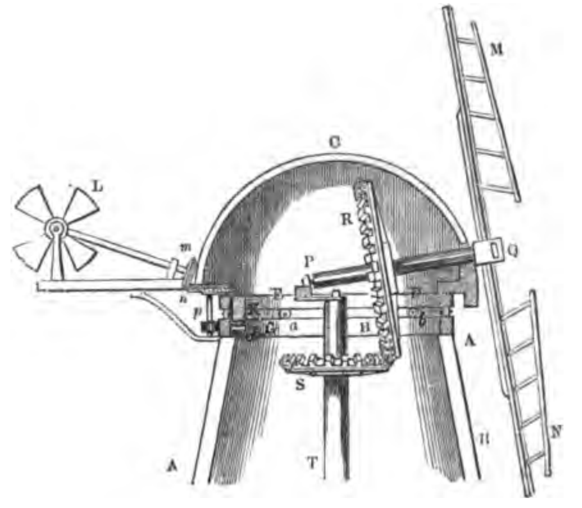
From the year 1775, when Dr. Hutton made his first experiments on the velocities of shot, the disadvantage attending a great windage was known, and a diminution of its quantity was proposed; but the precise amount of the force lost by it was not ascertained till the years 1784 and 1786, when experiments were made for the purpose, in part, of determining that important circumstance. From these it appeared that about one-fifth of the charge of powder was lost by a windage equal to ·06 inch, or $\frac{1}{33}$rd of the calibre (= 2 inches), and a further loss, amounting to between $\frac{1}{4}$th and $\frac{1}{3}$th of the charge, was occasioned by an increase equal to $\frac{1}{10}$th of an inch above the former windage.

The correct geometrical forms which are now given to the balls, and also to the bores, permit the windage to be reduced much below its former value; it now varies only from $\frac{1}{40}$th to $\frac{1}{32}$nd of the calbre, in no case exceeding 0·2 inch even for the largest guns, and is still in process of reduction, as the manufacture of shot and shells advances in precision.

WINDLASS, an apparatus for raising a ship's anchors. It is placed forward, as near to the hawse-pipe as convenient. A machine subject to such violent strains as those which constantly affect a ship's cable when in use, is necessarily built of the soundest oak and the best iron in all the parts constructed of those materials, and is secured by stout vertical pieces of timber called *bitts*, which rise above the deck and serve the purpose of fastenings for the cable, which has first two or three turns round the barrel of the windlass. The cable is wound either by means of handspikes or a winch. As windlasses for ships are so varied in form and principles, it is unnecessary to enter into detail. These dimensions have of late years been greatly modified in consequence of the alteration of form in ships, and especially steamers, where the narrowness of the bows admits but of little length to any cable-raising contrivance. [GROUND-TACKLE.]

WINDMILL is a building containing machinery for grinding corn, pumping water, sawing wood, or for any purpose depending on wheel-work, to which motion is communicated by the impulse of the wind. Windmills are of two kinds: in one, the wind is made to act upon vanes or sails, generally four, which are disposed so as to revolve by that action on an axis which is nearly horizontal, in a plane which is nearly vertical; and in the other, the axis of revolution being precisely vertical, any point on the surface of the vane revolves in a horizontal plane. The former is called a vertical, and the latter a horizontal windmill.

The building is generally a wall of timber or brickwork in the form of a frustum of a cone; and the smaller kind of mill when formed of timber is capable, by means of a lever, of being turned round horizontally on an axis, in order that the plane in which the radii or arms of the sails revolve may be placed perpendicularly to the direction of the wind, for the purpose of allowing the latter to act upon the sails in the most advantageous manner. In other kinds of mills the conical wall, A B, is terminated above by a wooden dome, C, which is capable of



revolving horizontally upon it. A ring, E F, of wood, forming the lower part of the dome, rests upon a ring, G H, of the same material at the top of the wall, and the surfaces in contact being made very smooth, the former may easily be turned round upon the latter, being prevented from sliding off by a rim which projects from it, as at K, and descends over the interior circumference of the lower ring. The revolution is however facilitated by placing between the two rings of wood one of metal, in which are fixed four or six small wheels or rollers, as *a b*, on horizontal axles. The weight of the dome is supported on these rollers, which turn by its motion. Small wheels or rollers, as *d*, are also fixed on vertical axes in the projecting rim just mentioned; and as the dome revolves the circumferences of these rollers press against and turn upon the interior faces of the ring which is fixed on the top of the wall.

The dome in turning carries with it the windsails, M N, and their axle, P Q; and thus the latter may be made to coincide with the direction of the wind, or the plane in which the radii of the sails turn may be made perpendicular to that direction. The revolution is sometimes accomplished by the force of a man applied to a winch near the ground. An endless rope, as it is called, or one whose ends are spliced together, passes under a pulley on the axle of the winch, and over one near the top of the mill; and the latter pulley in revolving gives motion to a wheel and pinion, the last of which works in teeth on the exterior circumference of the ring which forms the lower part of the dome.

But in general the wind itself is made to turn the dome of the mill so that the sails may continue in the proper position with respect to the direction of the wind. For this purpose there is provided a set of small vanes, L, which are situated at the extremity of a long horizontal arm projecting from the dome in a plane passing through the vertical shaft of the mill, and on the side opposite to the great sails. These vanes turn on a horizontal axis at right angles to that plane, and are set in motion by the pressure of the wind when the latter deviates from the plane of their motion, or from a plane perpendicular to that in which the radii of the great sails revolve. A pinion on the axis gives motion to a wheel, and the axle of this last carries a pinion, *m*, whose teeth work in those of the wheel *n*; the axle of this last carries a pinion, *p*, whose teeth work in others which are formed on the exterior circumference of the ring G H, forming the base of the dome. By this means the dome is made to revolve horizontally, so as always to present the axle (P Q) of the windsails in the direction of the wind. It is to Sir W. Cubitt that we are indebted for this simple but invaluable improvement in the details of windmill machinery. Strangely enough, it has never yet been applied in Holland or Northern Germany.

This axle is usually inclined about 10 degrees to the horizontal line. It is supported at the inner extremity, P, which is at or near the centre of the base of the dome, on the top of the vertical shaft, S T, of the mill, and near the opposite extremity on a block under a perforation in the dome. The axle passes through this perforation, and the radii, or arms of the sails, are affixed to it on the exterior; the axle and the sails which it carries revolve with the dome about the lower point of support. A toothed wheel, R, is fixed perpendicularly on the axle, and revolves with it by the pressure of the wind on the sails; and the teeth or cogs of this wheel drive those of a lantern or pinion, S, on the vertical shaft of the mill. To this shaft, as an axle, the upper millstone is fixed, so as to revolve with it in a horizontal position; and the corn being placed in a hopper, or funnel, is allowed to run from thence between the stones through a small channel, and through a perforation about the centre of the upper one. The lower millstone is stationary, and the corn being ground, the meal is received in vessels underneath. The principal wheel, R, is furnished with a *brake*, by which its motion may be checked or stopped at pleasure.

The four radii, or *whips*, as they are called, of the sails, are let into the axle at right angles to it and to one another, so that a plane passing through them will decline about 10 degrees from a vertical position. Into each of these radii or arms are fixed a number of staves of wood, each five or six feet long, at right angles to it and inclined to the plane passing through the arms, but approaching nearer to coincidence with such plane, as they are more distant from the axle. The ends of these staves are inserted in a rod of wood extending nearly the whole length of the arm; and thus there is formed a sort of lattice-work on which canvas is spread to receive the action of the wind. In most cases each radius or whip of a windmill sail is about thirty-three feet in length from the axle to its extremity.

The variations in the force of the wind require that the quantity of canvas on the sails should be varied accordingly; and the contraction as well as the expansion of a sail is usually effected by means of ropes fastened to it in three places or more. These ropes may be either drawn tight or relaxed as required; but for either purpose it is necessary that the mill should for a time be stopped; and as the stoppage is attended with great inconvenience, several methods have been devised for rolling and unrolling the sails while in motion. One of these, which was invented by Mr. Bywater, consists in the application, on each arm or whip, of a cylinder or roller to which the canvas is attached: this extends the whole length of the arm, and has a toothed wheel at the extremity nearest to the axle; the teeth of this wheel work in those of two other wheels, and the motion of one or the other of these being stopped, the cylinder rolls up or unrolls the canvas, being made to turn on its axis by the action of the wind on the sail. Several methods have also been proposed for equalising the action of the wind on the sails of a mill, and they consist generally in the employment of a series of valves fixed in the frame work of each sail. These valves revolve on pivots which are let into the frames; and as the force of the wind increases, they present, in turning, less of their surfaces to its action, so that the pressure is rendered nearly equable. None of the methods seems however to be in use, probably on account of the great additional expense with which the construction would be attended. Of late years wooden lattices working somewhat on the principle of the Venetian blinds, have been used instead of canvas for the sails of windmills, and their angle towards the wind is regulated by a species of governor fixed on the main shaft; but there seem to be mechanical difficulties in the way of this system which have hitherto opposed its general adoption.

A horizontal windmill is a great cylindrical frame of timber, which is made to revolve about a vertical axis, and its convex surface is formed of boards attached in vertical positions to the upper and lower parts of the frame. The plane of each board is oblique to the lines in which the wind impinges on it, the direction in which the latter blows being supposed to be parallel to the horizon; and the whole is inclosed in a fixed cylinder having the same vertical axis as the other: this consists of a screen formed by a number of boards which are disposed so that, in whatever direction the wind may blow, it may enter between them on one side only of a vertical plane passing through the axis. The wind thus entering acts upon the oblique surfaces of the boards about the interior cylinder on one side of the axis, while it is, in a great degree, prevented by the screen from acting upon the boards on the opposite side; these boards therefore meet with small resistance when, during each revolution, they come up towards the quarter from whence the wind blows. In horizontal mills one board may receive an impulse equal to that which the wind communicates to a sail of equal area in a vertical mill; but in the latter all the sails are acted upon equally at the same time, whereas in the former only one or two can receive the impulse of the wind, and there is always, besides, some resistance experienced in returning against the wind. Mr. Smeaton estimated that the power of a horizontal mill was only about one-tenth of the power of a vertical mill, the dimensions of the sails or vanes being equal in both; but it is observed by Sir David Brewster that in this estimate no account is taken of the resolved part of the wind's force which presses the pivot of the axle against its support, and which is lost on the sails of the vertical mill; and he concludes that the power of the latter is not more than three or four times as great as that of a horizontal mill. The effective power of the vertical mill is however so much greater than that of the other kind, that the latter is now seldom constructed.

The effective force of the wind in turning the sails of a mill is investigated in the article WINDSAILS.

(See Brewster's edition of *Ferguson's Lectures;* Smeaton, *On the Power of Wind and Water;* Borgnis, *Traité Complet de Mécanique;* Leendert van Naturus, *Groot Volkomen Moolenboek*, &c.)

WINDOW. Though almost unknown in ancient architecture, at least in the religious and other monumental structures of the Egyptians, Greeks, and Romans, which were not of a nature to require them, windows are exceedingly important features in the Gothic and other styles, and that not only for one, but every class of buildings. In the Pointed Gothic more especially they are so characteristic by their general forms and proportions, as well as their decoration and details, as to be in that style equivalent to what the orders are in the temple architecture of antiquity: the division of Gothic into periods, as First, Second, and Third Pointed, or Early-English, Decorated and Perpendicular, depends indeed mainly on the window-forms. [GOTHIC ARCHITECTURE; ROMANESQUE ARCHITECTURE.] Gothic without windows would be as deficient in expression as Grecian architecture without columns. Grecian architecture, on the contrary, hardly admits windows, since, instead of adding to, they rather mar its expression, and detract from its character. There are, indeed, some examples of windows, for instance in the Erechtheum at Athens, yet no more than barely to serve as authorities, and to show how apertures of the kind were designed. Besides being of exceedingly rare occurrence in Grecian architecture, the windows themselves were very few in number, and never placed so as to form more than one tier or story of them; consequently the effect was totally different from that attending two or more continuous ranges of windows placed one over the other. This arrangement was, however, adopted by the Romans in such buildings as their amphitheatres, and also in their basilicas, and in the former with a very fine effect, as may be seen in the Colosseum at Rome, and the amphitheatres of Verona and Nîmes.

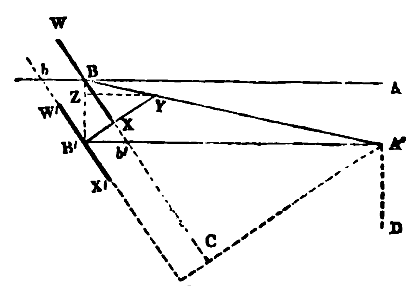
It is one very great advantage of the Pointed Gothic style, that there the windows derive strong architectural expression from the apertures themselves; which, with the mullions, transoms, and tracery inserted in them, mainly form the design and decoration; while the external mouldings and ornaments contribute to them only in a subordinate degree. Consequently, if otherwise quite plain, the windows can never appear mere vacant spaces. Widely different is it in those styles where the ornamental design is confined to the mere exterior or framing of the aperture; in which, however they may be so decorated, the openings will, if of very large dimensions, always have a vacant look, and the glazing of the windows will appear to be in want of adequate support. It is another advantage peculiar to Pointed Gothic, that it allows windows to be of any dimensions—of the smallest as well as the largest, and windows of very different sizes and proportions to be introduced into the same elevation. [GOTHIC ARCHITECTURE; ORIEL.]

In the Italian style, windows, by which we mean the window opening and the *dressings* around them, which last term is employed to designate the whole of the decoration bestowed on such apertures, or, in other words, the entire "composition," form as essential a feature as in Gothic, though admitting of comparatively little of the diversity of size, form, and character. French, German, and English Renaissance exhibit much greater variety of illustration than the Italian. [RENAISSANCE ARCHITECTURE; ELIZABETHAN ARCHITECTURE.] In Italian buildings of the better class, the principal story, or that immediately over the basement or ground-floor, is marked by windows more highly decorated and of loftier proportions than the rest. For these the apertures are generally made from 2 to 2½ squares, or even something more, that is, their height is something more than double their breadth; those on the next floor rather less than two squares; and for the third they are made *mezzanines*—either a perfect square or very little more. The character and proportions of ground-floor windows depend very much upon the manner in which that part of the elevation is treated; if it be no more than a low rusticated basement, the windows will only be of mezzanine form, without dressing; or at the most a few mouldings surrounding the apertures, the rusticated surface of the wall itself here producing a sufficient degree of finish and decoration; or if more be required, it is obtained by distinguishing the rustics around the windows, making them smooth if the others be rough, and *vice versâ*. Thus, while the windows are essential, they are still kept subordinate features in the design. What has been said in regard to the sequence of the different tiers of windows in an elevation, is to be understood only generally, there being many exceptions, and not a few anomalous cases. In the façade of the Palazzo Massimi at Rome, one of Peruzzi's best works, there are two tiers of mezzanine windows above those of the principal floor; in the celebrated Palazzo Farnese, on the contrary, the second-floor windows (which are also the uppermost) are somewhat loftier than the others, at least in their apertures, owing to these last being arched, and are further remarkable as having pediments, which are seldom used for windows higher up than the first floor. In Sangallo's façade of the Palazzo Sacchetti, there is a range of mezzanines between the windows of the first and the uppermost floor, and instead of being made principal in the design, the former are considerably less than those of the ground-floor, and are narrower at top than at bottom. The façade of the Palazzo Negroni, by Ammanati, is similar in its general character to the preceding, there being a row of mezzanine and square windows between the first and third floor; and it also resembles it in the importance given to the ground-floor windows. In regard to windows of the last-mentioned class, the Palazzo Buoncompagno at Rome, a work attributed to Bramante, offers an unusual example, for there the lower floor and its windows are made the next principal features after those immediately above them: in both the apertures themselves are round-headed, with imposts and archivolts, but flanked by pilasters supporting an entablature, whereby the general form of the *chambranle*, or dressing, becomes square-headed; the chief difference between these two tiers of windows is, that those above have pediments (alternately angular and segmental), while the others have none. Triple, or Venetian windows, as they are called, and grouped windows, are sometimes introduced in Renaissance buildings with excellent effect; and where a great degree of magnificence is desired, caryatides are substituted for columns as decorations. From the time of Palladio, balustrades have been added to windows, adding often greatly to their picturesqueness of character, but sometimes with a very different result. [ITALIAN ARCHITECTURE; RENAISSANCE.]

WINDS, TRADE. [WIND.]

WINDSAILS are the vanes, generally four in number, which, being turned by the action of the wind, give motion to the machinery of a mill. The wind being supposed to blow in a direction parallel to the axis about which the sails are to revolve, it is evident that the plane of each sail must have a certain inclination to that axis, or to the plane of the revolution, in order that a resolved part of the wind's force may act in the latter plane perpendicularly to the radii or arms which carry the sails so as to turn them constantly in one direction about the axis. If the pressure of the wind on the sails, supposed to be at rest, were to be alone considered, the determination of the angle which the plane of each sail should make with a plane perpendicular to the axis, or to the direction of the wind, in order that the pressure might be a maximum, would be comparatively easy. For by the resolution of forces it is easily seen that the pressure perpendicular to the radii, and in the plane of their revolution, varies with the term $\sin^2\theta\cos\theta$, where θ is the angle which the sail, supposed to be a plane surface, makes with the wind or with the axis of revolution: and the differential of this quantity being made equal to zero, the value of θ is found to be 54° 44′ nearly.

But it is evident that the effect of the wind in giving a revolving motion to the radii must depend on its pressure, and also on the velocity of the surface against which it acts; and the angle which the plane of the sail should make with the direction of the wind, when its pressure on the sail in motion is a maximum, must be determined by an investigation similar to that which follows.



Let A B, A′B′, parallel to one another, represent the direction of the wind; W B X, W′B′X′, also parallel to one another, be two positions of a section of the sail, which by the pressure of the wind is made to move so that B, B′, are in a line perpendicular to A B. Now if it be supposed that A′B′ is the space described by a particle of air while B would move to b (or b' to B′) in the same direction, or from B to B′ in a direction perpendicular to A B; the lines A′B′ and b'B′ will, respectively, represent the velocities of the wind and sail in directions parallel to A′B′, while B B′ will be the velocity of the sail in the direction of this last line. Draw A′C′ perpendicularly to W X or W′X′, produced, and meeting the former line in C; then A′C′ and C C′ will be respectively the velocities of the wind and sail perpendicularly to the line W X or W′X′, and consequently A′C will be what is called the velocity of the wind in the sail. Therefore, the pressure of a fluid being proportional to the square of the velocity, the pressure of the wind in the direction A′C′ will vary with $A'C^2$; and this being resolved in the direction A′D or B B′, will be expressed by $A'C^2 \cos CA'D$, or $A'C^2 \sin B'Bb'$. But A′B being constant, A′C varies with $\sin A'BC$; therefore the effective pressure of the wind will vary with $\sin^2 A'BC \sin B'Bb$.

Let the angle A′B B′ be represented by a, B′Bb' by θ; then $A'BC = a-\theta$, and the expression for the pressure becomes

$$\sin^2(a-\theta)\sin\theta.$$

Making the differential of this expression equal to zero, and reducing, we have

$$\tan(a-\theta) = 2\tan\theta,$$

when the pressure is a maximum.

Draw B′X Y perpendicular to B C, so that B′X and X Y may respectively represent $\tan(a-\theta)$ and $\tan\theta$; and let A′B′, B B′ be respectively represented by v and by v'; then

$BX = v'\cos\theta$, $B'X = v'\sin\theta$,

$XY\ (=2B'X) = 2v'\sin\theta$, and $B'Y\ (=3B'X) = 3v'\sin\theta$.

Again, draw YZ perpendicular to BB′, or parallel to A′B′; then

$B'Z\,(=B'Y \cos BB'Y) = 3v' \sin^2 \theta,$

$YZ\,(=B'Y \sin BB'Y) = 3v' \sin \theta \cos \theta,$ and

$BZ\,(=v'-B'Z) \qquad = v'-3v' \sin^2 \theta.$

But by similar triangles, BZ : ZY :: BB′ : B′A′, that is

$v'-3v' \sin^2 \theta : 3v' \sin \theta \cos \theta :: v' : v;$

whence $v-3v \sin^2 \theta = 3v' \sin \theta \cos \theta.$

Multiplying each term by v, and for v^2, the first term, substituting its equivalent $v^2 \sin^2 \theta + v^2 \cos^2 \theta$, we have

$v^2 \sin^2 \theta + v^2 \cos^2 \theta - 3v^2 \sin^2 \theta = 3vv' \sin \theta \cos \theta;$

or simplifying, and dividing by $\sin^2 \theta$, we get

$-2v^2 + v^2 \cot^2 \theta = 3vv' \cot \theta,$

which reduced as a quadratic equation, with respect to θ, gives

$$\cot \theta\,(=\tan ABX) = \frac{3v'}{2v} + \left(2 + \frac{9v'^2}{4v^2}\right)^{\frac{1}{2}}.$$

The angle ABX will evidently depend upon the relation between v', the velocity of the sail, and v, the velocity of the wind: if $v'=0$, or the sail is at rest, we should have $\tan ABX = \sqrt{2}$, that is, the angle ABX would, as above, be equal to 54° 44′ nearly; and when $v'=v$, the formula gives ABX = 74° 19′ nearly. It follows that as the velocity of the revolution increases, the inclination of the section WX to the wind, or to the axis of rotation, should be increased. Since, therefore, the velocity of the sail continually increases from the axis to the extremity of the radius or arm which carries it, it is evident that the sail, instead of being a plane, ought to have a curved surface such that the inclination of the section to the direction of the wind may increase with its distance from the axis conformably to the values which would be given by the above formula, the ratio between the velocity of the wind and sail at any given distance from the axis of rotation being known or assumed. It was observed by Mr. Smeaton that the velocities of the sails at their extremities are often more than twice as great as that of the wind. From several experiments which were made on a great scale by the same engineer, it was found that the effect is very advantageous when the inclinations of the axis, or the direction of the wind, with a section of the sail taken perpendicularly to the revolving arm at different distances from the axis, were as in the ollowing table:—

At one-sixth of the length of the arm			72°
At one-third	,,	,,	71°
At one-half	,,	,,	72°
At two-thirds	,,	,,	74°
At five-sixths	,,	,,	77½°
And at the extremity		,,	83°

Mr. Smeaton found also that when each sail is broader at the further extremity than near the centre, the effect is greater than when it has the form of a parallelogram; and that the most advantageous breadth at the extremity is one-third of the length of the arm.

There is a certain limit to the quantity of sail which a windmill can carry with advantage; and from Mr. Smeaton's experiments it results that, when the surfaces of all the sails exceeds seven-eighths of the area of the circle described by each arm in one revolution, the velocity is diminished; probably from the want of sufficient openings by which the wind, after impact, may escape. Mr. Smeaton also found that the ratio between the velocities of windmill sails when unconnected with the machinery, and when loaded so as to produce the maximum effect, is variable; but, in general, that ratio is as 3 to 2. The velocity of the sails when the effect is a maximum varies nearly with the velocity of the wind.

The form and position of the sails remaining the same, the load or resistance when a maximum, varies nearly with the square of the velocity of the wind; and the maximum of resistance which sails of similar figures, and in similar positions, will overcome at a given distance from the centre of motion, will vary with the cube of the radius or arm of the sail.

WINE. The chemistry of wine presents many points of interest, and may be treated of independently of its history, manufacture, commerce, and uses.

In the juice of the grape, fermentation is excited by the access of air, alcohol and carbonic acid being formed by the decomposition of the sugar contained in the fluid—

$$\underbrace{C_{12}H_{12}O_{12}}_{\text{Sugar.}} = \underbrace{2C_4H_6O_2}_{\text{Alcohol.}} + \underbrace{4CO_2}_{\text{Carbonic acid.}}$$

The process once commenced, continues independently of any further influence of the air. In addition to the alcohol and carbonic acid formed by the fermentation of the juice, there is also produced a yellow or gray insoluble substance, containing a large quantity of nitrogen. It is this body which possesses the power of inducing fermentation in a new solution of sugar, and which has in consequence received the name of *ferment*. [FERMENT.] The alcohol and carbonic acid are produced, as above indicated, from the elements of the sugar; but the ferment is formed from those azotised constituents of the grape-juice which have collectively been termed *gluten*. [GLUTEN.] Gluten dissolved in pure water undergoes a process of decomposition; but the decomposition which it suffers in an isolated state, and that which it undergoes when dissolved in a vegetable juice, belong to two different kinds of transformations. There is reason to believe that its change to the insoluble state depends on an absorption of oxygen; for its separation in this state may be effected under certain conditions by free exposure to the air without the presence of fermenting sugar. It is known also that the juice of grapes, or vegetable juices, in general become turbid when in contact with air before fermentation commences; and this turbidity is owing to the formation of an insoluble precipitate of the same nature as ferment. The oxygen consumed in the fermentation of wine or beer is not taken from the atmosphere, though the access of this is necessary to excite it in the first instance. Gluten seems to act towards sugar as diastase does towards starch, namely, imparts that impetus to it which enables it to alter its condition. When both gluten and sugar are present in a liquid, fermentation will go on till the decomposition of one or other be complete. When the quantity of ferment is too small in proportion to that of the sugar, its fermentative putrefaction will be completed before the transformation of all the sugar is effected. Some sugar here remains undecomposed, as the cause of its transformation is absent, namely, contact with a body in a state of decomposition: this happens in the *vins de liqueurs*, the *fruity* or sweet wines. But when the quantity of ferment predominates, a certain quantity of it remains after all the sugar has fermented, its decomposition proceeding very slowly on account of its insolubility in water. This residue is still able to induce fermentation when introduced into a fresh solution of sugar, and retains the same power until it has passed through all the stages of its own transformation. Hence a certain quantity of yeast is necessary in order to effect the transformation of a certain portion of sugar; not because it acts by its quantity in increasing any affinity, but because its influence depends solely on its presence, and its presence is necessary until the last atom of sugar is decomposed.

Climate and soil greatly modify wine both in kind and quality. Differences, however, in the vintage and manufacture often determine the character of wines made in the same district, and cause them to widely differ from each other in odour, flavour, and even colour. Such differences often occur spontaneously, as in the case of amontillado.

The quantity of *azotised matter* in the juice seems to be the same in whatever part the grapes may grow; at least no difference has been observed in the amount of yeast formed during fermentation in the south of France and on the Rhine. The grapes grown in hot climates, as well as the boiled juice obtained from them, are proportionally rich in sugar. Hence, during the fermentation of the juice, the complete decomposition of its azotised matters, and their separation in the insoluble state, are effected before all the sugar has been converted into alcohol and carbonic acid. A certain quantity of the sugar consequently remains mixed with the wine in an undecomposed state, the condition necessary for its further decomposition being absent. The azotised matters in the juice of grapes of the temperate zones, on the contrary, are not completely separated in the insoluble state when the entire transformation of the sugar is effected. The wine of these grapes, therefore, does not contain sugar, but variable quantities of undecomposed gluten in solution. This gluten gives the wine the property of becoming spontaneously converted into vinegar when the access of air is not prevented; for it absorbs oxygen and becomes insoluble, and its oxidation is communicated to the alcohol, which is converted into acetic acid. By allowing the wine to remain at rest in casks with a very limited access of air, and at the lowest possible temperature, the oxidation of this azotised matter is effected without the alcohol undergoing the same change, a higher temperature being necessary to enable alcohol to combine with oxygen. As long as the wine in the stilling-casks deposits yeast, it can still be caused to ferment by the addition of sugar; but old well-layed wine has lost this property, because the condition necessary for fermentation—namely, a substance in the act of decomposition or putrefaction—is no longer present in it. In hotels and other places, where wine is drawn gradually from a cask, and a proportional quantity of air necessarily introduced, its eremacausis—that is, its conversion into acetic acid—is prevented by the addition of a small quantity of sulphurous acid. This acid, by entering into combination with the oxygen of the air contained in the cask or dissolved in the wine, prevents the oxidation of the organic matter.

A knowledge of the facts just mentioned enables us to comprehend the nature and object of the practices adopted empirically for the preservation of wine; above all, of those which are requisite to prevent it passing into the state of acetic acid, to which the wines of northern countries, or poor weak wines, are most prone. Thus, the processes of racking, sulphuring, fining, mixing, bottling, and keeping in cellars the temperature of which is low, are obviously all directed against the occurrence of the *acetous* fermentation, as they are mostly inadequate to check the *vinous* fermentation, and indeed altogether unnecessary, since so long as the vinous fermentation is going on—that is, as long as the alcohol continues to be generated—the wine is gaining in quality. Once begun, the presence of atmospheric air is in nowise necessary for the continuation of the vinous fermentation; in fact, the more thoroughly it is excluded the better, for while the vinous fermentation, by which the wine is ameliorated, goes on, the acetous fermentation cannot commence.

From the above facts, established in the main by Liebig, it appears that while the azotised matter (gluten) in grapes, wherever grown, is a fixed quantity, the acids and saccharine matter are variable. When there is more saccharine matter, as in Rivesaltes, Frontignan, and Tokay, than there is gluten to transform into alcohol, a portion of undecomposed sugar remains, sufficient not only to give that taste which has acquired for them the name of *sweet* wines, but also to exert the usual preservative power of sugar, when present in large quantities, and resist decomposition. Thus, Muscadine wine has been kept two hundred years; Mountain, buried at the time of the Fire of London, and disinterred in 1811, was excellent; and old Tokay, called *vino vitrauno*, is in perfection at the end of a century. This wine needs neither sulphuring nor fining (Schams, 'Ungarns Weinbau,' erster band, p. 75); the casks are hermetically bunged; and the reason is obvious. To the juice of grapes grown in colder climates or cold seasons, sugar, especially starch-sugar, is added at the beginning of the fermentation, in order to consume all the leaven. Also to wine which it is apprehended is about to become sour, or *pricked*, as the first sign of its becoming acetified is termed, sugar is also added; but if vinegar has really been formed, this introduction of sugar, so far from hindering, only hastens the further transformation, as the presence of vinegar is the most powerfully disposing agent to this change.

The odoriferous principle, or *bouquet*, of wines, appears to be due to peculiar ethers, or ETHEREAL SALTS, and, according to Winckler, to combinations of volatile fragrant acids with a nitrogenous base of balsamic odour. The conditions of the formation and of the decomposition of these compounds are not very well understood at present; some of the ethers, however, can be formed artificially.

The intoxicating quality of wine is, of course, due to the *alcohol*, the cause of the production of which has already been described. The method of ascertaining the amount of alcohol present in any sample, and a table showing the centesimal proportions of alcohol in various wines, will be found described under ALCOHOLOMETRY.

Free acids, or acidulous salts, are present in most wines. Malic, tartaric, and citric are commonly met with. Port wine contains tannic acid, and the briskness of effervescent wines is due to carbonic acid. This natural acidity of wine must not be confounded with the sourness which wine sometimes acquires, and which is due to acetic acid, generated by oxidation of alcohol, as already described.

The *colouring matter* of wine is derived from the husk of the grape. If wine be prepared from the expressed juice only, it will have little or no colour, as in the case of Champagne; but if the skin be also present, its colour will go into solution during the process of fermentation, and will give the characteristic tint to the resulting wine. The presence or absence of the purple skin, therefore, and not the colour of the grape, as popularly supposed, determines the colour of wine.

The chief *saline constituent* of wine is bitartrate of potash, or *winestone*, or *argol*, as it is technically termed. It is the commercial source of tartaric acid, and has already been treated of in detail. [TARTARIC ACID.]

Wines are much adulterated. For the English market they are commonly "fortified" with brandy, and superior varieties are frequently diluted with those of inferior quality. Elderberry juice, called Cheripigo, also the juice of *Phytolacca decandra*, boiled must, and burnt sugar are used for colouring; kino and logwood are used for the same purpose, and to augment the astringency of port wine; and occasionally artificial ethers are added to give flavour.

WINE MANUFACTURE. Wine is the result of the fermentation of certain saccharine fluids, either existing naturally in the juices of plants, or artificially blended together. The natural juices susceptible of fermentation are found either in the roots of plants, such as the parsnip and beet-root; extracted from the stem, as in the birch and cocoa-palm; expressed from the leaves, as in the grape-vine; obtained from the spatha, as of the *Sagus vinifera*, the *Phœnix dactylifera*, and other palms; and in the mature or immature fruits of many well-known plants, such as gooseberries, currants, and, above all, the grape, to the fermented juice of which the term wine is always understood to be applied when used absolutely. Though alcohol is present in all wines, yet many other principles exist in them; the number of which, and the manner in which they are blended together, as well as their relative proportion, give to different wines their distinctive properties.

The *Vitis vinifera*, the only species which yields the most esteemed wine, has, from receiving the long-continued attention and culture of man, a very extensive geographical range. [VITIS, in NAT. HIST. DIV.] From 54° or almost 55° N. lat. to 45° S. lat., the vine may be found; but it by no means yields a grape fit for fermenting into a sound good wine in all the intermediate space. Up to the 51st degree of N. lat. the preparation of this beverage is conducted with various degrees of success and diversities in the qualities of the wines. In the hotter countries alone are the rich sweet wines, often called in technical language *Vins de Liqueurs*, prepared, as in those only is so much sugar present as to allow the fermentation to furnish sufficient of the vinous principles to the product, when the fermentation ceases from the leaven being all expended. The Muscat grape, which in the south of France yields the rich sweet wines termed Frontignan, Lunel, and Rivesaltes, on the Rhine only ripens sufficiently to furnish a grape for the table or dessert. Nor does the same latitude always permit the grape to acquire the perfection requisite for good wine. The isothermal lines and the degree of humidity, especially the clearness or cloudiness of the atmosphere, have more influence. Thus in France the beneficial cultivation of the vine scarcely extends on the western side higher than 48°, but the boundary-line mounts upwards towards the east till we find the most renowned of the Rhine wines produced between 50° and 51°. The longitude of Devonshire is nearly that of the province of Spain which yields the finest sherries; and it is not alone the difference of 14 degrees of latitude which unfits the south of England for ripening a grape suitable for wine, since that portion of the Rhine which lies between Coblenz and Düsseldorf, which produces good wine, has precisely the same latitude; but the greater humidity and cloudiness of the atmosphere in the south-west of England, by intercepting the sun's rays, prevent the full ripening of the grape; for the same reason, Holland scarcely produces grapes possessing sugar enough to yield wine (Mulder); and the observations of Dr. Daubeny have proved that the ripening of fruits depends more on the illuminating rays than on the calorific or chemical rays. The specious hopes held out by some writers that the grape might be cultivated in England so as to yield wine, would soon be dissipated by any extensive trials, which it is to be desired may never be made. (Barton's 'Lecture on the Geography of Plants;' and Watson, 'Geographical Distribution of British Plants.')

But different climates, though they may equally permit the grape to ripen, yet impress on it peculiarities easily distinguishable in the wines produced by the same kind of grape. Thus the Hock grapes yield a kind of wine possessed of distinct qualities when grown along the Main or Rhine; the same sort of grapes, grown near Lisbon, yield Bucellas, which only retains some of the peculiarities of the original; the same grapes at the Cape of Good Hope yield what is termed Cape Hock, scarcely bearing any resemblance to the true Rhenish; while the Sercial of Madeira, produced by the same sort of grapes, though a delicious wine, has scarcely a quality, except durability, like that of the original. Some local influences produce effects which are alike inexplicable and inimitable. These, though generally attributed to the soil, are not always or solely owing to its composition and qualities. In some instances the soil is the main cause of difference, as seen in the Constantia of the Cape. The climate there is most favourable to the growth of the vine, yet in one small space only is a tolerable wine produced, the two contiguous farms of the Great and Little Constantia yielding, the former the red sweet wine, the latter the white Constantia: the soil on which they grow is decomposed sandstone. Where no appreciable difference of soil can be pointed out, differences arise from the cultivation of a different kind of grape. It is stated, on the authority of Meyen ('Pflanzen-Geographie,' p. 369 of English translation, published by the Ray Society), that there are instances "of the same variety of vine being planted on the side of a hill or mountain, and the wine which is the produce of the grapes from the highest parts of the mountain will differ essentially from the wine which is the produce of the grapes of the lower part of the mountain. The wines known by the name of Johannisberger and Rudesheimer in Germany are the produce of vines growing close together, and resembling each other in external characters. The vineyards also that produce the Leistenwein, Würzburger, and Steinwein are very near to each other. It is probable that this difference is owing to the composition of the soil." This is not altogether correct. Johannisberg is only 150 feet above the level of the Rhine, and it is quite certain that the produce of the summit, close to the castle or Schloss of Johannisberg, is of a quality vastly superior to the produce of the place called Johannisbergerhöhl, not from any peculiar or insurmountable cause, but because the former, belonging to Prince Metternich (and the adjacent parts to some other large proprietors), can receive an amount of careful and skilful treatment, which the other, being divided among a number of small proprietors, never does. This subdivision is the cause of an annual loss of many thousands of pounds. (Bronner, 'Weinbau in Süd Deutschland, Dritte Heft,' p. 113.) The grape cultivated in both places is the little Riesling (*Der Kleine Riesling* of some, *Weisser Riesling* of others; the *Vitis vinifera pusilla* of Babo and Metzger's 'Wein und Tafeltrauben der Deutschen Weinberge und Gärten,' Heft viii, t. 46); but in the vineyard of Prince Metternich and the other great proprietors three gatherings of the grapes are made as they reach maturity, and other measures are adopted to ensure a produce of the highest excellence. Besides the protection of the castle wall, the whole has since 1824 been surrounded with a stone wall 10 feet high. This greatly promotes the steady progress to maturity of the grapes by securing a quiescent state of the air, which is known to be extremely beneficial, and which, when imitated on a small scale in this country by surrounding a bunch of grapes with a muslin bag, forwards its ripening very much. The wine of Luginsland and the Liebfrauenmilch owe their superiority over that of the neighbouring vineyards to the protection of the town-wall of Worms. (Bronner, Heft ii., pp. 18–20.) The advantage of protection against agitation of the air is so well understood in the Rheingau, that the belts of vineyards which clothe the height of Hochheim bring very different prices, according to their position. One morgen, close to the bed of the river Main, brings in the market two thousand florins; a higher morgen brings one thousand florins; and one at the summit only five hundred. (Bronner, iii., p. 14.) The geognostic character of the soil of Johannisberg is argillaceous schist, with a very moderate proportion of mica, and in one place passes into a reddish quartz, which is very hard, and undergoes but slowly any decomposition. This is overlaid with diluvial and alluvial deposits in most places except the south-west side. From these and other circumstances it follows that the soil is of a very diversified character. (Bronner, iii., p. 116.) The exposure is south-west, with a slope of from ten to fifteen degrees. Rudesheim is well protected by its natural position and a lofty forest called Niederwald: it is much steeper, so that the earth can be kept from being washed down only by numerous terraces, between which the air is as hot as in a conservatory. The soil is composed of stones of a dark colour, which radiate heat during the night to such a degree, that the grapes are surrounded by almost a southern climate. The grape most common, at least in the old vineyards, is the Orleans (*Vitis v. aureliana*, B. u. M., Heft x., t. 60), which has the property, in this stony and hot ground, of continuing productive until the age of fifty or more, which is not the case with any other grape. But as it only gives a good wine in very favourable years, and as the wine from the Riesling grape brings so high a price, the new vineyards are mostly planted with the Riesling: the propriety of this substitution is very doubtful. (Bronner, iii., 136.) These facts are sufficient to account for the differences between the Johannisberger and Rudesheimer wines.

The differences between Leistenwein and Steinwein are still more easily accounted for. The Leiste is on the left side of the river Main, the Stein on the right, the Stein being close to the river. The soil of both is argillaceous with calcareous portions, especially fragments of lime, and this is the soil commonly met with in Würtemberg and in all Franconia. Why these two wines should differ from all others of the district is unintelligible; but the difference between themselves is owing to the grapes. The vineyards of the Leiste (that is, the best portion, *gute Leiste*,) are planted in a great measure with the Riesling and Traminer (*V. v. tyrolensis*, B. u. M., Heft xii., t. 72), with about a third of the Elbling grape (*V. v. albuelis*, B. und M., Heft iii., t. 14); and in the other vineyards is the white Traminer, called *franken*, by some *gutedel* (*V. v. aminea*, B. u. M., Heft ii., t. 9), that is, both white and black. Besides these there occurs in considerable proportion the Hermitage grape, brought from France, which here succeeds well, retaining its fine aroma, though its natural site is granitic. The selection of the grapes, when ripe, is attended to with extraordinary care. (Bronner, vi., p. 82.) The predominant grape of the Stein vineyard is the Elbling, mixed with a few of the Riesling and other sorts. The Leistenwein is regarded as the second finest wine of the south of Germany. The Steinwein must not be confounded with the Steinberger wine of the Rhine. The Montillado of Spain is the produce of a white soil, containing 70 per cent. of carbonate of lime, with alumina, silica, and a little magnesia, while the Manzanilla is the produce of the terrains rouges et sablonneux. Yet the wines do not greatly differ in taste or flavour. More importance is attached to the soil than it deserves; its physical properties are of more importance than its chemical. Chaptal was clearly of this opinion, for he maintained that, provided it is porous, free, and light, its component parts are of little consequence. Perhaps calcareous is on the whole the best, simply because it readily imbibes the rain, and allows a clear atmosphere to surround the vines. Even Mr. Busby (see his 'Visit to the Principal Vineyards of France and Spain,' p. 131), who so strenuously maintains the superiority of a calcareous soil, when remarking on the reputation and limited extent of some of the first-rate vineyards, repudiates the idea of the soil being the cause. "In all those districts which produce wines of high reputation, some few individuals have seen the advantage of selecting a particular variety of grape, and of managing its culture so as to bring it to the highest state of perfection of which it is capable. The same care has been extended to the making and subsequent management of their wine, by seizing the most favourable moment for the vintage—by the rapidity with which the grapes are gathered and pressed, so that the whole contents of each vat may be in exactly the same state, and a simultaneous and equal fermentation be secured throughout—by exercising equal discrimination and care in the time and manner of drawing off the wine, and in its subsequent treatment in the vats or casks where it is kept; and lastly, by not selling the wine till it should have acquired all the perfection which it could acquire from age, and by selling, as the produce of their own vineyards, only such vintages as were calculated to acquire or maintain its celebrity. By these means have the vineyards of a few individuals acquired a reputation which has enabled the proprietors to command almost their own prices for their wines; and it was evidently the interest of such persons that the excellence of their wines should be imputed to a peculiarity in the soil, rather than to a system of management which others might imitate" (p. 133). But some experienced wine-factors, not proprietors of vineyards, hold a different opinion.

It is greatly to be wished that the truth of this important statement were impressed on all persons having the charge of vineyards, as it is certain that by attention to these and other circumstances quite within their control, the quantity of good wine might be much increased and its price lessened. Bronner distinctly states that in the Bergstrasse near Heidelberg, by obstinate adherence to old and indolent practices, the produce is annually one-third less than it might be (Heft vii., p. 20).

Where some peculiar strong-smelling substance exists in the soil, an odour is communicated to the wine which renders it unpleasant. This is the case when stinkstein (a native variety of subcarbonate of lime, called *pierre puante*) is present. The vine-growers of France and Portugal have so strong an aversion to manuring the vines, from the notion that it deteriorates the flavour of the wine, that in the latter country, at least in the port-yielding district of the Alto Douro, the use of manure is forbidden by law. This seems to be a prejudice, for the German cultivators manure the vines very freely, and no wines are more esteemed for *bouquet* than those of the Rhine; and Bronner justifies the practice (Heft iii. 44), not only with fresh cow-dung, which is used at Johannisberg, but with fragments of woollen cloth previously steeped in liquid manure and dried, which is found greatly to augment the produce. Professor Rau bears testimony to its utility. The practice is adopted oftener with the red than white grapes; the former every third or fourth year, the latter only every tenth. Even the proprietors of the vineyards near Bordeaux, which produce the highly-prized clarets, employ manure "once every four or five years." (Paguierre, 'Wines of Bordeaux,' p. 28.) But perhaps the best manure for vines is the cuttings of the vines themselves when pruned, as recommended in Liebig's 'Chemistry in its application to Agriculture,' 2nd edit., p. 250:—"The vines are pruned in the end of July or beginning of August, whilst still fresh and moist. If they are then cut into small pieces and mixed with the earth, they undergo putrefaction so completely, that at the end of four weeks not the smallest trace of them can be found." These restore to the soil the alkalies abstracted by the grapes, which are so necessary for the perfection of this fruit. Probably ferns, so rich in alkalies, would answer well. But the same vines will yield a wine having very different qualities, at least as to flavour and perfume, in different seasons. "These qualities are, in truth, of so delicate and inconstant a nature, that they may be said to vary from year to year; there being perhaps no two vintages, though collected from the same spot and managed in the same manner, that will be found completely identical in flavour and perfume." (Henderson's 'History of Ancient and Modern Wines,' p. 135.) The correctness of this statement is proved by the varying character of the vintages in different years. It rarely happens that the good Port years coincide with the good Claret years, as a heat which ripens well the grapes in the comparatively cold climate of Medoc scorches the grapes in the Alto Douro, and *vice versâ*. The year 1811, commonly called the comet year, was remarkable for the excellence of the vintage in almost all the wine-yielding countries of Europe.

The subject of the cultivation of the grape has been treated under VINEYARD; we proceed, therefore, to speak of the manufacture of wine. The stage at which the grape is fit for gathering depends upon the kind of wine intended to be made. When a brisk wine is wished, such as Champagne, the grapes are gathered before they are fully ripe; and they may be collected even in foggy weather, or before the dew is dissipated from the vines; though for all other kinds dry clear weather is proper. (Henderson, p. 15.) This author (in general so accurate) states that "if the object be to obtain a dry full-flavoured wine, the grapes should be gathered as soon as they have acquired their proper maturity, and before they begin to shrink or wither on the stalk." But in the case of the most esteemed German wines, which are the *driest* of all, the gathering of the grape is postponed as late as possible, by which many free acids are got rid of, and the wine at a much earlier period of keeping is so soft and delicate, that the new wines are preferred to the extremely old wines, which were in great request previous to the adoption of the plan of late gathering. The advantage of this was first accidentally discovered at Johannisberg in 1790; but it was so long opposed that its establishment as a practice dates only from 1822. (Bronner, Heft iii., pp. 149-150.) But frost, in November, 1858, destroyed to some extent the vintage of 1858. Thus at Johannisberg the vintage of 1811 was very late; that of 1831 did not commence till the 17th October, nor did it conclude till the 5th November: and in 1834 the grapes were all hanging on the vines, but perfectly sound, so late as November. Yet these are among the most renowned vintages of the present century. In the warmer parts of the south of Spain and of France, and also at Tokay, where vins de liqueurs are made, the grapes are allowed to remain very long on the vines; the stalks are twisted, so as to prevent the influx of any recent sap; the thinner or watery portion evaporates, and the dry or shrivelled grape almost resembles a raisin, and contains much sugar. On the Rhône a small quantity of sweet wine is made from the ripest grapes, which are hung up on hurdles, or spread on straw, for six or eight weeks, or until they become half dried. The liquor obtained from them, from the mode of preparation, receives the name of *straw wine* (*vin de paille*). In some cases the must is boiled; this is often done with the sherries of Spain: when the boiling is carried far, a very sweet luscious wine is produced, such as the wine of Cyprus, the *vino cotto* of the Italians (*vinum coctum* of the ancients), the original Malmseys of Candia, and the other rich wines of the Grecian archipelago. The colour of wine is not always dependent on the colour of the grape from which it is prepared. Champagne is the produce of a red grape: red and white grapes are used indiscriminately for Sherry; but white Port is made only from a white grape. The stalks promote the fermentation, and if they, as well as the hulls or skins, are withdrawn before the fermentation has proceeded far, as it is not till some alcohol is generated that the colouring principle is dissolved, those even of red grapes neither communicate colour nor taste to the wine. They are early withdrawn from the delicate red wines of Bordeaux; but retained longer in the red wines of Portugal; hence the greater austerity and astringency of the latter. The wine of Cahors, prepared from a grape called *Auxerrois*, or *pied de perdrix*, yields a wine almost black, the colour being deepened by an admixture of a preparation called *raugome*, which is merely a portion of the must of this grape, boiled for a few minutes with the strongest spirit of wine, in the proportion of one part of spirit to four of must, added to it. This extracts the colouring principle most thoroughly; and communicates not only to the wine of Cahors, but also to many of the Bordeaux wines, to which raugome is frequently added, a deep hue. "The more this preparation is required and added, the less the wine will bear keeping." (Paguierre, p. 112.)

TABULAR VIEW OF THE VINTAGES OF FOUR OF THE MOST DIFFERENT AND CELEBRATED WINE-COUNTRIES, EXTENDING FROM ALMOST THE MOST WESTERN TO THE MOST EASTERN POINTS WHERE FAMOUS WINES ARE PRODUCED IN EUROPE. IN THE COLUMN OF CLARETS ONLY THE MOST NOTED YEARS ARE GIVEN, THE INTERMEDIATE ONES BEING EITHER "NULL," "BAD," OR ONLY "MIDDLING." THE EXPRESSION "GOOD" REFERS ONLY TO THE QUALITY: SOME YEARS BEING GOOD, WITH AN ABUNDANT PRODUCE; OTHERS GOOD, WHILE THE QUANTITY WAS SMALL.

YEAR.	PORT.	CLARET.	RHENISH.	TOKAY.

The wines of the Moselle may be distinguished from those of the Rhine by having a greenish colour, while the latter have a yellowish colour. At Cotnar, in Moldavia, a wine is prepared which is green, and which becomes deeper by time; while the strength increases so much, that if the wine be kept in a deep and well-vaulted cellar, in three or four years it almost resembles brandy, but without so readily affecting the head. "On exposing red wines in bottles to the action of the sun's rays the colouring-matter separates in large flakes, without altering the flavour of the wine." (Henderson.) Sulphurous acid ought not to be used for fuming the casks into which red wine is to be put, as it destroys their colour. Spirit of wine should be used to rinse such casks. The colour of wine is judged of by placing some of it in a small silver tray or saucer (called in Portuguese *tambuladeira*) slightly raised in the centre; the colour it exhibits as it passes over the convex centre when agitated, is that which guides the broker.

To proceed with the steps towards the conversion of the must into wine. "Before beginning the vintage it is necessary to be assured that the fruit which is to be gathered has attained the proper and necessary maturity, for on this almost always depends, in a great measure, the quality of the wine. The cultivator is liable to fall into one of two errors, which, though very different and opposite to each other, are not less hurtful to the wine, especially to the red, which is more delicate and susceptible of injury in making than the white. If gathered too soon, and before the grape has attained to the fit degree of maturity, the wine is likely to be raw (*vert*), which is the greatest fault it can have, and the most difficult to correct; the wines having this defect becoming generally hard when old. The other error, though of less consequence, is leaving the grapes till they are too ripe, which may then rot before gathered." (In the north of France this is more liable to occur; in the south, less so: at Langoe, between Bordeaux and Toulouse, a white sweet wine is prepared from spoiled grapes.) "The wine made from grapes too ripe acquires a sweetish taste, which causes it to work a long while in the barrels, and renders it sour and difficult to keep. The wine attacked by this vice requires greater care than any other; for if neglected ever so little, either in racking or filling, it easily becomes sour. However, it is better to gather late than too soon." (Paguierre, p. 47.) At Tokay, where the grapes are allowed to hang on the vines till some of them lose their globular shape and transparency (*trockenbeeren*), the gatherers put these into a separate basket; and the juice which exudes from them simply by the pressure of one above the other is carefully collected, and known under the name of *Tokayer-essenz*. This thick syrupy liquid does not ferment, and always remains thick and muddy. It is not an article of commerce, as the cultivators keep it to add to the finest wine (called *Ausbruch*) either at the beginning of the fermentation or at the termination. The former is the preferable mode.

We may take Clarets as an illustration of the process of manufacturing: that being one of the most carefully prepared kinds of wine, it will serve as an example of all. In the words of Paguierre ('Wines of Bordeaux'), "the proprietors of the vineyards, and especially of the first growths, after having prepared the wine-vessels, gather the grapes together and pick them, that is, set aside all the bunches which are rotten, those which do not seem quite ripe, or which are withered, and, finally, all which might hurt the quality of the wine. Their first care then is to make a principal vat of the best fruit, which is called the mother-cask (*cuve-mère*), into which, after picking, they put the first and best grapes which arrive, without their stalks, and without treading them, till they are from fifteen to twenty inches deep; after which they throw about two gallons of old Cognac or Armagnac upon them, and then another bed of picked grapes, followed by two gallons more of brandy, and so on till the vat is full. When full they add spirit of wine, taking for proportion about four gallons of spirits of wine for a wine-vat of from thirty to thirty-six tuns. It must be observed that the quantity of brandy or spirits of wine depends on the quality of the vintage; for if bad, more must be put in order to excite fermentation, and replace what it wants by defect of maturity. (Of late it has become customary to add starch-sugar when the grapes are deficient in saccharine principles.) Raisins are often used for the inferior German wines. (Mulder, p. 51, English Translation.) The *cuve-mère* being filled, it is shut hermetically, and is well covered with blankets, in order that the air may not penetrate. This vat is left in this state for three weeks or a month without being touched. A small brass cock is put into the side of the vat, at about the height of the third of its depth from the bottom, in order to be able to judge at will of the progress of the fermentation, and to know the moment when, the ebullition having subsided, it may be racked off and put into casks, prepared beforehand by scalding and rinsing with a little spirits of wine. It is known that the liquor is fit to be drawn off when it has become cool and is sufficiently clear. While the *cuve-mère* is at work, the vintage is continued in the usual manner; that is, as the grapes are brought in and picked, they are trodden in the press, and put with their stalks into the vats, where the fermentation takes place naturally. These vessels are not entirely filled; about one foot or fifteen inches are left for the fermentation, which sometimes overflows, especially when the vintage has attained perfect maturity. They call *chapeau* the stalks, seeds, and skins, &c., which float on the surface of the wine. The vintage being finished, and the vats lightly covered, they are left to ferment, taking care to visit them twice a day. To rack them it is necessary to wait till they are quite cold, which is from eight to twelve days. From the moment that the cask has become sufficiently cool, it is necessary to draw it off; for if you leave the wine upon the lees (*marre*), or with its crust (*chapeau*), it would take the taste of the stalks, which is very disagreeable and difficult to get rid of, and is a great defect. If the cask be racked off too soon, the fermentation would not be complete, and the wine would run the risk of working too much in the barrel, and of not keeping. When the vats are found to be in a proper state for racking, the wine is drawn off into barrels prepared for the purpose, which are filled about two-thirds or three-fourths; after which the *cuve-mère* is emptied, and the wine is poured in equal portions into these casks so as to fill them; and the remainder is employed to fill up, every six or eight days, what is consumed by evaporation, or what the casks have ullaged. All proprietors have not the means or localities to make a *cuve-mère* by means of old brandy or spirits of wine, either because their vintage is not sufficiently extensive, or because they do not possess the things necessary for its execution. But the fermentation succeeds much better in large vessels, especially when prepared as above, than in the lesser ones used by small proprietors. The casks, being full, are left about eight days without being bunged; care, however, is taken for the time to cover the bung-hole with a stone, brick, or piece of wood. They are filled up every two days, and when bunged, every eight days at least, till the wine is in a state to allow the cask to be kept with the bung-hole at the side, which is not till after eighteen months.

Manner of making White Wine.—To make the white wine it is not, like the red, put into the vat to ferment, but the grapes are trod, and when taken from the press, the juice, skins, and seeds are put into casks (the stalks having been separated); here it ferments and becomes wine of itself. When the fermentation in the barrels has entirely ceased, it is racked off, and care is taken to fill up what has been consumed by evaporation, as often as possible, and this operation ought to take place at least once or twice a week.

The wine, if it has succeeded, ought to be clear, transparent, of a fine soft colour, a lively smell, and a balsamic taste, slightly piquant, but agreeable, inclining to that of the raspberry, violet, or mignonette, filling the mouth, and passing without irritating the throat, giving a gentle heat to the stomach and not getting too quickly into the head.

It is necessary to know what is meant by the *flavour* of wine, and what by *bouquet*, terms often confounded. The flavour, called by the French *sève*, indicates the vinous power and aromatic savour which are felt in the act of swallowing the wine, embalming the mouth, and continuing to be felt after the passage of the liquor. It seems to consist of the impression made by the alcohol and the aromatic particles which are liberated and volatilised as soon as the wine receives the warmth of the mouth and stomach. The *sève* differs from the *bouquet*, inasmuch as the latter declares itself the moment the wine is exposed to the air; it is no criterion of the vinous force or quantity of alcohol present (being in fact greatest in the weak wines), and influences the organ of smell rather than of taste. In the red wines of Medoc and the Graves, the *sève* and *bouquet* exist only in the old wines: these qualities cannot be known, but only conjectured in the new wines; and experience has alone taught the brokers, that when wines of particular growths present themselves without harshness (*verdeur*), with colour, body, and vinosity, they will, when old, acquire a balsamic flavour (*sève*) and mellowness (*moëlleux*), besides the colour and body; they will also keep well, which constitutes the perfection of wine. To give bouquet to the wine, two drachms of orris (the rhizoma of the *Iris florentina*) in powder are put into a fine bag of muslin, and hung for about fifteen days in the cask. Many persons, to make the wine appear older and higher flavoured, and at the same time to prevent injuring its quality, employ raspberry brandy. The bouquet which by these means is given to the common or ordinary wines never replaces perfectly the natural flavour of the choice wines of Medoc and Graves. It is very easy to distinguish the fictitious bouquet by even moderate experience in tasting wine. The bouquet is altogether a new product, and is in no way dependent on the perfume of the grape from which the wine is made. Red wines scarcely ever retain a trace of the odour of the grapes; the white muscadine wines do in some degree, especially Frontignan. It has been recommended to suspend some of the ripest and most odoriferous bunches of the grapes in the cask after the first fermentation has subsided, in order to heighten the perfume of the wine, a practice long pursued in the *vini raspati* of the Italians, and *vins rapés* of the French. But if the *œnanthic acid* and *œnanthic ether*, on which the bouquet depends, be the consequence of a true process of putrefaction (somewhat similar to what occurs in musk, by which the odour is evolved), by a mutual interchange of the elements of gluten and sugar, this process cannot accomplish the object, and only runs the risk of exciting a hurtful fermentation. The best account of the bouquet of wine is given by Liebig, who, with Pélouze, discovered œnanthic ether:—"It is well known that wine and fermented liquors generally contain, in addition to alcohol, other substances which could not be detected before their fermentation, and which must have been formed, therefore, during that process. The smell and taste which distinguish wine from all other fermented liquids are known to depend upon an ether of a volatile and highly combustible acid, which is of an oily nature, and to which the name of œnanthic ether has been given . . . The substances in wine to which its taste and smell are owing, are generated during the fermentation of the juice of such grapes as contain a certain quantity of tartaric acid; they are not found in wines which are free from all acid, or which contain a different organic acid, such as acetic acid. The wines of warm climates possess no odour; wines grown in France have it in a marked degree; but in the wines from the Rhine the perfume is most intense. The kinds of grapes on the Rhine which ripen very late, and scarcely ever completely, such as the *Riesling* and *Orleans*, have the strongest perfume or bouquet, and contain proportionally a larger quantity of tartaric acid. The earlier grapes, such as the *Ruländer* and others, contain a large proportion of alcohol, and are similar to Spanish wines in their flavour, but they possess no bouquet . . . . The acid of wines, and their characteristic perfumes, have some connection, for they are always found together; and it can scarcely be doubted that the presence of the former exercises a certain influence on the formation of the latter. Whatever opinion may be held regarding the origin of the volatile odoriferous substances obtained in the fermentation of wine, it is quite certain that the characteristic smell of wine is owing to an ether of an organic acid, resembling one of the fatty acids . . . On the Rhine, an artificial bouquet is often given to wine for fraudulent purposes, by the addition of several species of the sage and rue to the fermenting liquid; but the perfume thus obtained differs from the genuine aroma by its inferior durability, it being gradually dissipated." (Liebig's 'Organic Chemistry.')

The fermentation is more prompt and lively in proportion to the quantity of must; hence the best wine is made when a large quantity of must is operated on. In some cases, when the season is cold and the grapes are imperfectly ripened, it is necessary to promote the fermentation by artificial means; either adding some boiling must, or withdrawing some of the excess of water by adding baked gypsum. The fermentation is best carried on in covered vats: since in open ones not only the carbonic acid gas escapes, by which the wine is rendered flatter, but much of the alcohol and aroma are lost, and the wine rendered weak. The length of time that the fermentation is continued in the large vats depends on the kind of wine intended to be made. The temperature also influences its progress and the results.

In the Champagne country, the grapes which are to fill one *cuve* are all pressed within the space of two hours, and the must allowed to remain in the *cuve* for a period varying from six or twelve to eighteen hours, according to the temperature, during which it undergoes a process of spontaneous purification, becoming as clear as water. The moment when this is complete is watched for with the utmost care; it is then drawn off into small casks, which are well sulphured (a process which is hereafter explained), and put into cellars below ground, the bunghole being left open, but covered with a flint stone. The overflowing froth, or yeast, is removed from time to time till December or January, when the chief purchases are made, as then the wine can be tasted and proved. It is then also submitted to the process of *fining*.

At Tokay the must is allowed to remain in the vat from twenty-four to thirty-six hours, till the first signs of fermentation are manifested; it is then drawn off into small casks (which are never sulphured) and placed in a still part of the cellar. The effervescence lasts two or three months.

The fermentation spoken of hitherto is called the primary or active fermentation; but there is a subsequent one, called the secondary or insensible, which, though obviously a continuation of the former, is less attended to, but yet of great importance as relates to the ripening, keeping, and acidity of the wine. A knowledge of the causes of fermentation, and the conditions under which it can take place, is essential to the comprehension of the measures necessary for ripening the wine and preserving it in perfection. The subject has been fully explained in Liebig's 'Chemistry of Agriculture,' and Mulder's 'Chemistry of Wine,' London, 1859.

When a *dry* wine is wished, it is necessary that all the sugar should be transformed into alcohol. To do this the fermentation is excited from time to time, by *rolling* the wine, or returning it to the lees to *feed*. As the wine contains variable quantities of undecomposed gluten in solution or thrown down to the bottom of the cask, it is only necessary to stir up the lees to re-excite the fermentation. But lest the point should be passed at which the vinous fermentation is nearly complete, and the acetous would begin, all the undecomposed ferment is removed. Much of it remains in the vat in which the first and violent fermentation takes place; when the fermenting liquid is put in casks, these are generally kept nearly full, by frequent additions of fresh juice, so that much of the ferment works out at the bung-hole, which is seldom perfectly closed for two or three months. Racking is practised, for valuable wines, as often as three times the first year. This consists in transferring the wine to a fresh cask. It is in doing this that the practice of *sulphuring* is mostly adopted. It consists in burning sulphur-matches or linen steeped in sulphur in the cask previously well rinsed, by which all the oxygen of the atmospheric air is consumed, and a quantity of sulphurous acid gas produced. This must be carefully done, as, if in excess, the wine acquires the taste of sulphur, which it would keep for some time. White wines require most sulphur, especially when very *dry*. It is proper to transfer the wine immediately to the exhausted cask, otherwise it would speedily get filled again with common atmospheric air. Dr. M'Culloch recommends the following method, as he remarks that by the common method of tapping it is scarcely possible to draw the wine without mixing a portion of the lees with it:—"To effect it, a cock is introduced into the full cask at the usual place of tapping, three or four inches above its bottom, from which a leather hose (a flexible caoutchouc tube would be better) pipe passes into the bung-hole of the empty one. A common pair of bellows may then be so fitted to the bung-hole of the full cask as to force by its action the whole of the clear liquor through the hose into the empty vessel. By this means the least possible disturbance is created, and the wine is at the same time preserved from the injurious contact of atmospheric air." The whole of the wine should not be drawn off, as the *cap* frequently contains principles which would readily re-excite fermentation. What is left may be employed to form either brandy or vinegar, according to its kind or value. Another means may be used, instead of sulphuring, to preventing the acetous fermentation, namely, the use of *sulphite of potash*. A drachm is in general sufficient for a pipe of wine, and it communicates no taste. The utility of both agents consists in absorbing any trace of oxygen, and preventing it acting on the organic substance. Many volatile oils have the power of checking the vinous fermentation, but their odour is a practical obstacle to their employment. They probably act by hindering the development of the fungus (*Saccharomyces vini*). Alkalies, combining with the free acids, the presence of which is so essential to the process of fermentation, also hinder it, but as they are destructive of the qualities of the wine, they are inadmissible. Black oxide of manganese, though recommended by Dr. M'Culloch, should never be used for wine where sulphuring has been employed, as it would most readily give off oxygen. Racking can only free the wine from matters which are insoluble, and either deposited among the lees or floating on the surface. In order to get rid of some other matters held in solution, a different practice is adopted. This constitutes the process of *fining*. Isinglass in solution in wine, or white of eggs, is commonly employed for this purpose. The common and new wines require more isinglass than the fine and old ones. If the wines have been deprived of the tannin extracted from the seeds of the grape, isinglass has no influence in purifying them. If kept in oak casks, however, as is always the rule in France, they extract tannin from their sides. Numerous powders and compounds, as well as other expedients for keeping or improving wines, are detailed in Jullien, 'Manual du Sommelier.' The process of fining is always repeated previous to bottling the wine.

At Bordeaux the white wines are generally ready for the first racking in December, the red not till March; the second racking is to prevent the working which the great heats of July and August might occasion in them; and the third in October, before the cold comes on. A favourable state of the weather must be chosen for these processes. A fourth racking takes place in eighteen months after the vintage, in March; it is then that the casks may be stowed with the bung at the side. After this it only requires to be racked twice a year, in March and October. When it has attained the age of five or six years, it requires racking only once a year, which is always done in March, the moment when the wines are always finer and clearer than at any other season of the year.

One of the qualities of a good wine is firmness or durability; but in this respect there is great difference among wines, and one possessing every other requisite may be deficient in this essential. This may be imparted to it, however, by adding some other stronger wine, or one little disposed to undergo any deleterious change. Hence has arisen the practice of *mixing* wines, or, as it may be termed, their medication, vulgarly called *doctoring*, which being a judicious and honourable proceeding when the only articles employed are the real produce of the grape, is not to be confounded with unwholesome mixtures and dishonest practices, which deserve to be reprobated. Thus some of the *finest growths* of the Claret country require to be supported by the addition of Hermitage. It is obvious that no fraud is here contemplated, since the Hermitage is, perhaps, the more expensive wine of the two, and the maker can afford to add it only to the *best claret*. It in no degree impairs the fine characteristics of the choicest claret, nor diminishes the lightness for which first-rate claret is remarkable. Where *working* the wines is practised to fit them for the depraved taste of the majority of consumers in England, who are accustomed to the stronger wines of Spain and Portugal, the case is very different; and to the second and third growths the red wines of Roussillon, Bene Carlo from Spain, and brandy are added—to the detriment of the character of Claret. The latter addition is made under the pretext that it is necessary to enable the wine to bear the voyage. This, except so far as a very small quantity of brandy is concerned, is altogether erroneous, not only as relates to Claret, but also to Port and Sherry. The wines of Basseins and St. Eulalie-d'Ambares, two parishes near Bordeaux, furnish a wine which is generally purchased for the French navy, because it keeps well, and improves greatly at sea. The French wine-brokers at Bordeaux, familiar with the qualities of the first growths, and jealous for the reputation of their country, deplore the deterioration which much of their wines undergo to fit them for the English market. Still Claret with no other addition than Hermitage may be obtained here, provided a proper price is given, by resorting to wine-merchants of high repute. Two Sherries come to England devoid of brandy, *Amontillado* and *Manzanilla*; and it is now the wish of Port-wine merchants, of the highest character for science and probity, to introduce Port-wine with as small an admixture of brandy as possible, thereby consulting the health as well as palate of their customers. Brandy added after the early stages of fermentation is only mingled, not incorporated with, the wine — increasing its spirituosity, but not its vinosity, and producing on the human stomach, liver, and other organs the same effect as brandy merely diluted with an equivalent quantity of water. The extension therefore of a taste for the pure and unsophisticated wines in this country would be a national benefit. Sometimes the object in mixing wines is to produce a compound having a different or more agreeable quality than either of the wines singly possesses: hence the mixing of the Rhine-wines almost constitutes a science. Of all wines Sherry is the most mixed with the vintages of different years. "The wine-merchants of Xeres never exhaust their stock of finest and oldest wine. According to the price at which the wine expedited to the market is intended to be sold, it contains a larger or smaller proportion of old wine. But it is only in wines of a very high price that even a small portion of their finest wines is mixed. What is withdrawn from the oldest and finest casks is made up from the casks which approach them nearest in age and quality, and these are again replenished from the next in age and quality to them. Thus a cask of wine, said to be fifty years old, may contain a portion of the vintages of thirty or forty seasons." (Busby.) A sherry, the unmixed produce of one vintage, may now and then by a rare chance be obtained.

"It generally happens that when two distinct wines are mixed, the process of fermentation is partially renewed, or the mixture, in technical language, *frets*. This observation has led to a valuable practice in this manipulation, namely, *fretting-in*, technically so called. It is found by experience that mixed wines unite into one durable and homogeneous liquor only in consequence of this fermentation. A season and circumstances are therefore chosen, in which one or both of the wines to be thus mixed are either in a state of renewed fermentation or show a tendency to it." (McCulloch.) When wine is thus far made, it is left in the cask, or as it is termed, in the *wood*, to mature. The length of time required for this differs much in the different wines. It is the modern practice to send several wines either on voyages to warm climates or even leave them there for years. This is particularly the case with Sherry and Madeira; the fine qualities of the latter wine are very greatly developed by a few years' sojourn at Madras. Considerable evaporation, as well as ullage, occurs during this time; but it is remarkable that during the first years that the wine remains in the cask the watery particles chiefly evaporate, so that the wine gains in alcoholic strength, as well as flavour. Afterwards the alcohol begins to evaporate; and it is probable that at the period when the wines begin to lose alcohol they cease to improve in flavour. They are then fit to be bottled. The amount of evaporation varies with the climate, and the kind of wood of which the cask consists. In some cases it is as much as one-twelfth per cent. per annum—especially if the cask is of Spanish chestnut, which is a most objectionable wood from the taste it imparts. Memel or Danzig oak is exclusively used for the finer Port wines; American oak is cheaper, but not so good. The presence of two staves of chestnut in each cask has been known to impart a taste, slight at first, but at last so marked as to lead to the rejection of the wine. The ullage is greatest in new casks; and hence old ones, when clean and sound, are preferred. But large casks of glass are now proposed: in these ullage is impossible.

During the stay of the wine in the wood, a deposit of tartar and other substances occurs. The colour undergoes a change, especially of the red wines; which is not similar in all. Thus while Port wines become lighter, those of Medoc become deeper; hence, to give the appearance of age to Port wines, *white* Port is added; but to Clarets the black wine of Cahors is added. The wine is thought to ripen better in large than small casks: this led to the construction of the enormous tuns of Heidelberg. Where any of the wine is drawn off, it is necessary to fill up the void as speedily as possible with wine nearly of the same quality, otherwise the air causes the remainder to become sour. Where wine is not to be had, the introduction of a quantity of olive oil protects the wine. A fungus is very apt to stretch across the surface of the wine, if one or other of these precautions is neglected. While in the vaults or cellars, the casks are likely to become affected with the *dry-rot*, by which much fine wine may be lost, especially if the cellars be damp. To guard against this, the casks should be carefully inspected from time to time. Cellars and vaults should be as remote as possible from streets and other ways by which waggons pass, the vibration caused by these often disturbing the more delicate wines. When wines have been kept in the wood for the period which experience has fixed as that proper for attaining maturity, they are generally put into bottles or flasks. In these some further change goes on, by which they are still further ameliorated. In many red wines a deposit occurs, forming a crust on the lower side of the bottle. The operation of bottling should take place in fine weather, if possible in March or October. Before this is done the wine must be fined, either with white of eggs, very fresh, or isinglass; after which the cask must be left to repose ten or fifteen days, according to the weather. The bottles must be perfectly clean, and if not new, care must be taken that no lead-drops remain in them, as these spoil the wine and render it deleterious. The corks should be perfectly sound, and as elastic as possible, so that when driven home they may expand beyond the contracted part of the neck of the bottle, and thoroughly exclude the air. To assist in this object, as well as to protect the corks from insects, the mouth of the bottle is often dipped in melted wax. As Champagne is bottled after remaining at longest only three years in the cask, considerable deposit takes place in the bottle. When recorked this is got rid of by the process of *dégorgement*. The bottle is inclined, the mouth downwards, till all the sediment is lodged in the neck; the cork is withdrawn, some of the wine rushes out, carrying before it the lees; the escape of the rest is hindered by an adroit adaptation of the fore-finger. To fill up the void caused by the wine which has escaped, a solution of sugar-candy in any of the common red wines of the country is added: the permanent cork, or the caoutchouc stopper, is now introduced; when the latter, a simple but convenient piece of mechanism is used: it is then wired down, and occasionally covered with tin-foil. If preserved in a cool cellar, good Champagne may be kept in perfection from ten to twenty years. In the great stores at Rheims the breakage amounts on an average to ten per cent. The Italian wines often have only olive-oil poured into the neck of the bottle, without using a cork.

Wines are classified according to the predominance of certain ingredients. When much alcohol is present, they are termed *strong* or *generous;* when otherwise, *light* or *weak;* when much sugar undecomposed, *sweet* or *luscious* (vins de liqueur); when little, *dry;* if a free acid in considerable proportion be present, they are called *acid* or *acescent;* when much carbonic acid is present, then *sparkling* or *effervescing* (*mousseux* of the French, *schaumwein*, German). Water is more abundant in wines made in wet seasons, and in the wine from new vineyards or young vines. These are also most prone to become sour. With the ancients it was a great object to get rid of the watery portion, for which purpose they employed various expedients, and often rendered them as thick as tar. The plan now adopted is best, to add starch-sugar to the must. The alcohol present in wines exists from an early stage of the fermentation, and is not a product of distillation. The quantity, according to Christison, varies from 16 per cent. in inferior Rudesheimer, to 37 per cent. in the strongest Port and Madeira; this being the per centage of proof-spirit estimated by volume. The condition in which alcohol exists as the natural product of the primary and secondary fermentation of the grape is very different from that in which it is found when obtained by distillation, even of wine, as in the case of the finest French brandy. The addition of any distilled spirit to wine is always to be reprobated, as it destroys the finer qualities of the wine, making it flat and mawkish. "The first and most conspicuous effect is the loss of that undefinable lively or brisk flavour which all those who possess accuracy of taste can discover in French wines or in natural wines; and a flatness, which must be sensible, by the principle of contrast, to the dullest palate which shall compare the taste of Claret with that of Port, or that of Hock or Grave with Lisbon or Bucellas" (Dr. M'Culloch). It tends equally, although in a greater length of time, to destroy the union of the colouring principle, which is well known to be deposited in Port wines, and apparently in a great measure from the action of this foreign substance. This fact explains why dishonest wine-merchants add brandy to their Port wines, to give them earlier the appearance of age, by producing the *crust*, a criterion by which no experienced or intelligent wine-drinker allows himself to be misled. Moreover no quantity of brandy can hinder the process of acetification, if the circumstances favourable to it are present. The pure light wines of France and Germany produce an agreeable exhilaration of mind, very unlike the mere physical excitement which results from the largely brandied wines, which are too much in vogue in England. The diseases also which attend spirit-drinkers, chiefly disorders of the liver, are commonly met with among the consumers of wines to which brandy or whiskey has been adventitiously added, though such disorders rarely if ever follow even the intemperate use of pure wine. Intoxication is a very rare occurrence among the inhabitants of the wine-producing countries. *Acid* is another component in wine. A free acid is necessary for the development of the fungus with which the progress of fermentation seems closely connected, for the evolution of the bouquet, for the agreeableness of the wine, and probably for its wholesomeness. In the best Rhine wines it is about ½ per cent. It is, therefore a popular error to denounce the acidity of wine. The kind of acid present is however a very important point. Tartaric acid is the best. Whether malic acid be ever present in good pure wine is doubtful, except in red Bordeaux, in which no lactic acid is found. (Mulder.) Racemic, silicic, and, perhaps, formic and glucic acid, may be found in some wines. (Mulder.) It is said to prevail in wines made in wet seasons. Citric acid is perhaps found in wine made from unripe grapes. It is not certain that oxalic acid is ever found in wine. It may be formed in some rare instances. It is very likely, however, to exist in considerable quantity in the spurious wine now largely made from the garden rhubarb. On many persons it must have a very hurtful effect. Acetic acid, or vinegar, is that which mostly abounds in low poor wines, especially of northern countries, and in good wines which have been mismanaged and allowed to spoil. The flat taste of the fluid and a smell of vinegar declare its presence. When wine is drunk on draught or from tap, it is most apt to form acid, unless the consumption be rapid. It is to disguise its presence that one of the most dangerous practices is adopted by vintners, namely adding sugar of lead to the tainted liquid. When this is suspected to have been used, sulphuretted hydrogen will reveal its presence. Sometimes it is present in bottled wine from a leaden shot being left in the bottle. A small iron chain is safest and best for cleaning bottles. Carbonic acid not only renders the wine sparkling, but increases its exhilarating action, as felt in Champagne. Tannic acid is present in Port and Tent, to the former of which it imparts both roughness and astringency. Port, both red and white, has less free acid than some of the finest Sherries. In the German wines Berzelius states that there exists tartrate of alumina and potass. Bitartrate of potass is more common. It is precipitated along with the colouring matter, and termed argol, found in wine-casks.

Respecting the relative amount of acidity in different wines much error prevails, not only in the popular mind, but among medical men. Dr. Prout ('On Stomach and Renal Diseases,' 4th edit., p. 8) affirms that sound Sherry contains less acid and sugar than any other wine. But several very careful experiments on different wines by no means confirm this statement. If applied to Manzanilla, which is the favourite wine of the Spaniards, it is true; but that wine is scarcely known in this country, however well it deserves to be so, as its freedom from adventitious brandy and from much acidity, with its slight degree of bitterness, a quality always to be prized in wine, strongly recommend it as a summer wine. It will be found that Port wine, both red and white, has less free acid than even some of the finest Sherries, though this is not confirmed by Dr. Jones' Appendix to Mülder. Madeira has long laboured under a most unjust opprobrium in this respect. That bad Madeira, and the wine which, though produced elsewhere, was sold for it, contain much acid, and readily disagreed with the stomach, may be perfectly true; but genuine first-rate Madeira has certainly very little, especially after a voyage to the East Indies. "The Madeira wines had fallen off in quality from over-shipment, and thereby gave further effect to this taste for Sherry. In this a useful lesson was given to all wine-growing countries." The observations of Dr. Paris are too just to be omitted:—"What, for instance, is the acid contained in Madeira, and against which so many mighty objections have been urged?—An atom merely of tartar! And yet the person who fancies that his digestion can be deranged by its action, will swallow twenty times the quantity of the same ingredient in some other shape, with perfect indifference and impunity." "Before we quit," says the same author, "the subject of vinous acidity, I shall beg to say a few words upon its supposed influence in exciting paroxysms of gout. That such attacks have followed particular potations, I do not mean to deny; but a slight excess of any kind, whether in diet or exercise, will excite the disease in those predisposed to it. Where the train is laid, an additional glass of Claret may have acted as the match; but in all such cases the explosion would have equally taken place had, instead of Claret, some other exciting cause fired it" ('On Diet,' p. 198). Liebig unhesitatingly affirms that, while to the free acid the exquisite *bouquet* of the Rhine wines is owing, to the tartar present in them some of their most salutary properties belong. To this he attributes the immunity enjoyed by those on the Rhine and Moselle, indeed of all who use the German wines, from the uric acid diathesis. This statement of the utility of these wines might be suspected to originate in national partiality; but it is abundantly confirmed by Dr. Prout and many others who have attended to the subject, and who have investigated it free from prejudice or favour. An occasional use of them is objectionable, but the habitual use is most salutary. (See Prout, 4th edit., p. 210.) Being light, they can be drunk without dilution, which is preferable to reducing a strong wine by adding water, which is much more prone to produce acidity in the stomach. (Prout, p. 9.) The water furnishing the oxygen and hydrogen necessary to convert the alcohol into acetic acid, probably favours the production of the acid. Moreover, wine diluted with water more readily produces intoxication than the pure wine would do; perhaps, as Dr. Paris has suggested, by applying the stimulus to a larger surface of the stomach ('On Diet,' p. 191).

The classification of wines has engaged the attention of almost all writers who have treated of them; but no satisfactory one can be presented. Jullien, in his very valuable 'Topographie de tous les Vignobles connus,' has given a geographical one, followed by an arrangement of the wines of each country into five or fewer classes, distinguishing the wines, simply so called, from the vins de liqueurs, and subdividing each into the red and white. This for all commercial purposes is sufficient; but for dietetical, or as a guide to individuals desirous of procuring wine for their own consumption, is futile. The greater number of the different kinds mentioned are never heard of beyond the district where they are produced, either from being entirely consumed by the inhabitants, or from the difficulty or expense of transport, or from deficiency in those qualities which ensure their preservation or recommend them to distant lands. This is especially the case with what are termed the fourth or fifth growths, which are seldom, even in good years, worth the expense of transport, if sold under their real names and at their just value. The first, second, and even third growths in good years, bring a price on the spot which puts it out of the power of persons not possessed of large capitals to obtain even a small stock of them. The principal English shipping-houses at Bordeaux and the first-rate houses in this country make their purchases only in the good vintages; and it is their competition which then raises the price, and the absence of their demand which makes it sink again in the unfavourable seasons. First-rate wine must always be high priced, if it be borne in mind that the market-value of a renowned vineyard is very great; that the territorial extent of such is in general very limited; that the expense of cultivation is very high; that these expenses are as great in the bad years, when they bring no return, as in the good years; that the recurrence of favourable vintages are rare and distant; and that constant superintendence and expense are necessary till the wine reaches perfection—not to mention the loss from evaporation, ullage, breakage, and other accidents, and to say nothing of the accumulating interest of the original purchase-money for twenty or thirty years. Besides all these, the duty, though paid in the first instance by the merchant, is recovered by a charge on the consumer.

Attention is now being paid to the culture of the grape and the making of wine in the United States, South Africa, and Australia; with a view of determining whether temperate climates, and English or Anglo-American industry, can introduce this as a profitable culture, The taste of English wine-drinkers has been unquestionably vitiated by the long use of highly-brandied Spanish and Portuguese wines; the taste for light German and French wines, even if the price were low, is by no means extensive in England; and as the new vintages above-named would bear more resemblance to those of France and Germany than to those of Spain and Portugal, they will have some difficulties to contend against. Nevertheless, it is highly desirable that the new attempts should have a fair trial. When Professor Wilson reported on the New York Exhibition of 1853, he stated that vineyards are rapidly extending in that country, principally in Ohio; twelve kinds of grapes are cultivated for the purpose; and the matter is an interesting one to English colonists, seeing that the climate of Ohio is very much like that of many of our colonies.

Of the South African wine which is now coming over to this country, it is to be regretted that the importers give it such names as "South African Port," "South African Sherry," &c. If it be a pure and pleasant wine, it should depend on its own reputation, and not on the attempts to imitate what are really mixtures of wine, brandy, and adulterants.

In 1856, the Society of Arts awarded a silver medal to the grower of four kinds of wine from Australia, three white and one red. Two of the white kinds were satisfactory; one much resembled Cape wine, while the other was a dry and clean wine, with considerable body. The red wine was light, clear-tasted, and exactly like Bordeaux. These wines were made by Mr. Marking, in 1853 and 1854, at Irrawory, in the Hunter district of New South Wales. He found that the grapes suitable in Europe would be no criterion for those best fitted for the climate of New South Wales. The colony contains a large area of good vine land, some of which has been made to yield 1000 gallons per acre. It is believed that the freight would not necessarily be large, for the wine would form good ballast for wool ships to England. All the operations for making Australian wine are fully described in the Society of Arts' Journal for 1856. Professor Owen, as one of the jurors of the Paris Exhibition of 1855, said, "In the department for Australia were evidences of the increasing importations from the vineyards of New South Wales. The specimens of wine exhibited by Messrs. Macarthur, King, and Brown, are deserving of special notice. The wines included white wines akin to those of the Rhine; red light wines like those of Bordeaux; Mousseux varieties with a bouquet, body, and flavour equal to the finest Champagne; Muscats and other sweet wines rivalling the Montignac of the Cape. Some of these wines were of the vintage of 1839, bottled in 1842; others had made the voyage round the world in wood. The verdict of the experts (judges) was much in their favour; for, whereas, on the wines of Europe the numbers indicative of quality ranged from as low as 2 to 18, the lowest number assigned to the Australian specimens was 7, the highest 14, and the average number 10½, being as high as that of the wines of Austria, and much exceeding that of the wines of the Cape, or any other wine-producing colony." It has been since stated, however, that the Australians themselves care little for their own wine; those who can afford to drink wine at all, buy the port and sherry, the claret and champagne, of Europe. There is doubtless much of habit and conventionalism in this; nevertheless the exertions of the planters are worthy of all commendation.

Of wines, real or sophisticated, other than the juice of the grape, we speak in WINES, BRITISH. Of the extent and peculiarities of the trade, details will be found under WINE AND SPIRIT TRADE.

WINE, MEDICAL USES OF. These are distinct from the common or dietetical employment of wine. For very young children, wine may be pronounced to be at once needless and hurtful, as was proved by the experience of Dr. Hunter on his own children. The immense number of the children of the lower orders who fall early victims to gin prove it on a large scale. But in the case of great constitutional debility, or in states of exhaustion from depressing diseases such as diphtheria, scarlatina, or gastric fever, small quantities of good wine cautiously administered, are invaluable tonics. The best mode of administering them is, not to give them undiluted, or even simply with water, hot or cold, but with a very small quantity of hot water having mixed with it so much biscuit or rusk as shall form with the wine a *thick* pulp, requiring to be eaten rather than drunk. This prevents the coats of the stomach being so much irritated, and the wine does not so speedily reach the brain to over-excite it. At a more advanced period of life, if rapid growth should occur, wine in moderation is beneficial. But much caution is requisite, lest habits should be formed, difficult, if not impossible to break. Zealous students are sometimes tempted to prop up exhausted nature by wine; but the benefit is only temporary, while the injury is often permanent. Tea or coffee, or coca, [*Erythroxylon Coca:* See STIMULANTS] are preferable.

As life advances, and the circulation becomes languid, wine in moderation, at fit times, is commendable. It has been designated "the milk of old age," and may tend to prolong life—but in excess cannot fail to shorten it.

The selection of the kind of wine must be left to the individual, or to the judgment of his medical attendant. Every one should aim at obtaining *good* wine, and avoid mixing wines. Where gouty persons use wines, it should be Rhenish, Moselle, or Bordeaux (Claret), and these should be strictly adhered to.

In the treatment of fever, common or typhoid, there generally occurs a stage when stimulants are requisite. Of these, wine is most frequently employed. But as the type of fever so frequently varies, no rules can be laid down. Nothing shows the discriminating power of the physician more than his ability to decide when it is to be used, and how much is to be administered. States of great prostration need much. Port wine, Madeira, and Champagne are mostly preferred. But if erysipelas or affections of the liver occur, Moselle with Seltzer water is best. Tympanites is often dissipated by wine, given either by the mouth, or as an enema. (Abercrombie on the 'Diseases of the Stomach.') The same author gives cases where delicate females, unaccustomed to the daily use of wine, had been saved by the liberal use of wine, in cases of much exhaustion. But these are very extreme cases. Wine, especially port wine, given with very warm water, to persons much exhausted with over walking, or during convalescence from fevers or other weakening diseases, before out-of-door exercise can be taken, often insures sound refreshing sleep if administered about the usual time of going to bed. A rusk or biscuit steeped in it converts it into a digestible supper for such persons.

WINE AND SPIRIT TRADE. It will be convenient to treat this subject under two sub-headings.

Wine Trade. The wine trade of England has been governed for a century and a half almost wholly by a particular treaty with Portugal, called the Methuen Treaty; chiefly by creating an artificial taste for that particular wine which happened to be most easily procured. During many centuries, almost the only foreign wines consumed in England were French. In 1693, a change began, by favouring Portugal wines with a lower import duty; the favour was increased in 1697; and in 1703, Mr. Methuen negotiated a treaty, whereby England engaged to admit port wine at a duty of one-third less than that on French wine; on condition that Portugal received English manufactured goods on favourable terms. The English wine-drinkers, in fact, were sacrificed to the English manufacturers; and the effects have been apparent from that day to this. During the greater part of the last century, England took twenty times as much Portuguese wine as French wine, until the taste for the latter became almost extinguished, except among the wealthy classes. The wine-growers on the Douro and the great merchants at Oporto, finding they had nearly a monopoly, worked it in the usual way to their own profit. An Oporto Wine Company, established in 1754, purposely diminished the extent of the vineyards, with a view of keeping the price wholly under their own command; and this policy was successful until quite recent times. Almost every gallon of port wine was sent to England; other countries either did not like it, or would not pay the price demanded for it. The *natural* flavour and quality of the wines of the Upper Douro are almost unknown in England, and probably would not be relished; they are strongly flavoured for the English market, and require to be kept many years in the wood and in bottle, before they acquire the qualities familiar to English port drinkers.

In 1819 a reduction was made in the duty on French wines; and in 1831 the duty on *all* foreign wines was equalised—after 128 years of favouritism to Portugal. The consumption of port did not, however, yield to this change; because the English had become accustomed to the taste of that wine, and had not yet learned to appreciate the light wines of France. So signally was this the case, that in 1842, eleven years after the equalising of the duty, the English consumption of French wines barely amounted to one gallon for every sixty persons: the total consumption of all wines was about a quarter of a gallon per head, whereas, so far back as the year 1700, it was a gallon a head. It is well known that wholesome wine, of fair quality, can be exported from France at sixpence per bottle; and it still remains to be seen to what degree England will be able to avail herself of this advantage. It was stated before the Committee on the Wine Duties in 1852, by Mr. Forrester, an extensive wine-grower in Portugal, that no port is brought to England with less brandy in it than three gallons to a pipe of 115 gallons; and that the ratio varies from this minimum up to a maximum of 17 gallons. Unfortunately, too, many other substances besides brandy are added in all except the best kinds of port.

From 1697 to 1785, the quantity of foreign wine imported annually never varied far from 2,000,000 to 3,000,000 gallons; from 1786 to 1851 it varied from 4,000,000 to 11,000,000. The Portuguese wine (port) maintained an ascendancy over Spanish (sherry) till about 1830; since which year the balance has been rather the other way. The difference in the above-named quantities was in the *imports;* the *home consumption*, from 1830 to 1860, remained remarkably constant, never deviating far from an average of 7,000,000 gallons. The duty remained steady during that period (about 5*s.* 6*d.* per gallon, or 11*d.* per bottle), and the consumption barely increased as rapidly as the population.

At present, port is gradually giving place to sherry. The entries for home consumption of all kinds of foreign wine, in 1860, were as follow:—

From Spain	2,975,769	gallons.
" Portugal	1,776,138	"
" France	1,125,599	"
" South Africa	426,556	"
" Dutch possessions	222,725	"
" Italy and Naples	205,084	"
" All other countries	626,321	"
	7,358,192	"

Of this total quantity, 3,001,413 gallons belonged to the class of *red* wines, and 4,356,779 to that of *white*. The most noticeable feature in that year was the advance in the French wine trade. In 1857, 1858, and 1859, the French wine drunk averaged about 600,000 gallons annually: in 1860 it was nearly double. This resulted from only a few months' operation of the new tariff, which opened the way for the introduction of French wines at a moderate duty. By the Customs Duties Act, passed August 28th, 1860, foreign wines, during the remainder of that year, were to pay 3*s.* per gallon, and colonial wines 2*s.* 9*d.*, plus 5 per cent. From and after January 1st, 1861, all wines pay 1*s.* per gallon, if containing less than 18 per cent. proof spirit; the duty rises to 2*s.* 11*d.*, according to the alcoholic strength. There seems something reasonable in this, making the stronger wines pay the higher duty—provided the mode of testing the quality be not too complex and troublesome. [ALCOHOLOMETRY.]

We may here remark that Sykes's Hydrometer [HYDROMETER] is declared by the legislature to be the official means of deciding the alcoholic strength of wines and spirits; but as wine is now to be estimated by the quantity of spirit it contains, attention will naturally be paid to the easiest mode of making the estimate. Mr. Phillips, chemist to the Revenue Department, has reported favourably of Crookford's Patent Spirit Indicator for wines. This apparatus is based on the principle that the boiling point of any spirituous liquor depends on the quantity of contained alcohol. It consists of a spirit-lamp and stand, a boiler and condenser, and a thermometer with a moveable scale graduated to show the degrees per cent. of pure spirit, and fitting with an air-tight plug into the boiler. There is a tin vessel to hold water, which flows thence through a flexible tube to the inlet of the condenser; a similar tube is attached to the outlet whence the water runs to waste. The boiler is provided with a condenser, which returns to it whatever portion of the alcohol is exhaled, so as to include it in the estimate of the sample.

The Refreshment Houses and Wine Licences Act of 1860 is likely to have some influence on the consumption of wine in England. Any shopkeeper may take out a licence, varying from 10*s.* 6*d.* to 3*l.* 3*s.* per annum, according to the rated value of his house, for the sale by retail of foreign wine. The word "retail" is considered to refer to quantities less than two gallons, or one dozen bottles. The wine may be drunk on the premises, under certain specified conditions, and on payment of a higher licence-duty. All liquor sold as wine must contain less than 40 per cent. of proof spirit, or it will be regarded as spirit. Excise officers are to possess large powers in respect of the examination at all times of premises licensed as wine-shops. Standard measures are to be used. Numerous precautions are taken to insure the honest interpretation of the Act—rendered necessary by the fact that spirits now pay *ten times* as much duty per gallon as wine.

Spirit Trade.—The duty on spirits has been heavy for more than half a century past, varying from 200 to 600 per cent. on the value of the article taxed. The quantity of home-made spirits which paid duty rose from 9,000,000 gallons in 1802 to 23,000,000 gallons in 1849, and 26,000,000 gallons in 1854; while in the last-named year foreign spirits (rum, brandy, hollands, &c.) were taxed to the extent of about 5,000,000 gallons. Spirit drinking is *not* increasing among us. In 1858, 1859, and 1860, the home-made spirits charged with duty did not in any one year reach 24,000,000 gallons, being less than in 1854. The foreign spirits in 1860 (slightly greater than in the two preceding years) presented the following quantities:—Rum, 3,700,000 gallons; Brandy, 1,460,000; Geneva, or Hollands, 260,000. British and foreign together, there are about 30,000,000 gallons of spirits for 30,000,000 people, or a gallon per head per annum each.

An interesting matter concerning spirit duties is that of *methylated spirit.* Spirits of wine, or alcohol in a strong form, is used for many purposes in the arts. It is a solvent of resinous substances, which, when thus dissolved, are used in stiffening hats, and in making varnishes. It is used as a solvent in the manufacture of many chemical substances, including the alkaloids and other organic products, largely used in medicine. It is used in the production of ether, chloroform, sweet spirits of nitre, and fulminating nitre; as a solvent or menstruum for administering the animal and vegetable substances used in medicine in the form of tinctures; as a fuel for burning in spirit lamps; as an addition to oil of turpentine or other hydro-carbons in lamps; and as a solvent for essential oils and other odoriferous substances used in perfumery. For all such purposes alcohol is very valuable; but the high price is a bar to extensive use. There is, however, a liquid now well known to chemists, called *methylated spirit,* which will answer for these purposes nearly as well; and as this is not fit for drinking, manufacturers have for some years urged the Excise to remove the duty from it, simply in the interests of productive industry. In 1855, Messrs. Greatorex, Hofmann, and Redwood presented a report to the government on this subject. They tried to produce a substitute for spirit of wine that would not be drinkable, such as sulphide of ethyl, caoutchicine, &c. At last they found that wood naphtha, pyroxylic or methylic spirit, might be so prepared as to be useful to manufacturers, and yet not likely to be used by spirit drinkers as a substitute for gin. Messrs. Turnbull of Glasgow announced that they could make it at 8*s.* 6*d.* per gallon; and others have stated it might possibly be produced for 5*s.* Two gallons and a half of methylated spirit can be obtained from one ton of dry wood. Mr. Smith, the distiller, of Whitechapel, expressed a belief that publicans would not venture, if the methylated spirit were rendered ever so cheap by the removal of the duty, to mix more than $\frac{1}{10}$ part with their gin, for fear of exciting the suspicion of their customers. The chemists reported to the Excise that, in their opinion, methylated spirit might be set free from duty without affecting the ordinary revenue from ardent spirits. "It appears to us that it would be proper to mix the spirit in the distillery, and to declare illegal the possession of the methylated spirit by a rectifier or publican. The retail sale of the methylated spirit would then fall into the hands of druggists and oilmen, who could be supplied direct from the distillers." This advice has been acted on. A small per centage of pure methylated spirit, mixed with alcohol, is allowed duty free; it is suitable for all manufacturing purposes, but is not drinkable, nor can the alcohol be separated from it by any available process. All the government pyrotechnic or artillery compositions are now made with methylated spirit instead of spirit of wine; and the liquid is coming very largely into use.

The duty on spirits underwent changes in 1853, 1854, 1855, 1858, and 1860. In 1860 an act was passed, which repealed wholly or partially no less than twenty-six former acts, embodying all the regulations for the guidance of manufacturers of, and dealers in, spirits. In the same year, another act fixed the duty on British spirits at 8*s.* 1*d.* per gallon till July 17th, 1860, and 10*s.* after that date. By the Customs Act of the same year, foreign spirits pay an import duty about equal to the Excise duty on British spirits, namely, 10*s.* 2*d.* to 10*s.* 5*d.* per gallon.

WINES, BRITISH. British wines, or Sweets, as they are called by the Excise, are sweet beverages made as substitutes for real wine. The making of them forms a part of domestic chemistry or household skill, as well as a branch of trade. Generally speaking they are prepared from the juice of fruits; but a large number of other chemical substances are similarly employed. The common English fruit wines comprise gooseberry, currant, cherry, raspberry, mulberry, strawberry, apple, elder, whortleberry, blackberry, damson, bullace, apricot, orange, juniper, lemon, grape, peach, quince, and mixtures of these. The dry-fruit wines are chiefly raisin, fig, and date. The root wines are such as rhubarb, celery, parsnip, turnip, and beet-root. The flower and sap wines comprise cowslip, elder-flower, rose, clove, gilliflower, violet, carnation, lavender, primrose, balsam, pine-apple, birch, &c.

In the preparation of ordinary fruit wines, the fruit is selected mature and ripe, but not so sweet as over-ripe fruit. The stalks and the damaged portions are picked off. The rest is bruised in a tub, put into a vat, and steeped thirty or forty hours in water, with frequent stirring. The liquor is drawn off. The pulp is pressed in hair bags; sugar, tartar, &c., are added, and stirred for some time. Vinous fermentation then commences; during its continuance the liquor is frequently skimmed, and after three or four days is run off into casks. In about a week, flavouring ingredients are added; and several days afterwards brandy or some other spirit. Fining and racking complete the process. Some fruits are better for boiling before these operations; others would be spoiled thereby.

The Excise authorities first gave the name of *sweets* to raisin wine; but the name became afterwards applied to all the fermented beverages known as British wines. The making of raisin wine as a branch of trade arose in a curious way. In VINEGAR MANUFACTURE it is explained that a substance called *rape,* consisting of the stalks and skins of raisins, forms the best known filtering and clarifying substance for vinegar. When Mark Beaufoy established his vinegar works at Lambeth more than a century ago, he could devise no better way of obtaining rape then by purchasing raisins, steeping them, throwing away all the juicy portion, and retaining the rest. Dr. Fothergill, an eminent physician, suggested to him the making of raisin wine out of the juice, instead of wasting it. He did so; and thus commenced a trade which has been continued by his descendants ever since. The manufacture of raisin wine requires larger appliances than those which relate to familiar English fruits. The kinds of raisins chiefly used are Smyrnas, Malagas, Lexias, Faros, and Cape de Verds; these produce various qualities of wine known by such terms as *dry, sweet, strong-bodied, rich, full,* &c. The wholesale purchases of raisins are made chiefly towards the close of the year; and the wine is made from thence to spring. The hard masses of fruit are beaten open, and steeped in water till the raisins swell and float. All the vinous and saccharine juices are then pressed out by hydraulic-presses, screw-presses, or heavy weights, according to the scale on which the operations are conducted. Fermentation is then induced in the juice by a leaven or yeast. From the fermenting tuns the juice, which is now wine, passes to other vessels, where the racking, fining, and sweetening are carried on.

Home-made wines or sweets paid a small duty until 1834; but the duty was abolished in that year, since which time the extent of the manufacture has not been known.

A maker of sweets may be as honest a dealer as a maker of the best foreign wines; but unfortunately the cheaper wine has come to be used as an adulterant of that which is more costly. There is hardly any possibility now of determining to what extent the rectifier and the British wine maker are, knowingly or unknowingly, concerned in producing imitations of foreign wine. If the name given to the beverage be such as to denote home manufacture, there is no difficulty. There are in the market wines designated British champagne, British port, British sherry, British Moselle, &c. These are made in England mostly from English fruits, by processes in which the rectifier and the British wine maker are concerned. But the great fraud, which recent investigations have brought to light, is the making up of a mixture which shall bear the name and bring the price of foreign wine. It has been estimated that two out of three bottles of all the so-called champagne sold in England are surreptitious: the wine being made chiefly from English gooseberries. Cider is a chief constituent in a very large roportion of the low-priced port. Much of the port imported from Portugal, also, is adulterated. It was proved before a committee of the House of Commons on the Wine Duties, in 1852, that the Portuguese mix elder-juice, apple-juice, sloe-juice, and logwood decoction, in the port wine intended for the English market; and that the Spaniards are not more scrupulous in reference to sherry. They believe that the English taste for wine is so depraved, as to render detection improbable. When the wines reach England, various other ingredients are often added, including oak-bark, turnsole, elder, privet, beet, Brazil-wood, cudbear, red Sanders wood, and catechu—some to hide the fact that a large quantity of water has been introduced, some to imitate the right colour, some the right crust, &c. It has even been found that glass-makers are employed to make bottles of glass having a peculiar chemical constitution, such as to lead to the formation of a sort of skin or scum which shall imitate the "bee's wing" of "fine old crusted port." Many receipts for making so-called port wine are extant, some of which contain *not a drop* of real port. It is known that much of the port sold at public-houses can be made for 1*s*. 6*d*. per bottle, thus leaving a large profit, even when sold at what seems to be a low price.

It may be well to remark that brandy, either real, foreign, or imitative British, is used to mask the use of adulterants in port wine. In imitating most other foreign wines, the produce of the British wine-makers is more especially relied upon.

WINTER, SPRING, SUMMER, AUTUMN. The astronomical meaning of these words is derived from the considerations in SEASONS, and we are told and taught that winter begins at the winter solstice, spring at the vernal equinox, summer at the summer solstice, and autumn at the autumnal equinox. That is, according to the best authorities, it is spring from the middle of March to the middle of June, summer from thence to the middle of September, autumn from thence to the middle of December, and winter from thence to the middle of March again. At the same time the poets and the farmers, who have a much better right than the astronomers to settle the meaning of these terms for common use, agree in placing the rise of vegetation, the pairing of birds, and the first appearance of flowers in the spring; the hay harvest and the ripening of all the earlier fruits in summer; the grain harvest, the later fruits, and the fall of the leaves in autumn; and the heavier frosts, snow, and ice, in winter.

It is impossible to fix a common commencement of the seasons even for the parts of the earth which lie between the Arctic circle and the tropic, which are all that need be considered; for the polar and inter-tropical regions have each a set of seasons of their own. But this we may safely say, that the agricultural and poetical seasons are earlier than the astronomical ones. All that distinguishes spring from winter begins to take place before the vernal equinox, all that distinguishes summer from spring before the summer solstice, and so on. Most certainly it will be found that the greatest intensity of the several seasons happens, one year with another, at a period not long after the astronomical phenomenon at which the season is said to commence.

When the year is divided only into summer and winter without further subdivision, it is then an exact division to say that the two halves begin and end with the equinoxes. But here the principal phenomena, the solstices, on approach to which heat and cold depend, are in the *middle* of the halves. If we were to divide the year into four seasons, during which the earth should receive from the sun the greatest and least portion of heat in two of them, and intermediate portions in the other two, the four astronomical commencements should be made the middle points of these seasons. The consideration in SEASONS will easily make it appear why, for the same reason as the greatest heat is after the longest day, the middle of the agricultural seasons should fall after the astronomical point of separation.

WINTER'S BARK, the bark of *Drymis Winteri* (Linn.); called also *Wintera aromatica* (Murray and Willd.), the true Winter's Bark, or Magellanic Cinnamon, to distinguish it from the bark of *Canella alba*, or false Winter's Bark. As one of the names imports, this is obtained from a tree growing in South America, from Magalhaen's Straits up to Brazil. It is met with in cylinders, rarely flat pieces (these last are termed *caryocostin*), from one to two feet long, and from six lines to two or three inches in diameter. It is generally freed from the outer rind (which is tasteless and without aroma), and is of a yellowish-red colour, with reddish-brown points, the marks where the leaves and young branches have been. The inner surface is tolerably smooth, more or less clear, of a reddish-brown colour, which serves to distinguish it from the bark of *Canella alba*, which is much paler. The taste is aromatic, sharp, burning, and peppery. The smell, when first broken, is agreeable, resembling a mixture of cloves, cinnamon, pepper, and marjoram.

According to Henry, its chemical composition is resin, volatile oil, colouring matter, tannin, acetate of potass, chloride of potassium, sulphate of potash, oxalate of lime, and oxide of iron. The volatile oil is pale yellow, lighter than water, with a very hot and acrid taste. By standing, it separates into two parts: one, the most abundant, a greenish-yellow liquid; the other (heavier, but lighter than water), white, and of a fatty consistence. The volatile oil of *Canella* is heavier than water: this serves to distinguish them, as well as re-agents, showing in the true Winter's Bark the presence of both tannin and iron, which are wanting in the *Canella*.

Winter's Bark is an aromatic stimulant and tonic, of a very valuable kind, and it is to be regretted that its use has been almost entirely superseded by the false Winter's Bark (*Canella*). Dr. C. F. von Martius says: "This bark deserves the first place among the aromatic tonics of this country—that is, Brazil." When no inflammatory state of the stomach contraindicates its use, in debility of the digestive organs, with loss of appetite, or slow digestion, it is a valuable remedy.

WIRE-DRAWING. Wire is metal elongated into the form of a slender cylindrical rod, often so fine as to be comparable to a thread, by the operation of wire-drawing. This process consists in passing a piece of ductile metal through a series of holes, successively diminishing in diameter, in a hardened steel-plate called a *draw-plate*, so as to reduce its cross-section to the size and figure of the last or smallest hole, increasing its length at the same time in a certain proportion to the diminution of thickness occasioned by the process. Though ordinary wire is cylindrical, the nature of the process of wire-drawing renders it available for the formation of slender rods of any other required figure. An important application of the process to the production of other forms is to the manufacture of *pinion-wire* for time-keepers. This is produced of any required size and number of teeth, and the wire being cut to the required length for both pinions and axis, the teeth are filed away from the portion used for the latter. By this means pinions may be formed at much less expense than by the ordinary process of wheel-cutting. The grooved rims of spectacle-frames are another example of the useful application of the wire-drawing process, they being formed of wire made for the purpose.

In early times, metals were probably beaten out with a hammer into thin plates or leaves, which were then divided into small slips by means of scissors or some other cutting instrument; these slips were subsequently rounded by a hammer and file, so as to form threads or wires. Beckmann expresses his opinion that the rarity with which works made with threads of metal are alluded to strengthens the presumption that the ancients were unacquainted with the process of producing wire or metallic threads by drawing. So long as wire was formed by the hammer, the artists of Nürnberg, by whom it was fabricated, were styled *wire-smiths*, but subsequent to the introduction of the drawing process their designation was changed to *wire-drawers* or *wire-millers*; and as these appellations occur as early as 1351 and 1360, in the histories of Augsburg and Nürnberg respectively, Beckmann conceives that the invention of wire-drawing must be assigned to the 14th century. In all probability the earliest drawn wire was made by hand, but ere long a machine, impelled by water-power, and capable of drawing wire without the intervention of the hand, was introduced. Though the point is not certainly established, this ingenious machine appears to have been first constructed at Nürnberg by a person named Ludolf, who kept it secret for some time, and realised much money by the use of it. Nürnberg also gave birth to many subsequent improvements in the manufacture of various kinds of wire. The precious metals were undoubtedly among the first made into wire; and perhaps brass and iron were not drawn until some time after the invention of the art. Blanch iron-wire, or white wire, is, however, mentioned in a list of manufactured articles the importation of which into England was prohibited by an act of the reign of Edward III., in the year 1463; and in a similar act passed in 1484 both iron and latten wire are mentioned. Anderson records, under the year 1565, the granting of patents to certain Dutchmen or Germans for the prosecution in England of various manufactures, among which is that of wire. He states that prior to that time all English iron wire appears to have been drawn by manual strength, in the Forest of Dean and elsewhere; and that until these foreigners introduced the use of a drawing-mill, the quality of English wire was so bad that most of that used in the country, as well as ready-made wool-cards and similar articles, was imported from abroad. By the year 1630 the manufacture appears to have made such progress, that in a proclamation of Charles I. it is alluded to as a manufacture of long standing, and one which employed many thousand persons; and it is asserted "that English wire is made of the toughest and best Osmond iron, a native commodity of this kingdom, and is much better than what comes from foreign parts, especially for making wool-cards." The proclamation then forbids the importation of foreign iron wire, and of wool-cards, hooks and eyes, and other articles made of it. The first wire-mill in England was set up at Sheen, near Richmond, by a Dutchman, in 1662. The wire-drawing business either following the cloth manufacture or determined by the proximate localities of coal and iron-stone, took deep root in the neighbourhood of Barnsley in Yorkshire. The manufacture of copper and brass wire in this country was commenced about the year 1649, at Esher, by two foreigners; but they used Swedish rose-copper.

For the manufacture of iron wire the very best and toughest iron is selected. Before the process of rolling with grooved rollers had become common, this superior iron was prepared for the drawing-machine by extending it with the hammer into convenient rods, about the thickness of the little finger. These rods were further reduced in thickness and extended in length by a coarse kind of drawing, called *ripping* or *rumpling*, with the kind of machine described by Beckmann as probably the invention of Ludolf. Holland, writing about 1833, states that although this contrivance is now rarely to be seen in the large wire-mills of this country, it remains in use in some old establishments; and also that in France, and among the continental manufacturers generally, iron wire was, until within a late period, altogether drawn by such an apparatus.

In modern practice both iron and steel, but especially the former, are prepared for the final drawing by passing between grooved rollers, made with the greatest accuracy. The rollers used for this purpose are generally at least seven or eight inches in diameter, and are sometimes made to perform 350 revolutions in a minute. A bar of steel thirty inches long and an inch square, heated to redness, is passed between the rollers, through grooves successively diminishing in size, eight times in less than a minute, and is thereby elongated to from twenty to thirty feet. As it would be difficult and inconvenient to pass the rod back between each rolling, in order that it might always enter the grooves in the same direction, three rollers are used, placed one above the other, so that when the wire has passed in one direction between the two upper rollers, it may pass back in the opposite direction between the two lower rollers, and *vice versâ*, thus avoiding any loss of time, heat, or labour in passing it backwards and forwards. For ordinary wire the rods are commonly reduced to a thickness of about one-eighth of an inch by this process. The slender rods thus produced are called, from their appearance, *black wire*, to distinguish them from drawn or *bright wire;* and, on account of its cheapness, such wire is preferred for coarse purposes in which it is either to be painted or concealed from view. It is commonly used by tinmen and braziers for strengthening the rims of pots, kettles, and various kinds of tin-ware and copper-ware. The kind of cast-steel wire of which the best needles and some other articles are made, is not usually submitted to the rolling process, but, after being tilted to about a quarter of an inch square, it is rounded on an anvil previous to elongation by the draw-plate.

In whatever way the metal may have been prepared for the ultimate process of drawing, or whatever may be the motive-power employed in that process, it is essentially the same. The draw-plate is usually formed of a stout piece of shear-steel, about six inches long and an inch and a half in diameter, flattened on one side. It is pierced transversely with several conical holes, the larger orifices of which open upon the flattened surface of the plate, while their smaller orifices are carefully finished to the size to which it is intended to reduce the wire drawn through them. When the holes have become enlarged by use, their smaller orifices are reduced by hammering, and then reopened to the proper size and form by means of a long taper needle called a *pritchell*. The art of making draw-plates has been carried to much greater perfection in France than in this country; and in time of war French draw-plates have been sold for their weight in silver. The French plates consist of a bar of wrought-iron, about two inches broad and one inch thick, covered on one side with a very hard composition called *potin*, which consists of fragments of cast-iron pots, broken with the hammer, and mixed with pieces of white-wood charcoal. One side of the wrought-iron bar is hammered to a furrowed surface, and covered to the depth of about half an inch with pieces of the prepared potin; the whole is then wrapped up in a coarse cloth, which has been previously dipped in clay and water mixed to the consistency of cream, and finally put in the forge. Being more fusible than the wrought-iron, the potin is the first to melt: and as soon as it begins to do so, the plate is withdrawn from the fire and gently hammered; and the heating and hammering are repeated alternately until the union of the two metals is complete. The plate is subsequently reheated, and extended by hammering to double its original length; the harder metal being so perfectly united with the other as to form a malleable alloy with it; and while the bar remains hot the holes are formed by punching. For this operation the bar is four times heated, and after each reheating a finer punch is employed, so as to make the holes taper. The holes are formed from the wrought-iron side of the bar, and are not carried completely through by the plate-maker; the completion of the holes being performed with sharp punches when the plate is cold, by the wire-drawer himself. Another mode of producing draw-plates, practised at one of the principal wire-manufactories in France, that of the Messrs. Mouchel, at l'Aigle, in the department of l'Orne, is by arranging several pieces of wrought-iron in the form of a box without a lid, and filling the cavity with cast-steel. The whole is then covered with a luting of clay, heated until the steel begins to melt, and worked with a hammer in a similar way to that above described. When draw-plates have been hammered up several times, to reduce holes worn too large by use, they become so hard as to require annealing. After every precaution has been observed, draw-plates will vary somewhat in hardness; but those which are too soft for drawing iron wire may be used for brass, while the very hardest are reserved for steel wire.

The modes of determining the thickness of wire, and the improvements in graduation suggested by Holtzapffel and Whitworth for this purpose, are noticed under GAGE.

In drawing wire by hand the draw-plate is laid against two upright pillars fixed on a bench or table, and, the extreme end of the wire to be drawn being so reduced as to enable it readily to pass through the hole, a small portion is drawn through by a lever apparatus. When a sufficient length of wire has thus been brought through the plate, it is secured to a conical or cylindrical drum, which is mounted upon a vertical axis opposite to the hole in the draw-plate. The workman then takes in one hand the coil of thick wire to be reduced, and in the other a lever handle attached to the drum; and while he turns the drum so as to wind the wire upon its circumference, and consequently to draw it through the plate, he imparts a kind of twist to the wire which enters the plate, by a peculiar motion of the hand in which the coil is supported. In drawing coarse wire, which requires considerable power, the workman walks round the bench at each revolution of the drum, carrying the lever round with him; but for finer wire the apparatus is much lighter, and requires very little labour. In factories where inanimate power is used the winding-cylinders are turned by bevil-gearing underneath the bench, and the coil of undrawn wire is placed on a reel. This apparatus is accompanied by an ingenious contrivance which allows the drum to fall out of connection with the gearing, and consequently to cease to revolve, as soon as the piece of wire is drawn completely through the plate. In some cases, as for pinion-wire, which would be injured by winding upon a drum, wire is drawn upon a long draw-bench in a straight line, the power, which is equalised by the use of a fly-wheel, being applied to a winch-handle which, by means of spur-gear, imparts motion to a horizontal rack.

Between the repeated drawings which are requisite to reduce wire, especially of the finer or smaller sizes, to the required degree of tenuity, it is necessary frequently to heat and anneal it, by which processes the fibrous character imparted by the drawing is in some degree removed before a fresh extension takes place. The annealing-oven should be so contrived as to avoid oxidation as much as possible, and to heat all sizes of wire with tolerable uniformity, the thickest being placed in such a situation as to receive most heat; and after leaving it the wire must be scoured or washed to free it from whatever oxide may have formed upon its surface. In order more perfectly to remove the oxide (which, if left on the surface, not only impairs the appearance and the strength of the wire, but also injures the draw-plate) the coil of wire is sometimes immersed in starch-water or stale beer-grounds during the operation of drawing. A curious and important discovery was made some years since at an eminent wire-manufactory, where, in order to heat the acid liquor in which the annealed wire was steeped, some ingots of brass which happened to be at hand were made red-hot and quenched in it. It was subsequently found that, owing to the action of the acid upon the brass, the iron wire had become coated with a thin film of copper, which greatly facilitated its passage through the draw-plate, acting, it would appear, like a lubricating medium. So important was the advantage gained, that the practice has been universally adopted in that factory of using a weak solution of copper in the acid liquor in which iron or steel wire is washed. The film of copper is entirely removed by the last annealing process. The operation of drawing is also facilitated by the free use of grease, or, for the finer descriptions of wire, wax, to lubricate the wire as it passes through the plate. The repeated annealings of steel-wire would deprive it of too much of its carbon, but for the practice, which is not pursued with iron wire, of surrounding it with charcoal-dust while in the furnace. The rapidity of the drawing process must vary with the quality of the metal, the hardest steel wire requiring the slowest motion; but as each successive drawing increases the fibrous or filamentous character of the metal, the rapidity of the extension may be safely increased as the wire becomes more and more attenuated.

Even when made with the greatest possible care, the holes of iron or steel draw-plates will enlarge so much with wear as to render it impossible to draw any very great length of wire perfectly uniform in thickness. To remedy this, Mr. Brockedon obtained a patent in 1819 for making draw-plates, the holes of which consist of diamonds or other hard precious stones. Dr. Ure states that with a plate of this kind mounted with a ruby, pierced with a hole ·0033 of an inch in diameter, a silver wire 170 miles long has been drawn so perfectly uniform, that no difference could be detected either by weighing portions of equal length or by measuring with a micrometer.

Dr. Wollaston communicated to the Royal Society, in the year 1813, a method of drawing wire of extreme tenuity, suitable for use in micrometers. This he accomplished, in the first instance, by boring or drilling a rod of silver, longitudinally, with a hole one-tenth of its own diameter, and then filling it with gold. The compound bar being drawn into wire $\frac{1}{500}$th or $\frac{1}{400}$th of an inch in diameter, the silver was afterwards dissolved in heated nitric acid, leaving a perfect gold wire $\frac{1}{5000}$th or $\frac{1}{4000}$th of an inch in diameter. Finding the operation of drilling the silver rod very troublesome, he subsequently drew platina wire, and cast the silver round it, treating the compound bar as before. Even by ordinary processes, brass wire is made so thin, that gauze may be woven from it which will have 67,000 meshes in a square inch. The extreme ductility of the precious metals is still more strikingly illustrated by the manufacture of what is commonly known as gold wire, but which is really formed of silver gilt, actual gold wire being made only for filagree-work and a few other purposes. In the ordinary mode of making gold wire, a silver rod about an inch thick is covered with leaf-gold, and then extended to the required tenuity by successive drawings and annealings; the proportion of gold allowed to a pound of silver being seldom more than 140 grains, and sometimes as little as 100 grains. Fine gold wire is used for wrapping or twisting round thread to form gold thread; and its beauty is greatly increased, while it is enabled to cover a larger surface, by flattening it between polished steel rollers.

For making needles, cards for the woollen and cotton manufacture, and various other articles into which wire is fabricated, it is necessary to remove the curvature which it receives by being wound upon the cylindrical or conical drum above alluded to. This is done by drawing the wire between pins fixed in a piece of wood, and so arranged as to bend the wire into a wavy line, the flexures of which gradually diminish until they disappear altogether, leaving the wire perfectly straight. The size of wire is commonly measured by means of a gage, which consists of a plate of steel with a series of deep notches or slits at each edge, varying slightly from each other in width, and numbered according to the number given to wire of corresponding size.

Among the many uses to which wire is applied, the manufacture of wire-gauze or cloth is peculiarly interesting. Plainer kinds of weaving are performed by a modification of the common loom, the coarser varieties of woven wire-work produced being used for fences, pheasantries, coarse riddles or sieves, &c.; while the finer sorts are employed for lanterns, sieves, flour-dressing machines, paper-making machinery, window-blinds, &c. Aviaries, flower-trailing, skylights, garden borders, plant-guards, arbours and summer-houses, flower-bed canopies, flower-stands, chairs, garden-seats, window-blinds, bird-cages, fire-guards and fenders, lamps and lanterns, meat-safes, lattice for book-cases and windows, sieves and strainers, all are now made of wire. The property which renders wire-gauze so invaluable in the safety-lamp has been taken advantage of by the Chevalier Aldini for the construction of wire-armour for the use of firemen, which, though very light, is in a great measure flame-proof. Wire-gauze is also formed into dish-covers, baskets, and other useful and ornamental articles, by pressing it between moulds into the proper shape, which it retains permanently. After being pressed into the required form, the articles are strengthened and neatly finished off by the addition of hoops or rings to their edges before they are removed from the mould. Needle-making is one of the most important applications of steel wire. Some of the finest sorts of steel wire are made into watch-springs, in which form they receive an augmentation of value beyond the prime cost of the material probably unparalleled in the whole range of manufacturing industry. Of the delicate hair-like springs alluded to, which weigh only one-tenth of a grain, 70,000 are required to weigh a pound; and it has been repeatedly stated, though perhaps now the statement may be hardly correct, that the value of such springs is half a guinea each; so that while a pound of crude iron cost but one halfpenny, a pound of these delicate manufactured articles produced from it was worth 35,000 guineas. One of the most elegant applications of gold and silver wire is to the production of *filagree* or *filigrane* work. To form this, fine gold and silver wire, often curled or twisted in a serpentine form, and sometimes plaited, are worked through each other, and soldered together so as to form festoons, flowers, and various ornaments; and in many places also they are frequently melted together by the blow-pipe into little balls, by which means the threads are so entwisted as to have a most beautiful and pleasant effect. This kind of work is of great antiquity, and was formerly much employed for caskets, needle-cases, trinket-boxes, baskets, shrines, and various decorations for church furniture; but it has in a great measure fallen into disuse. *Spangles*, or *paillettes*, which are small round leaves of metal, pierced in the middle, and used for ornamenting garments, are also formed of wire. A piece of wire is twisted round a rod like the thread of a screw, and then cut into little spiral rings, each of which, being laid on a smooth anvil, is flattened by a hammer into the form of a spangle.

An important purpose to which iron wire has been recently applied is in the manufacture of ropes, which are very superior in strength to those made of hemp, weight for weight. An account of wire ropes is given under ROPE-MAKING, and of wire bridges under BRIDGE.

WIRE GAUZE LAMP. [SAFETY LAMP.]

WIRE-WORM, a name given by farmers to the larvæ of several insects injurious to various crops: they are species of the coleopterous genus *Elater*, popularly known as Skip-jacks, so called on account of their power of throwing themselves up in the air with a spring when laid upon their backs.

The *Elater* (*Agriotes*) *lineatus* produces a larva which is extremely injurious to oats, often appearing in great numbers and destroying whole fields of corn. It attacks the roots, when the leaves turn yellow and die off. The *Elater* (*Agriotes*) *sputator* is another destructive species. Its larva, like that of the last, resembles the common meal-worm in appearance, and may be found at the roots of withering lettuces, by destroying which plant it greatly annoys the gardener. It eats the root as far as the collar, when the plant dies. *Hemerhipous segetis*, another insect the larva of which is called the wire-worm, is less choice in its ravages, destroying plants of all kinds. Fifty wire-worms of this kind have been found preying on the roots of a single plant.

The wire-worm is injurious to all culinary vegetables, also to our various grain crops. The use of rape-cake in powder has been recommended as a manure to the ground drilled for wheat where wire-worms abound; but hand-picking seems to be the only effectual way of getting rid of them. The mole, fowls, and above all, rooks, are their natural enemies; and the last-named bird is a valuable ally of the farmer in following the plough tracks to devour these mischievous larvæ.

WIT, a term which is applied to a faculty of the mind and to the products of that faculty. As a faculty, it denotes not a distinct power, but certain specific modes of using or operating upon the notions or images with which the mind happens to be furnished. It ranges itself under the more comprehensive faculty of imagination, with which by early writers it was generally used as synonymous; they sometimes used it in a sense still more general, as denoting the intellectual faculty as distinguished from the will. The precise boundaries of the term are too unsettled to admit of any strict definition. It may, however, be described generally as consisting in the display of remote resemblances between dissimilar objects, or such at least as have no apparent resemblance. This species of wit is exhibited in great perfection in two poems of a very opposite class, the 'Hudibras' of Butler, and the 'Night Thoughts' of Young: ludicrously by Butler, to display the absurdities of hypocritical pretence; seriously by Young, to add force and point to his reasonings in favour of religious belief and conduct.

Other kinds of remote allusion, often without any actual similitude, but suggestive to the mind, by indirect inference, to make the comparison for itself, are considered as wit, and produce a similar effect of surprise and pleasure.

When, instead of the remote resemblances discoverable in things themselves, the different meanings of the same word are brought into equivocal contact, the operation is called punning, and the product is a pun. [PUN.]

WITCHCRAFT. There is probably no age or country in which there has not existed a belief in the possibility of mortal beings acquiring the use of supernatural powers for the purpose of accomplishing some object of their desire, good or evil. In this, as in other species of superstition, there will be more or less resemblance in the manifestations, wherever or whenever they are exemplified; but that peculiar class of examples which comes under the denomination of witchcraft admits of certain lines of demarcation, which may be serviceable in keeping the subject distinct from others. The proper field of this superstition was among the Christian nations of Europe—those of the north more particularly. It is to be found in full maturity about the middle of the 15th century, and flourished with tolerably equal vigour through Catholicism and Protestantism, till it gradually decayed before the progress of experimental science. In its doctrinal principles it was a mischievous application of the doctrines of Christianity, being held to be a manifestation of the powers of evil operating as antagonists to the authority of the Deity. It was not necessarily used to accomplish evil ends, because many of the accusations of witchcraft relate to acts which as ends are condemned by no known moral code, but which became crimes from the means made use of. The powers of evil thus employed by human beings had their personal embodiment either in the Prince of Darkness individually, or in certain sublunary agents called imps or familiars, the messengers between the contracting parties, who bore in this agency of evil the same position as that occupied by the angels in the holy hierarchy. The return given by the human being for the use of the miraculous powers thus obtained was generally his own eternal soul, which, according to a superstition entertained by the ignorant in all countries where the immortality of the soul is a standard doctrine, it was held to be in the power of the corporeal possessor to convey in remainder, for value given in wealth, luxury, power, or any other object of ordinary human desire. Besides the bargain in which the parties are supposed to covenant openly with each other, each party was usually presumed to have in view the secondary object of cheating the other. German romance, and, since the days of Balzac, French romance, have dealt largely in the horrors attending these mutual efforts of imposition, where the one party is struggling to recover his chances of eternal salvation—the other to abridge the promised rewards, or to shorten the duration of their enjoyment. In its most simple aspect, the struggles of the evil one to cheat his victim are exemplified in the ordinary Scottish superstition that he gives them money which, when they come to use it, is turned into slates or other rubbish; and the same instance is given, by way of example, by Biensfeldius, a German author, who in 1591 published 'Tractatus de Confessionibus Maleficorum.' This author, who is one of the most systematic of the numerous writers on this subject, and is one who, instead of venting the indignation of an excited and terrified mind against the lost agents of infernal power, treats all the horrors of sorcery with the gravity of an analytical philosopher, tells us that there are three elements necessary to the accomplishment of witchcraft: the divine will permitting it; the power of the devil instigating and assisting the operation; and man's corrupt will consenting to be the instrument. It is a further general characteristic of witchcraft, that from the commencement of its history the agents or victims have, in the majority of cases, been females; and that in later times, when the character of the superstition had degenerated both in the magnitude of the objects accomplished and the rank of the actors, witchcraft came to be considered a power exclusively possessed by old women. It is probable that a propensity to attribute the faculty of divination and the art of perpetrating supernatural mischief to females may have legitimately descended from the Pythia of the more early classical times, and the venefica or poisoner of the later periods of Roman history; and that the account of the witch of Endor may have tended to strengthen the opinion. In the superstitions, however, of nations which have had no means of acquiring knowledge from these sources—the African negroes, the North American Indians, and the Scandinavians anterior to their adoption of Christianity—females seem to have always been the prominent agents in the application of the minor supernatural influences. In the practice of witchcraft within the limits assigned to it in this article, it might be possible to find, in the nature of the connection between the supernatural being and the earthly agent, a tolerably sufficient reason why the influence of a female must generally be greater in the infernal court than that of a male. Whoever has perused the full records of the trials for witchcraft, or the books in which the subject is most minutely investigated, will observe how necessarily it must follow that the power of evil being endowed with the masculine gender, and communicating his sex to those spiritual emanations of his power which sometimes in his stead do his bidding upon earth, the mortal recipients of his malign influence must necessarily be of a different sex. The institutional writers on the subject, however, are not found to allude to such a cause, though they lay it down as a general principle that women are more liable to be the agents of Satan than men, a circumstance which Sprenger, in his 'Malleus Maleficarum,' traces to what he calls their inferiority in mental strength, and the natural wickedness of their hearts.

In going back to an earlier period than that which is here assigned as the time when the superstition of witchcraft was full grown, it will be found that the accusations most nearly resembling the more modern offence of witchcraft are of two distinct kinds—attempts to accomplish mischief through the operation of poison or other natural agents, and lapses from Christianity into heathen practices. The Anglo-Saxon laws against sorcery or witchcraft are simply levelled against the practices connected with the heathen worship from which the people had not been long converted. The corresponding accusations in the south of Europe are levelled against intercourse with demons who represent Diana and her nymphs, or Pan and his satyrs; and down to the ancient period of the belief in witchcraft we find the same personages officiating with changed names, and with natures adjusted to the religious opinions of the age. The secrecy with which the Waldenses and other early seceders from the Church of Rome were compelled to hold their religious assemblages, brought upon them charges of indulging in such unhallowed rites as were traditionally considered the characteristics of ancient heathenism. One remarkable practice of which the Waldenses were accused will be recognised by every schoolboy who has heard a witch legend in the nursery: they were called "scobaces," because they rode to their meetings on a scoba, or broom. The 'Narrative of the Proceedings against Dame Alice Kyteler, prosecuted for Sorcery in 1324,' edited by Mr. Wright for the Camden Society, and which is perhaps still more curious from the light it throws on the early conflicts between the ecclesiastical and the civil power than in its reference to this subject, exhibits both the classes of offence here alluded to. She was charged with having prepared noxious compounds, productive of debilitation which ended in death, and also with abjuring her belief in the Holy Church, with having deserted the mass and the eucharist, with having sacrificed to demons, and with having attempted to usurp the keys of the Church by impiously imitating the ceremony of excommunication.

During its earlier stages, the art of witchcraft was in far higher hands than those to which it afterwards descended, and was used for greater purposes. Witchcraft or sorcery was the means by which Joan of Arc was charged with having obtained her power as a warrior. The Duchess of Gloucester was banished to the Isle of Man for sorcery against Henry VI. Richard III. made repeated accusations of this offence, the most noted of which is the charge against Jane Shore. The earlier witch trials in Scotland generally implicate persons of rank. Sometimes the women who are accused are young, and they do not always use their power for mischievous and malicious purposes. Bessie Dunlop, who was tried in 1576, appears to have used her art for no other purpose than the cure of diseases and the performance of other benevolent acts, accomplishing them through the instrumentality, not of Satan or any of his emanations, as they are spoken of in the later canons of witchcraft, but through the aid of an amiable old gentleman, who had the misfortune to be a prisoner among the fairies in Elfland. Alesoun Pearson, tried in 1588, had a long intercourse with Elfland, which appears to have commenced when she was but twelve years old. She had many personal friends among the fairies there, one of whom was her cousin William Symsoun, a doctor of medicine and "ane great scholar." She was in the practice of appealing to her friends in fairyland for the means of curing earthly diseases, and Archbishop Adamson did not disdain to follow a prescription which she obtained for him, his reliance on it being probably not weakened by his acquaintance with the virtues of the principal ingredient, which was claret. These two trials so far exhibit the darker characteristics of the witchcraft of later times, that Bessie Dunlop's adviser from Elfland wished her to put her soul in his possession; and Alesoun Pearson was told that of the fairy host the tithe is taken every year to hell. The method in which the same occurrences are mentioned by writers of different ages shows the progress towards the accepted doctrines of the authorities of witchcraft; and, as may be afterwards more particularly mentioned, both in England and Scotland the investigations of King James did much to establish a settled creed in relation to this dark subject. Wyntoun, who wrote early in the 15th century, in describing the prophecies made to Macbeth, brings the three weird or fatal sisters to him in a dream, and makes him inquire after the auguries of his fate, as Crœsus is made to consult the Pythia. By the time the history had descended to Shakspere's days, it had acquired from the state of opinion on the subject which it passed through such adjuncts as enabled the poet, by selecting the grander and more terrific features, and adding some elements from the current superstitions of his day, to create those hags "so withered and so wild in their attire, that look not like the inhabitants o'th' earth, and yet are on't." Perhaps the latest conspicuous occasion in which rank and beauty have been allied with charges of the nature of witchcraft, is that of the Countess of Essex and Mrs. Turner, in the murder of Sir Thomas Overbury and the practices against the Earl of Essex; but the direct and palpable crimes exhibited in this horrible history throw the attempts at evil through supernatural influences into the shade. When in later ages it ceased to be encouraged by the great and the learned, witchcraft degenerated, till, in the end of the 17th and the beginning of the 18th centuries, it was entirely confined to such persons as Harsnet, so early as the year 1599, describes in this passage:—"An old weather-beaten crone, having her chin and her knees meeting for age, walking like a bow leaning on a staff, hollow-eyed, untoothed, furrowed in her face, having her lips trembling with the palsy, going mumbling in the streets,—one that hath forgotten her Pater-noster, and yet hath a shrewd tongue to call a drab a drab. If she hath learned of an old wife in a chimney end Pax Max Fax for a spell; or can say Sir John Grantham's curse on the miller's eels—All ye that have stolen the miller's eels, laudate Dominum de cœlis; and all they that have consented thereto, benedicamus Domino: why then beware, look about you, my neighbours. If any of you have a sheep sick of the giddies, or a hog of the mumps, or a horse of the staggers, or a knavish boy of the school, or an idle girl of the wheel, or a young drab of the sullens, and hath not fat enough for her porridge, or butter enough for her bread, and she hath a little help of the epilepsy or cramp, teach her to roll her eyes, wry her mouth, gnash her teeth, startle with her body, hold her arms and hands stiff, &c., and then, if an old Mother Nobs hath by chance called her idle young housewife, or bid the devil scratch her, then no doubt but Mother Nobs is the witch, and the young girl is owl-blasted."

There are two causes which account for the similarity often found to exist in the superstitions of different and distant nations:—1. Physical and mental phenomena common to all mankind and to all parts of the globe, producing like effects when brought into the same combinations; 2. A reference to a common origin anterior to the commencement of the superstition, by which the same opinions adopted by families of mankind separated far apart may be traced by ascent to a common parentage. A great portion of the witchcraft superstition of Europe may be traced to both these causes; but at the same time the identity of the phenomena of this mental disease, as exhibited in different nations, is so remarkable, as well as the rapidity with which the opinions adopted in one part of the world travelled to others, that it is evident some other causes have contributed to produce the effect. The similarity of the incidents narrated, not only in the books which convey the knowledge of these mysteries, but in the reports of criminal trials, and even in the confessions of the wretched victims of the creed, is so remarkable, down to the most minute particulars, as to justify the supposition that a large proportion of the witchcraft superstition was propagated by means of books or through the tuition of men of letters; and that thus, in that age of imperfect science, literature became for a time the means of propagating and concentrating the influence of one of the most baneful superstitions which has ever visited the human mind.

Among the most obvious means which the imagination would suggest for indicating to supernatural powers the exact evil effect which they are solicited to produce on mortal beings, would be the symbolical accomplishment or exhibition of its performance on an effigy of the person intended to be injured. The principles of human action which originally suggested this device are so wide spread as to include the deification of idols and the burning of an obnoxious politician in effigy; but in the practice of witchcraft, the method of symbolically producing death or corporal injury is so far uniform as to predicate a systematic opinion on the subject. An image of the devoted person was made of wax and melted before a fire, stuck through with pins or needles, or perforated with arrows. Sometimes the model was of the heart, or some other vital part; sometimes a picture was used in its stead. Ben Jonson, whose 'Masque of Queens' brings together all the prominent witch superstitions to be found in the classic authors, in the commentators, and in the practice of his own days, says in the third charm:—

> "With pictures full of wax and of wool
> Their livers I stick with needles quick:"

nearly a paraphrase of Ovid's—

> " . . . . simulacraque cerea figit,
> Et miserum tenues in jecur urget acus."
> *Heroides*, vi.

Jonson in his notes refers for this practice to so old an example as the epistle of Hypsipyle to Jason, from which the above is taken; he probably had the passage in his eye. He refers also to what he calls "the well-known story" of King Duffus, one of the imaginary kings of Scotland, the legend of whose sufferings is as old as the days of Wyntoun, by whom it is mentioned, but would be searched for in vain among those still older annalists who had not the means of ornamenting their writings with some of the wisdom of the ancients. Jonson says he remembers some such figures having been dug up in a dunghill in his youth. The story of Bolingbroke and the witch of Eye, in Fabyan's 'Chronicle,' illustrates this practice. In Middleton's 'Witch,' Hecate says, "Is the heart of wax stuck full of magic needles?" King James, in his 'Demonologie,' has a very full examination of the operation of this charm; and after receiving so high a sanction, it of course cuts a conspicuous figure in the subsequent witch trials both of England and Scotland. In the latter country it became united with a belief in the unearthly origin of the numerous small flint arrowheads of ancient workmanship, conspicuous for the regularity and beauty of their shape, which are frequently dug up in the north of Scotland. The witches of Auldearne, whose feats are recorded in Pitcairn's 'Criminal Trials,' described a cavern in the centre of a hill where the arch fiend and his attendant imps conducted a complete manufactory of these missiles; the inferior spirits hewing them out of the rough stone, and their master giving each as it was presented to him in a rough state the proper edge and finish, to adapt it for service.

Those objects which, from their connection with death and decay, are apt to produce loathing and horror in the minds of persons whom habit has not made familiar with them, are favourite instruments in the hands of witches, to whom their use seems to have descended from the necromancers. There are few narratives of witchcraft or sorcery, from Apuleius downwards, which do not present us with some of the spoils of the charnel-house. Animals loathsome to the sight from their structure being associated with notions of deformity, or from the venom with which their otherwise feeble frames are endowed, are naturally made use of by those who among the ignorant aim at the possession of supernatural powers. In this respect the medicine-man of the Indians, called on to try his charms when the traditionary usages of the tribe in the application of simples have failed, uses many of the same tools as the witch of the 16th and 17th centuries. In warm climates the serpent, the scorpion, and the lizard are among the charms resorted to; but in colder latitudes the adept must be contented with the toad, the frog, the mole, and the bat.

Cats are animals which hold out many inducements to the imaginative and superstitious. They bring to a certain extent the habits of a wild beast into the domestic circle. The contrast between their strength and agility, their gentle and fragile appearance, their tenacity of life, their silent and rapid movements, their mysterious gatherings at night and strange cries, invest their presence with a fascinating mystery. The tombs of Egypt and the history of the Knights Templars show that they have received attention in other quarters; but the very peculiar position which they hold in the councils of the powers of darkness, in connection with the ministrations of witches, shows by its uniformity that the opinions regarding them entertained by the authorities on witchcraft lore were widely adopted by the faithful. In several of the Scottish trials and confessions women are found to have assumed the shape of cats, and to have betrayed their pranks by exhibiting when restored to human form the wounds inflicted on them in their bestial capacity. At so late a period as the year 1718 a solemn judicial inquiry was made in the shire of Caithness, by the sheriff or local judge, into the persecutions suffered by William Montgomery, whose life was rendered miserable by the gambols of a legion of cats. The narrative of the circumstance, as given in Mr. Kirkpatrick Sharp's introduction to Law's 'Memorials,' is a lively and somewhat exaggerated picture of those general tumultuous gatherings of domestic cats which sometimes so unaccountably disturb the repose of a neighbourhood. The animals, it was solemnly maintained by the persecuted man's servant, "spoke among themselves;" and at length Montgomery, his patience being entirely exhausted, fell upon the conclave with a broadsword and an axe, and dispersed them with several casualties. The consequence was, that two old women in the neighbourhood died immediately, and a third lost a leg, which having been broken by a stroke of the hatchet, withered and dropped off. In a curious little book published at Leyden in 1656, called 'Magica de Spectris et Apparitionibus Spirituum,' &c., which is a complete repository of diabolical experience, consisting of a series of narratives extracted without comment from historical chronicles and books of magic, an occurrence is said to have taken place at a town in Calabria, so exactly like the above, that whereas Mr. Montgomery was a carpenter by profession, the hero of the foreign adventure was in the act of cutting wood when he was distracted by the presence of a turbulent bevy of cats, whom he dispersed with his implements. In this case the metamorphosis was made known by a charge being brought against the individual of having assaulted and wounded some women of rank in the neighbourhood, when he disclosed the fashion in which they had appeared, and the affair was hushed up. A belief in the metamorphoses of human beings into brutes is a superstition so widely exemplified in classical literature, and in the sculpture and paintings of all societies of men sufficiently civilised to provide such testimonies of their customs and belief, that it cannot be assigned as a special feature of the belief in witchcraft. The minuteness, however, of the analogy exhibited in the above, and discoverable in many like cases, seems to those who do not believe in the actual metamorphosis to leave no other alternative but the belief, that the doctrines promulgated in one part of the world were in all their minute particulars adopted in another. Lycanthropie, or the conversion of men into wolves, was so prevalent a belief in France and Germany as to be the subject of separate treatises and of various judicial inquiries. It naturally did not extend to Britain. This superstition may be perhaps more distinctly traced to the influence of a diseased imagination than most of the others connected with this subject: by the Greek physicians it is understood to have been treated as a disease. Both the English and Scottish trials frequently illustrate the power supposed to be possessed by those in league with Satan of converting their victims into beasts of burden, which they employ to convey them to the scenes of their unhallowed assemblies. This feat was performed on a large scale by the great army of witches charged with assembling at Blocula in Sweden, in 1669, according to the narrative of Glanvil, in his 'Saducismus Triumphatus.'

A power over the elements is one of those gifts with which superstition will be most likely to invest its invisible agents. In its less striking form it has the aspect of a malign interference with the natural fruits of the earth, either by blasting some particular district, or transferring its elements of fruitfulness that they may increase the produce of some other tract in which the sorcerer is interested. This species of incantation is prohibited by the Twelve Tables (Dirksen, 'Uebersicht, &c. der Zwölf-Tafel-Fragmente'), and the illustrations of it in the witch trials are too numerous to be mentioned. A trading or maritime population living on a stormy coast will endow their malignant demons with a more awful authority over the winds and waves. Olaus Magnus treats largely of the storm-raising powers of the Scandinavian witches. It was on his return from these regions with his wife Anne of Denmark, that King James produced so goodly an array of accusations against witches for aiming against his life; and coming from a spot where such a particular department of witch superstition was prevalent, it is natural that the aspect assumed by the accusations should be an attempt to create a storm at sea for the purpose of intercepting his voyage. In the accusations against the witches of Aberdeen in 1596 and 1597, the record of which is printed by the Spalding Club, the exercise of a power over the elements is one of the charges. In the curious narrative as to Margaret Barclay and others, preserved by Sir Walter Scott in his 'Demonology,' we find the same feature. This specific superstition does not seem to have taken root in England, and Shakspere, whose witchery in 'Macbeth' is essentially Scottish in character, has given it a place there:—

> "Though you untie the winds and let them fight
> Against the churches; though the yesty waves
> Confound and swallow navigation up."

It is a remarkable circumstance that nowhere are the identities between the opinions promulgated in doctrinal works and the practice of witchcraft more fully developed than in the confessions of the witches as produced in official documents. The horrible tortures, which the alarm produced by the supposed existence of a coalition with Satan seems to have prompted men of ordinary humanity to sanction, appear to have generally called from the exhausted victims an assent to whatever narrative was dictated to them, and the inquisitors being learned men, acquainted with the best authorities on the subject, would know how to connect the received doctrines of sorcery with whatever train of real circumstances may have been brought home to the victim. Knowing, in fact, the outline of natural events, they would be able to fill up the supernatural details. Margaret Barclay, tried in 1618, was, according to the record preserved by Sir Walter Scott, subjected to "gentle torture." Sir Walter calls this "a strange conjunction of words;" but it is not without precedent, and we can imagine it taken from Biensfeldius, who tells us of a lady who, in 1590, at Cologne was subjected to "modurata tortura." The Incubus and the Succubus—the former the visitant of females, the latter of males—are prominent in the confessions, and open up a world of psycho-physiological inquiry. These notabilia are enlarged upon in several of the Scottish trials. Reference may be made to the appendix to Pitcairn's 'Criminal Trials,' p. 610, and to a pamphlet called 'History of the Witches of Renfrewshire.' Reginald Scot goes over the same subject, and further curious matter will be found in Glanvil, 'Saducismus Triumphatus;' Sprenger, 'Malleus Maleficarum;' and Delrio, 'Disquisitiones Magicæ.' There is no doubt that some of the confessions were voluntarily made; and that, whether dictated by their own imagination or by their reading, the self-accusers did not speak on the suggestion of others. There are thus two mingled elements in these documents, the separation of which would be necessary to and would materially aid a philosophical examination of the causes which have produced such singular effects: the one would bring before us the physical and psychological causes from which the mind voluntarily imagines itself an actor in such supernatural occurrences; the other would explain the utterance of confessions of such acts by persons who, until they were subjected to torture, never imagined their existence. The confessions made under torture were, however, frequently revoked during moments of mental and physical resuscitation.

The influence on society of a belief in witchcraft was of the most pernicious kind. It gave an unchecked flow to all the malignant passions; some venting them in accusations, others in attempts to practise the nefarious art. In the year 1515 five hundred people are said to have been executed at Geneva on charges of witchcraft; and Remigius, the inquisitor, boasts that he put nine hundred to death in Lorraine. The first person who lifted his voice against these cruelties was Wierus, who wrote in 1568. He and his followers carried on a controversy with Delrio, Bodinus, Scribonius, and others, in which it is generally admitted that the defenders of witchcraft were the more successful logicians. The supporters of old and received fallacies have their compact and complete system of sophistry, and he who would break through it must, like a Bacon or a Locke, possess strength enough to destroy the whole fabric. Wierus and his followers ventured to raise their voice against the method only of the manifestation of Satan's power of diabolical possession, not its existence. Against the brutal practice of swimming a witch to see if she will sink or float, which may be traced as an ordeal succeeding that of the red-hot ploughshares, and which inferred that a body in which an evil spirit dwells is lighter than water, they could do no more than adduce the experimental fact, that the herd of swine into which Jesus cast the evil spirits, running into a lake, were drowned. Of all the early opponents of this superstition the English Reginald Scot, who wrote in 1584, was perhaps the most successful in the employment of an acquaintance with natural operations, a bold scorn of fallacies highly supported, and a ready sarcasm. He was followed by Harsnet in 1599, and in 1720 by Francis Hutchinson, who, however, appealed chiefly to the unlearned, among whom alone the belief lingered at the time when he wrote.

The learned men of Europe generally were believers in witchcraft down to the end of the 17th century. Selden has an apology for the law against witches, which shows a lurking belief. He says that if one believes that, by turning his hat thrice and crying 'buz,' he could take away a man's life; "this were a just law made by the state, that whoever should turn his hat and cry 'buz,' with an intention to take away a man's life, shall be put to death." The logic of Selden's mind, if untainted by superstition, would surely have shown him that a law waging war with intentions incapable of being fulfilled must be both useless and mischievous. Sir Thomas Browne and Sir Matthew Hale were believers in witchcraft, and attested their belief by being instrumental in convictions for the crime. It is supposed that there were no executions for witchcraft in England subsequent to the year 1682; but the statute of 1 James I., c. 12, so minute in its enactments against witches, was not repealed till the 9 Geo. II., c. 5. In Scotland, so late as the year 1722, when the local jurisdictions were still hereditary, and had not been put into the hands of professional lawyers, the sheriff of Sutherlandshire condemned a witch to death. It is worthy of remark, as one of the last vestiges of this superstition in educated and professional minds, that in a work called 'The Institutes of the Law of Scotland,' published in Edinburgh in 1730, by William Forbes, an author deservedly neglected by practical lawyers, after a specific definition of the nature of witchcraft, there is the following passage:—"Nothing seems plainer to me than there may be, and have been witches, and that perhaps such are now actually existing; which I intend, God willing, to clear in a larger work concerning the criminal law." This promised work never made its appearance.

WITENAGEMOTE, literally an "assembly of wise men," from the Anglo-Saxon "gemoth," an "assembly," and "witan," "to know," which has the same root, "wit" or "wis," as the words wit, witness, wise, and the legal phrase still in use "to wit."

Although the chief rulers of the Anglo-Saxon states, nearly down to the time of the Conquest, bore the title of king, and in their charters and letters attached to it many sonorous epithets, yet in fact they were little raised in power above the other chiefs of their nation. To election by these chiefs the king owed his office; and if the sceptre descended in his race, it was by means of the formal recognition of the new king by the nobles in an assembly convened for the purpose. Of this assembly the chief ecclesiastics in the kingdom, archbishops, bishops, and abbots, the judges (if such there were), and the largest landholders formed part. Whether the main body of the people had a voice in this great council is doubtful; but judging by the analogy of the shire motes, and of all the political and judicial institutions of our Anglo-Saxon ancestors, it is probable that the freemen who were near the spot had a right to be present. Any important law or regulation was transmitted for approval or consideration to the various folkmotes. While the folkmotes were small, and the occasions for assembling few, little inconvenience was felt, but ultimately it was found expedient for the king to summon an influential person from various parts of the country, perhaps occasionally the leading man of a folkmote, and thus form an assembly of counsellors, or witenagemote. This change was no doubt gradual, and no precise date can be fixed. It is certain that it was in existence in this form under Ethelstan, (A.D. 931) and that all the sheriffs of counties attended it. In 934 there were present at one of these assemblies the king, four Welsh princes, two archbishops, seventeen bishops, four abbots, twelve dukes, and fifty-two thanes. The members were not elected, in any sense but either nominated by the king or summoned by the assembly after having been constituted; and the members seem to have had the right, or assumed the privilege, of introducing a friend or counsellor.

The powers of the witan were extensive. As a consultative body they had a right to consider every public act which could be authorised by the king: they deliberated upon the making of new laws, which were to be added to the folc-right, and which were then promulgated by their own and the king's authority; they had the power of making alliances and treaties of peace, and of settling their terms; in them was vested the right of electing the king, whom also they had the power of deposing if his government was not conducted for the benefit of the people. They, together with the king, had the power to appoint prelates to the vacant sees; they had also the power to regulate ecclesiastical matters, appoint fasts and festivals, and decide upon the levy and expenditure of ecclesiastical revenue; and, with the king, to levy taxes for the public service. The king, with consent of the witan, had power to raise land and sea forces when occasion demanded. The witan possessed the power of recommending, assenting to, and guaranteeing grants of lands, and of permitting the conversion of folcland (common land) into bocland (book-land), and *vice versâ*. They had also power of adjudging the lands of offenders and intestates to be forfeit to the king; and they acted as a supreme court of justice, both in civil and criminal causes. (Kemble, 'The Saxons in England.')

A witenagemote in the reign of Ethelwolf (855) granted to the church a tenth, with the assent of the kings, thanes, barons, and people. The eighth law of Edward the Confessor names the people; and the 35th law recites that it passed by the common advice and assent of all bishops, princes, chiefs (procerum), earls, and of all the wise men and elders, and of the people (populorum) of the whole kingdom. Sergt. Ruffhead, in his preface to the Statutes, conjectures, confessing at the same time his ignorance, that the folcmote resembled our House of Commons, the ealra-witenagemote our House of Lords, and the witenagemote our privy council. Undoubtedly some of the functions which in far more recent times the privy council has performed did devolve upon the witan; for instance, their approval was required for certain acts of the king; and generally their office was less to devise measures than to consider and to sanction those which were submitted to them.

In concurring in royal charters and grants the witenagemote performed the double office of consenting to and of attesting these gifts or privileges; and here their office was analogous to that of the shiremote, which in those rude days distributed justice rather according to the notoriety of the facts than to any systematic rules of investigating the truth, and qualified itself for this office by requiring that the main transactions touching the rights and property of individuals within its district should pass in its presence.

In those cases where the administration of justice was impossible in the county courts, owing either to their want of jurisdiction, or to the power of one of the parties, the authority of the witan was appealed to; and the nation pledged itself to support the executive power of the king by giving to his arrangements the force of a law. Thus the great family of Godwin earl of Kent was outlawed in 1043, and restored in 1052 by the authority of the witan; in another case the title of a great landholder to estates of which the muniments had been destroyed was acknowledged, and a new deed setting out the bounds was granted.

During the Anglo-Saxon times the possessions of the king, and the ordinary payments made to the crown by every landholder, together with the duties paid by townships, were sufficient for the ordinary wants of the government, especially as the triple duty (trinoda necessitas) of repairing roads and bridges (*bryc-bote*), maintaining the walls of the burghs (*burgh-bote*), and resisting invasion (the *fyrd*), was invariable. The king too was entitled to tolls on goods sold in most markets and fairs, and to customs on imported goods; but in those emergencies when a pecuniary contribution was to be made by the nation, the witan were called on to accede to the tax.

It is very remarkable how these powers have been transmitted to our present parliament, though some have been separated and allocated between the House of Peers and the House of Commons. The witenagemote was of course abolished by the Norman invader; but the idea was evidently preserved and ultimately developed even by the Normans themselves. It assumed a distinct form when Simon de Montfort, earl of Leicester, issued writs in the king's name to the sheriffs of all counties, commanding them to return two knights for the county, and two burgesses for certain named boroughs, to sit in parliament to consult on the affairs of the nation.

(Sir F. Palgrave, *Rise and Progress of the English Commonwealth*, 1832; J. M. Kemble, *The Saxons in England*, 1849.)

WITNESS, from the Saxon *witan*, "to know." [EVIDENCE.]

WOAD (*Isatis tinctoria*) is a plant which was once cultivated in Britain to a considerable extent for the blue dye extracted from it. It has been greatly superseded by indigo, which gives a stronger and finer blue; but on some soils it might still be cultivated to advantage.

The woad is a plant of the natural order of the *Cruciferæ*, classed by Linnæus in the *Tetradynamia siliculosa*. It has a strong tap-root, which lasts two years. The height of the plant when in perfection is from three to four feet. It throws out many branches from the upper part of the stem. The leaves are alternate and smooth, the lower on foot-stalks, large and spear-shaped, the upper embracing the stem and arrow-shaped. The flowers are yellow, in panicles at the extremity of the branches. The fruit is a heart-shaped pod, with two valves containing one seed only.

It requires a good substantial soil of considerable depth and fertility; for the larger and more numerous the leaves are, the more profit is derived from the plant. A wet clay soil is not at all suited to its growth, nor a loose sandy one. When it was largely cultivated in England, old pastures ploughed up afforded the best soil for the woad to grow in. These were often taken at a very high rent for two years by men who made it their business to cultivate the woad and prepare the colour, and who found it a profitable speculation. To have good woad the land should be naturally very rich, or much manure should be intimately mixed with it some time before; nothing but completely decomposed dung should be used, or compost made on purpose a long time before.

The land, having been prepared by repeated ploughings and perfectly clean, is laid into narrow beds with deep intervals. On these beds the seed is sown in February or very early in March. It is sometimes sown broadcast, and the plants thinned out, but sowing it in drills, two rows on a four-feet bed, is much the best practice. The drills are one foot from the edge, with two feet clear between them; some make five-feet beds, and there is an interval of thirty inches between the rows, which allows of better cleaning, and gives the plants more room to spread. When the plants are come up in the rows, they must be thinned out by hand, leaving the strongest about two feet apart; the leaves will soon fill up the intervals. They begin to ripen in June. They are fit to gather when they begin to droop and become yellowish. This should be done in very dry weather, and after the dew is off. The leaves of the woad are either twisted off close to the stems or cut down with a sickle. Great care must be taken that no dirt or earth adheres to them. Some recommend taking off the lower leaves first, when they appear ripe by drooping and turning yellow, and letting the upper leaves remain till they show the same appearance; then nothing but ripe leaves will be gathered. This stripping may be repeated two or three times as the leaves grow again. The plants destined for seed are only stripped once or twice, for fear of weakening them. It might probably be advantageous not to strip them at all, but to leave the whole strength for the formation of the seed, which will be larger, and produce finer plants the next year.

The first gathering of the leaves is the best; they should, therefore, be kept separate to obtain the best dye. As soon as the leaves are gathered, the bed should be well and deeply hoed or dug, to give a fresh impulse to the roots.

The leaves are naturally full of sap, and soon begin to decompose if laid in a heap. They should, therefore, be partially dried, and immediately carried to the mill to be manufactured. The seed will vegetate when two years old, but cannot be depended on after that.

Woad is also occasionally sown as food for cattle; and has been brought forward for this purpose under its French name of "Pastel." Its vigorous growth and hardy nature have recommended it; but it will only grow in very rich soils. There are many other plants as vigorous and hardy, which will thrive well in inferior soils, and therefore are to be preferred. But for its dye this plant is well worthy of the attention of those who have good rich and deep soils.

WOMB, DISEASES OF THE. The organ which is devoted to the retention of the fœtus during the early stages of its development [REPRODUCTION IN PLANTS AND ANIMALS, in NAT. HIST. DIV.] and which is also called the uterus, is subject to all those pathological conditions which are found in other organs composed of similar tissues. The principal tissues to which attention need be directed are the muscular substance of the uterus and its lining mucous membrane. The latter is continous through the os uteri with the same membrane in the vagina, and the affections of the one are often found in the other. Like the mucous membranes in other organs, those parts may be inflamed or congested, or their function may be disturbed. One of the most common and troublesome forms of disease of these membranes is that which is called leucorrhea, and which is attended with an increased secretion from the mucous membranes. This may or may not be attended with pain and other symptoms of congestion. Where the latter is present, the disease requires a different treatment to those cases where no such symptoms are present. Rest, saline purgatives, and an antiphlogistic regimen is beneficial in these cases. On the other hand, where the pain is slight, and the pain more that of nervous irritation, and there are generally symptoms of a debility and want of tone in the system, there tonics, such as quinine and iron, especially the latter, will be found of great benefit. Rest, cold bathing, and a regimen adapted for debilitated states of the system, should be recommended. These cases are often accompanied by nervous symptoms, which more or less approach the condition of hysteria [HYSTERIA], and which also require special treatment.

In cases where the congestion is more active, the secretion from the mucous membrane becomes puriform, and has a yellow colour. In these cases the more active measures resorted to in inflammatory affections need be had recourse to. Where such an inflamed condition of the mucous membrane is kept up, ulcers frequently occur on the surface of the membrane, more especially in the contracted portion called the os uteri. These ulcers are frequently attended with excessive irritation of the nervous system, producing intense pain of the back, more especially in the region of the coccyx. The general system also frequently suffers in these cases, and great feebleness and exhaustion is the result. Although such ulcers will frequently pass away by judicious general treatment, it is in such cases that local applications have been found of most especial benefit. Injections of tannic acid, alum, sulphate of zinc, and nitrate of silver, are all to be commended. Occasionally, in inveterate cases, it may be necessary to apply lunar caustic, or even caustic potash, to the ulcer itself. This practice, which is very commonly pursued by French practitioners, does not commend itself so strongly in England.

The tissues of the uterus are especially liable to attacks of malignant disease. The nature however of the ulcerations produced by the development of cancerous formation is essentially different from the ulcerations last spoken of. Nor is there any evidence to prove that simple ulceration ever terminates in the malignant form. It is also important, however painful it may be to know, that where malignant ulceration has been once set up, it can never be arrested. This ought to prevent the local application of such powerful remedies as the actual cautery and caustic potash, which can only add to the sufferings of the patient without producing any beneficial result.

The uterus is subject to the occurrence of fibrous, cellular, and other tumours, which, although they produce great inconvenience, are not necessarily fatal. When these occur on the internal surface of this organ, they are frequently more or less pedunculated, and may be removed by ligature or the ecraseur.

The uterus not being attached directly to the solid framework of the body, is liable from the stretching to which its parts are subject during pregnancy to considerable displacements. It may be tilted over backwards, which is called retroversion; or it may be introverted, or it may sink lower than natural into the outlet of the pelvis, constituting what is called prolapsus uteri. For these mechanical defects various appliances have been made with more or less success.

Functional disorders of the uterus are very frequent in both unmarried and married females. The periodical and sanguineous effusion which passes off from the mucous membrane may be increased in quantity, or decreased, or changed. The amount of the catamenia varies in different women, and in the same woman at different periods of life, but occasionally the increase is so great as to produce fainting, and other symptoms of exhaustion. This is called menorrhagia. It sometimes comes on from over-exertion, on the abortion of the embryo, and all that is generally required is rest, and the same treatment as would be adopted in hæmorrhage from other organs. Sometimes the discharge is produced by an inflamed or congested condition of the uterus. There is pain in the back, and a full quick pulse, and other symptoms of inflammatory action. In these cases an antiphlogistic regimen should be pursued, and active purgatives with other lowering medicines may be given. It often happens, however, that the menorrhagia occurs in quite a different state of the system, and here quinine and sulphuric acid, or tannic or gallic acid, should be given.

The opposite state of this function is called amenorrhea. The suppression of the accustomed secretion may arise from various causes, and where any obvious impropriety can be detected of course this must be prevented. Amenorrhea comes on in opposite states of the system, but it is more frequently a symptom of general debility, and comes on as a symptom of most exhausting and debilitating diseases. Should there be amenorrhea without any other pressing symptoms, aloetic purgatives combined with chalybeates and tonics will frequently be found all that is required. The removal of girls from the impure air of towns to the more invigorating atmosphere of the sea-side is a potent remedy in such cases.

Accompanying either of the before-mentioned affections, or without any increase or decrease of the catamenia, there is frequently great pain. This is called Dysmenorrhea. In these cases the general health should be attended to between the periods of attack, and opium judiciously administered will be found the most valuable remedy in relieving the pain. This secretion is frequently lighter in colour, or presents other changed physical appearances, all of which indicate some general derangement, and such cases should be treated accordingly. The affections of the nervous system which may arise from disordered affections of the uterus are very numerous. Pain may be reflected from the uterus as the centre both upwards and downwards, and the parietes of the abdomen, the loins, and the thighs and legs, may be the seat of acute neuralgic pains. The nerves of motion may in like manner be affected, and convulsive movements or entire paralysis may be the result. Such affections retire when the local affection is removed, and all attempts at curing the secondary diseases will fail until the primary one is removed. [NERVOUS SYSTEM, in NAT. HIST. DIV.; HYSTERIA.]

WOOD. [TIMBER.]

WOOD, DECOMPOSITION OF. [TIMBER, PRESERVATION OF.]

WOOD-ENGRAVING is the art of producing raised surfaces, by excision, on blocks of wood, from which impressions can be transferred by means of a coloured pigment to paper, or other suitable medium, and generally applied to pictorial representations of objects.

The art of cutting both upon metal and wood for other purposes than those which are now understood as printing, ascends to a very remote antiquity. [ENGRAVING.] The Babylonian bricks [CUNEIFORM CHARACTERS] bear inscriptions that have probably been formed by a tool, not much unlike some that are now used in wood-engraving, but with the difference that these characters are incised. The Egyptians seem to have made a very close approximation to printing. Some of their wooden stamps are yet remaining, and are perfectly capable of giving impressions in the manner of our present wood-cuts, though their use was doubtless for stamping on clay or other ductile material; bricks so impressed being frequently found, of which some are in the British Museum.

The earliest application of wood-engraving to the production of a book originated, there can be but little doubt, in China, and about the middle of the 10th century, although it has been contested, chiefly on account of the silence of Marco Polo, whose work was written in the last two or three years of the 13th century. The omission is certainly remarkable; yet on the other hand the date here given does not ascend to the period of Chinese fable, but to a period which is reached by sober historical works, and the dynasty under which it is thus stated to have been invented (that of Soong) became remarkable for the rapid development of literary genius that took place under it. It is stated that the first essay in printing was made by cutting in stone, and transferring the impression to paper, the characters of their language being thus white and the ground black. This was speedily relinquished for the use of wooden blocks, in which the characters were cut in relief, and the appearance when transferred was that of our present books. No material alteration has since been made, except that of introducing pictorial representations, which occasionally form a whole volume, the subjects being sometimes connected so that though each page is from a separate block, they would join and produce a total length of some hundred feet. Such are the illustrations to the Wan Show, "pieces of music and songs sung in the streets on imperial birth-days," being a series of representations of the public entertainments and exhibitions, horse-racing, foot-racing, &c., of which there is a copy in the library of the Asiatic Society. The work itself is in 6 vols., of a size somewhat larger than our demy 8vo, and the illustrations form a separate volume of several hundred pages.

The material used by the Chinese is pear-tree, which is tough, but easy to cut, and of which slabs of considerable size can be procured. The method adopted in engraving and printing is thus described by Sir J. F. Davis, in 'The Chinese, a General Description of the Empire of China and its Inhabitants:'—

"The wooden plate, or block, of a thickness calculated to give it sufficient strength, is finely planed, and squared to the shape and dimensions of the pages; the surface is then rubbed over with a paste or size, occasionally made from boiled rice, which renders it quite smooth, and at the same time softens and otherwise prepares it for the reception of the characters. The future pages, which have been finely transcribed by a professional person on thin transparent paper, are delivered to the blockcutter, who, while the above-mentioned application is still wet, unites them to the block so that they adhere, but in an *inverted* position, the thinness of the paper displaying the writing perfectly through the back. The paper being subsequently rubbed off, a clear impression in ink of the inverted writing remains on the wood. The workman then with his sharp graver cuts away with extraordinary neatness and despatch all that portion of the wooden surface which is not covered by the ink, leaving the characters in pretty high relief. Any slight error may be corrected, as in our woodcuts, by inserting small pieces of wood: but the process is upon the whole so cheap and expeditious, that it is generally easier to re-plane the block, and cut it again, for their mode of taking the impression renders the thickness of the block an immaterial point. Strictly speaking, 'the press of China' would be a misnomer, as no press whatever is used in their printing. The paper, which is almost as thin and bibulous, or absorbent of ink, as what we call silver-paper, receives the impression with a gentle contact, and a harder pressure would break through it. The printer holds in his right hand two brushes, at the opposite extremities of the same handle; with one he inks the faces of the characters, and the paper being then laid on, he runs the dry brush over it so as to make it take the impression. They do this with such expedition that one man can take off a couple of thousand copies in a day."

In Europe, the first application of the art of wood-engraving took place in Germany, though the place is not exactly ascertained, but is supposed to have been near Nürnberg, about the close of the 14th or beginning of the 15th century. It was probably first used for the production of playing-cards, the outlines of which were formed by impressions from wood-cuts, and the colouring filled up by hand; for we dismiss as utterly unfounded the story told by Papillon, in his 'Traité de la Gravure en Bois,' of impressions of a series of wood-cuts seen by him, of a date between 1285 and 1287, executed by Alexander Alberic Cunio and Isabella, his twin sister; although the story is believed by Ottley ('Inquiry into the early History of Engraving'). Zani disproves the story. (See Zani, 'Materiali per servire alla Storia de' Progressi dell' Incisione in Rame e in Legno,' p. 222.)

The origin of playing-cards has been the subject of much contention, and the documents from which conjectures have been drawn as to the date have been singularly subject to perhaps unintentional variations by copyists. Thus the Abbé Rive ('Etrennes aux joueurs de Cartes') quotes a statute of Alfonso XI. of Castile, forbidding the use of cards in 1342; but his authority is only a French translation of a Spanish poem written by Guévare in 1539, and in the Italian translations first published in 1558 no mention is made of cards. John I. of Castile is also said to have issued an edict against the use of them in 1387 (Bullet, 'Recherches Historiques sur les Cartes à jouer'); but here again the authority is a collection of the laws of Spain printed in 1640, while, in an earlier collection, printed in 1541, the same law only forbids the playing at dice and trictrac for money, omitting all mention of cards. The early specimens of cards show that they were of two kinds: one, called *tarots*, was formed entirely of emblematic figures, and was probably used in games similar to those in which now we endeavour to convey instruction in some departments of learning; the other, called numeral cards, was in four suits, bearing different names in various countries, but essentially the same as our present playing-cards. It is almost certain that the first are of Italian origin; they are noticed in 1392, in a life of Philip Maria Visconti, Duke of Milan. In the same year the following entry has been found in the archives preserved in the Chamber of Accounts in Paris:—"Donné à Jacquemin Gringoneur, peintre, pour trois jeux de cartes, à or et à diverses contours, ornés de plusieurs devises, pour porter devers le seigneur Roi, pour son esbattement, cinquante sols Parisis." This, to some extent, confirms the tradition of their being invented for the amusement of Charles VI. of France. If not specially invented, they were brought into early employment for this purpose. These cards were painted, but as they came quickly into general use, the wood-cut was speedily adopted, and, in the Bibliothèque Imperiale of France, ten of the numeral cards are preserved of the date of 1425.

Cards soon became not only an amusement, but an important article of commerce. In the registers of the city of Ulm there is inscribed, in 1402, the name of a burgess who was a painter of cards. In 1418 the burgess-book of Augsburg contains the name of a "Kartenmacher," or card-maker. The trade in cards from Augsburg, Nürnberg, and Ulm became so great that Venice prohibited their importation, and in Sicily they were imported by the cask. It is thence almost certain that it must have been by means of some facility in multiplying copies that they could have been manufactured so cheap as to command so extensive a demand in foreign countries, but none of the specimens now remaining enable us to fix any precise date to their production. We give one specimen, copied from Mr. Singer's work on playing-cards:—

Knave of Bells.

Jäger ('Kunstblatt,' for 1833) found, under the year 1398, the name of one Ulrich, a wood-engraver (Formschneider), but whether he cut blocks for cards, for seals, or for prints, is at least doubtful. (Passavant, 'Le Peintre-graveur,' i. 11.) There also occurs, in the necrology of the convent of the Franciscans, at Noerdlingen, which terminated at the beginning of the 15th century, the name of a lay brother, Luger, who was an excellent engraver in wood. ("Optimus incisor lignorum;" Heller, 'Geschichte,' p. 25.) Luger was probably, as Passavant suggests, an engraver of religious subjects, and several wood-cuts of a very early date are still extant, which, if not executed in a monastery, were executed for one. (See list in Passavant, i., p. 22, &c.) But the first wood-cut with a date known to be in existence is of 1423. It was discovered by Heineken, pasted on the cover of a manuscript in the library of the convent of Buxheim, near Memmingen, in Suabia, and is now in the library of Earl Spencer. It represents St. Christopher carrying our Saviour on his shoulders across a river. The two figures are drawn with much spirit; but the accessories, a man with a loaded ass, a hermit holding up a lantern, and a man ascending a steep path toward a house, show a deplorable want of knowledge of perspective. It is by no means certain, however, that this print is the most ancient specimen we possess, as there are several others which, from their greater rudeness, have been held to have superior claims to antiquity. But this rudeness cannot be accepted as a proof, as there is reason to believe that these scriptural subjects were addressed to the wants of the poorer classes, and were intended to supply the place of the more costly illuminations of the rich, while they admitted of being made to occupy a middle place by being finished off by hand in colours; and, indeed, many of the remaining specimens owe part of their rudeness to the defect of parts intended to be so supplied. Cheapness was therefore an element necessarily required in the production of these prints.

The art, however, made rapid progress. The next great step was the production of block books and the adoption of moveable letters. [PRINTING.] Without entering into the disputed question of the dates of the 'Biblia Pauperum,' the 'Speculum Salvationis,' and others, it will be enough to say that they prove the extension of its use, and many of the early books with moveable types were illustrated with pictorial wood-cuts. Of one of these works we subjoin a fac-simile specimen. A selection of rare and beautiful specimens of block-books, including the 'Biblia Pauperum,' supposed to be the earliest, and the 'Opera nova Contemplativa,' the latest block-book, is exhibited in the British Museum, cases 1 and 2 in the Grenville Library.

Wise Men's Offering.

Maps also were engraved on wood. In an edition of Ptolemy, printed in 1482 at Ulm, there are twenty-seven; and in a later edition, printed at Venice in 1511, the outline, with the mountains and rivers, is in wood, while the names are printed with type, and in two colours, no doubt by separate workings. In England, the original map of London by Aggas, measuring 6 ft. 3 in. by 2 ft. 4 in., to which the date of 1560 was assigned by Vertue, though it was probably some years later, was on wood in several blocks, worked on separate sheets of paper. In 1486 the improvement known as "cross-hatching," by which the bold and free effect of a pen-drawing was endeavoured to be attained, was shown in Breidenberg's 'Travels,' printed at Mentz. This invention has been usually attributed to Michael Wohlgemuth, the master of Albert Dürer. This work, however, preceded by seven years the Nürnberg Chronicle, said to be by Wohlgemuth, but who probably only furnished the designs, and the execution of the cuts is in a very superior style to that of any existing contemporary production: two fac-simile specimens are given in 'A Treatise on Wood-Engraving, Historical and Practical,' executed by J. Jackson, the most complete work that has been produced on the subject in this country, and to which we are much indebted, although we have been compelled to differ from some of the opinions therein.

The art had now attained an excellence which induced artists of celebrity and talent to select it as the means of conveying their designs to the world. Among the most distinguished in this line was Albert Dürer, whose productions as a painter, and an engraver on copper and wood, are so numerous as to excite a doubt whether he was actually an engraver on wood himself, or whether he only put the design on the blocks, leaving them for other hands to execute. The majority of critics regard it as certain that Dürer engraved many of his own designs; the inequality of execution of those marked with his monogram forbids the belief that all were from the same hand. Bartsch, in his 'Peintre-Graveur,' and the writer of the work above mentioned, 'A Treatise on Wood-Engraving,' have agreed that Dürer did not engrave on wood. The last-named says, of all the wood-engravings marked with the initials of Dürer, about two hundred, "the greater part of them, though evidently designed by the hand of a master, are engraved in a manner which certainly denotes no very great excellence, and that none are so superior as to challenge a belief that they must be from his own hand; but he acknowledges that "the cuts of the 'Apocalypse' (published in 1498), five years after the Nürnberg Chronicle, and eight from the expiration of his apprenticeship) generally are much superior to all wood-engravings that had previously appeared, both in design and execution." Yet he asserts that this superiority in execution does not arise from any delicacy or skill in the engraving, "but from the ability of the person by whom they were drawn, and from his knowledge of the capabilities of the art." Another argument is the frequent employment in his cuts of cross-hatching, a work of no artistic difficulty, though one of minute and tedious labour, and which, as an artist, he could have easily avoided. This argument is also applied to others, Cranach, Burgmair, &c., who, it is urged, as draughtsmen on the wood, produced shade thus more easily than by thickening the lines, though in cutting the case is reversed. The last argument is, that, with his other avocations, Dürer could not have found time to execute the great number marked with his name. On this we may remark, that a knowledge of the capabilities of the art was most likely to have been acquired by practice—a fact that is felt even at present by persons who draw on wood; and it is remarkable that in the 'Apocalypse' the use of cross-hatchings is much more sparing than in many of his later works. There can be little doubt that, as he advanced in reputation, he availed himself of assistance not only in wood-engraving, but in painting and engraving on copper. It is known that he had many pupils, and of course it was in this way they were instructed. His wood-cuts are marked precisely as his engravings on copper are marked, and we think there are thus grounds for supposing that the cuts of the 'Apocalypse' are chiefly from his own hand, and that in the others he at least closely superintended their execution and gave the finishing touches. There is much in his designs that patient fidelity could successfully copy, but there is much of artistic feeling and expression that none but an artist of great talent could reach: we refer, as an example, to the Christ taken from the Cross, of which the block still exists, and from which impressions were printed in Ottley's 'Inquiry into the Origin and Early History of Engraving,' and in which the cross-hatching is but sparingly, though effectively, introduced. It is yet a common practice for engravers to employ their pupils in the more tedious and mechanical parts of their business, and this might lead him to adopt the cross-hatching more frequently than in those executed by his own hand, in which, however, he would not altogether omit it, as it was then understood to be an improvement. It would be hard, however, in such cases to withhold the merit of the engraving from the master because he had been assisted perhaps by various persons, according to their capacity, under his immediate supervision. This is also Ottley's opinion. He says, "Dürer or Burgmair might have found employment for a dozen young men;" and that of the Abate Pietro Zani ('Encyclopedia Metodica critico-ragionata delle Belle Arte,' Parma, 1821). On the other hand, Passavant, who has collected the whole of the evidence, and many of the opinions, on each side ('Peintre-Graveur,' vol. i.) inclines to the belief that Dürer's designs were certainly for the most part engraved by professional wood-engravers.

Thus much we have thought it necessary to urge in favour of Dürer's claims to be considered as an engraver on wood, though doubtless his merit as an artist is to be estimated rather from his other works as a painter, an engraver on copper, and as a sculptor, in all of which he excelled. In the history of the art, however, the question has but little real importance. The prints exist, the date of their production is well ascertained, the progress of improvement definitely marked, let the engravers have been who they might.

In the early part of the 16th century several artists of celebrity were either designers on wood or engravers: Louis Cranach, Hans Holbein, Hans Burgmair, Hans Schaufflein, Urse Graffe of Berne, and, in Italy, Ugo da Carpi. Their initials or monograms are on the works; but their claims to the engraving have been denied by Bartsch and by Passavant, as well as by the writer in the 'Treatise on Wood-Engraving.' To Da Carpi has been attributed the invention of imitating drawings in chiaro-scuro, effected by using three or more blocks; but it has been shown that this had been done earlier by Dienecker, if not by Cranach, though Da Carpi most certainly improved on it, and some of his designs are said to have been drawn on the blocks by Raffaelle himself, and many of them are from his designs. Books were also at this period most profusely illustrated; but, with the exception of those from the artists already named, and a very few others of some (though inferior) merit, the illustrations are very rude both in design and execution. The art was chiefly practised in Germany, being greatly patronised by the Emperor Maximilian, for whom Burgmair designed the great work called 'The Triumphs of Maximilian.' Carpi was the only distinguished name out of that empire at this period, and the Italian wood-engravings are, on the whole, even inferior to those produced in the Low Countries.' A selection of the early German and Italian prints in chiaroscuro may be seen in the King's Library at the British Museum.

From about 1545 to 1580 wood-engraving continued to be much used for the illustrating of books, but the style of the designs became much lowered; and during this period the execution of engravings improved in Italy, in Holland, and at Lyon, while in Germany the reverse took place, although the productions of Jost Amman may be deemed an exception, as they are designed with considerable spirit, and executed with great care and neatness. His works are very numerous: one of them, his illustrations to Schopper's 'De omnibus Illiberalibus sive Mechanicis Artibus,' contains 115 prints of the principal arts and trades then practised. From the end of the 16th century, while the art continued to decline elsewhere, the cuts in English works showed visible improvement. About this time, also, it became customary to designate the designer as well as the engraver (they had now become separate professions) in the impression; as, for instance, in the designs by Rubens, engraved by Jegher. From this period there is little to be recorded of essential importance, till the appearance of Bewick, though a regular succession of engravers on wood was kept up both in England and on the Continent. The principal names in England were E. Kirkall, who published prints after old Italian masters, in which the outlines were taken from copper-plates and the tints from wood blocks; and John Baptist Jackson, who resided for some time at Venice, and there executed a series of wood-cuts, intended as fac-similes of drawings by Titian and other of the great Italian masters, somewhat in the manner of those of Kirkall.

Bewick, to whom the revival of wood-engraving is chiefly owing, was born in 1753, at Cherryburn, near Newcastle-upon-Tyne. He was apprenticed in 1767 to Mr. Ralph Beilby, of Newcastle, a general engraver, who undertook anything from book-plates to clock-faces, and Bewick's first efforts in wood were made in engraving diagrams for Dr. Charles Hutton's Treatise on Mensuration; but though it is known that he endeavoured to improve himself in this line, it was in private, for his master had little or no employment of the kind for him. He devoted himself, however, to the art after the termination of his apprenticeship, and in 1775 he received a premium from the Society for the Encouragement of Arts and Manufactures, for the cut of the Huntsman and the Old Hound, which appeared subsequently in an edition of Gay's 'Fables,' published at Newcastle, in 1779, by S. Saint. After a short visit to London, he entered into partnership with his old master in 1777, his brother John becoming their apprentice. He continued the practice of his art, furnishing the cuts to the edition of Gay's 'Fables' just mentioned, and to an edition of 'Select Fables' in 1784. In 1785 he commenced engraving the cuts for his 'General History of Quadrupeds,' for which the descriptions were written by Mr. Beilby, and which was published in 1790. The excellence of the work insured its success, and editions rapidly succeeded each other. The merit of the work, however, did not consist merely in the execution of the cuts. Bewick drew all the designs himself; the drawing was in general remarkably correct, and the backgrounds and little vignettes full of the most natural expression, simplicity, feeling, and beauty. The success of the 'History of Quadrupeds' led immediately to the commencement of a 'History of British Birds,' of which the first volume appeared in 1797, and the second in 1804. Bewick had now taken pupils, and in this work was materially assisted by them.

From this epoch the art has continued to flourish. The pupils of Bewick were numerous, and possessed of great talent; the celebrity of their master procured them immediate employment. Illustrated works became fashionable, at first at very high prices, but by degrees at lower rates, and particularly by the example of the 'Penny Magazine,' wherein it was proved that a low price was not inconsistent with a high degree of excellence in the art of wood-engraving; and as it was thus brought within the reach of the very poorest, the public were familiarised with the best specimens, and a large sale was ensured.

For the purpose of illustrating books, wood-engraving is peculiarly adapted. Being worked in the same manner as type, impressions are produced with great rapidity. Any number of cuts may be printed at once on a sheet of paper that will come into the press or machine, and an almost infinite number of impressions may be taken off without material injury to them. This seems the proper purpose of the art. The attempts which have been made to imitate the effects of copper-plates are misapplied, and the endeavours have been failures. The extreme neatness, length and sweep of line, and bold outline of the copper cannot be reached in wood-engravings; while in depth of shadow and effect they equal even mezzotint, with more distinctness of detail.

It is not necessary to detail the history of wood-engraving beyond this period, as many of Bewick's immediate successors are yet living. Within the last few years, also, the wood-engravers of France, and also of Germany, have made such progress in improvement as to become no contemptible rivals of their English brethren. Nor is it any part of our plan to give practical instructions for engraving, which can only be effectively learned by instruction and practice. A description of the process, as practised in his time, is given by Papillon, in his 'Traité historique et pratique de la Gravure en Bois,' 1766; and a far more detailed account, with all the modern improvements, by Mr. Jackson, in the 'Treatise on Wood-Engraving,' already mentioned. We will only observe that one of the greatest practical improvements, that of lowering the surface of the blocks in parts, so as to graduate the shadows into the lights, was, though not invented, yet brought into use by Bewick, nearly all his blocks being so prepared for working; and that box is the wood now universally used for engraving upon.

WOOD NAPHTHA. [METHYL. *Hydrated Oxide of Methyl.*]

WOOD-SPIRIT. [METHYL. *Hydrated Oxide of Methyl.*]

WOODS. There are in England many old natural woods remaining, besides the royal forests, although the great demand for timber during the last war has greatly thinned them of their finest trees. When woods were abundant and covered a great portion of the land little attention was paid to the increase or preservation of the trees: kings and lords of manors readily granted to their tenants rights of commonage, with the privilege of lopping the branches, always supposing them to be useless dead wood. The consequence of this is still to be seen in all old forests, especially the royal forests, which never were enclosed or protected. Many fine old trees, whose age can scarcely be guessed at, which are very picturesque objects and a fit study for the landscape-painter, have evidently been lopped, at some time or other, for the sake of the wood for fuel, and for want of care have probably never been in such a state as would afford fine timber for ship-building. Windsor Forest, which has only been inclosed since 1813, affords many specimens of noble trunks now hollowed out by time and the admission of water from above, which might probably still be sound and solid, had they been duly protected, and only those branches carefully cut out which were dead and showed decay. The dates of the inclosures of different parts of Windsor Great Park can be readily discovered by observing the form of the oldest trees.

In many extensive woods on private estates the want of care may be readily seen at the first inspection. Oak-woods are chiefly found in stiff clay soils, where the water is apt to accumulate, by which the roots are injured, and the trees decay before they have attained their full growth. The water should be carefully let off by open drains and ditches, which should be regularly examined and cleared out every year before winter. The surface being thus kept dry, the timber, as well as the underwood, will grow much more rapidly, and the increased value of the wood will amply repay the outlay. Cattle should be carefully excluded from all woods; they destroy the young shoots by cropping them, and do much damage to the underwood. At the time when acorns and beech-mast are plentiful, pigs may be turned in without danger; they will turn up the ground in search of their food, and thus bury beech-mast and acorns, which may vegetate, and grow in time into fine trees; for it is well known that an oak raised from an acorn is always hardier and better rooted than one which is raised in a nursery and transplanted in the woods; and the same may be said of beech raised from the seed.

The sweet chesnut is one of the most useful trees in a wood, provided it has room to grow. Its timber, when of a certain age, is as durable as oak, and the shoots which spring up from the old trunks cut down give the most useful and profitable coppice-wood. When it is recollected that a coppice may be cut advantageously every tenth year, if a calculation be made of the value of growing timber after many years, it will be found that the underwood, properly managed, pays fully as well as the timber. It is usual to cut down such trees as begin to show decay at top, when the coppice is cut; but it is better to anticipate this decay, and cut them when they have ceased to increase from year to year as much as the interest of the money they would sell for amounts to. For example: Suppose that an oak standing measures fifty cubic feet, and with top, lop, and bark, may be worth 10*l.* If it does not increase above two cubic feet in a year, it will not be profitable to let it stand: but if, by cutting down others which interfere with the spread of its branches, its growth can be promoted, it may probably increase so much as to pay a good interest on its value; in which case it would be a loss to cut it. There is a period when the increase of the wood in a tree is a maximum, and this depends on soil and situation. The head and branches contribute much to the growth of the trunk; and unless they have room to spread, the increase derived from the action of the leaves must be checked. On this depends the practice of gradually thinning out young woods as the branches spread, the object being to let in as much air as is necessary, without leaving too great a space between the head of one tree and its neighbours. As soon as the branches begin to approach towards those of another tree, room must be made, by cutting out those trees which appear inferior in shape or in health. In the management of young plantations [PLANTING], it is a question whether it is more profitable to cut down trees at the age of thirty or forty years and replace them with young plants, or to let them arrive at their full size, which, for oaks, will take 150 or 200 years. The calculation is made on the annual increase of the wood, which is said to be greatest when the tree is about thirty years old. It has been often supposed that the slower a tree grows the stronger the wood will be; but this appears to be a mistake. Some wood taken from a very rapidly-growing oak, and some from one which, having been headed down as a pollard, had grown slowly, were tried by the action of a very powerful hydraulic press, and the wood of the quicker-growing tree was found to resist the pressure much longer before it was broken or crushed.

Although it is generally on soils unfit for cultivation that plantations of wood are made, yet there are proofs that, on a deep rich soil worth 2*l.* an acre as arable land, a plantation of oaks, well managed for fifty or sixty years, will pay a better rent than if it had been cultivated as a farm. On such land it is usual to plant oaks in the hedge-rows, where the trees, having room both for their branches and their roots, thrive well at the expense of the farmer. Most old farms consist of small inclosures surrounded with trees, chiefly oak, ash, and elm, according to the soil; and the landlord, having the benefit of their growth, only cuts them when fit for sale. The tenant is scarcely aware of the annual loss he suffers from the shade of the trees, as well as the exhaustion of his manure by the roots. If the inclosures are of the extent of twenty acres or more, a few trees here and there in the banks will not do much harm; but it would be far more advantageous to all parties if the woods and plantations were entirely separated from the arable land. A few single trees here and there in old pastures are both ornamental and useful as shelter for the cattle; but they should be extirpated in all arable fields. Clumps and woods may be made pictures in the scenery, whereas a country consisting of small inclosures surrounded with trees only looks like an immense wood when seen from a small eminence.

Trees of full size are sometimes transplanted to form shelter and ornament to parks and pleasure grounds. Sir Joseph Banks made some experiments in his grounds near Brentford, by cutting off the heads of old elm trees and transplanting the trunks by way of keeping up a proportion between the head and the roots, in the expectation of their growing out, but it failed entirely. Sir James Stuart Monteith, in Scotland, succeeded better by retaining the head, and saving, as much as possible, all the fibres of the roots. The removal of large trees is a troublesome and expensive process, but is often desirable for the production of immediate effect, as in laying-out parks and pleasure-grounds, or in landscape gardening generally. The method now usually adopted is briefly described under PLANTING, col. 553.

Wood is too valuable in Britain to be used for fuel, except in very distant and woody districts. Coals have everywhere superseded it; but wherever woods are cut down, and especially where the roots are grubbed up, they give an excellent and economical fuel for the poor, or to use in the lime and brick kilns. Where old hedge-rows are cleared in the progress of agriculture, it is a common practice to give the stumps and roots found in old banks to the poor, for the trouble of grubbing them up and levelling the ground. This work is generally done in winter; and the wood is stacked into cords six feet long, three feet wide, and three feet high.

In France and other countries where they use chiefly wood for fuel, the trees which are preferred are beech-trees, which are allowed to grow very close in the woods, so as to draw each other up and form long thin stems. They are cut down when about thirty or forty years old, and then do not average a foot in diameter; they are sawn in lengths of a yard, and thus sold, the purchaser generally having them sawn into shorter lengths and split for use. In Paris the trade in wood is very extensive, and employs many hands.

WOODS AND FORESTS. A considerable portion of the royal revenue consisted formerly of the rents and profits of the crown lands, which comprised numerous lordships and honours, together with forests and chaces: from the forests the principal source of profit lay in the fines or amerciaments levied for offences against the Forest Laws. [FORESTS.] The demesne lands which were retained by the king, or which came to the crown by forfeiture or otherwise, and were farmed out to subjects, were originally very extensive; but owing to the generosity or the necessities of different kings, so large a part of them was granted away, that the legislature was frequently compelled to interpose its authority in order to prevent the total alienation of the crown property. William III. had used the power of alienation so profusely, that upon the accession of his successor, it was enacted (1 Anne, st. 1, c. 7) that no grant or lease should be made of any crown lands for a longer term than thirty-one years or three lives, but permitting houses, &c., to be let for fifty years.

By the 26 Geo. III., c. 87, amended by 30 Geo. III., c. 50, commissioners were appointed to inquire into the state and condition of the woods, forests, and land revenues belonging to the crown. By the 46 Geo. III., c. 142 (altered by the 50 Geo. III., c. 65), an office of surveyor-general of his Majesty's works and public buildings was created; but this and some other offices were incorporated with that of "the Commissioners of her Majesty's Woods, Forests, Land Revenues, Works and Buildings" (2 Will. IV. c. 1, s. 1), who were called "the Commissioners of Woods and Forests," which office or board owed its shape to the statute 10 Geo. IV., c. 50 (amended and extended by 2 Will. IV., c. 1; 2 & 3 Will. IV., c. 112; and 3 & 4 Will. IV., c. 69). The commissioners, who were not to exceed three in number, are appointed by letters patent (2 Will. IV., c. 1, s. 1). They are to make a declaration (5 & 6 Will. IV., c. 62, s. 2, in lieu of the oath required formerly, 2 Will. IV., c. 1, s. 6) that they will faithfully and diligently execute the duties of commissioners.

Their powers are very large. The whole of the possessions (except advowsons) and land revenues of the crown in England, Ireland (10 Geo. IV., c. 50, s. 8), and Scotland (2 & 3 Will. IV., c. 112; 3 & 4 Will. IV., c. 69) are under their management; but the *property* therein still remains in the crown. (1 'Q. B. Rep.,' 352.) They are required, however, to observe all the orders and directions of the Lords of the Treasury touching the exercise of their powers (2 Will. IV., c. 1, s. 3).

The commissioners have the power of appointing and removing various officers, such as receivers, surveyors, &c., whose salaries however are fixed by the Treasury (10 Geo. IV., c. 50, s. 12). They may also appoint stewards of the royal hundreds and manors to hold courts, and different manerial and forestal officers to preserve game, fish, &c.; and they may grant licences to hunt, fish, &c. (Id., s. 14).

They are empowered to grant leases of any part of the crown possessions for thirty-one years (10 Geo. IV., c. 50, s. 22); or, in case of houses, buildings, &c., or building-land, for ninety-nine years (Id., s. 23); but this power of leasing does not extend to the royal forests in England (Id., s. 25), except for the purpose of making railroads (Id., s. 97). The leases are required to contain certain specified provisions, and the lessees are not to be made dispunishable for waste, except in leases of mines, and at the option of the commissioners, in leases for ninety-nine years (Id., s. 27). The leases are to be granted at a rack-rent, and no fine is to be reserved (Id., s. 28), except in building leases, in which a nominal rent may be reserved for the first three years (Id., s. 30), and a fine may be taken not exceeding one-third of the rent (Id., s. 31).

They may also *sell* any part of the crown possessions, except the forests (Id., s. 34), according to a mode pointed out (s. 35); and they may also sell rents, or manerial or forestal rights, to corporations, or trustees of incapacitated persons, who have estates subject thereto (ss. 39, 40).

They may *exchange* or *purchase* lands, &c. (Id., ss. 42, 52, 98).

They are declared to be exempt from all personal responsibility as to any covenants or contracts they may enter into in their official character (Id., s. 17).

All deeds relating to lands, &c., leased, &c., by the authority of the commissioners are required to be enrolled in the office of Land Revenue Records and Inrolments (10 Geo. IV., c. 50, s. 63; 2 Will. IV., c. 1, ss. 16, 18, 21), and to be certified by the commissioners to parliament (10 Geo. IV., c. 50, s. 125); and all conveyances and sales respecting such lands are to be free from stamp and auction duty (10 Geo. IV., c. 50, ss. 67, 68).

The commissioners are also empowered to give certain notices and claims, and to authorise entries on land for breach of covenant, &c. (10 Geo. IV., c. 50, s. 92), and to compound, in certain cases, for rent (Id., s. 93).

Their accounts are to be audited by the commissioners for auditing public accounts, under the 25 Geo. III., c. 52 (10 Geo. IV., c. 50, s. 19).

The receivers appointed by the Commissioners of Woods and Forests must be land-surveyors (Id., s. 80). They are required to account at stated periods to the commissioners (Id., s. 81), and to transmit all sums received monthly (s. 84); and they are empowered to distrain for rent (s. 90).

Notwithstanding the management of the crown lands is thus vested in the commissioners, and the general power of alienation has been taken from the sovereign, a power is reserved to the crown to grant sites for churches, chapels, and burial grounds, not exceeding five acres in extent, or 1000*l.* in value (10 Geo. IV., c. 50, s. 45); and by 1 & 2 Will. IV., c. 59, s. 1, churchwardens and overseers are empowered, with the consent of the Lords of the Treasury, to inclose a portion not exceeding fifty acres of any forest or waste lands belonging to the crown, lying in or near their parish, for the purpose of cultivating the same for the use of the poor.

Besides this general control over the crown lands, certain powers are given to the commissioners which are referable to the execution of the

Forest Laws. The powers and authorities belonging to the offices of wardens, chief-justice, and justices in eyre (which were abolished upon the termination of the then existing interests by 57 Geo. III., c. 61), are vested in the first commissioner (10 Geo. IV., c. 50, s. 95); and the commissioners are also empowered to make compensation to parties for old encroachments made upon the royal forests where they have been in uninterrupted possession for ten years (Id., s. 96).

The *verderers* of the royal forests are also required to make inquiry as to all unlawful inclosures, encroachments, &c., in their courts of attachment, and may impose fines upon the offenders (Id., s. 100), who may however be proceeded against by the ordinary course of law (s. 103). The verderers may appoint regarders, under-foresters and other officers of the forests and courts (s. 101), and may inquire into their conduct, and fine them for neglect of duty (s. 102). Other penalties may be recovered before a justice of the peace (s. 104); and all such fines and penalties are to be applied to the expenses relating to the forests (s. 105).

As to the general revenue arising from the letting, &c., of the crown lands, the commissioners are directed to pay in the moneys received by them, to a proper account with the Bank of England and Ireland respectively (10 Geo. IV., c. 50, ss. 117, 118) and the chartered banks of Scotland (3 & 4 Will. IV., c. 69, s. 17); and the annual income (after certain deductions) is to be carried to the consolidated fund (10 Geo. IV., c. 50, s. 118; 3 & 4 Will. IV., c. 69, s. 16). The transfer of the revenue arising from the crown lands to the consolidated fund is however the subject of a special arrangement between the crown and the subjects, terminating with the life of the sovereign in whose reign it is made.

The 10 Geo. IV., c. 50, contains some provisions peculiar to Ireland. Leases, grants, &c., of any of the small branches of the royal revenue (s. 128), and the powers appertaining to the chancellor and council of the Duchy of Lancaster (s. 130), are exempted from its operation.

The real property of the crown may be thus classified:—

1. Honours, manors, and hundreds, not in lease.
2. Other lands in the occupation of the crown, either for the personal convenience of the sovereign or for the public service.
3. Forests, chaces, and wastes.
4. Lands, tenements, and hereditaments, held of the crown by lease.
5. Fee-farm rents, issuing out of lands, tenements, and hereditaments, held of the crown in fee-simple.

The second class comprises the following royal palaces and houses:—Buckingham Palace; St. James's Palace; Windsor Castle; the palaces of Hampton Court, Kensington, and Whitehall; the King's House at Winchester; the Palace of Greenwich (converted into a hospital for seamen); Somerset House (used as public offices); the New Palace of Westminster, including the houses of parliament, Westminster Hall, and courts of law. The following palaces and buildings have been pulled down and their sites used for other purposes:—Carlton House; the Mews; Newmarket Palace. The following parks are also included in this class:—St. James's, Hyde, Bagshot, Bushey, Greenwich, Hampton Court, Kew Gardens, Richmond, and Windsor. This class is now under the supervision of the Board of Works mentioned below.

In the third class are included not only the royal forests which have preserved their *jura regalia*, but several nominal forests and chaces, warrens, wastes, &c. The following is a list of the real forests:—In Berks, Surrey, and Wilts, Windsor Forest; in Essex, Epping Forest; in Gloucestershire, the Forest of Dean; in Hampshire, Bere Forest, New Forest, and the Forest of Woolmer and Alice Holt.

In 1851 the offices were finally separated, and to the Board of Public Works and Buildings, and to the officers of this board, was consigned the important task of providing for the people public walks and access to the national buildings and collections. The duty of the state in this respect has only been recognised of late years, and perhaps we owe it to our intercourse with the continent, and especially with France, that it has been at all acknowledged. Fifty years ago Hyde Park and Kensington Gardens were the only public places of recreation open to the crowded and hard-worked population of London; since then, beside the improvements in those two places, and the formation of new streets and squares in those parts of the metropolis of which the land either belongs to the crown or has been purchased by parliament for public improvements, there have been opened the large parks and gardens of St. James's Park, the Regent's Park, and Primrose Hill, at the west and north; the Victoria Park at the north-east; and Kennington Park and Battersea Park at the south-west of London. The palace and grounds of Hampton Court have been repaired and adorned, and the collection of pictures has been arranged and enlarged; and Kew Gardens have been enlarged, filled with the rarest and choicest plants and flowers, and improved by the addition of magnificent conservatories and a new museum, and both Hampton Court and Kew Gardens have been thrown open gratuitously to the public. In Kensington Gardens an Italian garden has been laid out with fountains, statuary, and carving; which though not of very remarkable excellence or originality, are at least superior to anything of the kind hitherto given to the public.

WOODY FIBRE. [LIGNIN.]

WOOL. The present article will be devoted to the SHEEP with reference to its wool-producing properties, and as the subject of the art of the grazier. The natural history of sheep is given under OVIS, in NAT. HIST. DIV. The treatment of the fleece when removed from the animal is spoken of under WOOL AND THE WOOL TRADE: see also WOOLLEN MANUFACTURE.

The sheep belongs to the class *mammalia;* to the order *ruminantia* with four stomachs, and the organs of digestion disposed for chewing the cud; to the tribe *capridæ*, with horns persistent, and placed on an osseous nucleus; and to the genus *ovis*, with or without horns, but these when present uniformly taking, to a greater or less degree, a lateral and spiral direction. The forehead of the sheep is arched, and protruded before the base of the horns; there are no lachrymal ducts, the nostrils are lengthened and oblique, and terminate without a muzzle; there is no beard properly so called, the ears are small, and the legs slender. The hair is of two kinds, one hard and close, and the other woolly—the wool preponderating in proportion as the animal is domesticated. The sheep is principally distinguished from the goat by his convex forehead, by his spiral horns not projecting posteriorly, and more especially, and that in proportion to the care which is bestowed upon him, by the preponderance of wool over the hair, with which, in despite of every effort, the Cashmere goat is covered.

Different names are given to the sheep, according to its sex and age. The male is called a *ram* or *tup*. After weaning he is said to be a *hog*, a *hogget*, or *hoggerel*, a *lamb-hog*, or *tup-hog*, or *teg;* and if castrated, a *wether hog*. After shearing, and when he is probably a year or a year and a half old, he is called a *shear hog*, or *shearling*, or *dinmont*, or *tup;* and when castrated, a *shearling wether*. After the second shearing, he is a *two shear ram*, or *tup*, or *wether*. At the expiration of another year, he is a *three shear ram*, &c.

The female is a *ewe* or *gimmer lamb* until weaned, and then a *gimmer* or *ewe hog* or *teg*. After being shorn, she is a *shearling ewe* or *gimmer*, or *theave* or double-toothed ewe; and after that, a *two* or *three* or *four shear ewe* or *theave*. The age of the sheep is reckoned, not from the period of their being dropped, but from the first shearing.

The teeth give certain indications as to the age. The sheep has no incisor teeth in the upper jaw; but there is a dense elastic cushion or pad, and the herbage, firmly held between the front teeth in the lower jaw and this cushion, is partly bitten and partly torn asunder. The sheep has the whole of the incisor teeth by the time that he is a month old, and he retains them until the fourteenth or sixteenth month. They then begin to diminish in size, and are displaced. The two central ones are first shed, and the permanent ones supply their place, and attain their full growth when the animal is two years old. Between two and three, the next pair are changed; the third at three years old; and at four, the mouth is complete. After this there is no certain rule, until, two years more having passed, the teeth one by one become loosened and are lost. At six or seven years of age the mouths of the ewes should be occasionally examined, and the loose teeth removed. By good pasture and good nursing in the winter, they may produce lambs until they have reached the ninth or tenth year, when they begin rapidly to decline. Some favourites have lingered on to the fifteenth or sixteenth year; but the usual and the most profitable method is to fatten and dispose of the ewes when they are five or six years old, and to supply their places by some of the best shearling ewes.

The rings at the base of the horns afford very imperfect indications of the age of the sheep. Even when untouched, they are little to be depended upon.

The history of the British sheep will be most naturally divided according to the quantity and quality of the wool of the different breeds, and the quality of the flesh. The covering of the original sheep consisted of a mixture of hair and wool; the wool being short and fine and forming an inner coat, and the hair of greater length, projecting through the wool, and constituting an external covering. When the sheep are neglected or exposed to a considerable degree of cold, this degeneracy is easily traced. On the Devonshire moors, the mountains of Wales, and the highlands of Scotland, the wool is deteriorated by a considerable admixture of hair. Even among the Southdowns, the Leicesters, and the Ryelands, too many *kemps* occasionally lessen the value of the fleece. It is only by diligent cultivation that the quantity of hair has been generally diminished, and that of wool increased in our best breeds.

The filaments of wool taken from a healthy sheep present a beautifully polished and even glittering appearance. That of the neglected or half-starved animal exhibits a paler hue. This is one valuable indication by which the wool-stapler is enabled to form an accurate opinion of the value of the fleece. The mixture of hair in the wool can often be detected by close examination with the naked eye, but most readily by the assistance of a microscope.

Among the qualities which influence the value of the wool, *fineness*, and the uniformity of that fineness in the single fibre and in the collected fleece have hitherto held a first place. This fineness, however, differs materially in different parts of the fleece. It prevails on the neck, the shoulders, the ribs, and the back. It is less on the legs, thighs, and haunch, and still coarser on the neck, the breast, the belly, and the lower part of the legs. The fineness of the wool is considerably influenced by the temperature. Sheep in a hot climate yield a comparatively coarse wool; in a cold climate, they carry a closer but a warmer fleece.

The fineness of the fleece is also much influenced by the kind of food. An abundance of nutriment will increase both the length and the bulk of the wool. This is an important consideration with the sheep-breeder. Let the cold of winter come—let it continue for a considerable period, yet if the sheep be well kept, although the fleece may lose a little weight, this will be more than compensated by its fineness and increase of value. If the sheep, however, be half-starved while he is exposed to unusual cold, the fibre of the wool, although perhaps somewhat finer, will be deficient in weight and strength and usefulness.

What is called *trueness of staple*, or the fibres being of an equal size, is of much importance in the manufacture of wool, for whenever the wool assumes an irregular and shagged or *breachy* appearance, there is a weakness in the fibre and will be an irregularity in the manufacture, especially if the fleece is submitted to the operation of the comb. Connected with this, and a most important quality, is the *elasticity* of the woolly fibre—the disposition to yield, or submit to some elongation of substance, some alteration of form, when it is distended or pressed upon, and the energy by means of which the original form is resumed as soon as the external force is removed.

Referrible to this elasticity or yielding character of the wool is its *pliability* and *softness*, and without which no manufacture of it can be carried to any degree of perfection. The last quality which it is necessary to mention is its *felting* property, that quality by which it may be beaten or pressed together and worked into a soft and pliable substance of almost any size and form. It would seem that the process of felting is of far older date than that of weaving, and it is still continued not only by the nomadic tribes of south-eastern Europe and of Asia, but it is made occasionally to vie with the finest productions of the loom.

Microscopic observations have unravelled the whole mystery of felting, and of the employment of wool in almost every form. The fibre, examined under a powerful microscope, appears like a continuous vegetable growth, from which there are sprouting, and all tending one way, from the root to the other extremity, numerous leaves, or serratures, assuming the appearance of calices or cups, and each terminating in a sharp point. It is easy to conceive how readily one of these fibres will move in a direction from the root to the point, while its retraction must be exceedingly difficult, if not impossible. It was a fibre of Merino wool that was first submitted to microscopic observation, and the number of these serrations or projections counted. There were 2400 in the space of an inch. A fibre of Saxon wool finer than that of the Merino, and of acknowledged superior felting quality, was substituted. There were 2720 serrations. A fibre of Southdown wool, in its felting power well known to be inferior to that of the Saxony and the Merino, was placed in the field of vision. There were only 2080 serrations in the space of an inch, or 640 less than the Saxony exhibited. The Leicester wool is acknowledged to possess a less felting property than the Southdown. There were only 1860 in the space of an inch. Latterly the length of staple and the lustrous character of the wool have become qualities of high order, so that the long-wools of Lincolnshire are now of greater value than the short-wools of Sussex.

We now proceed to take a rapid survey of the different breeds of sheep, commencing with the *Southdowns;* for by them or their congeners the first woollen manufactory at Winchester was supported. As latterly improved by the Ellmans, Lugars, Rigdens, and Webbs, it has exerted an extraordinary influence for good on all short-woolled breeds of sheep in the country. The flock of Jonas Webb in particular has furnished rams to all the best breeders of short-woolled sheep; and the high estimation in which his breed is held was proved at its recent sale, when 960 sheep of all ages sold for nearly 11,000*l.*

The Southdown sheep have succeeded admirably in all the southern districts of the kingdom; but the northern hills have occasionally been too cold for them. Crosses between the Southdown and almost every breed of middle-wool sheep have answered well; while in counties where it could have been least expected, the old breed is in a great measure superseded by the Southdowns.

We pass from Sussex, Hampshire, Berkshire, Wiltshire, where a black-faced short-woolled sheep, much improved by the Southdowns, prevails, into Dorsetshire, and we find a very different and valuable breed of sheep. They are white; the face long and broad, with a tuft of wool on the forehead; the shoulders low but broad; the chest deep; the loins broad; and the bone small; a hardy and useful sheep. Their chief peculiarity is the forwardness of the ewes, which supply the market with lamb when it produces the highest price.

A very profitable variety is found in a cross between the Southdown and the Dorset sheep. The carcase is increased, and the wool is rendered more valuable.

Returning through Somersetshire, we again meet with the Southdowns, either pure or materially improving the native breeds. In Gloucestershire, the short-woolled sheep have given way to the Cotswolds.

In Herefordshire we still meet with a few flocks of that breed of sheep, which was in former times the pride of the agriculturist—the Ryelands. They are small, polled, with white faces, the wool growing close to and almost covering the eyes, the carcase round and compact, the animal quickly fattening, and the superabundant fat accumulating within. They are hardy, and peculiarly free from disease, and particularly distinguished by the fineness of their wool.

Shropshire contains now a valuable characteristic breed of short-woolled, large-framed sheep, which have of late years achieved a high reputation.

The Cheviots extend from Westmoreland far into Scotland. They differ essentially from both the black- and the dun-faced breeds by which they are surrounded. The following is a description of the pure breed, thirty years ago, before they began to be crossed by the Leicesters:—"The head polled, bare and clean, with jaw-bone of a good length; ears not too short, and countenance of not too dark a colour; neck full, round, and not too long, well covered with wool, but without any coarse wool depending beneath; shoulders deep, full, and wide; chest full and open; chine long, but not too much so; straight, broad, and wide across the fillets; horns round and full; the body in general round and full, and not too deep or flat either in the ribs or flanks; the fleece fine, close, short, and thick-set, of a medium length of pile, without hairs at the bottom, and not curled on the shoulders, and with very little coarse wool on the hips, tail, or belly."

There are many flocks of pure Cheviots, but in the majority of the flocks there is a cross of Leicester blood.

The other breed of short-woolled sheep which contend with the Cheviots in number and value, is the *black-faced Scots.* They extend from Lancashire to the very north of Scotland. The males are mostly horned, the horns of a spiral form, but the females are frequently without horns. The faces and legs are always black or mottled: they are covered with wool about the forehead and lower jaw: the fleece is long and somewhat coarse. The carcase is peculiarly compact; so much so, that on account of the shortness, roundness, firmness, and handsomeness of the carcase, it is called the *short* sheep, in opposition to the Cheviots or *long* sheep. Great numbers of these sheep are sent to the London market. The weight of the carcase does not differ materially from that of the Cheviot, and the fleece weighs about three pounds after it is washed. These sheep have been improved by selection, but have derived little advantage from any of the crosses that have been tried.

We now arrive at the *Long-woolled Sheep.* The following description of the *New Leicester* by Mr. Culley will, to a very considerable degree, serve for all the varieties of the long-woolled sheep. The head should be hornless, long, small, tapering towards the muzzle, and projecting horizontally forwards. The eyes prominent, but with a quiet expression. The ears thin, rather long, and directed backwards; the neck full and broad at its base, but gradually tapering towards the head, and particularly fine at the junction of the head and neck. The neck seeming to project straight from the chest, so that there is, with the slightest possible deviation, one continued horizontal line from the rump to the poll. The breast broad and full; the shoulders also broad and round, and no uneven or angular formation where the shoulders join either the neck or the back, particularly no rising of the withers, or hollow behind the situation of those bones. The arm fleshy through its whole extent, and even down to the knee. The bones of the legs small, standing wide apart, no looseness of the skin about them, and comparatively bare of wool. The chest and barrel are at once deep and round in the ribs, forming a considerable arch from the spine, so as in some cases, and especially when the animal is in good condition, to make the apparent width of the chest even greater than the depth. The barrel ribbed well home. No irregularities of line on the back or the belly; but on the sides the carcase very gradually diminishing in width towards the rump. The quarters long and full, and as wide as the fore-legs. The muscles extending down to the back, the thighs also wide and full. The legs of a moderate length; the pelt also moderately thin, but soft and elastic, and covered with a good quantity of white wool, not so long as in some breeds, but considerably finer.

Such is the Leicester sheep as Bakewell made him. He found him as different an animal as it was possible to conceive—flat-sided, large-boned, coarse-woolled, slow to fatten, and his flesh of little value. Were there room for its insertion, a detailed history of the different steps of the changes would be most interesting to the reader. The means were simple, and the effect was almost magical. The principle was, that "like produces like;" and therefore he selected a few sheep with aptitude to fatten, with a disposition to produce an unusual quantity of valuable meat, with little bone and offal, and with quietness of temper; and from these he exclusively bred. He cared not about near or distant affinities, but his object was to increase every good point, and gradually to get rid of every bad one. They were not different sorts of sheep that he selected, but the best of the breed to which he had been accustomed.

His sheep were smaller than those of his neighbours, but they retained every good point, and had got rid only of the bad ones. The alteration was rapid as well as great in his own flock, and the practice which he introduced of *letting* some of his rams quickly extended the benefit of his system far and wide. The first ram which he let was in the year 1760, at 17*s.* 6*d.* for the season. In 1789 he let one ram for 1000 guineas, and he cleared more than 6000 guineas in the same year by the letting of others. After that, so great was the mania, or desire for improvement, that Mr. Lawrence calculates that 100,000*l.* were annually spent by the midland farmers in the hiring of rams.

The chief value of the new Leicester breed consists in the improvement which it has effected in almost every variety of sheep with which it has been crossed, in which its influence has corresponded among long-woolled sheep with that which the Southdowns has exerted on breeds allied to it in the character of their wool.

The largest of the other breeds of long-woolled sheep was the Lincolns, "hornless, with long, thin, and weak carcases, large bones, weighing from 20 to 30 lbs. a quarter; the wool averaging from 8 to 14 lbs. the fleece; the sheep a slow feeder, and the flesh coarse-grained." This is the account of them given by a good, but a prejudiced observer—Mr. Culley. In fact, while Bakewell and his admirers were almost neglecting the fleece, the Lincolnshire farmer was quite as inattentive with regard to the carcase. Both parties were wrong. The old Lincolnshire sheep yielded a wool which in quantity and in quality was unrivalled, while the Leicesters could boast of a disposition to fatten which the other could never equal. At length the attempt was honestly made to amalgamate the valuable qualities of the two breeds. In consequence of the cross, the wether attained its maturity a full year sooner than it was accustomed to do, and the fleece became finer and improved in colour, but it was shorter and more brittle, and not fitted for some of its former purposes. On the whole, a great improvement has been effected both in the carcase and the fleece; and so satisfactory did this prove, that it is now difficult to find any sheep in Lincolnshire that have not been crossed with the Leicesters. This cross is deeper on the wolds than in the marsh lands, which may serve to account for the difference of the fleece in the two. The breed of these sheep generally has been greatly increased since the introduction of the turnip system. The lustrous character of the wools has given them a high value in the manufacture of woollen fabrics, corresponding to those made of Alpaca wool, with which they are mixed.

Among the long-woolled sheep that have been improved by the admixture of the old and new long-woolled breeds and the altered system of husbandry, the inhabitants of Romney Marsh must not be forgotten.

The Cotswold sheep, of Gloucester, were a long-woolled breed, yielding in the 15th century a description of wool much valued on account of the fabrics in the construction of which it was employed. Even they, like the rest, have amalgamated themselves with, and been in a manner lost among, the Leicesters. They were taller than the present sheep, flat-sided, deficient in the fore-quarter, but full in the hind-quarter, not fattening so early, but yielding a long and heavy fleece. Many of these good qualities have been preserved, and to them have been added that which is of so much importance to the farmer—the capability of rearing and fattening so many more sheep on the same quantity of land, and of bringing them so much earlier to the market.

This will be the proper place to speak of the *shearing* of the sheep, or the separation of the fleece from the animal. The animal is first washed in some running stream. Two or three days are then allowed for the drying of the wool previous to its being shorn, the sheep being turned into a clean pasture, and remaining there until the fleece is dried, and that the new yolk, which is rapidly secreted, may penetrate through it, giving it a little additional weight and a peculiar softness. As soon as the sheep is shorn, the mark of the owner is placed upon it, consisting of lamp-black and tallow, with a small portion of tar, melted together. This will not be washed away by any rain, but may be removed by the application of soap and water.

Few rules can be laid down with regard to the rearing and feeding of sheep that will admit of anything like general application. A great deal depends on the kind of sheep, and the nature of the pasture and the food.

Suppose the larger kind of sheep, and on arable ground. The ewes are generally ready to receive the ram at the beginning of October, and the duration of pregnancy is from about twenty-one to twenty-three weeks, bringing the period of parturition to nearly the beginning of March, at which time most of the lambs will be dropped. The ewes should be fed rather better than usual a short time previous to the male being introduced. Rams are fit to propagate their species in the autumn of the second year, and that is also the proper period for the impregnation of the ewes. The ewe is, after impregnation, suffered to graze on the usual pasture, being supplied, as occasion may require, with extra food, and especially in case of snow, until within five or six weeks of lambing, when turnips are given to her, and continued from that time until the spring of grass renders them no longer necessary. The turnips are laid out for the ewes in the grass fields in certain quantities each day, but by no means so many as they would consume if permitted to feed without restriction, as it is considered to be most important that they should not be too fat when the lambing season approaches. The hogs and the fattening sheep of the previous year, now one year and a half old, are put upon the turnips in October, or whenever the pastures cease to improve their condition. The turnips required for the cattle, or the ewe-flock, are then drawn off in alternate rows, in the proportion of one-half, one-third, or one-fourth, as the convenience of the situation, the goodness of the crop, or the quality of the land may dictate. The remainder are consumed on the ground by the other sheep.

As the period of parturition approaches, the attention of the shepherd should increase. There should be no *dogging* then, but the ewes should be driven to some sheltered inclosure, and there left as much as possible undisturbed. Should abortion take place with regard to any of them, although it does not spread through the flock as in cattle, yet the ewe should be immediately removed to another inclosure, and small doses of Epsom salts with gentian and ginger administered to her, no great quantity of nutritive food being allowed.

The ewes should now be moved as near home as convenience will permit, in order that they may be under the immediate observation of the lamber. The operation of *clatting*, or the removal of the hair from under the tail and around the udder, should be effected on every long-woolled ewe, otherwise the lamb may be prevented from sucking by means of the dirt which often accumulates there, and the lamber may not be able at all times to ascertain what ewes have actually lambed. The clatting before the approach of winter is a useless, cruel, and dangerous operation.

The period of lambing having actually commenced, the shepherd must be on the alert. The process of nature should be permitted quietly to take its course, unless the sufferings of the mother are unusually great, or the progress of the labour has been arrested during several hours. Experience will teach the course to be pursued in that case. If any of the newly-dropped lambs are weak, or scarcely able to stand, the shepherd must give them a little of the milk, which at these times he should always carry about him, or he must place them in some sheltered warm place; in the course of a little while the young one will probably be able to join its dam. The operation of castration should be performed nine or ten days after the birth of the lamb.

Unless the pasture on which the ewes are placed is very good, it will be advisable to continue the use of the turnips. A moderate quantity may be given twice in the day, care being taken that the whole of one quantity shall be eaten before any more is placed before them. This is a better practice than hurdling off certain portions of the field for the sheep, unless the land is perfectly dry. A little hay will always be serviceable while the flock is fed on turnips. It corrects the occasional watery quality of the turnips, and the sheep usually thrive better than if they are fed either on hay or turnips alone. Bran and oats, with oil-cake, have been recommended for the ewes before weaning time, but this is an expensive measure, and its cost can hardly be repaid either by the ewe or the lamb. By the end of March or the beginning of April the turnips are generally nearly consumed, and the farmer is occasionally a little puzzled to find sufficient food for his flock. He should have had some plots of rye to support them for awhile. Rye-grass and clover are very serviceable. Mangold wurzel and Swedish turnips that have been carefully stacked on dry straw will be most useful, for they will retain their nutritive quality until the flock can be conveniently supplied with other food.

At length comes the time for weaning. In a poor country it takes place before the lambs are much more than three months old. In a more plentiful one the lambs may be left until the fourth month is nearly or quite expired. If the pasture is good, and it is intended to sell the lambs in store condition, the weaning may be delayed until six months. Whichever time is selected, it is of essential consequence that the mothers and the lambs should be placed so far apart that they cannot hear the bleatings of each other. The ewes should be somewhat carefully looked after, and if any of them refuse to eat, they should be caught, the state of the udder ascertained, and proper measures adopted.

The lambs should not be put on too stimulating food. The pasture should be fresh and sweet, but not luxuriant. It should be sufficient to maintain and somewhat increase their condition, but not to produce any dangerous determination of blood to any part.

The Diseases of Sheep.—Commencing with the head, a parasite, having the appearance of a bladder filled with pellucid water, attacks the brain. The origin of it is connected with bad management, being scarcely known in upland pastures or in grounds that have been well drained. As the parasite grows, it presses upon the neighbouring substance of the brain, and interferes with the discharge of its functions; the sheep becomes giddy, is frightened at any trifling or imaginary object; he separates himself from his companions; he commences a strange rotatory motion even while he grazes, with the head always turned towards the same side. This is the characteristic symptom, and as soon as it is perceived the animal should be destroyed, for there is no certain cure, and many of the operations that some persons have described are cruel and inefficient.

A somewhat similar disease, but with which the hydatid has nothing to do, is *Hydrocephalus*, or *water in the head*, generally indicated by a little enlargement of the skull; a disinclination to move; a slight staggering in the walk; a stupidity of look, and a rapid loss of condition. This disease seldom admits of cure or palliation. If any amendment can be effected, it will be by the administration of good food, tonic medicine, and gentle aperients.

Another species of pressure on the brain is of too frequent occurrence —*Apoplexy*. A flock of sheep shall be in apparently as good and fine condition as the farmer can desire. They have for a considerable period grazed on the most luxuriant pasture, and are apparently in the highest state of health. By and bye, one or more of them is, without any previously observed change, suddenly taken ill. He staggers, is unconscious, falls and dies, and perhaps within a quarter of an hour from the first attack. With regard to how many over-fattened sheep is this the case? If there is time for resorting to curative means, the jugular vein should be opened, and aperient medicine administered.

Inflammation of the brain is a frequent consequence of over-feeding, It is ushered in by dullness and disinclination to move: but presently the eye brightens, and the animal attacks everything within his reach. If it can be managed, the same treatment must be adopted—bleeding, physic, and low feeding.

Hoove is a distension of the paunch with food, and the extrication of gas from that food. The hollow probang should be introduced into the stomach to draw off this gas. Four to five drachms of hartshorn in half-a-pint of water gives early relief to the animal.

There is however a disease of the liver—*the Rot*—far more frequently occurring in sheep than in cattle, and bearing a peculiar and more destructive character.

In the very earliest stage alone does it admit of cure. The decisive symptom, at that time, is a yellow colour of the eye that surrounds the pupil and the small veins of it, and particularly the corner of the eye, which is filled with a yellow serous fluid, and not with blood. There is no other apparent morbid appearance until it is too late to struggle with the malady; on the contrary, the sheep, although perhaps a little duller than usual, has an evident propensity to fatten. The rot is a disease of the liver—inflammation of that organ; and the vessels of it contain *flukes*. They are taken up in the food; they find their way to the liver as their destined residence, and they create or aggravate the disease by perpetuating a state of irritability and disorganisation. The rot is evidently connected with the state of the pasture. It is confined either to wet seasons or to the feeding on ground that is moist and marshy. In the same farm there are fields on which no sheep can be turned without getting the rot, and there are others that never give the rot. After long continued rains it is almost sure to appear. The disease may be communicated with extraordinary rapidity. A flock of sheep was halted by the side of a pond for the purpose of drinking: the time which they remained there was not more than a quarter of an hour, yet two hundred of them eventually died rotten. The fact is, they then received into their system the germs which ultimately assumed the destructive form of those flukes in the liver which destroyed them. In the treatment of the rot little that is satisfactory can be done. Some sheep have recovered, but the decided majority perish in despite of every effort. The patients however may, as giving them a little chance, be moved to the driest and soundest pastures, and there fed as liberally as possible; but, above all, plenty of salt should be placed within the animals' reach, and given to them in the way of medicine.

In the way of prevention the farmer may do much; he may drain the most suspicious parts of his farm. No money would be more profitably expended than in accomplishing this. Some of the little swampy spots which disgrace the appearance of his farm possibly lie at the root of the evil.

Redwater, or the effusion of a bloody serous fluid in the cavity of the abdomen, is a frequent and very fatal disease among sheep. The cause of it is a sudden change from one pasture to another of almost opposite quality, or the moving of the flock from a dry and warm to a damp and cold situation. It is most destructive to lambs if exposed to a hard frost or suffered to lie on a damp and cold soil. The sheep will separate himself from the rest of the flock; he will evince a great deal of pain by rolling about, and frequently lying down, and immediately getting up again; and, sometimes, he dies in less than twenty-four hours from the first attack. The belly will be found swelled and filled with the red water, or serous fluid tinged with blood, from which the disease derives its name. The treatment should consist of mild aperients, with gentian and ginger, and a liberal allowance of hay and corn.

Diarrhœa is a very prevalent disease among lambs, and especially after a change of diet or of situation. When it is not violent, and does not seem to be attended by colic, a little absorbent and astringent medicine, with a few grains of opium, may be administered. The diarrhœa of sheep may be similarly treated, but when the disease is assuming the character of *dysentery*—when the discharge is more frequent and copious, and mingled which mucus, a larger quantity of this medicine should be given, and some blood abstracted if there is any degree of fever.

The diseases of the *respiratory organs* are often of a serious character. During the greater part of the winter the nostrils will sometimes be filled with mucus, and the sheep is compelled to stop for a moment at every second or third bite, and snort violently, and stand with his muzzle extended and labouring for breath. If his general health does not seem to be affected, this will pass away as the spring approaches. If however any of the flock should now appear to be losing flesh and strength, it is too probable that *consumption* is at hand. The only chance of saving or doing them any good will be to place them in some comfortable pasture, letting them have ample food and salt within their reach.

Lambs, when too early and too much exposed, are subject to diseases of the upper air passages, one attended by a ringing cough, and the other by one of a more wheezing sound. Bleeding will always be necessary for the first, with aperient medicine. A mild purgative will usually suffice for the second, or possibly an ounce or an ounce and a half of common salt may be given dissolved in six ounces of lime-water.

Inflammation of the lungs, recognised by the difficulty of breathing, heaving at the flanks, and distressing cough, is a disease of frequent occurrence in sheep. It speedily runs its course, and the lungs are found to be one disorganised mass. Bleeding and purging are indispensable: but as soon as the violent symptoms seem to remit, tonics must follow.

Garget.—Inflammation of the udder is more frequent in the ewe than in the cow. The udder should be well fomented with warm water, and may then be returned to her lamb.

Diseases of the Feet.—The treatment of *foot-rot* essentially consists in paring away all loose and detached horn. This is the corner-stone of skilful and successful practice. All fungous granulations must either be cut away, or destroyed by the muriate of antimony, and the foot well washed with a solution of chloride of lime. The muriate of antimony must then be lightly applied over the whole of the denuded surface. This must be repeated daily until the whole of the foot is covered with new horn.

The Scab is a very troublesome disease, common in the spring and summer. The sheep is continually scratching himself with his feet, tearing off the wool, and violently rubbing himself against every protruding substance. It is a very infectious disease, for every place against which the sheep can rub himself becomes tainted with the poison. The sheep must be housed and shorn as closely as possible, and then well washed with warm water. An ointment composed of one part of mercurial ointment and seven of lard must then be procured, and such a quantity of it as the diseased parts seem to require rubbed in on every second day. Every place in the field and in the fold against which he can possibly have rubbed himself must be well cleaned and painted before he is permitted to return.

Lice and *Ticks* will be best got rid of by the application of the mercurial ointment just recommended.

The Fly.—Several species of fly frequently deposit their ova on the wool of the sheep. If there are any sore places, they are selected for the habitation of the larvæ. The head, as the most exposed part, is the one oftenest attacked, and the sheep are sadly tormented by the fly and the larvæ. The best preservative or cure is the application of a plaster composed of a pound of pitch and a quarter of an ounce of bees' wax, spread on soft leather or linen. The attack may however be generally prevented by the application of a small quantity of spirit of tar to the head, or any bare or sore part. Two or three applications of this will be sufficient for the whole of the summer, and not a fly will approach a sheep thus guarded.

WOOL AND THE WOOL TRADE. The term *wool* is now applied almost exclusively to the fleece of the sheep. The distinction between wool and hair is more easily understood than described. When the wool brought to bear in the comparison is that of sheep, the distinction is tolerably well marked; but in various other animals it seems often difficult to decide whether hair or wool be the proper appellation for the external covering; and hence perhaps the reason for the appropriation of the term wool principally to the coating of the sheep. Wool compared with hair is generally softer, more flexible, and more disposed to undergo the *felting* process, which imparts to it so much value in manufactures. Many of the wilder animals, such as the beaver, the racoon, the wild cat, and the otter, produce both hair and wool, the hair forming the long and conspicuous outer fibres, and the shorter fibres of wool lying hidden beneath. The goats of certain regions of Asia Minor, Tibet, and South America, yield woolly fibres of great beauty, which not only equal those of the sheep, but greatly surpass them; this wool, however, as we shall see farther on, is too costly to come prominently into competition with that of the sheep.

In a commercial and manufacturing point of view, a notice of wool may consistently be confined to that of the sheep; and for an account of the varieties of sheep, and of the wool they bear, as preliminary to the present article, we refer to the article WOOL, which immediately precedes.

The history of wool in its unmanufactured state, as regards the legislative enactments to which the commodity has been subjected, forms, however, a distinct subject, and is full of instruction in reference to the principles of commercial economy. It enables us to trace the gradual growth of just opinions on such matters, and the many conflicts by which these changes were wrought. Wool, as an article of wealth, has been singularly exposed to these contests; for the agriculturists and manufacturers for ages took different views of what measures in reference to the wool trade were for the national benefit, influenced perhaps by what they deemed their own interests. The reason lies in this circumstance: that whereas the silk and cotton manufacturers work upon materials brought wholly from abroad, the woollen manufacturer employs materials both of home and of foreign produce; and as this applies to foreign as well as to English manufacturers, there have arisen four distinct points upon which the legislature has from time to time had to decide, namely—the free exportation of British wool; the restrictions on such exportation; the free importation of foreign wool; and the restrictions on such importation. The reasons which have led the two great class interests to take opposite sides in the question, and the effects which that opposition has had on the wool trade, will be seen from the following brief details.

In the time of Edward I. a duty was imposed on the exportation of British wool; and great complaints were made on his increasing the duty in 1296 from 20*s.* to 40*s.* per bag. Lynn, Newcastle, Kingston-upon-Hull, Boston, Yarmouth, Ipswich, Southampton, Bristol, and

London were appointed ports from whence wool might be shipped, and at which customs' officers were authorised to receive the dues. When the king had terminated some of the wars in which he had been engaged, he lowered the duty from 40*s.* to half a mark per bag; but the high duty was again imposed at a subsequent period. In 1337 we hear of the first enactment for prohibiting the exportation of British wool, a measure coincident with the attempts of Edward III. to encourage the woollen manufacture in England. Subsequently the same king obtained grants of wool as the means of defraying the expenses of his wars; and the gross absurdity of his former restrictions could not be better shown than by the fact, that while he ostensibly prohibited the export of British wool, he sent his own quota for sale abroad, as he could there obtain a higher price for it than at home. Throughout the remainder of his reign Edward had frequent contests with the Commons and the merchants respecting his grants of wool, the duty payable on wool sold, and the prohibition to exportation; the contests being not between agriculturists and manufacturers, but between the king on one side and all his subjects on the other. By a statute of 27 Edw. III., the towns of Newcastle, York, Bristol, Lincoln, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, Caermarthen, Dublin, Waterford, Cork, and Drogheda were appointed *staples* for wool; that is, places where alone wool could be sold. Mayors of the staple were appointed to seal every sack of wool sold; a customs' duty of half a mark per sack was charged to denizens, and of 10*s.* a sack to aliens; and the power of exporting was limited to merchant strangers, or to Hanse town merchants.

During the reigns of Richard II. and Henry IV. there were repeated grants or subsidies of wool to the king, petitions from towns concerning the places for the staple, alterations in the customs' duty, and licences granted to particular parties in respect of exportation. The same, indeed, may be said respecting the next two reigns; but by the time of Henry VI. the merchants of the staple appear to have acquired a kind of monopoly, which was often made a subject of complaint. Edward IV. enacted that no alien should export wool, and that denizens should export it only to Calais; and in the next three reigns the policy pursued, however mistaken, seems to have arisen rather from a hope of encouraging woollen manufactures in England than to fill the coffers of the king. In the reign of Edward VI., the landowners of England, finding the sale of wool profitable, began to inclose common lands as sheep pasturages with so much eagerness as to cause great complaints to be made; and this may perhaps be taken as the commencement of a new order of proceedings, so far as the cultivators took up a position really or apparently opposed to the interests of the people. It was not, however, till the time of Charles I. that the absolute prohibition of exportation was determined on seriously; and this seems to have been, in the first case, not so much a measure demanded by the manufacturers, as a source of revenue to the king by granting licences to favoured persons. After the Restoration, in 1660, however, the prohibition became distinctly enacted.

From 1660 to 1825, the export of wool was strictly prohibited. The consequences of this prohibition soon showed themselves. The wool-growers, shut out from a foreign market, suffered from diminution of price; all kinds of extravagant expedients were resorted to, to increase the consumption of wool; a system of wool-running, or smuggling, became very prevalent; and many pamphlets appeared from parties taking opposite sides of the question at issue. The agriculturists, thus restricted in respect to wool, insisted on the prohibition of the import of Irish cattle, as one means of maintaining their rents; this disturbed the course of trade between England and Ireland; and the attempts made, at the instigation of the woollen manufacturers, to compel the use of woollen goods, excited the hostility of the silk and linen trades; and thus the whole commercial system became disarranged. Numerous pamphlets were published in the last century, of the following general tenor: from English wool-growers, to show that Irish wool ought not to be imported into England; from English manufacturers, to show that Irish wool ought not to be sent to foreign countries; from Irish graziers, to show that both of these restrictions were unjust; and from foreigners, to show that the non-exportation of British wool led to retaliative measures on their part. The agricultural and manufacturing classes felt that they were by legislative measures thrown into antagonism; and there arose from time to time complaints on both sides. A slight sketch of what occurred in 1781 will convey a correct idea of the usual state of party feeling concerning the wool trade, for a period long subsequent, as well as long previous, to that date. The price of wool being low, meetings were held in Lincolnshire and elsewhere, under the auspices of the great landowners; at which petitions to parliament were agreed to, praying that British wool might be exported, and that Irish wool might be excluded from England. Thereupon the Yorkshire manufacturers met, and came to resolutions that the exportation of wool would be ruinous to the trade and manufacturers of England; that the manufacturers would be obliged to leave the kingdom for want of employment; and that the importation of Irish woollen yarn ought to be interdicted. The worsted manufacturers were particularly vehement, for they had a notion, whether correct or not, that no other country produced long combing or worsted wools equal to that of Lincolnshire; and that if they could keep the whole of this wool in England, they might perhaps retain a monopoly of the worsted trade.

The union with Ireland, in 1800, was another cause of disagreement in the wool trade. By one of the resolutions of parliament preparatory to that measure, it was determined that the two countries should be placed on an equality as regards bounties, prohibitions, &c., on the natural produce of each. One effect of this would be to legalise the transit of wool from England to Ireland; and the manufacturers in a body opposed it, but without success. Thus was effected one step in the attainment of increased power on the part of the English wool-growers; and another step was made in 1802, by the imposition of a duty of 5*s.* 3*d.* per cwt. on the importation of all foreign wool. This latter measure of course enhanced the comparative price of English wool. It had long been urged that foreign wool was indispensably necessary to the manufacture of some kinds of goods, and towards the end of the last century the imports became considerable. Year after year the quantity increased, and by 1800 it reached 4,000,000 lbs. in the year, being about $\frac{1}{23}$th part of the quantity required in the manufacture. This alarmed the landowners, who thereupon procured the imposition of a duty of 5*s.* 3*d.* At various times the leading agriculturists made laudable attempts to improve the quality of English wool, by introducing the Spanish merino sheep; but they still found that when their wools came into the market with those from Spain and Saxony, the latter, notwithstanding the import duty, commanded a more ready sale for the manufacture of the finer cloths. Hence an increase of the import duty was constantly urged upon the government, and such an increase was made to a small extent in 1813, by fixing the duty at 6*s.* 8*d.* instead of 5*s.* 3*d.* per cwt. But this not satisfying the landowners, renewed demands were made; and by the year 1816 parties were placed in a curious antagonism, which may be thus represented:—

Landowners' Claims.	Manufacturers' Claims.
Restricted imports of wool.	Unrestricted imports of wool.
Unrestricted exports "	Restricted exports "

The landowners wished to keep out foreign wool, that their own might command a higher price; and at the same time wished for an unrestricted foreign market for their own wool. The manufacturers, on the other hand, wished for a free import of foreign wool, because it was best adapted for their work; and at the same time wished to prevent the export of British wool, as a means of monopolising woollen manufactures. Each party argued consistently with liberal policy in one instance, but displayed the narrow spirit of monopoly in the other: there was a right and a wrong on each side—a liberal and an illiberal; and the two parties were so far pretty equally matched. In most of the subsequent measures taken by the two parties in reference to the wool trade, the peers and commoners belonging to Yorkshire generally took the manufacturers' view of the question; while those in the sheep-rearing counties took the opposite view; and petitions and resolutions were poured forth in abundance by both parties. In 1818 the matter was brought on in parliament by the agriculturists, and lost by only a very small majority; but in the following year the country was taken by surprise by a government proposition, which was carried by a large majority, to increase the import duty on foreign wool from 6*s.* 8*d.* to 56*s.* per cwt.

The depressed state of the woollen trade, partly consequent on this impolitic tax, was one of the moving causes to the disturbances in the north between 1819 and 1821; and the attention of the government was repeatedly directed to this matter by the opposite statements of different parties. In 1824, Mr. Robinson, after alluding to the peculiar tinge of monopoly shown in the arguments of both parties, proposed to admit the export of British wool at a duty of one penny per pound, and the import of foreign wool at an equal duty—thus showing to both parties the same meed of fairness. Neither party seemed very well pleased with the proposal; but ministers brought it before parliament, and carried it into a law. In the following year (1825), Mr. Huskisson carried some of his measures, which still further opened the woollen trade.

In 1828 the wool-growers induced the House of Lords to appoint a Committee of Inquiry; but the evidence taken before it appears to have convinced the government that it would be wrong policy to re-impose the import duty as a protective measure; and there has not since then been any renewal of the obnoxious duties.

Many of the legislative enactments here alluded to depend evidently on some peculiarity in foreign wool which fits it for manufacture; and this was strikingly illustrated in the evidence before the Lords' Committee, in 1828, where several eminent manufacturers stated that they could scarcely find a sale for any woollen cloths if made wholly of English wool. This led to many laudable efforts to improve the character of both our long and short-woolled sheep.

We will now briefly trace the progress of the wool-trade, in relation to the produce of English fleeces, and the importation of others from abroad.

In the year 1800 Mr. Luccock estimated the quantity of wool produced in England and Wales thus:—

Short wool	202,737	packs.
Long wool	131,794	"
Skin wool	58,705	"
	393,236	"

Mr. Hubbard's estimate for 1828 was—

Short wool	129,917 packs.
Long wool	263,847 ,,
Skin wool	69,405 ,,
	463,169 ,,

a pack being equal to 240 lbs. It has often been asserted that the attempts to improve the quality of English mutton has deteriorated the *quality* of the fine wool, but increased the *quantity* of the long wool; and this seems to be borne out by the numbers here given. Mr. Bischoff gives a table to show the quantity of foreign wool imported every year from 1741 to 1841. We will give a few of the years.

	lbs.		lbs.
1771	1,829,772	1811	4,739,972
1781	2,478,332	1821	9,770,103
1791	3,014,511	1831	31,652,029
1801	7,371,774	1841	49,710,396

These numbers sufficiently show how prone English woollen manufacture is, when left to itself, to derive aid from the use of foreign wool. All the finer wools used to be brought from Spain; but in 1765 the elector of Saxony imported into his dominions a few Merino sheep, which have had a most surprising influence on the trade in wool. The Saxony Merinos, instead of degenerating, improved upon their Spanish progenitors, and the wool afforded by them has almost driven the Spanish wool out of the English market. In 1800 the imports of wool from Spain were fourteen times as large as from Germany; whereas in 1840 those from Germany were seventeen times as large as those from Spain.

The inquiries made within the last twenty years, into the history of the wool-trade, present many points of interest. How many sheep there are grazing in the United Kingdom at one time, and how much wool is obtained from them, are matters on which no trustworthy figures have been given. All is guess-work. In 1860 Mr. P. L. Simmonds gave a curious comparison of estimates made at different times during the present century, relating, in most instances, to the number of sheep supposed to be living at one time, but more especially to the supposed weight of wool annually obtained from them. These estimates are eleven in number. The quantities, or round numbers, are as follows:—

Year.	Computer.	Sheep.	Wool.
1801	Luccock	26,000,000	94,000,000 lbs.
1828	Hubbard	?	111,000,000 ,,
1834	M'Culloch	32,000,000	? ,,
1835	M'Queen	48,000,000	247,000,000 ,,
1845	Low	35,000,000	157,000,000 ,,
1851	Southey	55,000,000	275,000,000 ,,
1852	Poole	32,000,000	128,000,000 ,,
1857	Ashworth	?	148,000,000 ,,
1858	Baines	?	200,000,000 ,,
1860	Wray	55,000,000	275,000,000 ,,
1860	Simmonds	50,000,000	250,000,000 ,,

Mr. Leonard Wray, in 1860, made an earnest attempt to arrive at the truth; the opinions expressed to him by wool-growers and wool-staplers were most discordant; but he arrived at a hypothetical result very similar to one which Mr. Southey had put forth in 1851. Mr. Simmonds has given a curious comparison of the wool-producing powers of various kinds of sheeps' food, only possible since the wide development of the study of agricultural chemistry. According to this comparison, equal weights of the following kinds of food will lead to the production of the following weights of wool:—

Potatoes, raw, with salt	6¼ of wool.
Mangel-wurzel, raw	5¼ ,,
Wheat	14 ,,
Oats	10 ,,
Rye, with salt	14 ,,
Rye, without salt	12½ ,,
Barley	12½ ,,
Peas	16½ ,,
Buckwheat	10 ,,

Peas, wheat, and rye with salt, thus appear to be the best. What is the best *mutton*-producing food for sheep, as contrasted with *wool*-producing, we have no concern with here. There are six different qualities which manufacturers look for in wool—*fineness*, or equable thinness of fibre; *fullness*, or closeness in the growing of the locks on the sheep; *freeness*, or absence of entanglement in the fibres; *soundness*, or strength of fibre when pulled in combing; *length*, or a fitness in the length of fibre for each particular kind of manufacture; and *softness*, or a certain degree of silkiness to the touch. According to the degree in which wool possesses any or all of these qualities, so is the price which it will command in the market. During the latter half of the last century, English wool commanded from 6*d.* to 1*s.* 1*d.* per pound. During the first quarter of the present century, the price varied between the wide limits of 7*d.* and 3*s.* Since the freedom of import and export, the price has depended more consistently on the actual quality. While English wool, very little applicable to the manufacture of fine cloth, sells at 10*d.* or 1*s.* per pound, Saxony or Merino wool will often command 2*s.* to 4*s.* The good Saxony fleeces are always smaller in weight than the coarser English; the former varying from 2 lb. to 3 lb., the latter from 4 lb. to 5 lb. About half the home supply is used for worsted goods, and half for cheap woollens; the best woollens now depend wholly on the use of foreign wool.

One of the most notable present features in the wool trade is the competition of Australia. We have said that Germany nearly drove Spain out of the market; and now Australia is eclipsing Germany. It is found that the climate and soil of Australia, and the kind of labour obtainable, are favourable to the growth of wool. This has been done with very little encouragement from external sources.

Wool is largely imported from the British possessions in South Africa. India, it is believed, could easily supply us with 200,000,000 lbs. of wool annually, by the display of a little energy. Chinese sheep, brought to England and America, have proved very profitable, producing large fleeces of wool suitable for cheap goods. Australia could greatly increase her present supply, did not gold-digging frequently disturb the course of pastoral industry. The United States do not produce enough wool for their own manufactures; they import good wool from Europe, and cheap wool from South America. It affords a curious instance of the tendencies of trade when unshackled, that the United States' mills work up Australian wool which has come to them *viâ* England—a distance altogether equal to two-thirds of the circuit of the globe.

The total quantities of wool—whether sheeps', lambs', or Alpaca, imported in recent years, will conveniently be shown by taking certain dates, three years apart:—

	lbs.		lbs.
1843	49,243,093	1852	93,761,458
1846	65,255,462	1855	99,300,446
1849	76,768,647	1858	126,738,723

It will suffice to take one year, 1860, to show the trade a little more in detail:—

	lbs.
Wool from Australia	59,165,939
,, Northern Europe	38,840,961
,, East Indies	20,214,173
,, South Africa	16,574,345
,, Other countries	10,705,233
	145,500,651

Of this quantity, however, rather more then 30,000,000 lbs. were exported, leaving about 115,000,000 lbs. of foreign and colonial wool to be used up by our woollen and worsted manufacturers.

It will be desirable here to say a few words concerning the prospective supply of that peculiar kind of wool called *alpaca*. Under ALPACA WOOL it was stated that Australian sheep farmers were beginning to attend to this subject. We will here briefly notice what has been done since that article was written. It is to Mr. Charles Ledger that we owe most of what is known concerning the wool of the *alpaca*, *llama*, *vicuña*, and *guanaco*, animals which pasture on the high table-lands among the Andes. Those four kinds have slight differences; and by cross breeds between the animals it is believed that wool will be obtained of finer quality than any yet known. The Peruvians use llama wool for sacking, cordage, carpets, bed coverlets, &c., and alpaca wool for various textile fabrics. Mr. Outram, of Halifax, first overcame, in 1835, the difficulty of spinning alpaca wool by machinery; and Mr. Titus Salt, of Saltaire, made those further improvements which established alpaca among the staple manufactures of Yorkshire—especially when combined with cotton warp for strong but cheap goods, and with silk for waistcoatings and ladies' dresses. A demand having been thus created, the supply has gradually increased. Alpaca comes to England in small bales, from 60 lbs. to 150 lbs. each. 1835 was the first year of considerable import; it amounted to about 100,000 lbs.; this increased to 1,200,000 lbs. by 1845; and from 1851 to 1860 the imports averaged about 2,500,000 lbs. yearly. The price has fluctuated considerably, from 8*d.* to 3*s.* 9*d.* per lb.

Mr. Ledger, for many years a resident in Peru, conceived the idea of transferring alpacas to Australia, as a commercial speculation. In 1853 he went to Melbourne and Sydney, to ascertain whether the climate and soil of Australia were suitable for his purpose; and he found spots which possessed in an admirable degree all the requisite qualities. He returned to Peru and made arrangements for gradually buying and rearing a large stock of alpacas: undergoing great hardships while travelling repeatedly over the Andes. It was not until 1858 that he could get his flock into the Argentine States; for the government of Peru placed all kinds of obstacles in the way of their exportation. At length, in November 1858, a flock of 276 alpacas, llamas, and vicuñas arrived safely at Sidney. In May, 1859, he began a tour of inspection, at the instance of the New South Wales government, to select the best place for a breeding and pasture ground. He fixed on the Maneroo district, about 260 miles from Sidney. The first shearing, in November of that year, was too early, and the wool was pronounced in Yorkshire to be too short-stapled for the best goods. The flock was transferred to Maneroo; and the numbers are gradually increasing. Mr. Ledger has made a calculation that, allowing for accidents, deaths, bad years, &c., he very earnestly looks forward to

3000 alpacas by 1870; and if this estimate be borne out, the increase after that would be very rapid. The New South Wales government, regarding the subject as one of great colonial importance, have made liberal arrangements with Mr. Ledger; for Yorkshire will eagerly buy all the alpaca that Australia can produce; and especially will this be the case if the quality can be maintained at a high standard.

WOOLLEN AND WORSTED MANUFACTURES. The manufactures in wool and in worsted are so closely connected, in reference both to their past history and to the industrial arrangements involved in them, that it will be convenient to treat of them under one heading. Wools are divided into two great classes—*clothing-wools* and *combing-wools*, or *short-wools* and *long-wools;* and the fabrics woven from them are termed *woollens* or *worsteds*, according as the one or the other is employed. Clothing-wools possess in high perfection that peculiar property which enables the fibres to felt or interlace one among another, and to form thereby the dense compact material of which men's garments are so largely made in this country, as well as the still thicker felt for hats [HAT MANUFACTURE]; whereas combing-wools, though long in fibre, are deficient in the felting property, and are therefore employed for stuffs, merinos, hosiery, and a large number of fabrics which do not undergo the felting or fulling process.

History.—It is probable that no other of the textile manufactures is so ancient as that of wool. Sheep were reared from the earliest times, and there can be little doubt that the use of the wool for clothing was soon adopted. If a mass of woollen fibres be pressed firmly together in a flat layer, the fibres, by virtue of their felting property, will cohere into a continuous sheet even without the process of weaving; and this property could not fail to attract notice. The passages in the Bible which seem to allude to the use of woollen garments are well known; and we have indirect evidence from various quarters to show the prevalence of a similar custom in the East generally, in early times. The spinning of the fibres was most probably effected by the fingers; while the thistle or teasle, as at present, was used to comb out the fibres; the dyeing of the threads, too, it is quite evident, was well understood by the ancients. Among the Greeks and Romans the woollen manufacture was of a domestic character; but yet it would seem that the clothing of large armies must have required arrangements of a more extensive kind. The natives of India, after the epoch of Macedonian conquests in that country, made shawl-cloths of exquisite beauty, consisting, as is supposed, of short wool woven without felting: and the Greeks and Romans may have derived some of their modes of proceeding from such a quarter. But however this may be, the Romans of both sexes wore woollen garments very generally.

The decay of the arts consequent on the irruption of the barbarians into Rome did not appear to have extended to this manufacture. Woollen clothing was still made in most of the countries where the Romans had established colonies; and there are indications that in the 10th century the manufacture became the occupation of a particular fraternity in the Low Countries. The wool employed was at first the produce of their own country; but they afterwards imported wool from other countries, and carried on the manufacture to such an extent that the Low Countries became in a great measure the clothing district for Europe. Spain produced cloth for herself, and acquired, about the 13th century, considerable reputation for the beauty of the fabrics produced, consequent, we may suppose, on the fine wool which the Spanish sheep have for centuries produced. The Italians and French entered upon this manufacture at a later period.

In the time of William the Conqueror, an inundation which occurred in the Netherlands drove many of the clothiers into other countries, and some of them came to England. William of Malmesbury says that the king, glad of such an accession, placed these Flemish clothiers first in Carlisle and then in the western counties. From that time the mention of clothiers is frequent in the old chronicles; London, Oxford, Lincoln, Huntingdon, York, Nottingham, and Winchester, being enumerated as towns wherein the manufacture was carried on; while at other towns there were cloth-dealers who paid a licence-duty to the king for the privilege of buying and selling dyed cloths. It has been stated [WOOL AND THE WOOL TRADE] that the king frequently derived considerable revenues from English wool; and this circumstance led to the enactment of many laws, tending to the exclusion of foreign wool and the use of English wool only in our manufactures. The exclusion of Spanish wool from English broad-cloth; the limitation of the width of broad-cloth to two yards; the determination of the width of striped cloth made at Bristol; the appointment of towns where alone cloth could be bought and sold; the appointment of the office of king's *Aulnager*, whose duty it was to attend the cloth-markets, and measure all the cloth sold, to see that there was no deficiency of length, and who received a fee for every piece of cloth to which he attached his seal; the prohibition to export woollen cloths until they had been fulled; the granting of permission to make certain coarse kinds of cloth three-quarters of a yard in width; the fixing of a leaden seal to pieces of cloth wrought in London and the suburbs—these are some of the laws by which the government tried or hoped to regulate the manufacture; and they will serve to convey an idea of the general character of others.

Edward III. brought about a great extension of the manufacture by inviting over some skilful weavers from the Netherlands. English wool was said to be worked up more successfully in the Netherlands than in England; and Edward thought that by getting over some of the Flemings to this country, he could improve the native manufacture. This seems to have been done; and the following distribution of the manufacture, consequent on this immigration, shows how widely this branch of industry became spread—Norfolk, fustians; Suffolk, baize; Essex, says and serges; Kent, broad-cloth; Devon, kerseys; Gloucestershire, cloth; Worcestershire, cloth; Wales, friezes; Westmoreland, cloth; Yorkshire, cloth; Somersetshire, serges; Hampshire, Berkshire, and Sussex, cloth.

For several reigns subsequent to that of Edward III., the woollen cloths made in England appear to have been chiefly of a coarse quality; the majority of the manufacturers directing their attention chiefly to worsted fabrics; while the finer broad-cloths were imported from Brabant, a proof that the exertions of Edward, though successful as regards the extent of the manufacture, were not so in respect of quality. By the reign of Henry VIII. the exports of English cloths became very large, insomuch that when, through foreign wars, the markets of Spain and the Netherlands were closed to the English, great complaints arose among the manufacturers, who could not sell the cloth which they sent to Blackwell Hall, a kind of Cloth Hall whence London dealers and merchants were supplied. About this time the manufacture in the counties of Somerset, Gloucester, Wilts, and Worcester was limited to corporate towns; and the most absurd laws were passed to confine it to those favoured spots. During the reign of Elizabeth, owing partly to many of these restrictions being removed, and partly to the immigration into England of many weavers driven from the Netherlands by the persecutions of the duke of Alva, a considerable advance was made in the English manufacture. In the following reign the English dyers succeeded in obtaining a law prohibiting the export of cloth in the white or undyed state, under the expectation that they would be gainers thereby; but, like many other monopolies, it defeated its own aim; the Dutch and Germans refused to buy English cloth in the dyed state, and thus the exports fell so enormously that dyers as well as manufacturers lost by the impolitic prohibition.

During the time of the Stuarts a narrow policy almost ruined the manufacture. At one time there was an attempt to get all Spanish wool brought to this country, and to no other countries; at another time the exportation of English wool, of fuller's earth, and other materials of manufacture, was prohibited; English clothiers refused to receive Flemings among them, from a feeling of jealousy; the London merchants procured an act prohibiting all foreigners from buying and selling; and many other measures were passed, either by parliament or by corporations, tending to cripple the free spread of the trade and manufacture. Ireland suffered severely by this mischievous system; for after being compelled to give up the exportation of cattle to England, on account of the complaints of the graziers, she turned attention to the growth of wool; but this offended the English wool-growers; and if Irish cloths were sent to England, this roused the opposition of the English clothiers; so that from about 1640 to the end of the century there was one continuous struggle in Ireland to bear up against the selfish policy of England in respect to wool and its manufactures.

Throughout the greater part of the 18th century the manufacture steadily increased in England, especially in those fabrics made of long or combing wool. When the inventions in spinning-machinery gave an extraordinary impetus to the cotton-manufacture, that of woollen became thrown comparatively into the shade; but the application of improved machinery has since increased the power of the manufacturers; while the great improvements in the quality of German and Australian wools, combined with the maintenance of a liberal policy in commerce and interchange, have given to the woollen and worsted manufactures in England a more healthy tone.

Woollen Manufacture.—It has been before explained that the woollen manufacture relates to such fabrics as require the use of short or felting wool. This wool undergoes a very large number of processes in the course of the manufacture. If we take a piece of superfine broad-cloth as a representative of this manufacture generally, the following are the successive processes by which it is produced:—

1. Sorting the wool.	12. Carding.	23. Burling.
2. Scouring.	13. Slubbing.	24. Fulling.
3. Washing.	14. Spinning.	25. Scouring.
4. Drying.	15. Reeling.	26. Tentering.
5. Dyeing (when dyed in the wool).	16. Warping.	27. Teazling.
	17. Beaming.	28. Shearing.
6. Willying.	18. Singeing.	29. Boiling.
7. Picking.	19. Sizing.	30. Brushing.
8. Oiling.	20. Weaving.	31. Picking.
9. Moating.	21. Scouring.	32. Pressing.
10. Scribbling.	22. Dyeing (when dyed in the cloth).	33. Steaming.
11. Plucking.		34. Packing.

More than one-half of these, in the most improved forms of proceeding, are effected by machinery.

The sorting of the wool is the first operation, and is one of much importance, since the quality of the cloth depends greatly on a due admixture of different kinds of wool. Each pack of wool contains many different qualities, according to the part of the fleece whence it was taken, and other circumstances; and much tact and discrimination are called for in the separation. The sorter has to make his selection in relation to the *fineness*, the *softness*, the *strength*, the *colour*, the *cleanness*, and the *weight* of the wool; and in reference to these qualities he separates the wool into many parcels, which receive the names of *prime*, *choice*, *super*, *head*, *downrights*, *seconds*, *fine abb*, *coarse abb*, *livery*, &c. The finest fibre is that of Spanish ewe, the mean diameter of which is $\frac{1}{1370}$ of an inch; while the coarsest is that of Wilts ewe, measuring $\frac{1}{500}$ of an inch. All woolly fibres are thicker at one end than the other; but the less the difference in that respect, the more valuable is the wool; and this is one of the favourable points in Merino wool.

When the proper kinds are selected, they are next *scoured* and *washed*, to free them from the grease which invariably attaches to them. The wool is soaked in an alkaline ley at a temperature of about 120°, rinsed with cold water, and passed between the rollers of a powerful press to free it from nearly all moisture.

If the cloth is dyed in the wool, that operation succeeds the scouring; but if dyed in the piece, many other processes intervene; and it depends a good deal on the kind of colour as to which plan is followed. Supposing the dyeing to be completed, however, the wool undergoes the process of *willying* or *willowing*, which is somewhat analogous to the *batting* or *scutching* in the cotton-manufacture; the object being to open and disentangle the locks of wool, and cleanse them from sandy and other loose impurities. One among many forms of willy is a kind of hollow truncated cone, having an axis running through its centre; on this axis are fixed three wheels of different diameters, bearing on their circumference four longitudinal bars studded with sharp spikes. The cone revolves with a rapidity of three or four hundred revolutions per minute, within an outer cylindrical casing, whose inner surface is armed with similar spikes. The machine is fed, by means of an endless apron, with wool, which enters at the small end of the cone, and travels to the larger end by virtue of the centrifugal force produced by the rotation. As it passes onwards between and among the spikes, it becomes opened and disentangled, the fibres of each lock separated, and the impurities detached. When the wool has reached the lower end of the cone, it passes into a receptacle where a fan is revolving with great rapidity, by which a current of air is generated sufficient to blow away all the dust mixed with the wool; while at the same time a kind of revolving cage distributes the wool in a flat equable layer or stratum. Thus the same machine disentangles the fibres, separates the impurities, blows away the dust, and lays the wool in a smooth sheet.

Some kinds of wool require willying more than once; but this is not the case with the finer qualities. There are however frequently some impurities which cannot be removed by the willy; and such are afterwards picked out by boys or women, called wool-moaters, or wool-pickers. A further opening of fibres results from the process of *scribbling*; but before this is effected, the wool undergoes that of *oiling*; it being spread out on a floor, sprinkled with olive-oil, and well beaten with staves. The *scribbling-machine* consists of several cylinders, on whose external surfaces are rows of teeth or wires. These are combined in a strong frame, and so fitted as just to touch and work against each other; the wires on one cylinder are bent in a direction contrary to those in the adjoining one; so that when all the cylinders are revolving, and wool is applied to the first one of the series by an endless apron, it is caught from tooth to tooth, carried rapidly from cylinder to cylinder, separated completely from all entanglement, and finally given forth in the shape of a delicate fleece or sheet. It becomes wound on a revolving roller, after having passed through the scribbling-machine; but when it leaves the carding-machine it presents the appearance of slender rods, cylinders, or pipes, which are called *cardings*.

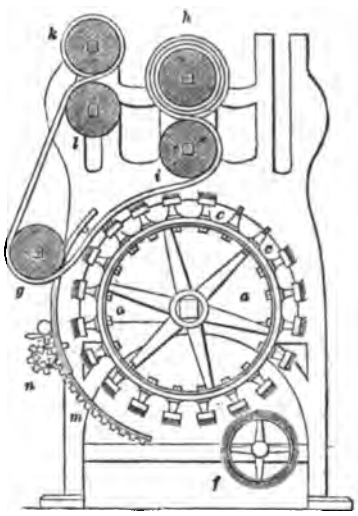
These cardings are then spun into yarn for the use of the woollen-weaver; the process of spinning being generally effected by means of the *slubbing-billy* or *slubbing-machine*, and afterwards by the common *jenny* or *mule-spinning* machine; the slubbing-billy bringing the wool to the state of a soft weak thread, and the spinning-machine giving it the proper firmness and hardness for yarn. The *slubbing-billy* has a wooden frame, within which is a moveable carriage, running on lower side-rails on friction-wheels. The carriage contains a number of steel spindles, which receive a rapid motion from a long cylinder, by means of separate cords passing round the pulleys of the respective spindles; this cylinder is a long drum of tin plate, six inches in diameter, covered with paper, and extends across the whole breadth of the carriage. The spindles are placed in a frame so as to stand nearly upright at about four inches apart; their lower ends being so formed as to act as pivots. The drum lies horizontally before the spindles, with its centre a little lower than the line of the spindle-pulleys. The drum receives motion by a pulley at one end with an endless band from a wheel placed on the outside of the main frame, turned by the spinner with his right hand applied to a winch; and by this movement the spindles are made to revolve rapidly. Each spindle receives a soft card or slubbing, which comes through beneath a wooden roller at one end of the frame. A child is employed here, who brings the cardings from the card-engine, and places them upon an inclined cloth. These cardings, being drawn beneath the roller, are then caught between two rails. The movement then is very similar to that in Hargreave's spinning-jenny; a small portion of each carding is allowed to pass between the rails or clasp; and this portion is then drawn out or elongated to the state of a thread by the recession of the carriage towards the other end of the frame. Meanwhile the spindles have been kept in motion, by which a slight twist is imparted to the thread or slubbing. A faller-wire and a rail assist in regulating the winding of the thread uniformly on the spindles. The process then is thus conducted. A child, called a *piecener*, takes the cardings from the carding-machine, and lays them on the inclined apron; they are thence carried up beneath the roller and between the clasp, and the workman or *slubber*, by managing his moveable carriage with one hand, and the wheel which turns the spindles with the other, elongates the *carding* into *slubbing*, and winds it on the spindles. The pieceners are employed and paid by the slubber; and some years ago great cruelty was said to be inflicted on the children by the workmen for any neglect of their duty; but the inspectorship of factories has removed such sources of discredit to the factory system.

In the *spinning* of the wool, which follows the slubbing, the kind of machines employed and the general character of the processes are so similar to those exhibited in the cotton manufacture, that it will suffice to refer to COTTON MANUFACTURE and SPINNING for details, with the following few additional remarks. The soft cord or sliver is caused to pass between two pairs of rollers; the space between the two pairs being rather more than equal to the length of the fibres. The two pairs of rollers between which the sliver is compressed do not separate farther from each other in order to stretch it, but that effect is produced by making the second pair of rollers revolve faster than the first. It is necessary to arrange the distance between the two pairs of rollers with reference to the average length of the filaments of which the sliver is composed; because if the two pairs of rollers were too far apart, the soft cord would be liable to separate between them, and if they were too near, so that the opposite ends of a filament should be compressed between them at the same time, the sliver could not extend or lengthen by the sliding of the filaments, but the filaments themselves must break with the strain. Hence, in machinery for spinning wool, on account of the variable length of the filaments, the drawing-rollers are so mounted that they may be readily adjusted to different distances. In consequence of the greater elasticity of wool, the relative velocities of the two pairs of rollers are so arranged as to produce a greater degree of stretching or extension than is usual with cotton.

The process next following that of spinning is *weaving*, by which the yarn is worked up into a textile fabric. If it be a plain cloth, the loom employed is very simple in its arrangements; if it be a twill or an ornamental fabric, the loom is somewhat more complex; but the general arrangements will be sufficiently understood by a reference to WEAVING. Hitherto woollen cloths have been principally woven by hand-weavers; but the power-loom is every year becoming more and more applied to this purpose. Some of the cloths are woven as broad as twelve-quarters, to allow not only for the shrinkage occasioned in the subsequent process of fulling, but for an edging or list, made either of goats' hair or of coarse yarn, into which the tenter-hooks are thrust in the process of *tentering*.

As the wool has been dressed with oil before spinning, and with size before weaving, it becomes necessary to cleanse it from these impurities immediately after the weaving. This is the object of a second *scouring* process, in which the cloth is beaten with wooden mallets in a kind of trough or mill; soap and water being let in upon it first, and then clear water. Being then carried to the drying-room, or the tenter-ground, it is stretched out by means of hooks on rails, and allowed to dry in a smooth and extended state. It is then taken into a room and examined by *burlers*, who pick out all irregular threads, hairs, or dirt. After this it is ready for the important process of *fulling*, or *felting*, which imparts to woollen goods that peculiarity of surface whereby they are distinguished from all others. A large mass of cloth folded into many plies is put into the *fulling-mill*, where it is exposed to the long-continued action of two heavy wooden mallets or stocks. Superfine cloth receives four fullings of three hours each, a thick solution of soap being spread between each layer of cloth every time. During the violent percussions which the cloth thus receives for twelve hours, the fibres, being at every stroke strongly impelled together, and driven into the closest possible contact, at length hook into each other by means of the little serrations on their surfaces, until they become firmly and inextricably united; each thread, both of the warp and weft, being so compacted with those that are contiguous to it, that the whole seems formed into one substance, not liable, like other woven goods, to unravel when cut with the scissors. This compacting process in the cloth manufacture is effected by beating, and is called *fulling*; in the hat-manufacture it is effected by pressure and rolling, and is called *felting*; but the two are clearly analogous in principle. This process thickens the cloth remarkably, but diminishes it both in length and breadth nearly one half.

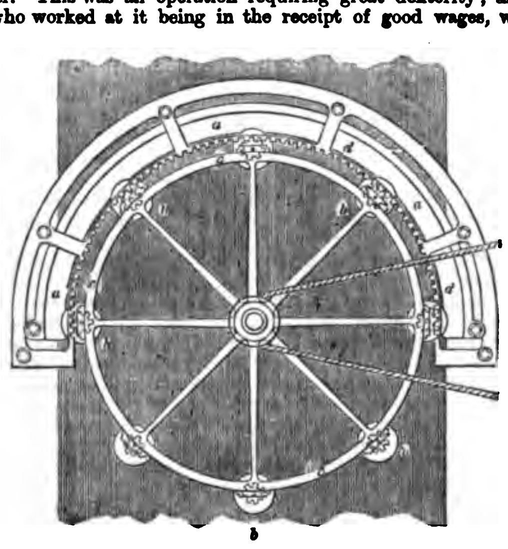
In the fulled state the cloth presents a woolly and rough appearance, to improve which it goes through the processes of *teasling* or *raising*, and *shearing* or *cutting*. The object of the first is to raise the ends of the fibres above the surface, and of the second to cut them off to a uniform level. The raising of the fibres is effected by thistle-heads, teazling-cards, or wire brushes. Teazles are the seed-pods of the *dipsacus follonum*, having small hooked points on their surfaces. They were formerly used in the cloth manufacture thus: a number of them were put into a small frame with handles, so as to form a kind of curry-comb; and this was worked by two men over the surface of the cloth, which was suspended horizontally, the direction of working being first parallel with the warp, and then parallel with the weft. From the trouble required to clean the barbs of the teazles when filled with woollen fibres, from the weakening of their points by the water with which the cloth was saturated, and from the high price which the large demand enabled them to command in the market, numerous attempts were made from time to time to substitute metallic points; but from various causes the teazles are still preferred, and are now used in a more efficacious way than formerly. The teazles are arranged on a cylinder in a machine called a *gig-mill;* the cloth is stretched on



Gig-Mill.

two cloth-beams; the cylinder moves in one direction and the cloth in another, and the fibres become thereby worked or combed up. The annexed cut shows the section of such a machine; where the cloth, passing from a roller *h*, round the roller *i*, comes in contact with the brushes *c* on the wheel *a*, and afterwards passes round *g* and *l* to the roller *k*; the roller *g* being so regulated by the pinion *n* and the rack *m* as to keep the cloth thoroughly stretched; and the revolving brush *f* being so adjusted as to clean the teazling-cards *c*. In some machines the teazling-points are made of wire, to obviate the waste of 3000 natural teazles, which takes place in the dressing of one piece of cloth.

When the ends of the fibres have been thus raised to the surface, they are next *sheared* or *cropped*, a process of great beauty and singularity. Originally this process was performed by means of large hand-shears, the cloth being stretched over a stuffed table, and the workman proceeding to clip the ends of the fibres in a regular and equable manner. This was an operation requiring great dexterity; and the men who worked at it being in the receipt of good wages, were so



Cloth-shearing Machine.

alarmed at the introduction of shearing-machines, in the early part of the present century, that serious riots occurred in the west of England. But the machines became by degrees extensively employed. They consisted each of a pair of shears, as in the hand-method; but all the movements were effected by machinery. More recently a machine has been introduced, the action of which is regulated on a different principle, as will be seen from the annexed cut: *b b b* are disk-formed cutters, working against a thin bar of steel, *a a a*, of a semicircular form; which cutters in their revolution travel round against the edge of the bar or blade in such a way as to shave off the filaments standing up on the surface of the cloth beneath. The cloth is represented by the shaded part. The wheel *c c c*, set in motion by machinery, imparts action to the circular cutters attached to it through the medium of the rack *d d*. It is easy to see that, whether the machine travels along over the cloth, or the cloth travels along beneath the machine, every part of the fibrous surface is acted upon in precisely the same way by the double rotation of the wheel and the disk-cutters. There are other shearing machines in use, of equal ingenuity.

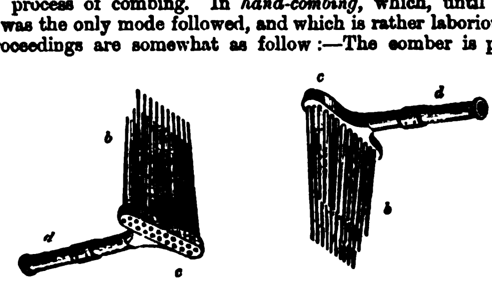
When the cloth has been raised and sheared (which operations are repeated two or three times for superfine cloth), it is *brushed* by a machine consisting of a system of brushes affixed to cylinders; the cloth being exposed at the same time to the action of the brushes and of steam. A few subsequent operations are carried on, having for their object the imparting of smoothness, gloss, &c. to the cloth, preparatory to its being placed in the hands of the dealers.

We have described most of the manufacturing operations in their simpler forms, for more ready comprehension; but it is well to bear in mind that new machines and new processes are being continually brought into this department of industry. A meeting of Leeds woollen manufacturers took place in 1860, to examine a new French machine invented by MM. Tavernier and Vouillon, "to convert slivers or rovings, as they came from the carding-engine, into threads suitable for weaving, by felting and friction, without any spinning process." It was declared that "many gold medals had been awarded in France for the invention; that many of the machines were at work; that no oil or size is necessary as a dressing; and that 30 per cent. of wool is saved." So far as we are aware, this favourable description failed to make the intended impression on the manufacturers. Many of the recent novelties in the trade relate to the employment of cotton for warp-threads, and of rag-wool mixed with new wool for weft; a subject briefly noticed under SHODDY MANUFACTURE. One inventor has brought into use a machine called a *combiner*, by which, when attached to the carding-engine, the wool is brought off in a continuous sliver wound on cylinders, ready to be conveyed to the spinning-machine. Mr. Archibald, of Tillicoultry, in 1858, introduced a machine for piecing the lengths of carded wool as they leave the carding-engine, and forming them into a continuous length or roving; the rolls drop into reversing channels, and thence to travelling belts, which convey them to a machine where they are connected into a length more uniformly than in the ordinary way. Without noticing the almost numberless new machines and processes, we may just mention a very curious process, patented by Messrs. Tolson and Irving, for imparting a metallic lustre to fine woollen cloth. The cloth, either in the yarn or when woven, is steeped in a solution of sulphate or oxide of copper, lead, or bismuth, and then exposed to steam charged with sulphuretted hydrogen gas, by which a metallic deposition takes place.

Other matters relating to the manufacture of woollen cloth will come under notice presently.

Worsted or Stuff Manufacture.—The long wools for worsted fabrics, not being felted or fulled, pass through a series of operations different from those hitherto noticed; since the object in view is rather to lay the fibres in a parallel position than to twist and entangle them one among another. All combing-wools are longer in fibre than the clothing-wools, but they are subject to the division into *long* and *short* combing wools; the long, varying from six to twelve inches in length, being used principally for coarse worsted goods; and the short, from four to seven inches, being used for hosiery and some other purposes.

After the wool has been *sorted*, *washed*, and *scoured* from the adherent grease, and *dried* in a heated room, it is carried to a machine called a *plucker*, containing a pair of spiked rollers, by the action of which the wool is cleansed, separated, and the fibres straightened, preparatory to the process of combing. In *hand-combing*, which, until modern times, was the only mode followed, and which is rather laborious work, the proceedings are somewhat as follow:—The comber is provided



Wool-Combs.

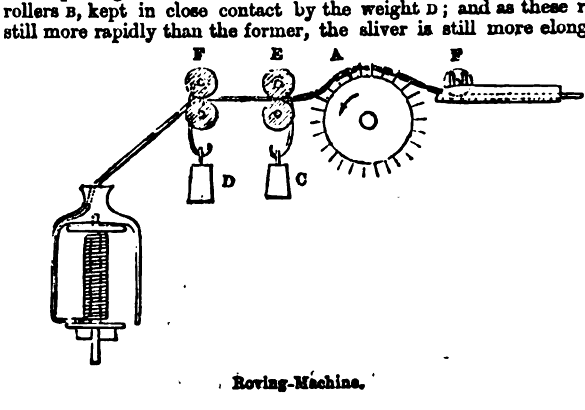
with a pair of combs such as are here represented, a comb-post to which to attach the combs, and a comb-pot or stove for heating the teeth. Each comb consists of two or three rows of steel teeth, *b*, one row longer than the other, inserted in a wooden stock or head, *c*, from which protrudes a handle, *d*, at right angles to the direction of the teeth. The workman first heats the teeth of one of the combs in the stove, and fixes it in the post, teeth uppermost. He then takes a small handful of wool, consisting of about four ounces, sprinkles it with oil to increase the pliancy and ductility of the filaments, and works it about between his hands to equalise the oil on every part of the fibres. The comber then takes half the bundle of oiled wool, and dashes it on the upturned teeth of the comb, till it is all deposited there, and caught between the teeth sufficiently firm to be retained. The comb with its wool is placed, points downwards, in the stove; and the comber next fixes the other heated comb in the comb-post, lays the other half of the bundle of wool on it, and places this likewise in the stove. When both combs with their supply of wool are properly warmed, the comber holds one of them over his knee with his left hand, while seated on a low stool, and with the other comb, held in his right hand, he combs the wool upon the first, by introducing the points of the teeth of one comb into the wool contained in the other, and drawing them through it. This is repeated till the fibres are laid parallel. The wool which remains uncombed on the teeth, and which constitutes about one-eighth of the length of the fibres, is unfit for spinning into worsted, and is consequently applied to other purposes. In *machine combing*, the apparatus sometimes consists of two wheels of large diameter, like the

Combing-Wheel.

one here sketched, having wires placed round the circumference, parallel with the axis, and pointed at one end so as to act like teeth. A boy, sitting on the ground, strikes wool on the points of the teeth in one wheel, so as to make it adhere to and between them. The two wheels are then made to rotate, the distance between them being such that the teeth of the one can draw through or comb the wool lying on the teeth of the other. This is effected with great rapidity; and when the combing is completed, the *top* or combed worsted is taken off by a boy or girl in a continuous sliver from the upper part of the wheel, while the *noils* or uncombed part is removed by another boy.

When the wool has been combed either by hand or machine, it is transferred to the *breaking-frame*, the object of which is to open out any fibres which may have escaped the action of the combs. In this machine the wool, after passing between rollers, is exposed to the action of a kind of endless comb, travelling round two rollers distant from each other; and the arrangements as to relative velocities are such, that the wool becomes somewhat drawn out as well as combed parallel, and leaves the machine in the form of a roll or narrow belt. The sliver of wool proceeds to a large bobbin or cylinder, round which it is lapped into a continuous roll. It is then passed a second time through a breaking-frame, having teeth finer and more closely set than the former. The soft woolly riband is then subjected to the action of a machine analogous in principle to the *drawing-frame* of the cotton manufacture; the object being to extend the length, diminish the thickness, and equalise the number of fibres of the sliver. Hitherto the woolly fibres are merely slightly coherent, without having any twist; but they are now passed through a *roving-machine*, preparatory to the process of spinning. The working parts of this machine are slightly shown in section in the annexed cut. The wool-carding or sliver passes beneath a roller F, towards a cylinder E, the surface of which is studded with points or teeth. The wool, after being acted on by these teeth, passes between the pair of rollers A, where it is pressed by the upper roller being urged downwards by the weight C. Of these rollers the upper one is of wood covered with leather, and the under one of iron, fluted parallel with the axis; and the rollers being made to rotate faster than the feeding-roller F, it necessarily follows that

the sliver of wool becomes elongated to a state of still greater tenuity while passing between them. It is then caught by a second pair of rollers B, kept in close contact by the weight D; and as these rotate still more rapidly than the former, the sliver is still more elongated,



Roving-Machine.

until its thickness is so small that the fibres can scarcely cohere. But in order to give them the requisite coherent strength, they are slightly twisted by the bobbin and fly G, that beautiful contrivance which is so extensively adopted in the textile manufactures. One fork or leg of the rotating flyer G is hollow or tubular, and down this tube the delicate cord of wool passes; then, by the rapid rotation of the flyer, the wool or *roving* becomes wound on the spindle of the bobbin concentric with the flyer. The straight or rectilinear motion of the roving while approaching the flyer, combined with the circular motion at the flyer itself, imparts a twist to the roving, sufficient to enable it to undergo the process of spinning.

The spinning of the worsted bears so close a resemblance to that of cotton, as described in COTTON MANUFACTURE, and SPINNING, that a reference to those articles will suffice to convey a general notion of the process. When spun, the worsted yarn is wound on a reel, and is thence made up into hanks of 560 yards each. These hanks receive denominations according to the number of them which go to a pound, and the yarn derives its name in like manner: thus, No. 24 yarn has 24 hanks to the pound. In some instances the hank is reckoned at 840 yards. The hanks are tied up into pounds; the pounds are combined into bundles; and the bundles are made up into bales of 240 lbs. each, ready for the market.

Here terminate the operations of a worsted-mill; for the dyeing of the yarn, and the weaving into the various kinds of textile fabric, lead us to other departments of industry. [DYEING; WEAVING.]

The worsted manufacture, like that of woollen, has been marked by the introduction of many new machines and processes within the last few years. Two or three of these may be briefly noticed. English wool is becoming less and less fitted for cloths, and more and more fitted for worsteds. Moreover, a length of staple, necessary under the old process of combing, is less needed under the modern. From both of these causes any kind of English wool, from three-inch staple upwards, is rendered available for one or other of the numerous kinds of worsted manufactures. Carding-machines in great variety have been adopted; and the chief inventor, Mr. Lister, made an attempt in 1855 to overturn the patent-claims for many of them, but failed in a court of law. Messrs. Croft and Steel's machine, introduced at Keighley in 1857, has a number of combs, each forming a circular segment; they are fixed to the outer ends of radiating arms carried by a horizontal disc, which rotates on a vertical axis. The combs, while rotating, pass in front of a feeding apparatus, and have a peculiar combing motion given to them by means of cranks; they advance and retire, rise and fall, and rotate, all at once. Each comb takes its proper quantity of wool from the feeder, and carries it round to the drawing-off roller. There are circular brushes to clean each comb after its passage, and a hot chamber in which the teeth are warmed. The great increase in the facility of machine-combing has been one cause of the more rapid advance of the worsted than of the woollen manufacture. Another is, that the fly-spindles, which so late as 1848 only made 2800 revolutions per minute, are now driven at the enormous velocity of 6000 revolutions. Another is, that while woollen cloth, from its great width (often 9 feet before being milled), cannot be woven at more than about 50 picks of the shuttle per minute, worsted weaving is often conducted at the rate of 160 picks. So great is the facility now offered for the use of cotton in mixed goods, or stuffs and worsteds, that out of 100 pieces of all kinds, taken indiscriminately from those produced in the Bradford district, it is estimated 95 have cotton warps; while the total weight of the whole produce is supposed to be two-thirds wool and one-third cotton. One of the curious novelties of recent years is Messrs. Saunders and Smith's process for utilising the *grease* resulting from the various scourings and washings to which the wool is subjected. Iron pipes convey the greasy water to a tank, whence a pump draws it up to other tanks, where it is heated by steam to 160° Fahr. Certain chemical substances are added, by which the creamy sud is converted into a scum and a sediment, with a liquor between them. The liquor is drawn off as useless. The scum and the sediment, nearly alike in composition, are drained in bags of matting, pressed forcibly, and made to yield an oily fluid. The fluid is used in making stearine, soap, and other saleable chemicals, while the refuse oil-cake is sold as manure. The patentees supply all the additional apparatus, besides buying the greasy wash at a stated price. *Creash*, or wool-waste so saturated with oil as to contain more oil than wool, is eagerly bought up by farmers as a powerful manure.

Localities and Varieties of the Trade.—When it is considered that woollen and worsted goods differ primarily in the length of fibre, it is easy to imagine that many varieties may be produced, according to the extent to which this separation is carried out. The various modes too in which the warp and weft threads are made to interlace, as explained in WEAVING, naturally lead to the production of many different classes of goods. These four conditions, namely, the length of fibre, the application or not of the felting quality, the production or not of a velvet-like nap or pile, and the diversities depending on the loom, give rise to innumerable and fancifully-named kinds of woollen and worsted goods. Blankets, flannels, stuffs, merinos, mousseline-de-laines, bombazines, tammies, shalloons, says, moreens, calimancoes, camlets, lastings, baize, and a host of other names, some of which are now nearly or quite out of use, or are giving way to others, point to the diverse applications of long-wool in the production of woven fabrics; while kerseymere and other names indicate distinctions in the felted-wool goods. But besides these diversities, there are others depending on various circumstances; such as the admixture of woollen with worsted, or of either of them with cotton or silk, in the same fabric; the dyeing of the material, sometimes in the piece, sometimes uniformly in the yarn, and sometimes in a party-coloured mode called *clouding;* and the printing of devices on one surface.

A few examples may suffice to illustrate this diversity. Plain *broad-cloth* is a specimen of plain weaving, followed by the fulling process; whereas *kerseymere* is a twilled fabric, similarly fulled. *Serges* are twills, having worsted warp and coarse woollen weft. *Blankets* are made of very soft yarn, afterwards worked up into a kind of pile by milling; and many varieties of coarse cloth are of analogous structure. *Bombazeen* is a twilled mixture of worsted and silk; whereas *Poplin* is an untwilled mixture, showing more silk than worsted at the surface. *Saxonies* and *Orleans* are made of wool, sometimes mixed with cotton, and afterwards printed. *Stuff* is made wholly of worsted; while *Merino* is a fine woollen twill, sometimes printed. The material called *Cashmere*, if properly so named, is made of the shawl-goat wool, much in the same way as merino; but most of the fabrics so called are made of sheep's wool. *Challis* is a mixture of woollen weft with silk warp, and is generally printed. *Mousseline-de-laine* was originally all wool, but is now frequently mixed with cotton, and generally printed. *Norwich crape*, unlike common crape, is composed of wool and silk, something like challis, but without being printed. *Crêpe de Lyon* is formed of worsted and silk; and *Italian net* of worsted only. In *Waistcoatings*, fancy-weaving adds another to the sources of diversity. Many of the above kinds are briefly described under their proper names in this Cyclopædia; while a number of additional kinds will be found noticed under SHODDY MANUFACTURE.

The West Riding of Yorkshire, the most important clothing-district in England, exhibits an area of nearly 40 miles by 20 occupied by clothing towns and villages. Leeds, Bradford, Halifax, Huddersfield, Dewsbury, and Wakefield are the great manufacturing centres. Mixed or coloured cloths are made principally in the villages west of Leeds and of Wakefield; white or undyed cloths are made chiefly in the villages occupying a belt of country extending from near Wakefield to Shipley. Flannels and baizes are the principal woollen articles made in and near Halifax, together with army cloth. Blankets are made on the line between Leeds and Huddersfield. Bradford provides very largely the spun worsted required for the various manufactures. Stuffs are made at Bradford, Halifax, and Leeds; and narrow cloths at Huddersfield. Saddleworth furnishes broad-cloth and kerseymeres. In the neighbourhood of Batley and Dewsbury are the shoddy mills. The West of England takes rank next to Yorkshire, and formerly took precedence of it. The finest kinds of broad-cloth, from Saxony, Australia, and Spanish wool, are made in Gloucestershire. The manufacture is carried on in a district called the *Bottoms*, and in other parts of the country; the town of Stroud being a kind of centre for the whole. Wiltshire produces very fine cloths, at Bradford, Trowbridge, Westbury, Melksham, Chippenham, and the surrounding villages; while cloth of various kinds is made at Wilton, Warminster, Heytesbury, and Calne. Taunton, Frome, Tiverton, and the surrounding villages constitute the Somersetshire clothing district. Devonshire and Dorset have little woollen manufacture. The Norfolk district was long the principal seat of the stuff or worsted manufacture. Bombazeens, crapes, camlets, and shawls have constituted the chief fabrics for which Norfolk has been celebrated. These are the three great English districts engaged in the consumption of wool; to which may be added Leicestershire, where nearly all the worsted stockings are made. It must be noted, however, that Yorkshire, with its abundant machinery and cheap coal, is every year absorbing a larger and larger proportion of the whole manufacture. In Wales the principal manufactures relating to wool and worsted are strong webs or high-country cloths, small webs or low-country cloths, flannels, stockings, socks, wigs, and gloves; the chief counties being Montgomery, Merioneth, and Denbigh. The strong webs are used principally for workmen's jackets, ironing cloths, &c.; while the small webs are largely used for slaves' clothing in the West Indies. In Scotland the fine woollen manufacture is upon a very limited scale; but a good deal is done at Aberdeen, Stirling, Galashiels, Jedburgh, Hawick, Inverness, Kilmarnock, and Paisley, in the production of various kinds of woollen and worsted goods, such as coarse plaiding, clan-tartans, woollen-hose, blankets, flannels, and especially carpets and shawls. The manufactures of woollen and worsted goods in Ireland are small in extent.

Different usages prevail in different counties respecting the connection between employers and employed, buyers and sellers, in the woollen and worsted manufactures. In the West of England the general plan of operation is this:—The master-clothier buys his foreign wool from the importer, and his English wool from the wool-stapler. He employs in all the different processes through which the wool passes in the course of manufacture, distinct classes of persons, who sometimes work at their own houses, and sometimes in the factory of the master-clothier. Each workman confines himself exclusively to a particular branch of the manufacture; and this has been supposed to have led to the excellence of the West of England cloth.

A second mode is on the factory system, now extensively adopted in the West Riding of Yorkshire. The master-manufacturer, who generally possesses a large amount of capital, employs a great number of workmen in one or more buildings, under the inspection of himself or a superintendent. In this system, as in the master-clothier system, the workman has no property in the material on which he is employed.

In the domestic system, which was the one originally adopted, the arrangement is altogether different. Under this system the manufacture is conducted by a number of small masters, who are generally possessed of very limited capital, and who, besides their business as manufacturers, mostly occupy farms of a few acres, partly for the support of their families, and partly for the convenience of their manufacture. The domestic clothiers have in their houses from one to four looms, on which they employ themselves, their wives, and children, and perhaps other assistants. During harvest their wives, children, and servants are sent out into the fields to work. Formerly these clothiers used to carry the wool through all the stages of its manufacture, till it was brought to the state of undressed cloth; but of late years they have availed themselves of public mills, which are established in and among the clothing-villages, for the performance of some of the processes. These mills have been erected on a joint-stock principle, by shares of 50*l.* or 100*l.* each, principally subscribed by the domestic clothiers. When machinery began to be extensively employed in the woollen manufacture, in the early part of the present century, the domestic clothiers became violently excited, under the apprehension that their trade would be taken from them by the newly-invented machines. A parliamentary committee was appointed to inquire into the probable operation of machinery in respect to the well-being of the domestic clothiers; and after examining numerous witnesses they made a report, in which they detailed the distinctive features of the factory and the domestic systems, and came to a conclusion that "the two systems, instead of rivalling, are mutual aids to each other; each supplying the other's defects, and promoting the other's prosperity." "Experience," says Mr. M'Culloch, "has proved the correctness of these conclusions. The number of small manufacturers, and the quantity of cloth produced by them, have both increased since 1806; but, as the number of factories, and the quantity of cloth made in them, have increased still more rapidly, the former constitute, at present, a less proportion of the trade." One circumstance which has enabled the domestic system to maintain its ground, is, that the great width of woollen cloth has been a difficulty in the way of power-loom weaving; the hand-loom cannot compete with steam in the stuff trade, but it can in broad-cloth. The domestic system would nevertheless have succumbed, had not the clothiers prudently adopted the joint-stock principle for their mills. Each shareholder takes his own wool to the mill to be cleaned, dyed, carded, and spun; brings it home to weave by himself and family; takes it to the mill to be fulled, washed, and tentered; and sells it at the cloth halls to merchants who employ dressers to finish it.

As respects the *sale* of the cloth, halls have been established for this purpose at Leeds, Halifax, Bradford, Huddersfield, and other towns, which are attended on the public market-days by thousands of the smaller class of manufacturers. The halls are divided into long walks or galleries, consisting of rows of stands, each of which is marked with the name of the person by whom it is occupied. On these stands the cloth is exposed for sale; and when the market opens, the manufacturers take their stations at the stands behind their goods, the merchants or buyers passing, to make their purchases, through the avenues between the rows. The time during which the halls are open is limited usually to about one hour and a half; but in this short interval purchases to a very large amount are made. The cloth-halls at Leeds are appropriated exclusively to the use of those who have served regular apprenticeship to the business of cloth-making. They are managed by trustees, and many of the stalls are the freehold property of the persons who occupy them. All the cloth sold in the halls is rough and undressed. Those by or for whom it is bought have what are termed finishing-shops, where the cloth is shorn, dressed, and fitted for use. This is analogous to a system pursued by the bobbin-net manufacturers at Nottingham, where the net is sold by the maker in the rough state as it leaves the loom, and purchased by other parties, who singe, dress, and finish it ready for the market.

Statistics of the Trade.—In 1739, the writer of a pamphlet on the subject of wool estimated the number of persons engaged in the woollen manufacture at 1,500,000, and their wages at 11,737,500*l.* per annum. This estimate was obviously an overcharged one. Dr. Campbell, in 1774, thought that there might probably at that time be 1,000,000 persons employed in the manufacture in England; that the value of the wool used was 3,000,000*l.* per annum; and that this value was increased to 12,000,000*l.* by the processes of manufacture. In 1800 the woollen manufacturers, in committee before the House of Lords, made the extravagant estimate that there were then 1,500,000 persons directly engaged in the manufacture; that an equal number were collaterally employed in it; that the value of the wool used was more than 6,000,000*l.* sterling; and that of the manufactured goods nearly 20,000,000*l.* sterling. In 1815 Mr. Stevenson supposed that there were half a million persons employed, receiving 9,600,000*l.* per annum wages; and that this sum, added to the value of the raw material, the interest on capital, the manufacturer's profit, &c., gave 18,000,000*l.* as the annual value of the cloth produced. Mr. M'Culloch ('Statistical Account') forms an estimate on the following data:—That there are about 150,000,000 lbs. of wool worked up yearly; that this may be worth about 7,500,000*l.*; that the value of the manufactured goods is three times that of the raw wool, making therefore 22,500,000*l.* per annum; that this value is thus made up:—

Raw material	£7,500,000
Oil, soap, dye-stuffs, &c.	1,600,000
Interest, profit, &c.	4,650,000
Wages	8,750,000
	£22,500,000

And dividing this amount of wages at the rate of 26*l.* a year to each operative on an average, he arrives at the number 334,600, which he thinks a probable approximation to the number of persons employed in the woollen manufacture in this country. Mr. Chapman (one of the Assistant Hand-Loom Commissioners) made an estimate which agrees pretty nearly with that of Mr. M'Culloch; although at the first glance the two estimates seem discordant. He thinks that, in 1831, the number of families directly dependent on the manufacture were—

In the West Riding of Yorkshire	85,096
In the West of England	20,851
In Norfolk and Kendal	17,570
In the hosiery district	20,464
In all other places	20,000
	163,981

Then, taking the average number of persons in a family at 5¼, he arrives at an aggregate of 874,565 persons directly supported thereby. He further supposes that this number must have increased, by 1841, to 226,298 families, or 1,218,424 individuals. Mr. M'Culloch's estimate is of the number of persons *employed*, while Mr. Chapman's is of the number of persons *supported*; and this may explain the apparent discrepancy between the two estimates. As to the value of the manufacture, Mr. Chapman proceeds thus:—226,298 families, earning, on an average, 17*s.* 6*d.* per week each family, which amounts to 10,296,559*l.*; and the relation between this and the other items of the cost he thus states:—

Value of wool employed	£10,000,000
Oil, dye-stuffs, soap, &c.	1,500,000
Wages	10,296,559
Wear and tear, profit	4,359,311
	£26,155,870

In the last edition of his 'Commercial Dictionary,' Mr. M'Culloch makes an estimate, which he supposes to approximate pretty nearly to the true figures for the year 1858. He takes the consumption of English wool at 110 million lbs. at 1*s.* 3*d.* per lb., and that of foreign at 60 million lbs. at 2*s.* Then he makes up four large items thus:—

Wool	£12,875,000
Wages	7,725,000
Soap, oil, dyes, &c.	1,200,000
Profit, interest, wear and tear	4,200,000
	£26,000,000

Besides 2,000,000*l.* worth of shoddy and mungo manufactures. So far as regards woollen and worsted mills, and the persons engaged in them, see FACTORIES. Some writers have guessed the total value at 50,000,000*l.*; but this is only a guess. At a recent period, in a woollen factory at Leeds, 570 persons were found to be earning 12*s.* 11*d.* per week on an average: namely, men's average 22*s.* 3*d.*; women and girls', 8*s.*; boys', 6*s.* 8*d.* Mr. Baines, in an article in the 'Statistical Journal' for 1859, estimated that the woollen manufacturers (without the worsted) use up 156 million lbs. of British and foreign wool, 45 million lbs. of shoddy and mungo, and cotton to the value of 200,000*l.*; that the value of these fibres is about 10,500,000*l.*; and that the wages, oil, soap, dyes, profit, interest, rent, and wear and tear, raise the total value to 20,290,000*l.* He estimates that 150,000 persons were employed in the woollen manufactures in 1858; Mr. M'Culloch estimates 275,000 persons employed in the *woollen and worsted* manufactures in the same year.

From 1725 to 1820 all the cloths made and fulled in the West Riding were measured and stamped by officers appointed for that purpose, and from the returns made, it appears that there were fulled, in the West Riding, the following number of pieces of broad and narrow cloth, in the years named:—

	Broad.	Narrow.		Broad.	Narrow.
In 1726	26,671	..	In 1786	158,792	123,025
1746	56,637	68,775	1806	290,269	175,334
1766	72,575	78,893	1816	325,449	120,901

The woollens and worsteds exported in 1820, 1830, and 1840, had a value of 5,587,758*l.*, 4,728,666*l.*, and 5,327,853*l.* respectively. In 1845, 1850, and 1855, the value rose to sums varying from nine to ten millions sterling annually. The figures for the year 1860, given somewhat more in detail, will show in what way the manufacture subdivides itself into kinds. The exports in the year just named were as follow:—

Woollen cloth of all kinds	579,135 pieces.
Mixed stuffs, flannels, blankets, and carpets	93,079,584 yards.
Mixed stuffs entered at value	£493,526
Worsted stockings	272,332 dozen pairs.
Worsted stuffs	2,616,756 pieces.
Woollen and worsted yarns	245,839 cwts.

The value of all these exports exceeded 16,000,000*l.* The United States were the largest purchasers of the woven goods; the yarn went in greater quantity to Germany.

WOORARI. *Wooraly, Œurari, Urari.* The extract of the bark of the *Strychnos toxifera*, which is used by the Indians of Guiana to poison their arrows. Recent investigation has shown that the poisonous principles of this extract are strychnine and brucine. [NUX VOMICA, ALKALOIDS OF.]

WORK, UNIT OF. The sum of the dynamical effect produced by a prime mover in a given time is known in books upon mechanism by the term of its *unit of work*; but in order to be able to compare the relative effective values of the various motors it is customary to refer them to the unit of work most generally considered to represent the normal conditions of an artificial prime mover. In such cases the amount of work is taken as being represented by a weight raised through a definite height in the time given; and as horse-power was formerly the one most commonly used for mechanical purposes, the custom has arisen of comparing the efficient power of machines in proportion to the units of work they can perform, each of which units is equal to the unit of work performed by a horse supposed to raise a weight vertically. Writers upon physics are far from being unanimous as to the real value to be assigned to the *horse-power*; but in England it is generally considered to be equivalent to a weight of 33,000 lbs. raised one foot high in a minute; or to 550 lbs. raised 1 foot in a second; and that unit of work is adopted as the term of comparison in the majority of cases when the powers of steam engines are compared. In the case of the pumping engines of the Cornish mines, the unit of work is made to refer to the weight of water actually raised by the combustion of a hundred weight of coals, and the unit of work is technically known in that district by the term, "duty."

Of course the amount of work performed by any prime mover must vary under the ever varying conditions of practice; and especially when men, horses, or other animals, are employed must the effort they can exert depend upon individual constitution, and upon accidental circumstances. The units of work assigned to the respective motors mentioned below must, therefore, only be considered to represent a rude kind of average in each instance, and particular attention must be paid to the fact that there is for all of them a velocity of the point of application of the power, an effort, and a duration of that effort, which are the most favourable for the useful effect. The average unit of work may often vary from ¼ to ⅓ above or below the quantities cited, according to the age, or the health, of the animal motors, or to the climate in which they work. The table is extracted from Poncelet's 'Mécanique Industrielle.'

The unit of work of steam engines, the horse-power, has long ceased to have any real meaning, for the real power, as ascertained by the dynamometer, is invariably in excess of the nominal horse-power of the engines. The common rule for calculating the *nominal* power of engines, whose pistons move at the velocities prescribed by Watt's rules, is however as follows: multiply the square of the diameter of the cylinder, in inches, by the velocity of the piston, in feet, and divide the product by 6000; the product will be the number of nominal horses' power. As this formula does not include any term expressing the expansive power of the steam, it must evidently be unsatisfactory; the real power may be ascertained by means of the indicator as follows. Multiply the area of the piston by the residual pressure, after deducting for the friction and the loss of power in working the air pump (this is usually 1¼ lbs.), and by the velocity of the piston in feet per minute; the product divided by 33,000 will represent the real *effective* horse-power applied to the main shaft. In both these cases, the unit of work of the horse-power is taken at 33,000 lbs. raised 1 foot high per minute. In Watt's time this amount of work could only be secured by the combustion of about 16 lbs. of coal per horse-power per hour; at the present day, in ordinary condensing engines, only from 7 to 8 lbs. are required; whilst in the best expansion-geared engines with surface condensation the same result is obtained by the combustion of 2 lbs. of coal.

Description of Work.	Weight raised.	Velocity per second.	Unit of work per second.	Length of working day.	Total work in a day.
	lbs.	feet.	lbs. × ft.	hours.	lbs. × ft.
A man mounting an easy staircase, or an incline, without a load, his work consisting simply in moving the weight of his own body	143	0·5	71·5	8	2,059,200
A man raising weights by means of a cord and pulley, which renders necessary the return of the cord without a load	39·6	0·66 say 0·67	26·53	6	573,048
A man raising weights by his hands	44	0·56	24·64	6	532,224
A man carrying a weight on his back up an easy incline, and returning without load	143	0·13	18·59	6	401,544
A man raising materials by a wheel-barrow, on an incline of 1 in 12, returning unloaded	132	0·065	8·58	10	308,880
A man throwing earth by a spade a height of 5 feet 4 inches	5·94	0·66 say 0·67	3·98	10	143,280
A man working a pin-wheel or a drum—					
1st, at the level of the axle	132	0·5	66	8	1,900,800
2nd, at bottom of wheel	26½	2·34	61·8	8	1,779,840
A man walking and pushing, or drawing horizontally, in a continuous manner	26·4	2	52·8	8	1,520,640
A workman acting upon a winch	17·6	2·5	44	8	1,267,200

WORKHOUSE. Relief to the indigent is of two kinds, in-door relief and out-door relief. In-door relief is relief in the workhouse. At first workhouses appear frequently to have combined the character of a bridewell. In the reign of Edward VI. the poor of London were classed into three great divisions, and the third comprised the "thriftless poor," namely, 1, the rioter that consumeth all; 2, the vagabond that will abide in no place; 3, the idle person, as the strumpet and others: and the king, who had been moved to the necessity of almsdeeds by a sermon of Bishop Ridley's, provided hospitals for "the poor by impotency" and "the poor by casualty," and Bridewell was allotted to the "thriftless poor." The workhouse at Hamburg, one of the oldest institutions of the kind in Europe, is still called the Correction and Poor House. The Canterbury Local Act, passed in 1727, expressly orders the bridewell and workhouse to be kept up within the same precincts; and they were only separated under an act passed in 1842. A century and a half ago it was common for writers to speak of the workhouse as a place where idlers and vagabonds were set to work. (See 'Workhouse,' Johnson's 'Dictionary.') The general character of our early statutes relating to the poor was harsh, and indigence was treated as a penal offence.

One of the great objects of the 43 Eliz., c. 2, the foundation of our present poor-laws, was to provide employment for the destitute. The overseers and justices of the peace were directed to set to work children whose parents were unable to maintain them; and also adult persons who had no means of maintaining themselves, and who used no ordinary and daily trade of life; for which purpose, with the fund raised for the relief of the poor, a convenient stock was to be purchased of flax, hemp, wool, thread, iron, and other ware and stuff. The 43 Eliz. also authorised overseers and churchwardens to build cottages on waste land for the poor to inhabit, and to place inmates, or more families than one, in one cottage or house, such cottages or houses to be used thereafter only for the poor. Workhouses in former times were generally called houses of industry, and for the most part a profit was expected to be derived from their labour, at any rate, to the extent of making such institutions in some measure self-supporting. The house in such cases became a linen or woollen factory; or sacks, nets, and a variety of other articles, were manufactured. Sometimes land was rented or purchased, and the inmates of the workhouse were employed in agricultural labour. The final extinction of poor-rates was regarded as a not impossible result of these schemes of workhouse industry. In 1704, when the popularity of these schemes was at its height, De Foe clearly pointed out their inevitable operation, and especially their effect on independent labour; but he was scarcely heeded. Nearly a century afterwards houses of industry were erected in Suffolk on a greater scale than had previously been attempted. Instead of being employed as a test of destitution, these houses were intended to provide occupation for all the unemployed.

Previous to the passing of the Poor-Law Amendment Act, in 1834, the poor-houses (or workhouses) presented, generally speaking, only accumulated instances of mal-administration. Absence of classification, discipline, and employment, and extravagant allowances, rendered them prolific nurseries of pauperism and vice. Some of the cases of workhouse corruption would be ludicrous, had they not exhibited practices so thoroughly demoralising. In by far the greater number of cases, the workhouse was a large almshouse, in which the young were trained in idleness, ignorance, and vice; the able-bodied maintained in sluggish and sensual indolence; the aged and more respectable exposed to all the misery that is incident to dwelling in such a society without government or classification; and the whole body of inmates subsisted on food far exceeding both in kind and in amount not merely the diet of the independent labourer, but that of the majority of the persons who contributed to their support. By 30 Geo. III., c. 49, passed in 1790, the right of visiting any workhouse at all times of the day was conferred on justices of the peace and clergymen; and on their representation the overseers were liable to be summoned at quarter-sessions, when the justices could make orders and regulations for the remedy of any defects in the workhouse management. The chief recommendation of the Commissioners of Poor-Law Inquiry in 1834 was to *unite* parishes for better workhouse management, and the relief of the destitute poor. This is the origin of the Poor-Law Unions. As soon as the Poor-Law Commissioners were appointed, they directed their attention to the uniting of parishes into unions for the purpose of the administration of relief by boards of guardians elected by the ratepayers, and to the general adoption of the workhouse system; but their main reliance for the discouragement of pauperism, and for the establishment of independent habits amongst the labouring classes, they said, was founded on the workhouse system. Out-door relief to the able-bodied poor is now prohibited in all those unions which have efficient workhouse accommodation,—with the following exceptions. 1. Where the destitute poor shall require relief on account of sudden and urgent necessity. 2. Where he or she shall require relief on account of any sickness, accident, or bodily or mental infirmity affecting him, or any of his or her family. 3. Where he or she shall require relief for the purpose of defraying the expenses, either wholly or in part, of the burial of any of his or her family. 4. Where the person, being a widow, shall be in the first six months of her widowhood. 5. Where the person shall be a widow, and have a legitimate child or children dependent upon her, and incapable of earning his, her, or their livelihood, and have no illegitimate child born after the commencement of her widowhood. 6. Where the person shall be confined in any jail or place of safe custody. 7. Where the person shall be the wife or child of any able-bodied man who shall be in the service of her majesty as a soldier, sailor or marine. 8. Where any able-bodied person not being a soldier, sailor or marine, shall not reside within the union, but the wife, child, or children of such person shall reside within the same, the Board of Guardians, according to their discretion, may, subject to certain conditions, afford relief in the workhouse to such wife, child or children, or may allow out-door relief for any such child or children being within the age of nurture, and resident with the mother within the union. These exceptions may, however, in special cases be further extended, with the sanction of the Poor-Law Board previously obtained. In all other cases the guardians may grant relief either in or out of the workhouse as they may deem expedient under the circumstances of each case.

Workhouses are governed under the rules and regulations which are contained in the consolidated order of the Poor-Law Board. Paupers are admitted to them in one or other of the following modes:—1. By a written or printed order of the Board of Guardians, signed by their clerk. 2. By a provisional written or printed order, signed by a relieving officer or an overseer. 3. By the master of the workhouse (or during his absence, or inability to act, by the matron), without any order, in any case of sudden or urgent necessity. The paupers are divided into the following classes:—1. Men; infirm through age or any other cause. 2. Able-bodied men, and youths above the age of fifteen years. 3. Boys above the age of seven years and under that of fifteen. 4. Women infirm through age or any other cause. 5. Able-bodied women, and girls above the age of fifteen years. 6. Girls above the age of seven years and under that of fifteen. 7. Children under seven years of age. The following officers are appointed for each workhouse, except in the case of very small workhouses, when some of the offices are combined—namely, a chaplain, medical officers, master, matron, schoolmaster, schoolmistress, porter, and nurse, with such assistants as may be deemed necessary. These officers are all appointed by the boards of guardians of the respective unions; and they are paid adequate salaries by the guardians, subject to the approval of the Poor-Law Board; and, with the exception of the two first, in addition to their salaries, are allowed board and lodging in the workhouse. Though the officers are appointed by the boards of guardians, unless they voluntarily resign they cannot be removed except by an order of the Poor-Law Board. For detailed information regarding the government of the workhouse, that is, the admission of paupers, their classification, discipline and diet, punishment for misbehaviour, and the duties of the workhouse officers, the 'Poor-law Board Orders,' edited by W. Cunningham Glen, Esq., Barrister-at-Law, should be consulted.

There are 623 unions and parishes under separate boards of guardians, and in which relief to the poor is administered under the provisions of local acts of parliament, all of which, with the exception of about ten unions, have workhouses capable of accommodating from a comparatively small number up to 3500 paupers (in the Liverpool workhouse), which is the largest number allowed in any one workhouse. There are 708 workhouses in England and Wales, and the maximum number of paupers to be admitted at any one time into each workhouse is in each case limited by the Poor-Law Board; the total accommodation afforded by all the workhouses provides for about 218,000 persons, besides accommodation for the officers of the establishments.

The following are the numbers of paupers of the respective classes who were maintained in the workhouses in England on the 1st July, 1860, and 1st January, 1861, respectively:—

		July 1, 1860.	Jan. 1, 1861.
Able-bodied	Males	3,260	7,589
	Females	9,848	15,813
	Children	12,142	19,441
Not able-bodied	Males	23,047	29,227
	Females	18,927	21,735
	Children	25,544	28,480
Lunatics, insane persons, and idiots.	Males	3,344	3,512
	Females	4,646	4,887
	Children	319	327
Vagrants		1,146	1,179
Total		102,223	132,140

Under ordinary circumstances, therefore, the workhouses are only about half full, and the excess of accommodation provided is reserved to meet any extraordinary pressure that may occur.

During the year ended the 25th March, 1860, the total expenditure out of the poor-rates in and connected with the relief of the destitute poor, amounted to the sum of 5,454,964*l.* 7*s.*, and of that sum 912,360*l.* 7*s.* was expended in the relief to the poor in workhouses; but to that sum must be added the cost of the workhouse establishments, including the salaries of the officers, to arrive at a correct estimate of the cost of workhouse relief. These items, however, are not separately distinguished from the cost of the union salaries generally; which during the year referred to amounted to the sum of 644,799*l.* 9*s.* Taking the whole of the workhouses, the average cost of maintaining each pauper therein averages about 3*s.* 2*d.* per week, which is the cost of food, clothing, and necessaries charged to the in-maintenance accounts; the cost of the food being about 2*s.* 11*d.* per week, and of the clothing and necessaries about 3*d.* per week for each pauper. In some workhouses, however, the cost is much higher, and in others considerably less than those amounts.

The cost of erecting the Liverpool workhouse, which is the largest, amounted to upwards of 120,000*l.* Some of the smaller workhouses cost as low as 1500*l.* building, but taking them altogether, the average cost of each may be stated at about 8000*l.*; so that, there being 708 workhouses, the total cost of these buildings may be taken as representing the sum of five millions and a half (exclusive of interest), which sum was raised by loans secured upon the poor-rates, repayable by annual instalments, including interest, in periods varying from ten to twenty years.

Further on the subject of the poor-law statistics the reader is referred to the paper on the 'English Poor-Rate,' by Mr. Frederick Purdy, in the 'Journal of the Statistical Society of London,' for September, 1860.

WORLD. [UNIVERSE.]

WORKS AND BUILDINGS, BOARD OF. [WOODS AND FORESTS.]

WORMS, HUMAN. The body of man, like that of the lower animals, serves as a locality for the residence of several of the lower forms of animals which are known by the general name of worms. These creatures all belong to the lower forms of the annulose group of animals, and are sometimes grouped together under the name of Entozoa [ENTOZOA, in NAT. HIST. DIV.]. This is not, however, a philosophical classification, as many animals belonging to this group in point of structure have not necessarily parasitical habits. Another reason for getting rid of the term Entozoa will be found in our present knowledge of the history of the development of some groups of these creatures, as there is reason to believe that they do not pass all their existence within the bodies of other animals. The most important observation made with regard to these animals in modern times, is the identity of those forms of worms called *cystic*, with those which have been called *cestoid*.

The researches of Siebold, Küchenmeister, Leuckart, and Rainey, have now placed this matter beyond a doubt. The history of the common tape-worm (*Tænia solium*) of the human body may be taken as a type of the whole. The eggs of this worm are contained in the segments of the mature worm, which are called *proglottides*. [ANTHELMINTICS.] These eggs, in order to their future growth and development, must be swallowed and submitted to a process of digestion by some other animal before they reach maturity. This process may occur in many species of animals, but that in which it takes place most commonly is the pig. In the intestines of the pig the egg becomes an embryo, which is supplied with six hooks, by means of which it penetrates the tissues of the intestines, and entering the blood-vessels is carried by the current of the blood to the various organs of the body. This embryo having reached a place of rest, is developed into the cystic worm known by the name of *Cysticercus cellulosæ*. This form of the worm is well known, and produces in the flesh of the pig that appearance which is called in the markets "measly pork." Here it remains and dies, unless the flesh containing it is eaten by some other animal. When eaten by man and submitted to the process of digestion, the cystic worm is further developed. In the cyst there is a head called the "Scolex head," supplied with suckers and hooks, adapted to laying hold of the mucous membrane of the intestines, which, when effected, results in the growth of those segments which are known as the characteristic of the tape-worm. The scolex head is now the head of the tape-worm, and the segments are the proglottides which continue to increase, and eventually each segment is developed into a sexual being, containing both the male and female organs of generation, and the eggs are produced. These facts have been well established by experiments, made by both Von Siebold and Küchenmeister. Man is also subject to the attack of cystic worms, *Echinococcus*, &c., which attain their mature development in other animals. The following is a classification of the worms at present known to inhabit the human body:—

Division ANNULOSA.
Subdivision ANNULOIDA.
Order SCOLECIDÆ.
Section PLATYELMIA—Flat worms.
Family TÆNIADÆ = CESTOIDÆ.
A. Mature States:—
Bothriocephalus latus—Broad Tape-worm.
Tænia solium—Common Tape-worm.
Tænia mediocanellata.
Tænia nana.
Tænia? (Cape of Good Hope.)

LIST OF MATURE AND IMMATURE WORMS, AND THEIR HABITATS.

Immature State.	Habitat.	Mature State.	Habitat.
	TENIADÆ.		
Cysticercus cellulosæ	Pig	*Tænia solium*	Man.
C. fasciolaris	Rat, mouse	*T. crassicollis*	Cat.
C. pisiformis	Rabbit	*T. serrata vera*	Dog.
C. tenuicollis	Sheep, horse, monkey, man	*T. ex cysticerco tenuicolli*	Dog.
C. innominatus Hyperdæi	Mole, field-mouse	*T. tenuicollis*	Marten, weasel.
C. longicollis Hyperdæi	..	*T. crassiceps*	Dog.
Cœnurus cerebralis	Sheep, ox	*T. cœnurus*	Dog.
Echinococcus veterinorum (*E. scoliciparions*, Küch.)	Man, ruminantia	*T. echinococcus sc.*	Dog.
E. hominis (*E. altriciparions*, Küch.)	Man, domestic an.	*T. echinococcus alt.*	
	TREMATODA.		
Cercæria	Fresh water mussel	*Distoma hepaticum*	Sheep, man.

The tape-worms of the lower animals have the same origin with those of man, and their history has now been traced in a large number of animals. Thus, the dog is liable to the attacks of a tape-worm (*Tænia cœnurus*). The egg of the *T. cœnurus*, on being swallowed by the sheep, produces a cystic worm in its brain, which has long been known by the name of *Cœnurus cerebralis*. This worm produces the "staggers" in the sheep; and when dogs get access to the brains of sheep under these circumstances they produce the *Tænia cœnurus*. The cat is liable to a tape-worm called *Tænia crassicollis*, the cystic stage of which is found in the liver of the rat or mouse, and is known to naturalists under the name of *Cysticercus fasciolaris*. Even the Trematode worms pass through stages of this kind, and the *Cercaria* of the mussel becomes the *Distoma* of the sheep.

A question of some interest has been raised as to whether we ought to regard these parasites as necessarily connected with a diseased state of the body, and therefore to be got rid of at any cost. It is a curious fact with regard to tape-worms and neuratoid worms, that they will exist for years without producing any inconvenience. By the Abyssinians they are regarded as indicative of health, and a negro slave among them is valued higher for it. It is often observed that persons who must have been the subjects of tape and other worms for a long time past do not suffer till they become aware of the existence of these creatures. At the same time there can be no doubt that certain states of the health favour the excessive development both of the immature and mature states of the various species of worm, and that they then become sources of serious inconvenience. The symptoms attributed to the presence of tape-worms are very numerous. Küchenmeister, in his work on the 'Parasites of Man' (translated for the Sydenham Society by Dr. Lankester), gives the following account of symptoms observed in 100 cases in which tape-worms were known to exist:—63 suffered from cerebro-spinal affections and partial or general convulsions; 49 from nausea, sometimes with vomiting and fainting; 42 with pains in the abdomen; 33 from disordered digestion; 31 from irregular and voracious appetite; 19 from headache; 17 from colic; 16 from abdominal movements; 15 from dizziness; 11 from shifting pains. It will at once be seen that none of them can be pronounced as undoubted symptoms of worms, as they may all result from other kinds of disorder. The only distinguishing sign that can be relied on without doubt, is the discharge of the proglottides, or portions of the worm, from the bowels. These being witnessed, the case is certain.

The remedies recommended for cestoid and other worms are very numerous. When the general health is bad it should be improved. There are, however, certain remedies which act in an especial manner on the worm in the intestines which should always be administered. These are called anthelmintics. [ANTHELMINTICS.] Most of these act in two ways:—1. They destroy the worm, and act as helminthicides. 2. They expel it when dead or enfeebled, and thus act as purgatives. The best of these is oil of turpentine. It has been used extensively in Great Britain; and Küchenmeister, whose authority is great on this subject, says—"It is certainly one of the most energetic remedies against tape-worm, and justly merits application in those cases in which pomegranate-bark has produced no result." It is a very disagreeable remedy, producing sometimes serious effects in the nervous system and sometimes strangury. Consequently medical men try other remedies first. Of these, koupo, male fern, pomegranate-bark, and camelea, are preferred. Koupo has undoubtedly proved of service, but Küchenmeister says he has always been more or less unlucky with this remedy. The male fern is also useful. The decoction of the root, the powdered sort, or etherial-oil, are given. Rapp says by far the most efficient form is the fresh root.

Küchenmeister gives the preference to pomegranate bark. He uses a thick extract of the bark, and says he "prefers it to all other remedies against tape-worm." It dislodges, he says, the head of the worm more effectually than any other remedy.

For a good abstract of the present state of knowledge with regard to tape-worms in man, see an Essay on this subject by Dr. D. F. Weinland, published at Cambridge, U.S., 1858.

WORSTED MANUFACTURE. [WOOLLEN AND WORSTED MANUFACTURE.]

WORT. [BREWING.]

WOUD. [WELD.]

WOULFE'S APPARATUS. Under various forms, and with several modifications, this apparatus is much employed in chemical operations. The arrangement, first described by its inventor in the 'Philosophical Transactions,' is inconvenient in form; we shall therefore give a description of one of several improvements to which it has been subjected. A retort *a* (*fig.* 1.) is attached and secured by means of lute to the first receiver *b*, which has a right-angled glass tube, open at both ends, fixed into its tubulure; and the other extremity of the tube is made to terminate beneath the surface of distilled water, contained, as high as the horizontal dotted line, in the three-necked bottle *c*. From another neck of this bottle a second pipe proceeds, which ends, like the first, under water contained in a second bottle *d*. To the central neck a straight tube, open at both ends, is fixed, so that its lower end may be a little beneath the surface of the liquid. Of these bottles any number may be employed that is thought necessary. The materials being introduced into the retort, the arrangement completed, and the joints secured in the manner to be presently described, the distillation is begun. The condensable vapour collects in a liquid form in the balloon *b*, while the evolved gas passes through the vent-tube, beneath the surface of the water in *c*, which continues to absorb it till saturated. When the water of the first bottle can absorb no more, the gas passes, uncondensed, through the second right-angled tube into the water of the second bottle, which, in its turn, becomes saturated. Any gas that may be produced, which is not absorbable by

Fig. 1.

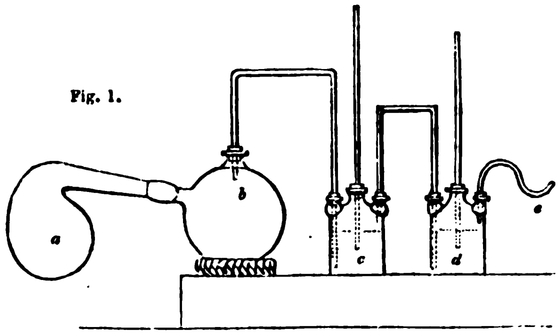

Fig. 2.

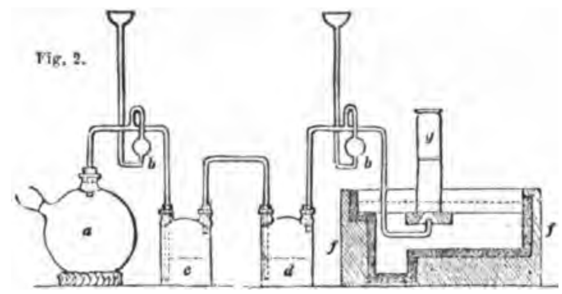

water, escapes through the vent-tube *e*, and may be collected, if requisite, in an air-jar filled with and inverted in water in the pneumatic trough. This is represented in *fig.* 2 by *f*, *f*, and *g*.

Supposing the bottles to be destitute of middle necks, and consequently without the perpendicular tubes, the process would be liable to be interrupted by an accident; for if, in consequence of diminished temperature, an absorption or condensation of gas should take place in the retort *a*, and of course in the balloon *b*, it must necessarily ensue that the water of the bottles *c* and *d* would be forced by the pressure of the atmosphere into the balloon, and possibly into the retort, which might cause a dangerous explosion; but, with the addition of the central tubes, a sufficient quantity of air rushes through them to supply any accidental vacuum. This inconvenience, however, is still more effectually obviated by Welther's tube of safety (*fig.* 2) *b*, which supersedes the expediency of three necked bottles. The apparatus being adjusted, a small quantity of water is poured into the funnel, so as to about half fill the ball *b*. When any absorption happens, the fluid rises in the ball till none remains in the tube, when a quantity of air immediately rushes in and supplies the partial vacuum in *a*. On the other hand, no gas can escape under ordinary circumstances; because any pressure from within is instantly followed by the formation of a high column of liquid in the perpendicular tube, which resists the egress of the gas.

We have already observed that various modifications of this apparatus have been proposed, an account of which may be seen in different chemical treatises: the above description is taken almost entirely from Dr. Henry's 'Elements.'

WOUNDING. [MAIM.]

WOUNDS, in Surgery, are solutions of the continuity of the soft parts of the body effected by some external agent, and attended with a greater or less amount of bleeding. Wounds vary in their character according to the kind of instrument by which they have been produced, as well as the greater or less amount of force with which it has been applied. In order to facilitate the description of treatment, surgical writers have divided wounds into several kinds. Thus they are spoken of generally under the terms incised, punctured, contused, lacerated, poisoned, and gunshot wounds. Wounds of particular parts, requiring peculiar treatment, are also described, as of the head, throat, chest, &c.

Incised wounds, cuts, or *incisions* are produced by cutting instruments, and are free from contusion and laceration. *Punctured wounds*, or *stabs*, are caused by pointed weapons, as bayonets, lances, nails, thorns, &c., penetrating deep into the flesh. *Contused* and *lacerated wounds* are produced by the violent application of hard blunt and obtuse bodies to the soft parts; and under this head might be included *gunshot wounds*. *Poisoned wounds* are those which are complicated with the introduction of a poison into the wounded part. Wounds are more or less dangerous according to the extent of soft parts they involve, the parts they occur in, and the state of health of the individual wounded. In small wounds, unless poisoned, the system generally suffers little in consequence; but when a large amount of soft parts is injured, symptoms of fever come on from twenty to thirty hours after the receipt of the wound, which require attention on the part of the surgeon, as, according to the constitution and circumstances of the patient, the fever may vary greatly, and require opposite modes of treatment. The fever is called symptomatic, and in most cases is inflammatory.

Incised Wounds.—The effect of a cut on any part of the body is to produce a gaping space, from which blood in most cases issues, and pain is felt. The blood arises from the blood-vessels of the part having been cut through or wounded, and the pain is caused by a similar injury to the nerves. The amount of blood that issues from a wound, as well as the pain, will always depend upon the nature of the part which is injured. Some parts of the body are very copiously supplied with blood-vessels which have few nerves, and *vice versâ;* so that neither pain nor bleeding is constant according to the size of the wound. The immediate danger of incised wounds does not so much arise from the extent of parts divided as upon the kind and size of the blood-vessels which are injured. Thus extensive wounds may occur on the back and other parts of the body without producing sufficient hæmorrhage to endanger life, whilst a small puncture of the jugular vein or femoral artery might speedily occasion death. The integrity also of some parts of the nervous system is so essential to life, that the slightest wound will produce an immediate cessation of the functions of the body. Thus a small puncture of some parts of the brain, cerebellum, and spinal cord will cause immediate death. The remote consequences of wounds also vary in some measure with the kind of tissues and the organs wounded. Wounds situated near moving parts sometimes never heal. Wounds of tendinous and ligamentous structures do not heal so rapidly as those of muscular and other tissues; and thus it is that wounds of the joints are frequently healed with great difficulty.

The amount of gaping of a wound depends on the kind of tissues cut through. The skin is elastic; and thus, whenever it is cut through, the wound gapes by reason of its elasticity. Where there is much cellular tissue the wound does not gape so much, as this tissue is not elastic. Wounds of muscles differ: if the cut is in the direction of their fibres, then the wound gapes but little; but if it be across the fibres, then, owing to their contractile nature, the wound gapes very considerably. Wounds may be also made to gape or to close their edges, according to the state of flexion or extension of the muscles under the part in which they are situated.

The vessels injured in incised wounds are either *arteries* or *veins*, and each require attention from the surgeon, as the bleeding from them requires somewhat different treatment. When an artery is wounded, there is an immediate retraction of the ends of its middle and internal coats within the outer or investing coat, and also a contraction of all the coats so as to diminish the calibre of the artery. Blood flows from both ends of a divided artery, but always in greater quantity from the orifice nearest the heart. The blood from an artery can easily be distinguished by its bright red colour and by its coming out in jerks. When a cut artery is left to itself, the effusion of blood is great, but the flow becomes less and less profuse, and in passing over the roughened surface of the external sheath, from which the two inner coats have been separated by retraction, particles of the blood adhere to its loosened filaments. These particles keep increasing in number, till at last the whole space between the end of the external sheath and the ends of the two retracted coats is filled up, the blood having formed there a firm coagulated mass. When this process is completed, the bleeding from the artery stops. This mass of coagulated blood is called the *external coagulum*, but the same process is carried on within the retracted inner coats of the divided artery, and the coagulum is continued up to the point at which the artery gives off one of its branches. This coagulum terminates with a conical extremity in the middle of the tube of the artery, and is called the *internal coagulum*. The blood also which is effused outside the artery altogether coagulates, and to some extent may assist in the natural process of arresting the hæmorrhage. But these coagula of blood would not be sufficient alone to restrain the hæmorrhage; another process follows, which permanently effects this. This consists in the effusion of lymph from the parietes of the artery itself. This lymph fills up the entire extremity of the artery, and is first deposited between the external and internal coagula, but it goes on increasing till at last it occupies their position, the coagula are absorbed, and the lymph, becoming eventually organised by the development within its substance of blood-vessels, forms a part, as it were, of the artery itself, and connects it more or less with the surrounding parts.

When an artery is only partially divided or punctured, a somewhat different process takes place. Blood is effused between the artery and its sheath, both above and below the wounded part. In consequence of this the artery is distended, and a difference in the relative positions of the internal coats and the sheath takes place, and the blood coagulating is confined by the sheath over the wounded part of the internal coats. Lymph is effused as in the former case, and the cure is only effected by the obliteration of the artery.

When the veins are wounded, the blood which is poured out is of a dark colour, and comes not by jerks, but in a uniform stream. There is not so much danger from the bleeding of a vein as an artery, and it is much more easily stopped. When a vein is cut through, the opposite ends are closed by blood and the subsequent organisation of lymph, as in arteries. If only slightly punctured, and longitudinally, veins quickly heal, as is seen in the common operation of venesection. When veins are wounded obliquely or transversely, the wound is closed by a coagulum of blood, and the lips of the wound secrete lymph, which eventually becomes organised, and blocks up the whole vein. Eventually the coagulum thus formed is absorbed. This reparative process is much longer in taking place than that which occurs in arteries under the same circumstances.

Treatment.—In the treatment of incised wounds the objects in view are, first, to arrest the hæmorrhage; secondly, to remove all foreign bodies that may have been introduced into the wound; and, thirdly, to promote the union of the divided parts.

The arrest of bleeding is easily accomplished by bringing the edges of the wound together, in superficial wounds, and wounds where no large arterial or venous trunks have been injured; but where large vessels have been injured, other means will be found necessary. There is nothing perhaps which distinguishes modern surgery more than the power which it has attained of arresting hæmorrhage. The surgeon, through his knowledge of the circulation and the means of arresting mechanically the flow of blood, can venture upon cutting through all but the principal trunks of the arterial and venous system. When the bleeding from a wound is great, the first thing that can be done to arrest it is to *compress* the trunk of the artery which supplies the part. This may be done by means of the tourniquet [TOURNIQUET], or a bandage so constructed as to press down upon the artery. The circulation of the blood in the arterial trunk being arrested, the hæmorrhage from the wound will in a great measure cease. Compression however can seldom be used for a sufficient length of time to act as a curative agent in stopping the flow of blood. In the first place, although pressure by bandage may stop the supply of blood through the principal arterial trunk, it will not stop it through deeper-seated branches; and, by arresting the return of the blood by the veins, it may, under certain circumstances, tend to increase the bleeding. Even when circumstances are most favourable, the tourniquet and bandages are likely to get displaced, and thus to suffer the return of the bleeding.

The most important of the means of stopping bleeding from wounds is the *ligature*. This consists in seizing the wounded ends of the artery with a pair of forceps, or passing through it a tentaculum, and then tying up the artery in the same way that the mouth of a full sack is usually tied. For this operation all the skill that is required is anatomical knowledge. Care should be taken, whilst the necessary instruments are being prepared, that the bleeding is prevented by pressure on the trunk of the artery, or by placing the finger over the bleeding orifice itself. The forceps which are mostly used on this occasion are the common dissecting forceps, but Mr. Liston recommends a pair of forceps with hooks at their points, and which, after having grasped the artery, are kept together by means of a button or hook. "When no assistant is at hand, and in cases of emergency, the surgeon provided with this little instrument, can tie vessels without the least difficulty; and in operations, when many vessels spring, several of these forceps can be applied: there is, besides, this great advantage in their employment, that a clumsy assistant can scarcely include the point of the instrument with the vessel." (Liston.) The immediate effect of a tightly-drawn ligature is to arrest the flow of blood, to divide the middle and internal coats of the artery at the ligatured part (the external sheath remaining entire), and to narrow the canal for some extent above the ligature. The same process of cure goes on then as when the artery heals spontaneously.

Other means of arresting hæmorrhage are sometimes employed, such as the application of styptics [ASTRINGENTS], sponge, the actual cautery, caustics, &c. These, however, are seldom advisable in the case of incised wounds. There is, however, a popular prejudice in favour of applying various styptics to cuts for the purpose of stopping the bleeding, and it cannot be too generally known that all these applications are injurious, and tend to retard the cure; and that in some instances loss of life is the consequence of these applications to wounds that would have got well had they been left to themselves. [HÆMORRHAGE; ARTERY; HEART.]

The second indication in the treatment of incised wounds is the removal of foreign bodies. Unless all extraneous substances are removed from a wound, its union will not be effected, and suppuration, abscesses, and perhaps sloughing, will occur. It is in gunshot wounds that this indication requires the greatest attention, but foreign bodies are occasionally introduced into incised wounds. [GUNSHOT WOUNDS.] Wounds from broken china, glass, and earthenware frequently have fragments of these substances in them. Sharp instruments are frequently covered with dirt and various impurities; hence the importance of cleaning even incised wounds. John Hunter advocated the leaving blood on the edges of the wound, as he supposed it was the blood that became organised and united the wound; but this is now found to be erroneous, and all surgeons advocate the practice of removing as much of the blood as possible from the wound.

The third indication in the treatment of incised wounds is to bring the edges of the wound together, and to retain them so in such a manner as shall favour their speedy union. Wounds may unite in two ways—either by the establishment of an inflammation, the result of which is the secretion of pus, and the formation of what are called *granulations*, or the throwing out from the wounded parts coagulable lymph, which, becoming organised, unites the edges of the wound together. This latter process is called *union by the first intention*, and should be the great object of the surgeon in treating wounds. Evident as it may appear, that to heal a wound as quickly as possible should be the great object of the surgeon, this universal rule amongst English surgeons is objected to by some continental writers of the present day. It was at one time supposed necessary that wounds should heal only after a long and tedious process of cure by granulation, and lint and tow, bandages, compresses, and a variety of other appliances were made use of to prevent nature from effecting the object in her own way. The remnants of this practice are still found amongst the populace in our own country and some surgeons on the continent. Amongst the latter, M. Roux, of Paris, has distinguished himself by advocating the cure of wounds made in surgical operations by bringing on the tedious process of granulation.

When the blood has ceased to ooze from the sides of a wound, an effusion of lymph takes place of a plastic character. Into this lymph vessels are projected by the process of growth from the sides of the wound, and an organised union of the whole wound will frequently take place in the course of forty-eight hours. Even the extent of surface laid open by amputation of the thigh is often securely united throughout its whole extent in the space of seventy-two hours. So readily does this process occur, that there are many instances on record of parts of the body having been totally severed, and yet union by the first intention has taken place. Garengeot, in his 'Traité des Operations,' mentions a case in which a soldier's nose was bit off by one of his companions, and, being restored to its natural position immediately, a permanent union of the separated part was effected. Fioraventi, Blegny, Balfour, Bossu, and others, have also recorded instances of the restoration of entire union of parts after total separation by accident. Hunter transferred the spurs of a cock to its comb, and the testicles of a cock into the abdomen of a hen, and found in each case that vascular union took place, and the vitality of the transferred part maintained. These instances only illustrated the restorative nature of the process of union by the first intention. It is not often that parts unite after having been once separated. A small vascular connection being preserved, tends greatly to render this process more likely to occur; and numerous instances are recorded of fingers and toes being nearly separated, and afterwards uniting by the first intention. One of the most remarkable examples in which the surgeon avails himself of a knowledge of this fact, is in what is called the Taliacotian operation. In this operation a new nose is made by paring the edges of the destitute part, and cutting a pyramidal piece of skin from the forehead, its union with the rest of the skin still being maintained at the point, and bringing it down upon the face in the form of a nose, when it unites with the pared edges, and a decent substitute for the lost member is thus produced. [TALIACOTIUS, GASPAR, in BIOG. DIV.]

In order to induce wounds to unite by the first intention, the edges ought not to be brought together till all bleeding has ceased, for the slightest quantity of blood retards and may altogether interrupt this process. When the edges of the wound are ready to be brought together, there are several modes which may be pursued of keeping them in contact. Previous to bringing the edges together, cold water may be applied to the wound upon lint. This will keep down any tendency to over-action or inflammation. It was at one time supposed that the process by which coagulable lymph was thrown out from wounds was one of inflammation, and that it was desirable that the part should be kept warm to encourage this sanatory inflammatory process. But the researches of the late Dr. McCartney, of Dublin, seem to have set this question at rest; and most physiologists look upon this process as a secretion going on under increased action, but not as an act of inflammation.

Of the various modes of keeping the edges of wounds in apposition, the application of adhesive plaster is the most common, and certainly applicable to the greater number of ordinary incised wounds. The plaster should be applied in such a manner as to maintain the edges of the wound in contact. There are, however, some wounds which are too extensive for the use of adhesive plaster, and then the suture is used, which consists in bringing the edges of the wound together by sewing them up. [SUTURE.]

On this subject Mr. Liston remarks, in his 'Elements of Surgery' (p. 208): "Of late I have greatly dispensed with stitches and the common adhesive plaster, using, instead of the latter, slips of glazed ribbon smeared with a saturated solution of isinglass in brandy, which is much less irritating and more tenacious than the common adhesive compost. The parts are fixed temporarily with a single stitch, or two at most, and cloths dipped in cold water are placed over the wound. The ribbons are not applied till the adhesive substance has partly congealed and the oozing of blood ceased. The divided margins being approximated by the fingers of an assistant, the ribbons are laid gently over and held for a few seconds. Soon after a sufficient number have been applied the stitches are withdrawn, being no longer necessary. No other dressing is required, unless suppuration occur; the ribbons will adhere firmly till the completion of the cure, and thus the pain and irritation caused by frequent dressing is avoided. Even the largest wounds, as after amputation, are treated in this manner with the most satisfactory results. Of late years a plaster, made by coating oiled silk with a solution of isinglass, has been used instead; the glazed surface of the slips is moistened and applied as here directed." Surgery is deeply indebted to Mr. Liston for the bold and fearless manner in which he has carried out a simple and natural treatment of incised wounds.

Wounds, however, under the best of treatment will not always unite by the first intention: the consequence is, that the parts which do not unite at once will suppurate, and granulations will be formed. This is called *union by the second intention*. [INFLAMMATION.] When this process takes place, then all applications to procure union by the first intention must be abandoned, and all attention must be given to curing the wound by the process of granulation. Plasters, sutures, and bandages must be removed; and where the inflammation is great, every means should be taken to arrest it. Suppuration should be encouraged by warm fomentations, by poultices, and above all by the warm-water dressing, which consists of nothing more than pledgets of lint dipped in warm water, and then covered over with oiled silk to prevent evaporation and cooling. When the inflammatory action is subdued and granulations are forming, gentle pressure should be employed for the purpose of avoiding the formation of more new matter by granulation than is absolutely necessary. The dressings at this period should be light. Some surgeons are fond of ointments, which may always be dispensed with; but in some cases of languid granulation a stimulating ointment is useful. Lotions are generally better. A weak solution of sulphate of zinc or nitrate of silver may be mostly employed with advantage. The wound itself does not require the washing and sponging and dabbing to which it is so frequently submitted; but the skin about the wound cannot be kept too clean and free from impurities of every kind.

Punctured Wounds.—These wounds are dangerous from their depth, and the internal effusion of serum and blood which usually attend them. In consequence of this, these wounds are frequently followed by severe inflammation and suppuration. These results used to be attempted to be obviated by the practice of dilatation. This, however, is severe practice, and only justifiable in cases of the existence of a foreign body. Setons are recommended by the French surgeons for these wounds, but there are so many objections to them, that they are seldom used by surgeons in this country. Whether these wounds unite by the first or second intention, they require to be healed upon the same general principles as incised and gunshot wounds.

Contused and Lacerated Wounds.—These result from the collision of blunt, obtuse, hard bodies, being forcibly driven against the living textures. Although these wounds may occur independent of gunshot, it is in the class of wounds called gunshot that the best examples of lacerated and contused wounds occur. The rapid introduction of powerful machinery into the manufactures of this country renders contused and lacerated wounds of very frequent occurrence in our large towns. In these wounds there is seldom much bleeding, arising from the coats of the arteries becoming twisted and doubled up by the force of their retraction. They are much more liable to have foreign bodies in them than incised wounds. Such wounds seldom unite by the first intention, but in their treatment this object should always be kept in view, as frequently portions of the wound may be induced to unite. During suppuration and granulation, the same plan of treatment should be pursued as when these processes occur in incised wounds. The constitutional symptoms arising from these wounds are generally more severe than from any others, and require attention. Symptomatic fever must be treated according to the same general principles laid down for the treatment of fevers. [FEVERS.] Another consequence of these wounds is that dreadful state of the nervous system called tetanus [TETANUS], which often resists all kinds of treatment.

Poisoned Wounds.—The principal forms of this class of wounds seen in this country arise from the bites of rabid animals, pricks and cuts received in dissection, and the bites of vipers and the stings of insects. The bites of rabid animals are unfortunately too common, and often in this country require the attention of the surgeon. When the poison is introduced into the system, it produces the fearful disease known by the name of hydrophobia, for which medical science has not hitherto found a remedy. [HYDROPHOBIA.] Where persons have been bitten by cats, dogs, or wolves in a rabid state, the wound should be immediately excised, and the nitrate of silver (lunar caustic) applied to the wound.

Dissecting Wounds.—Under this head may be included not only the punctures and cuts to which medical men are exposed in the examination of the dead human body, but all those wounds after which ill consequences ensue, in which there is reason to suppose some poison generated in an animal organisation has been introduced into the system. It is still sometimes discussed in books on surgery, as to whether the effects following these wounds are produced by a peculiar poison or are only the result of a slight wound in a constitution predisposed to disease. The frequency of the ill effects of these wounds amongst medical men, as compared with other classes of persons, equally liable to pricking and cutting their fingers, must decide this question in favour of the existence of a poison. It is not, however, as is generally supposed, that putrescent bodies and those advanced in decomposition are most injurious, for it is generally found that the worst consequences follow wounds from recent bodies, especially of persons who die of puerperal peritonitis. The consequences following these cuts are uneasiness and festering the wounded part, the absorbent glands up the arm become inflamed, there is pain felt in the arm and in the glands of the axilla: these symptoms are attended with more orl ess fever, and generally great anxiety. These symptoms sometimes increase, the cellular tissue of the arm and side becomes inflamed, abscesses form, and the patient sometimes dies from the fever or subsequent exhaustion. This disease is principally confined to medical men, and much difference of opinion has existed as to its treatment. Formerly tonics, wine, and brandy were administered, and active means taken to destroy the poison by caustic potash, liquor ammoniæ, nitric acid, &c.; but at the present day there is a general opinion in favour of mild antiphlogistic treatment, and having recourse only to tonics and wine when the symptoms seem to require it. Leeches, bleeding, purgatives, antimonials, and opium constitute the chief features of the treatment in the early and inflammatory stage. The application of lunar caustic, a solution of alum, and other things, have been recommended immediately after the receipt of the wound; but, after some considerable experience, it may be doubted if these things prevent the absorption of the poison. At any rate, if any good is to be done, the application must be immediate.

Bites of Venomous Snakes.—These are frequently fatal in tropical climates. The only snake that is to be feared in Great Britain is the viper. Its bite, however, is seldom fatal except where some peculiar state of the constitution is favourable. Immediately on the receipt of the bite a pain and a burning sensation are felt in the part, which are followed by rapid swelling and a livid discoloration of the part. The constitution becomes affected also rapidly, and there is giddiness, extreme prostration of strength, depression of spirits, faintness, syncope, a small quick irregular pulse, difficulty of respiration, profuse cold clammy sweats, confusion of vision, headache, vomiting of bilious matter, a general yellow tinge of the skin, and a great pain about the navel. These symptoms are observed in greater or less degree to follow the bites of most venomous snakes. The bite of some of the snakes of Africa and America is certainly fatal, and persons die in a few hours after receiving the wound.

In the treatment of cases of bites from snakes, the first object should be to endeavour to prevent the passage of the poison into the system. Various modes are adopted for fulfilling this intention. The most effective is the immediate excision of the part. This will hardly be required after the bite of the British viper, as it seldom proves fatal; but it is frequently the only remedy with regard to tropical snakes. The application of the tourniquet or a ligature above the wounded part has been recommended; also the application of cupping-glasses. These remedies, however, do not extract the poison, and only arrest its effect. The application of caustic may in some instances have the effect of destroying the poison. Various local applications have had a great reputation for their prevention of the effects of the poison of snakes, but none of them seem entitled to any consideration. The treatment of the constitutional symptoms consists in the administration of stimulants: of these, ammonia is preferred. It is the basis of the *Eau de luce*, a remedy once very popular for the bite of snakes. Mr. Ireland, whilst in the West Indies as a surgeon to a regiment, employed arsenic in doses of one grain as a remedy against the effects of the bite of the *Coluber carinatus*. In South America, the plant they call Guaco is said to have a very beneficial effect. Poeppig, in his 'Reise,' has collected all the evidence which he could procure of the value of Guaco in these cases, but this is far from being satisfactory as to the value of this remedy. Cases from the bites of rattlesnakes and other poisonous serpents have occurred in this country, as these reptiles are often brought over here for the purposes of exhibition. A man died a few years since from this cause in St. George's Hospital.

Wounds of Particular Parts of the Body.—When any of the viscera of the body are wounded, questions frequently arise as to the treatment, which can hardly be answered by general principles: hence the wounds of particular parts of the body require consideration. Wounds of the head are frequently accompanied with concussion and compression requiring a modification of the treatment. Wounds of the scalp are also frequently attended with severe inflammatory symptoms, and no injuries of the body require more attention and close watching than these. Of all wounds which the surgeon is called on to treat, those of the throat are perhaps the most common, and require the most prompt attention. These wounds are generally the result of attempted suicide, and vary in extent according to the greater or less determination of the individual, as well as the edge of the instrument used for effecting the wound. The first thing to be attended to in these cases is to arrest the hæmorrhage, which must be done by placing ligatures on the wounded arteries.

When the trachea is opened, the entrance of blood into the lungs should be avoided as much as possible, as its existence there as a foreign body may bring on inflammation of the lungs. When a wound occurs in the larynx above the rima glottidis, every attention should be paid to removing anything that may irritate the glottis or prevent the free passage of air to the lungs. When the œsophagus is wounded, all the food of the patient should be administered by means of a tube passed through the mouth, nostrils, or the wound. It is sometimes the case that a surgeon sent for to a cut throat will attempt immediately to bring the edges of the wound together by sutures. If this be done the chances are that the patient will die of suffocation as soon as this is effected. When the bleeding has ceased, an attempt should be made gradually to bring together again the disunited parts. This is frequently done with the most perfect success, and sometimes the very worst cases of cut throat will recover. It will, however, generally require great skill and attention on the part of the surgeon to meet all the difficulties that will arise in the treatment of cases where so many important organs are involved.

Wounds of the chest become dangerous when they involve the viscera of the thorax, and several important questions arise out of the nature and extent of these wounds. The most important complications of these are—1, the entrance of foreign bodies into the cavity of the thorax; 2, the injury of one or more of the intercostal arteries; 3, the protrusion of a portion of lung from the wound; 4, the occurrence of emphysema from the wounding the lungs; and 5, extravasation of blood in the cavity of the thorax. Wounds of the *abdomen*, when superficial, require the same treatment as wounds generally. In penetrating wounds of the abdomen there is always great danger of the occurrence of peritonitis, which requires watching on the part of the surgeon. In cases where there is protrusion, the same general treatment will be required as for hernia. [HERNIA.]

(Cooper's *Dictionary of Surgery*; Cooper's *First Lines of Surgery*; Cooper's, Sir Astley, *Lectures on Surgery*; Liston's *Elements of Surgery*.)

WRANGLER. In old times the word Wrangle was used in the universities in the sense of "to dispute publicly," that is, to defend or oppose a thesis. The verb has gradually acquired a meaning of reproach (being made to imply uncivil and indecorous opposition), which it had as early as the time of Shakspere. In the 'Taming of the Shrew,' the teacher of music says to the scholar—

> "*Wrangling* pedant, this is
> The patroness of heavenly *harmony*."

The substantive *Wrangler* is hardly ever used, except as significative of a person who has passed the mathematical examination for the Bachelor's degree in the university of Cambridge (the word is unknown in Oxford) with such credit as to have had his name inscribed in the highest list, or list of wranglers. Of these the first in merit is the *Senior* Wrangler: but persons not accustomed to the phraseology of the University are apt to confound Wrangler with Senior Wrangler, that is, to imagine that any one of their friends who may have obtained a wranglership must necessarily be the first man of his year. The second list is that of *Senior Optimés*, as they are called, and the last that of *Junior Optimés*. All who are in these three lists (which are collectively called the mathematical Tripos) are said to take the Bachelor's degree *with honours*, or to *go out in honours*; those whose names appear in the Classical Tripos are said to take classical honours; while the remainder, who are called the οἱ πολλοί, abbreviated into "the Pol," though they equally take the Bachelor's degree, are not supposed to be *honoured*. But in point of fact, the last of the Junior Optimés, or the last on the list of honours, has always been considered an unfortunate person, and the name of *the wooden spoon* * has long been attached to his place. It is not as if all were examined together, and the honoured were selected out of the whole list: those who wish to go out in honours declare their intention and are examined separately; so that it frequently happens that the last of the honoured graduates is a person of very inferior attainments to many at the head of the unhonoured multitude. With regard to the facetious terms current in the universities, it should be known that the nicknames invented by undergraduates are generally adopted in the university, which become therefore real and well-known denominations. From the vice-chancellor to the freshman of yesterday, the last of the honoured is the wooden spoon: and he must be a formal man (a "regular Don" the undergraduates would call him) who, in speaking of the "previous examination," as it is styled in the grace of the Senate which established it, should use those words instead of "the little go," a term which was borrowed from the Oxonians as soon as the grace was passed.

There is no history extant of the original introduction of the terms wrangler, senior optimé, and junior optimé. Huber, whose history of our universities has been translated by Mr. Newman, says that every attempt he has made to unravel the skein of university technicalities has made him giddy with headache. A Cambridge man however finds no difficulty in seeing how the word was used, as applied to the manner in which an examination (not a public disputation) is passed. The examination which takes place in January, and at which a young man is said to "take his degree" (because in fact he then does all that will be asked of him, the old disputations having long been abandoned), in old times was not an examination for the B.A. degree, but for the right of being admitted to perform the disputations necessary for a degree. All degrees were originally gained by disputations, the substitution of an examination, to see whether the candidates were fit to dispute, being a thing of comparatively modern times. The vice-chancellor, when

* Since the institution of the classical honours, to which mathematical ones are a necessary preliminary at Cambridge, the wooden spoon has frequently been a distinguished classic, who did not need nor wish for anything except the formal place on the mathematical list, which was required previously to competition for a place in the classical one, though by recent changes classical honours may be obtained without the necessity of passing the mathematical examination, and the degree of B.A. be obtained through the classical tripos.

the examination was over, admitted the candidates, not to the Bachelor's degree, but "ad respondendum questioni," and the person thus admitted was called a questionist. The form of asking some trifling question, or keeping a mock act [Act] was afterwards performed between the questionist and the *Father* of his college, which is the name given to one of the fellows whose duty it is to present the candidates of his college to the vice-chancellor. On the Thursday after Midlent Sunday the vice-chancellor used to declare all the questionists (who in the interval had borne the name and assumed the dress of Bachelor of Arts) "actualiter esse in artibus baccalaureos." The term wrangler then must imply one who is held more than usually qualified to proceed to the disputations which were once the practical test of his fitness for the degree.

The Tripos lists are given in the 'Cambridge Calendar' from 1747 downwards; but the wranglers and senior optimés form one list till 1752 inclusive. It is said that the regular order of previous years cannot be ascertained, as the proctors were in the habit of making honorary senior optimés, and placing them in the list at pleasure.

WRECK. [Shipwreck.]

WRIT, a law term, which in its proper signification means a *writing* under the king's seal, whereby he confers some right or privilege, or commands some act to be done. Writs are either *patent* (open, commonly called *letters patent*, *literæ patentes*), which are not sealed up, but have the great seal attached to them; or *close* (*literæ clausæ*), which are, or are supposed to be, sealed up. The former are addressed to all persons indiscriminately, generally in these terms—"To all to whom these presents shall come;" the latter are directed to some officer or other individual. Of the former kind is the creation of a peer by patent, which is a royal grant of peerage; of the latter, the creation of a peer by writ, which is a summons to attend the house of peers by the style and title of some barony.

Writ in its ordinary and more limited sense is a term applicable to a process in *civil* or *criminal* proceedings. Civil writs are divisible into *original* and *judicial;* original writs issue out of the Court of Chancery, and give authority to the courts, in which they are returnable, to proceed with the cause; judicial writs are awarded by the court in which the action is already pending. These are again subdivided into *mesne* and *final*. Original writs (which have been superseded by the writ of summons) used to contain a *brief* statement of the plaintiff's alleged cause of action; and such a writ was called in law Latin *breve*, in law French *brief:* and this term was afterwards applied to judicial and other writs. Original writs issuing from Chancery were always witnessed, or *tested*, in the name of the king; judicial writs issued from that one of the superior common law courts in which the original writ was made returnable, and were tested in the name of the chief judge of such court.

There are many kinds of writs, some of the more important of which may be here mentioned. There is the writ to the sheriff of a county to elect a member or members of the Commons' House of Parliament, in case of a vacancy or general election, which issues upon the warrant of the lord chancellor, or in certain cases of the speaker of the House of Commons. The writ of *habeas corpus* (*ad subjiciendum*), which is directed to any person who detains another, commanding him to produce the body of the prisoner at such a time and place, together with the cause of his caption and detention, to do, submit to, and receive (*ad faciendum, subjiciendum, et recipiendum*) whatever the court or judge by whom the writ is awarded shall think fit. [Habeas Corpus.] There are various other writs of *habeas corpus*, for the purpose of bringing up prisoners to be charged in execution, to give testimony, &c.—the writs of *subpœna ad testificandum*, by which a party is commanded to appear at the trial of a cause, to give evidence under a pecuniary *penalty;* and of *subpœna duces tecum*, by which the party is commanded to bring certain specified documents for the purpose of the trial. A defendant privileged from the particular suit, or from being sued except before some other tribunal, is entitled to a writ of *privilege*, by which the court is required to discontinue the suit. In modern times a party is allowed his privilege without suing out any *writ* of privilege.

WRIT OF ERROR. Writs of error in purely civil suits are abolished by the Common Law Procedure Acts, and a more simple procedure for reviewing and correcting the decisions of the superior and other courts of record was established. [Error.]

In criminal cases there is a writ of error from all inferior courts to the Queen's Bench, and from that to the House of Lords.

WRIT OF INQUIRY. In cases where a plaintiff seeks to recover a specific chattel (as in the action of *detinue*), or a specific sum of money (as in *debt*), if the defendant allows judgment to go against him by default, this is considered as an admission that the plaintiff is entitled to what he claims; and the judgment therefore is final in the first instance, provided the plaintiff is content to take a small nominal sum for the damages resulting from the detention of the chattel or the debt. But where a plaintiff only seeks to obtain damages for an injury done to his person or his real or personal estate, or for the non-performance of a promise, if the defendant lets judgment go by default, this, though an admission that the plaintiff has a cause of action, does not operate as an admission of the amount of damages to which he is entitled; and such judgment is called interlocutory. In such cases, and also where the plaintiff seeks to recover substantial damages for the detention of a chattel, or of a debt, the intervention of a jury is required in order to ascertain for what damages the plaintiff is entitled to have final judgment. For this purpose, a *judicial* process, called a *writ of inquiry*, issues to the sheriff, commanding him to summon a jury to inquire what damages the plaintiff has sustained. If the plaintiff offer no evidence before the jury, a verdict must be found for nominal damages, as existence of *some* damage is admitted.

When the *inquisition* (or finding of the jury) is returned, the plaintiff is entitled to judgment for that amount.

WRIT OF SUMMONS. [Writ.]

WRIT OF TRIAL. All trials of causes in the superior courts took place formerly either at *bar* before the whole court, or at *nisi prius* before one of the judges of the court, or a judge or serjeant named in the commission of assize; but now, by the 3 & 4 Will. IV., c. 42, s. 17, in any action depending in any of the superior courts for any *debt* or *demand* in which the sum sought to be recovered and indorsed on the writ of summons shall not exceed 20*l.*, the court, or a judge (if satisfied that the trial will not involve any difficult question of fact or law), may order the trial to take place before the sheriff of the county where the action is brought, or some judge of an inferior court, and for that purpose a writ shall issue (called the Writ of Trial) directed to the sheriff or such judge, commanding him to try the cause before a jury, and to return such writ with the finding of the jury thereon indorsed. The statute applies only to actions for a *debt* or *demand* indorsed on the writ of summons; it does not therefore extend to cases where the action is brought for a wrong, or where the demand, being for unliquidated damages, the amount claimed cannot properly be indorsed on the writ of summons. The proceedings under the writ of trial, when directed to the sheriff, usually take place before his under-sheriff or other his deputy; and they are conducted in the same manner as at a trial at *nisi prius:* and the court will grant a new trial for the same causes as if the trial had been before one of the superior judges; but a new trial will not be granted upon the ground that the verdict is against the evidence, where the amount of such verdict is less than 5*l.*, unless such verdict be manifestly *perverse*.

WRITER, in Scotland, is a term of nearly the same meaning as attorney in England, and is generally applied to all legal practitioners who do not belong to the bar. The body who in Edinburgh enjoy, concurrently with writers to the signet, the privilege of conducting cases before the Court of Session, the Court of Justiciary, &c., are called solicitors of supreme courts (abbreviated S. S. C.), and the practitioners before the sheriff court of Aberdeen are by local custom called advocates. In each county there is generally a society of writers privileged to practise in the sheriff court and in the other local judicatories, who frame their own bye-laws, and regulate the terms of admission to their body. Individually, they are responsible for their conduct to the local judges before whom they practise: and as bodies they are, on the one hand, protected from the infringement of their privileges by unlicensed persons, and on the other, liable to judicial control if they attempt unduly to restrict the means of admission to their privileges.

WRITER TO THE SIGNET, abbreviated W.S., is the designation of the members of that class of attorneys or procurators who enjoy, in common with the solicitors of supreme courts, and with one or two smaller bodies, the privilege of conducting cases before the Court of Session, the Court of Justiciary, and the Commission of Teinds. Their peculiar privilege, however, is that of preparing the writs which pass the royal signet. The signet was a seal or die under the control of the secretary of state, with which the writs by which the king directed parties to appear in court, or ordered them to obey the decrees given against them, and other executive instructions, were stamped for the sake of authentication. In the 16th century, the persons who were entitled to present the writs which received the impression of the signet are supposed to have been the clerks in the secretary of state's office; and it is not known how or precisely at what time the persons who transacted this department of official business became converted into a body of private practitioners. Since the Union of 1707, the signet has been under the disposal of the Court of Session; but down to about the middle of last century the keeper of the signet was deputed by the secretary of state for the home department. Since that time he has been appointed under the great seal, and he names a deputy, who is a member of the society of writers to the signet, and by usage presides at their meetings. In the general case the summons by which an ordinary action is brought into the Court of Session requires to be signeted, and to be, as a preliminary, signed by a writer to the signet; although a member of one of the other privileged bodies may conduct the case. Advocation [Advocation], and some other analogous classes of procedure, required formerly to have the interposition of the signet; but this step in the procedure has been abolished. The writers to the signet now possess few privileges which are not shared by the other practitioners before the supreme courts. They still retain their privileges as to summonses, and they have the exclusive right of presenting signatures in exchequer, or of presenting, through the judges acting in exchequer, the indorsed drafts of the writs passing under the great and other seals in Scotland appended to crown charters, appointments to offices, &c. They have thus a monopoly of the business of making up the titles of the crown vassals in Scotland. The society require of their intrants an apprenticeship of five years, with a curriculum of university study, which includes two sessions of attendance, the one at Latin and the other at some other literary class, and four courses of attendance at law classes. The writers to the signet possess a library, the collecting of which commenced in 1755, by the purchase of some law books, to which works on other subjects were added in 1778. It is now supported by an annual grant by the society.

WRITING. [ALPHABET.]

X

X to an Englishman is the representative of what might as well be denoted by the two consonants *k s*. But in the Greek alphabet it was merely a guttural aspirate, equivalent probably to the German *ch*. The cause of this change in the power of the symbol appears to admit of the following explanation:—Before the employment by the Greeks of their character Ξ or ξ, it was their common custom to represent this sound by X Σ, as may be seen in Boeckh's inscriptions, rather than by K Σ, of which there exist however a few examples, as in the so-called Vanian Inscription. [ALPHABET, plates ii. and iii.] Now the Romans copied this Greek practice, and we consequently find in Latin inscriptions such forms as MAXSVMVS, PROXSVMVS, &c. See the Index of Marini's 'Fratelli Arvali.' So again coins give us the proper name AXSIVS, where the later orthography would have been AXIVS; and even existing manuscripts still bear traces of this orthography. Thus the Medicean MS. of Virgil has EXSESA ('Aen.', viii. 418), EXSVIT ('Aen.', viii. 567). But the Romans, being generally averse to the aspirated letters (*h* itself, though written, seems not to have been pronounced by them), had little or no occasion for the character X except in this combination with an S. The very sight therefore of an X, even before the eye came to the S, raised in the mind the idea of a sibilant, and thus rendered the sibilant itself a superfluous letter; which, because it was superfluous, would before long be omitted, and thus the single letter X would perform the office of the two consonants X S. It may be objected to this view, that in one of the oldest inscriptions, the Bacchanalian (see the plate in the seventh volume of Drakenborch's Livy), we have the form EXDEICERENT, where the letter in question already has the power of our modern *x*. This perhaps is an erroneous idea. It would probably be more correct to look upon the character in this word as the simple guttural, thus: *echdeicerent*, from which the later form *edicerent* would easily flow. A sibilant in this word would have given the same offence to a Roman, as εξδιδοναι would have done to a Greek ear. It should be recollected too that the old Latin preposition had the form *ec*, as seen in *ecfari*, *ecferre*, &c. (for thus did Cicero write these words), and that a sibilant was added only before the sounds *p*, *k*, *t*, or before a vowel. An argument against the view we have taken in reference to the change of power in the symbol might be founded upon the fact that the Spaniards employ the very same symbol as a guttural. Thus in the geographical names Xeres, Xalapa, Mexico, the X has little or nothing of a sibilant character.

The letter X was the last in the Roman alphabet, neither Y nor Z belonging to it, although the majority of Latin grammars include them. On reflection however it will be admitted that the words in which those two letters occur are not really part of the Latin language, but borrowed from the Greek, as *zephyrus*, *zona*; or from some Eastern source, as *gaza*. Such forms as *lachryma*, *hyems*, *sylva*, are simply errors of modern editors. The Romans themselves wrote *lacruma* or *lacrima*, *hiems*, or rather *hiemps*, and *silva*. But the fact that *x* was the final letter of the Roman alphabet is established by an anecdote in the Life of Augustus by Suetonius (c.88).

The interchanges of *x* with other letters are as follows:—

1. *x* with *c*, as in the double form, already mentioned, of the Latin or Greek preposition *ex* or *ec*.

2. *x* with *sc* or *sk*. See S.

3. *x* with *g*, as in the Latin *augeo* compared with the Greek αυξανω, and μιγ-νυμι compared with *mix*, Eng., and *mix-tus*, Latin.

4. *x* with *ps*, as the Latin *exilis* compared with the Greek ψιλος. In the same way we find an illiterate Roman officer writing *ixi* for *ipsi*, and thus too *proximus* is the superlative of *prope*. This change is in fact only another instance of the interchange of *p* and *c*, so common between Greek and Latin. See C.

5. *x* perhaps with *h*. Thus ξενος is probably in the first syllable the equivalent of the Latin *hostis* and *hospes*. See O and N. So again *hasta* is probably connected with the Greek ξεστος.

6. *x* with *z*. Thus in Spanish a *z* is found where the Latin has an *x*. For example, the Latin words *crux*, *pax*, have become in Spanish *cruz*, *paz*, whence the names of the American towns, *Vera Cruz* and *La Paz*.

XANTHAMYLAMIDE. [CARBAMIC ACID. *Sulphocarbanate of amyl.*]

XANTHAMYLIC ACID. *Amyldisulphocarbonic acid* ($C_{12}H_{12}O_2S_4 = C_2S_4\left\{\begin{matrix}C_{10}H_{11}O\\HO\end{matrix}\right)$. Xanthamylate of potash is formed on treating a solution of potash in amylic alcohol with bisulphide of carbon until alkaline reaction no longer manifests itself: the salts then crystallises out in plates; it is soluble in alcohol or ether, gives precipitates of xanthamylates with most metallic solutions, and when acted upon by hydrochloric acid yields up its xanthamylic acid.

Xanthamylic acid is an oily liquid, colourless when quite pure, but generally of a yellow tint; it has a pungent disagreeable odour, reddens litmus paper, is heavier than water, burns with a luminous flame, and is readily decomposed by water.

XANTHEIN. A yellow colouring matter contained in flowers. It is extracted by cold alcohol from the petals of yellow dahlias. Xanthein is soluble in water, alcohol, and ether, but does not crystallise from any of these solutions. Alkalies communicate to it a very rich brown colour. It communicates a brilliant yellow to tissues, and unites with most metallic bases forming yellow or brown lakes.

XANTHELENE. [XANTHIC ACID.]

XANTHENE. *Xuthene, Melene.* An unimportant and problematical derivative of hydropersulphocyanic acid.

XANTHIAN MARBLES, the designation given to a collection of architectural and sepulchral remains, from their having been chiefly found in the city of Xanthus in Lycia, a province of Asia Minor. [LYCIA, in GEOG. DIV., col. 638.] They were for the most part obtained by Sir Charles Fellows, during researches conducted at the expense of the British government in the years 1842-46, and are now deposited in the Lycian gallery of the British Museum.

The Xanthian marbles comprise sculptural remains which are believed to range in date from the conquest of Xanthus by the Persians, B.C. 545, to the period of the Byzantine empire, and vary considerably therefore in character and value. The oldest and most important are the rilievi from what is known as the Harpy Tomb, which stood near the theatre at Xanthus. This tomb was found almost entire, and consisted of a solid rectangular shaft 17 feet high, surmounted by a small chamber. The friezes on the sides of this pedestal exhibit so much refinement of feeling, combined with an almost austere purity of style, that it may be doubted whether they do not belong to a period antecedent to the Persian invasion, and are not the work consequently of the descendants of the Grecian colonists, before their taste was vitiated by Persian influence. The date usually assigned to them is about 500 B.C.

The tomb has acquired its name from four figures of similar design on the four extremities of its north and south sides, which resemble the Harpy of the ancients. The head is that of a female, the breast is exposed, and the body, which terminates with the trunk, has wings and a tail like a pigeon's; from under the wings comes a bird's claw, clasping the legs of a child, which is carried in the bosom of the figure. They are all flying upwards and outwards from the middle of each group, and are carrying off female children. There was no inscription on the tomb, which, from the flying figures carrying off the children, is supposed to allude to the story of Pandarus, king of Lycia; these figures being the harpies carrying away the daughters of Pandarus. (Homer, 'Odyssey,' b. xx.) Besides these there are seated figures, probably deities, and other personages from the Greek mythology. The figures are about three feet high, and the four compartments, about nine feet in length, form the top of the tomb, and are elevated about twenty feet above the ground upon a square shaft or pedestal of gray stone, and roofed with two flat stones of a similar material; the bas-reliefs are in white marble.

Close to this tomb stood another similar tomb of the same dimensions, entirely covered with Lycian characters. These Xanthian tombs extend over several miles of country.

Another extremely interesting series consists of a broad and a narrow frieze, and various architectural members of a remarkable Ionic structure, the purpose of which is not determined, but of which there are in the room an excellent model, according to the restoration proposed by Sir C. Fellows, under whose direction it was made, and a picture showing the appearance of the spot prior to the excavations. The friezes represent contests between the heavily-armed Greek soldiers and more lightly equipped Asiatics; the siege of a city, and a sally of the besieged; and a Persian satrap receiving a deputation. The subject referred to is usually considered to be the conquest of Lycia by the Persians under Harpagus, and the building to have been the tomb of Harpagus, or a memorial to his honour, and to have been erected in the 4th century, B.C. By some, however, the bas-reliefs are supposed to represent the suppression of the revolt of the Lycians, B.C. 387. Be that as it may, the sculptures are thoroughly Persian in character, and both in subject and style recal to the memory similar subjects among the Assyrian rilievi. Another series of bas-reliefs, part of the tomb of one Paiafa, a satrap of Lycia, has representations of warriors fighting, while on each side of the tomb was an armed figure in a quadriga. Other slabs, statues, and sculptured fragments, of a more or less debased style, carry down the illustrations of Lycian art to the period mentioned above.

(Fellows' *Journal, &c.; Account of Discoveries in Lycia; Account of the Ionic Trophy Monument excavated at Xanthus;* and *Essay on the Relative Dates of the Lycian Monuments in the British Museum;* Scharf, *Observations on the Sculptures seen on the Monuments of Ancient Lycia;* Gerhard, *Archäol. Zeitung*, 1845; *Official Synopsis of British Museum.*)

XANTHIC ACID. *Sulphocarbovinic acid. Ethyldisulphocarbonic acid* $\left(C_6H_6O_2S_4 = C_2S_4\left\{\begin{matrix}C_4H_5O\\HO\end{matrix}\right.\right)$. Xanthate of potash is formed on treating an alcoholic solution of potash with bisulphide of carbon until all alkaline reaction be neutralised; the mixture artificially cooled deposits colourless prismatic crystals, which are very soluble in water or alcohol, but insoluble in ether; dilute hydrochloric acid decomposes them and sets free xanthic acid.

Xanthic acid is so named from ξανθός, *yellow*, because it gives a yellow precipitate with salts of copper. It is oily; heavier than, and insoluble in, water; has an acid, astringent, and bitter taste, and pungent odour. Heated to ebullition it is decomposed into alcohol and bisulphide of carbon, and is very inflammable. It strongly reddens litmus paper and decomposes alkaline carbonates with effervescence.

The *xanthates* are, with the exception of xanthate of potash, unimportant. The copper salt, already referred to, seems to be accompanied by a crystallisable compound. *Xanthelene* (xanthate of ethyl), an oily liquid, is also occasionally formed at the same time, but possibly is a product of the decomposition of the crystalline body.

XANTHIC OXIDE. [Uric Group.]

XANTHIN. This name has been applied to two distinct bodies, namely, to a colouring matter contained in madder [Madder, Colouring Matters of] and to the yellow colouring matter of flowers. The latter is best extracted by treating the sunflower with boiling absolute alcohol; on cooling, the alcohol deposits the whole of the xanthin, which is of a beautiful yellow colour, insoluble in water, but soluble in hot alcohol and water. It is an uncrystallisable resinous substance.

XANTHO-COBALTIA (Co_2O_3, $5NH_3$, NO_2). An ammoniacal base containing cobalt. It is obtained in the state of sulphate by transmitting a rapid current of nitrous acid through an ammoniacal solution of sulphate of cobalt, keeping the liquid alkaline by the occasional addition of ammonia. The sulphate of xanthocobaltia has the formula

$$Co_2O_3,\ 5NH_3,\ NO_2,\ 2SO_3 + HO.$$

The nitrate and chloride have the following formulæ:—

Nitrate . . . $Co_2O_3,\ 5NH_3,\ NO_2,\ 2NO_5 + HO$

Chloride . . . $Co_2OCl_2,\ 5NH_3,\ NO_2 + HO$

[Cobalt.]

XANTHOGENAMIDE. [Carbamic Acid. *Sulphocarbamate of ethyl.*]

XANTHOPENIC ACID. [Opium, Alkaloids of, *Opiammon.*]

XANTHOPHYLL. It is well known that in autumn the foliage of many forest-trees becomes of a bright yellow colour, which, according to Berzelius, is owing to the replacement of the green colouring-matter of the leaves, or *Chlorophyll*, by a peculiar yellow colouring-matter which he calls *Xanthophyll*. The properties of this are, that it is a fatty substance of a deep yellow colour, which melts between 100° and 120° Fahr.: it is insoluble in water, but dissolves copiously in alcohol and ether; its solution exposed to air and light is rapidly bleached; alkalis dissolve it sparingly.

XANTHOPICRITE. *Xanthopicrin.* A substance contained in the bark of the *Xanthoxylum Clava-Herculis, L.*, employed in the Antilles as a febrifuge. It crystallises in greenish-yellow silky needles, which are bitter and astringent, readily soluble in alcohol, slightly so in water, and insoluble in ether. It possesses neither acid nor alkaline qualities.

XANTHOPROTEIC ACID ($C_{34}H_{25}N_4O_{14}$?). According to Mulder, this acid is formed when albumen or any other protein compound is digested in nitric acid; these dissolve with the escape of nitrogen gas, and yield a yellow-coloured solution, while oxalic acid and ammonia are formed.

Two equivalents of protein, 1 of water, and 2 of nitric acid, yield 3 of oxalic acid, 2 of ammonia, and 1 of xanthoproteic acid. After being washed with boiling water, this acid exists as a tasteless orange-yellow powder, which combines with acids as perfectly as with bases; its compounds with the latter dissolve in water, and give dark-red coloured solutions.

XANTHORHAMNIN. [Chrysorhamnin.]

XANTHOXYLENE. [Essential Oils; *xanthoxylum.*]

XANTHOXYLIN. [Essential Oils; *xanthoxylum.*]

XIPHIAS (constellation). [Dorado.]

XUTHENE. [Xanthin.]

XYLENE. [Xylole.]

XYLIDINE. [Xylole.]

XYLITE ($C_{12}H_{12}O_6$?). According to Gmelin, when commercial pyroxylic spirit is submitted to distillation from chloride of calcium, a vapour rises, which condenses into a liquid, which he calls *xylite.*

The properties of this substance are, that it strongly resembles alcohol; its odour is like that of ether and agreeable, and its taste is empyreumatic; its specific gravity is 0·816, and its boiling-point about 143° Fahr.: it is miscible with water, and burns with a white flame. The density of its vapour was found by experiment to be 2·177; by theory it should be rather lighter.

With acids xylite produces ethereal compounds, which have not been minutely examined; and by partial decomposition it gives rise to *xylitic acid, xylite naphtha, xylite resin,* and *xylite oil;* these substances, however, have not hitherto been very particularly subjected to experiment, and the whole of these bodies require re-investigation.

XYLITE NAPHTHA. [Xylite.]

XYLOIDIN. *Pyroxam* or *nitramidine* ($C_{12}H_9(NO_4)O_{10}$?). A substance allied to pyroxylin. [Gun-cotton.] Starch is dissolved in nitric acid of sp. gr. 1·5, and the solution immediately diluted with water: a white, tasteless substance is then precipitated which is the body termed pyroxylin. It is insoluble in water, alcohol, or ether, and when heated to 356° Fahr. burns rapidly, after the manner of gun-cotton. It explodes when smartly struck on an anvil by a hammer, but less powerfully than gun-cotton. It also leaves much carbonaceous residue when burnt, and, unlike pyroxylin, is easily soluble in nitric acid. Protosalts of iron reliberate starch from xyloïdin.

XYLOLE ($C_{16}H_{10}$). *Xylene.* A volatile liquid hydrocarbon homologous with benzole, &c., of the series C_nH_{n-6}. It is one of the constituents of the oily impurities contained in commercial wood-spirit, and which separate on the addition of water. It is purified by agitation with concentrated sulphuric acid and fractional distillation.

Xylole is a limpid colourless fluid; boiling point 259° Fahr. Fuming nitric acid converts it into *nitro-xylole*, a yellow oil heavier than water and of an odour somewhat resembling, but less pleasant than, that of nitrobenzole. Nordhausen sulphuric acid slowly combines with it and forms colourless, deliquescent, acicular crystals of *sulfo-xyloic* or *xylenylsulphurous acid* ($C_{16}H_{10}S_2O_6$). Nitric acid acts upon the latter compound to form *nitro-sulfo-xyloic* or *nitro-xylenylsulphurous acid* ($C_{16}H_9(NO_4)S_2O_6$).

Xylidine ($C_{16}H_{11}N$). This alkaloid much resembles its homologues, toluidine, &c. It is produced by the reaction of nitroxylole and sulphide of ammonium. When pure it is almost colourless, but becomes purple on exposure to air and finally resinifies. It turns red litmus paper blue; boiling point 416° Fahr.

XYLORETIN ($C_{40}H_{33}O_4$?). A fossil resin found in Danish peat. It crystallises in confused prisms, which are insoluble in water, but very soluble in alcohol and ether.

Y

Y has found its way into the alphabets of Western Europe through the later Latin alphabet from the Greek. The oldest form of the Greek character appears to have had no vertical stroke, but to have been precisely the same as the English or Roman V, so that the small character *v* differed from the other form only in the usual substitution of a curve for an angle. We have said that the letter Y belonged only to the *later* Roman alphabet. This fact has been already remarked upon under X; and an argument in confirmation of what is there asserted may be drawn from the consideration that the Romans already possessed in their V the representative of the Greek letter. How then, it may be asked, was it that they subsequently adopted this letter? The answer would probably be this—that the Greek character had changed its power from the original sound of *oo*, such as is still represented by the Italian *u*, to a sound probably like that of the French *u*, or even to a weak *i*. If we traced the Greek letter Y or V still farther back, we should perhaps arrive at the opinion that it grew itself out of a carelessly written O. The Hebrew character which corresponds to O, namely, ע, already exhibits the opening above, just as the Hebrew ט does, compared with the Greek Θ. So too the English often write a capital O without joining the circle at the top. To these considerations may be added the fact that the Hebrew alphabet, which ended with a T, contains no other equivalent for the Greek Υ: and again the Etruscans had but one character, V, without any O. That the introduction of the character Y into Latin words has been carried beyond the proper limit has been already remarked [X]; and we would add to what has been there said, that in the well-known Medicean Manuscript of Virgil there is something suspicious in the fact that this letter always overtops the other letters in such a manner that the vertical shaft is of the same height with them; and thus it is possible that the horns, if we may so call them, were attached by a subsequent hand, the manuscript until then having merely an I. (See Foggini's reprint of that Manuscript, and the second line of the copperplate facsimile of the same (amadryades) in Burmann's 'Virgil,' vol. i., facing p. xxxvi. of the preface.)

In the English language there is a great tendency to use this letter at the end of words. This has probably arisen from our habit of giving a tail to the last unit of the Roman numerals, preferring *ij, iij, vj, vij*, &c.; so that to please the eye and give a sort of finish to a word, *say, boy, they*, were preferred to *sai, boi, thei*. Before we leave the form of the letter, it may be observed that in y^e, y^t, for *the, that*, the *y* has been by an easy error substituted for the Anglo-Saxon þ, which had the power of *th*.

The sound of *y*, so familiar to the English at the beginning of words, as in *yes, young, yoke*, was represented in Latin by a mere *i*, which however, when so used, received from the grammarians the distinctive name of *i consonans*. Our modern editors have for the most part substituted for it a *j*. Thus, *iugum*, or rather IVGVM, which is now written *jugum*, commenced with a sound which is commonly held to have been the same with our initial *y* in *yoke*. The insertion of the sound of a *y* before vowels is very characteristic of the Russian language, the alphabet of which has no less than four characters which denote such a sound. The English too have a habit of expressing the sound, though they do not write the letter, whenever a long *u* begins a word, as *union, unity, useful*; so that those who write *an useful contrivance* insert a letter at the end of the first word which no one would pronounce. In Anglo-Saxon the sound of a *y* was commonly represented by an *e* before *a* or *o*, and by an *i* before *e* or *u*, in which cases the allied languages of Iceland, Denmark, and Sweden for the most part employ a *j*. Thus the Anglo-Saxon writes *eorl, Eotaland, eow, Eadward, eahta, bebd-an* for *earl, Jutland, you, Edward, eight, to bid*. On the other hand, *iett, iúgoth*, represent *yet, youth*. (Rask's 'Grammar.') In several of these words the initial *y* no longer appears in modern English. But it would be unsafe to infer that the change always takes place in that direction, for one who observes children in their early attempts to speak, will find that many are apt to prefix either a *w* or a *y* to all words beginning with a vowel. Thus we have heard a child pronounce *Uncle, Agnes, apple—Yung, Yang, wap*; so that the prefixing a *y* where there was none, is just as possible as to drop a previously existing *y*. The sound of *y* again is heard where the French write *ll* or *gn*, as in *vaillant, agneau*; in the Spanish *ll* or *ñ*, as in *Mallorca, Coruña*; in the Portuguese *lh* or *nh*, as in *filho, Minho*; and in the Italian *gl* or *gn*, as in *figlio, agnello*. For the interchange of *y* with *g*, see G; for the use of *z* with the sound of *y*, see Z; lastly, for the connection between the sounds of *j* and *y*, see J and Z.

YACHT. A vessel used for pleasure on the water. The love of yachting indicates a prominent feature of the national character. Clubs and societies are formed all round the coasts of Great Britain, many of them possessing some of the finest specimens of naval architecture. Of late years pleasure trips to distant countries have much improved the style and class of vessels used for recreation. Wealthy owners have often encouraged novel appliances, and assisted in nautical experiments, which would otherwise have fallen into neglect.

There are two distinct species of yachts, which are recognisable at sight, namely: the mere racer, with enormous spars and sails, and deeply ballasted hull, with the finest lines imaginable, but sacrificing space and comfort to speed; and the elegant, well-proportioned, commodious, safe, but well-manned and fast-sailing family yacht, able to encounter the wars of the elements in any part of the globe. Those accustomed to river navigation only, and who desire to consult the models of thorough "sea-boats," will do well to examine some of the Cowes pilot cutters, and the pilot schooners of the Mersey. Every precautionary appliance needed for the roughest and nicest practice of seamanship may be found fitted in them with studied compactness. Our principal rivers and estuaries in the summer months abound with beautifully-modelled small craft, while the Solent pre-eminently offers the spectacle of a brilliant fleet, owned as well by the wealthy commoner as by the peer.

YARD. [WEIGHTS AND MEASURES.]

YARN. [THREAD.]

YEAR. Much connected with this article is to be found in KALENDAR, PERIODS OF REVOLUTION, MOON, SUN, CHRONOLOGY, TIME, &c. We here confine ourselves to matters of useful reference connected with the length and subdivisions of the year, omitting discussion of points of history, which do not directly bear upon chronological reckoning.

The year is, roughly speaking, the period of time in which the sun makes the circuit of the heavens, and the seasons of agriculture run through their course.

A *sidereal* year is the period in which the sun moves from a star to the same again; that is, the interval between the two times when the sun has the same longitude as a given star. The mean period is 365·2563612 mean solar days, or $365^d\ 6^h\ 9^m\ 9^s{\cdot}6$.

A *tropical* or *civil* year is the time in which the sun moves from the vernal equinox to the vernal equinox again; and its mean length is 365·2422414 mean solar days, or $365^d\ 5^h\ 48^m\ 49^s{\cdot}7$.

The *anomalistic* year is the time in which the sun moves from its perigee (or nearest point to the earth) to its perigee again; and its length is 365·2595981 mean solar days, or $365^d\ 6^h\ 13^m\ 49^s{\cdot}3$.

The tropical year is shorter than the sun's actual orbital revolution, or the sidereal year, because the equinox moves slowly backwards [PRECESSION], and therefore the sun meets it again before it arrives at the point at which it met it last. The anomalistic year is longer than the sidereal year because the perigee moves forward, and the sun is not nearest to the earth until it has passed the longitude at which it was nearest to the earth before. The *tropical* year is *the* year, when no distinctive term is applied; for the passage of the sun from the southern to the northern side of the ecliptic is the positive phenomenon on which the seasons *depend*, though it may not be correct to say that it is then that the succession of seasons *begins*.

The anomalistic year does not, and from the theory of gravitation most probably cannot, vary by any quantity which the human senses could appreciate; but the sidereal and tropical years vary very slowly in length. The reason is twofold. In the first place, the amount of the yearly precession of the equinoxes is slowly increasing; so that the part of the orbit by which the equinox moves backwards to meet the sun becomes greater, or the duration of the year less. In the second place, the gradual motion of the equinox, combined with that of the perigee, brings the part of the orbit which the sun is saved from performing by the recession of the equinox into different places with respect to the perigee in successive years; so that the excepted portion is in different years what would have been described in different times. The second consideration affects the sidereal year as well as the tropical; but since in both cases the effect is very small and slow, a few seconds in a thousand years, there is no occasion to do more than point it out in an article like the present. Laplace makes the tropical year to be 13 seconds shorter than it was in the time of Hipparchus.

The excess of the tropical year over 365 days has been given by different astronomers as follows:—

	h.	m.	s.
Euctemon and Meton	6	18	57
Hipparchus and Ptolemy	5	55	12
Hindus	5	50	30
Albatenius	5	46	24
Walther	5	48	50
Tycho Brahe	5	48	45
Delambre	5	48	51·6
Laplace	5	48	49·7

Whether the present length of the tropical year can be said to be determined within a second, we cannot collect from the writings of astronomers. The method of determining this length is by carefully observing solstices or equinoxes (that is, times when the sun is in the solstices or equinoxes) at distant periods, and taking the mean year from the whole interval elapsed. Unless that interval were a whole revolution of the solar perigee with respect to the equinox, the real mean tropical year could not be determined, from observation alone, so well as it might be.

The civil year must, for convenience, begin with a day, and contain an exact number of days. But any exact number of days would have the disadvantage of the old Egyptian year [SOTHIAC PERIOD], namely, that the seasons would be thrown into all parts of the year in succession. Those who lived in the intense heats of March (when that month is near the autumnal equinox) would read old poets who describe the spring as about to arrive in that month, or allude to the past winter, and that before the poets would have become properly ancient: this alone would be worth avoiding. Of the mode of doing it we shall presently say more; but in the meanwhile we have to observe, that it has always been the greater source of difficulty to combine the revolutions of the moon with those of the sun.

The Jewish, Christian, and Mohammedan religions all regulate their sacred anniversaries more or less by the moon. Various nations have constructed their years on the lunar revolution, though most of them have accommodated their years to the solar year by intercalated months. Now, the time between two new moons (that is, the average time) is 29·5305887 days, or about $29\frac{1}{2}$ days. If, then, months were made alternately of 29 and 30 days, 12 months would contain 354 days, and $11\frac{1}{4}$ days would be necessary to complete the Julian year of $365\frac{1}{4}$ days. This would amount to more than a month in three years. Taking the most exact values both of the lunation and the solar year, and applying the method in FRACTIONS, CONTINUED, it will be seen that the year contains, over and above 12 lunations, something less than 3 lunations in 8 years; more exactly, something more than 4 lunations in 11 years; more exactly, something less than 7 lunations in 19 years; more exactly still, something more than 123 lunations in 334 years, less than 130 in 353, more than 253 in 687, less than 1395 in 3788. Taking the Julian year, the above figures should be changed into less than 3 out of 8, more than 7 out of 19, less than 171 out of 464. This excess of 7 lunations in 19 years, which varies very little from the truth, whether as to the real, Julian, or even Gregorian year, is the foundation of the celebrated Metonic cycle [METON, in BIOG. DIV.], which, among the Greeks and all who have derived knowledge from them, has always been the foundation of the lunisolar calendar. It is now well understood that the Metonic moon, and not that of the heavens, is the referee in the settlement of religious festivals; that is to say, a moon moving uniformly at such a rate as to make 235 lunations in 19 calendar years.

Owing to the alternate acceleration and retardation of the sun's motion in its orbit, the lengths of the four astronomical seasons are different, as follows:—

	d.	h.
From vernal equinox to summer solstice . . .	92	22¾
From summer solstice to autumnal equinox . .	93	13½
From autumnal equinox to winter solstice . .	89	16¾
From winter solstice to vernal equinox . . .	89	1½

We shall now state the principal facts connected with the years of the nations who are most connected with history.

The Jews, from the time of their departure from Egypt, began their year with the vernal equinox in all religious reckoning, retaining the old beginning, which was at the autumnal equinox, in all civil affairs. In both cases they reckoned from the new moon near the equinox. By making twelve months in the year, each of 29 or 30 days, with an intercalary month once in three years, they secured themselves from the necessity of any but an occasional alteration. They might have gradually allowed the beginning of the year to slide away from the vernal equinox, but this their rites prevented them from doing, since the sacrifices required the offering of various specimens of agricultural produce, dependent upon season, at specified times of the year. The necessity of being provided with young lambs, for instance, at the Passover, obliged them to keep this feast at one time of the solar year, and fixed it at the full moon following the vernal equinox. How they managed their calendar in the first instance, does not appear; but as we know they once depended upon catching sight of the new moon to settle the beginning of the month, and only used 29 or 30 days when they missed their object, we must infer that they were in the habit of making corrections frequently, and at short notice; which could be done, as remarked by the editor of the 'Art de vérifier les Dates,' while they were in possession of Palestine, and within reasonable distance of each other. There is not any trace of astronomy in the old Jewish writings, nor reason to infer that they brought any knowledge of it from Egypt. But during the Captivity they acquired from the nations among whom they were thrown, either a period of 84 years or knowledge to construct one. Several of the Fathers mention this Jewish period, and state that it had long been used by them. It has the appearance of a CALIPPIC PERIOD of 76 years all but a day, with the period of eight years added, on the supposition that the making of three intercalary months in the additional eight years would have an error of a contrary kind from this contained in the Calippic period. But this is not the case; and 84 years is really not so near to an exact number of lunations as 76 years all but a day. Some of the early Christians used this period, and thereby contributed to the confusion on the subject of Easter.

The modern Jewish calendar is regulated by the cycle of 19 years, and its lunar years contain various adjustments which refer to the religious ceremonies. Their present usages date from A.D. 338, according to their own account. They have also a value of the length of a lunation $29^d\ 12^h\ 44^m\ 3^s$, which is within a tenth of a second of the truth. This has been stated as of extraordinary correctness by those who forget that the average month is much more easily found than the year. Hipparchus and Ptolemy had $29^d\ 12^h\ 44^m\ 3\frac{1}{3}^s$; reject the fraction, as was so often done, and we have the Jewish value; and as it happens that Ptolemy and Hipparchus had got just a little more than the fraction too much, this saving of trouble is an accidental correction. There is no accompanying value of the sun's motion more correct than that implied in the Julian year. On the Jewish calendar, see the 'Art de vérifier les Dates,' vol. ii., p. 113, the 'Jewish Calendar for 64 Years,' by E. H. Lindo, 1838, 8vo, which goes up to A.D. 1901, and also the Hebrew work, published with a Latin translation by Sebastian Munster, 'Kalendarium Hebraicum,' Basel, 1527.

The Hebrew months, as commonly spelt in English, are as follows:— opposite to them are written the names of the English months in which they severally most frequently begin, with their number of days:—

Nisan, or Abib	March,	30 days.
Jyar, or Zif	April,	29 „
Sivan	May,	30 „
Thammuz	June,	29 „
Ab	July,	30 „
Elul	August,	29 „
Tisri	September,	30 „
Marchesvan, or Bul	October,	29 or 30 „
Chisleu	November,	29 or 30 „
Thebet	December,	29 „
Sebat	January,	30 „
Adar	February,	29 „
Veadar (intercalary) . . .	March,	29 „

See an account of these months under their several titles.

For the Egyptian year, see SOTHIAC PERIOD.

The twelve months of the Athenian lunar year bear the following names; but there is a slight difference of opinion about the order in which they come, some putting Μαιμακτηριων before Πυανεψιων, and some after it:—

Ἑκατομβαιων,	30 days.	Πυανεψιων,	30 days.
Μεταγειτνιων,	29 „	Ποσειδεων,	29 „
Βοηδρομιων,	30 „	Γαμηλιων,	30 „
Μαιμακτηριων,	29 „	Ἀνθεστηριων,	29 „
Ἐλαφηβολιων,	30 days.	Θαργηλιων,	30 days.
Μουνυχιων,	29 „	Σκιροφοριων,	29 „

The intercalary month was a second Ποσειδεων of 30 days. It is said that anciently there were 30 days in every month, but that Solon first established the alternation of 30 and 29 days, and called the last day ἕνη καὶ νέα, old and new (moon). The shorter months were called hollow (κοῖλοι), the longer months full (πλήρεις); and these terms have been generally adopted by chronologers. The year in which a month was intercalated was called ἐμβόλιμος, or ἐμβολιμαῖος, and hence the word embolismic, which is frequently used in the same way.

The month was divided into three decads, the first two of ten days each, the third of ten or nine. The first day was νουμηνία, the second was δευτέρα ἱσταμένου μηνός, and so on. The eleventh was πρώτη μεσοῦντος μηνὸς, or πρώτη ἐπὶ δεκάδι, and so on to the last, which was εἰκάς. The twenty-first day was πρώτη ἐπ' εἰκάδι, and so on; the thirtieth was τριακάς. But the third decad was also reckoned by counting backwards from the new moon, thus: the twenty-first day was δεκάτη, or ἐνάτη φθίνοντος μηνὸς, according as there were ten or nine days in the decad. The last day, whether twenty-ninth or thirtieth, was ἕνη καὶ νέα.

There is some doubt whether originally the first of Hecatombæon was the day of the new moon nearest to the summer solstice, or next after it: this must have depended on the mode of intercalation. It is enough for most purposes to know that the Attic year began near the summer solstice. (Clinton, 'Fast. Hellen.,' Introduction.)

As to the intercalations, there is an old period mentioned of two years (διετηρίς), with an intercalary month of 30 days. This was also called τριετηρίς, because the intercalation was in every *third* year, including that of the former intercalation. This year was, with respect to the sun, more than 7½ days too long. There was also a tetra-eteris, but the first respectable period was the octa-eteris of Cleostratus, in which three months of 30 days each were intercalated in eight years, namely, in the third, fifth, and eighth. The average year of this period was wrong by 1½ hours with respect to the sun, and 1½ days with respect to the moon. The Metonic and Callippic periods followed (B.C. 432 and 330.) The latter was but little used compared with the former, which intercalated seven months in nineteen years. [METON, in BIOG. DIV.; PERIODS OF REVOLUTION.] It is not certain what the years of intercalation were.

The complete Roman calendar, as it stood immediately after the edict of Augustus, correcting the use which had been made of the edict of Julius Cæsar, is as follows:—There are twelve months, Januarius, Februarius, Martius, Aprilis, Maius, Junius, Julius, Augustus, September, October, November, December. The first of each month is its kalends, Kalendæ Januariæ, Februariæ, &c. The number of days in each month is well known by the old rhyme. The 13th of some months, the 15th of others, is called the day of the Ides (Idus); and the ninth day before the Ides, inclusive, is called the Nones (Nonæ); and every day is reckoned by its position with respect to the next simply denominate day, be it Kalends, Nones, or Ides. Thus the third day before the Nones of January, the day of the Nones itself counting as one, is *ante diem tertium Nonas Januarius*—a singular mode of speech, which does not appear to have been fully explained. It is generally rendered as if it were *diem tertium ante Nonas Januarius* (the third day before the Nones of January). These designations are usually written in a contracted form in the manuscripts, and these contractions are usually all that are to be found in chronological works. (See Gellius, iii. 2.)

31	Prid. Kal. Nov.		Prid. Kal. Jan.

The intercalary year, when introduced by Cæsar, had the additional day bestowed upon it by doubling the sixth day before the kalends of March (whence the year was called *bissextile*) [BISSEXTILE]: so that the month of February ended thus—

23	vii. Kal. Mart.
24	vi. Kal. Mart. poster.
25	vi. Kal. Mart. prior.
26	v. Kal. Mart.
27	iv. „
28	iii. „
29	Prid. Kal. Mart.

There was thus *ante diem sextum kalendas Martias posteriorem* and *ante diem sextum kalendas Martias priorem*. The general rules of this clumsy calendar are, that the ides are on the 15th of March, May, July, and October, and on the 13th of all the other months: that the nones are always on the eighth day before the ides, according to our mode of counting: that the kalends are always on the first day of the month: and that the intermediate days are numbered as far as numbering is required, backwards from the kalends, nones, or ides, each of these reckoning as one day in counting backwards from it.

The original Roman year is variously stated by historians at twelve and ten months: the latter seems the best supported, and the old year wanted January and February, and had Quinctilis and Sextilis in place of July and August: these two months yielded their names to those of the two emperors who reformed the calendar. Numa or Tarquin introduced what was meant for a lunar year of 355 days. The year is supposed to have been more assimilated to the solar year by the decemvirs; but there is a great deal of discussion upon all these points, which would be quite out of place in anything but an historical article. In the year 45 B.C. the correction made by Julius Cæsar, with the assistance of Sosigenes, was introduced, the preceding year having been lengthened into 445 days, in order probably that the new era might fall at the full moon following the shortest day. The pontifices maximi who came after Julius Cæsar mistook the meaning of his correction; by a bissextile every *fourth* year they thought was meant one every fourth year, counting the last bissextile, according to their interpretation of Cæsar's rule, by which the fourth numbers beginning from 1 were made not 5, 9, 13, &c., but 4, 7, 10, &c. This was corrected by Augustus, when Pontifex Maximus in B.C. 8, who directed that three bissextiles from that date should be omitted (being as many as had been then superadded to Cæsar's calendar in years preceding), and that the mistake should be avoided in future.

No further chronological difficulty occurred until the 3rd century, when disputes about the mode of determining Easter-day began to perplex the Christian world. It is commonly stated that the Council of Nice made that adjustment which lasted until the Gregorian reformation. This is not correct: the council, according to Eusebius and others, only ordained that all Christians should keep Easter on one and the same day. [EASTER.]

The Gregorian reformation (so called; we will not stop to give reasons for our protest against the word) was a consequence of the desire that the seasons should remain in the same months for ever. The Julian calendar gave a year which is too long at the rate of 3 days in 400 years nearly. At this rate, in 24,000 years midsummer and midwinter would have fallen in December and June. It was not so much to avoid this, as to keep the religious festivals in the same part of the year, that is, in the same kinds of weather, that the correction was insisted on by its advocates. The change had been discussed by individuals and even by councils during preceding centuries, and was finally decided on by Gregory XIII., with the authority of the council of Trent. In 1582 the reformation was carried into effect: ten days were struck out of the reckoning, that which would have been the 5th of October being denominated the 15th, so that the days 5, 6, 7, 8, 9, 10, 11, 12, 13, 14 of October, 1582, never existed in Italy and Spain, which accepted the change as soon as it was decreed. Some other countries, as France, which accepted it in the year 1582, but not so early, had to make their changes accordingly. See STYLE for the times of adoption in different countries.

There was one incorrectness about this part of the change, but not of any detriment. The equinox fell, at the time of the Nicene council, on the 21st of March, and the suppression of ten days was meant to make the equinox vibrate between the 21st and 22nd. But in point of fact, the Alphonsine tables, which were consulted, are wrong by a day in this matter, and eleven days should have been suppressed. The consequence is [PERIODS OF REVOLUTION] that the equinox vibrates between the 20th and 21st of March.

Leaving out the parts of the Gregorian correction which relate to Easter, we proceed to the alteration of the mode of intercalation. This is as follows:—Every year whose number is divisible by 4 is leap-year, except only when the number ends with 00, in which case it is not leap-year, except when the preceding figures are divisible by 4. Thus 1900 is not leap-year, but 1600 is. If we take the most recent value of the length of the year, 365·2422414 mean solar days, and apply the method in FRACTIONS, CONTINUED, we shall see that the excess of the real year above that of 365 days is something less than 1 day in 4 years, more than 7 in 27, less than 8 in 33,* more than 39 in 161, and

* The Persians are said to have used the intercalation of 8 days in 33 years

less than 242 in 999. This last excess, 242 days in 999 years, is so very correct, that it is most fortunate that Gregory's advisers did not know it, for they would in that case have adopted it and saddled our world with a most troublesome omission of intercalations for the benefit of posterity of 50,000 years hence. As it is, the excess of 1000 mean Gregorian years above as many of 365 days is 242·5 days: it would have been nearer the truth had it been 242·242 days. Accordingly 1000 mean Gregorian years are too long by about a quarter of a day; more correctly, 3600 years give an error of a day. Delambre proposed that the Anni Domini 3600, 7200, 10,800, &c., should not be leap years, which they are to be in the Gregorian calendar. If the world should last till A.D. 3600, we hope the correction will be called by Delambre's name; if his memory should then have perished, still more will that of the present article, so that there is no use in pressing the point.

The European years have been made to begin at such different periods, that the historical inquirer is frequently puzzled. We have mentioned those which relate to our country in PERIODS OF REVOLUTION. The 25th of December, the 1st of January, the 1st of March, the 25th of March, and Easter, have all been in use.

In regard to the common year as it now stands, there are several things which it will be useful to remember. We can hardly forbear to quote the verses which are so constantly in use, but we will do it from a version of 1596, in an arithmetical work:—

Thirtie daies hath September,
Aprill, June, and November,
Februarie eight and twentie alone,
All the rest thirtie and one.

The common year begins and ends on the same day of the week; leap-year ends on the next day. Thus 1843, not being leap-year, ends on Sunday, as it began; had it been leap-year, it would have ended on Monday. Many of those who call the year 52 weeks are hardly aware that it is 52 weeks and a day, or when leap-year, two days.

To find the day of the month without an almanac, it is very useful to know the first day in each month which has the same name as the first day of the year, as in the following list:—

1st of January, October,
2nd of April, July,
3rd of September, December,
4th of June,
5th of February, March, November,
6th of August,
7th of May,
} are of the same name.

Thus in the year 1843 all the days just mentioned are Sundays, the same as the first day of the year. If these days could be connected by some decent doggerel, such as that already quoted, any one who remembers them would only have to bear in mind the name in the week of the first day of the current year, and would thus have a point to start from in every month.

Since the above recommendation was given, such verses as were asked for appeared in the 'Notes and Queries,' as follows:—

"The first of October, you'll find if you try,
The second of April, as well as July,
The third of September, which rhymes to December,
The fourth day of June, and no other, remember,
The fifth of the leap-month, of March and November,
The sixth day of August, and seventh of May,
Show the first of the year in the name of the day.
But in leap-year, when leap-month has duly been reckoned,
These month dates will show, not the first, but the second."

The Mohammedan year is one of twelve lunar months, of 30 and 29 days alternately, the last month, however, having 30 days in intercalary years. To keep the months to the new moons, a cycle of thirty years is used, in which there are eleven intercalated years, being

2, 5, 7, 10, 13, 16, 18, 21, 24, 26, 29,

of the cycle. This makes a very good lunar cycle: it supposes 10,631 days to be an exact number of lunations, which it is within about a hundredth of a day, giving an error of a day in 2500 years. Of course the Mohammedan year is vague, its beginning retrograding through the different seasons of the solar year. The mode given in TURKISH CHRONOLOGY does very well to determine the commencement, except that when the Christian year contains the commencements of two Mohammedan years, the rule will only give one; the other, however, may easily be inferred. When the comparison of dates is to be very close, no easy rule will be sufficient, and recourse must be had either to the list in the 'Art de vérifier les Dates,' to the rule and supplementary tables in the 'Companion to the Almanac' for 1830, or to a sufficient method in De Morgan's 'Book of Almanacs.' The year 1 of the Hegira begins from July 16, 622, and the year 1260 begins January 10, 1844. But from and after the year A.D. 1583 (991 of the Hegira) the 'Art de vérifier les Dates' gives two commencements for every year (the second twelve days later than the first), which are, it says, according to the old calendar and the new one: no mention is made of this distinction, that we can find, in the introduction to that work, nor in other common sources. Our 'Nautical Almanac' gives the commencements according to the new calendar.

very far back in the middle ages; if so, their year was better than the Gregorian.

The unwise attempt made by the French, during their first revolution, to alter the names and dispositions of the years and months, might now be quietly consigned to oblivion, if it were not that many excellent works bear the revolutionary dates upon their title-pages, and political occurrences are frequently referred to them during the short period of their florescence. The year 1 of this period was made to begin September 22, 1792; each period of four years, or Franciad, had an Olympic or bissextile at its end. The three omitted leap-years of the Gregorian correction were found by the same rule as before, relatively to the years ending with 00: and the 4000th year was not to be leap-year. The year consisted of 12 months of 30 days each, with five sacred days at the end, dedicated to Virtue, Genius, Labour, Opinion, and Reward; the bissextile day being appropriated every fourth year to the renewal of the oath of liberty. For further detail see KALENDAR.

YEAR-BOOKS. [REPORTS.]

YEAST, or FERMENT, a substance which is deposited in an insoluble state during the fermentation of wine, beer, and vegetable juices. This substance, as is well known, is employed to produce fermentation in saccharine solutions. According to Liebig, the insoluble part of yeast does not cause fermentation, for he states that if it be "carefully washed with water, care being taken that it is always covered with water, the residue does not produce fermentation." Neither, according to the same authority, does the soluble part of yeast excite fermentation until it has been allowed to cool in contact with the air, and to remain some time exposed to its action; if in this state it be introduced into a solution of sugar, it produces brisk fermentation.

Yeast is a product of the decomposition of gluten, and when added to a solution of pure sugar, it gradually disappears; but when added to vegetable juices which contain gluten as well as sugar, it is reproduced by the decomposition of the gluten, in the same way as it was originally formed. According to Professor Graham, the action of yeast and all other ferments is destroyed by the temperature at which water boils, by alcohol, by acids, salts of mercury, sulphurous acid, chlorine, iodine, bromine, by aromatic substances, volatile oils, and particularly empyreumatic oils, smoke, and a decoction of coffee; these bodies in some cases combining with the ferments or effecting their decomposition.

Mr. Fownes gives the following as one mode of producing yeast without the aid of a ferment. Wheaten flour and water are mixed to the consistence of a paste, and slightly covered up in a warm place; a sour odour is produced, and carbonic acid gas given off, about the third day; by about the sixth day the odour becomes vinous rather than sour; and then the substance has practically become yeast, or a substitute for it. It may be either used at once, or laid by for future use. In the latter case, it is made into small thin cakes, and dried in the air; when about to be used, the cakes are dissolved. This is nearly equivalent to the ancient mode of making *leaven*. Mr. Cooley describes a mode of making yeast with the aid of a ferment. About ¼ lb. bean-flour is boiled for half an hour in 6 quarts of water. The solution is poured into a vessel; 3½ lbs. wheat-flour is added and stirred in; when cooled down to about 55° Fahr., 2 quarts of beer-yeast are added; and when the mixture has fermented for 24 hours, 7 lbs. of barley-flour or bean-flour is thrown in. The composition is kneaded into dough, made into cakes, and kept in a dry place till wanted for use.

This subject is further illustrated under BREAD; BREWING; FERMENT.

YELLOW FEVER. [FEVER, YELLOW.]

YELLOW OCHRE. [COLOURING MATTERS.]

YEW, *Economical Uses of.* Nearly every part of the yew tree is applied to some useful purpose. Considered as timber, the wood is hard, compact, of a fine and close grain, flexible, elastic, easy to split, and little affected by atmospheric changes. It varies in tint from orange-red to deep brown, with a hard white sap-wood. Both the real wood and the sap-wood will take a very high polish. It has been found that the wood, when cut into thin veneers before being seasoned, and steeped some months in a pond, took a purple-violet colour. Yew timber takes a long time to dry, but shrinks little during the drying; showing that the moisture contained, though not large in quantity, clings with great obstinacy among the fibres. The fineness of its grain renders it well fitted for cabinet-making purposes, when used as a veneer and polished. The wood is converted by the turner into vases, boxes, and numerous kinds of useful and ornamental articles. Beautifully veined pieces are often obtained from the root and the knots of the branches. Yew is one of the best of all kinds of timber for hydraulic engineering, such as water-pipes, pumps, piles, &c., on account of its power of resisting the action both of air and water. In France axle-trees are often made of yew. The branches are useful for making stakes and hoops; and the young shoots for baskets and ties. Yew, in its power of repelling or resisting vermin, has been recommended as a good material for wooden bedsteads. Before the invention of gunpowder the most important use of the yew was in making bows for the archers. Roger Ascham, in his 'Toxophiles,' published in 1544, states that "Ewe fit for a bowe to be made on," is the bough, the plant (stem?), and the bole; the bough is knotty, the plant is apt to break, and the bole, or boole, is pronounced to be the best. He adds, "If you come into a shoppe and fynde a bowe that is small, longe, heavye, stronge, lyinge streighte, not wyndynge, not marred with knotte, gaule, wyndshake, wen, freat, or pinch—bye that bowe of my warrant." The pieces of yew fashioned into bows were from 4 to 6 feet in length. In the time of Elizabeth foreign yew began to grow scarce; it was much preferred to English, insomuch that a bow of foreign yew was valued at 6*s.* 8*d.*, when one of English yew sold for 2*s.* Italy, Turkey, and Spain, were in succession nearly exhausted of yew for this purpose; until at length it became customary to join two pieces together—yew to make the belly of the bow, and ash or elm for the back. At the present day, very few yew trees are found with such a growth of trunk and branches as to be suitable for bows.

The nut yields an oil nutritious for fattening poultry. The dried leaves are sometimes used medicinally, and so are other portions of the tree, but not to any great extent, as there is much poisonous matter secreted by the yew. This poison is one of the causes of the durability of the tree, as it repels the attacks of insects.

YORK, CUSTOMS OF. [WIFE.]

YTTRIA. [YTTRIUM.]

YTTRIUM (Y). This very rare metal occurs as an oxide in several minerals. The names, sources, and properties of these minerals have already been described. [YTTRIUM, in NAT. HIST. DIV.] Yttrium itself is obtained on heating a stratified mixture of chloride of yttrium and potassium in a platinum crucible. After removing the chloride of potassium by water the yttrium remains in dark, iron-gray, shining, pulverulent scales. Under the burnisher it assumes a high metallic lustre; it is not oxidised by steam or at a red heat in the air.

Yttria (YO). Yttrium burns with splendid scintillations in oxygen gas, and yields a white protoxide, or yttria. Yttria is best obtained from the mineral gadolinite, which is digested in aqua regia, the mixture filtered, the filtrate evaporated to dryness, the residue digested in dilute hydrochloric acid, again filtered, the filtrate mixed with large excess of crystallised sulphate of potash, the solution carefully neutralised by ammonia, iron precipitated by succinate of ammonia, and ammonia added in excess to throw down basic sulphate of yttria. The latter by digestion in carbonate of ammonia solution is converted into carbonate of yttria, which by evaporation to dryness and ignition furnishes oxide of yttrium.

Yttria is a white powder of specific gravity 4·842; is inodorous and tasteless; is insoluble in alkalis, but soluble in their carbonates, especially that of ammonia. It occurs as a *hydrate* when precipitated from aqueous solutions of its salts.

Phosphorus, sulphur, iodine, bromine, &c., combine with yttrium to form more or less crystalline colourless salts. *Chloride of yttrium* is formed on passing chlorine over a mixture of yttria and charcoal heated in a porcelain tube; it forms white shining needles. *Sulphate of yttria*, obtained as above indicated, occurs in four-sided transparent prisms which lose water at 176° Fahr. and become milk-white without change of form.

Solutions of yttria are characterised by yielding a white precipitate with ferrocyanide of potassium.

Z

Z, like Y, was only found in the later Roman alphabet [X], from which it has been transferred to the alphabets of Western Europe. In the Greek series of letters it occupied the seventh place, the sixth being the property of the subsequently disused Vau or F. Two questions then arise which deserve an answer: how was it that the Romans gave this letter a place so different from that occupied by the Greek letter? and secondly, how are we to account for the Latin letter G occupying the place which should have been given to Z? We would first observe that the Greeks were surrounded on the north by Slavonic races, with whom an abundance of sibilants has always been in favour, so that the early position in the alphabet of Z need surprise no one. In the second place, we strongly suspect that the genuine sound of the Greek Z in early times was not, as is sometimes stated, that of *sd* or *ds*, for then it would have been a superfluous letter, and would scarcely have appeared so early in the alphabet. We would rather believe that the sound was similar to that of the English *j*, in which case the established interchange of ζ and δι before vowels would be explained. For instance, the form Ζευς in that case would not surprise us alongside of either Διος or *Jupiter*, *Jovis*, &c., or of the Italian *Giove*. [D; J.] Next looking to the Roman alphabet we are disposed to contend that the character G was originally employed with the same power. At any rate it was not the equivalent of the Greek Γ, for the third letter of the Roman alphabet, C, as it derived its form from the Greek Γ, merely changing its angle into a curve (a change not unknown to the Greeks themselves, see the tables of the old Greek character under ALPHABET), also possessed precisely the same power, a fact for which we have abundant testimony among the Romans themselves. [C.] But if G originally represented a sound different from the thick guttural Γ, what sound is more likely to have belonged to it than that of our English *j*, when we know that this sound is still current in Italy, although they want a single character to represent it, and, secondly, when it is an undoubted fact that the two sounds are very apt to be interchanged. In our own tongue the very letter in question performs the two offices we are speaking of, in *gender* and *get*, even before the same vowel; and we once met with a child already ten years of age, whose ear and tongue could make no distinction between *goose* and *juice*. In point of fact, the three sounds of *di* before a vowel, of an English *j*, and of our initial *y*, are closely related. Those who read the ballads in Percy's 'Reliques' will find many words where a *z* is used with the power of a *y*, as is still the case in the Scotch names *Dalzel*, *Mackenzie*, and the Scotch word *capercailzie*, for the English pronunciation of these words is incorrect in giving to them the sound of our English *z*. Nay, in words where an *n* precedes *z*, the sound *ng* is heard: thus *Menzies* is pronounced *Ming-es*. But if the Latin G and the Greek Z had originally the same power, as well as the same place in the alphabetical series, it becomes difficult to believe that the G alone of all the Latin letters did not derive its *form* too from the Greek symbol. Nor is the change so violent as would at first appear. If the Greek Z be written with its oblique shaft from north-west to south-east instead of from north-east to south-west (a supposition having little difficulty in it, if letters were originally pictorial), then the ordinary change from an angle to a curve would bring us to something very near the true Roman G Or again, taking the ordinary Greek Z, the upper horizontal line is already greatly shortened in the cursive character ζ, and in the same way might easily slip into the Latin character. The permutations to which Z is liable have partly been spoken of above, and all of them anticipated in the other letters. [D; G; I; J; S; T; Y.]

ZAFFRE. [COBALT.]

ZEMINDAR, a Persian word which signifies literally a landholder. The word was introduced into Hindustan by the Mohammedans, but it is probable that the office to which it is applied was previously in existence as a part of the system of village organisation which extends throughout the whole of Hindustan. A village in Hindustan is not simply a collection of houses smaller than that of a town; it is a tract of country comprising hundreds (sometimes thousands) of acres of arable and waste land, the inhabitants of which form a sort of corporation, with several officers, each of whom has his distinct duties. The head man of this village corporation is the *potail*, who has at his command the village police. A number of villages form a district, which is larger or smaller according to the number and extent of the villages. The head man of such a district is, in the greater part of Hindustan, called a *zemindar*, and the district itself a *zemindary*. The chief business of the zemindar is to collect the revenues of his district for the government; and that he may do this effectually, the police of the district is under his control. The collectorate, however, is not inseparable from the zemindary; and should the collection be withdrawn, as it occasionally was, the zemindar still remains the head man of the district, and the representative of it to the government.

This account of the zemindars applies to such of the states of Hindustan as were independent of the British government; but a change in the collection of the revenue was made under Warren Hastings in 1772, when the zemindaries were let to the highest bidder for a term of years, the zemindar in possession, however, being preferred when he offered terms which were deemed reasonable.

At length a permanent settlement was made with the zemindars during the government of Lord Cornwallis, in 1791, but was not completely carried out till 1793, forming, as it did, a part of the great financial and judicial reforms introduced by him. The amount to be paid to the government was settled at a fixed rate, in the first instance for a term of ten years; but this was to be rendered permanent if sanctioned by the authorities in England. The zemindars were recognised as proprietors of the soil, and thus have become, in fact, under the British government, what they had not been before, nor are yet under the native governments—landed proprietors of the zemindary. The ryots, all of whom had hereditary rights in their lands, were made over to the zemindars, who too frequently used their new powers oppressively. But in 1822 it was enacted that tenants holding lands by any hereditary or prescriptive rights should not be dispossessed so long as they paid the rents agreed upon, nor should the rents be increased except under certain specified circumstances. The zemindar may dispose of the lands as he thinks fit, and the government does not interfere, so long as the tax is paid.

(Mill's *History of British India*, by Wilson; Malcolm's *Central India*; Jones, *On Rent*.)

ZEND is the name usually given by Parsee priests to the language in which the oldest documents of their religion were composed. [ZEND-AVESTA.] It became current as such in Europe through Anquetil du Perron, who took the word Zend as the name of the language of the Avesta, and Pâzend as that of a corrupted dialect of the Zend. This view, however, has been shown by modern investigations to rest on a mistaken interpretation of a passage of the 'Ormuzd-Yesht,' and of one taken from the 'Ulemâ-i-Islâm'; for it is now certain that Thomas Hyde, whose work on the religion of the old Persians is the first noteworthy essay on this subject, was quite correct in calling Zend and Pâzend not languages, but books. In confirmation of his view, one passage from the Persian Dictionary Burhân-i-Qâti will suffice. It runs as follows:—"Zend is the name of a book which, as Ibrahîm Zerdusht affirmed, had come down from heaven on his account. Others say that it is the name of a book of Abraham; and others again maintain that Zend and Pâzend are two works or parts of this book. Zend is also the name of a Turanian Vezir of Sohrâb, the son of Rustem, who was killed by Rustem. . . . . Pâzend is a commentary on the Zend, and Zend is a book of Zerdusht. Some, however, reverse this definition, by saying that Zend is a commentary on the Pâzend. Again, others maintain that Zend and Pâzend are two books on fire-worship, composed by Ibrahîm Zerdusht; and one author says that Pâzend is a translation of the Zend." (Spiegel, 'Grammatik der Pârsi-sprache,' p. 3.) This passage clearly shows that neither Zend nor Pâzend is the name of a language or dialect, but it likewise gives evidence of the difficulty which even learned Persians evinced in ascertaining the correct meaning of the terms. Nor can we affirm that it is definitely solved by the present results of Oriental philology. Dr. Friedrich Spiegel, who has translated into German the sacred writings of the Parsees, expresses himself to the following effect (Introduction to 'Avesta, die heiligen Schriften der Parsen,' Leipzig, 1852, p. 45):—"Avesta, or, in its older form, Apestâk, means literally the *text*, and is the only correct designation which the later Parsees use for the text of their sacred writings whenever they do not employ the term *dîn*, or 'law,' which word, however, is probably to be taken in a more limited sense. In the invocations of the Yas'na, and elsewhere in the oldest period, the expression *manthrô çpênto* (that is, the holy speech) occurs for the sacred writings, and this expression has survived under the form of Mânser-çpent. For the language of this oldest period, the Parsees use the expressions, *language of the Manthra, language of the Avesta, divine language*. . . . . But *Zend*, a word not yet sufficiently explained, is reported to designate the commentary on the sacred books, probably the Huzvâresh translation. The language of this translation is called by the Parsees *Huzvâresh*, from the Zend huzaôthra, that is, bonum sacrificium habens. In connection with Zend we always meet with Pâzend, which word seems to mean the commentary on this translation."

A widely different opinion on this subject is given by another scholar, whose labours have for many years been devoted to an understanding of the old Parsee writings. In a lecture he has recently (on the 1st of March, 1861) delivered at Poona, on the Origin of the Parsee religion, Dr. M. Haug makes the following statement: "I have discovered in most of the books now extant, Yas'na, Visporatu, Vendidad, and Yashts, all the three classes of the ancient religious Persian literature which are spoken of by ancient Mohammedan writers and Persian lexicographers, viz., Avesta, that is, 'original text,' Zend, that is, 'commentary,' and Pâzend, that is, 'explanatory notes of the commentary.' The opinion of the Parsee priests that Zend and Pâzend are names of languages is wholly wrong. These three classes may be best discriminated in the Vendidâd, or code of religious, civil, and criminal laws, customs, and usages, chiefly in its fourth chapter. We find that verse 1 (in Westergaard's edition) is Avesta, being an ancient and scarcely more intelligible law; 2–10, its Zend, or commentary; 11–16, Pazend, or further explanation of the commentary. I shall treat this subject, as well as many other things fully in my 'Essays on the sacred writings and religion of the Parsees,' to be published, as I hope, in the course of this year."

To enter into any speculation on the different periods of the language of the Avesta would be premature, after the confession made by the best living Zend scholars, that they are unable as yet to cope with the considerable difficulties which beset its study. We must, therefore, confine ourselves here to the statement that this language, which—as observed—now passes by the erroneous name of Zend, is one of the Indo-European stock, and bears so great and intimate an affinity to the Sanskrit of the Vedas, that without a knowledge of the latter, we should probably never have arrived at a correct appreciation of the forms of the language of the Avesta. The ingenious comparisons between both languages made by the celebrated Sanskrit scholar, Eugène Burnouf, in his 'Commentaire sur le Yaçna,' have laid the first solid foundation of our present knowledge of Zend, and the place it holds amongst Indo-European languages is best illustrated in the excellent 'Comparative Grammar' of Professor Franz Bopp.

ZEND-AVESTA is the name commonly given to the sacred books of the Parsees, which are ascribed to Zarathustra or Zoroaster; it would be better, however, to call them *Avesta*, which word means *text*, or *original text*, since *Zend* designates the commentary on this text. Parsee tradition tells us that these books originally consisted of twenty-one noska or large divisions, but that they were destroyed by Alexander the Great, who had all that they contained of medicine and astronomy translated into Greek, and the rest burnt. There is much reason to doubt the accuracy of this report; but whether true or not, it is certain that the Grecian conquest was highly detrimental to the old Parsee religion and its sacred texts, and that the restoration of both did not take place before the elevation to the throne of Ardeshir, the first king of the Sassanian dynasty, or about 220 after Christ. He and the kings of his lineage ordered a collection to be made of all that remained of the sacred Parsee texts, and it is this collection which we possess now under the name of Avesta. But not all of the books deemed sacred by the Parsees can strictly speaking be included under this name. It belongs more particularly to the three which are severally called *Vendidad*, *Vispered*, and *Yas'na*, whereas the remaining writings are comprised under the denomination of *Khorda-Avesta*, or "small Avesta."

The latter contains short prayers, and especially the *Yashts* or *Yeshts*, hymns addressed to the different genii, on the days which bear their names and are sacred to them, or on the days of those genii who are considered to be the attendants of the former.

The *Vendidad* consists of twenty-two *Fargards* or sections, which treat of cosmogony, and, moreover, may be called the religious and civil code of the old Parsees. The first Fargard relates how Ahura-Mazda (now called Ormuzd), the good spirit, created the several countries and places—sixteen are named—excellent and perfect in their kind, but that *Angrô-Mainyu* (now called Ahriman), the evil or black spirit, created in opposition all the evils which infest these worlds. In the second Fargard, Zarathustra (or Zoroaster) bids Yima announce to mankind the sacred law he had taught him; but Yima refuses compliance with this behest. He then bids him enlarge the worlds and make them prosperous. This time Yima obeys, and carries out the orders given him by Ahura-Mazda. The third Fargard enumerates first the five things which are the most agreeable, then the five things which are the most disagreeable, and afterwards the five things which convey the greatest satisfaction, to this world. It concludes with questions and injunctions of a kindred sort. The fourth Fargard may be termed the criminal code of the Avesta. It enumerates, in the first instance, various offences which are considered to be so grave as to affect not only the person who commits them but also his relatives; and then proceeds to define the punishments incurred by the offender. The eight following Fargards contain injunctions in reference to impurities caused by dead bodies. The thirteenth Fargard begins with the description of two kinds of dogs,—the one created by Ahura-Mazda, the other by Angrô-Mainyu,—the killing of the former being a criminal, that of the latter a meritorious, act; and the remaining part of the book is devoted to the proper treatment of dogs in general, a subject of much importance in a country apparently much infested by wolves, and continued in the fourteenth Fargard, which enumerates also the penalties for injuring dogs. The treatment of young dogs is likewise the subject-matter of the latter part of the fifteenth Fargard, which in its first sections treats of sexual offences, and the bringing up of illegitimate children. The sixteenth Fargard teaches how to treat women in their menses, or when otherwise affected with impurities. Impurities caused by the cutting of hairs and trimming of nails, are the subject-matter of the seventeenth Fargard. The next Fargard is more of a mixed character; it treats of various ceremonies, such, for instance, as are to be practised during the night and at sunrise; and gives injunctions on cleanliness, decency, and moral conduct. The nineteenth Fargard relates how Angrô-Mainyu endeavoured to kill Zarathustra, but how the latter successfully defended himself with the weapons given him by Ahura-Mazda. The evil spirit, it continues, being aware that it had no material power over Zarathustra, then resorted to temptations; but these too were defeated by the prophet, who now resolved to conquer the evil spirit, and for this purpose addressed to Ahura-Mazda various questions on the rites of purification and the condition of souls after death. The twentieth Fargard contains some information about the first man who understood curing disease. The twenty-first Fargard is devoted to the phenomena of the sky and the luminous bodies; it comprises invocations of the clouds, the sun, the moon, and the stars. The last Fargard relates that Angrô-Mainyu having engendered diseases, Ahura-Mazda is compelled to devise remedies against them. In the first place he has recourse to *Manthra-ćpenta*, the sacred word, but it is powerless. He then sends Nairyo-sangha to Airyama with the command to produce several useful animals and things for this purpose; and the Fargard, evidently a fragment, concludes with relating that Airyama produced nine kinds of male horses, nine kinds of male camels, nine kinds of oxen, nine kinds of small cattle, and nine kinds of pasture ground.

The form of all these Fargards is nearly always that of a dialogue between Ahura-Mazda and Zarathustra, and the same form is now and then also observed in the two other portions of the Avesta, which differ materially in their contents from those of the Vendidad.

Vispered and *Yas'na* bear prominently a liturgical character. They are invocations of nature, of the deities who are believed to govern its course, of time, seasons, and other objects connected with acts of pious veneration; they also contain views of creation of a speculative kind; in short, they are chiefly the religious and liturgical code of the old Parsee religion, whereas the Vendidad, as observed, is chiefly—though not exclusively—concerned with the regulation of social and daily life.

The religious belief taught in the Avesta rests on the dualism of the two great principles, *Ahura-Mazda* or "the good," and *Angrô-Mainyu*, or "the evil principle." The genii subordinate to the former are the *Amesha-s'pentas*, six of whom are named in the Yas'na, namely: Vohumanô, who protects living beings; Asha-vahista, or the genius of fire; Kshathra-vairya, or the genius of metals; S'penta-ârmaiti, or the (female) genius of earth; Haurvat', or the genius of water; and Ameretât', or the genius of trees. They are severally opposed by the *Daevas*, or demons, subordinate to Angrô-Mainyu,—by Akomanô, Andar, S'aurva, Nâonghaithi, Tauru, and Zairicha. Other demons occur in the tenth Fargard of the Vendidad. Both these principles—which in the more philosophical language of the second part of the Yas'na (the Gâthâs) are also conceived of as the principles of existence and non-existence, of life and death, of good and evil—pervade creation and are in permanent strife. The worshippers of fire belong to Ahura-Mazda, whereas the worshippers of the Daevas are possessed by Angrô-Mainyu, the spirit of evil.

It is the latter class of deities which throws a strong light on the obscure antiquity of the sacred books of Zoroaster. The Daevas are in substance and name the Devas of the Hindus. To the latter, however, they are the good and friendly gods, protectors of men, and worshipped by them in sacrificial acts. The religion of Zoroaster assumes, therefore, the character of being antagonistic to the Hindu creed; and, in accordance with this view, we find that Indra, one of the principal Vaidik gods, and one of the principal Hindu gods of the later literature, is in the Avesta the Daeva Andar; that the *Nâsatyas*, or As'wins of the Hindus, are the Daeva Naônghaithi; and S'arva, a later name of S'iva, is the Daeva S'aurva. It would seem, therefore, that Zoroaster belonged to a period of antiquity when great religious dissensions had already separated, or begun to separate, the two sister nations of the Hindus and Parsees; but it would be hazardous to extend this inference to any allegation of date, or even to the assumption that Zoroaster preceded the Vaidik songs of the R'igveda poetry; for though a belief has been recently expressed that the word *faradashti*, in a R'igveda hymn, is the Sanskrit form for the name Zarathustra, this bold conjecture is noways warranted, neither by a sound comparison of both words nor by the context in which faradashti occurs; whereas, on the contrary, there are circumstances which seem to indicate that Zoroaster inveighed against that form of Hindu worship which belongs to a period posterior to that of the R'igveda hymns. It is remarkable, for instance, that though there is a manifest tendency in the Avesta to invert the character of the friendly deities of the Hindus, the Zend *Ahura*, which emphatically occurs as a propitious name in Ahura-Mazda, corresponds in meaning and form with the word *Asura* of the R'igveda; whereas this same word *Asura* means a demon in the literature of the Hindus subsequent to the Vaidik poetry, and then only is the counterpart of the Avesta word.

The worship taught by Zoroaster seems to have been of the simplest kind, the adoration of fire by means of hymns and offerings, chiefly, if not exclusively, taken from the vegetable kingdom. An essential concomitant of the sacrifice is the juice of the Haoma, or the Soma plant, which occupies an important part also in the Vaidik rites. [VEDA.] This worship however must not be confounded with the complicated ritual of later periods of the Parsee creed, which assumed a similar development to that based by the Hindus on the R'igveda text, and is indicated by several portions of the Avesta, which cannot be looked upon as its earliest part.

This part evidently consists of the second division of the Yas'na, or the Gâthâs, for some of them are quoted several times in the remaining portions of the Avesta. But whether all the Gâthâs precede the first part of the Yas'na and the rest of the Avesta, and whether the dialect in which they are written differs from the language of the rest merely on account of local peculiarities, as Professor Westergaard holds, or on account of its earlier date, as other scholars assume, is a question which it would be difficult to decide in the present imperfect state of Zend philology. Nor would it be safe to say whether Zoroaster, to whom the original Avesta is ascribed, composed all or any of the remains in which the present collection has come down to us. Dr. Haug, it is true, who has given us a translation of the Gâthâs, says in a lecture he delivered at Poona, on the 1st of March, 1861: "I shall now give the proofs that these collections of ancient songs (the Gâthâs), or at least some of them, were really composed by Zarathustra himself, with some remarks which will throw light on the origin of the religion. 1. Whilst in those portions of the Zend-Avesta which are written in the usual Zend language (or it might perhaps more properly be called Bactrian) we find Zarathustra spoken of in the third person; now in these songs he is speaking in the first person, and sometimes calling himself by his own name, so says he in one passage (Yas'na, 43, 8): 'I am Zarathustra, I shall show myself as a destroyer to the wicked, and a comforter to the good.' 2. From the whole tenor of these songs (chiefly of the second collection, called Gâthâ-ustavaiti) we are led to the opinion that a man of quite an extraordinary stamp stands before us, acting a grand part, not only on the stage of his country's history, but on that of the universal history of the human race. He says that he is a prophet or a messenger, sent by God to propagate civilisation, especially agriculture and the blessings of a settled state of life (once he is called a prophet of the spirit of the earth, Geusurvâ), and to destroy idolatry as ruining the body as well as the soul." But it is clear that arguments of this kind do not warrant the certainty with which the inference is propounded that Zoroaster himself composed these songs, and that no later writer, according to the tradition he had received, could have indited the poetry which has called forth the foregoing remarks. Questions like these it seems premature to decide at a time when the grammatical laws of the language of the Avesta are not yet definitely known, when no real dictionary of this language is yet in existence, and when the few translators of the Avesta reproach each other, apparently not without good cause, with having misunderstood, or imperfectly understood, the most important parts of the sacred texts, either from clinging too much to tradition, which is not always safe, or from neglecting it altogether and inventing fanciful meanings of words. Those seriously engaged in the study of the old Parsee texts will not be misled by bold assertions of dates and confident interpretations of texts, but to the general reader it is wiser to confess that the time is not yet come to decide whether Zoroaster is the real author of all or any of the fragmentary portions of the Avesta which are the subject of this brief notice, nor to venture upon a guess at the period at which he may have founded the Parsee religion. All that is really settled by modern investigations is that it would be erroneous to assign to him the date of Darius' father, since it is indubitable that the Kavâ Vistas'pa of the Zend-Avesta, under whose reign Zoroaster lived, is not the Vistas'pa or Hystaspes, who is the father of the celebrated king Darius, the lineage of the latter being totally different to that of the former. When therefore the modern Parsees assign to their prophet the date of 550 B.C. they must be wrong; and if Zoroaster really lived at any of the remote dates which have been guessed by European writers, this fact would give us the interesting conclusion that there is a religious community which believes its founder to have existed about 1000 years later than he actually lived.

ZENITH and NADIR, two Arabic terms, imported into Europe with astronomy, to signify the point of the heavens immediately above the spectator, and the opposite (invisible) point below him. The latter term, though still mentioned in books on the use of the globes, is quite obsolete among astronomers; the former is very frequently employed.

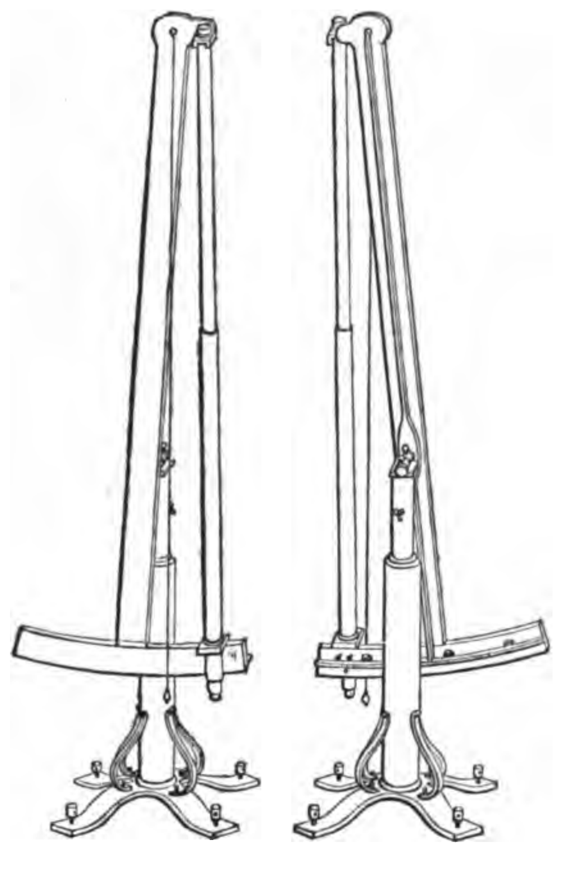
The zenith is the point at which a vertical line cuts the heavens. If the earth were a sphere, this vertical line, or that in which a plumb-line hangs, would pass through the centre of the sphere. But the earth being a spheroid, the vertical line, which is everywhere perpendicular to the tangent-plane, does not pass through the centre of the spheroid, but a little nearer to the spectator's side of the equator.

ZENITH SECTOR. This instrument is, as its name implies, a *portion* of a divided circle, which is employed in measuring the *zenith* distances of stars. Picard, in his celebrated operation for determining the figure of the earth, first applied a short arc to a long telescope, thus obtaining at the same time great accuracy with portability. The instrument which he used for measuring the celestial arc between Malvoisine, Sourdon, and Amiens, is figured and described in his tract entitled 'Mesure de la Terre;'* the following is a copy of his plate and description. The instrument is of iron, strengthened with edge-bars, and covered with copper in the places required. The limb contains only about the twentieth part of the circumference of a circle of ten feet radius, and is divided by transversal lines [VERNIER] to thirds of a minute. The telescope is ten feet long, and the wires are illuminated either from the top or by an aperture on one side of the telescope. The plumb-line is enclosed in a tin tube to protect it from the wind, and the observations were always made in a close apartment through an aperture in the roof.

The figure shows all this sufficiently, and also the foot-screws for setting the axis vertical, which it is when, on turning the instrument round, the plumb-line hangs before the same division of the limb. In making the observation, suppose the axis to be vertical and the limb to be towards the reader, as in *fig.* 1 (the limb should also be in the plane of the meridian), and the telescope directed to a star, at its transit. Now if we suppose a line to be drawn through the centre, parallel to the line of sight of the telescope, the angle between the line so drawn and the plumb-line is the zenith distance of the star; but as the point where the arc is cut by the line supposed is not as yet defined, except by its parallelism to an optical and intangible line, there is as yet no measure. Read off, however, the division on which the plumb-line beats. Turn the instrument half round on its vertical axis, when the plumb-line remains on its former division, and the telescope points to the same zenith distance, but on the other side of the zenith; if, then, we would observe the same star as before, the sector must be turned on its horizontal axis through twice the zenith distance; and as the plumb-line always keeps parallel to its position, and passes through the centre, the division on which it now beats must be distant from the division first bisected by twice the angle moved through, that is, by twice the star's zenith distance, and the division which bisects the two readings is the zero point, or reading which corresponds to the zenith. It is not necessary that the star should be observed in both positions on the same night, provided the centre and arc of the sector continue to have the same position with regard to the line of sight. In this case, reversion on a following night will serve just as well for determining the division which corresponds to the zenith direction of the

* The first edition of this admirable work was published in 1671; there have been numerous reprints of it since.

telescope. If this reading is not that which was intended by the maker, the difference is called the error of collimation, and is applied



as a correction, additive or subtractive, to all the observations, according as they are on one or the other side of the zenith.

Picard enters into no details with respect to his observations, but gives at each place a zenith distance, which is the mean of a considerable number. He only observed one star, and that to the north, namely, the Knee of Cassiopeia (δ), giving as a reason, "that a star nearer to the zenith would have been more difficult to observe, and that if the star had been between the two zeniths, the error of the instrument (the division corresponding to the zenith, or error of collimation), which might have been imperfectly determined, would have been doubled in the apparent distance between the two zeniths, because then the sum of the two observations must have been taken; whereas when a star is always observed on the same side of the zenith, there is only the difference to be taken, which must be correct, provided the instrument is well centred and well divided."*

In 1674 Hooke published 'An Attempt to prove the Motion of the Earth from Observations,' in which he describes the instrument he contrived for observing the distance of γ Draconis from the zenith of Gresham College, and the apparatus for measuring the variations which might occur. This consisted of an object-glass of 35 feet focus length, fixed at the top of the house, and referred by two plumb-lines hanging from a bar in the object-cell and passing through apertures in the floors, to a system of wires below. Before each observation Hooke set certain marks in his wire-cell to the plumb-lines, then fixed the wire-cell, removed the plumb-lines, and bisected the star; after the observation, he verified the position of the wire-cell on replacing the plumb-lines. There is a great deal to admire in this simple and ingenious contrivance, but his *mensurator* for noting the small variations seems clumsy and inexact. "Inconvenient weather and great indisposition in his health" limited Hooke's observations to four in number, from which he erroneously concluded that there was an annual parallax of the earth's orbit, and therefore that Copernicus's

* We have given the above extract from Picard because it shows, we think, that he did not reverse his sector at each place; if he had, he must have got a double zenith distance free from all *fixed* errors but those of centre and division, and his reasoning is not correct. The assumption which he tacitly makes, that the error of collimation continued to be the same during his observations at *different* places, is not allowable. It is evident that with such an instrument the exact adjustment to the meridian would be difficult, and hence probably his choice of a star, which, being distant from the zenith, required less nicety in this adjustment.

theory was true. With very little alteration, such as a nicer reference of the plumb-lines to the cell of the eye-piece, and a screw micrometer for a mensurator, Hooke's apparatus would still be applicable; and if his idea of using a deep dry well for the telescope-tube were adopted, we conceive that most accurate determinations might now be made.

Several observers about this time discovered a motion in the stars which they could not account for. Picard, Roemer, and Flamsteed all found that the position of Polaris varied at different times of the year, and Flamsteed fancied that the change was due to parallax. In or about 1725, a gentleman of the name of Molyneux, then resident at Kew, employed Graham to make him a *parallactic* telescope, so called from its object, namely, to discover the change of place in the stars occasioned by the earth's change of position in her orbit. This is described in Smith's 'Optics,' book iv., cap. 7, and more fully in Mr. Molyneux's own words in Bradley's 'Miscellaneous Works and Correspondence,' p. 93. It consisted of a telescope 25 feet long, with a short cross axis at the upper end, just at the place of the object-glass. This axis was so adjusted on its supports that the telescope moved in the meridian. A plumb-line hung on one end of the axis and passed over a dot in a plate fixed on the tube near the eye-end. The telescope was drawn forwards in the meridian by a string and weight passing over a fixed pulley, and pushed back by an antagonist-screw, which had a divided head and index. To make the observation, the plumb-line is first made to bisect the dot by the screw, and the division read off; then the star is bisected also by moving the screw, when the division is again read off. The revolutions and parts through which the screw is moved measures the angular distance of the star from a line in the heavens, which continues fixed, if there is no change in the relation of the object-glass and wires to the axis and dot.

Observations were made at Kew for some time with this instrument by Molyneux, Graham, and Bradley; and in 1727 Bradley had a zenith-sector constructed by Graham with which he made his celebrated discoveries of aberration and nutation. There is a short description of this instrument by Maskelyne in the first volume of his 'Greenwich Observations,' p. 9, which Rigaud has reprinted, with some memoranda by Bradley, in the 'Miscellaneous Works,' &c.; but Bradley himself gave no description in his Memoir on Aberration ('Phil. Trans.' vol. xxxv., p. 637), and in his following Memoir on Nutation ('Phil. Trans.', vol. xlv., p. 1) satisfied himself by referring to the description of a sector on a similar construction. ('Dégré du Méridien entre Paris et Amiens,' 1740.) This last-mentioned sector was made by Graham for the measurement of the degree in Lapland, and afterwards employed in the remeasurement of Picard's arc. We have now a full and minute description of Bradley's instrument, with numerous plates, in a work entitled 'Operations for the Verification and Extension of the Abbé de la Caille's Arc of the Meridian,' by Thomas Maclear, Esq., pp. 67-81, published by order of the Lords of the Admiralty. This account is by the astronomer-royal, who directed the alterations required to fit the sector for the field. The principal parts of this instrument, as originally made by Graham, are a telescope with a short sector attached to the eye-end, and a short cross or transit-axis to the object-end, which causes it to move in the meridian when properly adjusted. A plumb-line passes over a fine dot at the extremity of the upper axis, and beats on the divided sector below, that is, it almost touches the dot above and arc below, but still hangs perfectly free. To prevent any disturbance from the wind, the plumb-line is screened by a tube, and the bob hangs in water that it may sooner come to rest. To make the telescope describe the meridian correctly, as well as to get a proper fixing for the clamp and micrometer-screw, another arc is fixed to the wall, and the telescope carries a frame with rollers at its eye-end, and is thus kept in contact with the fixed arc before and behind. A clamping apparatus, which slides along the fixed arc, and can be attached to it by screws in any position, carries a fine screw with a micrometer head, which pushes the telescope by acting on a piece of hardened steel, while the telescope resists either by gravity or by a counterpoise weight. There are numerous parts and contrivances for different adjustments, which will be easily understood from Mr. Airy's account. In making the observation, the telescope is first to be set, or nearly so, to the star, the bisection of the upper dot is verified, and then a division below is bisected by carrying the screw one way, *forward*, for instance, and the micrometer head is to be read off. When the star is in the centre of the field, it is bisected by carrying the screw still *forward*, and the micrometer is again read off. Finally, the screw is still to be carried *forward* till the next division is bisected, and the micrometer read off. A simple proportion will give the quantity, which is to be added to the first reading, or subtracted from the second reading, in order to get the reading corresponding to the star.* Bradley's sector as originally made was not reversible, and was therefore only fit for measuring differences or variations. When, after its removal to Greenwich, actual zenith distances were required, the instrument was shifted across the room, from the east to the west side, where a second fixed arc, &c. were ready to receive it. We need not say that this was very objectionable, as

* In some of the books referred to, it will be seen that the dot bisected before observing the star is directed to be bisected again, and the *mean* of the readings taken. But a screw which carries weight never reads the same when moved forwards and backwards, and it is always safest to carry the screw the same way in the same operation.

such an operation, take what care you may, is always liable to derange the relation of the parts of the instrument, and so to lead to untrue conclusions. Even while it was at Wanstead, and considered to be immoveable, a slight change seems to have taken place, which has been investigated by Dr. Busch, in the 'Reduction of the Observations made by Bradley at Kew and Wanstead,' Oxford, 1832. In remounting it, the astronomer-royal has given the property of reversion very satisfactorily, and Mr. Maclear's observations with it are of extraordinary accuracy.

A sector was used in the measurement of the meridian in France, by Cassini de Thury and La Caille, which greatly resembled the sector of Picard, except that the arc was of much greater extent, being 52½° and framed with three radii. The telescope was fixed at the back of the instrument, so as to be at once more firmly fastened and out of the way of the plumb-line; and, lastly its micrometer-screw was applied to the wires of the telescope (sometimes called the *interior* micrometer), instead of moving the whole sector. In this mode of observing, the instrument is set approximately to the star, and the nearest dot accurately bisected. When the star is in the centre of the field, it is bisected by the micrometer-screw which carries a wire in the focus of the object-glass, and thus the excess or defect from the nearest dot is ascertained. This improvement in the application of the micrometer-screw is due to the Chevalier Louville, and in this respect we prefer the French to the English construction. See 'La Méridienne de l'Observatoire Royal de Paris verifiée,' par M. Cassini de Thury, Paris, 1740. The sector is figured at page 31, and described at page lxxi.

Bouguer and La Condamine, in their measure of the arc of Peru, were compelled to fabricate their own zenith sectors, and adopted a very elegant mode of graduation, the merit of which is given by La Condamine to their colleague Godin. The telescope and arc being prepared, a star is selected which has pretty nearly the same zenith distance at both extremities of the arc of the meridian. Now calculate approximately the value of the chord of the double zenith distance of the star, and find what fractional part it is of the radius. Suppose it is nearly $\frac{1}{17}$ of the radius, then take a beam compass, mark two dots on the arc, and step seventeen times with the same opening along the radius, and so fix the dot over which the plumb-line is to pass. The instrument is now graduated, and is used as follows:—After being adjusted to the meridian, the plumb-line is made to pass over the upper dot and one of the lower dots, after which the star is bisected by the interior or Louville's micrometer. On a following day the instrument is reversed, and the plumb-line being brought over the upper dot and the other lower dot, the star is again bisected by the micrometer. It is plain that the double zenith distance of the star, corrected for refraction, aberration, &c., is measured by the arc subtended at the central dot by the two dots below $\pm$ the sum or difference of the micrometer readings. But the arc is, by construction, that the sine of which is $\frac{1}{34}$, which is found from the tables; and the value of the micrometer readings being also known, the zenith distance of the star is known. The operation may be repeated at the other end of the arc with the same star, and using a different submultiple of the radius. See 'Mesure des trois premiers degrés du méridien,' par M. de La Condamine, Paris, 1751, pp. 105 et seq.; 'Figure de la Terre,' par M. Bouguer, Paris, 1749, pp. 176 et seq.

We insert here the method employed by Maupertuis, La Caille, and others to ascertain the value of the total arc of the sector. A line of considerable length was carefully measured from a well-defined spot and a signal erected; then a perpendicular was measured from the signal, of such a length as very nearly subtended at the spot the arc to be verified, and here a second signal was placed. The sector was then laid horizontally on a bed prepared for it, the centre being exactly over the defined spot, and the telescope pointed to the first signal; when this was done satisfactorily, a fine line was stretched over the centre and the first dot of the divided arc. Now shifting the sector round, the second signal was bisected, and it was seen what division was bisected by the line which continued to pass over the centre. The true angle is evidently that marked on the ground, and is calculated from the given length of the perpendicular and the distance. The value of the arc read off on the sector is compared with this, and the error of the total arc detected, which is afterwards used for correcting all the angles observed. At present the value of the total arc of a sector would be determined by a comparison with the mural circle.

In 1775 Bird erected a zenith sector at the Observatory of Oxford, which is in most respects similar to Graham's, but it is fixed to an upright pillar which revolves freely, so that the instrument is reversible. From some cause or other, though observations have been made with this instrument, they have not been considered satisfactory. It appears to us to be an excellent instrument, and one capable of doing good work, though one chief use of zenith sectors, namely, ascertaining the index error of the meridian declination instrument, has been supplied to modern circles by observations by reflexion.

The zenith sector of Ramsden, which was used in the trigonometrical survey of Great Britain, and in the Holstein arc, is described and figured in great detail in the 'Phil. Trans.' for 1803, and in the second volume of the 'Account of the Ordnance Trigonometrical Survey of England and Wales.' It was burned in the fire which consumed a considerable part of the Tower in 1841. As this instrument is very fully detailed in the account referred to, it is useless to enter into particulars here. Ramsden viewed the upper dot by a long microscope, which saved considerable trouble, as well as avoided the chance of deranging the bisection by mounting to read it. The 'Astronomical Observations with Ramsden's Zenith Sector,' reduced by Lieutenant Yolland, R.E., were published in 1842 by order of the Board of Ordnance.

After the destruction of Ramsden's sector, Colonel Colby applied to the Astronomer Royal for his advice as to the best form of instrument for determining latitude *in the field*. The construction given by Mr. Airy, and executed by Mr. Simms, differs in many respects from any which preceded it. The description, with explanatory figures, is to be found in the 'Monthly Notices of the Royal Astronomical Society,' vol. v., p. 188. The vertical axis, which is cast in one piece, and strongly framed, carries at its back three levels, one above the other, which being read off at the moment the star is bisected, determine the position of the axis with respect to the zenith. The telescope-frame with the eye- and object-end is cast in another solidly braced piece, and is held at its middle on a centre in front of the vertical axis. This second frame moves freely for a few degrees on each side the zenith. The divided arcs are graduated on the vertical axis near its top and bottom, and there are four micrometer microscopes, one at each side of the object and eye-end, the tubes of which are bored in the solid telescope-frame. There is a wire-micrometer in the focus of the telescope. A stop to the axis enables the observer to turn the instrument exactly half round by touch, and almost instantaneously. The observations are made thus:—The instrument being pretty nearly in the meridian, and the axis vertical, the telescope is set nearly for the star, and the microscopes are read off. Before the star reaches the centre of the field, the observer bisects it with the micrometer-wire, noting the time, while the assistant reads off both ends of each level. The whole instrument is then turned half round, and the star is again observed, the bisection being now performed by the tangent-screw of the telescope-frame, the time is again noted, the assistant reads off the levels as before, and, finally, the arcs above and below are read off by the micrometer microscopes. In this way the double zenith distance of a star, free from all error of collimation or of the vertical axis, may be obtained in a few minutes. This instrument performs very satisfactorily. The telescope is one of 3½ feet focal length, and the instrument bears the same relation to a mural circle that the ordinary sector does to a quadrant.

When Troughton first proposed the mural circle as the best form for a meridian declination instrument, great doubt was thrown on the practicability of observing by reflexion with sufficient nicety, and in that case, as the mural circle does not reverse, a supplementary instrument was wanted to show the position of the zenith or horizon. Partly on this account, but chiefly to settle the constants of aberration and precession with the greatest precision, Troughton planned a *zenith tube*, consisting of a telescope of 25 feet focal length, without any sector, and in which the variations of zenith distance of γ Draconis and close zenithal stars were to be measured by a micrometer-screw. The telescope rests on its lower end, continued beyond the focus, on a piece which has adjustments for verticality, and a collar below the object-glass is pressed by a spring into a Y bearing. The wires at the focus are moved by a micrometer-screw, and the star and wires are seen through a diagonal four-glass eye-piece. The plumb-line hangs within the tube, and is viewed above and below by micrometer microscopes. Instead of adjusting the plumb-line before each observation, it is bisected by the micrometers after the observation, and a correction applied which is deduced from the upper and lower readings. Mr. Airy having had some reason to suspect that the wire twisted on reversing the instrument, gave a double suspension to the plumb-line, and made the instrument reversible on a star in the same night, by using a stop as in the ordnance sector. The observations with the zenith tube are printed yearly in the Greenwich Observations.

The zenith sector has not been much used upon the continent since the great surveys made in the middle of last century for ascertaining the figure of the earth. In the French arc from Dunkirk to Formentera, the latitudes were observed by the repeating circle, and in some of the stations there is reason to suspect that error has been committed. More recently, the transit in the prime vertical has been employed in Germany and Russia for ascertaining differences of latitude, and as it would seem with great success. [TRANSIT.] A prime vertical transit was constructed by Repsold for the imperial observatory of Pulkowa, of which a most favourable account has been given by Professor Struve. While admitting the excellence of this kind of instrument for telescopes of moderate size, we do not see how they can equal, far less surpass, the zenith sector when made reversible and of the proper magnitude.

Some years ago Mr. Babbage proposed a construction for a zenith sector ('Memoirs of the Astronomical Society,' vol. ii., p. 101) which might perhaps be applied in the following manner:—Conceive a parallel ruler to be placed upright, one of the bars being made into a vertical axis with the necessary adjustments, and the other carrying a telescope. It is clear that if the bands were equal the telescope would continue parallel to itself whether the ruler be open or shut. But if one of the bands is a little longer than the other, then a very large angular motion of the band will give a small angular motion to the telescope-bar, and as the measurement of the former angle can be easily made with tolerable accuracy, the latter angle can be computed with great exactness.* Exquisite workmanship would no doubt be required to make such an instrument answer, but we think that for this and other differential purposes Mr. Babbage's suggestion is deserving of attention, especially where telescopes of limited size are used.

The adjustments of a zenith sector or zenith tube will differ according to the construction of the instrument. Where it is not reversible, the time of the transit of a star near the zenith must be got from observations with another instrument, and the star *made* to pass the meridian-wire at the calculated time by the proper adjusting screws. When this is done and the telescope secured, a star must be made to pass along the declination-wire (this should be carried by a micrometer-screw) by twisting the wire-cell, when the adjustment for a fixed zenith telescope is complete. If the telescope rest on a cross axis and carries a sector, the cross axis must be made horizontal, the transits of stars towards the extremities of the arc must be observed, and the azimuthal deviation ascertained [TRANSIT] and corrected; or, the time at which an extreme star *should* pass being known, the cross axis at top and fixed arc below must be turned so as to *make* the star pass at the right time.

When the instrument is reversible, the axis is first to be set truly upright. Suppose the instrument in its meridian position nearly, and face east, read off the division bisected by the plumb-line, or the two ends of each level. Now turn half round, read off again, and bring, by the adjusting screws, the plumb-line or the levels half-way to the first readings, and finally adjust each level by its own screw to read each end alike. If this be carefully done, when the instrument is restored to its first position, the plumb-line or levels will remain undisturbed by the last reversal. Now turn the axis one-quarter round, and correct whatever change is thereby caused, by the east and west screws of the axis. The axis is now vertical, or by a repetition of the process may be made so. The next adjustment is to make the line of sight describe a great circle. This is the collimation error of the transit. This may be done as described above, from knowing the true time; or by observing one star or two stars near the zenith in *reversed* positions, when the disagreement between the observed and computed difference will give the quantity and direction of the alteration required. In a modern instrument this adjustment would be by antagonist screws carrying the wire-plate. If the instrument be simply a zenith-tube, make a star run along the declination-wire, and the adjustment is finished. With a sector place the instrument nearly in the meridian, observe the transit of a zenith star, which gives the time. Then by turning round the axis, make an extreme star pass at the proper time and clamp the axis. In the present ordnance sector the instrument rests on a tray which is adjusted as to meridian by strong screws on the stand, acting against the sides of the tray. Finally, twist the wire-cell till a star runs along the declination-wire. A comparison of the zenith distances of the same stars observed in reversed positions of the instrument, will give the error of collimation, and this *may* be corrected if the observer wishes, but it is better to leave it untouched, and to consider the sum of two observations, Face East and Face West, as a double zenith distance.

(For plates and descriptions of some of the constructions here referred to, and others which we have omitted, see Pearson's *Practical Astronomy*, vol. ii., pp. 531, 554, plates xii., xiii., xxvi., xxvii.)

ZENZO, ZENZIC. The Arabs used a word for the square of a number which has the same meaning as the Latin word *census*; accordingly Leonard of Pisa, Lucas Pacioli, and the early Italians, used *radix* and *cosa* for the unknown quantity, and *census* for its square, which became *censo* in Italian. The Germans corrupted these into zensus and zenso, and hence in their algebraic writings, and in some of the early English ones, the zenzic power is the square. From this and the word cube, various denominations of powers were formed, as zenzi-cubic for sixth, zenzizenzizenzic for eighth, &c., from which we are now happily delivered.

ZERO. [THERMOMETER.]

ZERO. [INFINITE, &c.]

ZETETICS, a name given by VIETA [BIOG. DIV.] to the part of algebra which consists in the direct search after unknown quantities: it is now disused.

ZEUS, the supreme deity of the Greek Olympus, the god of heaven and of earth, to whom the Jupiter of the Romans nearly corresponds both in power and attributes, was probably originally an elemental divinity, who was worshipped as the god of rain, snow, lightning, &c. Apart from other considerations the etymology of his name, both in Greek and Latin, would seem to lead to this conclusion.

According to Homer, Zeus was the son of Kronos and Rhea. [KRONOS.] In order to save her son from being destroyed by his father, Rhea concealed him soon after his birth in a cave in Crete, where he passed the first years of his life. As Zeus grew up, Kronos called to his aid the Titans, in order to secure his dominions against his son; but they were eventually conquered, and Kronos himself dethroned by the youthful Zeus. In the Homeric poems Zeus is represented as the supreme ruler of the gods and of men; and though subject himself to the decrees of Fate, his commands cannot be disobeyed; his wisdom is infinite, and his power irresistible. His wife was Hera, and their children Hephæstus, Ares, and Hebe. The worship of Zeus was co-extensive with the Grecian race. His temples were numerous, the chief being at Elis and at Athens—the former contained Phidias's sublime chryselephantine statue of the god, the latter being, when perfect, the noblest temple perhaps of the ancient world.

Cicero informs us ('De Nat. Deor.,' iii. 21) that there were three Roman deities of the name of Jupiter: one the son of Æther; the second, the son of Heaven; and the third, the son of Saturn. The last was worshipped at Rome under various names, and many temples were erected to his honour, of which the most celebrated was the one on the Capitoline Hill, where he was worshipped under the name of Jupiter Optimus Maximus.

As the supreme god, Zeus taxed the highest powers of the artists of ancient Greece. The Greeks themselves believed that Phidias, in the seated chryselephantine statue of Zeus which he executed for the temple of Elis, had attained the loftiest conception of the divinity. Zeus himself, Pausanias tells us (b. v. c. 10), gave a visible expression of his approval of the sculptor's art; and Quinctilian declares that the work equalled in majesty the god himself, and added somewhat to the religion of those who saw it. The statue has long been lost, but several attempts have been made to restore it from contemporary descriptions—the best known being that of M. Quatremère de Quincy, in his 'Jupiter Olympine.' This work of Phidias seems to have been accepted by the Greeks as an authoritative model for the form and features of the deity. Phidias probably followed in the general conception some more ancient type, but his was thenceforward the normal form which all succeeding artists, according to their ability, sought to reproduce. Müller thus characterises the external features of Zeus, as found in works of the best and later periods of Greek art:—"The hair rose up from the centre of the forehead, like that of a lion, and then fell down on both sides like a mane; the brow clear and bright above, but greatly arching forward beneath; eyes deeply sunk, but wide open and rounded; delicate mild lineaments round the upper lip and cheeks; the full rich beard descending in large wavy tresses; a noble, ample, and open chest, as well as a powerful, but not unduly enlarged muscular development of the whole body." ('Ancient Art,' § 349.) From this general character, which belongs to the best statues of Zeus, deviations occur, where he is represented in a youthful form, or as an excited and vengeful deity.

Zeus was usually represented seated on an ivory throne, with a sceptre in his left hand and in his right a thunderbolt. The Olympian Zeus of Phidias bore in his right hand a Victory, made like the statue itself, of gold and ivory. In early art the representations of Zeus chiefly have reference to his divine character, and his more sublime attributes. Later, and especially as art became the minister of luxury, and too often of voluptuousness, the intrigues of the god with the lesser goddesses, and with mortals, afforded a more acceptable class of subjects, and Jupiter and Io, Jupiter and Ganymede, Leda and the like, were figured in every variety of form and material; and at the revival of the study and imitation of classical art, it need hardly be added that this series of circumstances in the mythic history of Jupiter was seized upon with avidity by the painters and sculptors of Italy.

ZIF. This name, written זו in Hebrew, occurs only in the first book of Kings, in the 6th chapter, and in the 1st and 37th verses. It is the month now called Jyar. The word is derived by the Jews from a root signifying to be splendid, in reference to the splendour of the season when the month occurs, April and May. The word is found several times with a slight orthographical difference in the book of Daniel, and is usually translated "brightness." [BIB.]

ZINC (Zn). *Spelter*. A commercial metal which has been known in the metallic state since the time of Paracelsus. It is never met with in the native state, but is extracted from two ores—*calamine*, or carbonate of zinc, and *blende*, or sulphide of zinc. A native oxide of zinc found in New Jersey has also recently been rendered available for the extraction of the metal.

The commercial metal is never pure, though usually sufficiently so for most chemical purposes. The pure metal may be obtained by dissolving common zinc in dilute sulphuric acid, filtering, treating

* Let the length of the upper band be a, of the lower band $a+h$, the distance between the bands b, and let the bands be horizontal; the telescope-bar makes with the zenith an angle the tangent of which $= \frac{h}{b}$; when the bands are inclined at an angle θ, the tangent of zenith distance $= \frac{h \times \cos\theta}{b}$. The quantity h may be measured and regulated by a micrometer-screw and such a tilt given to the telescope, that the star can be observed in reversed positions of the axis, and thus the double zenith distance found. The zero of the micrometer-screw is found from its position, when opening and closing the bars makes no change in the place of a star. We prefer this construction of a zenith sector to that of Mr. Babbage. The zenith point is only to be got by reversion, and the upright bar must be watched and ascertained by levels, &c. Mr. Babbage has given an exact formula, when the points of attachment of the telescope-bar are constant. We have supposed an adjustment in one of these points, which allows the bands to be horizontal, while the telescope-bar is inclined.

with excess of sulphuretted hydrogen, again filtering, and precipitating the boiled filtrate with carbonate of soda. The washed and ignited carbonate must then be distilled in a porcelain retort with charcoal from lump sugar.

Zinc is a bluish-white crystalline and hard metal, brittle at 400° Fahr., malleable and ductile between 300° and 200°, but again somewhat brittle at ordinary temperatures. It melts at 773°, and boils at a bright red heat estimated by Deville at 1904°. In contact with air the vapour burns with a magnificent greenish-blue flame, forming copious white flocculi of protoxide. At ordinary temperatures zinc gradually oxidises in a moist atmosphere, but the superficial film of oxide preserves the remaining metal for a long time unchanged. It readily dissolves in dilute mineral acids, and in concentrated solutions of potash and soda. It also combines with chlorine, iodine, and bromine at ordinary temperatures. The equivalent of zinc is 32·7, and its specific gravity 6·8 to 7·1.

The following are the principal compounds of zinc:—

Oxide or Protoxide of Zinc (ZnO), *Zinc-white*.—This is the oxide which exists in the native carbonate. It may be prepared in various modes: first, by merely igniting the metal in contact with air; in this case combustion takes place readily, and a light white compound is formed, which was called by the old chemists by the various names of *nihil album*, *lana philosophica*, *pomptolix*, and *flowers of zinc*.

Oxide of zinc may also be procured by dissolving the metal in a dilute acid, either the sulphuric, nitric, or hydrochloric, and decomposing the solution by a carbonated fixed alkali; carbonate of zinc is first precipitated, but this, when heated, loses its carbonic acid, and the oxide is obtained as a yellowish powder.

In the manufacture of brass an impure oxide of zinc condenses in the flues of the furnaces and is sold under the name of *tutty*.

The properties of oxide of zinc are,—that it is inodorous, insipid, insoluble in water, and infusible by heat; it combines readily with acids, and also with the alkalies ammonia, potash, and soda. So that when it is precipitated by them, they redissolve it if added in excess. It is the basis of all the oxisalts of zinc.

Peroxide of Zinc, probably a binoxide (ZnO_2?), is obtained by taking gelatinous hydrate of zinc, and pouring upon it an aqueous solution of binoxide of hydrogen (oxygenated water), containing about eight times its volume of oxygen gas, and shaking the mixture thoroughly; the peroxide of zinc resulting from this operation is white, inodorous, insipid, and decomposes spontaneously when kept moist or when heated. It is also decomposed by acids, which dissolve protoxide of zinc and reproduce binoxide of hydrogen.

Chloride of Zinc (ZnCl) may be formed by the direct action and combination of these elements. When zinc filings are thrown into chlorine gas, heat and light are evolved, owing to their combination; it is more readily prepared by dissolving oxide, or still better metallic zinc, in hydrochloric acid, and evaporating to dryness; or by heating the metal in a tube through which dry hydrochloric acid gas is transmitted.

The properties of chloride of zinc are,—that it is colourless, has a very styptic taste, is readily soluble in water, and crystallises from it with difficulty; it is very volatile at a red heat. It was formerly called *butter of zinc*.

Bromide of Zinc (ZnBr) is formed by passing bromine in vapour over zinc heated to redness; or it may be obtained in solution by agitating a mixture of these elements and water: the solution is colourless, and when evaporated till a pellicle is formed, it becomes a crystalline mass on cooling.

This bromide has a sweetish, astringent taste, and is very deliquescent; it becomes dry when heated, and fuses at a red heat.

Iodide of Zinc (ZnI) is readily obtained by heating iodine and zinc together in water; the solution, when perfect, is colourless, and is to be evaporated in a retort, and when the water is entirely separated, the iodide of zinc fuses and volatilises in fine prismatic crystals. By exposure to the air this iodide is decomposed, the metal being oxidised, and the iodine set free.

Sulphide of Zinc (ZnS).—This compound, which exists plentifully in nature, is obtained artificially with considerable difficulty, and by the direct action of its elements is perhaps scarcely possible; but when oxide of zinc is heated with sulphur in excess, a yellow brown sulphuret of the metal is obtained; when also sulphuret of potassium is added to a solution of a salt of zinc, a white hydrate of the sulphide of zinc is precipitated.

Phosphide of Zinc is procured by strongly heating in a retort a mixture of six parts of oxide of zinc, six parts of phosphoric acid, and one part of powdered charcoal; a sublimed mass is obtained, which is of a silvery-white colour, metallic lustre, and vitreous fracture. Its composition has not been determined.

Selenide of Zinc.—If the vapour of selenium be passed over zinc heated to redness, the mass takes fire and explodes, and the exterior of the vessel is covered with a lemon-yellow powdery substance, which is selenide of zinc; this is partially soluble in nitric acid with the evolution of nitric oxide; and a red powder is deposited, which is however finally dissolved.

We shall now briefly describe some of the oxisalts of zinc, or those consisting of acids combined with oxide of zinc.

Nitrate of Zinc ($ZnONO_5 + 6HO$).—This salt is readily obtained by the action of the acid upon the oxide of the metal, or upon the metal itself; in the latter case nitric or nitrous oxide is produced according to the degree of concentration of the acid.

The solution of nitrate of zinc is colourless, and by due evaporation it yields colourless crystals, which are deliquescent; very soluble in water and in alcohol: they are decomposed by ignited charcoal, and impart to it a greenish-blue flame.

Sulphate of Zinc ($ZnOSO_3 + 7HO$).—This, which is the salt of zinc most extensively employed both in medicine and the arts, may be prepared by dissolving the oxide of the metal in dilute sulphuric acid; but it is always procured by acting on the metal itself, which is oxidised by the decomposition of water, with the oxygen of which it combines and evolves the hydrogen. The solution is colourless, and by evaporation readily yields crystals, which are usually small, and the primary form of which is a right rhombic prism. Sulphate of zinc has a disagreeable metallic taste; it is not altered by exposure to the air, but if moderately heated loses its water of crystallisation, and when subjected to a high temperature is entirely decomposed, the acid being expelled, the oxide only remaining. This salt is very soluble in water at 60°, and much more so in boiling water. There is an impure sulphate of zinc used in the arts, under the name of *white vitriol*; it is a colourless granular mass, obtained by the oxidisement of the native sulphide of zinc or blende.

Carbonate of Zinc ($2\,ZnO\,CO_2 + 3\,ZnO\,HO$).—Metallic zinc and hydrated oxide of zinc are both dissolved by an aqueous solution of carbonic acid; but the nature of the carbonate formed, when the excess of carbonic acid is expelled by spontaneous evaporation, has not been ascertained. When an alkaline carbonate is added to a solution of a salt of zinc, a white precipitate is obtained, which is the above compound of carbonate and hydrate of zinc, and not a simple carbonate.

Acetate of Zinc ($ZnOC_4H_3O_3 + 3HO$) is prepared by dissolving either the metal or its oxide in the acid, or by decomposing sulphate of zinc by acetate of lead. The solution is colourless, and yields thin rhombic plates, which are not deliquescent, but are very soluble in water. It is occasionally employed in medicine.

Characters of the Salts of Zinc.—They are usually soluble in water, colourless, have an unpleasant metallic taste; the alkalies ammonia, potash, and soda decompose them, precipitating a colourless hydrate, which is soluble in excess of these precipitants. The alkaline carbonates also decompose the salts of zinc, but the carbonate of ammonia only, when added in excess, redissolves the carbonate thrown down in any notable quantity. Hydrosulphuric acid decomposes neutral, but not acid or alkaline solutions of zinc; the precipitate obtained is a hydrated sulphide of zinc. Tincture of galls gives no precipitate, and ferrocyanide of potassium a white one with the salts of zinc.

Alloys of Zinc.—Potassium and sodium form with zinc brittle alloys, decomposable by exposure to air and moisture. With copper it combines to form brass, and with iron it yields a very hard alloy, which is very energetically acted upon by sulphuric acid. If plates of hot iron be dipped into melted zinc, they acquire the appearance of tin-plate, and the iron is prevented from rusting. Such coated iron is termed *galvanised iron*.

Sheet-zinc is now largely employed for covering buildings. Plates of this metal are also used in the construction of voltaic batteries.

ZINC, *Medical Properties of*.—In the purely metallic state, zinc produces no effect on the human system, but its combination with oxygen, forming oxide or flowers of zinc, is sufficient to invest it with considerable power over various organs, both those with which it comes into direct contact and some remote ones, especially the nervous centres. Its local action is that of an irritant, astringent, and desiccative, while its remote action is that of a tonic and antispasmodic. The emetic properties of the oxide are less than those of the sulphate or acetate, unless it meets with acids in the stomach. In this way it is rarely employed. It is for its remote effects that oxide of zinc is valued. While it has the properties common to all the metallic antispasmodics, it is distinguished by its power of restraining inordinate action of the nervous system; being calming and soothing. The brain and the function of sensation appear to feel less of its influence than the spinal cord. Hence the nerves of motion, and the functions of the circulation and respiration, are chiefly acted upon; it produces its effects speedily, but they quickly disappear when given in such doses as can be safely administered. The long-continued use of it seems to produce a dryness and induration of the frame, which, if carried to excess, is dangerous, but the lesser degree of which is in all probability the source of the utility of this medicine, by diminishing the mobility of the system; irregularities in the circulation, and sudden congestions of blood, being the immediate causes of attacks of epilepsy and hysteria, the diseases which are most benefited by oxide of zinc. This desiccating property renders it the most potent means yet discovered of checking the colliquative perspirations of consumptive persons. (See 'Clinical Lectures on Pulmonary Consumption,' by Theophilus Thompson, M.D., p. 194.) For use in this way, and even for use as an ointment, it requires to be prepared in a state of far greater purity than it is met with when prepared for use in the arts. Above all, it must be free from admixture with sulphate of zinc.

In spasmodic affections of the chest, such as asthma, angina pectoris, and palpitation of the chest, when these do not proceed from organic derangements, oxide of zinc is often serviceable, especially when combined with conium. In the cramps of the stomach to which habitual drunkards are subject, it is very useful.

Impure oxide of zinc is called tutty. It is sometimes used externally as a dusting powder, as a mild absorbent, on excoriations, and to heal chaps and cracks in the skin. It is also used as an ointment. Pure oxide of zinc forms an ointment of much value where a mild astringent is needed, especially in the chronic inflammation of the eyelids.

Carbonate of zinc when impure is termed calamine. This, after being subjected to divers processes, is called *prepared* calamine. The only use made of it is to form an ointment, which is most useful as an application to burns, excoriations, and superficial ulcers.

Sulphate of zinc is in small doses a very valuable astringent, tonic, and antispasmodic; in larger doses it is a very certain and speedily acting emetic; and in very large doses it is poisonous. It is the most useful emetic in cases of narcotic poisoning, as it is not so apt to inflame the stomach as tartarised antimony: but the stomach-pump is preferable to either.

The tonic effects are best seen in affections of the mucous membranes. In the suffocative catarrh of aged persons, and the extreme defluxions on the chest after influenza, sulphate of zinc affords a valuable remedy: it must be given in small doses, as the sudden suppression of the secretion may cause inflammation. Its utility is increased by combining it with the compound rhubarb pill, or with myrrh only. The use of the solution as an injection requires the same caution.

Acetate of zinc is possessed of nearly similar properties, but in a weaker degree; and as an injection, seems in some cases entitled to a preference.

Chloride of zinc, called also butter of zinc, is a powerful escharotic or caustic; this action results from its strong affinity for albumen and gelatine, which principles it abstracts from the living tissues, and so forms an eschar. Its powers in this way have been taken advantage of to destroy parts affected with malignant diseases, such as cancer and lupus, and to remove nævi materni, or mother-marks. In none of these is it to be resorted to unless they are very superficial. Deep-seated cancer of glands can scarcely be removed by it, but other forms are often successfully treated by it. (Walshe, 'On Cancer,' p. 219.) Properly diluted, chloride of zinc is most beneficially used to correct the fœtor from suppurating ears of children.

Cyanide or cyanuret of zinc is a powerful antispasmodic and tonic. No medicine is so potent in allaying irritability of the stomach, attended with great debility. The dose must be small and often repeated. Velerianate of zinc has lately been much recommended as a remedy against tic-douloureux and other nervous affections. Where the patients can tolerate the repulsive odour and persevere in its use, it often proves very serviceable.

Zinc pans have been much recommended for use in dairies, as the milk speedily coagulates in them, and the quantity of cream is great: but if the milk becomes sour while in them, the acid acts upon the zinc, and forms unpleasant, though perhaps not poisonous compounds. Upon the whole, white porcelain vessels, kept thoroughly clean, are the best material for milk-vessels.

ZINC MANUFACTURE. The mode of obtaining zinc from the sulphuret and other ores is explained in the article ZINC. As brought to market, commonly under the name of *spelter*, it is a bluish-white metal, having considerable hardness and toughness. The chief English supply is from Flintshire and the Isle of Man; but the market is mostly supplied from Upper Silicia, where the ore is smelted, and the spelter sent for shipment from Dantzic, Stettin, and Hamburg: shippers are willing to convey it freight-free, to serve as ballast for the ships that bring German wool to England. Mr. Robert Hunt has given the following as an account of the British ores of zinc brought up to the surface in 1857:—

Cornwall	1675 tons.	£4,697
Devon	775 ,,	2,478
Cardigan	1371 ,,	4,452
Isle of Man	2917 ,,	10,772
Cumberland	492 ,,	697
North Wales	2060 ,,	7,887
	9290 ,,	£30,983

presenting an average of about 66*s*. per ton. The largest mass of zinc ever described was that which was displayed at the Great Exhibition in 1851, and which weighed 16,000 lbs. It was smelted from the ore by Messrs. Detmold, of New Jersey, in the United States. There is a vein of zinc-ore 9 feet thick, at a spot about 50 miles from New York, and easy of access, as it is not far beneath the surface. The ore is carried to Newark, in New Jersey, where it is converted partly into metallic zinc, but mostly into zinc-white for house-painting. The metal is separated from the other ingredients of the ore by a process of vaporisation, as described in the article ZINC; but at Messrs. Detmold's establishment some of the operations are conducted in a remarkable way. A vapour, containing nearly all the zinc, is sent by blast along pipes to a *catching-house*, where it passes into enormous bags of cotton 5 feet in diameter by 150 feet long; the gases pass through the meshes of the bag, while an oxide of zinc cools down to the state of a white powder, which is shaken out of the bag at intervals. This is the mode adopted, not in procuring metallic zinc, but as the preliminary stage in making zinc-white. The powder is either sold in a dry state, in barrels containing 200 lbs., or is ground up with linseed-oil and sold in kegs.

In reference to the zinc-white above mentioned, it may be observed that the substance is recommended as a substitute for white lead in house-painting—not as being better suited in itself, but as being less injurious to the workmen. Some persons, moreover, attribute to it much greater permanency, and other qualities superior to those possessed by white lead. Linseed-oil and spirit of turpentine are mixed with the zinc-white. Oil in good proportion gives it durability and efficacy of covering the surface of the work; in excess, it has a softening and darkening effect. Turpentine in good proportion gives a ready fluidity for spreading; in excess, the paint becomes too transparent, and has a tendency to pulverise.

Metallic zinc is mostly used in the form of plates or sheets. When heated to a certain temperature it becomes malleable and ductile, and may then be rolled out to any convenient degree of thickness; and although brittle before this heating, the brittleness never returns after the cooling. This is found to be a valuable property in zinc. In the form of sheets, zinc is largely used for baths, cisterns, tanks, spouts, pipes, chimney-pots, roofing, as also for plates for engraving, sheathing for ships, and as one element in voltaic batteries. Being so much lighter than lead, zinc is found to be very useful for roofing. The joining of plates of zinc requires to be effected in a peculiar way. [SOLDERING.] In the making of zinc door-plates, a sheet of rolled zinc is cut to the proper size and shape, scraped to a clean surface, hammered flat, planished with a broad and smooth-faced hammer, and polished. Plates for zincographic engraving require, not a smooth, but a fine granular surface; they are rubbed first with ordinary sand, and then with fine sifted sand and water applied by means of a woollen rubber.

Many modes of coating iron and other metals with a thin layer of zinc have been described. Among these, one has been patented by Mr. Alexander Watt, editor of the 'Chemist.' Steel or iron is pickled in a solution of sulpho-muriatic acid, and then exposed to galvanic action in a battery supplied with cyanide of potassium, liquid ammonia, metallic copper, metallic zinc, hydrochloric acid, and carbonate of potash. This subject is further treated under TINNING.

The chief use of zinc, perhaps, is as a compound in the formation of brass. [BRASS.]

In 1860, metallic zinc, under the name of *spelter*, was imported from foreign countries to the extent of 24,000 tons.

ZINCOGRAPHY. [LITHOGRAPHY.]

ZI'NGIBER OFFICINA'LE (GINGER), *Medical Properties of*. The native country of this plant seems unknown, though Goebel asserts that it is Guinea. It is however extensively cultivated in China, Java, and the East and West Indies. From the cultivated plant alone is the ginger of commerce procured. Of this there are two varieties, the black and white; but some writers affirm that these are the produce of two distinct species, while others ascribe the difference of appearance to diversity of treatment after the rhizome is dug up. The rhizome, or root-stock, is perennial, but it is only that of a young plant, or the annual shoots from an old one, which are met with in commerce. When first dug up, the colour internally is red. Those procured the first year are used fresh, or preserved in sugar, and constitute the sweetmeat known as *preserved ginger*. This, when sent from the West Indies, is in small, round, tender pieces; when from the East, larger, flat, and stringy portions: the former is preferred.

Black ginger is stated to be the rhizome dug up, scalded in hot water, and dried in the sun. White ginger is also scalded, and then scraped to free it from the rind before it is dried, which last operation is said to be effected by artificial heat, but probably mostly by the sun. Both kinds are very liable to the attacks of an insect. To prevent these attacks the rhizomes are dipped in a solution of lime, the white particles of which often adhere to the surface. To cause black ginger to resemble the white, it is bleached, after its arrival in this country, in a solution of chloride of lime, or exposed to the fumes of burning sulphur. This impairs the activity of the article.

Ginger occurs in commerce in pieces termed *races*, of various shapes, but generally flattish, branched, lobed, or palmated, rarely more than four inches long. The unscraped has a wrinkled epidermis; the scraped is devoid of this covering. Jamaica ginger, which is most esteemed in this country, occurs in races larger, rounder, and thinner than the other kinds; externally of a yellowish white, internally of a yellower hue. The taste is agreeably aromatic and pungent, but this is lost with age, so that old pieces are worthless, as are also portions which have been digested in alcohol to form *essence of ginger*. Ginger, when chewed, excites a flow of saliva; the powder applied to the nostrils causes sneezing. The quantitative analysis of 100 parts of ginger have been given by Buchols:—

Pale yellow volatile oil	1·56
Aromatic, acrid, soft resin	3·60
Extractive soluble in alcohol	0·65
Acidulous and acrid extractive, insoluble in alcohol	10·50
Gum	12·05
Starch (analogous to bassorin)	19·95
Apotheme, extracted by potash	26·00
Bassorin	8·30
Woody fibre	8·00
Water	11·90
	102·51

Morin's analysis yields also acetic acid, acetate of potash, and sulphur, and a resin insoluble in ether and oils; while the ashes give numerous metallic salts and alkaline salts.

The volatile oil is of a pale yellow, lighter than water; taste at first mild, then hot. The soft resin, obtained by digesting the alcoholic extract of ginger first in water, then in ether, and evaporating the etherial tincture, is not quite analogous to the principle *zingiberin*, procured by Beral, and by him termed *peperoid*. This last is got by submitting ginger directly to the action of sulphuric ether. Beral recommends many preparations of this principle, but, except from their smaller bulk, it is difficult to perceive what advantage they possess over common ginger and its preparations. Ginger is an aromatic stimulant of considerable power. The effects are greater on organs with which it comes into direct contact than on remoter ones. Thus, when chewed, it is a powerful sialogue, and relieves toothache, rheumatism of the jaw, and also relaxed uvula. When received into the stomach, it promotes digestion in languid habits, and relieves flatulent colic. Gouty subjects are much benefited by it, and for such persons no form is more beneficial than that of preserved ginger taken at dessert after a mixture of viands. But it has the disadvantage of impairing the flavour of the wine taken at the same time.

The action of ginger on remote organs is greatest on the mucous membranes. Hence the lungs are markedly excited in the relaxed and suffocative catarrh of old people. The mucous membranes of the urino-genital organs are also excited by it in languid habits. Many feeble females receive much advantage from the domestic preparation termed ginger-tea. Some headaches of a sympathetic kind, originating in irritation of the intestinal canal, are often relieved by it. A poultice of scraped ginger, to which warm water has been added, forms a substitute for a mustard poultice, and often relieves headache when applied to the forehead. Ginger-beer is often a grateful beverage in summer heat, but with some persons it disagrees; this is owing to the sugar, for if made without it, it agrees with such persons well. Lemon-juice, when taken with sugar, often disagrees, as for example with pancakes. The lemon-juice alone is most wholesome.

ZIRCONIA. [ZIRCONIUM.]

ZIRCONIUM (Zr). A rare metal found in the minerals zircon and hyacinth, which contain the oxide of the metal united with silicic acid. To obtain the metal, the double fluoride of potassium and zirconium is to be strongly heated with potassium; from the cold residue diluted hydrochloric acid dissolves out everything except pulverulent zirconium, which must be washed first with solution of chloride of ammonium and then with alcohol. Zirconium has not yet been fused: obtained in the manner just described it presents the appearance of a black powder, which assumes a slight metallic lustre under the burnisher and scarcely conducts an electric current. Zirconium in this pulverulent form indicates the properties of the massive metal as little as pulverulent aluminium did those of the latter beautiful metal before it was obtained in malleable masses by Bunsen and Deville. When heated below redness in air or oxygen, zirconium takes fire and burns with a very intense light, producing zirconia. It is also gradually oxidised in boiling water, diluted hydrochloric and sulphuric acids do not act upon it, but hydrofluoric acid dissolves it with evolution of hydrogen. The equivalent of zirconium is 33·6 if zirconia be written Zr_2O_3, but if written ZrO_2 the equivalent is 22·4.

Zirconia (Zr_2O_3, or ZrO_2). Zirconium and oxygen form only one compound, zirconia, which is obtained by fusing finely-powdered zircon with caustic potash or soda and then dissolving the fused mass in dilute hydrochloric acid. Excess of acid and moisture are expelled by heat, when on the addition of water the chlorides of zirconium and potassium or sodium are dissolved, leaving insoluble silica; from this solution excess of ammonia precipitates zirconia as hydrate, which must be washed, dried, and ignited. It then presents the appearance of a white infusible and insoluble powder. The hydrate is gelatinous, insoluble in the caustic alkalies, but readily soluble in acids, and sparingly so in carbonate of ammonia.

Zirconia forms salts with acids, which possess the following characters:—They have an astringent taste; they are precipitated by the caustic alkalies potash and soda, and an excess of them does not redissolve the precipitate. When boiled with sulphate of potash, a subsalt of zirconia is formed, and being insoluble subsides. Infusion of galls produces a yellow precipitate, and phosphate of soda a white one: carbonate of zirconia, when recently precipitated, is soluble in bi-carbonate of ammonia and of potash.

ZO'DIAC (in Greek, *ὁ Ζῳδιακὸς κύκλος*, "the Zodiac circle") is a name given to a zone of the visible heavens, extending in breadth to certain equal distances on both sides of a great circle of the celestial sphere, in the plane of the earth's orbit produced. This circle, with which the apparent annual path of the sun coincides, is called the ecliptic; at present it makes, with the plane of the earth's equator, an angle equal to about 23° 27′ 35″, and it is divided into twelve equal parts, called *signs*, which receive their denominations from those of the figures intended to designate the constellations or groups of stars about it. Most of the figures being those of animals, the name of zodiac (from *ζῴδιον*, *zōdion*, the diminutive of *ζῷον*, *zōon*, "an animal") has, in consequence, been applied to the zone.

The planes of the orbits of all the planets, when produced to the celestial sphere, are supposed to be comprehended within the breadth of the zodiac, and that breadth is determined by two small circles parallel to the plane of the ecliptic. Before the discovery of Ceres, Pallas, and the other asteroids, the greatest inclination of the orbit of a planet to the ecliptic scarcely exceeded 7 degrees, and therefore the breadth of the zodiacal zone was imagined to be about 16 degrees, or 8 degrees on each side northward and southward of the ecliptic. The orbit of Pallas (that which deviates most from the ecliptic) is inclined about 35 degrees to that plane; and it might now be understood that the breadth of the zone is about 70 degrees.

The line in which the plane of the ecliptic intersects that of the terrestrial equator, being produced indefinitely, cuts the celestial sphere in two points diametrically opposite to each other; and one of these meeting the heavens, in the age of the earliest Greek astronomy, near certain stars forming a constellation to which the figure of a ram (Aries) was assigned, is generally called the first point of Aries. From this point are reckoned, on the ecliptic, the longitudes of celestial bodies; and on the equator, their right ascensions. The twelve equal parts or signs into which the ecliptic is divided are distinguished by the names of the constellations which, in the age above alluded to, fell within their respective extents in longitude; and the names both of the signs and constellations are as follow:—Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, and Pisces.

The distribution of all the visible stars into groups or constellations was the first step in laying the foundation of astronomical science. It must have taken place in the earliest ages of the world; and there is the highest degree of probability that the zodiacs of all nations have been derived from a common source, though in passing from one people to another it may be easily conceived that the figures would suffer changes from the vanity or caprice of individuals. Among the ancients, the place of the sun in the zodiac served to regulate the seasons of the year; the representations of the figures associated with the groups of stars were almost constant ornaments of the religious edifices; and superstition assigned to the regions of space influences on the lives and characters of men depending upon the qualities of the animals or objects which distinguished the constellations in the corresponding parts of the celestial sphere.

The loss of the writings of the ancient Babylonians, and the entire destruction of their edifices, have deprived the world of every monument by which light might be thrown on the state of astronomy among a people whose priests, according to Strabo, were mostly engaged in the study of the science. In fact, our information respecting it consists chiefly of the notices given by Ptolemy concerning a few of their observations, and from the evidence of Geminus. Diodorus Siculus states ('Biblioth. Histor.,' ii. 30) "that the Babylonians had twelve chief deities, to each of whom they assigned a month, and one of the so-called twelve animals," by which he means the twelve parts of the zodiac; and from this it may be inferred that they divided the zodiac into twelve signs. Sextus Empiricus ('Adversus Math.,' lib. v.) makes a like statement, and shows how, by means of a clepsydra, the division was or may have been made. With respect to the astronomical monuments which adorned their edifices, a few fragments only of stone, having on them figures which may or may not have been intended as representations of those which distinguish the constellations, have been dug up near Bagdad; and the most remarkable of these is one having on its face a solar disc accompanied by a serpent: the figure may have designated Ophiuchus, and it is possible that it may have been part of a Chaldæan planisphere. The division of the zodiac into twelve signs may have been originally made for the convenience of distinguishing the portions which the sun passes through in the several months; and a division into twenty-eight parts is alluded to by Geminus (*Εἰσαγωγὴ εἰς Φαινόμενα*), which was probably made to denote the space daily described by the moon by her proper motion. The former division was used by the Egyptians, the Greeks, and by all the civilised nations of Asia; and the latter is found among the Persians, Arabs, Hindus, and Chinese: the twenty-eight parts are called the *stations* or *abodes* of the moon, because this luminary is in some one of them each day.

During the invasion of Egypt by the French, in 1798, General Desaix discovered some remarkable sculptures on the ceiling of an apartment in the great temple at Denderah (the ancient Tentyra), and MM. Jollois and Devilliers almost immediately perceived among them figures nearly similar to those which are traced on celestial globes at the present time. The whole of the astronomical figures are within the circumference of a circle above five feet in diameter; and the apartment in which they were found is in the upper part of the building: adjoining it is an apartment of equal size, which is open to the sky, the ascent to both being by steps in the interior. Bas-reliefs, apparently of an astronomical character, are found in several other apartments within the same temple; and in the ceiling of its portico are figures resembling constellations, among which are those of the zodiac disposed in two lines, one near each extremity of the portico, and parallel to the longitudinal axis of the temple.

The zodiacal figures in the apartment first mentioned are disposed nearly within the breadth of an annulus formed by two circles, whose common centre is at some distance southward from the centre of the whole; the figure which is conceived to represent Cancer is however within the space inclosed by the interior circumference of the annulus, and nearly opposite the interval between Gemini and Leo; that interval being occupied by a human figure with a bird's head, above which are a bird and certain hieroglyphical symbols. The figure of Cancer is also surmounted by a hieroglyphical symbol, which, according to Visconti, seems to express a proper name.

Except the zodiacal figures, scarcely any in the ceiling resemble those which are now assigned to the constellations; and a great effort of the imagination is required to discover in what manner they may be considered as emblems of the latter. From the zodiacal figures only has it been possible to form opinions concerning the nature of the projection employed in the execution of the work, and the epoch to which the aspect of the heavens represented by it is to be referred.

The first discoverers of this ancient monument immediately perceived that the horary or declination circles, if drawn upon it, would be represented by straight lines diverging from the centre: the latter is consequently the pole of the equator; but we are indebted to M. Biot (' Recherches sur l'Astronomie Egyptienne') for the very probable idea that the space within the exterior circle represents a development of the whole surface of the celestial sphere, the radii of the circle being equal to half the circumferences of the hour circles, so that the exterior circle represents the south pole of the equator in the heavens. The figures of the constellations are supposed to be placed on the radii corresponding to the circumferences of the hour circles passing through the groups of stars to which the figures belong, and at distances from the centre of the planisphere equal to the angular distances of the figures from the north pole of the equator. The distortion produced by such a development of a spherical surface is evidently very great near the margin; but a spectator when duly instructed, on comparing the figures near the centre with the groups of stars about the north pole in the heavens, might distinguish those to which the figures were intended to refer; and the apartment without a roof, adjoining that which contained the planisphere, is supposed to have been intended for the purpose of facilitating such comparison. One property of the species of projection or development just mentioned is, that in the direction of a line passing through the centre, or pole, the distance between two points corresponding to two which are diametrically opposite to one another in the heavens is equal to half the circumference of a great circle of the sphere; and M. Biot found that this condition is satisfied by the planisphere as nearly as can be expected in a representation which does not admit of great precision.

In order to ascertain, if possible, the epoch of the planisphere, M. Biot assumed as correct the positions of four stars upon it, which, being accompanied by figures of men and by hieroglyphical symbols, appeared to have been distinguished on account of some particular interest attached to them; and concluding from their positions with respect to the nearest zodiacal signs that they must represent Fomalhaut, Antares, Arcturus, and β Pegasi, he first verified them by the near agreement of their measured distances from each other on the planisphere with the distances obtained by computation from their known angular distances in the heavens; then computing the angles of the triangle formed by two of the stars and the centre, or pole, of the planisphere, and also the angles of the triangle in the heavens between the arcs joining the two stars and the pole of the ecliptic in 1750, he found, by comparison, the latitude and longitude of the centre of the planisphere with respect to the positions of the ecliptic and the equinoctial point for that year. The position of the centre, thus found, is that which the pole of the world must have occupied about the year 716 B.C.; and he thence concludes that the planisphere presents the state of the heavens at the latter epoch. M. Biot afterwards calculated for that epoch the places of the principal stars, and determined their situations on a plane by the rules of the projection supposed, as above mentioned, to have been used in constructing the Egyptian monument: on comparing the map so formed with an exact copy of the planisphere, he found the stars to fall upon or near the figures to which they were presumed to belong. Thus the stars of Ursa Minor fall near the centre, precisely on the figure of an animal resembling a dog or wolf, probably the Cynosura of the Greeks; and those of Orion on the figure of a man, apparently intended for Horus, the son of Osiris, to whom, according to Plutarch ('De Iside et Osiride'), Orion was consecrated.

Several indications exist in the planisphere of an intentional displacement of the figures designating the constellations. In some cases, apparently when a constellation could not be conveniently introduced in its proper place for want of room, it has been transferred to the margin in the direction of a line drawn from the centre through the true place of the constellation. In other cases a constellation appears to be removed and a hieroglyphic figure substituted for it. Thus a line drawn from the centre of the planisphere, through Taurus, leads near the margin, to a group of seven stars, which probably designate the Pleiades; and near it is another group, which may represent the Hyades. Again, between Aries and Pisces, and a little above them, is an animal in a sitting posture, which is found to coincide with the computed places of the stars in Cassiopeia; and near the margin of the planisphere in a line drawn through the centre and this animal, there is a human figure seated in a chair, as Cassiopeia is always represented. In a few cases some emblem of a constellation is found at the margin opposite the figure denoting the constellation: thus the head of a ram surmounted by a winged globe is in the direction of a line drawn from the centre through the front of Aries in the zodiacal ring. A great figure, which is supposed to represent a hippopotamus, is situated near the centre of the planisphere in a place corresponding to a part of the heavens very near Ursa Major, but where there are no remarkable stars; and M. Biot conjectures that the animal may be an emblem of that constellation: he conceives that it may indicate Typhon, who, according to Plutarch ('De Iside'), is represented by a hippopotamus, and to whom Ursa Major is assigned. That the ancient Egyptians had a constellation which was designated by this name is stated by Plutarch and by Diodorus Siculus (i. 27); the latter has given translations of two inscriptions in hieroglyphics, which appear to have existed in his time; and in one of these Osiris is made to say that he had been to the uninhabited parts of India, to the regions of the *Bear*, and to the sources of the Ister (Danube).

In the direction of a line drawn from the centre of the planisphere, towards the north, and passing through the figure of Cancer, is the representation of a cow having a great star between its horns; and near it, in the direction of a line coinciding with the longitudinal axis of the temple, is a tall lotus-stem surmounted by a hawk, the symbol of deity. On this stem the place of Sirius, computed for the epoch of the planisphere, is found to fall; and the cow probably represents Isis, to whom the star Sirius was consecrated. The solsticial colure being due north and south, it is probable that the planisphere was intended to show the aspect of the heavens at the time of the vernal equinox, when the colures pass through the four cardinal points of the horizon; and the line passing through Cancer and the cow being in the plane of the solsticial colure is an indication that at midsummer, at the epoch of the planisphere, Sirius rose with the stars of Cancer. The line representing the direction of the equinoctial colure passes, on the eastern side, between two symbolical figures of men, a little way from which is a small figure (supposed to be Harpocrates) issuing from a lotus-flower, and having above his head a star with a hieroglyphical inscription. According to Plutarch ('De Iside') the Egyptians represented the rising sun by a child issuing from a lotus; and hence it is inferred that the symbols indicate the rising of the sun in the east point of the horizon on the day of the vernal equinox.

The heads of all the figures, with scarcely an exception, tend towards the centre of the planisphere, and the figures in the southern half of the zodiac are arranged so that, to a spectator standing in the centre of the room with his face to the south, and looking upwards, they must have appeared as if moving from east to west; that is in the direction of the apparent diurnal motion of the heavens. The longer axis of the temple is inclined to the meridian in an angle of about 17 degrees, and the walls are directed so that the points at which the remarkable stars Sirius and Antares must have seemed to rise coincided with the directions of the north and south ends of the building. A temple near Esne (Latopolis), in the portico of which is a representation of the zodiacal signs, is disposed so that the longitudinal walls tend to the points at which Antares and Sirius set; and though no great stress ought to be laid upon this circumstance, there is some probability that the dispositions may have been intentional, since no reason can be assigned why, otherwise, the temples should not, like the pyramids, have had their walls directed to the cardinal points of the horizon. The golden circle of Osymandyas, which is mentioned by Diodorus Siculus (i. 49) as being placed in the tomb of that ancient king at Thebes, was 365 cubits in circumference, and to each cubit was assigned one of the 365 days of the year, with the risings and settings of the stars for each day marked on the several divisions.

The ceiling of the portico belonging to the temple at Denderah is nearly covered with sculptured figures, many of which resemble those in the circular planisphere, and the twelve signs of the zodiac are distinctly represented in two bands parallel to the axis of the building: six of the figures appear to be entering the temple on the eastern side of the portico, and of these Cancer is the last; the other six, of which the first is Leo, appear to be quitting it on the western side, so that (the front of the portico being towards the north) the direction of their motion corresponds to that of the apparent diurnal rotation. Within the two lines of figures are those which belong to the northern constellations, and beyond them, near the eastern and western extremities of the portico, are figures relating to the southern constellations. Among the former is a human figure surrounded by seven stars, disposed similarly to those of Ursa Major in the heavens, and near them is a lotus-stem surmounted by a hawk, like that which in the circular planisphere is in the place of Sirius: this emblem in the planisphere of the portico is therefore supposed to be an indication of Sirius; and the opinion is confirmed by the fact that it is preceded by a cow (Isis) and a great hieroglyphical inscription.

In the planisphere of the portico, as well as in that of the temple, the figure supposed to be that of Cancer is placed on one side of the position which it should occupy among the zodiacal constellations; and this circumstance has given rise to a doubt concerning the justness of that supposition. Some persons have imagined that the figure might have been intended for the mythological scarabeus; but as in this temple, as well as in those at Esne, it has eight feet, while the scarabeus has but six, it is more probable that it represents the zodiacal sign; and that, agreeably to the hypothesis of Biot, the displacement was in order to make room for some emblem. In fact, the place of Cancer is, in the portico, occupied by a head of Isis, which is plunged in the solar rays; and, since Sirius was consecrated to Isis, it is reasonable to suppose that the emblem was intended to express that, at the epoch of the planispheres, the star Sirius rose heliacally. By calculation it is ascertained that about 700 years before Christ, in the latitude of Denderah, Sirius rose with the star of Cancer when the sun was in that constellation, that is, at the summer solstice.

The two temples at Esne have, in the ceilings of their porticoes, representations of the twelve zodiacal constellations in two lines parallel to the axes of the buildings. In the smaller temple six of the figures appear to be entering on the southern side, and six to be issuing on the northern side: the front of the portico being towards the east, the direction of their movement corresponds, consequently, to that of the diurnal rotation, as in the temple at Denderah; but there is this difference in the division of the figures, that at Esne, Leo is the last to enter, and Virgo the first to quit the temple. M. Biot endeavours to account for this difference by the different inclinations which the axes of the two temples have to the meridian; the axis of the temple at Denderah deviating 17 degrees, and that of the small temple at Esne 71 degrees, both of them being from the north towards the east. He observes that, in the former temple, a meridian line passing through the centre of the circular planisphere cuts the zodiacal band in Cancer towards the north, and in Capricorn towards the south; thus dividing the twelve figures so that the six which are on the western side constitute all those which at a certain hour are descending towards the west, and those which are on the eastern side are ascending towards the meridian. At the head of this descending series is Leo, which is the first to pass the inferior meridian and enter the eastern series; and at the head of the ascending series is Aquarius, which is passing the upper meridian: this distribution corresponds to that which is represented in the zodiac of the portico. A like correspondence would be found to exist in both the temples at Esne if a circular planisphere were supposed to be placed in the ceiling of each, with the lotus-stem in the longitudinal axis, towards the north, and the planisphere were cut by a meridian-line so as to divide the figures into such as ascend and such as descend.

That there were among the ancient Egyptians a variety of sculptured representations of the heavens is evident, since the planisphere described by Scaliger, in his 'Notes on Manilius,' contained, among many animals having no correspondence in form or situation with those which have been mentioned, the figure of a man holding a scythe, and of another who is killing a bear; and in the 'Mémoires de l'Académie des Sciences,' 1708, there is described, by M. Bianchini, a fragment of an Egyptian planisphere consisting of a circular space surrounded by five concentric bands: in the centre are two bears separated by a serpent, as in the present spheres; and in the nearest band are twelve figures representing constellations, most of which differ from the zodiacal signs above described; the place of Gemini, for example, being occupied by a serpent. In the two next bands are the signs of the Greek zodiac, and on the exterior of these is a band divided into 36 parts, in each of which is a deity; these are the spaces of 10 degrees, into which, in the East, the zodiac was sometimes divided.

There can be little doubt that the Egyptians and Chaldæans distinguished the groups of stars in the visible heavens by the figures or symbols of the deities which they worshipped, and of the men who, among them, had signalised themselves by great actions; but it has been also assumed, that the names of the zodiacal constellations were given from circumstances relating to the apparent motion of the sun, to the labours of husbandry, or to the productions of nature in different seasons. Macrobius mentions ('Saturnal.,' lib. i.) that the constellation in which the sun is, at the season when he ascends from the winter solstice towards the equator, received the name of Capricronus, because the goat is an animal accustomed to ascend to the highest points of ground; and that the constellation in which the sun is when he returns from the summer solstice towards the south was designated

Cancer from the crab being an animal which is said to have a backward movement. Bishop Warburton in this country, and M. Pluché in France, carrying out the same idea, have imagined that the constellations Aries, Taurus, and Gemini received their names from the young of animals being brought to the fields in the spring; that Leo indicates the violent heats of summer, and Virgo, presumed to be a gleaner, denotes the time of harvest, and so on. M. Dupuis, assuming that the zodiacal constellations were first imagined in Egypt, and that they indicated circumstances connected with the labours of husbandry in the different months of the year, endeavoured to ascertain at what epoch, in the climate of Egypt, the symbols would be in accordance with the circumstances which they were supposed to represent; and the result of his inquiry was, that the agreement could have subsisted only when the vernal equinox was in the constellation Libra. At present it is in the constellation Pisces; and computing the time during which, by the effect of precession, the equinoctial points would move over about half the circumference of the ecliptic, he assigned 15,000 years before the Christian era for the time of the invention of the zodiac. This extravagant epoch he afterwards reduced to about 4000 years before Christ. ('Origine des Cultes,' 1796.)

M. Fourier, in his 'Recherches sur les Sciences et le Gouvernement de l'Egypte,' assumes that the representation of the head of Isis partly plunged in the solar rays near the figure of Cancer, among the sculptures in the portico of the temple at Denderah, is an emblem of the heliacal rising of Sirius when the sun was in the sign, or in the constellation Cancer; and observing that Cancer is the last of the figures which appear to enter the portico of that temple, while in the zodiacs at Esne the lion is the last which enters, he conceives that the latter circumstance is an indication of the sun being in Leo when Sirius rose heliacally. Supposing, then, that the epochs of the zodiacs at Denderah and Esne are such as the positions of the sun denote, he determines, by computation founded on the progressive displacement of the point of the heliacal rising, that the interval between them is 1800 years, the sculptures at Esne referring to the more ancient period. This result must, however, be considered as overthrown by the calculations of MM. Ideler and Biot, who have determined the longitudes of the sun at the terminations of three sothiac or canicular periods of 1460 years, within which the heliacal risings of Sirius return to the time of the summer solstice; and have found that between the year 2782 B.C. and 139 A.C. the sun was in the constellation Leo and in the sign Cancer at all the three epochs. M. Biot concludes therefore that the zodiacs at Denderah and Esne do not indicate that the sun had passed from one constellation to the next in the interval between the epochs to which they are supposed to refer.

In the temple at Denderah, according to Dr. Young, Leo may be intended to represent the leading sign of the zodiac, or the sign preceding that in which the sun was on the first day of the *annus vagus* (year of 365 days); and on this supposition it would follow, from the known rate at which the place occupied by the sun in the ecliptic at the commencement of such year retrogrades, and also from the fact that the year of 365 days began on the day of the vernal equinox in the year 130 B.C., that the epoch of the planisphere is between 11 B.C. and 108 B.C., or in an age earlier by 1500 years. If Virgo were the leading sign, as it may be supposed to be in the small temple at Esne, the epoch of the zodiac would be the year 900 B.C., or 1500 years earlier.

It has been ascertained by MM. Champollion and Letronne from the Greek inscriptions on the temples of Denderah and Esne, that those edifices were constructed, or finished, during the times of the Roman emperors ('Précis du Système Hieroglyphique, Recherches, &c.'); yet, as it is known that during the reigns of the Ptolemies, and even after the conquest of the country by the Romans, the Egyptians continued to build temples, which they consecrated to their deities, with decorations similar to those which were executed in more ancient times, it may be presumed that the present sculptured zodiacs are copies of others which were the works of the earliest artists; so that though they determine nothing respecting the time of the construction of the temples, they may still serve as indications of the manner in which the heavens were represented in the East in the infancy of astronomical science. The circular planisphere which once adorned the interior of the temple at Denderah was removed to France in 1821.

The country from whence the Greeks derived the figures of the constellations is not with certainty known: that all the extra-zodiacal signs in their descriptions of the heavens did not, from the first, receive their designations from subjects connected with the Greek mythology is evident, since in the notices given by the earliest writers on astronomy, two of them, which subsequently received the appellations of Hercules and Cygnus, have the general names ἐν γόνασιν, *a kneeling figure*, and ὄρνις, *a bird*; and that some of the figures were borrowed from the Chaldæans is probable, since in the time of Herodotus it was supposed that the Greeks acquired from the Babylonians the knowledge of the *polus* (πόλος), the gnomon or style, and the division of the day into twelve parts. (Herod., ii. c. 109.) It may be imagined that, from the intercourse between the Egyptians and Greeks in very early times, a great resemblance should be found among the figures employed by the two people to represent the groups of stars; but that they differed in some respects from one another may be inferred from the testimony of Achilles Tatius, who states that the Egyptians had not the constellations Draco, Cepheus, and Cassiopeia; and it follows that these must have been introduced by the Greeks, or at least that the latter people substituted them for corresponding figures in the Egyptian sphere. It may be remarked, however, that in the oldest descriptions of the Greek zodiac σκορπίος and χηλαί, the *scorpion* and the *claws*, make one constellation; whereas in the Egyptian zodiacs the corresponding part of the heavens is divided between the scorpion and the balance, the latter occupying the place of the claws. Now in a work on the "constellations," ascribed to Eratosthenes, who lived in the time of Ptolemy Euergetes, it is stated that the great length of the constellation caused astronomers to divide it into two parts; and in a poem attributed to a certain Manetho, supposed to be the priest of that name, and dedicated to one of the Ptolemies, it is expressly stated that "the claws of Scorpio' were by the priests changed into "the balance." It would seem therefore that the Egyptians, in or before the time of Manetho, adopted in their zodiac a name which had been given by the Greeks: yet as an argument in favour of the great antiquity of the sign it may be observed that, according to Ptolemy, the Chaldæans designated by a word signifying a balance the constellation called by the Greeks χηλαί: it may be, however, that he alluded then to the Chaldæans of his own time.

The designations which are given to the constellations in the writings of the Greeks apparently indicate persons or objects connected with the Argonautic expedition; and it is reasonable to suppose that, about the epoch of that expedition, the Greeks, having acquired a knowledge of the manner in which the Chaldæans or Egyptians represented the visible heavens, transformed such of the figures as they did not reject into others having relation to the actions of their own heroes. On this hypothesis it has been assumed that Aries represents the ram whose golden fleece was the object of the expedition; Taurus, the bull or bulls which were tamed by Jason; Gemini, Castor and Pollux, and so on. The ship, among the southern constellations, is supposed to be the Argo; and Ursa Major, the nymph Callisto. The history of Perseus is imagined to be represented by Perseus, Andromeda, Cepheus, Cassiopeia, and Cetus; and the labours of Hercules, by Draco, Leo, and the constellation bearing the name of that hero. Newton, in his 'Chronology,' appears however to assume too much when he considers that Chiron, whom he supposes to have given the names to the constellations, disposed Aries, Cancer, Libra, and Capricornus so that the equinoctial and solstitial colures passed through their middle points: the precise determination of these points was beyond the science of the Greeks long subsequently to the age of Chiron.

Hesiod mentions ('Opera et Dies') the Pleiades, Arcturus, and Orion, stating that land should be ploughed at the heliacal setting, and corn reaped at the heliacal rising of the Pleiades (about the middle of April); he directs also that corn should be threshed at the rising of Orion, and vines pruned when Arcturus rises in the evening. Homer also mentions the Pleiades, Hyades, the Bear or Waggon,

ἄρκτον θ' ἣν καὶ ἅμαξαν ἐπίκλησιν καλέουσιν,

and Orion in the description of the shield of Achilles ('Il.,' xviii., 487); it is evident therefore that already in the time of Homer those constellations were introduced in the sphere of the Greeks. Plutarch asserts that Anaximander (probably about 600 B.C.) constructed a dial; and that representations of the clusters of stars, together with figures of the constellations, were frequently executed in Greece in the time of Hipparchus, is evident from a passage in the commentary of that astronomer on the poem of Aratus: planispheres, he observes, are constructed for men's use, and therefore the figures on them are traced just as they appear in the heavens to the view of the spectator.

In the work of Autolycus, entitled 'On Risings and Settings' of the Stars (περὶ Ἐπιτολῶν καὶ Δύσεων), and in the 'Phænomena' (Φαινόμενα) of Euclid, the signs of the zodiac are mentioned, and the parts into which that band of the heavens was divided are called dodecatemories, or twelfths; but it is in the astronomical poem of Aratus that the most complete knowledge of the celestial sphere of the Greeks is to be obtained. This writer lived about 270 years before the Christian era, and his poem is a paraphrase of two works which were composed by Eudoxus of Cnidus, who lived 100 years previously, that is, in the age of Autolycus and Euclid.

In describing the constellations, Aratus begins with those immediately about the north pole of the equator, and proceeds from thence to the zodiac, nearly in the directions of the declination or hour-circles of the sphere. He mentions Ursa Major and Ursa Minor, observing that they are placed so that the tail of one corresponds to the shoulders of the other, and he adds that the constellation Draco winds between them. Near the head of Draco he places the figure of a man, who is said to be on his knees (Hercules, whose attitude has since been changed), and behind him the northern crown. Near the kneeling figure is Ophiuchus, the serpent-carrier, and under the latter are the great claws (of Scorpio). Behind Ursa Major is Arctophylax (Bootes), with the star Arcturus below his girdle; and under his feet is the constellation Virgo. Near the head of Ursa Major are Gemini (Δίδυμοι); under his body is Cancer, and under his feet Leo. Auriga and the star Capella are said to be on the left of Gemini, opposite Ursa Major; and at the foot of Auriga are the horns of Taurus, whose head is indicated by a cluster of stars (the Hyades). Cepheus is behind Ursa Minor, and near him is Cassiopeia, the stars of which are said to be arranged in the form of a key: Cassiopeia has her hands raised above her head as if bewailing the fate of her daughter Andromeda, who is placed below her. The arms of the latter are extended and chained (to a rock); and under her head is Pegasus. Aries is below the girdle of Andromeda, and, as well as the claws of Scorpio and the girdle of Orion, it is in the equator; the triangle (δελτωτὸν) is above Aries. The constellation Pisces is below the triangle; and Perseus stands with his hand near the chair of Cassiopeia. Below his left knee are the Pleiades, and the names of the seven daughters of Atlas are given to the stars of the cluster. Aratus observes that there are but six stars in the cluster; but Hipparchus, in his commentary on the poem, states that against a dark sky seven may be seen. The bow of Sagittarius tends towards the tail of Scorpio. The Lyre, and the eagle which carries it, is between Perseus and the head of the bird (ὄρνις). (This is the constellation Cygnus, which also by Manetho and Ptolemy is called the Bird. The name Cygnus is first applied to it in a work on the constellations which is ascribed to Eratosthenes.) Cygnus extends towards the other eagle (Aquila), and near the head of Pegasus is the right hand of Aquarius, which, it is remarked, rises before Capricornus. Over the latter is the Dolphin. All the above constellations are stated to be between the zodiac and the north pole; and the zodiacal constellations are afterwards mentioned in order, beginning with Cancer and ending with Gemini. Libra (elsewhere called ζυγὸν) is not mentioned, while Scorpio and the Claws are described as if they formed two constellations.

In the description of the constellations between the zodiac and the south pole, it is stated that Orion is placed obliquely to Taurus, and that Canis Major is at his feet. Under him is said to be Lepus, and at the tail of the dog is the head of the ship Argo. Under Aries and Pisces, and above the river (Eridanus), Cetus advances towards Andromeda, and below Capricornus is the Southern Fish. Under Sagittarius is a circle of stars (the Southern Crown), and below the sting of Scorpio is the Altar. Under the Scorpion is Centaurus, while farther on is Hydra, having its head under Cancer, and its tail above Centaurus: about the middle of its body is Craterus, and near the tail is Corvus. The bright star Procyon is under Gemini.

Such, nearly, is the description given by Aratus of the celestial sphere; and the constellations are, in general, the same as those which are represented on the modern globes. Some inconsistencies which exist in it were pointed out by Hipparchus, who lived about 100 years before Christ, and wrote a commentary on the poem. It is plain that the descriptions have been compiled from observations made by persons at different places, and probably in different ages; for in one part of the work it is stated that the extremity of Draco, and in another the girdle of Cepheus, touches the horizon, while in a third place Bootes is said to go below that circle, except his hand: and these circumstances are quite incompatible with observations made in the same latitude. It should be remarked that, in the Greek sphere, the stars are not always placed in the same parts of the figures as they occupy at present: thus the principal star of Aries is placed by Hipparchus in the front foot of the animal, while on the modern globes it is placed in the head.

It would be desirable to ascertain from the poem of Aratus the position of the equinoctial or solsticial points, in order to find the epoch of the observations on which the description is founded, but it is to be regretted that nothing satisfactory can be discovered concerning the subject. It is stated in the poem that the southern tropic cuts the middle of Capricornus, and hence the equinoctial colure should pass through the middle of Aries. Now, in the presumed age of Eudoxus, the first remarkable star γ in Aries was nearly at the point in which the trace of the ecliptic in the heavens cuts that of the equator; and if we suppose the extent of the constellation to be 30 degrees, the middle point, reckoning from that star, would be nearly at the 15th degree of longitude. The longitude of that star is now about 30°, and hence the equinoctial colure would have retrograded as much as 45 degrees, which at the known rate of the precession would take place in about 3200 years: consequently the epoch would be about the year 1400 B.C. Or, if with Ptolemy it is supposed that the extent of the constellation between the first star γ of Aries and the first star of Taurus (now δ Arietis) is only 18 degrees, the middle point would be in the 9th degree of longitude, and the retrogradation would be 39 degrees, which would place the epoch about the year 970 B.C. Nothing, however, can be more uncertain than conclusions drawn from such data.

The taste for ornamenting buildings with sculptures representing astronomical subjects appears to have existed in ancient Rome, as well as in Egypt and in the East; for in 1708 a fragment of a planisphere was discovered in that city. It has in its centre a serpent, probably an emblem of time, and near it two animals, apparently bears; about the serpent are the remains of three concentric rings, divided into compartments containing figures, among which are some of the zodiacal constellations.

That the Romans adopted the Greek sphere is evident from the descriptions of the constellations in the 'Astronomicon' of Manilius: those of the zodiac, in particular, are given in the verses "Aurato princeps aries in vellere fulgens," &c.; and the poem contains a detailed account of their astrological dispositions and qualities. The twelve signs are divided into masculine and feminine alternately, and are appropriated to different deities. There is also a division of the zodiac into twelve parts, which are designated Athla, or labours, and relate to the occupations or professions of men (lib. iii., v. 93). Four constellations, comprehending a space equal to one-third of the circumference of the zodiac, are said to constitute a trigon; three a tetragon, and so on; and there are four trigons arising from the different constellations, which may coincide with the angles of an equilateral triangle supposed to be inscribed in the zodiac: the like is to be understood with respect to the tetragon, hexagon, &c. Each sign of the zodiac is supposed, in the poem, to give a certain number of years to the life of a man; and his profession or fortune is imagined to depend on the particular sign which is rising at his birth, according to the qualities or uses of the animal by which the sign is distinguished (lib. iv., v. 122). It is also asserted that the characters of men depend on the qualities of the extra-zodiacal constellations: thus, persons born when the ship Argo rises are said to become seamen or to have an interest in naval affairs (lib. v., v. 39).

Scaliger, in his notes on Manilius, has given, from a manuscript of Aben-Ezra, a description of three planispheres, of which one is supposed to have related to the astronomy of the ancient Persians, and another to that of the Hindus; the third is supposed to be either Egyptian or Greek. The significations of the figures in the Persian sphere are very uncertain; but among those which have been recognised are Ursa Major and Ursa Minor, and a winged horse, besides Virgo, Leo, and Taurus. The figures of men and women are without designations; but among the former is one on a throne, which is thought to represent Cepheus, and one in a kneeling posture, which may be Hercules; of the latter, there is one which is presumed to represent Cassiopeia or Andromeda. A figure of a ship is also distinguished. It is asserted in the 'Zend-Avesta' [ZEND-AVESTA] that the ancient Persians divided the zodiac into twenty-eight constellations, or houses of the moon, and also into twelve signs: to these last are assigned names which correspond to those at present given to the constellations in that region of the heavens; and the cluster called the Hyades (in Taurus) is described as a bull with gilt horns. The division of the zodiac into twenty-eight lunar mansions prevailed also among the Arabian astronomers in or before the 9th century. It is mentioned by Alfragan, who states ('Elementa Astron.,' A.D. 850) that the first was called Xartan, and that it commenced near the three principal stars in Aries.

The Hindu zodiac, which is described in the 'Philosophical Transactions' for 1772, consists of twelve figures disposed on the four sides of a square. In this the place of Gemini is occupied by a figure of a man apparently with a shield on each arm; Virgo is represented by a female figure naked and seated; Libra is represented by a pair of scales similar to those in common use at present; and in place of Capricornus are figures of a ram and a fish, which are close together, but do not, as in the modern sphere, constitute one body. A globular vessel represents Aquarius; and for Pisces, one fish only is delineated. The figure in the place of Scorpio cannot be made out. This remarkable monument was discovered in the ceiling of a choultry or pagoda at Verdapettah, in Madura; and the separation of the figures in Capricornus seems to indicate that it is of great antiquity, as it may be reasonably supposed that such a disposition preceded in order of time that of a union of the two bodies in one.

In the second volume of the 'Asiatic Researches' there is given, by Sir William Jones, a paper containing a description, from the Sanskrit of Sripeti, of an ancient zodiac, which is divided into twelve parts, each of 30 degrees, corresponding to the modern signs. The ram, the bull, the crab, the lion, and the scorpion are said to have the figures of those animals, and in the plate which accompanies the memoir the entire figure of the bull is given: the twins consist of a male and a female figure, and in the description, the woman is said to play on a musical instrument, while the man holds a club, but the figures are not so represented in the plate. Virgo is represented by a woman in a boat; in one hand she holds a lamp, and in the other a blade of corn. Libra is represented by scales, which are held by a man who appears to be placing a weight in one of them. Sagittarius is the figure of an archer, whose legs are like those of a horse. Capricornus is the figure of a gazelle. Aquarius is represented by a man pouring water from a vessel which he carries on his shoulders; and lastly, Pisces consists of two fishes, the head of one being turned towards the tail of the other. The zodiac is also divided into twenty-seven parts, constituting the mansions of the moon: these are not represented in the plate, but their names, as well as those of the twelve signs, are given. The age in which Sripeti lived is unknown.

The Zodiacs of India and of ancient Persia may be presumed to have been originally the same as that of the Greeks or Egyptians; for although all of them differ from one another in the details, the points of coincidence are too numerous to be accidental, and it is probable that in the course of time the primitive sphere was altered in the countries eastward of Egypt and Chaldæa, as it was by the people of Europe. On the subject of the Indian zodiac the reader may consult Bohlen, 'Das Alte Indien,' vol. ii., p. 252, &c., and the references in the notes.

The representations of the heavens which have been found among the people of northern India, China, and Japan correspond to those which were in use in the western parts of Asia, in the zodiac being divided into twelve parts, which are called mansions of the sun, and also into twenty-eight parts; but, according to the accounts of the Jesuit missionaries, the Chinese at one time gave to these the names of the seven planets, each of which was repeated four times. In the ancient Chinese histories mention is frequently made of machines exhibiting the apparent movements of the heavens; and Père Mailla has given a plate representing a sphere which is supposed, though without sufficient reason, to have been executed about the year 2285 B.C. From those histories it appears that the Chinese were, at a time long prior to the commencement of the Christian æra, instructed in astronomy by a people from the west; and it is therefore probable that they thus acquired a knowledge of the method followed by the Persians and Arabians in the division of the zodiac. A table of the twenty-eight constellations into which the Chinese have divided the zodiac, with their names and the extent which each occupies, is given in Delambre's 'Histoire de l'Astronomie' (tom. i., p. 380), from the work of Père Souciet entitled 'Observations Mathématiques Astronomiques,' &c., 1729; and it is stated that the first, which is named *Pi*, commenced, in 1683, with the fourth degree of Aries. Delambre has also given a table of the twelve constellations; and from the records of the eclipses which the Chinese have observed, it is evident that the place of the sun has always been referred by that people to the signs of the zodiac. From a very early period they made their year commence when the sun is near the winter solstice, and they designated that part of the zodiac the resurrection of the spring, or of the year. The rat, the bull, the leopard, the hare, the dragon, the serpent, the horse, the sheep, the ape, the hen, the dog, and the hog are names supposed to be given, both in China and Japan, to the zodiacal signs; but it is more probable that they are applied to the twelve years of a cycle which is frequently used in the east, or to the twelve hours into which, in those countries, the day is divided.

The extra-zodiacal stars are distributed in constellations, which are distinguished in general by the names of the emperor and his ministers or courtiers; but that which in Europe is designated Ursa Major is represented by a vessel for measuring corn; the four stars of the quadrilateral figure forming the body and the others the handle. Biot relates, from information communicated by M. Remusat, that in the Chinese sphere the constellation which corresponds to Orion is designated by a name signifying a conqueror.

That a few coincidences should exist among the names given by different people to the groups of stars in the heavens, may be conceived without supposing that any of the people borrowed from one another: it may, therefore, be considered as purely accidental that the Iroquois called the stars of Ursa Major by a name which in their language signifies a bear (Lafitteau, 'Mœurs de Sauvages,' tom. ii.), and that the people living about the Amazonas designated the stars in the head of Taurus by a word signifying a bull (Condamine, 'Mémoires de l'Académie des Sciences,' 1745). But it is remarkable, and may be deduced as a proof, among many others, of the descent of the ancient Mexicans from the people of Asia, that the former should have executed sculptured representations of their calendar, and placed them as ornamental objects in their religious edifices. It has been ascertained that the Toltecans and Aztecs made the year consist of eighteen months of twenty days each, to which they added five complementary days, introducing a period of thirteen days at the end of fifty-two years in order to complete the cycle [AZTECS, in GEOG. DIV.]; and this division of the year is represented in a chronological table executed by the latter people. (Carreri, 'Giro del Mundo.') Among the ruins of Palenka have been found sculptured figures of serpents, which have been thought to indicate the existence of the Ophite worship in that part of the country, the seat of the Toltecans; and at the same place has been found a piece of sculpture, supposed to be a planisphere, on which are eighteen compartments representing months, which are disposed three together in the interior of a ring ornamented with hieroglyphical figures. In 1790 there was discovered, in the city of Mexico, among the foundations of the temple of Mexitili, a block of porphyry, on which are described symbolical figures, apparently constituting a planisphere or a chronological table, in which the several days of the year are distinguished by particular names and objects, and a few of them are stated to correspond nearly to the signs on the Chinese planispheres. Humboldt remarks ('Researches,' &c.) that the name of the first day is also the name of water, and that the symbol of the day consists of undulating lines resembling those which indicate Aquarius in the Greek and Egyptian zodiacs.

ZODIACAL LIGHT, a luminous appearance seen at certain times after sunrise and before sunset, from which it is inferred that there is a slight degree of nebulosity about the sun, if indeed it do not arise from the denser parts of that medium which [COMET] is more than conjectured to occupy the spaces in which the bodies of our system move.

The following description of the zodiacal light is from the pen of that careful observer, Sir John Herschel:—"The zodiacal light, as its name imports, invariably appears in the zodiac, or, to speak more precisely, in the plane of the sun's equator, which is 7 degrees inclined to the zodiac, and which plane, seen from the sun, intersects the ecliptic in longitude 78° and 258°, or so much in advance of the equinoctial points. In consequence it is seen to the best advantage at, or a little after, the equinoxes, after sunset at the spring, and before sunrise at the autumnal equinox, not only because the direction of its apparent axis lies at those times more nearly perpendicular to the horizon, but also because at those epochs we are approaching the situation when it is seen most completely in section.

"At the vernal equinox the appearance of the zodiacal light is that of a pretty broad pyramidal, or rather lenticular, body of light, which begins to be visible as soon as the twilight decays. It is very bright at its lower or broader part near the horizon, and (if there be broken clouds about) often appears like the glow of a distant conflagration, or of the rising moon, only less red. At higher altitudes its light fades gradually, and is seldom traceable much beyond the Pleiades, which it usually, however, attains and involves; and its axis at the vernal equinox is always inclined (to the northward of the equator) at an angle of between 60° and 70° to the horizon; and it is most luminous at its base, resting on the horizon, where also it is broadest, occupying, in fact, an angular breadth of somewhere about 10° or 12° in ordinary clear weather."

ZONE (the Greek ζώνη, "a belt"), a portion of a sphere intercepted between two parallel planes. When, on the globe of the earth, one plane is the equator, and four others are drawn parallel to the equator, two of which contain the circles in which the sun is vertical at the summer and winter solstices, and the two others, the circles of which are as far distant (on the earth) from the poles as the former are from the equator [ARCTIC CIRCLE], the earth is divided into six zones (the polar segments being called by that name as well as the others). Of these the portions which contain the two poles are called the north and south *frigid zones*: throughout these zones the sun never rises during a part of the winter, and never sets during a part of the summer. The parts intercepted between the arctic circle and the summer solstice parallel, and between the antarctic circle and the winter solstice parallel, are called the northern and southern *temperate* zones: in every part of these there is always rising and setting of the sun for every day in the year; but in no part of them is the sun ever vertical. The parts between the summer solstice parallel and the equator, and between the winter solstice parallel and the equator, are called the northern and southern *torrid* zones: in these there is always night and day, and at every point the noon-day sun is vertical twice in the year.

The torrid and frigid zones deserve their names; but the temperate zones partake of both excessive heat and cold in those parts which are near the boundaries of the torrid and frigid zones. Every zone, in fact, partakes of all the qualities of the adjacent zones in those parts which are near the boundary. Thus near the arctic circle there are places where the shortest day is only ten minutes, and the shortest night no longer; near the solstice parallels there are places at which a part of the sun's body may be vertical, though the centre of the sun can never be so; all being within the temperate zone.

ZYMOME. A name sometimes applied to vegetable fibrin. [FIBRIN; *Vegetable Fibrin*.]

SUPPLEMENT.

BANKRUPTCY. Since the article BANKRUPTCY in the first volume of this Cyclopædia was written, the law relating to bankruptcy and insolvency has undergone such extension and alteration by the legislature during the last session of parliament (24 & 25 Vict., c. 134) that a short review thereof is necessary.

The Court of Bankruptcy will henceforth consist of the present Commissioners in Bankruptcy, and to them is confided all needful powers of the Superior Courts of Law and Equity and of the Court for Relief of Insolvent Debtors. The county court judges are henceforth to exercise in the country all the powers of the present district commissioners, and vacancies in the country district commissionerships will not henceforth be filled up; and the London commissioners are, as vacancies occur, to be reduced to three. The Court for Relief of Insolvent Debtors is abolished, and the jurisdiction of the County Courts in insolvency is discontinued. The present Court of Appeal in Chancery is preserved, and appeals lie to it from the County Courts in bankruptcy as well as from the Court of Bankruptcy proper.

Questions of fact may, under the directions of the Court of Appeal, be tried in bankruptcy by juries, or issues may be sent to be tried at law. Sworn shorthand writers may be appointed; and these will certainly form a novel feature in our administration of justice.

The principal feature of the recent act is that non-traders are brought within the privileges and liabilities of bankruptcy, although the distinction between a trader and a non-trader is still for some purposes preserved. This distinction will appear from the following summary of the alterations introduced as to acts of bankruptcy.

Acts of Bankruptcy by traders are continued as hitherto, subject to such additions and alterations as are here noticed. Any person whether a trader or non-trader, may be adjudged a bankrupt for lying in prison for debt or after a detainer for debt, or in the case of a trader for *fourteen days*, instead of twenty-one days as heretofore, and in the case of a non-trader for *two months*, unless he is prepared with sufficient security for the debts in respect of which he is so imprisoned or detained; or for escaping from prison where detained for debt,

A Trader Debtor whose goods are seized and sold under judgment for a debt or money demand exceeding 50*l.*, is held to have committed an act of bankruptcy at the time of the seizure; notwithstanding which the sheriff may, unless a petition for adjudication intervene, proceed to sell the goods seized; but he must retain the proceeds for seven days, after which period he may pay them over to the execution creditor, who, however, has to pay them back, subject to deduction of the costs of action and execution, to the assignees in bankruptcy if the execution trader debtor is adjudicated a bankrupt within fourteen days from the day of sale. A *non-trader* may be made bankrupt by departing or remaining out of this realm with intent to defeat or delay his creditors, or by making some fraudulent gift or conveyance of any of his property, or by filing in court a declaration of insolvency followed, within two months, by a petition for adjudication of bankruptcy.

Acts of Bankruptcy after Judgment Debtor Summons.—Every judgment creditor for a debt of 50*l.* or upwards, may sue out against his debtor at the end of *one week* from the date of the judgment, if he be a *trader*, or at the end of *one calendar month* if he be a *non-trader*, a judgment debtor summons requiring him to appear and be examined touching his ability to pay the debt. In the same way disobedience to a peremptory order in equity, in bankruptcy, or lunacy, directing payment of money on a day certain may be followed by a similar judgment debtor summons after the expiration, in the case of a *trader*, of *seven days*, or in the case of a *non-trader* of *two calendar months*, from the day fixed for payment. Trader debtor summonses should be served personally, except in the case of persons in custody when service may be made on the sheriff, or other person in whose custody the debtor is. Where personal service cannot be effected, and the debtor is keeping out of the way, the summons may be advertised as directed by the act. The procedure upon the return of the summons is particularly provided, and the court may, upon non-payment of the debt, and whether the debtor appears or not, adjudge him a bankrupt without any petition for adjudication; but a debtor thus adjudicated upon in his absence may, within seven days from receiving notice of the adjudication, appear and show cause against it.

Proceedings to obtain Adjudication.—A debtor may himself petition for adjudication without filing any previous declaration of insolvency; but he must file a statement upon oath of his debts and liabilities, and of the causes of his embarrassments. In the case of *non-traders*, in order to support a petition for adjudication, or a judgment summons, the debt must have accrued after the 6th day of August, 1861 (the date of the passing of this act). Debtors in prison may petition in *formâ pauperis*, upon making affidavit of poverty. Jailers are to make monthly returns of all their prisoners detained for debt; and a registrar of the court for the district is monthly to visit all jails within the jurisdiction of his court, and to examine touching their estate and dealings all such prisoners included in such return who have been in custody *fourteen days* in the case of *traders*, or *two calendar months* in the case of *non-traders*. Prisoners not submitting to such examination may be committed to jail for a month, with hard labour, and also be adjudicated bankrupts. But prisoners detained solely under County Court or Small Debt warrants are not within these latter provisions, nor are they entitled to petition in *formâ pauperis*.

Procedure after Adjudication.—The official assignee must forthwith take possession of the bankrupt's estate, and must hold it until the appointment of a creditors' assignee. The first meeting of creditors and the president thereof are to be appointed by the court; and the majority in number and value of the creditors may transfer the proceedings to any County Court out of the metropolitan district; and a majority in value may then determine upon any allowance to be made the bankrupt up to the time of his passing his last examination. The proceedings in bankruptcy may be superseded, and an arrangement for winding up and administering the estate out of bankruptcy may be come to by due majorities of the creditors; and the debtor may then, upon making a full discovery, be entitled to an order of discharge. Some important provisions are made as to sale of real estate belonging to bankrupts, and particularly as to the settled real estate of non-traders; but these are of too technical a nature for discussion here.

Creditors' Assignee.—The majority in value of creditors who have proved may choose their assignee, in whom, upon confirmation and certificate by the court, the estate and effects of the bankrupt are to be exclusively vested; and the official assignee is thereupon forthwith to render to such creditors' assignee a full account of the bankrupt's estate, and of all dealings therewith, which account is to be formally audited and furnished to every creditor who has proved. The creditors' assignee may be required to give security; and he may be removed by the court at the instance of the creditors, and a new assignee may be chosen. The duties of the creditors' assignee are similar to those hitherto discharged by the official assignee; but to the latter is still entrusted the collection of all debts under 10*l.* The creditors' assignee must, from three months to three months, account to the official assignee for his dealings with the estate; and his accounts are to be printed and furnished to the creditors.

Dealings with the Estate.—Assignees may occupy leasehold premises of a bankrupt up to some day on which rent is payable not beyond six months from the adjudication, and may then elect to decline any lease or agreement for a lease under which the premises had been held. Creditors' meetings may authorise the mortgage or pledge of the bankrupt's estate.

Proof of Debts.—Creditors may prove their debts by forwarding through the General Post to the assignee a statement thereof, verified by their own declaration of its truth. False proofs entail the punishment of perjury. Landlords may prove for rent *pro ratâ* in respect of current periods. Unliquidated damages may be ascertained by the verdict of a jury before, or under the direction of, the court. Contingent liabilities may be determined and valued by the court at the instance of the person claiming the benefit of such liability.

Orders of Discharge.—The classification of certificates is abolished. Where a bankrupt is charged with any misdemeanour under this act, he may be tried by the court, or, if the bankrupt require it, by a jury either in the Court of Bankruptcy, or, in the option of that court, in *any* "of the ordinary courts of criminal justice." If the bankrupt be convicted of such misdemeanour, his discharge may be refused, or suspended, absolutely or conditionally. If he be not convicted of any such misdemeanour, his conduct is still to be inquired into by the court, and his order of discharge may be granted, or refused, or suspended, either absolutely or conditionally; and the bankrupt may be
