Lettuce.—Sow seed frequently to keep up a succession, and transplant to a cool and shady place.

Melons.—Treat the same as cucumbers.

Onions.—Thorough weeding and thinning are more necessary to success with this crop than to any other. Every weed must be kept down, and if good bulbs are desired, thin to 3 or 4 inches in the rows. Boiling water poured through a colander is one of the best remedies for the maggot. When the tops of potato onions fall over, pull them.

Parsnips.—Weed, thin and hoe as soon as plants are large enough to handle.

Peas.—Stick with brush as soon as well up, as when the plants fall over, it is very difficult to get them to stand up. Late planted peas should be put in deeply worked soil. If seed is to be saved, the earliest and best vines should be reserved for this.

Potatoes.—Hoe, and at the same time give a handful of plaster to each hill,

Radishes.—Otherwise vacant places may be sown to radishes for a succession.

Rhubarb.—If any flower stalks appear, cut them down. Now is a good time to dry or bottle a supply for winter. Keep the beds free of weeds.

Ruta Bagas.—Sow latter part of June; as soon as up, dust with lime and ashes to keep off the fly.

Salsify.—If not already sown, seed may still be put in. Treat the same as carrots.

Spinach.—The New Zealand spinach is best for hot weather, but a supply of the ordinary kind may be kept up by sowing at intervals.

Squashes.—Plant as directed last month. More vigilance will be required to keep off insects.

Sweet Potatoes.—Plant if not already done. See directions for preparing the ground, last month.

Tomatoes.—Plants for the late crop may be set. We have given in the present and previous numbers sufficient directions for those who wish to follow any of these different methods of training.

Watering.—The free use of the hoe and cultivator will do much in helping plants through a dry time. If watering must be done, let it be thorough, and soak the ground well. A mere sprinkling of the leaves of the plants, and the surface of the soil are of little use. Liquid manure, applied in a "growing time," will help wonderfully. Apply it weak.

Weeds.—We can only emphasize what is said above. When one gets large enough to be seen, it is already too large to live.

Fruit Garden.

There is no operation in the fruit garden more beneficial in its results than thinning the fruit, and there is none so generally neglected. Over-bearing is generally permitted, to a fault. Fruit should be thinned not only for the benefit of the present crop, but for that of next year. The earlier the surplus is removed after the fruit is set, the better, as the tree need not be expending its energies in developing fruit that is ultimately to be destroyed. It will even pay to thin the

Currant, where extra specimens are desired. Rub off useless suckers and branches as they start, and and if the soil around the bushes is not mulched, keep it stirred by hoeing. The worm on its first appearance is to be sprinkled with powdered white hellebore, as before directed, and if the borer appears, cut off the affected shoots and burn them.

Gooseberries, when heavily loaded with fruit, will need props to keep the branches from the ground. Use sulphur if mildew appears. In city markets both these and currants often bring a better price if marketed when green.

Raspberries and Blackberries.—All suckers that are not needed for making new plants, are to be cut off as fast as they appear. Tie the canes now growing for next year's fruiting to the trellis or stake.

Grapes.—Thin out the bunches freely, especially on young vines. One bunch to the shoot is as much as a vine should carry the first year of its fruiting. Stop the shoot at three or four leaves beyond the last cluster. Young vines should grow only a single cane the first year, and be kept tied up. See treatment of mildew on page 223. Hand picking must be resorted to for the large beetles and caterpillars.

Dwarf Pear and other fruit trees may be shaped at will by pinching the young growth. The systematic practice of this is given in full in Rivers' *Miniature Fruit Garden*. The disagreeable slimy slug which appears on pear and other trees is killed by a dusting of air-slacked lime.

Strawberries.—If the plants are not already mulched, they will need it before the fruit gets large. Straw is generally used, but corn stalks or any other material that will keep the fruit off of the ground will answer. After the fruit is off, clean the beds with the hoe. Newly set plants are to be kept free of weeds, and unless it is desired to multiply plants, the runners are to be cut off.

Flower Garden and Lawn.

In this month of abundance of flowers, there is constant employment for the cultivator. He finds

Weeds growing rapidly both in the beds and borders and on the lawn. A sharp steel rake is a capital implement to dress over the beds with, and the bayonet hoe will serve to work the soil where plants are too near together to allow of the use of the rake. Do not let perennial weeds get established on the lawn, but pull them while still small.

Bulbs that bloomed this spring should be allowed to remain as long as the leaves continue green. When they begin to fade, take up the bulbs, allow them to dry a few days, remove the tops, wrap the bulbs in paper and store them in a dry cool place, where they will not be injured by mice.

Annuals will need transplanting, and those sowed where they are to bloom are to be thinned. Crowding is a common fault with those who grow annuals, and we seldom see a well developed specimen. Seeds of many sorts may still be sown. See p. 227.

Bedding Plants.—*Ageratums*, *Gazanias*, *Verbenas*, etc., may be made much more effective if they are pegged down, so as to best cover the surface. This is especially necessary in windy places. When

Potted Plants are used in the decoration of the grounds, it is much better to plunge them, putting coal ashes under the bottom of the pot to keep out worms. When the pots are not plunged, care must be given to the watering.

Herbaceous Perennials of many kinds, such as *Phloxes*, etc., may be multiplied by making cuttings of the stems before flowering.

Neatness of a garden is in good measure through the agency of sticks and strings. Plants that need support should be kept tied up, but the means by which the effect is produced should be, as much as possible, concealed. Under head of neatness is included the care of gravel and other walks, frequent mowing of lawns, keeping edging in trim, etc.

Green and Hot-Houses.

The majority of the plants being out, all necessary repairs can be made. The plants that are left within, will need shading from the burning sun, and watering and syringing. The plants kept in pots out-doors should be so sheltered from high winds, that they will not be thrown over, and it is well to stand them on a layer of coal ashes, to keep worms from working their way up into the pots. Many things may be turned out with advantage.

Azaleas, **Oranges** and many others make a good growth when treated in this way.

Camellias and other plants of temperate climates should be well shaded.

Insects, other than the usual pests of the house, will often attack plants that are set out, and they must be looked to frequently, and

Water must be given as often as needed.

Stock for winter bloom may be propagated from cuttings, and sowing seeds of green-house plants.

Potting Soil should be provided for in advance, and a yearly provision made by stacking up sods from an old pasture to decompose.

Cold Grapery.

All sudden changes are to be avoided, and the temperature kept from 85 to 90, at mid-day, allowing it to sink very gradually to the night temperature. During the time the vines are in flower, it is well to go through the house and give the bunches a gentle flirt with the finger, in order to facilitate the distribution of pollen. While the vines are in flower, the use of the syringe is discontinued, but after the berries are set, it is freely used. One bunch to a spur is enough fruit to leave, and the shoot is stopped by pinching it at the third or fourth leaf beyond the bunch. The number of bunches to be allowed to a vine will depend upon its strength. It is well to avoid an excessive crop. When the berries attain the size of peas, they are to be thinned and one half or more, according to the variety, removed from each bunch. As the

fruit increases in weight, the bunches will need to be tied up to the wires.

Apiary in June.—Prepared by M. Quinby.

June is the swarming season, though bees often commence in May, and sometimes wait until July to begin. Any one wishing to increase his colonies to the utmost, must secure at least one swarm from each stock that is sufficiently strong. This is a matter which is to a great extent under control. A hive will often exhibit all the indications of swarming, except actually issuing, and yet not swarm. Make artificial swarms as directed last month. If you do not intend to make all the swarms possible, it is well to put on the surplus boxes, but do not expect the greatest yield of surplus honey, and at the same time great increase. Often the non-swarming hive will store honey enough to buy a good hive or two of bees when sold. Prepare the surplus honey boxes before placing in the hives by sticking in the top of each some nice white combs the right distance apart, to serve as guides to the bees; pieces an inch square will do. Mr. Harbison says, instead of melting beeswax into which one edge of the comb may be dipped to make it stick, these pieces may be glued. Stocks not strong enough to swarm by the last of this month, should be made to show cause. If diseased, drive out as directed June, 1865. If queenless, give them a new queen, unless too weak to keep out worms. If the queen is barren, destroy her, and replace with another, in a few days. In a good season, bees quite often swarm too much—more proportionally in small, than in large apiaries. When no queens are reared artificially to supply stocks or swarms, it is usually most profitable when practicable, to limit the issues from each, to one. With the movable combs, this may be controlled. As a rule, five or six days after the first issue, take out the frames, and cut out all queen cells but one, leaving the oldest. If any are not sealed, it may be necessary to open the hive again in three or four days, and cut off any cells that may subsequently be started. "After-swarms" usually issue from the 8th to the 13th day after the first; they need not be expected after the 18th day. It takes two second, or four third swarms to be equal to one of the first. If two or more can not be united, it is better commonly to return them to the old hive. With a half dozen or more movable comb hives, it is needless to have any very weak, at least, after the weather becomes warm. Bees are increasing much faster when all are strong, than when some are much crowded, and others very weak. They are easily equalized, in a few days, by taking some combs from the strong hives, filled with brood, ready sealed, and exchanging them with the weak ones. Should chilly nights occur before there are bees enough hatched to protect these combs, the entrances should be nearly closed, and old carpets or blankets used to help keep the hive warm.

"Gift Enterprises" at Washington.

"D. D. C.," a well informed correspondent at Washington, under the head of "Sturdy Beggars," has furnished some facts and hints recently printed in the *Tribune*, *North American*, and other journals, which are worthy of still wider circulation. We print portions of two of his letters, all we have room for, not merely to criticize the way things are done at Washington, but as suggesting a reform which the people themselves may help carry out:

"The gift-book and seedsmen business, as carried on by our national Government, actually compels members of Congress to neglect their legitimate duties to a great extent, and act as book, seedsmen and general agents to a clamorous constituency.—The experimental garden of the Agricultural Department, a most excellent feature of our Government, should be removed from the dust of the City, enlarged to the size of a farm, conducted as at present, and the results of the experiments spread freely throughout the country by means of reports to the agricultural and other presses, willing to devote the necessary space to the subject. The superintendent should, as at present, send a few seeds of his own raising to the various agricultural societies, with particular instructions as to their propagation, etc. But the practice of pur-

chasing miscellaneous seeds by the ton, and forcing members of Congress to act as seedsmen in general to their constituency, is a nuisance which calls for abatement.

"Members of Congress are sent here to deliberate and legislate for the best interests of the country. But the amount of work they are called upon to perform, as claim agents, seedsmen, gift-book agents, and showmen to sight-seers, surpasses belief. And in some cases the amount thrown upon members by their constituencies, is sufficient to employ constantly four or five active business men. Some of our members receive as many as 200 letters per day, requesting all sorts of favors, from a gold pen up to a library, completely overwhelming the unfortunate recipients, leaving them actually no time for legislation.

"But," says one, "it rests with Congress itself to change all this." Not at all. No member likes to be considered churlish and indifferent to the wishes of the people; and though greatly overworked, he is the last to complain. Thus it is left with the people themselves to consider well the legitimate duties of their representatives in Congress, and having done so, cease at once to regard them as claim agents, seedsmen, clothiers, or gift-book agents.—If thought necessary that the national Government should continue to transact a general retail business, let us by all means have a department created for the purpose, called, say, 'The Department of the Retail Trade,' with a commissioner and force sufficient to attend to the business, and take a burden off the shoulders of Congress that it may attend to legitimate duties...."

"The abuses flourish, however, and will continue so to do, so long as Congress continues to appropriate money for the purposes of purchasing seeds, printing books, or making clothing even, for free distribution among the thousands ready to take whatever they can get at others' cost.

"I am in favor of judicious expenditure of money in public printing, but am entirely opposed to the publication of expensive books for indiscriminate distribution as at present carried on. For instance, the Report of the Census of 1860 is published in four volumes, the last volume being now nearly ready for the binder. These volumes cost, so I am informed by the officer in charge at the Interior Department, about \$12 each, and are circulated free by the tens of thousands. I have seen these \$12 volumes for sale at paper rag stores in this city, at seven cents per pound, before they had been from the press a month! I may almost say they went direct from the Government press back to the paper-mill. Millions of dollars of the people's money are thus absolutely thrown away.

"Another instance is the seedsmen's division of the Department of Agriculture, the original intention of which was to distribute a few samples of choice seeds of rare production to different parts of the country, to introduce and foster the cultivation of new productions, but which has grown into an erroneous abuse, a mere machine for the free distribution of tons and tons of miscellaneous seeds, purchased with the people's money in every direction. I have received 10 packages of these seeds, which I forward to you, as samples, by express, the mails being too much encumbered by franked matter to render it certain you will get them by that conveyance. Though immense amounts have already been distributed, I see that the Department has a few more left." A morning paper states that:

"On Wednesday, at 1 o'clock, the first floor of the agricultural seed-room on F-st., between Sixth and Seventh, gave way, letting down about three tons of seed to the basement. Mr. McDonald, one of the employees, went down with the floor, and received a few bruises. The seed being in bags, the damage was only to the building."

"An additional appropriation will doubtless be needed to procure a store-house sufficiently strong to hold the 'tons of seed' sufficient to supply a constantly increasing demand. I am well aware that our present Congress is immaculate; but it must bear the sole responsibility of these abuses. So long as that body appropriates the people's money for useless expenditure, it will be expended.

A Show of all Kinds of Wheat.—An Important Request.

There is a great lack of accurate knowledge about the various kinds of wheat which are cultivated in different sections of our country. Many of these are introduced varieties, which may have maintained to a considerable degree the characteristics known where they originated, or their characters may have been greatly modified by our soil and climate. Besides, distinct varieties have probably originated in this country; the same variety is known by different names in various localities, and one name is applied to very diverse kinds. We propose therefore to the readers of the *Agriculturist* to join with its Editors in collecting and classifying our wheats. The present postal regulations offer great facilities for so doing, and the result will, we hope, be of very great value to each contributor and to the whole country; but this can only be if our suggestion meets with the hearty co-operation of

our readers who are wheat growers all over the country.

Please send to the *American Agriculturist*, 41 Park Row, New York, by mail, marked "Plants only"—or "Seeds only," as the case may be, the following:

1st.—1 doz. heads large and small as they run, cut when just out of blossom, and dried in the shade, (best in the house, but not near the fire.)

2d.—A stool or two with the stubble 6 inches long—or better the whole plant, pulled up by the roots with the straw broken as little as possible in bending for packing.

3d.—A quart of the grain—being a good average sample.

Accompanying these the name in every case written clearly, and the name of the sender with P. O., County and State. Postage prepaid is 2 cents for each 4 ounces.

4th.—By letter at the same time, a concise history and description of each variety, especially *time of flowering in comparison with several other kinds*, the time of ripening, liability to winter kill, to be injured by the mildew or fly, or by rust; its tendency to shell out, or not to shell; also the stiffness, length and general character of the straw, the amount of leaf, and other peculiarities; also the different names the variety is known by, and any other facts which may be deemed of interest.

We will see to it that samples are sown side by side under good circumstances, and so try to ourselves make fair comparisons between them, and of course report from time to time. Should it be too late, or inconvenient to send the samples of heads, or of the whole mature plants, we hope the sample of grain with the description may still be sent, as the importance of a thorough investigation of this kind can hardly be over-estimated.

The samples of the heads and of the grain will be kept on exhibition and for reference, at the *Agriculturist* office.

Married.

At Palisades, Rockland County, N. Y., Thursday, April 26, by Rev. S. Hitecock, MASON COGSWELL WELD, Associate Editor of the *American Agriculturist*, of New-York, and MAATUA M., daughter of Henry Coles, of Palisades.

Containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

TAKE NOTICE!—All Subscriptions begin with the Volume, unless otherwise desired and specified when subscribing. All subscriptions received up to June 25th are entered down for the entire volume, and the numbers from January 1st are forwarded. We keep on hand, or print as needed from our stereotype plates, the entire numbers of the volume, to supply to subscribers, and to others desiring them. Subscriptions received after June 25th, begin at the middle of the volume, unless otherwise desired or specified.

Clubs can always be increased at the original club price, if the subscriptions begin at the same time. The back numbers are sent to the new names added.

The Postage on this Paper is positively only 3 cents per quarter, or 12 cents per year, when paid quarterly in advance at the office where received. The law fixes this rate definitely on monthly journals weighing not over 4 ounces, and we carefully keep within this weight, having all our paper specially manufactured with this end in view.

Books.—Several valuable new books are being issued the present season, some of which are referred to in "Basket items," and a full list of those regularly supplied, is given on page 233.

Those Premiums—Last Call.—On page 232 we publish the lists of general and special premiums, which we propose to close up at the end of the half year (June 30), allowing sufficient time thereafter for names to come in from the Pacific Coast and other distant points. These premiums are certainly valuable, and worth all the effort required to get them. Every Present Subscriber can readily get one or more of the "One Subscriber Premiums." The books are valuable, ranging in price from 30 to 50 cents each. No books, however large, have ever been issued on Flax, Hop, Tobacco, and Onion Culture, which are so valuable, as those named in the list. None of the works offered are "old stock," but they are all newly printed, and most of them are just from the press.

Missing Numbers.—The mails seem to have been unusually irregular lately. In several in-

stances, papers that we positively know were mailed, have failed to reach their destination. Though it is hardly just that we should make up all the deficiencies of the Government agents, we cheerfully send duplicates of numbers lost by mail, without charge—not of course for such as are lost or torn after their reception.

930 Strawberry Plants from One.

—F. A. Rich, Wallingford, Conn., writes, that from one "Agriculturist" plant, received from this office the previous autumn, he last season obtained 930 plants, and "thinks that doing pretty well for one plant in one season in the open ground." So do we; and we hope the fruit will be proportionally productive, which, of course, can only be looked for this year on the first formed and most fully developed plants.

A Bread Kneading Machine Wanted.

—M. B. Rodman, speaking in behalf of the New Bedford Orphans' Home particularly, and of house-keepers generally we suppose, asks if we can not have a small handy machine for mixing and kneading bread, the staple food, which requires so much hard woman's work. We know of no such machine of practical utility. Here is an unoccupied field for clever inventors.

The Advertisements are curtailed this month, to make room on pages 232 and 233, for some matters usually placed in the first pages, so as to leave more space here for basket items, which many consider the best part of the paper. Several interesting announcements of implements, plants, etc., etc., will be found in the advertising pages, which will no doubt attract attention. We repeat the usual suggestion, that those willing to advertisers for circulars, for information, or ordering of them, will confer a double favor, by letting them know where their advertisements were seen.

Sundry Humbugs.

—We have not space to describe each of the scores of swindling operations that have come to our knowledge within a month past. A large proportion of these are so similar to those previously described, that nothing further need be said of them. Most of the operators in gift enterprises, prize jewelry schemes, watches, lockets, chains, sewing machines, to be given by tickets, etc., etc., have changed their names and places of business. To-day we dropped into a new swindling shop, as we know it to be, (though it is difficult to prove it so, without calling sundry witnesses here from Iowa,) and we found precisely the same parties operating, that last month were at another place under a different name. There are still thirty to forty of these swindling shops here, operating only at distant points, through the mails; but we are happy to learn that the aggregate receipts of letters by these cheats are not half what they were before the *Agriculturist* began its fresh warfare upon them the present year—a saving to the people of at least \$5000 a day! We add a few notes: Jno. H. Bancker, of Schenectady Co., N. Y., sends a circular left at the houses there by a set of sharpers, who called themselves agents of a failed New York house, (never in existence,) and promised to be along in three or four days with an immense stock of goods, at far below half price. This was a blind. They merely "sold" a few samples of cloth they "happened" to have along, which, after they were gone, proved to be worthless shoddy, well glazed over. The throngs of people who came together to get a chance at the promised sale of cheap goods, went home with the countenances of two-year-old lambs.... Mitchell, Arrandale & Co., (one of them, if there be more than one) a long time operator in New York, has opened a swindling address at Plaietow, N. H., and sends out tickets, pretending to have been paid for them, offering an immense number of things "worth" \$6 to \$350, on receipt of \$5. These, like fifty other similar operators, are the veriest swindlers. They do not send watches worth \$50 for only \$5. L. A. Kirkwood, Bentonville, Ind., sends word to them that he has read the *Agriculturist* too long, and has too much else to do, to attend to the agency of such rascals. Many others send us tickets from the same concern.... Wm. J. Elliott & Co., Lottery dealers, with no advertised place of business except a P. O. box, are operating on eloquence or highfalutin. On the back of their schemes they go into extasies over the details of numerous prizes they claim to have distributed to "factory girls," to "bed-ridden old ladies," to sundry "farmers," etc., etc. Why don't they give the names of these lucky people, for they ask the privilege of sending just such prizes for purpose to be able to publish their names, and to have them "make it generally known where they got the money," as an advertisement. Oh! Mr. Elliott, why are you so partial? Why don't you give us your place of business, so that we can call in and get one of them are \$40,000 prizes you profess to be scattering round so freely? Pray come out of that little P. O. Box and let us find you; we ache to get \$40,000 for only \$10 invested. It now costs \$1 to get \$1.07

a year.... What *loving* fellows are *Bergen, Schultz & Co.*, up the river, who offer to send the "Perfume of love," "possessing the power to create love."—Why surely everybody ought to have a bottle of that; what a loving world this would become! Then they supply a liquid to contract ladies feet!—regular John Chinamen they are. But hold! they advertise "female pills" reprobated last month. Away with them, their love is love of money, however obtained. A little boy in Pennsylvania received one of the circulars addressed to himself, and wonders "how they got his address, and what the circular was sent to *him* for." So do we.... A disgusting raulderer of morals, as well as of lives, sends out private circulars, many of them reaching decent people, in which, under the name of *Mrs. M. Simmons & Co.*, are offered offensive "instructions," instruments, etc., ostensibly to married people, but designed to deceive and lead astray the young. The representations are not to be trusted in the least, and those offering such things deserve to be lodged in the closest cells so long as they may trouble the world by living at all.... The "Company of Merchants and Manufacturers of New York," with a long list of "officers," only one of whose names can be found in the New York City Directory, is a very ingenious plausible scheme to get people's money. It was in a basement room 542-4 Broadway, but put forth an engraving of the whole building. It was gone May 17!

Trichinae in American Pork.—Those of our contemporaries who have attempted to throw ridicule upon the subject of Trichinae, as well as those who, like the *Country Gentleman*, have volunteered a flat denial of their existence in American pork, are referred to the report of the committee of the Chicago Academy of Natural Sciences. This committee examined the flesh of 1394 hogs, from the markets and packing houses, and found that about one in 50 was more or less infested. The committee state that a heat of 150° will destroy the parasite. It is to be hoped that this statement is based upon actual experiment, as it is important, and if true will enable those who eat pork to avoid all danger by thoroughly cooking the meal.

Don't Do It.—The N. Y. Independent, a professedly religious paper, among other miscellaneous matter has a column devoted to agriculture and kindred branches. If its theology were as loose as its horticulture, we would pity its readers. Among other absurdities, it recommends setting out cabbage *stumps* for raising seed. If there is any seed that needs care in raising, it is that of the cabbage, as this plant is far removed from its natural condition, and will revert to it, more or less, with the least neglect. Therefore don't follow this wise man of the Independent, but use only the best developed and best kept cabbages, *with the head on the stump*, for seed raising, and then allow only the central flower stalk to grow. Any other course will be sure to degenerate the variety.

Horticultural Humbugs.—Persons who buy plants at auction, unless they are from some known reliable source, are liable to be sadly taken in. One of the most flagrant cases of imposition that we have met, was recently brought to our notice by an amateur, who showed us the catalogue of an auction of plants to be sold at 100 Liberty St., N. Y. The catalogue was profuse in names and descriptions of plants, but gave neither the name of the auctioneer, nor of the grower of the plants. Our friend says: "I strolled into the auction store half an hour before the sale. Upon my arrival I found the plants arranged for sale, and an uninteresting looking Dutchman decorating the walls of the auction room with a collection of the most unique and startling floricultural and pomological illustrations, that the most fertile imagination could design. Attracted by the plates, I commenced an inspection of them. My attention was first directed to the greatest pomological production of the age—something ahead of mock auctions, dollar shops, or Barnum. It proved to be a 'correct illustration' of a small branch of the wonderful and *bona fide* 'Strawberry Tree.' The small branch was loaded with beautiful crimson fruit measuring from 10 to 13 inches in circumference—an actual strawberry tree, casting into the shade the *Agrioculturist*, *Jucunda* and all other creeping humble strawberries! Fancy, Mr. Editor, the pleasure of climbing a real genuine Dutch strawberry tree, and supplying the inner man with mammoth strawberries, free of sand, dust, or earthy taste. The climate prevents a man from setting under his own fig tree; but thanks to the progressive Dutchman, every man can sit under his own strawberry tree; one fruit being large enough to make a pudding. Continuing my explorations, I discovered a beautifully executed plate of a remarkable floricultural novelty—that of the *Aucuba Japonica*, fl. pl. The flower was about 5 inches in diameter, very double, and the petals nicely imbricated; color intense dark crimson, with a broad white stripe running the length of each petal. These two samples are not specialties selected from the

host of floricultural monstrosities exhibited; but simply types of the majority. Leaving the 'correct illustrations,' I shall refer to a few articles in the catalogue which I enclose for your inspection. The first I shall notice is a recent introduction excelling the efforts of a Fortune, a Low, or a Veitch. I refer to Lots 57 and 58. 'Three Trumpets of the Last Judgment assorted.' But the publisher of the catalogue neglected to state that he had furnished a Dutch Gabriel to blow these 'trumpets.' If you refer to Lots 179 and 180 you will find that my old and favorite Rose, Jules Margottin, has abandoned his old plain cherry crimson, and has assumed the stripes of the American flag. In the pomological line you will find described: blue chestnuts; blue raspberries; jet black apricots; pure blue Italian gooseberries, and some new apples, as follows: Jerusalem Pigeon; Happy Apple, and a veritable 'Eve's Apple.' I am convinced that a taste for horticulture and floriculture is rapidly gaining ground among the masses; but a few such trashy importations as the one referred to, will do a great injury. The young beginner will be attracted by such descriptions, and will freely spend the needful for such trash. Night and morning he will nourish, protect, and admire his floral pets, and when they drop their masks, he will become discouraged and disgusted. It is the duty of the *Agriculturist* to expose such impositions, and to advise the uninitiated not to be seduced by foreigners' descriptions, but to purchase *bona fide* plants and flowers from nurserymen who have reputations to lose, and under no circumstances to waste their means upon foreign adventurers."

A Hint to Secretaries of Agricultural Societies.—*Gentlemen*: Your reports are, many of them, strewn broadcast over the land, falling into the hands of many who do not value them, except to fill empty shelves in libraries, or to be sold to the paper makers or to the rag man. Now, if they were stereotyped, neatly bound, as many of them are, and sold at cost with a fair allowance for extra trouble, small editions might be printed, and reprinted as occasion might demand, and they would be productive of a small income to the society. (That is, if the States print them.) Useful knowledge would be more accessible than now to the public, and the books would be esteemed more highly by the community. We all value things somewhat in proportion to their cost.

Messrs. J. E. Tilton & Co., Boston, (Publishers,) request us to ask Secretaries of Agricultural Societies to send to them their published reports.

The American Dairymen's Association.—through its efficient Secretary, Mr. G. B. Weeks, of Verona, Oneida Co., N. Y., has already issued its first annual report, (135 pages, 8 vo.). It came to hand in April too late for a notice in our May number. It demonstrates what we have always claimed, that the reports of agricultural and kindred societies need not be kept back a full year before their members and patrons receive them, as is usually the case. This report covers the operations of the factory dairies of New York, and the doings of the Ohio Dairymen's Association for the past year; it gives a list of the factories of the United States and Canada in operation last year, and the admirable address of X. A. Willard, delivered at the annual meeting, January 10th. We presume the report may be had of the Secretary, by becoming a member of the Association (fee \$3.00), and perhaps for a less payment.

The West-Jersey Fruit Grower's Association.—The annual reports of this society are always received with pleasure, for they have a positive and practical character, truly commendable. The report of their fruit committee is a valuable record of local experience; and one, after reading it, feels thoroughly posted up as to the state of fruit culture for the past year, in Burlington and Camden Counties. We learn that 775 acres of land in strawberries, blackberries and raspberries, produced nearly \$200,000, or about \$250.00 per acre. Clayton Lippincott is President, and Jonathan G. Williams, Secretary, both of Moorestown, New Jersey.

My Vineyard at Lakeview.—An unavoidable delay has occurred in the production of this work, which is now ready. It is an account of the attempts of one of our western cultivators to establish a vineyard, and is put in an attractive narrative form. As it is the only work that gives an account of grape growing as actually practiced at the successful vineyards in the grape region of the West, it will be welcomed by a large class of readers. Price by mail \$1.25.

Culture of the Grape. by W. C. Strong. Boston: J. E. Tilton & Co.—We have here another work upon the grape, produced in the sumptuous style of paper, printing and binding adopted by the house of Tilton & Co. The work in itself is about as good as several others upon grape-growing. It is illustrated with engravings, some of which are as bad as well can

be. The three engravings, representing the flowers of the grape, are curiosities in their way. If such flowers could be found in nature, our botanists would indeed be puzzled. While it adds to the number of books, it does not add at all to our knowledge of the subject. It is the well known story presented in handsome shape by another author, and will be a safe and useful guide to a novice in grape culture. Price by mail \$3.00.

The N. Y. Evening Post, in its 65th year, has been edited for almost half a century by the favorite American Poet, Wm. Cullen Bryant, now over 70 years old. Though we do not always agree with its political and financial views, yet, all things considered, we have long esteemed the *Evening Post* more highly than any other Daily, especially as an always safe journal of general news and literature to carry to the home circle. Our profession requires the constant reading of newspapers, but we could hardly choose between having the newsboy miss us with the *Post* that we read on our way home, and having the cook forget the supper.

Interesting Publication.—As many of our readers are aware, 1866 brings the one hundredth anniversary of the establishment of the Methodist Episcopal Church in this country, and it is to be generally commemorated by benevolent enterprises worthy of this widely extended and powerful denomination. A Centenary Pictorial, illustrative of the history and spirit of Methodism, is issued under the direction of the Centenary Committee, by N. Tibbals, 145 Nassau-st., N. Y. City, which will be an attractive and valuable compendium of interesting matter pertaining to that branch of the Christian church. Price 25 cents.

Study of Entomology.—"H. C. M."—Harris' Insects is the best work we have, but that is devoted to injurious insects only. Tenny's Natural History gives a general outline of classification, and there are monographs of several families of insects published by the Smithsonian Institute.

The Fair of the N. Y. S. Agricultural Society will be held at Saratoga Springs, on the 11th to 14th inclusive of September next.

Spear's Fruit Preserving Solution.—To save answering individual inquiries in regard to this, we will state that we have seen fruit perfectly preserved by its use; that from our knowledge of its composition, it appears no more likely to prove injurious than the use of cream of tartar and soda in bread.

The Turtle Soup Bean.—Letty Ermin writes as follows, after experience with this bean, which is now becoming popular. Its culture is the same as other bush beans: "The wonderful bean—not 'Jack's bean,' but wonderful, inasmuch as it will make *turtle soup*. Try it and see. It is not a new bean, but has a new and sounding name, *Turtle soup bean*. Indeed, it is very palatable and nutritious, and without of trifling cost, when compared with turtle soup, which, in appearance, it is so like. A pint of beans will make a gallon of soup. Put the beans to soak over night, boil them soft, add salt and pepper, and pass all through a colander. This is the simple form. By adding meat stock, cloves, hard boiled eggs cut in slices, a lemon sliced, and a pint of wine, you have an excellent dish, with small trouble and cost."

Experience of the 18th Onion Grower.—"L. L." somewhere in the latitude of Philadelphia, gives us his onion experience in so pleasant a manner, that we are sorry not to have room for it. He read the experience of 17 growers in our Onion book, and gives his as that of the 18th. He has established two points: one, that onions can be grown from seed in his locality, for he succeeded with a small patch in 1864. Encouraged by this, he went into it on joint account with another, who was to do the work, but who didn't, and he had to mow the weeds to get at his onions, what few there were of them—thereby settling, to his satisfaction, the second point, that onions are a crop that requires great care in cultivation.

A Miniature Egg.—Numbers of persons have sent us eggs remarkable for large size and great weight. Now, Master Willie Judd, or rather his hen, has tried what can be done in the opposite direction, and he sends us an egg not much larger than a good sized marble. None of this breed of hens are for sale.

Soap Water.—"G. H. B." New Haven, Conn., says he can secure daily a considerable amount of soap water from a silver burnishing establishment, and asks how to use it?—Conduct it in rills over the grass, or through the vegetable garden, to soak into the soil, watering one plot at a time; or lead it upon dry muck, that it may be absorbed, if there are no deleterious metallic salts.

The Rinderpest.—The fact that this terrible malady has abated to a considerable extent in Great Britain, (though confessedly not on account of the measures used by the government to stay its progress, for these have been most imperfect and ill advised), should not make us less vigilant that it should not be imported here. The great danger is from cows used for milk on our passenger ships, and we hope that now stringent measures will be taken in regard to these. The law of the State of New York we give in full on page 220. The Commissioners appointed are well known and honored throughout the country. No man in the State is more identified with the cattle interest than L. F. Allen, of Black Rock, Erie Co., a man of more energetic executive talents than Gen. Patrick could hardly have been selected, and Mr. Kelly is discreet and conservative, and is identified with the agricultural interests of the State. The law requires owners of cattle suspected of having the disease, to communicate the facts to the Commissioners, but does not give the P. O. address of either. We give Mr. Allen's address above, but are not quite certain where to address the other gentlemen.

Horse and Cattle "Doctoring."

We are constantly in receipt of remedies for horn-all, horse-distemper, fowls, heaves, hog-cholera, worms, etc., etc., and publish but few. In fact we always dread to publish a remedy for any disease without accurately describing the malady, its nature and symptoms, for common names are so uncertain, and among the owners of cattle of any kind the desire is so strong to do something, that it is an even chance that they do not do exactly the wrong thing. With regard to ordinary ailments, nature is the best nurse and doctor, and in cases of the chronic character, especially if the disease be one not thoroughly understood, the advice of a good veterinarian is most important. There are, however, some acute ailments, like Hoove, or Bloat, caused by eating much green food, which ferments in the stomach, Colic, Garget, etc., which are very properly subjects for anybody's discreet treatment. And again there are some simple disorders, like colds, sores, slight fevers, scours, etc., which all farmers should understand, and for which they should have and use simple remedies. In all things careful investigation of symptoms, and an approximation to certainty in regard to the nature of the distemper should precede any other treatment, than, thorough grooming and the removal of the animal seen to be "out of sorts" to most comfortable and isolated quarters, where it may have the best of food and care.

The Sheep Show at Rochester

was in some respects a success and in others a failure—a success so far as the exhibition of "American Merinos" was concerned and a failure in respect to other breeds. There were a few fair Cotswold and Leicester sheep from this State and Canada, and one or two pens of ordinary South Downs. There was also a splendid lot of Silesian Merinos shown by Mr. Chamberlain of Red Hook, and that was all. The "Gas Tar Merinos" were out in great force, and if one did not know that these twenty-five-pound fleeces of which so much was said, were made up of four or five pounds of wool and twenty pounds of grease, they would be objects of real agricultural interest. But when we think that this grease probably costs as much to produce as two or three times as many pounds of tallow, or even more of flesh, and that this offensive product is absolutely worthless, and furthermore the wool is not of first quality, we can but wonder that this breed should receive so much favor from intelligent men. If this grease growing be persevered in, we fear ultimate injury to the great wool producing interest of the country. The Silesian sheep were in many respects admirable. Good constitution affording a fair carcass and fine wool. We hope the breeders of these sheep will develop the mutton producing qualities, as far as is consistent with the production of heavy fleeces of pure fine wool. Put the tallow inside rather than outside among the wool. We feel confident that this can be done. The skill and intelligence required to produce heavy fleeces of grease and wool combined, can, if properly directed, give us as much wool without the grease and at least an equivalent for the grease in the form of good mutton and tallow. Success to all efforts in this direction. We admire the Merino sheep—they are admirably adapted to the nature of American agriculture, and if bred with the right object, will prove of untold value.

Rev. Edward A. Wilson.

—The man who operates under this name, though often exposed and denounced, continues to advertise extensively from year to year, and of course finds poor dupes enough to pay him for doing so. Indeed the numerous letters of inquiry from our new subscribers indicate that his plausible statements, his assumed clerical name and garb, and his pretended benevolence, are effective with a large number of people. Our older readers will re-

member that he claimed to be a minister of the "New Haven Methodist Conference," until we exposed his falsehood by stating that there was no such Conference. He then studied up the church documents and claimed to have belonged to the N. E. Conference.—Here is a copy of his advertisement, to be found in many papers:

To CONSUMPTIVES.—The advertiser, having been restored to health in a few weeks by a very simple remedy, after having suffered for several years with a severe lung affection, and that dread disease, Consumption—is anxious to make known to his fellow-sufferers the means of cure.—To all who desire it, he will send a copy of the prescription used (free of charge), with the directions for preparing and using the same, which they will find a sure cure for CONSUMPTION, ASTHMA, BRONCHITIS, COUGHS, COLDS, and all Throat and Lung Affections. The only object of the advertiser in sending the Prescription is to benefit the afflicted, and spread information which he conceives to be invaluable, and he hopes every sufferer will try his remedy, as it will cost them nothing, and may prove a blessing.—Parties wishing the prescription, FREE, by return mail, will please address REV. EDWARD A. WILSON, Williamsburg, Kings Co., New York.

Generous man to pay tens of thousands of dollars a year in advertising, and then give away the recipe. We will publish it free, and do more too. We will publish also, to our million readers, the Recipe just as (Rev.) Wilson furnishes it, and thus we save to all of them the expense of postage, and save (Rev.) Wilson the expense of printing and mailing his prescription. Here it is as (Rev.) Wilson gives it:

"Extract Blodgett's 3 oz.; Hyphosphites of Lime and Soda ½ oz.; Alantin, (Pura) 1 dr.; Meconin, (Pura) ½ oz.; Extract Cinchona, 3 dr.; Loaf Sugar, 1 lb.; Pure Port Wine, ½ pt.; Warm Water, 1 qt.—Compound and mix well all the powders and extracts, place in a bottle, with ½ pt. warm water, shake well; add rest of water, the sugar and wine (or rum or gin); shake well and when cold it is ready for use. Dose, 1 large tablespoonful 4 times a day, before each meal, and on going to bed."

There now, are we not generous, to give all this space which others would gladly pay \$2 a line for? But let us see about the value of this prescription: "Blodgett's." Nobody knows it, except this (Rev.) Wilson: no regular druggist in the country can supply it. So the benevolently given prescription of (Rev.) Wilson is useless. "Alantin (Pura)"—in other words a starch from elecampagne root, no better and no worse than so much potato starch, and therefore not made or kept on sale by druggists. "Meconin (Pura)," a constituent of opium, which no druggist finds it worth while to keep. "Hyphosphites of Lime and Soda," recommended for lung diseases in Paris, but not yet proved effective enough to be adopted in the United States Pharmacopia, and of very doubtful utility. The extract of Cinchona, and the Wine are common, and will often stimulate weak or consumptive persons so as to make them "feel better" for a little while. There is not a doctor in the land who could not give or would not give a prescription quite as safe and valuable as the above. But see where the laugh, or the humbug, or the "benevolence" of (Rev.) Wilson comes in. He knows that his prescription cannot be put up by anybody in the world; so he generously informs his dupes, that when they chance to be unable to get it, he will condescend from his ministerial duties, and make up the package (except the sugar, wine, and water), and send it for \$3.30 by mail, or in a bottle ready mixed, for \$4, express unpaid. That's where he gets money to pay for advertisements; that's where his "benevolence" comes in.—Any one calling at "165 South 2d St., Williamsburg," to see the "Rev.," if not frightened away by the big dog at the front door, may be informed on entering that the "Rev." is "not in just then." We hope this extended notice will suffice to put all our readers, and their friends, on the guard against the assumed piety and benevolence of the self dubbed "(Rev.) E. A. Wilson," and a host of other similar "pious" pretenders, for this year at least.

How Swindlers Get Names.—Caution to Post-Masters.

—In referring to this matter last month, we did not particularly speak of the most common method, which has been described to us by a multitude of Post-Masters. A party sends out to a thousand or ten thousand Post-Masters a circular, in which he proposes to have a new implement or other invention that he wishes to introduce, and asks the favor of having a hundred or so of the names and P. O. addresses of farmers and others. In return for the favor he usually promises a fine painting, or engraving, or something else. The thing looks so plausible, that a great number of persons have gathered and forwarded their names, but the Post-Masters seldom if ever hear from the swindler again, or from the engraving. The men whose names are forwarded soon after get the humbug circulars from the same party under a different name. Afterwards he assumes a still different name and place, and sends out a new scheme. Sometimes the lists of names thus procured are sold to other swindlers. One man by the name of Todd, who was the real Hayward & Co., of 229 Broadway, Hammond & Co., of Brooklyn, etc., has privately operated directly and indirectly under a score or more of names. Post-Masters will consult their own

interest, and that of their neighbors, if they cast all these applications for names into the waste basket or fire.

Those Garden Plots.—It would be gratifying could we know how many profitable, pleasure and health yielding garden plots have been developed throughout the country, mainly through the influence of the *American Agriculturist*, during the past dozen or twenty years. We are continually hearing of them in every direction. Some one, prompted by our premium offers, starts a list, and persuades a number of his or her neighbors to try the paper a year, though only clerks or mechanics, or professional men, or day-laborers, and having only a house lot or garden plot. Well, something they read sets them to thinking about improving their grounds, they go to work, and then read more, think more, and work more, and the result is a pleasant garden, beautiful flowers, fine vegetables and fruits, in short, an attractive homestead, and better health. We know this has been the direct result in thousands of cases. This is of course a great satisfaction to us. So our work, our premiums, our business efforts pay in more ways than one.

One of the Garden Plots—What it Yields.

—The following is one of a large number of similar examples on hand: H. Johnson, Windham Co., Conn., who is engaged in a manufacturing establishment, describes his twenty square rods (¼ acre) garden or house-yard. It contains paths, grape-trellises, clothes-dryer, pen for pig, compost heap, etc.; 11 grape vines, of which 6 bore fruit, that last year drew 5 prizes and gratuities at the county fair; 5 dwarf pear trees, one of which netted \$4.35 for one bushel of fruit sold; 4 peach trees; 2 cherry trees; 32 currant bushes; English raspberries, rhuahb or pie plants, horse radish, sage-hed, plot of sweet corn, early potatoes, and sundry other vegetables, plenty of flowers of various kinds, and last but not least, strawberry plants that yielded about 5 bushels of berries, of which 100 boxes returned \$25.40 above expenses of selling. In this garden his one *Agriculturist* strawberry plant, received the previous autumn, increased to 250 plants last year. Do not such plots pay aside from the healthful pleasure and amusement they afford? It was tilled at odd morning and evening hours.

The Weather and the Crops.

—We have had a remarkably dry, cold spring. Never was there a better time for getting in spring crops. Low, wet land is now drier than it usually is in July and August, and thousands of acres have been planted in good season that are generally reserved for buckwheat. The wheat and grass crops are not promising, but a few warm showers will revive them.

Garden Flowers: How to Grow Them.

—A treatise on the culture of Hardy Ornamental Trees, Shrubs, Annuals, Herbaceous and Bedding Plants, by Edward Sprague Rand, Jr. Boston: J. E. Tilton & Co. In his first work, "Flowers for the Parlor and Garden," Mr. Rand gave us a very useful hand-book on floriculture. In the present work he has taken wider scope and attempted to give a florist's dictionary or reference book for hardy ornamental plants. The genera are arranged in alphabetical order, the family to which each belongs is indicated, brief remarks upon the culture follow, and then a list is given of those species desirable for cultivation. In all that relates to the cultivation of plants the author is clear and to the point, that being a subject in which he is evidently at home; but when he touches the botanical names and relationships of the plants he describes, we find his botany as loose as that of a nurseryman's catalogue. A work of this kind should agree with the present state of botanical science, or, if it adopts the peculiar views of some European botanists, it should agree with itself; but this work does neither. In proof of the justice of this criticism we will cite a few instances out of many we marked during a perusal of the work. Leaving out the numerous examples of bad spelling and incorrect terminology, we find the author quite confused as to the names of natural families. The Grass Family, for instance, is called *Gramineæ* in some places, and *Graminaceæ* in others; which will the author have us adopt? *Abies*, we are told, belongs to the *Pinaceæ*, while *Pinus* itself is referred to *Coniferae*. Only a botanist would know that these were two names for the same family. The Mint Family is honored with three different names; *Labiatae*, *Labiaceæ* and *Lamiaceæ*. While several of the family are referred to *Lamiaceæ*, *Lamium* itself, which has given this name to the family, and one which is not used in this country, is given as belonging to *Labiaceæ*. Surely the amateur with a limited botanical knowledge will conclude that botany is "all a muddle." Still worse is the case of *Clintonia*. Under *Smilacina*, which is properly placed in *Liliaceæ*, we find "*S. borealis*, more properly called *Clintonia borealis*, is a very pretty, etc." If it is "more properly"

called *Clintonia*, the amateur who desires to be correct in his names will naturally turn to that name in the arrangement and will find *Clintonia* given there as a genus of *Lobeliaceae*. He may well consider botany, at least in this book, as "rather mixed." The talent required to give a good work upon floriculture, and that to prepare one which shall be botanically correct, are so different, that we seldom find them united in one person, and while we give the author credit for his practical directions, his ignoring of all acknowledged botanical authority and usage in retaining such names as *Dielytra*, *Washingtonia*, and others, without giving any clue to the proper names of the plants to which he applies them, induces us to advise him to submit the other works he announces as in hand to some one whose counsel will insure a nearer approach to accuracy than the present volume presents.

Fruit Growers' Meetings.—"B.," Nantucket, Mass., asks why we have stopped reporting the Fruit Growers' Meetings. The reason is that the meetings themselves are no longer held. The addition of the book business to that of the paper, makes it impossible to give the necessary room to these gatherings.

The American Pomological Society.—This association will meet at St. Louis, Mo., on Tuesday, Sept. 4th. All interested in fruit culture are invited. Those wishing to become members will address the Treasurer, Thos. P. James, Esq., Philadelphia. Parcels of fruit for exhibition at the meeting, are to be addressed "American Pomological Society," care of C. M. Saxton, cor. 5th and Walnut sts., St. Louis, Mo.

Rhode Island Horticultural Society.—This society will hold an exhibition of fruits and flowers, for which liberal premiums are offered at Providence, June 20. Our friends in the Providence and other Plantations should turn out in force. This ought to be one of the most prosperous societies in the country.

California Tree and Other Seeds.—We understand that Mrs. Thos. Bridges, widow of the late naturalist, proposes to collect seeds for exportation. Her address is care of Saul Hubbard, P. M. S. S. Co., San Francisco. We wish success to her enterprise.

Raising Radish Seed.—C. O. Mapes, Schuyler Co., N. Y.—The finest and best-shaped roots are selected and transplanted to rows 2½ feet apart, setting them down to the leaves. They should be watered at planting, and afterwards if they need it, until they start to grow. They will soon throw up stems and produce pods which are gathered as they come to maturity.

Destroying Garlic.—D. Madden, Millin Co., Pa., wishes to know how to get rid of the wild garlic.

Garden Vegetables and How to Cultivate Them.—By Fearing Burr, Jr. Boston: J. E. Tilton & Co. We have had occasion to speak of previous editions of this work in terms of praise, and can now only say that this recent one is much improved, and brought up to the present time. It contains a full account of our esculent vegetables, showing great industry and research on the part of the author, while the beautiful illustrations and general mechanical execution of the work make it creditable to its publishers. Price by mail \$2.50. Supplied at this Office.

Breck's New Book of Flowers.—Such has been the demand for this work that we have been obliged to put a new edition to press. The familiar style in which it is written commends it to popular favor, and as far as we have examined it, it possesses an accuracy of nomenclature quite remarkable in a book of its kind. Handsomely bound, 480 pages. Price by mail \$1.75.

A New Style of Earthen Pot.—Our friend, Titus Oaks, Esq., has left at our office a new style of pot for flowers, and for starting early vegetables with the superadded compliment of tomatoes already growing in them. It was just like him to show not only the pots, but how they worked, or rather how the plants worked in them. We are greatly obliged for the plants, and still more for the pots, which are both antiques and gems in their way. We are struck with the exceeding economy of the earthy material used in their manufacture, and at the same time with their strength and durability. They are not of the usual potter's clay, but of carbonate of lime, with perhaps a trace of phosphate and other material. They are nearly egg shaped, not more than the thirty-second part of an inch in thickness, of an attractive white color, just the thing for conservatory or parlor ornaments. What is marvellous about them is the low temperature at which they are baked, not much above blood heat. The kilns in which they are burnt are said to be easily transported, and not to cost over three

dollars each. The fuel is rather expensive in this region, though out West, where they burn corn, that article might be used to advantage. We speak of them as a new style of pot, though it is rather the application than the pot that is new. Indeed, the patent is as old as Noah's ark, if not older. They are just the thing to start tomato plants in, and can be had of Goose, Hen, Duck & Co., an extensive firm, with branch-houses in all the principal places in the country. This advertisement is gratis on the score of favors long since shelled out to us by this enterprising firm.

Fuller's Grape Culturist.—The great popularity of this work is shown by the increased demand for it. We know of no treatise on the grape that so concisely sets forth first principles and illustrates them so clearly. The methods of pruning the vine are numerous, but they all depend upon first understanding the manner in which the vine grows, and this the author makes so plain that all can comprehend it. The engravings are numerous and true to nature. The scope of the work covers the whole ground, from starting the vines from the bud or cutting, to the management of a vineyard. The chapter on the garden culture of the grape gives numerous plans for growing the vine in city yards, etc., and renders the work as important to the owner of a few vines as it is to the vineyardist. Price by mail \$1.50.

Downing's Landscape Gardening. This work has already established its reputation as a standard work on landscape gardening. Even our conservative friends of the London Gardeners' Chronicle commend it to their readers as among the acknowledged authorities. Our object now is to state that we are at last able to supply the demand for it, and that the recent issues contain the new portrait of the author. The book is bound in a style corresponding to the value of its contents. Every one who contemplates laying out a large or small place, should be familiar with the teachings of this work. Price \$6.50.

The Book of Roses, by Francis Parkman. Boston: J. E. Tilton & Co.—Mr. Parkman is a well-known rose amateur and contributor to our horticultural journals, and in this book he has embodied his experience with this favorite flower. The work treats upon cultivation in the open air and in pots, and gives directions for the different methods of propagation and lists of varieties which include the newer sorts. As the work is brought up to the present time, is well written and handsomely published, we predict it for a wide popularity with the growers of roses. Price by mail \$3.00.

Budding Orange and Lemon Trees.—Several inquirers. The proper time is when the tree is just starting to make a new growth, and the time of this will depend on the manner in which they have been treated. Whenever the new shoots are about two inches long, buds from wood which has become ripe and hard, may be inserted and the plant kept in the shade for two or three weeks after the operation.

Specimens of Seed.—We are always glad to receive samples of any seed that our subscribers think unusually valuable, but it is almost impossible to test field seeds unless a considerable quantity is received. An ounce or two sown in the garden is apt to be destroyed by the birds, and it is about as well to feed them to the chickens at once, as is usually done with the small packages of wheat, oats, etc., sent out by the Department of Agriculture. If enough be sent to sow a small patch in the field, it can be easily tested.

American Manufactures — The American Watch Co. of Waltham, Mass.—Every one knows that the mechanism of the best manufactures of this country is unequalled in any other part of the world. The genius of American mechanics produced the cotton-gin, the mechanical reaper and mower, the sewing-machine, and last but not least, the wonderful machinery of the American Watch Company of Waltham. This Company was established in 1850, and has grown to proportions which entitle it to a first rank among the manufacturing enterprises of the new world. It employs between 900 and 1,000 artisans of superior skill and character, and a large and thriving town has grown up in its vicinity. The factory covers over three acres of ground, and as an illustration of its extent, we may mention that it is supplied with more than 60 miles of iron pipes, and produces an aggregate of nearly 75,000 watches per annum. The founders of this Company believed that the same delicate mechanical processes which had produced such remarkably perfect results in larger machines, might be applied with even greater advantage to the production of the watch. The foreign time-pieces are made principally by hand, and except when of high cost, an imperfect article, often out of re-

pair, and of little value, is the result. Abroad, these mysterious and infinitesimal organs which, when aggregated, produce the watch, are the fruit of slow and toilsome manual processes. In the results, there must of course be lack of that perfect uniformity which is indispensable for correct time-keeping. The constituent parts of the American watch, on the other hand, are fashioned by the most delicate and accurate machinery. Wheels, pinions, springs, screws, absolutely uniform in weight, circumference, dimensions, and in every possible particular, are turned out in myriads by unerring fingers of steel, and their proper combination and adjustment by skillful workmen have given the Company its high reputation. Its watches not only go with the trade and go in the pockets of 200,000 people, but they go right and go everywhere.—*Exchange.*

A Good Silver Wash.—We have repeatedly condemned the silvering fluids and powders hawked about the country, as worse than worthless, for they contain mercury (quicksilver) which puts on a silverlike gloss that is not permanent, while the mercury will corrode and injure metals to which it is applied. We have recently tested a new preparation from Messrs. Dixon, Clarks & Hallet, called "Silverine," and had it analyzed. It proves to be a genuine preparation of cyanide of silver, such as is used in electro-plating, combined with certain organic substances which hasten the reduction of the silver without the aid of a battery, and with polishing materials. Numerous trials show that it will deposit a thin silver coating when rubbed upon metals, and we think it therefore valuable for the purposes for which the manufacturers recommend it, viz., for cleaning silver and plated ware, and at the same time partially re-coating the portions of plated ware worn off. The covering is of course thin, but a frequent application is convenient, and if the manufacturers will keep up its purity and strength equal to that we have tried, as we suppose they will for their own credit and interest, it will doubtless come into very extensive use. With care not to waste it, a 50 cent bottle will last a very long time, and afford a good deal of satisfaction to house-keepers. But be very cautious of using the common silver fluids and powders generally peddled around the country. Messrs. Dixon & Co. should adopt some effective method to prevent counterfeits or imitations of their genuine preparation.—Though this preparation is perfectly safe to handle, it should not be left where it can be tasted by children, as injurious effects might result from swallowing it.

American Wines at the Paris Exhibition.—"The Lake Shore Grape Growers' Association" has made arrangements to have the products of our vineyards represented at the Paris Exhibition of 1867. The matter will be in charge of Mr. William Griffith, the well known vineyardist of North East, Pa., who will give all necessary information. "The wines must be pure, free from addition of sugar or other extraneous substance; at least two bottles of each variety, distinctly labelled, giving name of grape, location of vineyard, name and residence of maker, date, etc.; to be sent to Wm. Griffith, North East, Pa., so as to reach there not later than Nov. 1st, 1866, when they will be inspected and classified by a committee consisting of L. F. Allen of N. Y., J. A. Warder and Chas. Carpenter of Ohio, and J. E. Mottier and Wm. Griffith of Pa."

Can any thing be done with Hams not sufficiently Salted?—We fear not. It will not be safe to put them in the brine again after they are smoked. A friend of ours tried it a year or two ago, and had to make soap grease of his hams in consequence. He says the smoke turned the brine or pickle sour, and spoiled the hams. A good deal can be done toward preserving those that are not salt enough, by smoking them thoroughly and for several weeks, keeping up a fire until the smoke has completely saturated the hams.

Keep Bolts and Screws on Hand.—Every farmer should keep a few bolts of different sizes always on hand. They can be purchased of any desired size at reasonable rates, and a bolt will frequently save half a day's work. It is astonishing how much can be done with a few bolts and screws in repairing ordinary farm implements and machines. Try it, and you will never willingly be without them.

Mole Ditching Plows.—Those who have good ones should advertise them; we have numerous inquiries, but are not sufficiently familiar with the best modern ones to recommend any particular one.

Artificial Honey Comb.—W. W. Sewall, Verden, Ill., wishes to know if any attempts have been made to produce artificial comb. He thinks that a successful invention of this kind would revolutionize the present systems of bee-keeping.

Bloody Milk.—S. P. Strong, Johnson Co., Iowa. This comes from what is commonly called *Garget*, a name rather loosely applied to any inflammatory disease of the udder. Sometimes the bag cakes, and becomes hard and very sore. This generally yields to external applications, as hot soap suds, hot brine, hot amica water (tincture of Amica in twice as much hot water), with all the rubbing and kneading of the bag the cow will bear. At other times the udder is only a little tender, and there is internal bleeding coming from sores. The hot bath is good for this also, but it is well to accompany it by a dose of epsom salts (1 lb.) and ginger ($\frac{1}{2}$ oz.) given in a bran mash, well salted to disguise the taste. Where it can be obtained, the root of *Phytolacca decandra*, (Poke-weed or Garget-root,) is excellent for any form of Garget. Three or four ounces are cut up fine, and fed with oats or roots.

For Feeding Young Calves.—M. N. Russell writes: "I think a small trough is preferable to a pail, any way it can be fixed. M. Hester's plan, on page 130, March number, is no doubt a good one, but by using troughs the milk can be poured in and the calf left to drink it at its leisure; it also saves trouble of waiting for the pail until the calf is done."

What is the matter with the Little Pigs?—In some sections of this State there seems to be some trouble with the little pigs. Whole litters die a few hours after they are born. It would seem to be a kind of epidemic. Can any of the readers of the *Agriculturist* throw light on the matter?

To Prevent Hens Eating Their Eggs.—Give plenty of lime, old plastering, oyster shells, powdered bones, etc.; supply a little animal food, such as bits of fresh meat from the table or any fresh meat chopped fine; besides, provide good large nests well filled with leaves or hay, and set in snug darkish corners, away from observation. Then your hens will not eat their eggs and will lay abundantly.

Experience with Hens.—"P." writes: My experience with hens during several years has led me to the following conclusions: 1st, Hens, well fed and cared for, usually lay the first season, daily, small or medium sized eggs, until they take a notion to set, which is generally when they have laid two or three dozen eggs. If not permitted to set, they will begin to lay again in two or three weeks. Some hens, however, do not incline to set very often—these, of course, will not lay so constantly as those which are more ambitious to realize the fruit of their labor.—2d, The second season, hens lay large eggs, quite too large to sell by the dozen, but seldom or never oftener than every other day.—3d, Pullets hatched from eggs laid by hens more than twelve or fifteen months old, are apt to be like their mothers—to lay large eggs, but not daily. . . . Therefore, I would never keep a hen through the second winter, and never set eggs of hens after they have moulted, or of those that are more than a year and a half old.

"Quit, quit"—A Turkey Item.—Mrs. Sarah Fries, of Ontario Co., N. Y., is a very successful poultry raiser, having sold the past winter \$400.00 worth of turkeys alone, all the product of one season. If any one can report a greater crop, Mrs. Fries will continue to cry "quit, quit" till she tries again.

No Water in Lime Stone.—The N. Y. Farmers' Club.—"W. A. F." writes: "Mr. Quinn is reported in the Tribune as saying, at the Am. Institute Farmers' Club, that 'the action of fire upon lime is to expel about one half its weight of water and carbonic acid,' and that the farmer who would adopt Mr. Williams' views and apply ground limestone, 'would have to haul a large quantity of water combined with the lime.'—Is this so?"—The reporter adds: "These views of Mr. Quinn seemed to be unanimously sustained by the members present."—No. It is not so. There is no water at all in limestone, the unanimous opinion of the Farmers' Club to the contrary notwithstanding. Limestone contains over 40 per cent of carbonic acid gas, and this is expelled by heat alone. The Farmers' Club of the American Institute is famous for bringing out good practical ideas, as well as absurdly impracticable ones, for advocating sound theories as well as very unsound and absurd ones. It is entirely safe to weigh whatever is reported of its discussions in the scales of practical common sense, and to refer scientific statements to the text books. For if all the ridiculous practical statements and false science of the "N. Y. Farmers' Club," from the doctrine of the *Progression of Primaries*, to the expulsion of carbonic acid from soda by heat alone, and the great percentage of water in limestone, which in their day have been implicitly believed, were to be brought up afresh, it would so disgust sensible people, that the reports

of the proceedings of that venerable institution would lose many readers. When a man states things as facts, let him be sure of his facts, and when he guesses, say so.

Sea Weed as Manure.—J. Albee.—All the organic products of the sea, whether vegetable or animal, are of great value as manure. In the fresh state the bladder weeds, kelps, etc., contain much water. A portion of this is rapidly evaporated, and in this condition these weeds are worth nearly or quite as much as common yard manure. The eel grass is not worth so much, yet is valuable. All contain quite a large percentage of animal matter in the little polyps, shellfish, sponges, etc., which are attached to them. They are best employed, as a general thing, in a compost with muck or soil.

Don't neglect to Sow Plaster.—Red Clover is the great renovating crop of American agriculture, and plaster is the well tried manure for clover. The plaster, in most sections, costs but little, say from \$3 to \$5 per ton, and from 100 lbs. to 200 lbs. is sufficient for an acre. We have now machines that will sow from fifteen to twenty acres a day, and the farmer who neglects to sow plaster on his young clover, omits one of the essential means of enriching his soil—for plaster increases the growth of the clover, and clover enriches the farm. Peas, like clover, are a leguminous plant, and on most soils plaster has a beneficial effect on this crop. It may be sown broadcast, say from one to two bushels per acre at the time of sowing the peas, or if they are already up, sow the plaster broadcast over them. There are those who think this the better way—that the plaster does most good on the foliage. Hence in sowing plaster on corn it is usual to wait until the plants are up a few inches high, and then scatter a tablespoonful or so on the hill and over the plants. We have experimented a good deal with manures for corn, and while many artificial manures greatly increased the crop, plaster is the only fertilizer that has given us an increase, sufficient at 50 cents a bushel to cover the cost of the manures employed. When corn usually brings a dollar a bushel bone dust, superphosphate, and guano, if of good quality can be frequently used with profit. But plaster can almost always be used on dry upland with advantage, even if the corn brings only 40 cents a bushel.

Woolen Factory Waste.—"S. K." Such waste as you can get, though full of seeds, is still valuable manure. If it contains a great deal of wool, it is a very strong fertilizer. Used to litter animals in the stable, the weed seeds would probably be killed, but the manure would be so rich, that the most economical way to use it, would be to farther compost it with muck, or soil.

Buckwheat as a Green Manure Crop.—"H." On very poor and light land, buckwheat is by far the best common green manure crop. Oats do very well on soils of a little better quality, and clover is best for clayey soils that need organic matter. The amount of the crop varies exceedingly. 150 to 200 lbs. of good Peruvian guano will almost uniformly ensure a crop of buckwheat, and two crops may be plowed in in one season. Oats need a little more guano, with the addition of some ashes and plaster perhaps, and clover needs very thorough plowing. It may also have a dressing of lime plowed in, also lime harrowed in, and an application of guano and plaster at the time of sowing, which may be in September, or you may plow in a crop of buckwheat or oats, and sow clover in the fall.

Bone Dust in the Garden.—E. Wheeler, Kalamazoo Co., Mich., has a quantity of bone dust and asks how to apply it. If used at planting, it will not hurt the seeds, but the best way is to spade it in abundantly—a peck to a square rod is a fair quantity, and its effects will, in some cases, be manifest for years.

The Barberry as a Hedge Plant.—The Wallingford Circular says: "One of the wants of the agricultural community at the present time is a good hedge-plant; one that is reliable under all circumstances and conditions. Nearly every one that has been tried thus far, has exhibited some radical defect that unfits it for the purpose. A hedge-plant, to become popular, must be perfectly hardy, and easy to propagate. It should also be vigorous enough to grow well in ordinary soils without manure. It should be thorny, to keep cattle from hooking it, and strong enough to keep them from breaking through. Finally, it should be low enough to require little or no pruning. The common barberry (*Berberis vulgaris*) combines these qualities better than any other plant I am acquainted with. The barberry is a native of the northern part of Europe and Asia, but has become thoroughly naturalized, and is now found growing wild in the waste grounds of New England. It is a remarkably hardy plant, thriving well in a great variety of soils, and is said to live for centu-

ries. It has a shrubby habit (growing from six to ten feet in height), yellowish thorny wood, leaves in rosettes yellow flowers on drooping racemes, and scarlet oblong berries, very acid, but making delicious preserves. We have a barberry hedge on our grounds at Wallingford, Ct., 25 rods long, and 9 years old from the seed. Two rows of plants were set, the rows one foot apart, and the plants one foot apart in the rows: alternately, to break joints. This hedge has been clipped a little, two or three times, to keep it even, and is now six or seven feet high, with a firm, compact base, perfectly impervious to the smaller animals, and stout enough to turn ordinary farm stock, except for a short distance at one end where the soil is quite thin. On our grounds at Oneida we have a barberry-hedge 50 rods long, and seven years old from the seed. In this case but one row was planted, and the plants were set one foot apart. It has been kept clean with the cultivator, and clipped a little, once or twice, and is now five feet high, thick and compact at the base, and already so strong that the fence was taken away last fall, leaving in its place only a slight railing of a single board, six or eight inches wide, as a temporary guard, until the hedge can gain another year's growth, it being situated on a highway where cattle are passing daily. An important item in regard to this plant is, its habit of sending up suckers from the bottom, by which, in a few years, it comes to have a base from six to twelve inches in diameter."

White Willow for Fences.—In the fall of 1864 we described in the *Agriculturist* some White Willow hedges and fences, which we saw in Illinois, and before and since that time many have tried them—no doubt a good many on account of the favorable report which was made in this paper. We know that in Illinois, if good cuttings are planted and treated well, the willow will make a fair fence—in some cases an excellent one in a few years. On poor dry soils it will not do so well, if well at all, but with good care we know it will live and grow. If any body knows where the true White (Gray or Powder) Willow has been well planted, and where it lived and did well for two years, and then after several years more has proved not to be good as a live fence or hedge, we would like to know about it, how it was treated, and wherein it failed.

A Screen for Out-Buildings.—J. B. Bowman, Alcona, Norway Spruce, Hemlock or Arbor vitae, will each of them make a screen close enough. The first mentioned is the most rapid in its growth. We do not know who has the seeds you ask for.

Thorns from the Seed.—T. Braybrook, Allen Co., Ind. The seeds of the White, and all other Thorns, do not come up the first year after planting. Mix the seed with earth in a box or other vessel, and bury it for a year, and the next spring sow it without allowing it to become dry.

The Sunflower for Fuel.—Hosea Barnes of Kenosha Co., Wis., writes, that seeing an article in the Country Gentleman on corn for fuel, he wishes to suggest an economical substitute. "There is perhaps no annual plant which will furnish so much woody fibre as the sunflower, yet I have never heard of the stalk and seed of this well known plant mentioned as fuel. It requires but little cultivation; a great quantity will grow on an acre, and the seed is valuable, if gathered when ripe, for feed, and much more valuable than corn for fuel, as it contains a great deal of oil. After the heads have been gathered in autumn, let the stalks remain until the frost kills them, and then gather, cut and dry, and in connection with the seed you have a stock of fuel. Sunflowers will do well planted as thickly as corn. Try it, and see if it is not cheaper and better than corn at 20 cents per bushel, or wood at \$12 per cord." It must be remembered, however, that there are few crops so exhausting to the soil as this, on account of the great amount of potash it takes up.

Grafting the Wild Grapes.—T. H. King, Tompkins Co., N. Y., is clearing land for a vineyard, and asks if it would pay to graft the wild vines already there. We should say not; among other reasons, we do not see how it is possible to prepare the land properly for a vineyard and leave the old roots undisturbed.

Number of Vines to an Acre.—J. Grable. If put 6 feet each way it will take 1210, and if set 6 by 8 feet, 905 plants to the acre.

Chickens in Cold Graperies.—"A. S.," of Chester Co., Pa., writes: "After laying down the vines in autumn, I put about twenty hens into a small cold graperie, not more than 25 feet in length by 10 in width, and find they have plenty of room, and furnish a beautiful supply of fresh eggs during the whole winter.

The hens can be set about the first of February, and the young chicks will do well, making early spring chickens for market, or will come in as laying hens early in autumn, and may be depended upon for eggs the next winter."

Ailanthus Injurious to Pears.—W. I. Allen, N. Y., asks if "an Ailanthus tree planted in the midst of and overshadowing a lot of dwarf pear trees, would have any injurious effect upon them." Yes, it would probably injure them seriously—and so would any other tree, if the dwarfs are as near together as usual. If he fancies the Ailanthus, let him put it by the roadside.

Bad Luck with Cherry Pits.—H. L. Southworth, Utah Co. The Mahaleb pits probably became too dry, from the overland journey, to grow. Get them in winter if possible, and mix with earth, in a box, exposed to cold but sheltered from rain. The advantage of the Mahaleb is, that it is a dwarfing stock.

The Raspberry from Cuttings.—J. T. H. Waite, Somerset Co., Md., asks if he can propagate the Raspberry from cuttings. Green wood-cuttings, in moist ground and properly shaded, will grow.

Rust on the Raspberry.—E. A. King. Last year we had several other complaints of this trouble, besides yours. The rust is a parasitic fungus which grows upon the leaves, and probably finds some seasons more favorable to its development than others. We have not known any remedy to be tried, but should make an experiment with sulphur on its first appearance. If any one has found an effectual cure, we should be glad to hear of it, as the trouble threatens to be a serious one.

Winter Cherries.—"Subscriber" asks what these are. The Winter Cherry, also called Strawberry Tomato, is a species of *Physalis*, a plant closely related to the tomato; it bears a small round berry as large as a medium sized cherry, and quite enveloped in the enlarged calyx or husk. These berries have a very fruity flavor, and will keep for a long time, if allowed to remain in the husk. They make a very pleasant preserve with sugar. The plant is raised as easily as the tomato, and is very fruitful. The seed is sold by all the dealers, who usually catalogue it as Strawberry Tomato.

The Snail Flower.—A correspondent in Pomeroy, Ohio, succeeds in growing in the open air the Snail Flower, figured in February last. The seed is started in a hot-bed, and the plants transferred to the open border when the weather is warm. "It does not flower the first season, but if kept over winter from frost and damp, will grow luxuriantly and bloom the second year, and I think it will continue to bloom perennially."

Propagating Roses.—Hattie.—Layering, is the surest way, but there are some Roses that require two years to root. Make a slanting cut near a bud in the part that goes into the ground. See that the soil is rich and keep it from becoming dry in summer, by a mulch of moss or similar covering.

Rose Layer.—Mrs. L. H. James, Hillsborough Co., N. H. If the layer was put down in September, it was quite late and may not be rooted. A little careful digging will determine this point. Should it not be rooted, let it be another year. The shoot should have been "langued" or cut half way through with a sloping cut with something put in to keep the wound from closing. This may be done now, if neglected then. If well rooted, the layer may be removed to a good, rich soil. From the description we guess it is Queen of the Prairie.

Propagating the Oleander.—L. Taylor. Young growth, taken just as it is becoming firm, will root with great ease in warm weather. A very common way is to put the cuttings with their lower ends in a bottle of water, and when rooted set in rich soil.

Bud-eating Birds.—J. Hyde, Washington Co., Ill., finds his peach twigs wholly stripped of buds; thinks it was done by a bird, and wishes to know what bird does it. Partridges will sometimes, in a scarcity of food, eat the buds of apple trees, but we never knew them to trouble those of the peach.

Newspapers on Strawberries.—It has become the fashion of late for the secular and religious papers to have an "Agricultural Department." Some papers by selections from the standard Agricultural Journals, make a very readable column, while those which attempt to be "original," are frequently so in every sense of the word. The N. Y. Times has an article on "How to Raise Strawberries," in which it gravely says: "Three things were suggested to our mind while looking about the fields of Mr. Lambert, as being absolutely es-

sential to the successful and profitable cultivation of strawberries, namely, a sandy soil, a liberal supply of manure, and clean cultivation. These things comprehend all the important requisites in raising a remunerating crop of strawberries. Clean cultivation and manuring bountifully will prove eminently satisfactory on heavy soils; yet, a light sandy soil is the place for this kind of fruit."—There are some strawberries that will succeed on sandy soil with plenty of manure, but these are not, as a general thing, the choicer varieties, and though one may by artificial means overcome the natural barrenness of a spot, no one who knows anything about strawberries, would ever put a sandy soil down as an important requisite. A good rich, not stiff, soil is necessary, if one would grow the best fruit.

House Sewage in the Garden.—Those who have not tried it have no conception of the utility of liquid manure when applied to growing plants. Many of those who buy poudrette, and other commercial fertilizers, probably allow materials to run to waste on their own premises, which are equal in value to those they purchase. All the house slops, including sewage of all kinds, should somehow find their way upon the land. In January last, page 14, we have given methods for utilizing the contents of privies, and in August, 1865, a plan for a tank for liquid waste was shown. The method shown in the last named article is only practicable in peculiar situations. In England, much more attention is

given to saving domestic manures than with us, and we give, from the Gardener's Magazine, an engraving of the form of receptacle employed there. The cistern is built with two compartments, and deep enough to secure a good fall for the contents, which enter at *b*, into the compartment, 1. Here the coarser portions settle at *c*, and the more liquid portions overflow through the syphon, *d*, into the other division of the tank, and are removed as wanted for use by a pump attached to the tube, *e*. The sediment at *c*, is removed once a year, or as often as it accumulates in sufficient quantity, and is highly valuable as a fertilizer.

Deodorizer.—"T. C. H." asks: "What will deodorize the contents of a privy, as soon as applied?"—An abundance of good loamy soil will do it as quickly as any thing, and bring the materials into a condition to be shoveled over, and used as manure immediately, though it is better to let it lie in a heap a few days. Dry swamp muck and finely crumbled peat require a less weight to affect the same result—hence make less cartage—but do not act so promptly as fresh soil.

Bushels of Corn in the Ear.—A bushel of ears of corn is obviously a measure full of ears of corn, heaped a full peck above the rim; but a bushel of corn in the ear is, as obviously, a bushel of corn, with the cobs counted out. By common consent the cobs that hold a bushel of corn, are allowed to weigh 12 pounds, and so, where the weight of a bushel of corn is fixed legally at 56 pounds, that of a bushel of corn on the ear is legally fixed in many States at 70 pounds.

Our Farm of four Acres.—This pleasant account of experience in farming in a small way, has a freshness of style which makes it a readable work to any one; and to those who have only limited possessions, it offers many useful suggestions as to the manner of making the most out of a small amount of land. Price, by mail, 60 cents bound; 30 cents in paper covers.

Book on Indian Corn.—The value of a thorough book on this subject has long been felt. The one before us in part supplies the want, though the subject is so great that no one could expect it to be exhausted

in a 12mo. of 300 pages. The author shows himself quite familiar with the only literature upon his theme, which is really reliable, viz: the articles in the agricultural journals. From these and from other sources not so easily accessible, a mass of practical information is condensed, and very well arranged. No cultivator of the great American cereal can peruse the volume without learning much which he may well apply in the preparation of his soil, selection of his seed, cultivation, harvesting and feeding of his crop. Sent by mail for \$1.75.

Doty's Washing Machine.—Among other commendations of our premiums, R. F. Roberts, of Racine, Wis., writes: "The American Agriculturist Premium Washing Machine, sent me for subscribers, has done the washing every week since it came, for a family of eight persons, without the least hand rubbing, in less than half the time, and with a good deal less than half the labor, it would have required with the washboard. It can not be too highly recommended...."

Commercial Questions.—"Inquisitive." We cannot undertake to answer queries about the prices of oils and other articles not in the line of our experience.

Unfermented Wine.—H. Neff, Huntingdon Co., Pa. We cannot tell you how to make it, as there is no such thing as unfermented wine. Any kind of syrup may be called wine, but it is a misuse of the term. Wine, according to the authorities we accept as guides in the use of language, is defined as the fermented juice of the grape. When used for the juice of other fruits, the name of the fruit is always mentioned, as currant wine, etc. Unfermented grape juice is called "must."

Blackberry Root.—We have inquiries as to which variety to use the root of medicinally. It makes little difference which. All are astringent.

The Medical and Surgical Reporter.—This has always been a welcome exchange, not only for its medical news, but for general scientific intelligence. Our professional readers will be glad to learn that this excellent medical journal is now enlarged to 40 pages, and is published both in New York and Philadelphia weekly, at \$5 per year. S. W. Butler, M. D., Philadelphia, is the principal editor.

Red Ants.—"H. P." writes: "I have tried various remedies—'Persian insect powder,' and sponges dipped in sugar and water, etc., but the cry is still they come. What will prevent them?" (See page 228.)

Glue—Its Preservation in Hot Weather.—"C. H. E.," Rockingham Co., N. H., writes to the *American Agriculturist*: "It will be useful and convenient for pattern and cabinet makers and others, to know that if a piece of zinc, the usual thickness 1-6th of an inch, and 2 or 3 inches in diameter, be placed in the bottom of the pot containing the glue, and kept there, it will prevent the glue from becoming putrid and spoiled. I do not say positively that it will prevent putrefaction in every case, but I saw it tried with perfect success during last July and August in a shop where eight or ten men used glue every day."

Pictures Sent.—A. L. Skinner, Panola, No. 10 to her State. The sketches show an appreciation of humor, but a lack in knowledge of drawing. Our best advice is, to study good drawings and learn to draw outlines correctly before attempting elaborate work.

Not "He," but Soap.—E. Northup, of Fairfield Co., Conn., sends a specimen of a substance found in a brook. As the material burns, he jocularly inquires if he has "struck ile." The article in question is apparently *Adipocere*, a soap-like compound, sometimes found where animal matter is long under water or buried in a wet place. Whole bodies have been found to be changed into this substance.

To Start Rusty Nuts.—A little carbon oil (kerosene), dropped on, will penetrate the threads, and the screw can be immediately turned.

Big Crops.—The Salt Lake Telegraph is reported as saying, that on two and-a-half acres President Young raised last year 750 bushels of peaches, 400 bushels of apples, 22 bushels of plums, 25 bushels of strawberries, 2 bushels of pears, 25 pounds of cherries, 1,875 pounds of grapes, and gooseberries, raspberries and currants in multitude.—The absurdity of this will be apparent when one foots up the figures and finds, allowing 56 pounds to the bushel for cherries and grapes, that the product of these various fruits is very nearly 500 bushels per acre, and more than 3½ bushels to each square rod.

REAR ELEVATION OF BARN.

Improving Old Barns.

Our readers have been presented of late with several excellent plans for rather expensive new barns. In connection with these, the principles which should be kept in view in building, or indeed in using barns and stables, have been discussed. No doubt many of the readers of the *Agriculturist* have given these plans far less study than they would have done had they been cheaper and simpler. We fear they forget that a principle is the same, whether fully carried out or not, whether applied on a very humble, or on a grand scale. No one of the large plans may be such as any of our readers would like to build after, yet each contains hints which will be of great value to any one who proposes to build even a very humble structure of the kind.

The 30x40-foot barn is an "institution" known from one end of the country to the other, almost—certainly throughout the older Northern States. They are unsightly, inconvenient, and poorly adapted to any use but that of storing hay and straw. A barn of this size may be constructed so as to be very convenient for a small farm—but those of the usual style, with a wide bay, a narrow barn-floor, and a still narrower row of stables, are poor, inconvenient barns. "F. W. L.," of Monroe Co., N. Y., sends us the drawings and descriptions of a way in which he cheaply converted an old barn of this description into a convenient and excellent one.

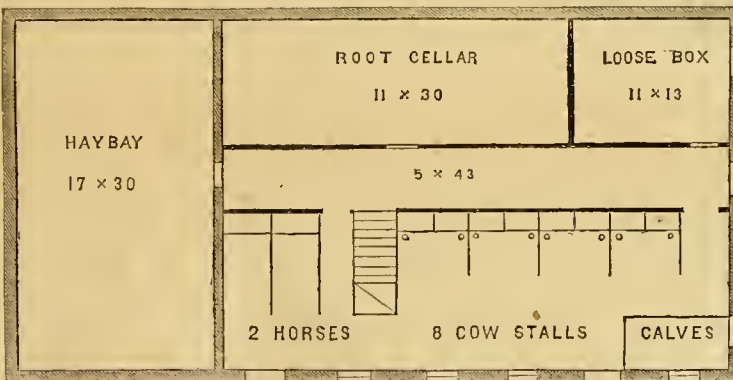

MESSRS. EDITORS, —We see in all parts of the country the old-fashioned 30x40-foot barn, built years ago, with a hay mow at one end, stables and granary with loft over them, at the other, and barn floor between. Such a barn is almost no barn at all, and having such a one in tolerable repair, I set myself to improve upon it without going into great expense. With a couple of

Jack screws we raised it up eight feet from the ground, underpinned it with a good wall, and added 20 feet to the length at the end used for stabling, making the basement of the building 30x60. We also built a cross wall at the edge of the hay bay, and covered it with matched boarding. We laid a matched floor over the entire basement, except the hay bay, which goes to the ground, and graded a wagon way up to the great doors. In the basement we made a

PLAN OF MAIN FLOOR AS ALTERED.

passage way 5 feet wide, lengthwise eleven feet from the front wall, extending from the east end to the hay mow. The space on one side of the passage for 30 feet is boarded up to the ceiling with matched boarding, and is used for a root cellar; this leaves room for a box stall at the end. At the other side of the passage we have our stables for cattle and horses, with stairs descending into the passage. This is a very simple improvement upon an old barn, and may be

PLAN OF BASEMENT.

varied according to circumstances. I have found mine very convenient and comfortable, and not too expensive for an ordinary farmer. Many farmers think they can not build a basement on level ground; mine is level, and I found no diffi-

culty in getting into it with any load that my team can draw on my farm. I send a rough diagram which perhaps you can make use of.

Walks and Talks on the Farm.

No. 30.

This is a great storm, but I do not think it will do any harm. We have had charming weather and the ground is quite warm. A heavy snow like this looks rather hard, but on land that is dry and warm, plants will stand considerable cold weather. I have five acres of barley that was sown on the 12th of April. It is now (April 24th) just out of the ground, and the Squire "hopes I shall not lose it," as he did an early-sown field some years ago. I have no fears. If the ground was wet and cold, the snow would probably injure it. An old traveler says, if you will only keep your feet and legs warm, you can stand any amount of cold. It is so to a certain extent with plants. If the ground is warm, the sap in the plants is warm also. In warm weather the pores of the leaves open, and the evaporation of moisture from the leaves proceeds rapidly, but when we have a sudden cold these pores close up almost entirely, and the warm sap in the plants does not escape. The heat is retained. Even tender plants, such as geraniums, if sheltered from the winds and having good "bottom heat," will stand two or three degrees of frost.

In this climate, which is so changeable in the spring, we should direct our attention to making the ground as warm as possible. I do not think we can afford to heat bricks and bury them in the soil, in order to warm the land, as was proposed some years ago, but we can drain off all the surplus water and stir the soil to let in the air and sunshine, and in this way we can gain two, three, or even five degrees of heat.

In six hours after it commenced to rain, I went to the underdrains and found them discharging to their utmost capacity. The drains were cut last spring, and though they carried off a great deal of water, they did not act as quickly as I expected. It took sometime for the water to soak through the soil and reach the tiles. But now the ground is very porous. The drying effect of the drains has extended to a greater distance. Little fissures have been formed all through the soil, and the rain percolates through them very rapidly and passes into the drain. Old ditchers tell me that this is almost always so—that you get more benefit from underdrains the second year and afterwards, than you do the first season. At all events these drains are now running full, and it is "fun" to see the water come spouting out of the main drain five inches in diameter. They say I have "ditching on the brain," but even the Squire admits that my big ditch "will pay." By the way, I had a little pride in sowing this five acres of barley so early. When I came here it was the wettest land on the farm. I cut a main ditch five feet deep, and have eight underdrains running into it. This is now the driest and mellowest land I have, and if I do not get a good crop of barley, I shall be mistaken.

The experiments of De Candolle, alluded to in the *Agriculturist* for April, in regard to the temperature of the soil at which plants germinate, should be repeated in this country. We do not pay sufficient attention to the temperature of the soil. We keep a record of the weather, but overlook the soil. If meteorological observers in different parts of the country

would give us the temperature of the soil and state its character, we should, I am persuaded, soon be in the possession of facts of great value. Three years ago I found the temperature of the soil in the garden on the 30th of April to be 52°; and on the 19th of May 53°. The thermometer was placed upright in the ground—the bottom being 12 inches from the surface, and the top of the hole being covered with a sod to keep out the air. I placed a thermometer, horizontally, two inches deep, and covered it with surface soil, and it marked 59°—showing that the surface soil was 6 degrees warmer than that a foot deep. I presume the surface soil, say half an inch deep, would be warmer still.

We are going to have an Agricultural School in this neighborhood. The parties have bought one of the best farms in the town, paying over \$125 an acre for it. They propose to teach the boys the ordinary branches, and in addition show them how to perform agricultural operations. They design to have them work on the farm three hours a day. I wish them the fullest success, though I think that a farmer's boy can learn how to work at home as well as at an institution of this kind. For city boys who wish to become farmers, such a course of training is all very well, but I should not be willing to pay much for their labor. On a farm, work must be done just at the right time, and it will not do to wait for the boys. Fancy a field of hay all ready to carry just as the bell rings for school, and the day's work of three hours is over! If the farm manager could stand it, I should like to take a term with him myself to learn patience.

The best article on American Agricultural Education I ever read, is in the *Agriculturist* for April. I do not know which of the editors wrote it, but whoever he may be, he exhibits far more practical knowledge and common sense than any other writer on this subject that I am acquainted with. The fact is, as he says, the real education of the future farmer must be obtained at home. Let him be encouraged to learn the use of mechanic's tools, so that he will not in after life be under the necessity of running to the blacksmith, the wheelwright or the saddler for every little repair that may be needed.

I was examining my cultivators the other day to see if they were all in order, and while tightening the bolts, a farmer called with a package of marl in his hand that he wished analyzed. "I understand," said he, "that you are a chemist."—"Well not much of a one," I replied, "and I was just wishing, not that I had studied chemistry less but mechanics more. Here on the farm I find it more useful to know how to put a machine together than to take a marl to pieces—to repair a cultivator than to analyze a soil." And this is so. I would on no account give up my chemical training, but chemistry is not, as some would have us suppose, the one grand thing necessary to make a farmer. Give a farmer's son all the scientific education you can, but do not neglect to teach him those things which he will most need when he comes to carry on the practical operations of agriculture. I think these things can not be taught him at an Agricultural College any better than at home. Let him have the best and most liberal education you can afford to give him, and above all let it be thorough.

I was showing a farmer's son the other day a plan for a work shop. He objected to it on the ground that it was too large. "On our farm,"

he said, "they would have it full of old harrows, ox-sleds and hay rakes before it had been built a week. I would have it so small that no one could get into it but myself." I told him that I wanted it large enough to draw in a wagon or a reaping machine. But I am not sure that he is not right. A work shop ought to have a stove in it, and if it was too large it would be difficult to keep warm. Perhaps a better plan would be to have a small work shop with a very large ante-chamber. The latter if desirable might be merely a shed in which every thing that needed repair might be placed as soon as it was broken, and where it could remain till we had leisure to attend to it. Such work ought to be done in rainy weather; but the trouble, on my farm at least, is that the things that you need are in different places, and you stand a chance of a good soaking before you can get them together. Now, if we had a large shed connected with the work shop and tool house in which we could keep plank, boards, sticks of timber, poles and every thing of that kind that is needed, many an hour that is spent listlessly hanging round the barn could be turned to good account. One corner of such a shed could be profitably occupied as a receptacle of all the broken tools, machines, pieces of hard wood, etc. There are many such things that are now either burnt up or lost that would often prove useful, if they were kept where they could be easily found.

I wish some one would get up a really good "tool chest" with an assortment of the necessary tools of the best quality. Those that are now sold are generally a miserable farce. There is plenty of varnish on the chest, but the tools inside are seldom what farmers need, and what there are, are of poor quality. I was talking to Mr. Judd on the subject a few months ago, and urged him to get up a really good chest, properly arranged, with a choice set of tools. He appreciated the importance of encouraging farmer's sons to learn the use of tools, and of having them so arranged in the chest that keeping them in their places, would do much to develop habits of order and system. His boys have a complete tool chest, filled up with the best tools, which he says are far the cheapest in the end, though costing most at the start. No one else is allowed to touch these tools for any purpose, and the boys have a reward for keeping every tool in its place, from which a fine is deducted for every one found out of place when not in use. He said it not only educates them in the use of tools and in keeping things in order, but also furnishes them much amusement and healthful occupation. Even the lads of 7 and 9 years of age are quite expert in handling tools.—I really wish he would get up such chests for the benefit of the young farmers of the country, and put them on sale.

I got a letter to-day from the agent of the "Boston Bone Flour." He does not like what I said in regard to the value of the article as a fertilizer. I should really be very sorry if anything I may have said should discourage the use of artificial manures. I had no such intention or desire. On the contrary, I would do all that I could to favor their general introduction. To me farming would be stripped of one of its pleasures if I could not get artificial manures. I have used them more or less for over twenty years, and fully appreciate their value. I know also the difficulty of manufacturing a good manure, and selling it at a price that farmers can afford to use it. I would encourage all honest efforts in this direction. I would pay more, and

would advise other farmers to pay more than the manures are actually worth for a year or two, in order to encourage their manufacture until the business gets thoroughly established. I would show no mercy to humbugs, but would extend the right hand of fellowship to all intelligent and honest manufacturers. They should understand what farmers want, and then devote their energies to supply it at the lowest cost. What we want in an artificial manure is ammonia and phosphates, and the more immediately available these are, the better. The reason why we need these two ingredients more than any others is this: *The main difference between good and poor barn-yard manure is that the former contains more ammonia and phosphates than the latter.* I will not say that it would not be cheaper to make richer manure by feeding the animals more grain, rather than to buy ammonia and phosphates. That is not now what I am talking about. My barn-yard manure is not as rich as it ought to be, and this has been the case on the farm for many years, and the quickest way I can make it rich is to use artificial manures that will supply the deficiency.

I received a letter on this subject a few days since from Mr. Thorne. He grows a great many roots for his thoroughbred cattle and sheep, and uses large quantities of artificial manures. He says: "I see you were somewhat astonished, as well as myself, at the exorbitant price asked for the Boston Bone Flour. Bone dust reached such a price this spring, that I was forced to try and find a substitute, and have just ordered quite a large quantity of manure from Chicago, made from the carcasses of animals that die in the cars and otherwise, which, after being tried out, are ground up, flesh and bone together. This is mixed with an equal quantity made from blood and haslets obtained from the large packing houses. My own impression is, that it will prove a very valuable manure, though probably not as lasting as pure bones, but quicker in its action. I remember to have seen some wonderful effects in England from the use of blood manure, and do not see why this is not very much the same thing, with the addition of a certain percentage of bones. It costs me delivered less than \$40 per ton."

The manufacturers of Bone Flour say, the reason why they have to charge so much for their manure is, that they have to pay \$36 per ton for bones. The agent told me that they get their bones principally from Africa and from the Southern States. The question with farmers is not what the bones cost the manufacturers, but whether they can afford to use the manure made from them. The price is higher now than a year or two ago, while farm produce is much lower. We cannot afford to pay as much for manures now as we could a year ago, and it is certainly very unreasonable to ask us to pay more.

A day or two ago I got a couple of the revolving land-side plows advertised in the *Agriculturist* for March. They were warranted to run easier and do better work than any other plow. I thought I would give them a benefit. I have ten acres of rough land that has not been plowed for ten years. It is so hard and stony that the previous owner of the farm had shrunk from attacking it. It did not produce grass enough for a good flock of geese, and when the rain stopped us from sowing barley, I concluded to see what could be done with this old grass field. Two of the men took the two new plows, and the other one of the best and strongest of our old ones. After breakfast I went up to see how they got along, anticipating

trouble. "Well, Thomas," I asked, "how does the new plow go?" "It's the best plow I ever see in this country." Thomas is an Englishman, and of course has to qualify his commendations. Hanna was less enthusiastic, but could find no fault with it, and at night asked me to let him have the new plow. Now this is a great triumph. It is the first new thing that has given satisfaction to my men. But the plow is an excellent one, and they had sense enough to see it. It runs very easy, turns over a handsome furrow, and lays it up in such a way as to afford, when harrowed, a large quantity of loose soil. The revolving land-side plow works admirably, and if it is not liable to get out of repair, is a decided improvement.

How much land can a man plow in a day? I have heard men tell of plowing two acres and a half, but never saw it done. In England, where they plow narrow furrows, say 9 inches wide and 6 inches deep, an acre is considered a fair day's work, taking one day with another. Here we plow, unwisely as I think, much wider, but do we not lose nearly as much time is resting the horses as would make up for the difference? Narrow furrows, say 10 inches wide and 7 inches deep, turned over at an angle of 45°, is both theoretically and practically the best style of plowing; and if we plow wider, we should go deeper, and unless we use three horses, no ordinary team can keep steadily at such hard work without injury. With a team that walks naturally at a good pace, it is better to plow narrower furrows and let them walk at a fair speed, than to tax them too heavily with a wide furrow, which necessitates their resting every other bout. The time lost in this way is far greater than is generally supposed. But I am regarded already too much in the light of an innovator to attempt anything more than a very gradual change. I find it better to let men do pretty much as they have been accustomed to. Still I would really like to know what is about the average rate of plowing in different parts of the country, and what hours are kept. By looking at my record, I find that we plowed a thirty acre field of corn stubble for barley, with three teams, in 7½ days—say 30 acres in 22½ days, or just 1½ acre per day for each team. Hours, 6.45 to 11.45, and from 1.30 to 6.30, say 10 hours a day. With a furrow slice 10 inches wide, it takes about 16½ miles of travel to plow an acre and a half. In a field 200 yards long the experiments of the Earl of Mar, as given by Sinclair, show that over two hours are lost in turning. Even, then, if no time is allowed to breathe the horses, they would have to walk steadily along at the rate of over two miles an hour to plow an acre and a half. I doubt very much whether farmers really plow as much in a day as they think they do. They do not keep an exact account of the time, or measure the land accurately.

This want of accuracy I fear is rather an agricultural characteristic. "My cows give ten lbs. of butter a week," said a neighbor the other day. "That is capital," I said, "but do you weigh the butter?" After a little hesitation he confessed that he did not, but felt sure from the size of the roll that there was at least as much as he said. He is a good farmer, and takes much pains with his cows, and it is not improbable that he gets the amount of butter he says, but it is a loose way of reckoning. It is a pretty good dairy that averages 6 lbs. of butter a week from a cow. Of course it ought to be more, and easily might be, but in how many dairies is it so?

We should aim to get a higher general average of farm produce. It is not an occasional large yield that is the test of good farming, but a high general average. I have had portions of a wheat field that would go over 35 bushels per acre, while the average of the whole crop was only fifteen. Last year one of my sheep sheared 12 lbs. of washed wool, while the average of the flock was not quite 5 lbs. We hear too much of the exceptional large yield, and too little of the low general average. I think we are improving, but our general system of agriculture is still lamentably defective. What we most need is faith—faith in good culture, in high manuring, and in liberal feeding. Of course we must add to our faith patience. Agriculture is slow, but if you stick to it, the result is sure.

"We need smaller farms." Perhaps so, but I am not sure on that point. It must be confessed, however, that as a general rule small farms are best cultivated. More labor is expended on a given area, and it is a more intelligent labor. On a large farm, as a general rule, either little labor is employed, or it is not efficient from want of proper supervision. The tendency, however, is to larger farms, and to the employment of more machinery. This will necessitate a more intelligent class of farm laborers, and also a more intelligent class of farmers.

But I cannot stop to talk much now. The weather is charming and everything presses. I often think of a story John Johnston once told me. He had some fat cattle to sell. A butcher called to look at them. Mr. J. was plowing in the summer fallow. The day was intensely hot and the butcher was warmly clad. Mr. J. told him where he could find the cattle. After looking at them, he returned. "What do you ask for them?" Mr. J. named the price. "It is too much. Beef is down in New York, and the West is full of cattle." "I can't stop to talk now," said Mr. J., "so if you have anything to say walk along." The ground was soft and mellow, and the butcher managed to go one bout round the large field. When Mr. J. got back to the road he turned in again and started his horses. "For pity's sake, Johnston, stop," said the butcher, "I'll take 'em." If farmers would serve all their callers in this way, they would soon be rid of them. It is very annoying when you are busy to be stopped by a gossiping acquaintance who merely wants to talk.

You don't believe in summer fallows. Neither do I—unless they are summer fallows. A good summer fallow on heavy land is the best of all preparations for wheat. But it must be thoroughly worked. The object is to clean and mellow the land; if this is not done, there is little use in summer fallowing. Whether it is necessary to plow three or four times as Mr. J. used to do before he got his land so clean and in such high condition, I will not say, but one thing is certain, whatever system is adopted, the land should be worked until it is as clean and mellow as a garden. If this can be done by once plowing, and the repeated use of the cultivator and harrows, all very well. It is cheaper than plowing so often, and now that we have so many good and efficient cultivators, there is no excuse for having foul wheat fields.

I am inclined to think that we can dispense with summer fallows, or rather that we can grow corn and summer fallow the land at the same time. If we planted corn with this idea of cleaning the land, and kept cultivating it until not a weed was left in the field, and then

seeded it down with barley or oats the following spring—mowing the clover one year, and pasturing it the next, I believe it could then be plowed just before sowing the wheat, and would give a good crop, especially with the aid of a little manure.

Drain tiles are absurdly high. They ask me more for them than they did last spring. I have been draining as little as possible for two years, thinking that tiles and labor would be cheaper. Labor is cheaper, but not so tiles. I have plenty of stones on my farm, but if the manufacturers would sell tiles at reasonable rates, say \$10 a thousand for 2-inch pipes, they are far cheaper and better than stones. The ditches can be dug so much narrower, and a man that understands it, with proper draining spades and a long handled scoop for cleaning out the bottom, will dig a ditch in half the time, certainly with less than half the labor required to dig a wide drain. There are few men, however, that can be induced to dig narrow drains. They have more muscles than brains. If a man will dig a wide ditch, say 18 inches at the top and a foot at the bottom, at the same price per rod as a narrow drain, and if the manufacturers still persist in charging such exorbitant rates for tiles, we had better use stones.

Keeping Goats for Milk.

Goats are very common in almost all our larger towns and their suburbs, and are constantly increasing in numbers. The milk sells readily at double the price of cow's milk, and goes fully twice as far in use as such milk as the laboring people can ordinarily buy. Goats will walk on the tops of fences, sheds, walls, etc., and do almost anything except fly and climb a tree. They can not be kept among fruit trees or they will kill them, nor closely stabled, or they will die. They will eat with impunity every thing that they should, and almost every thing they should not, (except paving stones,) from newspapers and old boots to the "wash" on the clothes line. Horace Greeley said some years ago, in a communication to the *Agriculturist* on this subject, that he did not think his goats "would have barked a crowbar, unless very hungry," and such is their reputation generally. This is prefatory to the following letter from "a country village in Maine."

"In December 1864, I purchased a pair of young goats to keep in the barn with my horses, as I had heard that horses would be more healthy if stabled with goats. When the teamster landed the goats in the front yard, every neighbor was on the alert and horribly alarmed, expecting nothing short of the murder or maiming of half their children. Nanny had a kid the last day of April 1865, and has supplied our family with excellent milk ever since; and now, in February, she gives a half pint every morning, which is worth more than a pint of such milk as I buy of the neighbors. And now the lady of the house says she would not take fifty dollars for Nanny if she could not get another. The goat has all the oats and hay she will eat—but she is rejoiced to get brakes, twigs, bark of small trees, acorns, and occasionally a 'chew of tobacco.' She has a small field to range in summer, and I never have to chain or hamper her, as she is not breachy. I have a board with cleats nailed on at the pitching window in the barn, so that the goat can go in and out as she pleases. If cows become sick and unhealthy, don't you think we had better keep goats?"

Fig. 1.

About Cisterns.

BY GILBERT J. GREENE, HUDSON, N. Y.

Every good house should have a cistern, indeed a barn can hardly be considered complete without one. A good cistern is a good thing, and a bad one is not much short of a nuisance: How to build a good cistern is a thing worth knowing, and having built one, it is a thing to be proud of. All cistern water should be filtered to take from it whatever impurities may have been gathered from the roofs, pipes, etc.: and how to filter cistern water, or to build cisterns with filters, is the subject of the present article.

Cisterns are usually built under a piazza, or beside the kitchen, sometimes under it, occasionally a portion of the cellar is walled off for a cistern, and if well constructed no special objection can be urged to this plan, further than that it is not always advisable to have such a body of water under the house. Under the piazza or kitchen, or adjoining it, is perhaps the proper place, but whatever the locality, every cistern should be provided with a good substantial filter.

Fig. 1, represents a style of filter in use in many portions of the West, which answers an excellent purpose where the area of roof is not great, as it is not capable of filtering water very fast. It is simply a box about thirty-two inches

Fig. 2.

in height, and two feet square; the bottom is full of small holes, and this (5) is covered with coarse gravel to the depth of four or five inches; next (4) clean sand, say five inches; then pounded charcoal (3), ten inches, on this (2) another layer of clean sand; and in the top (1), clean, coarse gravel. The water passes from the leader into the top of the box, and in passing

through the strata of sand and charcoal, is freed from all deleterious matter, and the water is fit for any use. The pump is usually placed upon this box and the pipe passes through it into the cistern; such a filter can be attached to almost any cistern already built.

Fig. 2, represents a round or square cistern, built of brick or stone, and well cemented in the sides and bottom; across the middle a wall is built of soft bricks to the height of the cistern; these are laid in cement, but the face of the wall is not cemented. This remark is made to prevent the recurrence of a mistake made by a friend of the writer, who wrote to him some time since to know what kind of a cistern he should build. A cistern similar to fig. 2 was recommended, and soon after he learned that the cistern was completed, that one side was full of water, but the other side was dry. Inquiry was made as to the construction of the partition wall, and it was found that it was all right, was made of selected brick, well laid, and cemented on both sides. Of course nothing could be done but build a new wall, or break a hole through and let the water fill both parts.

Fig. 3.

Now the philosophy of this filter is this: the water passes from the roof into compartment A, and is filtered through the bricks into compartment B, in which the pump is placed; this wall should be eight inches thick, great care should be taken that the joints are well closed with cement, and no holes left for the passage of water except through the bricks, each alternate layer of which should be laid across the wall. Such a wall, if well constructed, is the best and most reliable filter the writer has seen.

Fig. 3 is a brick filter, easily constructed, and can be readily applied to any cistern now in use: it consists of a sort of box or pen built of brick on the bottom of the cistern, fifteen or twenty inches in diameter, and the same in height, and can be built of one or two thicknesses of brick laid in cement, the top arched and the joints well closed. The lower end of the pump pipe enters this box, and as fast as the water is exhausted in the box it filters in through the bricks. One hundred bricks would make a filter, and almost any one could build it, it is the acme of cheapness, simplicity and durability.

We prefer square cisterns to round ones, because they are in all respects as good, and are more readily constructed. If built adjoining a building, the foundation wall could be used for one side of it. If this be a basement or cellar wall, a faucet could be placed in the cistern as A, in fig. 1. A waste pipe as B, in fig. 1, should be placed in all cisterns, the end of this should

be so arranged with a valve as to close itself, except when water is passing out of it, otherwise mice and insects would get into the cistern, and injure the water. Cisterns outside of buildings should be covered with earth, as in fig. 1, to prevent their freezing, and the covers should be constructed with a trap door (A, fig. 3), so that they can be entered to be cleaned or repaired. If the covering is of plank it should be well jointed, laid in cement upon the walls, and the outside thickly coated with coal tar and sand, and be of durable timber.

Brick filters are not new; the Egyptians used them three thousand years ago. In New Mexico the water from the muddy sluggish streams are filtered in this manner, the natives dig a hole beside the stream, several feet below the surface, this is bricked up, and the water that percolates through the brick is clear and limpid.

Cheap Water Carrier.

Mr. Gainford Ennis, Morgan Co., Ind., sends the following with very clear illustrations, which we try to copy as well as they were drawn:

"I have prepared a description of a cheap Mechanical appliance, now in use on our farm, for the benefit of those readers of the *Agriculturist* who have to carry water from the spring to the house. I can recommend it to those so situated, or at least, I will say, it has proved itself, in every respect, indispensable, in our case, not only effectually obviating that very laborious task of carrying water, but at the same time, has saved incurring the expense of a well, to say nothing of the pleasure of having at command at any moment, a cool and refreshing draught.

Take a sufficient number of good posts (fencing posts will do), allowing one for every six feet space. Five inches from the top of each post, mortise in an arm, or bracket, projecting ten inches, with top edge at right angles with the post (see fig. 1). Then set your posts firmly on the line already surveyed for that purpose, allowing space above mentioned, and have the brackets all turned one way, the ends forming a straight line, to receive the track. In setting the posts, there should be maintained a descent of eight degrees at least, to insure sufficient momentum to the bucket, and as springs almost universally issue from much lower ground than where buildings

Fig. 1.—POST AND BRACKET.

Fig. 2.—INCLINED AND ELEVATED TRACK.

stand, the lack of proper descent is not likely often to prove an impediment. The greater the descent the better. Now procure some boards for track (I use poplar), one inch thick, four inches wide, and twelve feet long; dress the

upper edge slightly rounding; measure and saw them in proper lengths, and nail securely to the ends of the brackets, letting them project two inches above the brackets as shown in fig. 2. The joint which occurs at every alternate bracket,

Fig. 3.—WINDLASS, BUCKET-CARRIAGE, ETC.

should be neatly and firmly constructed, with a miter cut at the top, so as to form a lap, to receive a nail to prevent lateral movement, as seen at *a, a*.

The first section of the track, commencing at the windlass, should be made from a board of greater width than the others, to admit of cutting a few feet level, to form a rest for the bucket when drawn up; this will be better understood from fig. 3. In this, *a*, represents a portion of the first section of track, cut to a level; *b, b*, pulleys for the cord to pass over; *c*, windlass, with wooden crank, which can be constructed either out of boards, or solid wood. It is 18 inches long, by 15 inches in diameter. The windlass should be hung in a substantial frame under the cover of an open porch, or portico, located within a convenient distance from the kitchen.

The other terminus of the track should extend directly over and close down to the spring, fastening in the extreme wall, or to a stake firmly driven for that purpose. The dimensions of the basin should be about 1½ x 3 feet, and of sufficient depth for filling an ordinary bucket.

The construction of the pulley carriage to which the bucket is attached, will be understood by examining fig. 4. The frame (*a*), is made from one piece of wood, with the leader (*b*), attached, which will freely apply itself to any degree of descent; *c*, is a pulley 4½ inches in diameter, turned with a groove half an inch deep, and wide enough to run freely on the track. The opposite portion of the frame (*a*), extends 1½ inches below the edge of the track, forming a guard against the carriage flying off. The cord, *d*, is fastened to the leader (*b*); *e*, is the attachment of bucket to pulley frame. An ordinary well bucket will do. Place the pulley upon the track, with bucket attached; connect the

Fig. 4. BUCKET CARRIAGE.

cord which should be half-inch manilla, to the windlass. This "Water Carrier" can be constructed by any one who possesses a little of mechanical ingenuity; and the entire cash expenditures connected with its construction should not exceed a very few dollars."

How to Dress Beef on the Prairies.

Every one who has had, like the writer, any experience in doing his family marketing with rifle bullets, knows that a dead beef is a very awkward thing to manage flat on the ground. How far the practice of long range marketing is prevalent at the West we do not know, but from a communication received from Daniel Laniman, Macoupin Co., Ill., it seems that Illinoisians are more or less in the habit of shooting their beeves on the prairie, and distant from buildings where they can be hung up. Mr. Laniman takes with him a sort of tripod, which he calls a 'beef-hanger,' constructed as follows: "Take three round poles, strong enough to hold a beef, (or 2x3 scantling will do), about fourteen feet long. Chamfer off the ends of two at the top, so as to allow them to spread at the bottom; place the third piece as a brace between them, and put a strong bolt through the three. There are two strong hooks inserted in the side pieces, as represented in the diagram, and several holes are made so that these may be set higher or lower, according to the size of the beef. This 'hanger' is easily made, simple, cheap, and easily carried to wherever you may chance to shoot your beef."— Its working is

plain, though not described. The steer is shot; his throat cut; the hind legs are cut off below the hocks and skinned down a little way; then the frame is placed over the carcass, only a little elevated, and the hocks are hung on the hooks. Then, as the skinning and dressing progresses, by lifting up on the brace piece the frame is gradually brought nearly into an upright position, and the beef will finally swing clear of the ground. The head, legs and offal are left for the buzzards and crows, while the hide and quarters, nicely dressed, are drawn home.

Convenient Farm Gate.

The following description of a handy farm gate, or substitute for bars, is sent us by Edward Hicks, of North Hempsted, L. I. He writes:—"The accompanying sketch represents a cheap, durable and handy farm gate. It can be as easily opened as one bar can be removed and thrown out of the way. As it cannot sag it needs only ordinary bar posts for support. It is opened by sliding it one-half way back, where it is nearly balanced, then turning it one-half way round. Snow banks interfere less with this gate than with almost any other. To make a dozen gates cheaply, to be used instead of

bars, procure a lot of 10-inch pine boards, sawed into two equal (5-inch) strips for the bars, and one-fourth as many sawed into four equal (2½-inch) strips for braces, uprights, etc. Let the lumber be wet, so that it will not split in driving a wrought nail. Lay the bars on the barn floor, the right distance apart; nail on the up-

FARM GATE.

rights, strips and braces, putting upright strips on each side of the gate, and a narrow strip on the top bar, flat-wise, to give the gate stiffness. It takes about half an hour to make a gate as above described. The gate is shoved back a little in the drawing to show the construction."

Peruvian Maize—Introduction of, etc.

BE HON. E. GEO. SQUIER, NEW YORK CITY.

I have, made some efforts, necessarily in a small way, to introduce into the United States some varieties of what I regard as the finest maize or Indian corn in the world, and which I found growing, in great luxuriance, in the Valley of the Rio Vilcamayo, Urubamba, in Peru, about sixteen miles to the westward of the city of Cuzco, the Capital of the Inca Empire. The river Vilcamayo, which, lower down, takes the name of Ucayali, is the true source of the Amazon. Its valley is narrow throughout, often no more than a mere cañon, shut in on both sides by high and snowy mountains. Nevertheless there are sections where it widens out to the width of from a quarter of a mile to a mile, affording room for cultivation, which is often much extended by an elaborate system of terracing up the hills and mountains to great heights. The particular intervals to which I refer, was the country seat or resort of the Incas, outside of their Capital, where they had a palace and extensive "hanging gardens," which are nearly as perfect to-day as when first built.

Fig. 1. Fig. 2. Fig. 3.

The place then as now was called Yucay, and was celebrated in the yaravis or songs, as the "Seat of Delights."

The mountains shutting in the charming vale of Yucay, are of a disintegrating limestone, and the soil is remarkably fertile and well irrigated through *azoquias*, dating from the time of the Incas. The principal article of production in the valley is maize, of which there are three varieties—the white, yellow, and black or purple. The white is the largest in grain and most valued; the yellow is smallest, more compact, and probably harder; while the black is sweetest, and most in demand for fermentation in making *chicha*. I give herewith accurate drawings of average kernels of three kinds.

The *maize blanca*, or white variety, is that

which most impressed me. The ear is rather short and thick, the cob small, the stalk stout and vigorous, with fleshier leaves than our varieties of maize throw out, and the roots start out in rings, two inches or more apart, for a height of from twelve to twenty inches from the top root. It requires therefore a deep soil and to be planted deeply. The natives plant it in rows, in rather deep furrows, and plow between the rows twice in the season. The numbers and grasp of the roots, give the stalk, as I have said, an appearance of vigor and strength, such as I have seen nowhere else. Each stalk sends out from six to eight, and even more ears. The kernels have a thin pellicle, and are exceedingly farinaceous, so sweet and pleasant to the taste as to be rather agreeable food, even when eaten raw, and absolutely delicious when boiled or made into bread. The meal or flour is as white and delicate as that of wheat.

The valley of Yucay is about 10,000 feet above the sea, and produces wheat and barley. The peach and apple grow in it, and the wild black cherry is indigenous. There is no winter, in our sense of the word, but there is the dry, cold season, which pretty much suspends vegetation, and gives the fields the aspect of early December. Regarding these circumstances, I thought it not impossible that this maize, as well as the yellow and black, might be acclimatized in some parts of our own country, and I accordingly brought home some ears, and last spring distributed it, in small quantities, pretty widely. I have not heard the result in all cases. Some planted in rather light soil, rather late in the season, in the ordinary way, in Schenectady County, in this State, grew to the height of fourteen feet, tasselled, but only sent out rudimentary ears, and was much afflicted with the blight. The stalks sent out their root rings for a foot or more above the highest hilling. Some planted in various parts of Westchester County, also rather late, grew vigorously to the height of from fifteen to sixteen feet, developed a few ears, containing, however, but few kernels, and was cut off by the frost. Altogether, the experiments in this latitude were not very satisfactory, leading to the conclusion that our season is not long enough to enable it to ripen. Mr. Solon Robinson, who planted a few grains, says, "it grew immense stalks, without ears," and thinks that "if we could get seed every year it would be very valuable here for fodder." He is of opinion it will not ripen north of Philadelphia, but would succeed in South Carolina. Some planted on Staten Island, sent up stalks to the height of fourteen feet, with air roots three feet above the ground.—The most successful experiment was made by Mr. Bayard Taylor, on his farm not far from Lancaster, Pa., who writes: "My dear Sir,—These are the facts of my experiment with the Peruvian maize.—The grains were planted in small pots about the middle of April, and set in a hot-bed. Three weeks afterward, when the shoots were four or five inches high, they were planted in the open ground. The growth of the canes was rapid and vigorous, and they attained the height of twelve to fifteen feet, before there was any sign of tassel. Even after the tassels came, two or three weeks more elapsed without the indication of a single ear, and it was only in September that eight or ten small ears made their appearance. About the middle of October, seeing that there was no possibility of these ears ripening sufficiently to furnish seed, I pulled them. Three or four showed only two or three scattered grains; the others were tolerably well set, the grains being fully as large as the original

seed. When cooked we found their flavor far beyond that of any maize we had ever tasted,—wonderfully succulent, sweet and delicate.

I was struck with the growth of circles of roots from each joint to the cane, to the height of twelve or eighteen inches from the soil, and it occurred to me, but at too late a period to make any change, that the plants should have been set in trenches, and these new roots covered with earth as fast as they were thrown out.

This is about all I have to communicate. I shall be very glad to try again, because my climate is a little more favorable, I think, than that of New York, and I want to secure seed if possible. The flavor of the corn is so delicious that it would be a pity if we cannot somehow naturalize it." Very truly yours,

BAYARD TAYLOR.

I think the introduction of this maize would be a real boon to the country, and I am sure it could be grown in the Southern States.—It would cost about \$50 to get three or four bushels of this maize over the Andes, and to this port. I propose that fifty gentlemen send a dollar each to the editor of this paper, for this purpose, so that the experiment of introducing this maize may be tried on an adequate scale. I will undertake the correspondence and arrangements to get the seed here. E. G. S.

Have Entozoa any Connection with Rinderpest?—N. Y. Rinderpest Law.

Some interesting observations have lately been published by Doct. Lionel S. Beale, Professor of Physiology, etc., in King's College, London, etc., upon some bodies found in the muscles of animals which have died of the cattle plague. These bodies are very minute, and though their precise nature is not made out, they appear to be entozoa, or parasitic animals in some stage of their existence. We have only room for the briefest abstract of the article. In almost all, if not in all animals dying of cattle plague, these bodies exist in considerable number in the voluntary muscles and in the heart; they are also occasionally found, but in comparatively small numbers in animals apparently in perfect health when killed. In the muscles of a calf killed by cattle plague, under six months of age, these bodies were found in immense numbers. These bodies are found imbedded in the muscular fibre, are usually spindle-shaped, and vary in length from the $\frac{1}{12000}$ th to $\frac{1}{4}$ of an inch. When submitted to a high magnifying power, they are found to be made up of minute granules, less than $\frac{1}{20000}$ th of an inch in their longest diameter, resembling one another in shape, which is oval, flattened and slightly curved, with one extremity blunt and the other almost pointed. While the author does not commit himself to the statement that these bodies are really "worms"—but speaks of them as only worm-like—he evidently thinks that close observation will make them out to be independent organisms. He is equally cautious in attaching any special relation between these and the cattle plague, but suggests that their presence may indicate an unnatural state, caused by a forced nutrition which predisposes the animal to the attacks of disease.

The Law of the State.

AN ACT to prevent the introduction and spread of the disease known as the Rinderpest, and for the protection of the flocks and herds of sheep and cattle in this State from destruction by this and other infectious diseases. Passed April 20, 1866; three-fifths being present.

The People of the State of New York, represented in Senate and Assembly do enact as follows:

SECTION 1. It shall be the duty of the health officer of the port of New York, in addition to the duties now imposed on him by existing laws, to examine and inquire whether any animals are brought in any vessels arriving at said port in violation of any regulation of law passed by the Congress of the United States prohibiting the importation of such animals.

Sec. 2. Whenever any animal brought as a ship's cow, with no intention of landing the same or of violating any such law or regulation of Congress as aforesaid, the same shall be carefully examined and kept in quarantine for the space of at least 21 days, and if any symptom of the infection or incubation of the disease commonly known as the rinderpest or any other infectious or contagious disease shall present themselves, it shall be the duty of the said health officer immediately to cause the said animal or animals to be slaughtered, and their remains boxed with a sufficient quantity of quick-lime, sulphate of iron or other disinfectant, and with sufficient weights placed in said box to prevent the same from floating, and to be cast into the water at the nearest wharf. It shall be the duty of the said health officer, and of suitable agencies the berth or section of the ship in which said animal or animals were lying or slaughtered, and also to cause the clothing and persons of all taking care of the same or engaged in slaughter and burial to be cleansed and disinfected.

Sec. 3. William Kelly, of Dutchess County, Marsena E. Patrick, of Otsego County, and Lewis F. Allen, of Erie County, are hereby appointed, as commissioners under this act, and with powers and duties as hereinafter enumerated.

Sec. 4. In the event of any such disease as the Rinderpest or infectious disease of cattle or sheep breaking out or being suspected to exist in any locality in this State, it shall be the duty of all persons owning or having any interest whatever in the said cattle, immediately to notify the said commissioners or any one of them of the existence of such disease, whereupon the said commissioners shall establish a sanitary cordon around such locality. And thereupon it shall be the duty of the said commissioners to appoint an assistant commissioner for such district with all powers conferred by this act on the said commissioners or their agents or appointees, which said assistant commissioner shall immediately proceed to the place or places where such disease is reported to exist, and cause the said animals to be separated from all connection or proximity with or to all other animals of the ruminant order, and take such other precautionary measures as shall be deemed necessary, and if in his opinion the said disease shall be incurable or threaten to spread to other animals, to cause the same immediately to be slaughtered, and the carcasses to be deeply buried, and all places in which the said animals have been confined or kept, to be cleansed and disinfected by any of the agencies above mentioned; and also to cause the same to be carefully locked or barred so as to prevent all access to the same by any animals of a like kind for a period of at least one month. Any animal thus slaughtered shall be appraised under the supervision of the said Commissioners, and one half of the value of said animal shall be paid by the State to the owner thereof.

Sec. 5. It shall be the duty of the said assistant commissioner, immediately on his being notified of his appointment, or at any time thereafter, of the breaking out of the said disease in any place contiguous to the same and within the county in which he resides, to give public notice of the same in at least one newspaper published in the said county, and to cause notices to be posted up in at least five conspicuous places in said neighborhood, and it shall be his duty to enjoin, in said notice and otherwise, all persons concerned in the care or supervision of neat cattle or sheep not to come within 100 feet of the said locality without the special permission of the said assistant commissioner.

Sec. 6. It shall be the duty of the commissioners appointed under this act, whenever they shall ascertain that any such disease has made its appearance within the limits of the State to publish in the State paper and in at least one paper published in any county where such disease exists, a statement of the methods approved by the New-York State Agricultural Society for the treatment of cattle affected by the same, and to cause the same to be printed, and the disinfection of the premises or buildings in which said animals are found affected as aforesaid, and for the prevention of the spread of the same through any agencies of whatever kind.

Sec. 7. The commissioner aforesaid and all such assistants as they may appoint, whenever in their judgment or discretion it shall appear in any case that the disease is not likely to yield to any remedial treatment, or whenever it shall seem that the cost or worth of any such remedial treatment shall be greater than the value of any animal or animals so affected, or whenever in any case such disease shall assume such form of malignity as shall threaten its spread by processes either contagious or infectious, or otherwise, are hereby empowered to cause the said animals to be slaughtered forthwith and buried, as above provided, and to do all such things as are mentioned in the fourth section of this act.

Sec. 8. The said commissioners or their assistants are hereby empowered to enter upon and take possession of all premises or parts thereof where cattle so affected as aforesaid are found, and to cause the said cattle to be confined in suitable inclosures or buildings for any time requisite in the judgment of the said commissioners or their assistants, and prior to the slaughter and burial of the said animals and the full and complete disinfecting and cleansing of such premises; and all persons whether owners of, or interested in such cattle or otherwise, who shall resist, impede or hinder the said commissioners or their assistants in the execution of their duties under this act, shall be deemed guilty, and on conviction of the same, of a misdemeanor, and shall be punishable with fine not exceeding one thousand dollars, or imprisonment not exceeding the term of six months, or both, in the discretion of the court before which they shall be adjudged guilty as aforesaid.

Sec. 9. The commissioners shall have power to establish all such quarantine or other regulations as they may deem necessary to prevent the spread of the disease or its transit in railroad cars, by vessels or by driving along the public highways: and it shall be proper for the Governor of the State by proclamation as aforesaid, to enjoin all persons concerned or engaged in the traffic or transit of cattle or sheep, not to enter upon any places to take therefrom any such animal or to pass through any such locality, and within such distances from the same as in the said proclamation may be prescribed.

Sec. 10. The sum of \$1,000, or so much thereof as may be necessary, is hereby appropriated to pay to the said commissioners for their services while actually engaged in the duties enjoined upon them in this act, at the rate of \$5 per day to each, and such further sums as may cause them actual expenditures in traveling to and from the places they may be called upon to inspect or visit, and in the printing and publishing of the regulations or notices mentioned in this act. And the further sum of \$15,000, or so much thereof as may be necessary, is hereby appropriated out of any money in the Treasury not otherwise appropriated to pay for animals slaughtered by the provisions of this act, and the Controller is hereby directed to pay for the same on the warrant of the said commissioners.

Sec. 11. The assistant commissioners are to receive for each and every day while actually engaged in duties provided by this act, the sum of \$3 per day, and all actual expenses and disbursements paid or incurred in the discharge of their duties as aforesaid, which said sums shall be a charge upon the county for which he is appointed, and shall when permitted by the Board of Supervisors of the said county, be paid by the County Treasurer.

Sec. 12. The slaughtering of animals for beef, after having been exposed to the contagion, or supposed to have been so exposed, may be permitted by the commissioners or prohibited by them, as they may judge proper.

Sec. 13. This act shall take effect immediately, and shall continue in force for one year.

Tim Bunker on the Cotton Fever and Emigration Down South.

MR. EDITOR,—Your notice in the May number took me considerable by surprise. The fact is, I have been so awful busy with my own affairs, and Hookertown matters, that I had pretty much forgotten the world outside.—Court business of course I had to attend to. And then I never had so much advice to give in cases out of court, since I have been Justice of Peace. I have pretty much come to the conclusion that I am worth more to keep folks out of lawsuits than to settle cases after they come into court.

You see Hookertown has been in a great stew all winter, about going down South and raising cotton, and betwixt the meetings and the private talks around to the houses, there has not been much else done or thought on. You know our son John went to the war, and a lot more of the Hookertown boys, and they came home full of the matter, and they have kept the pot a boilin' ever since. To hear them talk about the Cotton States you would think there was never such a land lying out a'doors any where.—Canaan want a touch to it.—If it didn't flow with milk and honey, it did with cotton bales, which was enough sight better.—Their heads were completely turned with the tall timber—the smooth rich land—the magnolia blossoms, the cypresses, and the live oaks, and would you believe it—the pretty girls.—Every one of 'em seems to have come home as uneasy as a fish out of water. It is mighty dull work squatting down in the land of steady habits after one has been tearing through the cotton States with Billy Sherman and his troopers. John, for the first few days, said it seemed as if he should suffocate in Hookertown—there was nothing doing, or going to be done.

I talked with the boys in general, and my boy in particular, and argued agin the emigration scheme, and the more I argued the more sot they were in their way of thinking; and that wasn't the worst of it, for they seemed to infect every body with the Southern fever, and one while, I thought they'd carry off Hookertown bodily—Mrs. Bunker and the grandchildren, and there wouldn't be any body left but Mr. Spooner, myself, and a few other old fogies. As it is, Hookertown has lost some of its best citizens, as well as some others that we could comfortabler spare.

I felt very bad when John stated the case pretty soon after he got home. "Now," says I, "my son, what is the use of your going down to Mississippi, to farm it, when you have got three hundred acres of as handsome land as lies in the Valley of the Connecticut, or as lies out doors anywhere, as to that matter. We old folks have been thinking, when you got back from the wars you would settle down on the old farm, and hand down the Bunker mansion and name to your children. It is kind o' weak in us, but we thought we should have somebody to lean on, when we got a little older. I can't always hold the plow, and mother's eyes will get past fine sewing and clear starching, one of these days."

There was a tear in John's eye as he got a glimpse of the picture we had been looking at during his long absence, and he said:—

"I expect to do jest as you say father. I have always been brought up to mind, and I expect to mind you now. You and mother felt very bad about my going to the war, but on the whole, thought it was best; and when you come to look at this emigration down South on all its sides, you may think it is just about as necessa-

ry for me to go down there now as it was three years ago. I spose I shall feel worse about leaving Hookertown than you will, for you will have the dear old sod under your feet, and all the associations of your lives around you, the old home, the old church, and old friends, while I shall go mostly among strangers. You have taught me not to follow my feelings always, but to do my duty, and the precept and example have struck in pretty deep. Mr. Spooner has preached that way, and I have come to believe it. I didn't join the regiment because I had any appetite for fighting or seeing sights; I thought Hookertown was a part of my country, and the rebs were to be kept out of it. If I didn't go and meet them on Southern soil, they might come up here, and be watering their horses in the Connecticut, which would not be so pleasant. We who went down there to fight have given you a life lease of your peaceful homes, and we feel as if we had a right to go and carve out homes for ourselves, in the land we have won by the sword. The boys talked it all over before they were mustered out, and we mean to go back, unless it is clear that Providence is against the movement.

"You who are on the stage have had your chance, and help'd make Hookertown what it is. You have cultivated and improved your farms, built your houses, and established your schools and churches, and got every thing going in good shape. The land is all occupied, and there isn't room here for more farmers. The farms are too small already. Your population will only grow in the cities and villages."

"But who is going to have my farm when I'm through with it?" I asked.

"Well, father, there is Timothy Bunker Slocum, a smart boy in his first pair of boots, and big enough to ride a horse and go to mill already. Sally thinks she's going to send him to college and make a minister of him, but unless I'm a good deal mistaken the Lord has made a farmer of him from the start, and if Sally undertakes to turn him off of that track, she'll find she's having a sharp fight with the Almighty and give it up. These things run in the blood, and the Bunker's have always stuck to the soil and haven't amounted to much in any other calling. Little Tim takes to a horse as naturally as a young Arab, and his voice has just the right coop for driving oxen. He is your own flesh and blood, and you ought not to feel very bad if a grandson takes care of the Bunker mansion when you have done with it.

"As I was saying, you have had your chance to make a home and build up society here. We want to take our chance down South where there is plenty of room. The South wants people, New England people, and brains especially, more than anything else. It is almost a wilderness, with only a few little clearings and scratches upon its surface. Its worn out and abandoned fields are only worn out upon the surface. The riches of the soil are hardly touched yet. The forests are magnificent, and the climate probably quite as healthful as the Valley of the Connecticut, when it was first settled. It seems a pity that it should lie waste any longer. We want to start a new Hookertown down there, and are willing to take our chances of soil and climate. What is the use of conquering Canaan unless the people go over Jordan and possess the land?"

John said this, and a good deal more in the same vein, and, as Mr. Spooner would say, there was in it a considerable food for reflection. The more I argued the warmer he grew. It

was just like trying to put out a volcano with a squirt gun. "Ah," said Mrs. Bunker, with a sigh after John had gone out, "He isn't a boy any longer, Timothy. It is of no use talking. The fire burns in him, and who knows but the Lord has kindled it."

I couldn't answer that. It was pretty clear that fire was there, and burning strong, and it seems to be spreading all through this region. It is a big subject, and of a good deal of importance to your readers, and with your permission I shall have to load and fire agin on it.

Hookertown, } Yours to command,
April 13th, 1866. } TIMOTHY BUNKER, Esq.

Sweet Herb Culture.

BY PETER HENDERSON, JERSEY CITY.

The cultivation of Sweet Herbs for market purposes, is but little known in this country, except in the vegetable gardens in the vicinity of New York; there it is practised to an extent of perhaps 60 or 70 acres, a fair average product of which would be about \$500 per acre. Like the crops of celery, spinach, or horseradish, it is grown only as a second crop, that is, it is planted in July, after an early crop of peas, cabbages, beets, or onions, has been sold off. The varieties used are Thyme, Sage, Summer Savory, and Sweet Marjoram, the former two being grown in the ratio of ten acres to one of the latter. The seed is sown in April in rich mellow soil, carefully kept clean from weeds until the plants are fit to plant out, which may be done any time that the ground is ready from middle of June until end of July. As the plants are usually small and delicate, it is necessary that the ground be well fined down by harrowing and raking before planting. The distance apart for all the varieties is about the same, namely, 12 inches between the rows, and 8 or 10 inches between the plants; the lines are marked out by what is termed a "marker," which is simply a mammoth wooden rake, with the teeth 12 inches from centres, and having 6 or 8 teeth, this number of lines is marked at once. (This "marker" is used for many other purposes; in the lining out the rows of early cabbages, for instance, every alternate line is planted, thus leaving them 2 feet apart, their proper distance.) In 8 or 10 days after the herb crop has been planted, the ground is "hoed" lightly over by a steel rake, which disturbs the surface sufficiently to destroy the crop of weeds that are just beginning to germinate; it is done in one-third of the time that it could be done by a hoe, and answers the purpose quite as well, as deep hoeing at this early stage of planting is perfectly useless. In 10 or 12 days more, the same operation is repeated with the steel rake, which usually effectually destroys all weeds the seeds of which are near enough to the surface to germinate. We use the steel rake in lieu of a hoe on all our crops immediately after planting, for, as before said, deep hoeing on plants of any kind *when newly planted*, is quite unnecessary, and by the steady application of the rake, weeds are easily kept down, and it is great economy of labor *never to allow them to get established*. The herb crop usually covers the ground completely by the middle of September. Then, every alternate line is cut out, each plant making about 2 "bunches." The object in cutting out the lines alternately is, to give room for the remaining lines to grow; in this way nearly double the weight of crop is taken off the ground than if every line had been cut, and it frequently happens, on particularly rich soils, that at a second cutting every alternate line is

Fig. 1.—THE GOLDEN CARP, OR GOLD-FISH—NATURAL SIZE.

again taken, when the remaining lines now standing 4 feet apart will again meet. I had about an acre of Thyme treated by this process, in the fall of 1864, that sold for over \$2000,—but this was an exceptional case, the crop was unusually fine, and prices at that time were nearly double the usual. As before stated, the average yield is about \$500 per acre. Herbs are always a safe crop for the market gardener, they are less perishable than any thing else grown, as if there be any interruption to their sale in a green state, they can be dried and boxed up and sold in the dry state, months after, if necessary. The usual price is from \$10 to \$15 per 1000 bunches, and we always prefer to dry them rather than sell lower than \$10 per 1000, experience telling us that the market will usually so regulate itself as to handsomely pay for holding back the sale. The cost of getting the crop raised and marketed will average about \$150 per acre, the principle expense being in tying it in bunches. But with many of our industrious German gardeners it does not cost half that, as tying up is usually done by their wives or children in the evenings; a pleasant as well as profitable occupation.

The Golden Carp, or Gold-fish.

(*Cyprinus auratus*.)

There are few fish which may be properly classed among the domestic animals of this country, but the Gold-fish is unquestionably one. True, it escapes from confinement and regains its wild habits, but it is universally known in a condition of entire domestication as the denizen of fountains, fresh water pools, and fish ponds,

Fig. 2.

and of the globes and aquariums which ornament our dwellings. In the globes we see usually only the golden fish, with those spotted more or less with dark blotches and white, but in the ponds where they breed, almost all tints of silver, bronze, and purple, are seen, besides the orange and golden colors which give the fish its

name and value. These colors are more or less dependent upon age, while the size of the fish at any particular age bears more direct relation to the quantity and quality of their food.

These beautiful fish are natives of China, where they are very common in domestication, but they will live and thrive in the fresh waters of every temperate latitude. They bear the heat of our summer and the cold of winter perfectly well, being often frozen into the solid masses of ice which fill the shallow basins where they are kept, but we presume this is detrimental to them.

Fig. 3.

They do not object to clear limpid water, but seem to prefer that which is roiled and muddy, filled with infusorial plants and animals upon which they feed. In such waters they multiply rapidly, breeding twice, or several times, in the season. The young, hatched from eggs laid among the grass and weeds along the warm edges of the ponds, are at first of a dark bronze color, inclining to olive, and do not gain their true colors till they attain considerable maturity. From their conspicuousness they are a prey to ravenous fish, and their rapid increase is checked, but they are themselves perfectly harmless.

The Gold-fish belongs to the genus *Cyprinus*, to which also the Carp of Europe, *C. carpio* belongs. The flesh of the Gold-fish is edible, but not very good, yet the dark kinds are frequently eaten by persons unsuspecting that they are eating Gold-fish. The size which these fish attain, if they have food enough, is about that of the specimen so well represented in fig. 1, though this is not unusually large. If, however, they are kept on short commons, as in globes where they are seldom fed, they will remain an inch and a half or two inches in length for a long time. Domestication seems to disturb the balance of nature not only in color, but in shape. Fish with two or three tails, or with split or double fins are common, and so also are those deformed by the loss of important fins, as in outlines shown in figures 2 and 3.

There is at all times a ready market for Gold-

fish in the cities, the price varying with the supply and demand. A few years since they sold at \$3, or \$4 to \$8 per hundred, and retailed at 10c. to 15c. each; at present, however, the price is higher and they sell for \$15 to \$20 per hundred, or from 25c. to 75c. a piece, the cost being regulated by the perfection of the fish in health, coloring, size, etc. The smaller sizes being the favorites. No fish is more easily bred; any pond which does not go dry, if a pair are introduced, will swarm with them after a few years. They are easily transported in winter, simply in water changed once in a few days, and in summer, in water kept cold with ice.

In China they are said to grow to be a foot or more in length, and to live 50 years. They were probably first brought to Europe by the Portuguese, and after their introduction as a great curiosity into the ornamental waters at Versailles, near Paris, which was about 1700, they became before long common all over Europe.

The ease with which they may be tamed adds greatly to the interest of keeping them. The fish soon learn to come to a call, or to the sound of a bell, or to blows upon the water, and will eat from the hand, allow themselves to be taken out of water, etc. We need hardly suggest to our readers a practicable application of the facts we have stated. Notwithstanding they are so common, the demand for them falls far short of the supply. Many a pond might be made to yield a very pretty income in the course of a few years, provided only the present fashion of fish globes continues, as it is likely to. Small gold fish may be secured by catching the young fry and confining them a year or less in contracted basins or boxes, where they will have plenty of fresh water, but little or nothing to eat, except what they find in the clear water. Many will become golden; many will not; but we believe the proportion of golden ones might be greatly increased were the golden fish only allowed to breed. The present scarcity and high price, is, we presume, in a good measure, due to the fact that the gold, silver, and bronze fish, are allowed to breed together indiscriminately. Besides, those who take the fish for market, often most heedlessly throw out the dark colored ones, old and young, to die on the shore; not regarding the fact that a great many, if not all, of the gold fish do not gain their color until they are fully a year old.

The Buffalo Berry.—(*Shepherdia argentea*.)

When the blackberry was first introduced as a cultivated fruit, one of our horticultural writers remarked that probably there were others of our wild fruit-bearing shrubs that would soon be included in the garden, and as one of these he mentioned the Buffalo Berry as promising to reward the attention of the cultivator. We are not aware of any attempts to cultivate the shrub for the economical value of its fruit, though it is grown here and there in collections, on account of the ornamental appearance it presents when its berries are ripe. The Buffalo berry is found on the banks of the upper Missouri, the Saskatchewan, and other large rivers of the Northwest, where it forms a low tree, with its smaller branches ending in stout spines. A small branch of the natural size is given in the engraving. The leaves have a silvery hue, and are found, when closely examined, to be covered with scurf-like scales. The flowers are small, without petals, yellowish and inconspicuous, with the staminate and pistillate ones on separate plants. The berries are about the size of small currants, of a fine scarlet color, and produced in such abundance as to give the trees, late in summer, or early in autumn, a showy appearance. The fruit is of a pleasant acid, and is highly valued for preserves, being esteemed, by those who are acquainted with it, as preferable to currants. The shrub was first described by Nuttall, who named it in honor of Mr. Shepherd, a former curator of the Liverpool Botanical Garden; the specific name, *argentea*, refers to the silvery character of the leaves. The Canadian French used the berries to give a relish to their dried meat, and called them by the rather fanciful name of "Buffalo-fat," whence we get the name Buffalo-berry; it is also called Rabbit-berry in some parts of the country.

Nuttall long ago called attention to this as a plant likely to prove serviceable for hedges. It is perfectly hardy, bears cutting well, is of sufficiently rapid growth, and holds its leaves well in autumn. A tree near Boston is said to have reached the height of fifteen feet in eight years from the seed. The plants are sold at the nurseries for 50 cts. each. In order to obtain fruit it is necessary to set out both staminate and pistillate kinds. It is propagated by sowing seeds, and from suckers. We hope to see this native shrub more common than it now is.

Mildew and its Treatment.

Despite the assertions that we know nothing about the cause of mildew—we know very little about the *cause* of anything—there are some facts in its history that are well established. It is just as well established that mildew is a plant that lives upon the tissues of other plants—microscopic in size, but nevertheless a plant and capable of reproducing its kind—as it is that an oak or a vine is a plant. There is one point, however, not so well fixed, and that is whether mildew ever appears on a healthy plant, but is not an indication of, rather than a cause of disease. Without committing ourselves to either

side of the case, we may say that the weight of evidence seems to point toward the view that some predisposing cause, some sudden debility in the plant, prepares it for the attacks of the minute parasite, which a perfectly healthy plant is able to repel. The discussion of this point is not our present object. We wish to call attention to the remedy, which general experience has shown to be serviceable in checking the ravages of mildew. The trouble is not confined to

mon bellows may be modified so as to serve. The vines should be dusted on both surfaces of the leaves on the very first appearance of the pest, and we call attention to the matter thus early that all may be prepared with proper arms and ammunition before the enemy appears.

A writer in the English Journal of Horticulture, recommends the use of sulphur in the form of Sulphide of Calcium. This is not new, but it has long been in use in this country. We give his directions for preparing it: "One pound of quick lime and one pound of flowers of sulphur are well mixed together in one gallon of water, boiled about half an hour, and stirred at intervals while boiling. When it is quite cold, the clear liquid is poured into bottles, and in this state kept for use. About a quarter of a pint of the liquid to four gallons of water, and stirred until the whole becomes of a pale yellow, I have generally found sufficiently strong for use, but half as strong again will do no harm." This preparation is used on vines by means of a syringe, and is found efficacious in destroying both mildew and red spider. Another method is to take twice as much lime as sulphur, put them together in a barrel and slake the lime with hot water. After the mixture is cool, add water, in the proportion of twelve gallons to each pound of sulphur employed. This is less trouble, but it does not ensure so complete a solution of the sulphur as in the process given above. Much of the efficiency of either dry sulphur or the solution, depends upon faithfully applying it upon the very first appearance of the mildew, and arresting its progress before any material damage is done.

The Garden uses of Ivy.

By Ivy, of course we mean true Ivy—*Hedera helix*—which in its different varieties is known as English, Scotch, Irish, and several other Ivies; and none of the native plants that are popularly so called. The different kinds of Ivy present great diversity in the size and shape of the leaf, and there are some in which the dark green is beautifully marked with white and yellow. It endures almost every treatment, except exposure to a burning sun, and though it is not as a climber very suitable where the winter is much more severe than that of New York City, it can in much colder places be grown low and made to serve a useful purpose. Wherever it will flourish there is nothing more beautiful as a climber to cover stone or brick buildings than Ivy; it makes a dense sheet of evergreen foliage that no other plant can equal, and it clings by means of its abundant rootlets with a tenacity that is remarkable. Growing upon buildings, stone walls, and the like, it serves an excellent purpose, but there are other uses to which it can be put, and though every one may not have a stone house, or live in a suitable climate, yet all can have plenty of Ivy. When grown prostrate upon the ground, it forms a dense mat of dark verdure, and is useful to clothe shady spots where grass will not flourish. Grown in this way nothing can be more beautiful in cemetery decorations, and a grave may be covered by it with a mantle that is always green. Trained along the margins of borders it makes a most

BUFFALO BERRY.—(*Shepherdia argentea*.)

the grape alone, but many other plants suffer in this way. Last year the celery crop both in this country and in Europe, was severely injured by mildew. It is not likely that the minute fungus is the same on plants so different as the grape and the celery, etc., but they are similar in character and the same treatment is found efficacious. The remedy is sulphur, and when properly and promptly applied, it, (even in the great mildew year of 1865,) checks the progress of the destroyer. In July last we gave a figure of a bellows for applying sulphur; a very convenient apparatus, and one which should be kept by the horticultural warehouses. Last year this bellows was difficult to procure, and many were the complaints of those who lost their grapes for the lack of it. All that is needed is a contrivance that will throw sulphur dust, and other expedients may be made use of, or a com-

useful edging, and deserves more attention in this respect than it has yet received in this country. No plant is so valuable as the Ivy for indoor green, and it has the great advantage that it grows well in the shade, and will endure neglect, and the extremes that the temperature of our dwellings often present. For hanging baskets, vases, and all such uses, it is always in requisition, and it is often grown in pots and trained around pictures, over doors, windows, etc. There is one house which we frequently pass, which has a complete window screen of Ivy, which is so fresh and beautiful that we always stop to pay it the homage of our admiration. We said that the plant would endure neglect, but it well re-

pays attention and an occasional washing of the foliage is labor well bestowed. Now is the time to prepare for these indoor decorations by starting the plants; and nothing is casier. We have raised fair plants in one season from a single joint, but it is better to use cuttings a foot or so long. Put in good soil in a shady place, they will seldom fail to take root and make plants. Where the plants are intended for indoor uses, they should be trained up to stakes, as if allowed to lie upon the ground they will root at every joint, and will also be quite oversized when they are potted in autumn. Those who have Ivy in pots, etc., indoors, should put them in a shady place and give them sufficient water. It is well to repot in rich soil in order to get a good growth during the summer, and if the plants are grown upon frames to give a little care now and then to pruning and training.

Fig. 1.

Fig. 2.

but it well re-

stake and bow system, from the fact that the bearing canes are secured to the wire, as shown in the sketch, affording a better opportunity for sun and free circulation of air, as well as for pinching the laterals. The two canes grown

this year, fig. 2, are trained to stakes. In November these will be pruned to 4 feet in length, and the next year fastened to the wire, as in fig. 1. The next summer two more canes will be grown to the stakes, to replace the canes that have fruited, and which will be cut away at the next pruning. To make a support of this kind, set at each end of the row a good sized fence post, to which fasten No. 10 or 12 galvanized wire, at about 18 inches from the ground. Split or sawed stakes, 6 feet long and 2 inches square, are set at each vine, and a saw scarf is made at 18 or 20 inches from the ground, to receive the wire. [Better use staples.—Ed.] A good distance for rampant growing vines is 6 feet apart, in rows 8 feet apart. This plan has the advantage of bringing the fruit near the ground, which is especially desirable in cold localities."

The author of My Vineyard at Lakeview has another modification of this mode of training. His vines are supplied with strong stakes, and are placed 6 feet apart. Two canes are grown each year to bear fruit the next. Finding that four canes to a stake made a crowded mass of foliage and rendered pruning difficult, he took strips of iuch board, 9 1/2 feet long, and nailed them from near the bottom of one stake to the top of the next. Upon these diagonal slats are trained the canes for next year's fruit, while those in bearing are kept upon the stakes. The

explanation unnecessary. While the author does not think it the best method for large vineyards, he finds it very satisfactory in plantations of moderate size and in garden culture.

Mr. C. G. Green, Hudson, N. Y., communicates a method practised by Messrs. J. F. Crank & Co., Penn Yan, N. Y., in layering the Delaware, which is slow to root with the ordinary treatment. They lay a cane down in a trench 6 inches deep, and fasten it there by pegs. The cane is kept in this position until the shoots have made a growth of three or four inches, when it is taken up, and the bark cut from the lower side of the cane for its whole length. It is then replaced in the trench and covered with one or two inches of earth, and as the young growth increases in height, more earth is gradually added. Roots readily push from the portion deprived of its bark, and in autumn he gets as many well rooted plants as there were buds upon the cane. The only thing peculiar to the process of Messrs. C. seems to be the removal of the bark; the treatment of the layer in other respects will be found described, and illustrated on page 61 of Fuller's Grape Culturist.

In England a ground vinery has been for a few years past quite popular among fruit growers. It is there used for growing the European grape, and will doubtless become more or less used by us. It is simply a low cold-frame placed over the vine, which is trained close to the ground. So much are these in demand in England, that we find them advertised by several makers as regular articles of trade. We

Fig. 4.—GROUND VINERY.

Notes on Grapes and Grape Culture.

Perhaps no plant has been made to assume so many shapes as the vine, and whoever looks over the various European and American works on vine culture cannot but be astonished at the number of plans that have been described. All rational training of the vine has the same object in view: the production of the greatest quantity of the best fruit in the smallest space. In striving to attain this end, it is not surprising that different persons hit upon the same plan, and it has happened several times that our correspondents have sent us an account of their methods of training, which were simply repetitions of old ones. A method has recently been described by F. M. J., Augusta, Iowa, which is almost precisely one that has been for a long time in use in France, but as it is one which we believe we have not given, we illustrate it. It is no doubt original with Mr. J., but he will find the same thing in principle, though differing in unimportant details, in Guyot and other French writers on vine culture. Mr. J. says: "I send you what I consider an improvement on the

Fig. 3.—TRAINING BY THE AUTHOR OF "MY VINEYARD."

result is, the fruit ripens better, and the new wood has a better chance to develop and mature, while the operation of summer pruning is greatly facilitated. The cut, fig. 3, taken from the work above mentioned, will render other

raising the vines above the slates, giving more care to the ventilation, etc., practice can only determine. While in England the vines need no protection during the winter, with us they would need to be covered with great care,

give a figure of one from Rivers' Miniature Fruit Garden. It consists of two sashes put together like a roof. The usual length is 7 feet, width of base 30 inches, slope of roof 20 inches, depth in center 16 inches. These are the dimensions for a single vine, but for two vines they are made larger. By placing frames end to end, the length of the vinery may be increased as required. The ends are closed, an aperture being arranged at a, which may be opened for the escape of hot air. The frame is set upon bricks, (d, d), laid a few inches apart, leaving spaces (c, c) for ventilation. The ground within is covered with slates or tiles, and the vine, planted at one end, is laid directly on the slates and is fastened there by pegs. The fruit ripens laying upon the slates, and the BlackHamburgh, etc., are said to attain perfection when grown in this way. How far our intense suns will require a modification of this method, by

raising the vines above the slates, giving more care to the ventilation, etc., practice can only determine. While in England the vines need no protection during the winter, with us they would need to be covered with great care,

A House for Drying Fruit.

BY W. W. SEWALL, VERDEN, ILL.

However superior canned or preserved fruit may be, there is always a large demand for the dried article, and when well prepared, it meets with a ready sale. The more rapidly the fruit is dried, and the more it is excluded from light and flies, the better it will be, and there are several contrivances for accomplishing this end. Some of the fruit drying arrangements are patented, while others, perhaps equally effective, may be made by any one. We give drawings and description of a fruit drying house furnished us by Mr. W. W. Sewall, of Verden, Ill., who says it is both economical and satisfactory. "The house, fig. 1, is eight feet six inches long, by four feet two inches wide, outside measurement, and seven feet high to the eaves. There is no frame except the sills and plates, which are 2x4 scantling, to which the boards on the sides are nailed; and the cracks are battened as shown in the engraving. The roof is shingles or boards, and it would be much better if it projected some feet over the sides and front end, to afford protection to those preparing the fruit.

"The ends of the house are enclosed by a series of doors, marked A in fig. 1. Each of these doors moves independently of the others, and is hung by means of pivots near its upper edge, which pivots drop into sockets like that shown in fig. 2. Each door may be readily lifted from its place, by lifting the pivots from the sockets. Both ends of the house are exactly alike. The fruit is spread upon shallow drawers, which are four feet square and 1½ inches deep; fig. 3. The sides and bottom are of common laths; placing the laths that form the bottom just close enough to prevent the fruit from falling through. The ends of the bottom pieces project half an inch beyond the sides, to rest on slats nailed to the walls of the house, and the bottom of the drawer is strengthened by having a lath nailed across it, as shown in fig. 3. To support the drawers, laths are nailed to the sides of the house, two inches apart from center to center; the drawers rest upon these by means of their projecting ends. A set of these drawers is introduced at each end of the house, and they rest very close together, as seen at B, fig. 1.—The house is set on a brick foundation, level with the ground, of which a plan is given in fig. 4. The furnace (A) is sunk two feet deep; it is covered with heavy sheet iron, which to better regulate the heat, may have a covering of sand. The pipe (B) is six or eight inches in diameter, carefully riveted at the joints to prevent the escape of smoke, except at C, C, where the joints are put together in the usual manner, so as to allow the pipe to be taken apart and removed to a dry place when not in use.

The chimney (D) is made high enough to insure a good draft. The covering of the furnace is ten or twelve inches below the top of the wall, and the pipe rises gradually until it reaches the chimney, in order to increase the draft and bring

the apex of the roof. The ventilator consists of two boards nailed together and placed over an opening four inches wide, which runs the whole length of the roof; it may be raised or lowered to decrease or increase the temperature.

The drawers should be made all alike, to fit in any part of the house, so that they may be moved up as the fruit in them becomes dry, and others containing green fruit be placed near the fire. As the fruit dries, the contents of several drawers may be thrown together. By arranging one side of the cellar to receive the drawers, they may be made very useful in storing away green fruit for the winter; for this purpose the slats to support them should be placed far enough apart to accommodate the different sizes of fruit. Fruit thus stored keeps well, and this use alone pays for the cost of the drawers. This dry house demands a machine to halve peaches rapidly, and it is hoped that Yankee ingenuity will soon supply one."—We would suggest that a house of this kind would be more satisfactory, if the foundation were built higher with air holes made to admit cold air below the pipe, and thus keep up a constant flow of dry air through the house, and dry the fruit all the more rapidly.

Fig. 1.—FRUIT DRYING HOUSE.

the cooler portion of the pipe nearer the fruit. It may be necessary to regulate the heat by covering the joints of the pipe that are nearest

FIG. 2

FIG. 3

Figs. 2 and 3.

to the chimney with a strip of sheet iron. A pit (E) is in front of the furnace to admit of firing, and should be sheltered from the rain.

Fig. 4.

The heat rises through the successive layers of fruit and passes off at the ventilator C (fig. 1) at

Old and New Styles in Gardening.

In conversing a few days ago with an old gardener we asked him why he did not go into the propagation of "bedding stuff" for which there is so great a demand. He replied, in substance, that "he would not touch it, an I pander to the present barbaric taste; that there was now no true love for flowers, but that all that was aimed at was to produce effects of color, while all regard for beauty of flowers was lost. That it was a prostitution of flowers to use them for producing an effect of color which could as well be done by the use of cloth or any other material of gay hues."—There is much truth in our friend's view, but in discarding bedding plants altogether and giving up the effects obtained by massing, he runs to extremes as much as do those who go altogether for ribbon work and lawn embroidery and neglect mixed borders. It may be necessary to explain these gardener's terms to some of our readers. By *mixed borders* is meant the old-fashioned flower-bed, in which everything that suits the owner's fancy is collected, the only attempt at arrangement being that each should have a favorable place, and not be overtopped by its taller growing neighbor. In this, flowers are grown for the beauty of the individual specimens, and when properly managed, will give a succession of flowers from the first peeping of the crocus till the hard frosts put an end to the chrysanthemums. The *ribbon* and other styles require but few kinds of flowers and a great many of each, and they are planted so that each color will be by itself and contrast with an adjoining mass of some other color.

Where there are long bands of different colors side by side, it is *ribbon planting*; when variously shaped beds are cut in a lawn and each planted with one color, or a few colors, it is *mosaic* or embroidery work, and it is sometimes carried to the refinement of using gravels of different colors to heighten the effect of the flowers. Planting of this kind appears best when looked down upon, or from a point where the character of the individual plants is lost in the general effect. If asked which of the two styles of gardening we prefer, we unhesitatingly choose the mixed border, as it is here that the true lover of flowers is gratified with the best development of each, and has constant enjoyment in the succession of beauties which each day reveals. Still we would not give up planting in masses altogether. Decorative beds in a lawn are always pleasing, and if not indulged in to the exclusion of the proper mixed borders, are to be commended. We do not get much show from the bedding plants until rather late in the season, and whoever depends upon them entirely, is deprived of at least two months of floral enjoyment. Sometimes a mixed bed is planted so as to give a great variety and succession of bloom and yet be effective as a whole. Breck, in his lately published *New Book of Flowers*, recommends the following disposition: For a large oval bed, sow Mignonette all around 18 inches from the edging; after the plants are through the ground, set all the various colors of Portulacas alternately, one foot apart in the same row. In the second row, 3 feet from the edging, plant all the fine colors of Phlox Drummondii, 8 inches apart. Sow a third row, four feet from the edging, with white Candy-tuft, putting China Pinks 3 inches apart in the same row. Five feet within the edging, plant a row with Purple Globe Amaranths, 8 inches apart, alternating with German Ten Weeks Stocks. The fifth and next row is made up of the finest Double Asters, and the remaining space in the center of the bed is filled with Petunias, with bulbs of French Hybrid Gladiolus set about one foot apart among the Petunias.

THE CENTAUREA CANDIDISSIMA HARDY.—This ornamental leaved plant has usually been treated as tender. Last year we left out three

plants in the worst possible exposure, where a part of the time they were flooded and frozen. This spring, we find, much to our surprise, that one of the plants is alive and is pushing a new growth. We have no doubt that in a favorable situation and with a moderate protection of straw, leaves, or evergreen boughs, this useful decorative plant will winter with safety.

DWARF SNOWBALL.—(*Viburnum plicatum*.)

The Dwarf Snowball.—*Viburnum plicatum*.

We are indebted to China, and the labors of Mr. Fortune for many beautiful plants, most of which, such as the Wiegela, Forsythia, and Dicentra, have become so generally distributed among cultivators that they are well known. But here is a most charming plant, introduced about the same time as the others, that is, in this country at least, still quite rare, for some reason that we do not know. It is not difficult to propagate, is perfectly hardy, and has every quality to render it popular. We give a figure and a notice, which will probably create such a demand for the plant that our nurserymen will see that it can no longer be called rare. The common Snowball, so long cultivated in our gardens is still prized as an ornamental shrub. This species is far more beautiful; it seldom

grows more than six feet in height, and has a very neat habit. Its foliage is very fine, being firm and of a rich dark green. It is marked by such strong veins as to give the leaf something of a plaited appearance, whence the name *plicatum*. The flowers are of the purest white; indeed truly like balls of freshly fallen snow, and of a most agreeable, though not very strong fragrance. The figure shows a flower cluster of

the natural size, but no engraving can represent the purity of the whiteness of the petals. The plant readily grows from layers, and it may doubtless be raised from cuttings. Beauty and fragrance of flower, neatness of foliage, and hardiness and ease of propagation are not often all combined in one plant; so in behalf of the lovers of beautiful shrubs we beg the nurserymen to give us a supply of *Viburnum plicatum*.

Tomato Training.

We have given several plans for training the Tomato, by the use of trellises, surrounding the plant by a frame of sticks and hoops, and the French method of growing to a single stem as given on page 173, last month. The following description is given us by Mr. William Stewart, Oswego, N. Y., of a method of training that we have seen and with good results. "Tomatoes may be trained up to a wall or fence, or any outbuilding having a proper aspect for their ripening, if such positions are not required for other purposes. I trained them during

last season to fifteen feet in height, on the southern side of the barn, and they had an ornamental appearance and were much admired.

I planted them at about four feet apart, and from time to time selected enough leaders to cover the entire available space, training them at about nine inches apart; the soil was rich and they grew rapidly, produced abundantly, were well flavored and — always clean. In training them, cut or pinch off all weak or useless laterals, bearing in mind to leave enough of those having on a sufficiency of fruit, pinching off all points near the fruit except those required for leaders.

The fruit, when it is beginning to ripen, may be exposed by cutting off such foliage as would be likely to shade it. The training requires to be attended to at least once a week, otherwise they quickly get into a state of disorder, and proper success is not attainable. It is astonish-

ing how a large space of them may be regulated if not too long neglected. The trouble is no more than would be required to support them in any other way. Those who adopt the method will, I am pretty sure, be well satisfied with the result. My way of fastening them has been with staples, which I make quickly out of common wire with a pair of pliers, a hammer, and a stone to sharpen them on."

Mr. S. sends us samples of the staples he uses, which have the points sharpened in the direction of the staple or at right angles to it, according as they are to be driven into boards running horizontally or perpendicularly.

Asparagus, White or Green?

We are asked if asparagus should be blanched to fit it for the table. By no means. It is blanched for the city markets by growing it under a coating of manure, but though it looks delicate and tender when treated in this way, it is tough, bitter, and nearly unfit to eat. City people, who do not know any better, will select white asparagus in preference to green, just for the looks, and as long as they are willing to pay for having it spoiled, market gardeners will supply it in this way. Generally, all of the shoot that grows below ground is worthless, and were it not for leaving a portion to decay, there would be no need of cutting below the surface.

Late Blooming Flowers.

By a little management the flower garden may be kept brilliant until frosts put an end to growth and flowering. Nothing among the bedding plants makes a greater show, late in the season, than the Mexican Sage, *Salvia splendens*. Then there are Chrysanthemums in great variety. The Tritoma has spikes of flowers so brilliant that it has in England received the somewhat absurd descriptive name of the "Red-hot-Poker-Plant." There are tuberoses, late unless forced, Ageratum, and others, not forgetting the "foliage plants," Coleus, Iresine (Achyranthes) and others. It is not too late to sow annuals for late blooming, and those who have been obliged to delay sowing them can yet do so and get a very satisfactory bloom. Asters, Zinnias, Helichrysums, (and other everlasting,) if sowed as late as the early part of the present month, will pay for the trouble, and Candytuft, Mignonette, and many others usually sown in spring, may be put in for a fall crop.

Striking Cuttings in Sand.

Noticing that the method of rooting cuttings in wet sand is highly commended in the recent English horticultural journals, we would remind our readers of a communication in the *Agriculturist* two years ago.—In February 1864, Mr. Henderson gave us an article describing the plan, and most of those who have followed it have met with success, while some have failed, probably from not complying with the essential requirement, i. e., to keep the sand constantly wet. It is very convenient for those who wish to multiply bedding plants and make other cuttings during the summer, and we have succeeded in this manner with a number of shrubs, taking the young and rather soft wood. A common saucer or soup plate is filled with sand—any kind will do that is free from salt—add enough water to thoroughly wet the sand and form a kind of mud, and into this insert the cuttings

quite thickly together. The cuttings are made from one to two inches long, and when inserted are not to be shaded but exposed to full sunlight, and, as stated above, the sand to be kept constantly wet. Once dried they seldom recover.

THE HOUSEHOLD.

Deodorizers and Disinfectants.

In conversation some time ago with an officer of one of the gas companies, we asked him why he did not render his gas less disagreeable to the smell. His reply was, that it was a great advantage to the consumer to have the gas thus unpleasant, for were it odorless a leak would not be observed, as it now is at once. As the unpleasant odor of the gas enables us to detect a defect in the pipes, so other odors point out defects in the household and domestic economy, and indicate that something is escaping that ought to be stopped. Whatever may be the cause of certain epidemic diseases, there is one thing that is well established,—they are invited by filth and repelled by cleanliness. Decaying animal and vegetable matters, if they do not cause disease themselves, put the air in a condition to propagate it. Fortunately these processes of decay give us warning, for the most part by the unpleasant odor given off. Cleanliness of the house and its surroundings should at all times be observed, but especially when the warm weather hastens decay of all kinds. Prevention in this case is better than cure, and the removal of all offensive matter from about the dwelling is the first thing to be thought of. An existing smell may be treated in one of three ways; it may be disguised, absorbed, or destroyed. The disguising of smells is not to be commended, though much of the so-called disinfecting is of this character. The sprinkling of perfumes, the burning of pastilles and other substances which give off an odor by the application of heat, only substitute one odor for another, and do nothing towards actually removing the trouble. Absorbents are useful in many cases. One of the most powerful of these is charcoal, but dried peat or muck, or even loamy soil will answer a good purpose. By the use of either of these, privies, piggeries, and heaps where animal matter is being made into manure, can be kept from giving off offensive odors. Among the substances that have been used for destroying odors chemically, are Chlorine, Nitric oxide, Permanganate of Potash, Sulphate of Iron, Nitrate of Lead, Chloride of Zinc, and others, besides several secret or patented compounds. Of these there is but one likely to be employed by the public generally, and that is Chlorine in the form of what is called Chloride of Lime, or Bleaching Powders. It is cheap, easily applied, free from unpleasant after effects, and quite as efficacious as any other. When sprinkled about in offensive places, it destroys unpleasant odors as they are generated, and if a more prompt action is desired, it may be dissolved in water, allowed to settle, and the clear liquid used. There are other ways for applying chlorine more thoroughly, but they are not to be commended for general use. While this and other disinfectants are of great use in producing a wholesome state of the atmosphere, medical men doubt if they possess any considerable efficacy in destroying the poison, or whatever it may be that causes epidemic and contagious diseases after it is once introduced.

For the American Agriculturist.

About the Fashions—Sundry Hints.

FURNISHED BY MADAME DEMOREST.

We cannot congratulate the ladies this season upon their sensible fashions. They are full of bright effects, and pretty colors seen from a distance, but in detail they are exaggerated, and in many respects absurd, as well as inconvenient. The bonnets are ridiculously small, setting high like the crown of a Normandy cap, on top of the head, or laying low, and flat, like an inverted soup plate, tied close at

the sides, but in either case affording no protection from sun, or storm, and leaving the hair exposed to all the dust of the streets and roads. [Very, very true.—Ed.]

The new styles of skirts, on the contrary, particularly at the base, are enormously wide, and tilt at every touch in a way that verges slightly on the indecent.—The fashion of looping up the skirts over the Balmoral petticoats, was a very good one, but the original object has been almost wholly lost sight of, in the desire for display, in the temptation to exhibit elegant cambric flutings, rich embroidery, and a fanciful *chaussure*. A well-dressed foot is a pleasant object to contemplate, and it is indispensable to a lady's good appearance, but the beauty of the shoe and stocking, consists in its perfect fit and fineness, not in color, and showy ornament.

We do not object to the introduction of bright colors, even in street attire, but it requires to be done with great taste and judgment. A mixture of colors is always vulgar, and persons who cannot afford a great variety in their dress, should be careful to select only such colors as will harmonize, and prove lasting and serviceable.

White has been largely introduced into street toilettes of late years, in the shape of white veils, white bonnets, white sacks, and the like. These are all very well for those who possess outside garments, suited to every occasion, but for those limited to one, or at most to a "best," and a "hack," they are entirely unsuited. Nothing looks worse than a white bonnet, or veil, or a light, showy sack, and a dingy dress. A neat suit all of a color, or of a neutral tint, relieved by some bright shade is infinitely preferable.

The great temptation this season is to a vulgar profusion of trimming. In addition to the usual ornaments, a great many new ones have been introduced, such as buttons, chains, strings of beads, cameos, buckles, clasps, and mixtures of straw with jet. In addition to these, not a few milliners pile on lace, ribbon, flowers, veil, until the diminutive bonnet is completely hidden, and its original shape quite lost sight of.

Properly, the bonnets this season require very little trimming. They are very small, and the braids are all of the fancy sort, alternating with bands or puffings of silk. A "*Benoiton*," that is to say, a chain, fastened with cameos, a bandeau, and strings, are all that is required for these.

The *Princesse*, or gored style of dress is more fashionable than any other, but can never be very popular, because it is not easily made, and cannot be made over with the same facility as the ordinary styles. Moreover, it is inconvenient for looping up, and is not graceful for the street. Skirts may be partially gored, however, so as to give much of the effect of a gored dress, with very little trouble and a positive saving in the material, and the breadths of a rich silk may be turned in, and all cutting avoided, by those who wish to obtain the effect, without injury to material.

Dresses for house and evening wear, are worn with immensely long trails. In Paris two yards is considered moderate. These dresses are worn without hoops, almost without sleeves, and with a very short, low corsage, quite in the old Empire style. Looped up dresses are still worn over hoops in the street.

Artificial Memory.

A frequent Contributor to the *American Agriculturist* writes: One of our contemporaries recommends the use of a slate hanging up in the pantry, on which to note down whatever is wanted for daily supplies, or whatever family duties need attending to. One morning, perhaps the entry will be, "Send for soda and saleratus and allspice." "Examine brine in beef-barrel." "Weed the onions." This is for the man's side of the slate. On the woman's side we shall find such things as: "Brown the coffee," "Seal the bread-box," "Finish Mary's apron," etc. Whenever anything occurs to the head of the family that is very important to remember, it is put on the slate, rather than trusted

to the memory. Now, this looks well at first, and it may answer for old people, whose memories are failing, but it is a bad practice for the young, and those in active life. It *weakens* the memory. With the faculties of the mind, or with the organs of the body, whatever we wish to strengthen, we must *exercise*. If an able-bodied man should use crutches, or carry his right arm in a sling, he would soon cease to be able-bodied. So with the memory, or reason, or imagination. By no means employ an artificial memory, be it slate, piece of paper, or tablet, but write everything on the tablet of your mind clearly and distinctly, and learn to hold it there firmly, and then to recall it when needed. It will make one more self-reliant and strong every way. We speak from an experience of the injury of trusting to an artificial memory, and would caution others against it.

"Information Wanted."

Under this head we throw together sundry queries taken as we find them in a bundle of letters in the "Housekeeping Drawer." The questions are "open to the meeting" for discussions and replies. Please let answers refer to the numbers:

- 1—Best kind of salt for butter?
- 2—How much salt to a pound of butter?
- 3—How to color kid gloves?
- 4—Patterns (sketches) for making cone frames?
- 5—How best to get rid of flies?
- 6—A cement for fastening knives in handles?
- 7—Best pork brine?
- 8—Best mode of hulling corn?
- 9—A good home-made ink?
- 10—To extract wheel-grease from unwashable garments?
- 11—Best home-made binding for copies of this paper?
- 12—To preserve bacon from flies in summer?
- 13—Labor-saving soap that will not cause garments to fade or rot?
- 14—To restore faded Buffalo robes?
- 15—To remove mildew from muslin?
- 16—To color cotton and flax warp green for carpets?
- 17—Best economical icing for cakes?
- 18—Is scalded brine as good as fresh?
- 19—Best mode of pickling martynias?
- 20—To make a good home-made toilet soap?
- 21—Best mode of bottling and barreling pickles?
- 22—How to make the "Free and Easy Soap"?
- 23—Best way of making salsify soup?
- 24—Best proportion of lard and rosin for protecting metals?
- 25—To keep sad-irons smooth, and free from rust?
- 26—When to cut wood for rustic work, so as to have it retain the bark most firmly?
- 27—Best mode of cooking egg plant?
- 28—Best mode of boiling potatoes?

"Salt Rising" Bread.

[We have never quite got over the liking for the old fashioned "salt rising bread" so common in our boyhood days, at the West, before the times of brewers and brewer's yeast. The writer of the following gives the *modus operandi* very clearly.—Ed.]

I saw in a recent number of the *American Agriculturist* a request for a process of making bread when yeast cannot be obtained. There seems to be a prevailing idea that bread cannot be made without "Hop yeast."—I have been a housekeeper for over twenty years, and for the most of the time have made my bread after the following process. My neighbors also use the same, and we pride ourselves on being good bread makers.—Take a pint bowl about one-third full of quite warm water, put in a bit of soda as large as half a pea and a small pinch of salt; thicken the water with flour until as stiff as batter for pancakes, then set the bowl in a vessel of very warm water and place it where it will keep about the same temperature, taking care not to scald, as that will spoil it. In from five to seven hours this will ferment; let it rise until the bowl is nearly full, then warm about three pints of

milk (water will do very well, but the bread will not be as white and tender), stir in flour enough to make a stiff batter, and add the above yeast, mixing it all thoroughly together, and set where it will keep quite warm. In about an hour it will be light enough to mould into loaves by adding more flour. The above quantity will make three good sized loaves. Mould, and put in tins, and set them again where they will keep warm until they rise to about double size, then bake in a quick oven.—If any one will follow this process in every respect, I think they cannot fail to make a wholesome and healthy bread.—I sometimes use a part Canaille to make the yeast, as it will ferment quicker, but of course the bread will not be as white. The yeast should be stirred occasionally for the first two or three hours, but never after it begins to ferment.—*E. C. Lyndon, Winooski, Wis.*

Sundry Notes on Cooking, etc.

[The following extracts from letters to the *American Agriculturist* are selected by a lady assistant in this department, in whose judgment we rely, but who wishes us to say that while each selection appears good, she could not positively recommend everything here given without a more thorough trial.—Eds.]

Tomato Soup a la Oysters.—To one quart of canned tomatoes, or others which have been boiled about 15 minutes, add 2 quarts water and boil 15 minutes more; then drop in carefully, a little at a time, enough pulverized saleratus or soda to neutralize the acidity, which you may know by its ceasing to foam—usually about an even teaspoonful to a quart. Then add one quart of rich milk, six or eight crackers pounded finely; butter, salt, and pepper as for oysters; let it boil up and serve immediately. It strongly reminds one of oysters, and is very nice for sick persons as well as highly palatable for well ones.—*Mrs. M. Ingalls, Muscatine, Iowa.*

Pies without Fruit.—Mix 1 teacupful each of sugar, molasses, and water, $\frac{1}{2}$ teacupful of vinegar, and butter the size of a walnut; stew together 10 minutes, and spice to your taste. Then thicken with crumbs of bread [or better of crackers. Ed.], adding a few raisins if convenient or desirable, and bake in crusts.—*Jersey Farmer's Daughter.*

Rice Pudding without Eggs.—Cook one cup of rice thoroughly; add 1 cup of sugar, 3 cups milk, 1 tablespoonful butter, with spice and fruit to the taste.—*Mrs. P. E. Mulher, Victoria, Ill.*

Cooking Beef Steak.—Prepare the steak by pounding and otherwise, as for broiling. Have ready a pan *quite hot*; grease it as for bread, lay in the steak, turn frequently to prevent its adhering to the pan until the juice is extracted. When cooked through, turn the gravy upon a platter in which has been previously put about *half* the usual quantity of butter, with a *little* water. Slightly brown the steaks on both sides, then take up, and boil up a little water in the pan to secure any remaining juices; season as desired. By this method a much larger and richer amount of gravy is obtained, with less butter, than by the usual process.—*Mrs. C. M. H., Hanksbury, Canada.*

Good Home-made Yeast.—The following is in general use in the community where I reside: Boil a handful of hops in two quarts of water about 20 minutes. Pare and grate three good sized potatoes. Add 2 tablespoonfuls of wheat flour, 1 do. of sugar, 1 do. of salt; strain the hop water hot into this mixture, stirring well together; then boil about 5 minutes. Set away to cool to milk warmth, then add a cup of yeast, and keep in a warm place until light and foaming. Put away in a jar or close vessel in a cool place. It will keep some weeks.—*Mrs. L. B. Bradford, Montague, Mass.*

Candy from Sorghum Syrup.—Boil the syrup 20 to 40 minutes according to its previous thickness, until a little dropped into water will harden to brittleness in a minute or two. Then pour it into large dinner plates previously well buttered, leaving it not more than $\frac{1}{4}$ inch thick.

When cool enough, work and stretch it well with two fingers of each hand, smeared with butter to prevent its adhering. It can thus be made beautifully light and porous. When worked enough, stretch it out and cut it into sticks; it thus makes a very nice candy.—*F. C. Smith, Fairfield Co., Conn.*

Fly Destroyer.—C. P. of Fallston, Mo., writes that the following simple preparation, originating with her servant, has proved very effective: "Beat up the yolk of an egg with a tablespoonful each of molasses and finely ground black pepper; set about in shallow plates every two or three days for a week, and the flies be rapidly destroyed, and may be swept up in handfuls."

For Red Ants.—John H. Ferguson, of Rensselaer Co., N. Y., writes, that he has thoroughly cleared an old house of this pest twice, within the past 15 years, thus: "Grease a plate with hog's lard, and set it where the ants are troublesome; they will desert the sugar bowl for the lard. Place a few sticks around the plate for the ants to climb up on. Occasionally turn the plate bottom up over a fire, where there is no smoke, and the ants will drop off into the fire. Reset the plate, and in a few repetitions you will catch all the ants. They trouble nothing else while lard is accessible."

BOYS & GIRLS' COLUMNS.

Amusing Toy for the Little Ones.

Cut out from wood the figure of a dancer, somewhat like the one here given. It will be easier to form the head, body, and arms separately, and afterward glue them together. The legs should be quite thin, and hung so as to play loosely upon a wire running across a hollow place cut in the bottom of the body, as shown by the dotted lines in the figure. Keep them separated by a small slip of wood placed between them on the wire. When this is done, take four strong bristles, each about an inch long, and insert them as pins for the image to stand upon. They should be long enough to just keep the feet of the image from touching the floor, or whatever it is set upon.

It will improve the image to paint it in bright colors. Place it upon a tea-tray or tin-pan, letting it stand upon the bristles, then whistle or sing a tune, and at the same time drum with the fingers upon the pan, and the image will dance about in a way to give great amusement to the little folks.

Puzzle for the Eye.

Persons, by practice, may become very expert in judging of distances, and measuring by the eye. It will often afford considerable amusement to test this ability in a person by asking him to mark on the side of a room the height of a man's silk (stove-pipe) hat, measuring from the floor. Very few will come within an inch of it. As another pleasant experiment of the same kind, request some one to draw the size of a ten-cent coin—most per-

sons will give very full measure. The above illustration will also furnish a somewhat similar test. Look at the parts A and B, and judge for yourself how much longer the lower one is than the upper one. Then to prove how near you have come, cut out two pieces of paper of the same size and shape as the figures, and lay one upon the other. The difference in length, when found, will surprise those who have never tried the experiment.

The Game of Checkers or Draughts.

POSITION NO. 6.—White to play and win. Black.

White.

GAME NO. 6.—DYKE OPENING. (*)

Table showing game moves for Black and White, including numbers and board positions.

(*) Is so called from its fancied resemblance to a "Dyke." (Scotch—A fence or stone-wall) for, at various stages of the game the pieces form straight lines.

(a) 30 to 25, draws, or 22 to 18, Black wins. (b) 9 to 14, draws. (c) 23 to 18, or 28 to 24, Black wins. (d) 7 to 11 White wins. (e) 9 to 14, or 6 in 10 draws.

How to Play Base Ball.

The game of Base Ball may now be fairly called a national one in this country, just as Cricket is the great outdoor game in England, and Curling in Scotland.

boys in this vigorous pastime, which is admirably calculated to promote health while affording exciting, but innocent amusement.

If possible, select for the ground a perfectly level, open field, 500 to 600 feet square, which should be covered with close, smooth turf.

each side, is first marked out. At the corners of this square are the "Bases." H.B., home base, 1 B., first base; 2 B., 2nd base; and 3 B., 3d base, each of these occupies the space of a square foot; on well regulated grounds, the 1st, 2nd, and 3d bases, are marked by stout canvas bags, painted white, and filled with sand or sawdust.

The pitcher's position, P, is marked by two lines parallel to the striker's line, each 12 feet long, the first one 45 feet, the other 45 feet, from the center of the home base. These lines may all be permanently fixed by a plank set edgewise into the ground.

A full game is played by nine on a side, the leader on each side being styled Captain. A larger or smaller number, however, can conduct the game. In playing, one side takes the bat, the other the field; the first choice is decided by lot between the Captains.

A Little Boy's Experience.

April 3d.—This is my birthday. I am twelve years old. Mother says I ought to keep a diary. I asked father about it, and he smiled and said it would be a fine thing for a week.

I wonder what father will give me for a birthday present. Last year he gave me my dog Jumper. He's a real wide-awake, lively fellow, and knows more than any other animal on the farm.

April 4th.—I was too tired and sleepy to write last night. Jumper had the woodchuck in the wall. I took away a few stones, Jumper dove into the hole, gave a bite and a few shakes, and that was the end of Mr. Woodchuck.

I helped father plow the oat field yesterday. I drove the oxen. It's not very hard work, but there's so much of it to do in a day, that it makes me tired.

and after breakfast I must go and practice gee-haw-graphy with the oxen all day again I suppose.

An Ingenious Monkey.

An English gentleman relates the following trick of a pet monkey, that was kept chained in his yard. About three feet beyond his reach, stood a trough in which a pig was fed.

Answers to Problems and Puzzles.

The following are answers to the puzzles, etc., in the May number, page 191:

No. 206. Enigma.—Pen-knife. One sends us the answer, "buttermilk;" another, "bread-pan," both of which meet the conditions of the question.

The following have sent correct answers up to May 7: Alanson Hey, W. Lewis, A. Jackson, Edwin Andrews, Ruthanna Stratton, John F. Stratton, Luman F. Parmenter, Amanda E. Still, Madison E. Gustin, J. K. Hallock, A. McDonald, Henry Krell, Daniel Bolton, James E. Eshleman, R. Ellis, Wilson J. Spink, Chas. H. Deartrich, Jennie Lucas, Daniel Frohman, Rudolph Haffax, Doc, Henry E. Mann, Sophie E. Mann, Louie Lorillard, L. J. Barton, C. L. Clark, Eden Relder, "Diamond," Ellen A. Carpenter, Emily J. Gregg, M. M. Rand, Thomas H. McMullin.

New Puzzles to be Answered.

No. 210. Illustrated Rebus.—Good advice for the young.

No. 211. Illustrated French Rebus.—For students.

No. 212. Illustrated Rebus.—Much in little space.

No. 213. Mathematical Problem.—A squirrel carried away nine ears of corn from a box, taking three ears away each time.

No. 214. Enigma.—I am composed of 21 letters. My 4, 1, 6, 10, 5, 16, 8, 17 is cultivated and flourishes in China.

The Pet Lamb.

"Mary had a little lamb," thousands of girls and boys will say or think to themselves, as they look upon this pleasant picture. That simple little story in verse, which we used to read many years ago, is the delight of children now, and will be as long as the English language lasts. Why? Because there is *love* in it. A lamb is a very lovable pet. Its innocence and playfulness make it a favorite with all. One of these creatures was many years ago brought up at the homestead of the writer. It was found motherless and chilled in the field, one spring morning. The ewe had refused to own it, and it was then adopted by two little girls who soon nursed it into a strong, and frolicsome playmate. A young puppy and a kitten were being cared for at the same time, and the three used to take their meals from the same dish, and afterward made great sport by their playful pranks—scampering up and down the yard, barking, bleating, mewling, butting, scratching and biting, each after its own fashion. The final history of the three was somewhat sad. "Dick," the lamb, grew large and saucy. Several times he gave a younger brother of the girls a pretty severe drubbing, butting him without mercy; and he was finally turned into mutton by a butcher who bought and carried him away. Kitty died a victim to experiments with some drug, made by a boy in the family. "Tip," the dog, grew to be a most useful farm assistant. He would drive away or bring home the cows as well as a boy could do, except letting down the bars; but no stray cattle or swine would he allow to trespass on the premises. He was, however, an inveterate fighter, and would attack any dog, no matter how large, that came near him. One day he "caught a Tartar." He challenged a much stronger animal than himself, and in the battle which followed, was so badly injured, that he was killed by his owner to put him out of misery. Thus, one of the pets perished by misfortune, the other two suffered the penalty of bad habits, which had grown out of their youthful sports.

Scene in a Mock Auction Shop.

Our artist heard the old cry of "Going! going! gone!" while passing a store on Broadway, the other day, and stepped in to look on. Having his eyes well trained by long and careful use, he soon saw that it was a mock auction shop. The auctioneer was a sharp looking man with a brazen voice, and a brassy face, selling a gold (brass) watch. Nobody appeared to be buying any thing. One man was pretending to examine a watch, but he was only a "stool pigeon," that is, one who makes believe purchase, in order to lead others into being swindled. Another of the gang was disputing with a not very respectable looking young woman. However, the auctioneer did not seem at all discouraged for want of customers. He talked and hammered away as though doing a most lively trade. On looking a little more closely, our artist discovered something more. He saw two pickpockets at work, one of them busy at the pocket of a man who stood looking at a large bill which said, "Beware of pickpockets," and the other standing ready to take from his companion's hand what he might succeed in stealing. On looking around he also saw a policeman

with club in hand, standing close by, watching the whole proceeding, and ready to pounce on the two rascals. This was one secret of the mock auctioneers' trade. He was trying to keep a crowd of people together, while his assistants picked their pockets, if he himself could not succeed in doing it by selling them sham watches and jew-

THE PET LAMB.

elry. Below is a sketch of the scene. The pickpockets and the policeman are shown, although it may take some careful looking to see them. They are no more concealed, however, than pickpockets and thief catchers usually are, and we hope that after studying out the picture, some will remember it when they come to New York, and keep clear of mock auction shops, and "Beware of pickpockets," in a crowd. The old proverb, "Birds of a feather

Why is there Uniformity?

In Barum's Museum, in this city, among other curiosities, is a bull having three perfect horns; the additional one grows straight out from the center of its forehead. In all other respects the bull resembles other ordinary animals of its kind. Cases are known where horns have grown on the heads of men and women. One such was recently described in the Medical and Surgical Reporter, published in New York. Many of our readers may have seen persons having six fingers on each hand, and six toes on each foot; there are many such in the world. The Bible speaks of a race of giants in Ancient Palestine, who had this peculiarity. Other strange "freaks of Nature," as they are called, occasionally appear, such as lambs with an extra leg, or calves with one head too many. Among vegetable growths there are occurrences not less singular. Not very many years since a beech tree was observed whose branches all drooped like those of a weeping willow. Clions from this were grafted into other trees, and by this means the weeping beech was propagated, so that now it is for sale at most large nurseries. Similar unaccountable "sports" are found among flowers and vegetables of almost every variety; the four-leaved clover will occur to many as a common example. Now to us, the wonder is not that such things occur, but that they do not take place more frequently. Why is it that among the thousand million and more human beings on the globe, the innumerable animals, and the countless vegetables, so few are found which do not follow the same general formation. This is the more worthy of thought when we notice that no two individuals of any species are exactly alike in all particulars. Each one has some peculiar mark by which it may be distinguished from every other one. Thus, no two faces have precisely the same shape, color, and expression, yet in every one we expect to find two eyes, a nose, a mouth, and all in the same relative position. So with animals. The

different sheep in a large flock may each be recognized by an experienced shepherd, as each has its own peculiarities, but not one in ten thousand shows any departure from the regular pattern. The same thing is true in all living things. This is the more wonderful when we consider the great number of processes going on in each individual body, by which the different parts of the frame are built up. One part of the blood is to furnish bones, another flesh, other portions supply nerves, skin, hair, nails, etc., etc. How few apparent mistakes are made in the complicated work. What confusion would result if it were otherwise. Who could tell that what should be a finger nail might not soon grow from the end of his nose; or that a tuft of hair should not spring from the center of his eye, or that the bony substance might not be deposited on the outside, and soon envelop him in a shell like a lobster! What if there were uncertainty as to how apples or peaches would grow, one year showing them on the branches, the next clinging to the roots of the tree, like potatoes? These few illustrations from the thousands that might be found in every department of life, show as plainly as any evidence can, that an intelligent controlling power directs the course of all matter, causing it to conform to a general plan which He has laid out, and which He in mercy as well as wisdom designs shall be observed by all His creation, thus preserving harmony throughout all nature.

SCENE IN A MOCK AUCTION SHOP.—A PUZZLE PICTURE.

flock together" will be found especially true in this case. "Cheap jewelry," gift enterprises, mock auctions and lotteries, pretended "Bankrupt Stocks," etc., are generally conducted by those whose company it is safest to avoid.

The Best Children's Paper in America.

Forney's Philadelphia Daily Press says of it: "THE LITTLE CORPORAL is destined to become the great children's paper of America."

THE LITTLE CORPORAL is the most interesting and instructive monthly in the Union.—Louisville Democrat.

THE LITTLE CORPORAL is universally admitted to be the best juvenile paper now in existence.—Dubuque Daily Times.

It is the cleverest thing of its kind yet realized in America.—Roxbury (Mass.) Journal.

After a careful examination, we can cheerfully say of THE LITTLE CORPORAL, that it deserves all the praise that has been lavished upon it by the press everywhere.—Philadelphia Episcopal Recorder.

The Little Corporal for one year will do your children more good than a Quarter's Schooling.

We favor the reader with a cut of a pure Italian Queen Bee, from a breeder of Italian Bees, who assures us was taken from a Queen imported from Italy, for price of Queens Address K. P. KIDDER, The Apiculturist, Burlington, Vt.

N.B.—All persons are forbidden under the penalty of the Law to copy this cut, as it is copyrighted.

50 PER-CENT SAVED BY USING

B. T. BABBITT'S
 LABOR-SAVING SOAP.

This Soap is made from clean and pure materials, contains no adulteration of any kind, will not injure the most delicate fabric, and is especially adapted for woollens, which will not shrink after being washed with this Soap. It may be used in hard or salt water. It will remove paint, grease, tar and stains of all kinds. One pound warranted equal to two pounds of ordinary family soap. Directions sent with each bar for making three gallons handsome soft soap from one pound of this Soap. Each bar is wrapped in a circular containing full directions for use, printed in English and German. Ask your grocer for "B. T. Babbitt's Soap," and take no other.

B. T. BABBITT,
 Nos. 64, 65, 66, 67, 68, 69, 70, 72, and 74 Washington-st., N. Y.

LOVE, COURTSHIP, and MARRIED LIFE.—Whom to Marry, When to Marry, and Whom not to Marry. Likes and Dislikes; Adaptation; Right Age to Marry; Marrying Cousins; Jealousy, its Cause and Cure; Useful Hints to both Married and Single; with Physiology, Ethnology, Phrenology, and Psychology, in the PHRENOLOGICAL JOURNAL for 1866. REDUCTION IN PRICE

OF THE

AMERICAN WATCHES,

Made at WALTHAM, MASS.

In consequence of the recent great decline in gold and silver and all the materials used in the manufacture of our goods, and in anticipation of a still further decline, we have reduced our prices to as low a point as they can be placed

With Gold at Par,

so that no one need hesitate to buy a watch now from the expectation that it will be cheaper at some future time. The test of ten years and the manufacture and sale of

More than 200,000 Watches,

have given our productions the very highest rank among timekeepers. Commencing with the determination to make only thoroughly excellent watches, our business has steadily increased as the public became acquainted with their value, until for months together, we have been unable to supply the demand. We have repeatedly enlarged our factory buildings until they now cover over three acres of ground, and give accommodation to more than eight hundred workmen.

We are fully justified in stating that we now make MORE THAN ONE-HALF OF ALL THE WATCHES SOLD IN THE UNITED STATES. The different grades are distinguished by the following trade marks engraved on the plate;

1. "American Watch Co.," Waltham, Mass.
2. "Appleton, Tracy & Co.," Waltham, Mass.
3. "P. S. Bartlett," Waltham, Mass.
4. "Wm. Ellery."
5. OUR LADIES' WATCH of first quality is named "Appleton, Tracy & Co.," Waltham, Mass.
6. Our next quality of Ladies' Watch is named "P. S. Bartlett," Waltham, Mass. These watches are furnished in a great variety of sizes and styles of cases.

The American Watch Co., of Waltham, Mass., authorize us to state that without distinction of trade marks or price,

ALL THE PRODUCTS OF THEIR FACTORY ARE FULLY WARRANTED

to be the best time keepers of their class ever made in this or any other country. Buyers should remember that unlike the guarantee of a foreign maker who can never be reached, this warranty is good at all times against the Company or their agents, and that if after the most thorough trial, any watch should prove defective in any particular, it may always be exchanged for another. As the American Watches made at Waltham, are for sale by dealers generally throughout the country, we do not solicit orders for single watches.

CAUTION.—The public are cautioned to buy only of respectable dealers. All persons selling counterfeits will be prosecuted.

ROBBINS & APPLETON,

AGENTS FOR THE AMERICAN WATCH COMPANY,
 182 BROADWAY, NEW-YORK.

THE PIONEER ESTABLISHMENT.—In 1846 the manufacture of Melodeons, Organs, &c., was commenced in the city of Buffalo. At that time, but few reed instruments, comparatively, were manufactured in the United States or Europe. And these were of so imperfect and clumsy construction, that they found but little favor with the music loving public. Since the commencement of the manufacture of Prince & Co.'s instruments over 40,000 have been put in use, including from the Singing Teachers' Melodeon, up to the splendid Automatic Organ for the Parlor, or the magnificent Organ Melodeon for the Church. Over 39 different styles are made by Prince & Co., varying in price from fifty-two dollars to one thousand dollars each. A new illustrated Catalogue has just been issued, which is mailed free of expense to all addressing Prince & Co., Buffalo, N. Y.

50 MAKE YOUR OWN SOAP PER-CENT SAVED BY

USING B. T. BABBITT'S
 Pure Concentrated Potash

OR
 READY SOAP MAKER.

Warranted double the strength of common Potash, and superior to any other saponifier or ley in the market. Put up in cans of 1 pound, 2 pounds, 3 pounds, 6 pounds, and 12 pounds, with full directions in English and German for making Hard and Soft Soap. One pound will make 15 gallons of soft soap. No lime is required. Consumers will find this the cheapest Potash in market.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for a month, ending May 15, 1866, and the exports of Breadstuffs from this port thus far, since January 1:

TRANSACTIONS AT THE NEW-YORK MARKETS. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. SALES. Flour, Wheat, Corn, Rye, Barley, Oats. Comparison with same period at this time last year. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. SALES. Flour, Wheat, Corn, Rye, Barley, Oats. Exports from New-York, January 1 to May 14. 1866. 1865.

CURRENT WHOLESALE PRICES.

PRICE OF GOLD. Flour—Super to Extra State, Extra Western, Extra Genesee, Superfine Western, RYE FLOUR, CORN MEAL, WHEAT—All kinds of White, All kinds of Red and Amber, CORN—Yellow, Mixed, OATS—Western, State, RYE, BARLEY, HAY—Bale 100 lb., Loose, STRAW, 100 lb., COTTON—Middlings, HOPS—Crop of 1865, FEATHERS—Live Geese, SEED—Clover, Timothy, Flax, SUGAR—Brown, MOLASSES—Cuba, Coffee—Rio, Tobacco, Kentucky, Seed Leaf, Wool—Domestic Fleece, Domestic, pulled, California, unwashed, FALLOW, OIL—Coke, Pork—Mess, Prime, Beef—Plain mess, LARD, BUTTER—Western, State, CHEESE, BEANS, PEAS—Canada, EGGS—Fresh, FOWLTY—Fowls, Turkeys, POTATOES—Mercers, Peach Blows, Buckeyes—New, APPLES—Barnet.

Gold has risen to 130 1/2, influenced by the less favorable financial and commercial advices from Europe. The breadstuff trade has been quite animated, during the past month. Reports of the deficiency of sound wheat of last year's growth, and exaggerated accounts of the poor appearance and prospects of the growing crop of winter grain, have led to heavy purchases of flour and wheat in all the leading markets of the country at rapidly advancing prices. A very considerable portion of the business of the month was on speculative account. The regular trade inquiry, however, has been good, and has tended to strengthen confidence in the upward course of the market. Toward the close, the extreme buoyancy was not maintained, as many of the speculative holders, eager to realize, were disposed to make some concessions to buyers. The latter are less inclined to operate, as they anticipate an early reaction, which will enable them to buy on more favorable terms. The current receipts are very light, and stocks here are diminishing gradually. The resumption of inland navigation has not thus far added to the available supplies. Corn has been freely offered at easier rates, which has led to a revival of the export demand, and the market closes more firmly. There has been a livelier business in Rye, Barley, and Oats at, however, irregular prices. Provisions have been more sought after, mainly on speculative account, and Hog products have advanced. Beef has been also quoted firmer. Butter and Cheese have declined, under more liberal arrivals. Cotton fell off materially early in the month, under very unfavorable advices from England, but closes firmly, with a fair inquiry. The stock now here is about 160,000 bales. Wool has been in more demand, and though prices have not advanced, the market closes in favor of sellers. There is now some disposition to purchase on speculation, in anticipation of a rise in prices. Hay, Straw, and Hops, have been active and steady. Seeds in less request, closing irregularly. Tobacco dull, but without material change in price.

New York Live Stock Markets.—Beef Cattle.—The supply, for a month past, has been

good, and on May 7th very large, reaching nearly 7000. With a full demand, owing to the cold weather which has increased the consumption of meat, and prevented the usual catch of shad, prices have been well maintained. The sales to-day are 16c@17c per lb. estimated dressed weight for really good, first quality of cattle; a few extras 17 1/2c@18c; medium to common 15c@14c; poor to worst 13 1/2c@12 1/2c. MILK Cows have increased in value a little recently, owing to light receipts and increased demand. Medium to good \$55@65; good to first quality \$70@80; extras \$85@90; an occasional fancy animal at \$95@100 and upward; inferior \$50@60, with a few bad ones at \$35@40. VEAL Calves, two and three weeks ago, were over-abundant and prices much depressed. Last week and to-day, with somewhat lighter receipts, prices are firmer. Very good and extra calves sell at 9c@10 1/2c per lb. live weight; good to common 8 1/2c@7 1/2c; poor 7c@6c. SHEEP and Lambs—Receipts fair, and prices very changeable from week to week. Last week they were very low; to-day good sheared sheep sell at 7 1/2c@8 1/2c per lb. live weight; medium and common 7c@6c. Spring lambs are arriving freely and sell at \$4@6 each, or 12c@16c per lb. LIVE Hogs.—Receipts have been unusually large for the season, and prices variable. To-day Western corn-fed sell at 10 1/2c@10 3/4c per lb. live weight.

GENERAL PREMIUMS.

ONE MONTH

yet remains for all who want any of the general premiums in the table below, to secure them. During May several entirely new lists have been made up, and many lists under way have been filled. A thousand others can do the same this month. We have many partially completed lists on our Premium Record, waiting for a few more names only. With the six numbers of this volume to show what this paper is, it will not be difficult to secure subscribers. We have not room to describe the premiums which are all very good, but will send a full Descriptive Sheet free to all desiring it. As it is too late to send grape vines now, we will send premiums 5 and 6 next autumn, if they are secured this month. We omit 2, 3, 4, and 8, as it is too late to use them.

Table of Premiums and Terms, For Volume 25. Open to all—No Competition.

Table with 4 columns: Names of Premium Articles, Price of Premiums at \$100 each, Names at \$100 each, Names at \$100 each. Includes items like Good Books, Grape Vines, Concord Grape Vines, Downing's Landscape Gardening, American Encyclopedia, Worcester's Great Illustrated Dictionary, Any Two back Volumes, Any Three do, Any Four do, Any Five do, Any Six do, Any Seven do, Any Eight do, Vols. XVI to XXIV, The County Election, Steel Plate Cold, Halt in the Woods, Morton's Best No. 5 Gold Pen, Silver Case, Best Family Clothes-Wringer, Doty's Washing Machine, Tea Set (Best Silver Plated), Sewing Machine (Grover & Baker), Sewing Machine (Florence), Sewing Machine (Wheeler & Wilson), Sewing Machine (Wilcox & Gibbs), Sewing Machine (Ellis Howe), Melodeon (Best Four Octave), Melodeon (Best Five Octave), Piano, 7 Octave (Steinway & Sons), Barometer (Woodruff's Mercurial), Barometer (Woodruff's Mercurial), The Aquarius, or Water Throver, Buckeye Mowing Machine No. 2, Allen's Patent Cylinder Plow.

No charge is made for packing or boxing any of the articles in this Premium List. The Premiums, 1, and 13 to 25, are DELIVERED to any part of the United States and Territories, free of all charges. The other articles cost the recipient only the freight after leaving the manufactory of each. Every article offered is warranted new and of the very best manufacture.

Premium 1.—Good Books.—Any person sending 25 or more subscribers, may select Books from the list on next page, to the amount of 10 cents for each name sent at \$1; or to the amount of 30 cents for each name sent at the (ten) club price of \$1.30 each: or to the amount of 60 cents for each name at \$1.50. This is only for clubs of 25 or more. The Books sent by mail or express, prepaid by us.

[Only for May and June, 1866.]

Special... Extra PREMIUMS FOR One Subscriber.

Everybody can get one of These.

One Hundred Thousand Subscribers was, until recently, our highest aim, but that point was easily secured some-time ago, and we are going so rapidly towards 150,000 that we have set that down as the figure for this Quarter-Century Volume. We intended to make it a superior volume, and the general testimony of our readers is, that this is being splendidly accomplished. The first six numbers contain 240 pages, instead of the standard 192, and the engravings are certainly large, beautiful and instructive, while so far they count up nearly 200, large and small. The character and style of many of these engravings is scarcely equaled by any of the Illustrated Journals in the Country. Well, why should not the cultivators of our country have a beautiful and tasteful journal, as well as a practical one.—We think our readers will agree that the reading matter has been valuable so far.—We mean to make the rest of the volume at least equally valuable. Do we say too much then, in asserting by advertisement or otherwise, that this 25th volume will be abundantly worth the small subscription price to every one who can be informed of its character and persuaded to subscribe for it?

But about the 150,000 subscribers. A single name more from each of a small part of our present readers will do the work. The paper will pay those induced to take it. Will the reader please send one of these names?

As an acknowledgement of any such favors, we propose to send one of the following books (whichever may be desired) to any one who will forward the name and pay of one subscriber for this volume. (This is only for names received between May 1st and June 30th—none before or after—and we can only send to those who specify which book is wanted for each name.) The books, one for each subscriber, will be delivered at our office, or sent free (post-paid) wherever desired. Of course two names will be acknowledged by any two books desired, three books for three names, and so on. These names can not count in the general premium list (on page 169). That list will also be continued to June 30.

- Premiums (Post-paid.) For all of 1866—\$1.50. A—The Rural Annual for 1866. For One Subscriber. B—The Rural Register for 1866. For One Subscriber. C—American Bird Fancier. For One Subscriber. D—American Rose Culturist. For One Subscriber. E—Bement's Rabbit Fancier. For One Subscriber. F—Dog and Gun (Hooper's). For One Subscriber. G—Fuller's Strawberry Culturist. For One Subscriber. H—Flax Culture, Complete. For One Subscriber. I—Hop Culture, Complete. For One Subscriber. K—Onion Culture, Complete. For One Subscriber. L—Our Farm of Four Acres. For One Subscriber. M—Richardson on the Dog. For One Subscriber. N—Tobacco Culture, Complete. For One Subscriber.

The above are all neatly bound in colored paper covers. The Rural Annual and Rural Register are wanted in every family. The eleven others are each wanted by a large class. The books on Flax, Hops, Onion, and Tobacco Culture, are the best works on these several subjects that ever have been produced, and are very valuable to every one growing the smallest quantity of any one of these crops. See further descriptions of the above books, in the list on pages 201, 202, 203. We have electrotype and stereotype plates of all these works, and can supply all copies called for.

Here then is an opportunity for everybody who desires one or more of these to get them without expense, by simply soliciting the subscription of a neighbor or acquaintance. The back numbers of this volume of the Agriculturist, of which new editions are printed as needed, will be sent to all subscribers, as soon as the names are received, and the premium books will be promptly sent to the address given for them.

BOOKS FOR FARMERS and OTHERS

[For sale at the Office of the Agriculturist, or they will be forwarded by mail, post-paid, on receipt of the price.]

THE YANKEE BLADE.

Work Table and Writing-Desk Companion. Recommended by N. Y. Tribune, Mne. Demorest, N. Y. Independent, American Agriculturist, and hundreds more.

IT COMBINES

- 1st.—A Patent Sewing Ripper which takes out a seam faster than a sewing machine can make it. 2nd.—Button-hole Cutter for any size wanted. 3rd.—Gathers Scratcher; just the thing for it. 4th.—Praser Cutter and Folder, always handy. 5th.—Eraser for removing blots, errors, etc. 6th.—Letter Opener for men of Business. 7th.—Nail Cleaner and Trimmer for everybody.

MONEY TO BE MADE.

I will give a Town Agency, except where there are over 10,000 inhabitants, to first person buying one gross of the Yankee Blade. Send price for sample, and Circular. Address W. A. FITCH, 151 Nassau-st., New York.

WHEELER & WILSON

SEWING MACHINES.

WOMAN'S GREATEST BOON.—We would advise a man to forego a Thresher and thresh wheat with a flail, rather than to see the wife wear her health, vigor and life away in the everlasting 'stitch, stitch, stitch,' when a Sewing Machine can be obtained. The WHEELER & WILSON is an invaluable aid in every household. We have had several different kinds on trial, and after a six year's service, the WHEELER & WILSON has taken the precedence as the best, where all kinds of sewing are to be done in a family.

The Charter Oak Life Insurance Co., of Hartford, Conn.

Every one should insure his Life.—See page 129, April 1866 issue, of the American Agriculturist. Insure this year in THE CHARTER OAK LIFE INSURANCE COMPANY.—See page 153, of the same Journal. The Charter Oak Life Insurance Company has no superiors among the Life Ins. Co.'s of this country.—Its Assets April 1st, 1866, are, \$1,770,167.63, being an increase of nearly \$200,000 in three months. Its business is increasing with unparalleled rapidity.—Its expenses are less than the average of Life Ins. Co.'s.—Its losses are less.—Its dividends are greater.—It pays annual dividends, commencing with the second premium.—It originated the system of annual dividends.—Its business is confined to the healthy and thoroughly settled portions of the country. For further information concerning the Company, see April No. of the American Agriculturist, page 153.

OFFICERS. JAS. C. WALKLEY, Prest. S. H. WHITE, Secretary. NOYES S. PALMER, Vice-Prest. S. J. BESTOR, Ass't Sec.

DOTY'S CLOTHES WASHER.

Important Improvements and New Arrangements. This valuable Washing Machine has lately been greatly improved by enlarging the size, and changing somewhat its form and construction. Two more Patents are applied for to cover the late improvements, and the price for the new Machine will in future be \$14. The Territory heretofore reserved by DOTY BROTHERS, will after June 1st, be managed by the undersigned, to whom all orders from any part of the United States, should be sent. Every one likes it, and canvassers make money and do good selling it. R. C. BROWNING, Gen'l Agent, 32 Courtland-st., New York.

"Has a decided value for all who are interested in the Art of Cookery, which means all who eat."—Commercial Advertiser.

EVERY HOUSEKEEPER

should read the series of papers on Cookery now appearing in

THE GALAXY,

THE NEW FORTNIGHTLY ILLUSTRATED MAGAZINE.

These articles are full of practical suggestions on this subject to which their author,

Professor PIERRE BLOT,

Editor of the Almanac Gastronomique, etc.,

has devoted many years of study, and in connection with which he has become so widely known by his

lectures in New York, Brooklyn, and Boston. Besides the articles of PROFESSOR BLOT, THE GALAXY contains

articles from RICHARD GRANT WHITE, JOHN

ESTEN COOKE, FRANCES POWER COBBE, ROSE TERRY, GEORGE ALFRED TOWNSEND, EDMUND C. STEDMAN,

THE AUTHOR OF "EMILY CHESTER," DR. W. H. IRELAND, GENERAL CLUSERET, EUGENE BENSON, J. K. MEDBURY, S. S. CONANT, WM. SWINTON, and many others

equally well known. THE GALAXY is also publishing serially, simultaneously with their appearance in

England, THE CLAVERINGS, BY ANTHONY TROLOPE, and ARCHIE LOVELL, BY MRS. EDWARDS.

The price of THE GALAXY is 25 cents a number; \$5 for the year of 24 numbers; \$3 for the half year of 12 numbers.

The yearly subscriber receives over 2,300 pages of matter, (about 600 pages more than is given by any other magazine in the country.) Illustrated by at least 25 full-page engravings

on tinted paper, and innumerable smaller illustrations inserted in the text.

Specimen copies sent to any address on receipt of 25 cents. Subscriptions are received for any length of time.

Address W. C. & F. P. CHURCH, Proprietors, 39 Park Row, New York.

Day's American Ready-Reckoner, containing Tables for rapid calculations of aggregate Values, Wages, Salaries, Board, Interest Money, etc., etc.

Also, Tables of Timber, Plank, Board and Lot Measurements, with full explanations how to measure them, either by the square foot (board measure), or cubic foot (timber measure). Also, how to Measure Wood by the Cord, with Tables applicable to Piles of Wood of any Shape, and showing in a simple manner how to ascertain the Contents in Cords of a

Pile of any shape. Also, Tables of Land Measurements, showing the Contents of a Piece of Land of almost any shape, from a quarter acre up to ten acres, and telling exactly how to Measure Land in any quantity by Chains and Links, or by Yards and Feet. Also, telling how to describe a piece of land in deeding it. Also, giving information as to acquiring and locating a Farm on the Public Lands of the United States. This Ready-Reckoner is composed of Original Tables which are positively correct, having been revised in the most careful manner. It is a book of 192 pages, and embraces more matter than 500 pages of any other Reckoner.

Price in boards with cloth back, 50 cents. Price in cloth, gilt back, 75 cents. Price in leather tucks (Pocketbook Style), \$1.00. Sent post-paid, on receipt of price, by O. A. ROORBACH, 122 Nassau-st., New York.

Agents Wanted TO SELL

Short-Hand Without a Master,

by which the nature of taking down Lectures, Sermons, Trials Speeches, &c., may be acquired in a few hours. FIFTY-SECOND EDITION, with a Supplement. Price 25 cents. Sent post-paid, on receipt of price, by O. A. ROORBACH, 122 Nassau-st., New York

SPEAR'S PATENT FRUIT-PRESERVING SOLUTION,

For the preservation of all kinds of **Fruits, Vegetables, Jellies, Wines, Cider, etc.,** without Sugar, and without expensive Sealing or Air-tight Jars.

One Bottle will preserve 128 Pounds of Fruit, or 48 Gallons of Wine or Cider, Price \$1.

Cheap, Healthful and Effectual.

This Solution, when properly used, effectually prevents fermentation or decay of Fruits, and, by the most simple and inexpensive process, every variety may be kept in a fresh and perfectly wholesome condition the year round. It is no new and uncertain experiment, but has been in practical use for the past eight years, yet has been, for the most part, kept from the public for the purpose of ascertaining the result of a series of experiments, all of which have proved the validity of all that is now confidently claimed for it.

Fruits preserved by this Solution are as good as the best "canned" fruits, while the use of the Solution avoids the trouble of sealing, costly jars or cans, keeping from the air and light, frequent examinations, and the many other troubles and annoyances well known to every housewife.

Fresh native fruits the year round have become almost a household necessity, both on account of their healthfulness and as a luxury; and by the use of this Solution this great luxury is within the reach of every family, rich or poor. In the land, as all kinds of fruits may be preserved during pleasure at less than one-half the expense of any other method.

The Solution is perfectly free from objection on the score of health. Professor Buche, under date "U. S. Naval Laboratory, New York, September 14, 1874," says: "By direction of the Chief of the Bureau of Medicine and Surgery, I have examined your Preserving Solution, and meats and fruits preserved by it. I have a high opinion of its value, and believe it can be used in the preservation of those articles in a fresh state for the Army and Navy very advantageously. The Solution is perfectly free from objection on the score of healthfulness."

[A. A. HAYES, M. D., State Assayer of Massachusetts, says.]

I have been made acquainted with the principle adopted by Mr. Lewis H. Spear in preserving fruit, so as to prevent change of color and subsequent fermentation, and have made some observations in connection with his process. Analysis proves that nothing is added to the fruit which is objectionable in articles of food or decidedly foreign in origin. My trials to induce fermentation in the prepared fruit failed, and I am confident that fruit prepared as he directs will long resist fermentative changes.

[THEODORE HOLT, a Practical Fruit-grower and Preserver, says.]

Mr. L. H. SPEAR—Dear Sir: During the past season I have made numerous and severe tests of your Fruit-Preserving Solution, and have applied, pears, peaches, plums, quinces and grapes, kept in jars in a hot, damp room, without sealing and only loosely corked, from five to eight months, which have never exhibited the slightest indication of mold, sour or fermentation, and are called by those who try them equal to any they ever saw.

Tomatoes preserved by your process proved entirely free from the injured taste of canned fruit, and could hardly be detected from fresh fruit.

Although by your process keeping from air is not indispensable, yet it is advisable also to seal and keep cool when practicable.

While your Solution is evidently a most powerful antiseptic, knowing well its composition, I believe it is in no respect injurious—in fact is as harmless as salt, and must be a valuable aid to those who desire the healthful luxury of the delicious fruits of summer at all seasons of the year.

Yours, etc., THEODORE HOLT,
Fourth Avenue and Seventy-ninth Street,
New York, March 10, 1866.

Other Certificates from distinguished Chemists, confirming the above, may be seen at the Office of LEWIS P. WORTHALL, the General Agent, No. 91 Hudson-street, New York, to whom all communications should be addressed.

For Sale by Druggists and Storekeepers everywhere.

Squire's Patent

The only Glass Jar for
This Jar has secured
The Perforated
Elastic Rubber
Feet or Pedestals

Fruit Jar.
EFFECTIVE JAR MADE
out the aid of Sugar,
preserving vegetables,
to it by Letters Patent
Glass Cover.
Fastenings,
on bottom of Jar.

A combination of advantages that renders it emphatically the most desirable jar for family use; for by these the fruit can be cooked in the jar; the jar sealed while cold; completely filled to the total exclusion of all air—is in no danger of breaking from fermentation, or from heating or cooling in use, and can be opened with scarcely an effort.

Directions for preserving fruit and working, accompany each jar.
Dealers will do well to see this before ordering—as it is the newest and best jar out.
Send for a Circular.

MENDENHALL'S IMPROVED SELF-ACTING HAND-LOOM.

The MENDENHALL IMPROVED LOOM is the only SELF-ACTING HAND-LOOM that has stood the test of years of practical use, and has never failed to give entire satisfaction.

It weaves goods on Woolen Warps equally as well as Goods on Cotton Warps, and possesses superior advantages over all other Looms ever invented, is more simple in its construction and operation, more durable, more reliable, and will weave a greater variety of goods with less Machinery, and with less Power than any other Loom. Every thing is performed by turning a crank. A child ten years old can operate it, and from fifteen to forty yards can be woven on it in a day.

FARMERS can weave all their goods for home wear, on the Improved Loom.

Every LOOM is Warranted to perform as represented.

For Descriptive Circulars, List of Prices, and samples of Weaving done on the Loom, address (with stamp)

The Lamb Family Knitting Machine.

The Lamb Knitting Machine Company, Springfield, Mass., hold the exclusive right to manufacture, sell and use this Machine in the following States: New York, (all East of the Counties of Cayuga, Seneca, Schuyler and Chemung.) Maine, New Hampshire, Vermont, Rhode Island, Connecticut, New Jersey, Pennsylvania, Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia and Alabama.

The Machine manufactured by this Company received the highest premium, A GOLD MEDAL, at the Fair of the American Institute, in New York, and at the Exhibition of the Mass. Mechanic's Charitable Association, Boston. It has also taken the highest premium at all the various State and County Fairs where it has been exhibited, eclipsing all others.

It is really the only Family Knitting Machine invented, as no other has a range of work that entitles it to be called a Family Machine.

For Stockings, as it knits the heel and narrows off the toe, making any size required, it is the greatest labor-saving Machine ever brought before the public, being in this respect far in advance of its great rival the Sewing Machine.

It knits any and everything in the way of Fancy and Staple worsted articles that the ingenuity and taste of the operator can devise. Every Machine warranted perfect.

For further particulars, see Agriculturist for May, or enclose stamp for Circular, to THE SILVER'S PATENT BROOM CO., 119 Nassau-st., New York.

Pure Flour of Unburned Bone,

Manufactured only by the Boston Milling and Manufacturing Co., C. H. GARDNER, Agent of the Co., 16 Courtlandt-street, New York.

BRIGGS & BRO., Rochester, N. Y., Agents for that part of N. Y., west of Hudson River, the Canadas, and the States West of Ohio and Lake Erie.

R. H. STAIR & CO., Cleveland, Ohio, Agents for Northern Ohio, Erie Co., and the Oil Territory, Pa.

A. F. DEVEBEUX & CO., Boston, Ag'ts for New England. JOHN S. REESE & CO., Baltimore, Agents for the Southern States.

Orders from the above Territory should be sent accordingly, and from all other Territory, to C. H. GARDNER, 16 Courtlandt-street, New York.

Packages for \$1, \$2 and \$3, may be sent by Express. Larger quantities shipped by Freight line.

It will be shipped from the Mills in N. Y., or Boston, direct to customers when expense in freight can be saved thereby.

Pure Flour of Unburned Bone is pronounced by the best authority to be the cheapest, best, and most reliable manure for all agricultural purposes. Every package will be marked with the Trade Mark of the Co., (none genuine without it), and is guaranteed to be made from pure unburned bones, and free from adulteration or admixture, except five per cent. of salt added, only to prevent decomposition. In order to remove any prejudice or doubts that may exist or arise hereafter as regards the responsibility of the Co., and their Agents, or as to the purity of their Flour of Bone, we offer the following extracts from the New England Farmer, of May 12th, 1866.

"This Co. is a responsible corporation, composed of some of the best known and most highly respected merchants and citizens of standing in our city." Messrs. John A. Blanchard, Benjamin P. Cheney, Bradley N. Cummings, Joseph Jasigi, Horatio R. Storer, Jacob J. Storer, and James D. Whelpley; are the officers of this corporation. None could inquire in our community about either or all of these gentlemen, without receiving the most satisfactory evidence of their responsibility in every respect. They own the only machinery known in the world which will regularly, constantly, and unfailingly pulverize bone to a fine state of comminution, and the sole right to the Trade Mark of 'Flour of Bone.' We feel confident in saying that it is not adulterated, and will not be.

Parties can buy coarse Bone cheaper than Flour of Bone, but with the guarantee of equal purity, such as is offered, the Flour of Bone is the cheapest at its present price." [New England Farmer.]

"Benj. H. Stair & Co., Dealers in seeds, grains, fruits, &c., in the City of Cleveland, are honorable, reliable, and every way responsible, in all their business transactions. Mr. Stair is a long time resident of Cleveland, and is well known to all our citizens as a gentleman of good reputation, having been for many years in the business he now follows, with credit to himself, and much to the benefit of the people of this region. We are glad to learn that this House will furnish the Pure Flour of Bone, of the Boston Milling and Manufacturing Co.—S. D. HARRIS, Ag't Ed. Ohio Farmer."

"Having known the firm of Messrs. Briggs & Brothers, for the past twenty years, I consider the Flour of the Flour of Unburned Bones by them, a sufficient and substantial guarantee of its purity." F. W. COLLINS, Rochester, N. Y., May 10, 1866.

Pamphlets containing directions for use, Analysis, Testimonials, &c., sent free to all applicants.

ENCUMBERED HOMESTEADS.

Few Homes are free from encumbrance by mortgage or otherwise, and in very many cases on the decease of the husband and father, the wife and children are rudely forced from their long-cherished homes. Could that husband and father look back, would he not admonish husband's and father's, one and all, to guard against a similar calamity, to their own families by Life Insurance.

JUDD, Gen'l Agents, Active and efficient Agents wanted, apply as above.

THE EMPIRE SHINGLE MACHINE

IS acknowledged to be, by all odds, the best Shingle Machine in America. With only ONE HORSE POWER 3000 ELEGANT SHINGLES per hour are easily made. The machine is built entirely of iron, very compact and easily transported. It works VERTICAL and BOX STEEP, and cuts out the same number of bolts of timber, one-third more Shingles are made than can be done by the Sawing Machines. All the saw-dust is saved by the Empire and goes into the Shingles. ABRAHAM REQUA, Gen'l Agent, 141 Broadway, New York

BRICKS.

The NATIONAL BRICK MACHINE is a clay tempering machine, and with only TWO HORSES MAKES 30,000 GOOD BRICKS PER DAY.

If the machine does not do this, it will be TAKEN BACK AND THE MONEY RETURNED. For Rights and Machines Address ABRAHAM REQUA, General Agent, 141 Broadway, N. Y.

Price \$1.50, Sent by Mail, Post-paid.

NEW-YORK:

ORANGE JUDD & COMPANY,

41 PARK ROW.

GRAPE VINES. PARSONS & CO.,

offer for the Fall Trade, **600,000** Grapes of all the best varieties, including **Delaware, Iona, Israella, Concord, Hartford Prolific, Diana, Creveling, Adirondac,** and many other fine sorts.

Among these is the **IVES SEEDLING**, a grape which is now being planted about Cincinnati, on a very large scale. It is said neither to rot nor mildew, and during the last year on our own premises, its leaf was always as fresh and clean as that of a Maple. A letter from **ISAAC F. WARING**, in the *Cincinnati Gazette*, states its average product to be five hundred gallons per acre. **J. McCULLOUGH & Son**, of Cincinnati, write, that in 1854, one Vineyard of 1,500 plants made 1,600 gallons which were sold at four dollars per gallon. It is said to be superior to Norton's Virginia.

All these different varieties will be sold at their usual low prices by the hundred, lower still by the thousand, and yet lower where ten thousand are taken.

FLUSHING, N. Y.**

**IMPORTANT TO FRUIT GROWERS.
The Great Result at Length Attained!
Best and Cheapest Fruit Basket in the
World!**

The Cheapest and Best Ventilating Basket for Marketing Strawberries, &c.
Illustrated Circulars sent free.

This new Basket, made of Veneer, for Strawberries, &c., is the most simple, useful, ingenious and cheap article of the kind now in use. It seems to have overcome all the objections known to Fruit Growers or Fruit Dealers, as all alike are at once impressed with its manifest utility. The fact is now well known to every one that a tight box should never be used. This new Basket is thoroughly ventilated, remarkably attractive in appearance when filled with fruit—and can be packed in one-quarter less space than the round basket or box. It is not only very strongly made, but is sold at a much less price than anything of the kind now in market. Substantial Crates, to hold from 12 to 96 Quart Baskets, and so arranged that the berries can not spill out, even if the Crates are overturned.

LIST OF PRICES.

Quart Size, \$30.00 per thousand baskets.
Crate for 32 Quart Baskets, (iron bound),..... \$2.00 each.
(Will hold 96 Baskets when nested full.)
Crate for 60 Quart Baskets, (iron bound),..... \$2.50 each.
(Will hold 180 Baskets when nested full.)
All styles and sizes of Crates made to order at the lowest prices.

VINELAND

FARM AND FRUIT LANDS, in a mild and healthful climate. Thirty miles south of Philadelphia by Railroad, in New Jersey, on the same line of latitude as Baltimore, Md.

The soil is rich and productive, varying from a clay to a sandy loam, suitable for Wheat, Grass, Corn, Tobacco, Fruits and Vegetables. This is a great fruit country. Five hundred Vineyards and Orchards have been planted out by experienced fruit growers. Grapes, Peaches, Pears, &c., produce immense profits. Vineland is already one of the most beautiful places in the United States. The entire territory, consisting of forty-five square miles of land, is laid out upon a general system of improvements. The land is only sold to actual settlers with provision for public adornment. The place on account of its great beauty as well as other advantages has become the resort of people of taste. It has increased five thousand people within the past three years. Churches, Stores, Schools, Academies, Societies of Art and Learning, and other elements of refinement and culture have been introduced. Hundreds of people are constantly settling. Several hundred houses are being constructed, and it is estimated that five hundred will be built during the summer. Price of Farm land, twenty acre lots and upward, \$35 per acre. Five and ten acre, and Village lots for sale. Fruits and Vegetables ripen earlier in this district than in any other locality north of Norfolk, Va. Improved places for sale.

Openings for all kinds of business, Lumber Yards, Manufacturing, Foundries, Stores, and the like. For persons who desire mild winters, a healthful climate, and a good soil, in a country beautifully improved, abounding in fruits and possessing all other social privileges, in the heart of civilization, it is worthy of a visit.

Letters answered and the Vineland Rural, a paper giving full information, and containing Reports of Solon Robinson, sent to applicants. Address CHAS. K. LANDIS, Vineland P. O., Landis Township, New Jersey.

From Report of Solon Robinson, Agricultural Editor of The Tribune: It is one of the most extensive fertile tracts, in an almost level position and suitable condition for pleasant farming that we know of, this side of the Western Prairies.

Maryland and Virginia Farms for Sale.

Owing to the Civil War, fine Southern farms are now offering for sale at reduced prices, in the most fertile portions of Maryland and Virginia. The mildness of the climate and variety of productions offer peculiar inducements to Northern Farmers. The subscribers have constantly on hand Farms improved and unimproved, Dairy, Fruit and Grazing Farms, Country-Seats, Coal and Timber Lands, in all sections of Maryland and Virginia.

Also Residences and Building lots in and around Baltimore and Washington.

Faithful and accurate descriptions can be had by addressing JOHN GLENN & CO., 59 Second-st., Baltimore.

SUPERIOR FARM LAND.—20,000

Acres, Franklin Tract, at Newfield, Gloucester County, New Jersey, on the Railroad running from Philadelphia to Cape May, 30 miles South of Philadelphia—adjoining the Vineland Tract, and 2 miles North of the Vineland Station—for sale at low prices and on easy terms, in lots to suit purchasers. Circulars, with reports of Solon Robinson, Hon. William Parry, and others, with full information, sent to applicants, free. Address JOHN H. COFFIN & CO., Newfield, Gloucester Co., N. J. Improved Farms also for Sale.

600 Maryland and Virginia Farms and Timbered Lands.

Catalogue of Maryland and Virginia Lands, with Geographical description of Maryland, for sale by E. W. TEMPLERMAN & CO., Land Agents, 371 California-st., Baltimore City, embracing a description of the soil and products of Maryland. Send 25 cents for a copy of Catalogue.

New Strawberries.

Draud's Seedling Strawberry, believed to be the best in existence, may be seen in fruit in season at the Nursery of FRANCIS BRILL, Newark, N. J.

TO FARMERS, Poudrette! Poudrette!

80,000 Barrels of Lodi Poudrette

For sale in lots to suit purchasers. This Poudrette has been on the market for 25 years, and has held its place among all other fertilizers as the Best and Cheapest, being sold for \$40 per ton less than other fertilizers, with just as good results. It is manufactured from the night soil of New York City, which the subscribers have the exclusive contract for removing to their works. Its chief recommendations are its economy, the quick growth it gives to the plant, ripening a crop from two to three weeks earlier, and an increased yield of 50 to 100 per cent. It is used most extensively upon Corn, Tobacco, Potatoes, and Garden Vegetables. Is perfectly inodorous, harmless to vegetation, can be applied directly to the seed without injury, and yet is as powerful as Peruvian Guano, and unlike Guano, does not leave the soil in an exhausted condition. A pamphlet with the experience in its use of several hundred farmers in different parts of the United States, some of them having used it for over 20 years, will be sent to any person applying to our address. Price—\$3.00 per Barrel of four Bushels. Address THE LODI MANUFACTURING COMPANY, 66 Courtland-st., New-York.

No. 1 Peruvian Guano,

of recent importations, for sale by

CHAPMAN & VANWYCK,

Bruce's Concentrated Fertilizer.

The Cheapest Manure in use—Price \$50 per 3000 lbs. Sent for Circular.

JOHN VANDERBILT, 33 Fulton-st., New York.

FRANK,
FEARLESS,
 AND
INDEPENDENT of PARTY CONTROL.
THE EVENING POST.
 NEW-YORK.

THE EVENING POST, NOW IN ITS sixty-fifth year, having begun with this nineteenth century, has always maintained a leading position among the metropolitan journals.

The fearless and hearty support which it has always given to the great principles of universal justice and freedom has made it the almost indispensable companion of brave and true men, who are more deeply interested in the success of principles and the progress of humanity than in the triumph of party.

During the war **THE EVENING POST** was one of the most earnest and vigorous supporters of the cause of the Union; it held up the hands of our brave soldiers in the field, and encouraged the hearts of our noble men and women at home; every project for pushing on the column had its zealous support; while it no less zealously lashed and rebuked treason in all its forms, whether open and courageous, as at the South, or covert and mean, as at the North.

At the same time, with all its enthusiasm for liberty and Union, **THE EVENING POST** did not close its eyes to the dangers of an abuse of power; it was the enemy of all undue exercise of the central authority, of all kinds of political jobbery and corruption; it has insisted upon economy in expenditures and of the strictest adherence to the Constitution. To these principles **THE EVENING POST** intends to adhere.

But **THE EVENING POST** has always aimed to be more than a political and commercial journal. It desires besides to be "a good newspaper." In its columns will be found a complete history of the events of the day, important political or State documents entire, proceedings of Legislative bodies, Summaries of European intelligence, and News from all parts of the world, accurate Reports of Financial and Commercial matters, trustworthy correspondence, and a carefully selected literary miscellany, comprising Poetry, Reviews of new works, with liberal extracts, gossip and anecdotes—the whole forming an excellent variety, in which every reader will discover something to his taste.

CHANGE OF TERMS.

We are gratified to announce that the decline in the price of paper enables us to reduce our rates to a very low standard.

We hope to have the co-operation of our friends in extending our circulation, as formerly, and shall be pleased to send specimen copies, posters and blank lists to persons whose facilities or inclination may prompt them to get up a Club.

EVENING POST—Weekly.

The first Book of an American Author.
IN TRUST,

—OR—

DR. BERTRAND'S HOUSEHOLD,

BY MISS AMANDA M. DOUGLASS.

1 VOL. 12MO. \$1.75.

This new novel (by a new author) is meeting with great success among readers and critics. Three large editions have already been sold, and the press are sending us favorable and even enthusiastic notices of the book.

"Richard Bertrand, the hero of the story, is a noble character, whose model is worthy of close study."

"The idea of the book is admirable. It represents the elder brother of a family, left comparatively helpless by the death of its head, sacrificing his own dearest ambitions in order to assume a father's duties to his brothers and sisters."

"From no source have we heard the work spoken of otherwise than in terms of praise."

It is of the highest order of works of fiction, written with that true genius which has high moral and spiritual aims, and whose mission is to improve and elevate the human mind.

Sent by mail post-paid, on receipt of price, and for sale by all booksellers.

A New Fruit Book.
PRACTICAL AND SCIENTIFIC
FRUIT CULTURE.

BY **CHARLES R. BAKER,**

Of the Dorchester Nurseries.

1 vol. 8vo. Profusely Illustrated. Price \$4.00.

A work of rare excellence, which is destined to take its place beside the best works on American Pomology. Its author is extensively and favorably known among fruit-growers, both as a skillful pomologist and a ripe scholar, and is every way qualified for the preparation of a book on this, his favorite subject. In fruit culture he was educated by Hon. Marshall P. Wilder, of world-wide fame, with whom he is at present associated as business partner, and to whose valuable library and ripe experience he has had the freest access for many years.

In this volume he gives no delineations or descriptions of Fruits, but treats with exhaustive fullness the arts of production and cultivation, together with the scientific principles on which these arts depend; how persons may supply themselves with the best fruits in variety and abundance, with the least labor and expense, and in the shortest possible space of time.

No family, no cultivator can do without this book, which will save them many times its cost every year.

** Sent by mail, post-paid, on receipt of price, and for sale by all booksellers.

No. 363 NINTH AVE., near Thirty-seventh-st.
No. 303 FELTON-ST., BROOKLYN, corner Concord-st.

Country Clubs, Hand and Wagon Peddlers, and small stores of which class we are supplying many thousands, all of which are doing well, can have their orders promptly and fully filled; and in case of Clubs, can have each party's name marked on their packages as directed by sending their orders to Nos. 31 and 33 Vesey-st.

Our friends are getting up Clubs in most towns throughout the country, and for which we feel very grateful. Some of our Clubs send orders weekly, some not so often, while others keep a standing order to be supplied with a given quantity each week, or at stated periods. And in all cases (where a sufficient time has elapsed) Clubs have repeated their orders.

Parties sending Club or other orders for less than thirty dollars, had better send Post-Office drafts, or money with their orders, to save the expense of collections by express; but larger orders we will forward by express, to collect on delivery.

We return thanks to parties who have taken an interest in getting up Clubs.

Hereafter we will send a complimentary package to the party getting up the CLUB. Our profits are small, but we will be as liberal as we can afford.

CLUBS.—The manner of getting up Clubs is shown by the following:

AUGUSTA, Hancock Co., Ill., April 4, 1866.

PURELY MUTUAL LIFE INSURANCE.

NEW YORK LIFE INSURANCE COMPANY

ESTABLISHED 1845.

Home Office, Nos. 112 and 114 Broadway, New York.
ASSETS, OVER \$5,000,000—SECURELY INVESTED.
(See 21st Annual Report April No. Agriculturist.)

This is one of the OLDEST, SAFEST, and most SUCCESSFUL Life Insurance Companies in the United States, and offers advantages not excelled, and in some respects NOT EQUALED, by any other. Its Trustees in New York City are of the very first and most reliable names.

It is Strictly Mutual, the Policy-Holders Receiving the Entire Profits.

Special care in the selections of its risks—strict economy—and a safe and judicious investment of its funds—emphatically characterize the management of this Company.

Dividends are, and always have been Declared Annually.

The mortality among its members has been proportionately less than that of any other Life Insurance Company in America—a result consequent on a most careful and judicious selection of lives, and one of great importance to policy-holders. It offers to the assured the most abundant security in a large accumulated fund, amounting now to over

FIVE MILLIONS OF DOLLARS.

It accommodates its members in the settlement of their premiums, by granting, when desired, a credit at once on account of future dividends, thus furnishing Insurance for nearly double the amount for about the SAME CASH PAYMENT as is required in an "all-cash company."

The Annual Income, exclusive of Interest on Investments, NOW EXCEEDS

TWO AND A HALF MILLIONS OF DOLLARS.

THIS COMPANY

ORIGINATED AND INTRODUCED THE NEW FEATURE KNOWN AS

THE NON-FORFEITURE PLAN,

which is rapidly superseding the old system of life-long payments, and HAS REVOLUTIONIZED THE SYSTEM OF LIFE INSURANCE IN THE UNITED STATES, and which has been adopted (generally in a less favorable form) by all Life Companies; thus attesting the force of public opinion in favor of a system so favorable to policy holders as that established by the NEW YORK LIFE for the benefit of its members.

It has received the unqualified approval of the best business men in the land, large numbers of whom have taken out policies under it, purely as an investment.

AT THE END OF TEN YEARS

ALL PAYMENTS CEASE ENTIRELY.

By the table on which this class of policies is based, a person incurs no risk in taking out a policy. Insuring to-day for \$5,000, if he dies to-morrow, the \$5,000 immediately becomes a claim; and if he lives ten years, and makes ten annual payments, his policy is paid up—nothing more to pay, and still his dividends continue, making

HIS LIFE POLICY,

A SOURCE OF INCOME TO HIM WHILE LIVING.

The only weighty argument offered against Life Insurance is that a party might pay in for a number of years, and then, by inadvertence, inability, etc., be unable to continue paying, thereby losing all he had paid. The "NEW YORK LIFE" have obviated this objection by their

TEN YEAR NON-FORFEITURE PLAN.

A party, by this table, after the second year, CANNOT FORFEIT ANY PART OF WHAT HAS BEEN PAID IN, Thus, if one insuring by this plan for \$10,000 discontinues after the second year, he is entitled to a PAID-UP POLICY, according to the number of years paid in, viz.:

Second year, two-tenths of \$10,000 (amount insured), amounting to \$2,000, with dividend on same for life.			
Third year, three-tenths of " " " " " "	3,000	"	"
Fourth year, four-tenths of " " " " " "	4,000	"	"
Fifth year, five-tenths of " " " " " "	5,000	"	"

And so on, until the tenth annual payment, when all is paid, and dividends still continue during the life-time of the assured.

This feature, among others, has given to this Company a success unparalleled in the history of Life Insurance.

Persons desiring information, or Policies, or to be connected with the Company as Agents, will please apply to the Home Office, either personally or by letter.

There has been Paid to the Widows and Orphans of Members of this Company an Aggregate Sum Exceeding \$3,500,000.

The Dividends Paid (Return Premiums) Exceed \$1,700,000.

MORRIS FRANKLIN, President.

WILLIAM H. BEERS, Actuary.

AMERICAN AGRICULTURIST,

VOLUME XXV—No. 7.

NEW-YORK, JULY, 1866.

NEW SERIES—No. 234.

[COPYRIGHT SECURED.]

HEAD OF 4TH DUCHESS OF THORNDALE.—DRAWN FROM LIFE BY EDWIN FORBES, FOR THE AMERICAN AGRICULTURIST.

4th Duchess of Thorndale, bred and owned by Samuel Thorne, of Thorndale, Dutchess County, N. Y.—Red; calved July 10th, 1859; Got by 2d Grand Duke (12961).—Dam Duchess (—) by Duke of Gloster (11382); g dam Duchess 66th by 4th Duke of York (19167); gr g dam Duchess 55th by 4th Duke of Northumberland (3649); gr gr g dam Duchess 38th by Norfolk (3377); gr gr g dam Duchess 33d by Belvedere (1706); gr gr gr g dam Duchess 19th by 2d Hubback (1423); gr gr gr gr g dam Duchess 12th by the Earl (646); gr gr gr gr gr g dam Duchess 4th by Ketton 2d (710); gr gr gr gr gr gr g dam Duchess 1st by Comet (155); gr gr gr gr gr gr gr g dam by Favorite (252); gr gr gr gr gr gr gr g dam by Daisy Bull (186); gr gr gr gr gr gr gr g dam by Favorite (252); gr gr gr gr gr gr gr gr g dam by Hubback (319); gr gr gr gr gr gr gr gr gr g dam by J Brown's Red Bull (97).

In this country we know very little about long lines of ancestry among our citizens, and though now and then some old family can trace its descent back five or six generations, not one man in a hundred can tell the names of his great grandfathers. This may give interest to the fact that the beautiful cow whose head is faithfully presented above, is the 10th in a line of "Duchesses," and that her pedigree on the side of her dam may be traced back uninterruptedly 15 generations. They are an honored

ancestry too, and worthful, as we shall show.

4th Duchess of Thorndale is of a prevailing red color of almost faultless, and for her large size, delicate proportions; her head, small and boney; eyes, full and very prominent, and the jaws, remarkably clean. Her coat is like broadcloth, and her skin pliable and soft as buckskin. To say nothing of the first Duchess, Mr. Colling's White Bull, Favorite, the Hubbacks, and the Dukes of Northumberland, her rich heritage of blood is shown by the fact that

her sire, 2d Grand Duke, cost 1000 Guineas in England; her Grand Sire, Duke of Gloster, 650 Gs.; her Grand-dam, Duchess 66, sold for 700 Gs. at the Ducie Sale, and her (66th's) sire at the same sale sold for 500 Gs. (These are Guineas, not Pounds Sterling, remember.) Her son, 6th Duke of Thorndale, by 3d Duke (27749), now 4 years old, is emphatically the finest bull we ever saw. She is herself the queen of the Thorndale herd, and, it is no more than fair to say, that no picture, however fine, can do her justice.

Club Additions.—To Clubs of subscribers at club prices, additions can be made at any time at the same prices, if the additions begin at the same time as the others.

Back Volumes Supplied.—The back volumes of the *Agriculturist* are very valuable. They contain information upon every topic connected with rural life, out-door and in-door, and the last nine volumes make up a very complete library. Each volume has a full index for ready reference to any desired topic. We have on hand, and print from stereotype plates as wanted, all the numbers and volumes for nine years past, beginning with

1857—that is, Vol. 16 to Vol. 24, inclusive. Any of these volumes sent complete (in numbers) at \$1.75 each, post-paid, (or \$1.50 if taken at the office). The volumes neatly bound, are supplied for \$2 each, or \$2.50 if to be sent by mail. Any single number of the past nine years will be supplied, post-paid, for 15 cents each.

AMERICAN AGRICULTURIST.

NEW-YORK, JULY, 1866.

If farmers get what they hope and pray for, we shall have hot weather throughout this month with just rain enough to keep things vigorously growing, and the rain will most of it come in showers, without wind, at night. A few drizzly days, coming in pairs at intervals through the month, would be most gratifying to those who want to reset tobacco plants, or to plant out cabbages, but what we most need is bright clear weather for haying. We caution our readers not to over work, and so lose an hundred fold more than they gain. Let farmers see to it that their men and teams have time to eat and rest. Give the hands good wages, good food, pleasant quarters, and friendly treatment, and exact in return, prompt, active, diligent labor, and devotion to their employers' interests. A word to those who have never had the charge of farm hands:—Take care that you know how much a man should do in an hour or day, and never exact too much, nor be satisfied with too little. He is a very faithful man who will not take advantage of the ignorance of his employer in these particulars. When there is necessity for lively work, or work during hours of rest, the men will always give it freely if they see the need, but a few "spurts" gotten up without cause, will do much towards spoiling otherwise good hands.

Hints about Work.

Many of the hints given last month are equally applicable to this, especially those that have reference to buildings, dairy matters, haying, etc.

Grain Fields may demand attention early in the month, particularly if many coarse weeds are seen in them. When possible, it will pay to go into the grain and pull, or cut with a spud, such weeds as dock, mustard, charlock, etc. After the grain heads have their development, look out for

Saving Seed Grain.—Inspect the whole field and pick out those parts which are best; pull the weeds, and inferior stools of grain. If it can be done, a hoe may be used in loosening the surface, and drawing earth up to the plants to some extent. Clip off also inferior heads, so that a very superior stand only is left. Allow these selected portions to become dead ripe, at which time cut with a sickle or very carefully with a cradle, and handle the sheaves so that the grain will not shell out.

Oats, blown down or lodged from their own weight, should be cut and cured for hay. Wheat and barley may sometimes be treated in the same way, but they fill better than oats after they lodge, not being so leafy.

Barley.—Cut before fully ripe, and protect from rain in well made stooks. There is a great difference in price between that well and that poorly handled in harvesting, and the gain in the feeding quality of the straw will pay over and above for the labor. Eastern farmers, who raise much grain, ought to have

Hay Caps.—Perhaps it will not pay to use them at the West, but in the Eastern and Middle States it will, though we apprehend there have been very few made within the last four years.

Wheat is especially benefited by them, for it is best to stook up the sheaves almost as soon as cut, not giving the straw a chance to dry much. Cut wheat before it is ripe, while the heads are just beginning to droop, and the kernels are in the dough. To this end on very large farms it is best to have different kinds of wheat ripening one after another. Both hay and grain

Stacks are best built long and narrow. One side

being a little higher than the other, a course of 16-foot boards will cover the stack. The boards may be nailed together in threes. Such a stack may be made with a horse fork, and a simple pair of shears.

Hoed Crops.—If we were directing the preparation of the soil for corn, potatoes and other root crops, we might say that a lack of manure could not be made good by subsequent treatment, but nevertheless we will say now that it is also true that frequent and thorough tillage will do as much for these crops as manure, though in a different way. It will defend against drouths; it will let the air into the earth, with moisture, and it will promote the disintegration and decomposition, thus affording the plants a fuller benefit of the manure and fertility of the soil.

Corn.—At the last hoeing, turnip seed may be sown, and hoed in.

Potato Ground.—If dug early for market, set cabbages as fast as the ground is cleared.

Cabbages may also follow field peas if the ground is rich, and if not, a fine rich compost may be plowed in. (See Hint last month.)

Corn Fodder.—Corn, sorghum, millet, and Hungarian grass may be sowed for soiling, or for hay.

Tobacco.—The labors in the tobacco field will be steady and irksome, but a good crop depends upon having every spot in the field occupied by a good plant as early as the first week in July, and then hoeing thoroughly, keeping the ground loose and open, all the weeds down, and the worms picked off. Poison tobacco worm moths, see basket item.

Grass.—Cut and cure grass whenever it lodges badly, even though the rest of the field cannot be cut. Cut Timothy when just out of blossom, and clover when in fullest bloom. All grasses should be cut before they are tough and wiry.

Mowing Machines and Hay Tedders make quick work with hay. Cut the grass when the dew is off, and within half an hour follow with the tedder and repeat the tedding as often as once in half an hour until past midday; then, when the grass is hottest, rake into windrows, and throwing it into cocks let it lie till the next day;—or keep the tedder going till 2½ o'clock, and then rake up and get in all cut before 11. All cut before noon may be gotten in in the forenoon of the next day, if the weather is good. When you have not these machines, try the following plan for

Curing Hay.—Stir well as soon as the sun is hot, and when the grass is well wilted and hot, rake it into loose windrows; turn these frequently, shaking out wet locks until say 3½ o'clock, then cock up and let these lie a day or two if need be, but employ the first convenient sun-shine after the next day to shake the cocks out and warm them through; then get the hay in. This curing in the cock is especially good for clover, but all hay is sweeter for it. It should never get dry and parched. If dried slowly, the juices have a sort of honey-like character, and will neither sour, mould, nor ferment in the mow, nor will the leaves and heads drop off.

Turnips.—Sow Cowhorn, or Purple-top Strap-leaf, both good sorts. Sow in drills, except on ground that cannot be plowed, or among other crops. Usually after the 20th is early enough.

Buckwheat must be sowed before the 20th usually; though many take the risk of early frosts, which are fatal to the crop, and delay to the last of the month. The kernels fill better in the cool weather later in autumn, if frosts hold off. 24 to 32 quarts of seed per acre is the usual quantity.

Animals of all kinds require the farmer's attention during this as much as any other month; that is, a lack of needed care is just as injurious. See that all have pure water—if possible, running water—always within reach. Change pastures often enough, so that none shall get very short, and provide extra feed of corn, grass, oats, etc., cut green and wilted before feeding, if there is any failure of pasturage. Feed and water working cattle and horses well, regularly, and give regular rest. Take care of harness and yoke galls, bathing with cold water and shifting the harness, padding it, or the yokes of cattle. See

items in the "Basket" on the *Sheep-bot*, or grub in the head, and on *warbles*, or grubs in cattle's backs.

Orchard and Nursery.

We shall probably have a fair crop of all kinds of fruit, except peaches, and in some localities the grapes will be short from the killing of the new shoots by frost. If we expect successfully to raise

Peaches, some mode of culture must be adopted, which will protect the buds from the severe cold of winter. In April last we gave an account of a plan followed in Ohio. Others cut the young tree back at planting, and thus cause all the limbs to start near the ground, and these as they grow are trained by stakes into a nearly horizontal position, so that they may be readily covered with earth or litter during the winter. Whoever hits upon and adopts a practicable method for preserving the buds from the effects of cold, will find it profitable, as the demand increases faster than the supply.

Birds and Insects are the theme of a large portion of the letters we now receive in this department. In cultivation we have broken up the natural order of things, and must not be surprised if now insects and now birds are a source of annoyance. The best way we have seen to keep off birds is practised by Mr. Knox's workmen, who make small wind-mills, so arranged as to make a clatter, and put them up here and there in the vineyard. We have said enough last month about the Tent Caterpillar, and have only to add that one correspondent finds a mulden-stalk, fastened to a pole, a very efficient brush with which to dislodge the pests.

Borers were sufficiently discussed in May on page 187. If the trees were not protected, they should be looked to before the eggs hatch, and the grub finds its way into the trunk. Read the May article.

Pruning may now be done on old or neglected orchards; take out superfluous limbs, and head back those disposed to too vigorous growth.

Budding is sufficiently described on page 258, to enable any one to practice it. If this year's buds do not take, the same stocks may be grafted next spring. We cannot too often insist upon the necessity of care in selecting buds or clons for propagating. It is a notion among many that merely budding or grafting a tree helps its fruitfulness. The object of these operations is to get a kind of fruit that we know to be good, rather than take the rare chance of a seedling stock's producing choice fruit. Therefore get buds from only desirable varieties.

Thinning should not be omitted. Sufficient is said in an article on page 255.

Layers may be made of vines and shrubs as soon as the present season's growth gets firm. Grape vines layered now will have good roots by autumn. Prepare the soil well, and if it is light, use a good mulch over the layer to keep it from drying.

Weeds should be kept from occupying the ground, whether in orchard, nursery row, or seed-bed. Seedling stocks, when young, are apt to suffer from weeds; they need as careful weeding and thinning as any other plants. It is not too late to

Mulch trees, and it should be done with those planted this spring, as it will save many that would not survive without troublesome watering. Besides the usual mulches, we have seen shavings from a planing mill used. Anything that will prevent evaporation, from stones to bog-hay, will answer.

Grafts set this spring still need the care suggested last month. It often happens that the stock will throw out vigorous shoots, which will rob the graft of nourishment and cause it to become feeble or die. Rub off all such as soon as they appear, and control the growth of the grafts by pinching.

Seedlings, especially those of evergreens, will need shading as directed on page 147 (April.)

Seeds.—The collection of these needs care. As soon as the ornamental shrubs ripen their seeds, collect and sow, or keep in earth. Collect cherry pits and seeds of other fruits.

Slugs upon pear and cherry trees are to be dusted with lime from a bag of open texture tied to a pole.

Kitchen Garden.

June opens with cold rains, and if these are long continued, many seeds will rot in the ground. Lose no time in replanting. See article in "Basket," "Not too Late" for some of the things which may be successfully sown this month. In all profitable gardening the land is kept constantly at work, producing two and sometimes three crops in the year.

Transplanting still needs to be done with late cabbages, etc. It will be successful in the hottest weather, if the holes are watered before putting in the plants, and the plants are properly prepared by grouting, i. e., enveloping their roots in mud.

Vacant Places.—Many allow the land from which an early crop has been taken to lay idle and run to weeds. This should never occur. Fill up with ruta-bagas, fall spinach, and other late crops.

Asparagus.—Now that cutting has ceased, encourage as much growth as possible to repair the loss. A dressing of manure will not come amiss, and weeds should be kept from the bed until the tops shade it. If the larvæ of the beetle appear—small, black, leech-like bodies—cut all infested branches and burn them.

Beans.—Limas are usually allowed to run too high. Most vines will go to the end of their support before they begin to bear, and the Lima bean may be made to fruit earlier by only allowing it to run as high as one can reach. Silted string beans are very good in winter, and a planting made now will give a supply.

Beets may be planted for a late crop, which will be realized unless very dry weather comes on. Hoe often, and as soon as large enough, thin to 6 or 8 inches in the row.

Cabbages and Cauliflowers.—The later plants are to be put out as soon as large enough. Plenty of manure, with some lime, which is said to prevent club-foot, should be put upon the land. Caterpillars are to be looked out for and hand picked, and slugs trapped as recommended on page 257.

Celery.—Those who grow in trenches should see that the bottom of the trench is well enriched. For a complete account of flat culture see an article in *Agriculturist* for July, 1865.

Carrots.—Keep well hoed until the tops prevent working, and sow seed if young carrots are wanted.

Corn may still be planted to give a supply for late use and for drying.

Cucumbers for pickles may be sown in well enriched hills. Select the best of the early crop for seed.

Egg Plants.—Give good cultivation, liquid manure and mulch.

Endive.—Sow for a late crop of salad.

Herbs.—These are in perfection just at flowering time, and then is the time to cut. Dry in the shade and preserve from flies and dust.

Lettuce, if sown this month, is apt to soon run to seed, unless it is in a partial shade. The Silesian is best at this season.

Melons often set more fruit than can be ripened. Remove what seems to be superfluous. Hoe the plants until the growth of vines prevents it.

Onions need continued care in weeding. From the press of haying and other work they are often neglected this month, much to the injury of the crop. If the sowing was properly done, but little thinning will be needed, but, if crowded, thin.

Peas.—Some of the early varieties may be sown. They are very apt to mildew; deep planting tends to prevent this. Gather pods from vines reserved for seed, taking those only that ripen early.

Potatoes.—As the early sorts are dug for use, bury the tops, which soon decay and enrich the soil. Late cabbages, turnips, or spinach, may occupy the ground when the potatoes are off.

Rhubarb.—Flowering and seed bearing tend to exhaust the plant, hence the direction to cut off the flower stalks as soon as they shoot up. Now that fruit is abundant the pulling should diminish or cease altogether, and the plants allowed to recuperate by rest. Give a dressing of manure.

Seeds.—It is better to buy seeds than to save poor

ones. Many take the first and best products of the garden for the table, and use what is left for seed. Just the reverse of this should be the case. The earliest, best shaped, and finest of everything should be chosen. By pursuing this course the kinds will not only not run out, but improve.

Sweet Potatoes.—Keep the ground of the ridges or hills clean and mellow until the vines cover it.

Squashes.—Hoe until the vines get so large as to interfere, then do not disturb them, but allow them to take root. Look under the leaves early in the morning for the black bug, and destroy it, and crush any eggs that may be found. The spotted *Galeruca*, an insect shaped like a lady-bug, but yellow, with black spots, is very destructive to the leaves. They must be caught very early in the morning, as they fly when it is warm. The borer is a great pest in many localities; usually its presence is not known until the whole vine wilts. The grub enters near the root, and if a hole is found, carefully split the vine with a knife, and take him out. Cover the wound with earth if practicable, otherwise bind it up.

Tomatoes.—The large green "worm" devours the leaves and green fruit. If any droppings are seen, hunt for the worm at once, as in every day of undisturbed foraging it makes wonderful havoc with the plants. If the plants are not trained in any of the several ways we have described, they will fall over with the weight of fruit; in this case place brush or some rude support for the branches to recline upon, and thus keep the fruit clean.

Weeds are to be fought all the season. A sharp steel rake, frequently used, will keep them down, and leave the surface open. If a deeper working is desired, use the hoe fork figured last July. This leaves the soil in splendid condition, and in a dry time it will benefit the plants more than watering.

Fruit Garden.

In most places the strawberry harvest is over. Remove the mulch, and fork in a dressing of manure. If plants are needed, allow sufficient runners to grow and take root; otherwise stop them.

Raspberries follow the strawberry, and will now need a daily picking. Some cultivators remove the old canes as soon as the fruit is off, while others prefer to let them remain until the fall pruning. Suckers are to be kept down unless they are needed for new plants, as three or four canes are all that are needed to a stool.

Blackberries.—The crop of fruit is often so heavy as to make it necessary to tie up the branches. A heavy mulch around the vines is beneficial, as it is difficult to use the hoe among them.

Currants, if trained in the tree form, are apt to lose their branches from the weight of fruit, and will need support. Treat the worm with hellebore, and cut away the borer as directed last month.

Dwarf Trees should have the fruit thinned when there is any disposition to overbear. See article on page 259. Dust the slugs with lime, as noticed under Orchard. Trees put out this spring, will be helped by a thorough mulch. The red spider frequently injures the pear; he is a little fellow and his work is often seen before the insect itself is noticed. Frequent syringings of soap suds will keep it in check. The shape of the tree may be controlled, and its fruitfulness increased by judicious pinching.

Grape Vines.—Keep the shoots tied up. Thin freely, especially on vines fruiting the first time. Pinch the laterals to one leaf; if they push again, repeat the pinching, reducing each new growth to one leaf. Bearing canes are to be stopped at 3 or 4 leaves beyond the last bunch. Hand pick beetles and caterpillars. Mildew makes its appearance in small greyish patches on the leaves, new wood, and fruit. See article on its treatment on page 223 (June). Apply the remedy on the first attack.

Flower Garden and Lawn.

Grass, whether on the lawn or edgings to beds, needs care to keep out weeds. Plantains, thistles, and other coarse weeds should be pulled while they

are small. Keep all margins trimmed neatly. Mow often, and if the grass is not heavy, it need not be raked from the lawn.

Borders and Beds should always be kept neat. Dress the surface with the rake, and hand pull weeds that grow up in clumps of flowers and shrubs. Unless flower seed is wanted, remove the clusters or stems after blooming is over.

Bulbs are to be taken up when ripe, which may be known by the fading of the leaves. When dry, they may be packed in papers, or in dry sand.

Tie up all plants that need supports, before they fall over, keeping the stakes as much out of sight as possible. Dahlias need a great deal of care in this respect, and not only the main stalk, but the heavier branches, will require support.

Pruning of shade and ornamental trees may still be done. Evergreens may be shaped by a judicious use of the knife. Hedges, whether deciduous or evergreen, are to be clipped.

Propagation of shrubs, vines, etc., by layers and cuttings, is done when the new growth is firm enough. Many shrubs will grow from cuttings of green wood that are not easily propagated in any other way.

Annuals will need transplanting and thinning. Seed still sown of the quick growing kinds, will probably give plants that will blossom before frost.

Seeds of perennials and other plants should be sowed as they ripen. Many of the perennials do better if the seed be sown as soon as it is ripe.

Roses will be attacked by various enemies, all of which, except the rosebug, will yield to syringing with strong soap suds or tobacco water. The bug must be picked by hand or shaken off and caught upon a cloth. Tie up the new growth of pillar and climbing roses; make layers to increase the stock; cut back the remontants to within three or four buds of the stem.

Bedding Plants may be pegged down to evenly cover the ground, and

Plants in Pots ought not to be neglected. They often suffer from dryness.

Green and Hot-Houses.

There is little to be added to the notes of last month. The plants which remain in the house will need watering, shading, and ventilation, as well as care in regard to insects.

Alterations and repairs, painting and cleansing, overhauling the heating apparatus, etc., is usually put off too late, when the work has to be hurried. Better have everything ready, months too soon than days too late.

Budding of green-house shrubs may be done whenever growing, and prune such as need it.

Potting Material—Old hot-bed manure, good pasture loam, leaf-mold, and clean sand, should be laid in under cover.

Propagate stock for winter blooming from cuttings, and pot rooted cuttings and seedlings.

Camellias and other shrubs, set out of doors, must not suffer for want of shade or water. See that they are not overturned by the wind.

Cold Grapery.

The temperature of the house should be 90° to 95° at mid-day, and sink to about 85° during the night. If there is a lack of sufficient moisture in the borders, mulch those outside, and if necessary, water them with weak liquid manure. Continue to pinch the laterals. The berries will need thinning, removing sufficient to prevent crowding. Slender scissors are made to use in thinning. The amount of thinning will depend upon the variety of grape, it is usually necessary to remove one-half and often more. Sprinkling is to be continued every evening, unless mildew attacks the vines, in which case it must be discontinued and the air of the house kept dry. At the first sign of mildew on the leaves, sprinkle sulphur freely over the floor of the house, and discontinue the sprinkling until the danger is over.

Containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

The Second Half of Volume 25 commences with this number, and new subscribers can begin for a half or whole year, though most persons will desire the six splendid numbers already issued. We solicit a continuation of the friendly aid of our readers, so freely bestowed in the past, in extending the circulation of the *Agriculturist*, promising on our part to spare no effort to make it a useful messenger wherever it may be sent.

To Secretaries of Agricultural and Horticultural Societies.—Please send us your announcements of Fairs, Exhibitions, etc., early, as soon as you see this, if the time is fixed. Moreover, please indicate the State in which County Fairs are to be held. A good share of the circulars that come to us have this important item omitted. Our list of fairs is always eagerly sought for, and we wish to have it as complete as possible.

The American Association for the Advancement of Science.—We are glad to learn that this body, which remained in a state of suspended animation during the last four or five years, is still alive, having survived both the war and its own ungainly name. In former times these meetings used to be both pleasant and useful. Persons engaged in the different departments of science came together at some convenient point and told what they had been doing through the year, and had a pleasant time socially. These meetings were not only useful to the members themselves, but to the communities in which they were held, as they served to awaken a popular interest in matters of science, and showed the people at large that philosophers and savants were not so different from others, but that they ate, drank and had their little quarrels just like other folks. The meeting will be held this year at Buffalo, N. Y., on the 15th of August. Prof. J. Lovering of Cambridge is Permanent Secretary. The sessions are open to the public.

Market Gardening—New Work.—There has long been a demand for a work upon Market Gardening, and we are glad to announce that an experienced New Jersey market gardener has one in preparation. The gentleman engaged upon it has been a frequent contributor to the columns of the *Agriculturist*, and from the practical character of his writings we look for a book of great value. It is his intention to give the whole art and mystery of profitable gardening, adapted both to market growers and the private family gardener.

The Minnesota Agricultural Society will hold its annual exhibition Oct. 3d, 4th, and 5th, at Rochester, Olmstead Co., situated in the heart of a rich agricultural region, and accessible from all parts of the State. We learn that great exertions are being put forth by the officers, executive committee, and others, to make the Fair a very large one, and of extraordinary value to all the cultivators of the State, and to the country at large. It will become every Minnesota farmer to lend a helping hand to the enterprise, both for his own benefit, and for the credit of that rapidly developing agricultural State.

Sundry Humbugs—General Hints.—We have before us several hundred letters, sent in from all parts of the country, which show that the swindlers are yet active, but with greatly diminished profits. Multitudes of cases are given in which our words of caution and exposures have prevented the sending of money where it would have been inevitably lost. The Post-masters, generally, are doing a good work in warning people who bring in letters to mail to the humbug operators.—The largest class of these are those who offer to sell watches, jewelry, etc., by means of tickets. Some claim to be agents of foreign manufacturers, and nearly all profess to have a stock which must be sold on account of the great fall in gold, or the failure of large establishments. We again pronounce all these statements unmitigated falsehoods! There have been no such failures. The value of gold and silver watches, jewelry, etc., is just as high relatively as ever, as can be learned from any honest, reliable dealer.—Of the great number of persons offering these things, at least three-fourths never intend to make any return for the money sent them. True, when we personally call upon them with the tickets sent us, as we often do, they offer us the article called for by

the tickets, on payment of the sum required, and sometimes it is perhaps worth nearly that sum. But these cases are rare; and further we are usually put off from time to time, as we call, with the answer that the "boss" or head of the concern has just stepped out, or has gone to Philadelphia, or elsewhere, and we must call again, which we often do to receive the same answer.—But their usual course is, to make no reply to letters containing money. If hard pressed, they plead that the money letters were lost by mail, or that the money was abstracted before its arrival. We estimate that of at least \$300,000 sent to this city recently, no response was given for \$250,000 of it. There is a small class of operators, five or six perhaps, who do send out the article they promise, but the cheating is done by making false representations as to the value. They send out tickets (sometimes to be paid for and sometimes not) promising for from \$1 to \$12 to send say a watch "valued at" or "marked at" \$50 or \$60, or \$80, and so on. Some of them intend to, and do send the article promised, but in the end the receiver will find it "valued at" or "marked at" ten times its actual value, if not fifty times. There is a great business done in watches containing cheap "works" put into cases of brass or britannia, but so finely covered with a thin galvanized film of gold or silver that only a practiced eye can detect the fraud until after a few weeks. The cost of these watches is from \$2 to \$3 or \$4, and yet they are "valued at" or "marked at" from \$50 to \$100 each. They are of little or no real value. Some send a little better watch, but one costing a fifth or even a tenth of their represented value. It is the same with the whole of this jewelry, etc., etc., offered by tickets. The parties operate until the gilt begins to wear off, and then change their names. In the letters before us are circulars from a dozen or more parties who have changed their names within two months.... Humbugs are springing up more numerously in country towns. "Henry H. Ulman & Co.," Camden, N. J., is a sample of the class. They (or he) offers \$300,000 to be distributed in prizes from \$1 up to \$40,000—a downright swindle that will be patronized by none except fools, but that class "are not all dead yet."... Jason H. Tuttle of Flatbrookville, N. J., one of the biggest swindlers out of jail, we thought had quit business under that name, but we receive frequent circulars and tickets of his issuing. Perhaps they are old ones, as they have no date.... J. Folsom of Moriah, N. Y., forwards us 30 circular letters sent to persons of his name, including at least a dozen different ones to himself. These come apparently from different parties (swindlers), but the hand writing on them shows that several of them were addressed by the same person. We have previously explained that the same operators often run several different concerns.... Many letters of inquiry about different concerns come, desiring answers. To save writing, we say here, every one inquired about is a swindle.... Sewing machine tickets (\$5 to \$10 each) are offered by several parties. Those who send anything, send a little instrument which is sold in quantity at \$2.50 each, and not worth buying at that price.... Those advertising to cure eyes and ears, with apparatus for the former, are little if any better than humbugs.

Pleuro-Pneumonia, not Rinderpest.—Just as we go to press, we notice an associated press dispatch in the N. Y. daily papers, which purports to be an extract from a circular from the President and Secretary of the N. Y. State Agricultural Society. We have not received the circular and cannot believe that these gentlemen do not distinguish between the *Rinderpest* and the *Pleuro-pneumonia*. The former name is by common consent confined now to the terrible infection which is and has been working such devastation among the herds of Great Britain, while *Pleuro-pneumonia* is applied to the Jung murrain, which prevailed in Massachusetts a few years ago, and which has for several years been supposed to be *domesticated* in the swill milk stables of the city of New York and Brooklyn, whence it is occasionally carried to the farms of the vicinity. The subject comes properly under the consideration of the commissioners appointed under the new Rinderpest law, for the disease called *Pleuro-pneumonia* is exceedingly contagious and liable to do immense damage. The cautions said to be contained in the circular against buying cows from these stables, and advising careful examination of all cows offered for sale, are timely and wise.

American Tea Company.—To Several inquirers. Before admitting the advertisement, we learned that a large number of our clerks and others had for several months been buying their Tea and Coffee from this Company, without its being known who they were, and that they had been highly pleased with their purchases, both as to quality and price, and were all recommending their friends to the same course. As we have published the advertisements for many months, and received no complaints, we conclude there is no humbug about the establishment.

Soiling Cows.—Few farmers get into the way of soiling cows, except those to whom it is a very important thing to keep up the supply of milk, as when it is furnished to city customers, who will be lost for the season if they cannot have their regular quantity every day, or when the milk is taken to a cheese factory, and the farmer's income bears direct relation to the number of pounds of milk he furnishes. It will pay to cut the best grass on the farm to feed green, rather than to have the milk fall off so much as not to regain its full flow when the dry spell is past. Corn, oats, sorghum, and millet may be sowed any time, and will make either pasturage or green fodder. Turnips, sowed thick, rape seed also, or seed of any of the cabbage or turnip family, will make green forage in a very short time. When cut and fed, green fodder should always be suffered to wilt considerably, as it loses water rapidly, saves weight in carting from the field, and is better masticated and digested.

When to Cut Timothy.—"J. A.," McKean Co., Pa., writes soundly: "One says 'cut timothy hay early,' and another says 'cut it late.' I have tried both ways with working cattle and milch cows, and I value one ton of early hay above two tons of late cut hay. The stock eat the early cut hay clean, waste none, and thrive much better, and do a vast deal more work, than on late cut hay. If the season is favorable, I am generally nearly through haying when others commence. Late cut hay may last longer, and bass-wood chips would last longer still. This question would be settled forever, if men would try the experiment fairly."

The Sheep Gad-fly.—The great distress which sheep suffer from the attacks of this insect (the *Oestrus Ovis*) can hardly be imagined by one who has not seen it. It lays its eggs in July and August, chiefly in the nostrils. That death is occasioned by the grub in the head is not probable, but when great numbers exist in the head of a sheep, the irritation they produce, especially when they take their departure in May and June, is great, but little or nothing can be done for the poor sheep. Tar upon the nose is quite an efficient preventive. It should be applied repeatedly during the summer, and even when smeared above the nostrils has the desired effect, and does not rub off so soon. Hence it is, that, as no passage can be discovered for the grubs to get into or out of the frontal sinuses, (cavities in the bone between the eyes,) many suppose the tar prevents the fly laying its eggs in the bones of the forehead. The eggs are laid in the nostrils, as above stated, the worms which hatch, work their way up into the head, passing through the very thin bones. It is said, too, that the merinos with their woolly foreheads are not troubled with them, but this we cannot believe without further evidence, as it is a matter not covered by our own experience. Very few sheep are free from these grubs, and from one to more than twenty are found.—Capt. Shaff, of White Co., Ind., thinks his sheep are killed by them. He reports taking 21 from one sheep. R. H. Cook also attributes the death of his sheep to the same cause, but his Spanish Merinos are never troubled.

Paring the Frog.—"W. H. B.," Danbury, Conn., asks: "Should a horse be shod so that the frog will touch the ground?" In a state of nature the hoofs of horses wear quite flat and even. We shoe horses only to protect the hoofs against injury on our hard roads, and to prevent too much wear, and the shoe should never be made so as to contract the hoof; neither should the frog be pared away, except when it is torn and ragged. Let it touch the ground if it will. Do not have any nails driven more than half-way from the toe to the heel of the shoe.

The Trial of Mowers and Reapers by the N. Y. State Agricultural Society, for which great preparation has been made, will take place at Auburn, commencing July 10th. Entrees must be made at least one week previously at the Secretary's office in Albany. Schedules of duties of committees, requirements, etc., will be furnished by Col. B. P. Johnson, the Secretary.

The Trial of Implements, Horse Powers, etc., conducted under the auspices of the same society, takes place at the same time and place, and subject to the same conditions. Schedules are prepared for Horse-rakes, Tedders, Hay-presses, Thrashing Machines, Horse-powers, Fan-mills, Hay and Stalk-cutters. Arrangements for Loading Hay, Unloading, Sheaf-binders, and Portable Engines. This meeting will be an exceedingly important and interesting one. Every machine will be put to severe practical tests of every part, under the eye of numerous committees of practical farmers and mechanical experts.

Kidney Worm in Hogs.—S. P. Rogers, Uniontown, Knox Co., Ill. Swine are subject to a variety of parasites, such as *Cysticercus cillulosa*, *Asearis*

suilla, *Spiroptera strongylina*, *Trichina spiralis*, *Distomum hepaticum*, etc., etc. Without seeing the parasites to which you refer, or having a more full description, it would be impossible for us to classify them.

Not Too Late to Plant and Sow.—If there be any land in the garden from which early crops have been removed, it should not lie idle, for it is not too late to get another crop than weeds, from it. If a crop has failed from bad seeds, late frost, insects, or "bad luck," which is usually another name for neglect, it is not too late to put in another. There are yet three months at least of "growing weather," and it is not too late to do a good amount of gardening. The whole class of salad stuffs can be kept going—cress, radishes, lettuce, and endive, the best of all late salads. Pickles are to be looked out for, and cucumbers, the staple pickle, may be planted now with good results; melons will make fruit large enough for mangoes, gherkins, the little prickly West Indian fellows, may be grown if one likes them, and Nasturtiums will grow famously in the hot months. Bush beans, for snaps and pickles, and a patch of Early Sweet Corn may be put in for a late supply. Young beets and carrots may be had for the sowing, as may Kohl-rabi and spinach. Now is as good a time as any other for sowing ruta-baga and French turnips. There are probably other things which may yet be sown. Better plant every spare space and get only a partial return, than to allow it to run to weeds, or to keep it clean and get nothing.

A New Way of Raising Forest Trees.—The N. Y. Times, in matters relating to agriculture and horticulture, manages to print more absurdities and crude things, than any other daily paper, and that is saying a good deal. Here is something from its issue of May 27th, which, while it may mislead a few, can only be amusing to those who have but the most general notions about propagating plants.—We quote: "A correspondent, writing to us on this subject, Raising Forest Trees, says he knows of a case in which the experiment of sowing the pollen of the elm, maple and other hard-wood trees has been made with perfect success. That of the English and American varieties of elm, and the maples, never fails to grow in moderately good soil. Our correspondent is satisfied from his own observation that if the pollen could be scattered over any good soil, even if in no other way than by the high winds which prevail on those plains, it would in many cases, particularly if the soil is at all loose, produce young trees. Whether they would stand the heat and want of shade of the region referred to, is, however, a question for decision. Bushels of the pollen of the elm and maple trees can be gathered at this season at any place where these trees abound, and that of some others can be had later."—How could a paper print such nonsense? When this writer has raised his trees from pollen, we recommend him to keep a flock of cocks for their eggs, and a herd of bulls for dairying purposes.

Early Peaches.—Early in May we had from the orchard house of Isaac Pullen & Son, Nightstown, N. J., some very fine specimens of peaches. The variety was Hale's Early, beautiful to look at and as good as they looked. This variety besides being very early and good, is also a very knowing peach, for one of the specimens, instead of taking on the usual red cheek, blushed into the name of the senior Publisher. This producing names on fruit is a very pretty trick. It is done by cutting out the letters from a piece of paper and binding the paper on the fruit just before it colors. The light passes through the openings in the paper and produces the color, while the rest of the fruit remains green.

Sweet Hard-shelled Almond.—"L. H. C.," New Madison, O.—This almond is usually budded on the plum. The tree is hardy in N. Y. State, and will probably do well with you. It is worth cultivating for its beauty while in blossom, even if it yielded no fruit.

Warder's Fruits.—We are able to announce, as we go to press, that we have in hand a book on American Fruits, to be fully illustrated and brought down to the present season, by that distinguished pomologist Dr. JOHN A. WARDER, whose name alone will place it among the standard literature of this subject.

Gladiolus from Seed.—"Subscriber" has often tried to raise Gladiolus from seed. "They come up well and grow finely during the spring and summer, and that is the last of them." As soon as the leaves begin to turn yellow, water should be withheld and the pots kept until spring in a dry place where they will not freeze.

French Flour in New York.—Two or three small invoices of French flour (equal in quality to the highest grade of Southern Ohio Family Extras) have

been received and sold in the market within the past month at \$14.50 to \$15 per 100 lbs.

The Strawberry Crop.—We have made several incursions upon the strawberry growers, but as we go to press before our observations are completed, we must defer our notes until another month. Suffice it to say that near New York the crop is small, though from the increased number of growers there is plenty of fruit in market. Last winter was very hard on the plants, and our notions of hardiness have to be considerably modified. Wilson's Albany, which has heretofore been most reliable, does not, in New Jersey, give more than half a crop, and in some cases none at all. This season we shall know more about the merits of the newer varieties. In Southern New Jersey the "Agriculturist" has done splendidly, in other places not so well. We get the first report from the West from the Terre Haute, Ind., Express:—"Yesterday morning Mr. G. W. Shaffer of the Elmwood Nursery 'dumped' on our table several baskets of the finest strawberries ever placed on said table. The varieties embraced the great Triomphe de Gand, the Austin Shaker, excellent for table use, the plump sweets Hooker, the prolific Wilson's Albany, and the much talked of Agriculturist. We saw nothing at the late exhibition that equalled the "Agriculturist." Among the Wilson's Albany was one berry that measured six inches in circumference. These berries were grown at the Elmwood Nursery of Messrs. Shaffer & Co., and exhibit rare culture."

Spattering Churns.—J. J. Powell, of Ontario Co., N. Y., stops the spattering of his wife's churn by passing the handle of the dasher through a block 5 inches long, with a hole through it a little larger than the handle; the block resting on the churn top. A leathern washer on the handle, made of a circular piece with a cut from the center outward, and the edges lapped so as to give the washer the shape of an inverted funnel, is often used, to good advantage.

The Growing Crops—What is their Condition and Prospects?—As a matter of general information, we solicit frequent and continued reliable information in regard to the condition and prospects of the staple grain, grass, and fruit crops in all parts of the country. Let every one writing a business letter, and a multitude of others who have nothing else to write about, send us brief but careful notes upon the crops, extending over as wide a section as possible, within their personal observation. We cannot publish many of such reports, but a multitude of them concentrated here will enable us to form a correct general estimate for the whole country, highly valuable to all our readers.

A Woe Swarm.—Mr. Bidwell, of Bidwell Brothers, writes: "Our little girl wishes me to send the following message: 'My wee, small swarm of bees, is little smaller than Master Judd's little hen's egg. It's only my two little hands full; and such beauties—while papa's swarms are two big hats full!' I will add, that the day being windy, only a few came out, with a young queen. On the next morning the old queen swarmed with 8½ lbs. of bees, while the wee swarm only weighed with the little bush on which it lit a quarter of a pound!"

Subsoiling (To "J. B.") is of greater benefit upon thorough-drained land than on that not drained.

Architecture.—A new book of "Designs, etc., for Street fronts, Suburban Houses and Cottages, etc.," by M. F. Cummings, Trny, N. Y., and C. C. Miller, Toledo, O.—Just as we took up the book before us with the view of writing a notice of it, the following question from "W. S. W.," Kokomo, (State not given), was laid upon our table.—"Mons. Ed.: Where can carpenters get an 'Architect' (book on architecture) that will give the most extensive details, together with plans and elevations of both city and country buildings, etc. Please answer, giving price, etc."—Except that there are few or no plans, and these anybody can make, (no one is suited with ready-made plans), this, it strikes us, is just the work called for. The book is a folio, and consists of 52 elaborate plates, in which the designs are drawn rather small, and enlarged in detail on a scale ¾ inches to the foot. The details, etc., are both simple and elaborate, and in the enlarged portions every board and moulding may be directly seen and measured. It is published by the authors. For sale at the Office of the *American Agriculturist*, or sent post-paid for \$10.00.

The Little Corporal deserves promotion among the little folks. It has made a good year's campaign, "Fighting for the good, the true, and the beautiful," and now takes the field again with 35,000 troops to back it. Volunteers are still called for in our advertising columns, and good rations are promised to all who enlist.

Top-dressing Grass.—"You say in the March number of the *Agriculturist*: 'We do not believe in top-dressing with animal manures in the spring.' Please inform me, why you do not?" 1st. Practically, it has been demonstrated to our satisfaction that grass makes the best use of bulky manure in the late summer, or autumn. That there is no time when the crop will be so much affected by manure as just after one crop is removed, so much so that we advocate applying manure or compost directly upon the freshly mowed fields.—2nd. Theoretically.—The grass in the autumn and after cutting has no chance to mature seed, hence its strengthening its roots to bear the winter and produce seed in the spring. The manure comes in time to help it do this very well. The dry ground is open, and as the showers carry down the enrichment, it is quickly taken up. In the spring, the feeding roots are not very active until the leaves have pushed well, and the ground is full of moisture, and so does not take up the manure with such avidity; besides there is danger of washing rains. We approve entirely of liquid manure, or of soluble top-dressings like guano, unleached ashes, plaster, etc., applied in spring.

Plants Named.—G. Taylor, Hammonton. Apparently the Grape Hyacinth, escaped from cultivation. The plant was figured in October last. M. R. A. York Co., Me. *Geranium maculatum*, Cranesbill; and the one previously sent; *Aralia trifolia*, the Dwarf Ginseng, sometimes called Groundnut. M. Helme, Adrian, (no State). *Anemone nemorosa*, the Wind-flower; *Senecio aureus*, Golden Rag wort, or Squaw Weed; *Equisetum arvense*, often called Ground Pine; and a *Vicia*, too poor to make out. L. Lauber, Lane Co., Pa. The "little bell" is *Staphylea trifolia*, the Bladder-nut, figured in May, 1865; the other is *Viburnum Lentago*, Sweet Viburnum, and also called Nanny berry about New York. Jas. B. Hay, Watertown, C. W. *Atrage Americana*, a beautiful climber related to Clematis, and the Pearly Everlasting, *Antennaria margaritacea*. N. C. A. Hawley, Pa. *Trillium erythrocarpum*, the Painted Trillium. J. K. Kepner, Olmstead Co., Minn. The prostrate evergreen shrub is *Arctostaphylos Uva-ursi*, the Bear-berry, sometimes called Upland Cranberry.

Hollyhocks from Seed.—M. Irvine.—If seed from double flowers were planted, you may expect a good share of yours to be double. If any come single, pull them up as soon as they show their character, and save seed only from the best flowers.

Bone Dust in Pot Culture.—Mrs. M., Washington, D. C.—A very small quantity might be serviceable to roses and similar plants, but not enough should be added to produce active fermentation. There is always great danger in the use of manure upon delicate plants. Good earth with plenty of leaf mold and sand, is usually rich enough. If manure is used at all, let it be well decomposed, like that from an old hot-bed, and thoroughly mixed with the soil before potting.

"China Cabbage and Beans."—R. J. Thank you for your good intentions, but the seeds did not reach us.

Tan Bark for Strawberries.—C. Stick, Union Co., Ill. There was a notion sometime ago, that tan bark was a specific manure for strawberries on account of the tannic acid it contains. Now it is generally admitted that its chief, if not its only value, is its mechanical action as a mulch.

Potatoes Under Straw.—J. Holloher, Manchester, Mo., will find this subject discussed in the *Agriculturist* for November, 1865. We cannot see any reason why they should not keep as well and be as wholesome as potatoes raised in any other way.

The Grape-vine Flea Beetle.—C. Brinton, Lancaster Co., Pa., sends us specimens of this little steel blue beetle, which is the *Haltea chalybea*, of the Entomologists. It is very destructive to the buds of the vine, and we have heard more of it this year than ever before. The insect is only about one-sixth of an inch in length, and appears very early in the season. They are easily shaken from the vines, may be caught on a sheet and destroyed. We know of no other remedy.

Grapes and Wine.—"The Cultivation of the Native Grape and Manufacture of American Wines. By George Husmann, of Hermann, Mo." The above is the title of a new work on the grape, published by Geo. E. & F. W. Woodward, New York; and written by a gentleman well known as a contributor to our horticultural journals, and as an extensive cultivator of the grape. The work is eminently practical and tells in plain language just how the author raises grapes and makes wine. There is a great deal of individuality about ev-

erything that Mr. H. writes, and this book is no exception; as to varieties, he claims to give only his experience in his own locality, and here he is very decided. What will make this work particularly acceptable is the treatise on wine making, in which the directions are full and clear. Probably the author will receive some adverse criticism for his advocacy of Gall's method, but this is a subject that has two sides, and we know of no one better able to defend himself than Mr. Husmann. For sale at this office and sent by mail at \$1.50.

Filling up around Trees.—H. O. Crane wishes to know if it will be likely to insure his trees to fill up around them nearly two feet. It will be very likely to damage them. It puts the roots too far from the surface.

A Batch of Tree Queries.—M. L. Carter, De Kalb Co., Ill. Quince stocks are more generally budded than grafted. Stone fruits may be grafted, but the wood is apt to gum, the plum less so than others. It is better to graft one year old stocks by whip-grafting, than those two years old by cleft-grafting, as a much more perfect union results. Whip-grafting may look difficult in the description (Jan. 1864), but it is perfectly easy in practice. Try it on a few twigs. Any blacksmith can make a scuffle hoe, if you show him the engraving. The other queries we are unable to answer.

What is the Matter with the Twig?—H. O. Crane, Brown Co., Wis., sends a twig from an apple tree which exhibits about the worst case of the bark scale we ever saw. It should have been attended to before the leaves appeared. A strong solution of soft soap or moderately strong ley, (1 lb. potash to 4 gallons of water,) applied thoroughly with a scrubbing brush, will remove them. Head back the tops if the small limbs are affected, and get a fresh growth.

Poppies for Bugs.—Mr. Julius Price, Whitehall (no State), sows poppy seed in the hill with his squash, and other seeds, and finds that the bugs do not trouble the vines. The poppy is usually so slow and uncertain about coming from seed, unless self sown, that we doubt it will be a very reliable remedy.

A Persevering Lily.—D. C. Martin, Dauphin Co., Pa., writes that he filled up his yard 2½ feet with solid yellow clay, and that a Tiger Lily that was in the soil beneath forced its way to the surface, where it found a board a foot long and half as wide, which it lifted as it grew.

Birds and Cherries.—D. Yarrington, Luzerne Co., Pa., complains of the raids of armies of birds—which do not leave him a single early cherry. Scarecrows, cow-bells, and colored streamers have no terrors for them, and he pathetically asks: "Is there no help for this evil?" Probably the only sure way is to grow trees with low heads and cover them with netting.

A Mad Stone.—One of our correspondents wishes us to advertise a "mad stone," which we must decline doing, and advise him, if the stone is very mad, to send it to the nearest Lunatic Asylum. This is a revival of an old superstition that certain stones have the power to cure those bitten by rabid animals. We are surprised to find that any believe in it at the present day.

The Civil War in America, by Benson J. Lossing. We have received from the publishers the first volume of this work, a handsome book of over 600 pages, very copiously illustrated. The author is well known for his industry and accuracy in collecting historical materials, and he has brought together in the present work a picture gallery of persons and places identified with our great struggle, which is of great interest now, and will be of immense value in the future.

Sponge for Rats.—"Piper, of Hamlin, Jr.," sends us an old prescription for getting rid of rats and mice that may be new to some. He soaks bits of sponge in melted tallow, and when cold, places them where the vermin will find them. They eat, get the dyspepsia, and either die or go where they are not "sponged upon."

An Article on Trichinae.—A gentleman sends us a communication on this subject, but as he fails to say where he lives, we cannot reply by letter and take this method of informing him that no amount of argument can overthrow a fact. Our article was not published without its first being seen by the editors, and its statements are in accordance with later and more extensive investigations in this country and in Europe.

The Rinderpest, notwithstanding the great precautions taken, has broken out in Ireland. A

single case occurred in County Down, where immediately measures were taken to prevent its spread. This time there was no temporizing—no attempts at cure, no time taken to study the pathology, nor to get a diagnosis of the case, nor to allow veterinary surgeons nor homeopaths to try to cure or arrest the infection, but the pole-axe had everything its own way. The cow was killed; all that had been exposed were killed and buried, a cordon was placed around the farm, and all travel by cattle upon the roads was stopped, and all the cattle fairs were put off throughout that entire region. We can but confidently think there is hope for Ireland that these energetic measures will stay the plague.

Tobacco Worm Moths.—These large moths fly at night and suck honey from flowers which open towards evening, and are not visited by the bees. Such are especially the showy flowers of the common Evening Primrose (*Oenothera*), and the Stramonium, which indeed is open all day, but it is showy, and they find it easily at night. Poisoned honey may be placed in these flowers, and it will kill great numbers of the moths. Get the apothecary to rub a grain of strychnine in an ounce of honey, dilute it with about half its bulk of water and put a few drops in these or any flowers visited by these large night-flying moths. It is best to take flowers that will wither when the sun rises, or to pick the flowers, so as not to kill bees, when they come out.

Mississippi Crops.—"Subscriber" writes from Columbus, May 27: "Freedmen entered their new career with laudible industry, and in most cases have complied with contracts, giving very general satisfaction. Owing to unfavorable weather our hopes have very much decreased. Cotton has germinated badly. Excessive rains have hindered cultivation, and crops have suffered very much. The low lands have been drowned out. The corn crop is the poorest I have ever seen in this county. There was not a sufficiency planted for home use, many thinking it cheaper to raise cotton and buy corn; and the wheat crop is almost a total failure. It is too late to replant cotton; corn may yet be planted on the overflowed lands, and if the season is favorable, make something."

Sunburnt Bricks — Adobe.—Hawley Ross, writing from Quincy, Ill., says, in answer to a question in the February *Agriculturist*: "There was a Congregational Church built in Niles, Michigan, in 1846, of unburnt brick. As near as I can remember the size is about 40x80, walls about 20 feet high. I saw the bricks when they were building; they are 6 inches thick and 2 feet square with a good deal of straw mixed in the clay to hold them together, and then dried in the sun. The roof is shingle, put on the same as for a brick house; it is plastered with cement on the outside, and common plastering on the inside." The church has a steeple with one of the largest sized Western church bells. I attended meetings most of the time in this church for 15 years, but have not seen it for four or five years."

Adobe Houses.—"G.," of Eden Gardens, Canada West, writes: "A neighbor of mine built a house of adobe twenty-two years ago, and up to last summer it had stood perfectly sound. The house was built one and half stories high, 18x36 feet, and covered with shingles. The walls were plastered on the outside with lime mortar and rough-casted with gravel. The proprietor, wishing to make some alterations in the building last summer, took down a portion of the walls and used the adobe again in the same building. The bricks were made 18x12 inches and 6 inches in thickness. There was one small spot in the wall near the base where the plaster had been knocked off; the adobe had suffered somewhat from the action of the weather. Latitude here 44½ Degrees."

Double Dashers in Churns.—John Bennet, of Rivler Co., Ind., says: "Tell your readers that it pays to put a double dasher in their churns. It saves half the trouble churning."—Perhaps it does.

Cranberries.—E. H. Webb, Wayne Co., Ind.—A piece of ground covered during the winter with water from surrounding slopes, dry in summer, and which cannot be drained, is not a promising place for cranberries. Drainage and command of water are considered essential. We have no confidence in the profitable culture of cranberries on upland.

Trouble with a Lemon Tree.—Mrs. Judge B., Butler, (no State). The little bug that "seems to have no life," is probably the cause of the trouble with your lemon tree. It is one of the scale insects, and is often very injurious to hard-wooded house plants. Strong soft soap suds, if applied with a stiff brush, will usually kill them, if they do not yield to the brush, rub the bark with a soft pine stick, or corn cob, to remove them.

Darkened Counsel.—"A" thinks that he does not profit much by reading agricultural articles as "Statements are made by the learned writers one week to be flatly contradicted the next." We judge from his quotations that he reads the reports of the Farmers' Club, which is great on flat contradiction. It cannot be expected that men from the sandy portions of Long Island and New Jersey should agree with those from Westchester Co., upon manuring strawberries, or anything else. Whether it be true that Isabella Grapes "will make a pig squeal," we cannot say. Those we had last year, from Crooked Lake and Doct. Underhill, were too good to waste in such experiments.

Poisoned Flour—Caution to Millers.—A whole community in Orange Co., N. Y., have been poisoned, some fatally and most of them seriously, by means of lead which was introduced into their flour through the almost criminal carelessness of a miller. The lead was used to fill cavities in an old mill stone, and in the process of grinding was of course rubbed to powder and mixed with the flour. In this way, some 300 persons have been subjected to more or less severe lead-poisoning. If other millers are in the habit of repairing their stones with lead, let them take warning. The lead in this case was so finely divided as to be invisible, and its presence was only suspected from the cases presenting the symptoms of lead-poisoning.

Transplanting Carrots.—"L. H. C." asks, if it will pay to transplant Carrots. Probably not, as a general thing; though in the small way in the garden, it may be well to fill wide gaps in this way. To succeed, it must be done when the plants are very small.

Which is Best?—Mr. Hayes writes: "I have no tame grass yet. Which is best for corn fodder; to plant in hills, take off the ears and cut the stalks in the usual way, or to plant thickly in drills and cut stalks and all?"—The latter usually, for most fodder.

Mullein Leaves to Drive Away Rats.—At the suggestion of a friend, the writer, with little faith in the measure, once tried laying Mullein leaves around the rat holes in his cellar, to drive the rats away. In a short time, the leaves were mainly gone. More were laid down, but were not taken away. The rats were gone. These are the facts in that case. Why the rats went, is not known, unless the leaves gave them pain or alarm.—Other like experiments will be easy, where Mullein grows.

Walks and Talks on the Farm.

No. 31.

A few days ago I received the following letter from our friend, John Johnston:

New Geneva, N. Y., May 17th, 1866.

Dear Sir.—"Draining on the brain" will never hurt farmers. They will gain grandly during the disease, and get fat after they get over it, that is, if it has continued long enough.—I believe if I had you here for an hour I would give you another brain complaint that would ultimately help to fatten you. True, I could write out the prescription, in a way, but I can tell you there is nothing like seeing to make people believe. I would meet you any morning at the depot for the early train, bring you over to breakfast on ham and eggs, give a dinner of the same; take you over for the 4 P. M. train, and if not satisfied with what you have seen, you can charge me your fare back."

I went, and, of course, had to pay both ways! I think it was Walter Scott who said he was never thrown into the company of any man, however illiterate, without learning something useful. And certainly he must be a dull scholar who can visit a farmer of over forty years' experience, without picking up information that can be turned to good account. I have visited John Johnston a great many times, and wish every young farmer in the country could enjoy the same privilege. He is so delightfully enthusiastic, believes so thoroughly in good farming, and has been so eminently successful, that a day spent in his company cannot fail to encourage any farmer to renewed efforts in improving his soil. "You must drain," he wrote to me when I commenced farming, "I never made any money till I began to underdrain." But it is not underdraining alone that is the cause of his

eminent success. When he bought his farm, "near Geneva," over forty years ago, there was a pile of manure in the yard that had lain there year after year till it was, as he said, "as black as my hat." The former owner regarded it as a nuisance, and a few months before young Johnston bought the farm, had given some darkies a cow on condition that they would draw out this manure. They drew out six loads, took the cow—and that was the last seen of them. Johnston drew out this manure, raised a good crop of wheat, and that gave him a start. He says, he has been asked a great many times to what he owes his success as a farmer, and he has replied that he could not tell, whether it was "dung or credit." It was probably neither. It was the man—his intelligence, industry, and good common sense. That heap of black mould was merely an instrument in his hands that he could turn to good account.

His first crop of wheat gave him "credit," and this also he used to advantage. He believed that good farming would pay, and it was this faith in a generous soil that made him willing to spend the money obtained from the first crop of wheat in enriching the land, and to avail himself of his credit. Had he lacked this faith—had he boarded every sixpence he could have ground out of the soil, who would have ever heard of John Johnston? He has been liberal with his crops and his animals, and has ever found them grateful. This is the real lesson which his life teaches.

On my return home, I got from the post office a book entitled "High Farming without Manure." I thought, when I first saw it, that it was probably an account of the Rev. Mr. Smith's experiment in raising wheat year after year on the same land without manure, in which he succeeded in raising heavy crops simply by good tillage. There are many examples of the same principle in this country with corn, on rich bottom land. Good, clean culture has given, for many years in succession, large crops of corn. It is well understood—or rather it ought to be well understood—that good tillage, or stirring the soil, decomposes the organic matter in these rich lands, and enables them to produce large crops without manure. But in reality the manure is in the soil, and working the ground simply makes it available. The principle is true of all naturally good soils, upland and alluvial. It is a great truth, and those farmers are wise who recognize it, and keep the cultivators running.

But shall we depend on tillage alone? A man may be so placed that for a year or two he has nothing else to depend upon. He may have taken a "run down" farm, and cannot get manure. In this case he will cultivate a portion of his land in the best manner possible. He will kill the weeds, and make the soil clean and mellow, and if the soil is naturally good, and the season favorable, he will get a fair crop. But will he adopt this as a system? Not he. I will guarantee that any farmer who has energy and intelligence enough to work his land thoroughly, who will cultivate his corn, for instance, every week or ten days as long as he can get a horse through it; such a man, I say, will not stop here. He will make all the manure he can. And so on the other hand, if you find a man who takes special pains to make and apply manure, you will find that he also cultivates his land thoroughly. I have never known an exception.

As a general rule, there can be no such thing as "high farming without manure." Were such a thing profitably possible, our barn yards and premises would soon be reeking with decomposing matter, and noxious gases would pollute the air. We should lose one of the grand incentives to cleanliness, and nothing but the fear of some malignant disease would cause us to keep our premises sweet and clean. But now the very things which are most injurious to health, are the very things of most value in increasing the crops. Depend upon it, no discovery will be made whereby we can profitably dispense with manure.

"But you did not tell us what Mr. Johnston wanted to show you." I am coming to it. Mr. J. makes a great deal of manure, and what is better, he makes good manure. He fats a flock of sheep

every winter, giving them corn and oil cake, and in the spring, after he has sold his sheep, he throws the manure up into loose piles, and turns them once or twice till they are thoroughly rotted. This manure he spreads early in the fall on his grass land that he intends breaking up for corn in the spring. This is his usual practice. But a year ago last fall, when sowing his wheat, he put on a slight dressing of manure on two portions of the field that he thought were rather poor. The whole field was seeded down with Timothy in the fall at the time of sowing the wheat. No clover was sown. This spring those portions of the field dressed with manure are covered with a splendid crop of clover. You can see the exact line in both cases where the manure reached. It looks very curious. No clover seed was sown, and yet there is as fine a crop of clover as one could desire.

On looking into the matter more closely, we found that there was more or less clover all over the field, but where the manure was not used it could hardly be seen. The plants were small, and the Timothy hid them from view. But where the manure was used, these plants of clover had been stimulated in their growth till they covered the ground. The leaves were broad and vigorous, while in the other case they were small and almost dried up. This is doubtless the right explanation. The manure did not "bring in the clover"; it simply increased the growth of that already in the soil. It shows the value of manure for grass.

This is what Mr. Johnston wanted to show me. "I might have written and told you, but you would not have got a clear idea of the matter." This is true. One must see the great luxuriance of that piece of clover to fully appreciate the effect of the manure. Mr. J. said the manure on that grass was worth thirty dollars an acre—that is on the three crops of grass before the field is again plowed. I have no doubt that this is true, and that the future crops on the land will also be benefited—not directly from the manure perhaps, but from the clover roots in the soil. And if the field were pastured, the effect on future crops would be very decided.

I spend an hour or so on Mr. Sheldon's beautiful farm—looking at his splendid herd of Shorthorns. As I drove up I passed the finest field of young grass and clover I ever saw. I asked a man who was at work near it what Mr. Sheldon had put on the field that made the grass so big. "Nothing, as I know of," he said, "it's capital land." Is this high farming without manure? Not a bit of it. The field,—about twenty acres,—was manured heavily in the fall on the sod, and plowed up and planted to corn, receiving good culture. It was then sown with oats, followed by wheat, and seeded down with a peck of Timothy in the fall, and six quarts of clover in the spring. The wheat received a good dressing of manure. And those acquainted with Mr. Sheldon's mode of feeding, will know that the manure is not simply rotted straw. It is as rich as can be made from stall-fed cattle. This is the secret of the magnificent crop of grass. It will doubtless cut three tons to the acre, at least—and this fed out will give more manure, and so the land is kept continually improving. Good grass and clover are the bases of good farming.

What a pest red root is! You have heard me make that remark before! Well, if you suffered as much from it as I do, you would excuse me. You recollect where I had beans last year. No land could be cleaner. It was in wheat the year before when I took the farm, and was so full of couch-grass that I concluded not to seed it down, but to try my hand at killing the quack. After the wheat was off, I plowed the land and harrowed it, and just before winter set in I plowed it again. In the spring I run the cultivator through it, and harrowed; then plowed again, and harrowed, and cultivated again, and then harrowed and raked up the quack into heaps, and burnt it. I then planted it to beans, and kept them thoroughly cultivated and hoed. Last fall I sowed it to wheat. I do not think there is a root of quack left, but the red root came up by the million!

Now what I ought to have done is this: Instead

of sowing wheat, I should have sown rye, and manured it. Then this spring it could have been fed off with sheep, or cut for the milch cows, and the land then plowed and planted with corn or beans. Red root, it is said, only grows among winter wheat; but if you will prepare the land precisely as you would were you going to sow wheat, and then let it lie bare, or sow rye, the red root will be checked! It will germinate in the fall, and you can plow it up in the spring. Red root is easily destroyed. What renders it formidable is, the fact that it only germinates in autumn and gets into our winter wheat, where we have no chance of destroying it. If we prepare our land for wheat, and then sow rye instead, and eat this off or mow it in the spring, and then plow the land and plant beans, we should destroy large quantities of it—and as we could sow wheat after the beans, it is only delaying the wheat crop one year. The rye, if sown early and manured, would give us a great crop of succulent food early in the spring, and would be just what we need for milch cows, or for ewes and lambs. For the latter purpose, rye is frequently grown on light lands in England. Where lambs are raised early for the butcher, I do not see why it would not be very valuable. You think it would make the land too rich for beans. If so, give up the plan of sowing wheat the next fall, and plant corn instead of the beans; or, what is usually done in England, sow turnips or some other root crop. But I do not believe the manure would hurt the beans. I think it is a mistake that beans require such poor land. If well cultivated, they will mature quite as early on rich land as on poor, and give a far better crop. But they must be kept clean. My beans last year paid me better than any other crop I raised, and I have put in ten acres this season. If the price is low, it will still pay to raise them to feed to sheep and milch cows. No grain makes such rich manure, and nothing is better for milch cows than corn and bean meal mixed together. Then there is this advantage about beans, they need not be planted until you are through the busy of spring work, and they are off in time to sow wheat in the fall, and as they are drilled in rows two and a half feet apart, the land can be cultivated with the horse-hoe and *can* be made as clean as if summer fallowed. I say *can* be, because this is seldom the case. Harvest work comes on, and the cultivators are thrown aside, and before you know it, the beans are full of weeds, and you lose one of the chief advantages of the crop. Then what a pleasant work it is to pull beans among thistles! I have known farmers "go into beans" with great enthusiasm, thinking to make their fortune, who soon gave them up in disgust simply because they neglected to keep them clean. I saw a crop last year that was completely smothered with weeds, and was not worth pulling.

Beans are an excellent crop, but must have clean culture. They should not be worked amongst while the dew is on, as it is said to rust the leaves, but otherwise you cannot cultivate them too frequently. "What do I suppose is the reason there is so much red root in the wheat after beans?" Simply because the land had been so frequently plowed and cultivated, that all the seed in the ground germinated. It was just what was needed to destroy the red root, provided it could have been plowed under this spring. As it is, it will trouble me for years to come. I believe it would have paid to have plowed up the wheat and sown it to barley. As the seed that was in the ground doubtless all germinated from the repeated plowing and harrowing it received, this would have rid me of the pest.

I have just been sawing wood with a machine and three horses and four men. I believe I could have got it saved cheaper by hand. That is not a "progressive" idea, but I am inclined to think it is a fact nevertheless. I know if you have everything just right you can do work cheaper with machinery than by hand, but the trouble is to get everything just right. If a man made a business of sawing wood, he could saw it cheaper with a good machine than by hand, because he could keep his machine in order. But when you have only a little wood to

saw, it takes half the time to get fairly started and everything working right. The saw perhaps is a little rusted, or it is not sharp, or it is not set quite true; or if the saw perchance should be all right, something may be wrong with the horse-power. It is not set right, and the belt rubs or comes off, or there is a screw loose, or a little casting breaks—and you have to stop all hands and send a hundred miles for a new one. Those who depict so eloquently the pleasures of modern farming by machinery, draw more on their imagination than their experience. I have tried it, and while I do not despair, I am often discouraged. I have a machine with which I can, and do, turn the grindstone, cut fodder, thrash, grind the grain, drive the cider mill, saw wood in the log with a drag saw, or cord wood with a circular saw. This it will do, and do well, but oh, the care of keeping all these things in order and getting them to work well. I have a potato planter, that at one operation marks out the rows, cuts the potatoes, drops the sets, covers them up, and rolls the ground. Also one that drills twelve acres of corn and beans in a day, and does the work well. We have cultivators that leave very little to be done with hand-hoes. We have mowing machines and reapers that leave little to be desired in this direction. The tedding machine shakes out the hay as well as it can be done by hand and five times as fast, the wooden revolving rake pulls it into wind-rows, a pitching machine attached to the back end of a wagon will carry the hay on to the load, and a steel toothed sulky rake makes all clean. Then at the barn we unload with a horse fork, and the farmer can sit in the shade smoking the pipe of contentment as he witnesses the operation. Then we have a machine for milking cows, and another to work the butter, while, if you make cheese, the American vats and presses make the labor mere child's play, compared with the old Cheshire system. I have not tried these last named machines, but I have little doubt that they work as well as some of the others I have named. The grain binder, too, I have faith enough to believe will soon be attached to every reaper, and then with a steam plow and a good potato digger, won't farmers have an easy time? Not a bit of it. If these things would run themselves; if they never got out of repair; if they had no disposition to lie round loose, but would put themselves up, then indeed we should be "gentlemen of leisure." But this will never be. We can change our work, but we can never get rid of it. If we do not work with our muscles, we must with our brains. And the encouraging feature of this age of invention is not that these "labor saving machines" do the work so much cheaper, as that they change the character of the labor required in agriculture. They lessen back-breaking drudgery, and increase mental activity. A farmer who uses a good deal of machinery cannot be dull and stupid. It will make a man of him.

I expect great things from the young farmers of America. There is everything to encourage them: soil, climate, social position, political influence. The destiny of the country is in their hands. But they must not expect to live lives of ease and luxury. Brains rather than muscles will be required in the new condition of our agriculture. Machinery will stimulate mental activity, and encourage the growth of that rare grace, patience!

I look forward with much interest to the trial of implements at Auburn on the 10th of July. Great pains have been taken to secure reliable results. I think, however, from the Programme on Horse Powers, the only one I have seen, that too much importance is given to "effective force," as a test of merit. Of course, other things being equal, effective force—or ease of draught in accomplishing a given amount of work—should secure the award. But unless the "other things" are taken into consideration, we may get a decision that will be an injury to agriculture rather than a benefit. I can imagine a horse power that runs very easy, and which might take the prize, that would prove a nuisance on any ordinary farm. The one great defect of American agricultural machines is, their liability to breakage, and to get out of repair. No

matter how effective a machine may be when it is properly set and run by an experienced machinist, if from an inherent defect in the principle of its construction, or of workmanship, it is very liable to break when not set exactly true; or if its arrangements are complicated, so that ordinary farm men cannot run it. I should greatly prefer some less effective but simpler machine, that is strong enough to stand the abuse that it will be sure to meet with in ordinary farm practice. On a farm large enough to use a sweep power to advantage, an extra horse at a season when it is most used is of little consequence. In the winter season, for instance, in chaffing fodder, or grinding feed, or sawing wood, I would about as soon put on three horses as two, or five as four—that is if there is anything gained by it. I am not arguing in favor of keeping more horses than we need. I think this a great mistake. All I wish to show is, that an extra horse, during a leisure season, or at a time when all the men on the farm are employed in attending the machine, is nothing compared with the loss of time and annoyance caused by a machine that is forever getting out of order. In the hands of a careless man an ordinary watch, for his purposes, would prove more useful than a delicate chronometer.

How wretchedly poor most farmers keep their store hogs. Having more milk than my pigs would eat, I rode round to see if I could buy a few. I called on a dozen farmers or more, and did not see three that keep their hogs decently. In two or three cases the pens were filthy in the extreme. There is no excuse for it. If short of straw, the horse litter might be thrown into the pen. It would keep the pigs dry and comfortable, smother that horrible stench, and make a great quantity of rich manure. The pig is naturally the cleanest animal on the farm, why compel him to be the dirtiest?

"Breeding sows should not be kept too fat," is one of those popular notions, half true and half false, that leads to grave mismanagement and loss. Most of the sows I saw were ravenously hungry, and some of them appeared to have barely strength enough to walk, let alone suckling the little ones. Such treatment is cruel—and monstrously absurd. "Pigs are very scarce this spring," said one who asked me four dollars a piece for a litter five weeks old. "Mr. Blank, at the Corners, has six breeding sows, and only raised two pigs." I presume if he had twelve he would not have raised one. I bought one litter six weeks old, of a man who was overstocked, for \$2 a piece. Had they been fed as pigs should be, I would have given him \$4, and they would have been better worth it, for an animal starved when young never fully recovers.

High feeding and high farming must, as a general rule, go together. We cannot farm high without good manure, and we cannot get good manure without high feeding. This little French book of Prof. Ville advocates what he calls a new system of "high farming without manure." There is much in the book that is both new and true; "but what is true is not new, and what is new is not true." The Professor has been making some experiments on the Imperial farm at Vincennes, and found that by using nitrogen for wheat, phosphates for roots, and potash for leguminous plants, he could get large crops. This is not new. Mr. Lawes published the same thing sixteen years ago, as the result of his experiments, and thousands of farmers in England have acted upon it ever since. But will the use of these artificial manures enable us to dispense with ordinary manure, and will they pay? They are of great value when used in addition to manure; but, as a general rule, it is neither safe nor profitable to depend upon them alone. The real value of these experiments in France is their striking confirmation of Mr. Lawes' experiments in England. Ammonia for wheat, bones for turnips, and potash for clover, peas and beans. The practical difficulty is to get the former. It cannot be purchased except at a high figure, and in ordinary practice any system that will give us ammonia, will at the same time give us phosphates and potash. We get the whole in rich manure.

Gophers.—The Striped Gopher.

It would be a rather difficult task to describe all the animals which go by the name of Gopher. In March 1864, (p. 77), we published a description of the Pouched Gopher (fig. 2) which does much damage in many parts of the West, and is reputed hard to catch. If persistently followed up with the traps described in the April Number, (p. 138,) they would probably leave the farms. This animal is readily recognized by its very large cheek-pouches, short tail, big head, and peculiar claws, adapted for underground work. It is 9 to 10 inches or more in length to the tail, which is only about 2 inches long, and sparsely covered with short hairs. A family of them will do great damage to grain fields, and in laying in their winter stores. We are led to give this notice of the gopher, because a Wisconsin "critic," writes us about his gopher, as follows: "I find you have an erroneous idea of the gophers. They are not nearly as large as musk-rats, [we own here to a little not altogether unintentional exaggeration], but about the size of a weasel, and nearly of the same shape. One can carry about as much grain in its cheeks as a chipmunk, and they are similarly striped, except the lightest colored stripes are dotted with black dots. In heavy soils one or two pailfulls of water will drive them out of their holes; in sandy soil, it will take more. They do not like to have their holes disturbed, and in working my corn, I dig into and fill up their holes, and drive off most of them." The animal described by our friend, is the striped gopher, represented in fig. 1. The wiseacres have given it the pleasant little Latin name of *Spermophilus tridecem-lineatus*. This beautiful little animal is about the size of the common Red squirrel, the tail is somewhat bushy, and half the length of the body. The color is dark brown above, with light stripes, and lines of light spots alternating with each other. The fourteen species of this genus are characterized by their squirrel like bodies, well developed cheek pouches, and by burrowing.

The Duchess Family of Short-Horns.

We give upon our first page a fine portrait of the head of Mr. Thorne's "4th Duchess of Thorndale." The Duchess family was brought into notice by the late Thomas Bates, of Kirkleavington, Eng., he having bought a fine cow of Mr. Chas. Colling, in 1810, which

was called Duchess. She was called by Mr. Bates, "Duchess by Comet No. 1," and was produced by a remarkable course of in-and-in breeding, and gives the name to this most remarkable and valuable of all the tribes of Short-horns." After he became possessed of his first Duchess, he "never," as he says, "used any bull that had not Duchess blood." The first Duchess was an extraordinary butter maker, and of Duchess 34th, dam to the fa-

have been brought to this country, for some of which prices, considered in England enormous, were paid by our enterprising countrymen. Altogether, 15 head have been brought here, and 3 others purchased, died on the passage.*

In 1857, Mr. Samuel Thorne purchased of Morris & Becar, their entire herd, and as they had never sold a female of pure Bates blood, he obtained all the imported ones then living, and their female progeny. The cow "4th Duchess

of Thorndale," is one of the best in the herd of Mr. Thorne, and is the mother of his famous bull, "6th Duke of Thorndale," an animal which has been repeatedly pronounced, by gentlemen familiar with the best herds of England, the best bull they ever saw. There has never been a public sale at Thorndale, but Mr. Thorne's private sales, 32 in number, all of Duchesses or Oxfords, and these mostly calves, and, with 7 exceptions, bulls, brought the sum total of \$45,650, or an average of \$1,427.50 each. Of these, 12 head were sold to English breeders and shipped thither in 1861 and 1862.

Fig. 1.—STRIPED GOPHER.—(*Spermophilus tridecem-lineatus*).— $\frac{2}{3}$ NATURAL SIZE.

mous bull Duke of Northumberland, Mr. Bates says, as a proof that Short-horns had improved under his care, that this cow "consumes one-third less food than my first Duchess (purchased in 1804), and her milk yields one-third more butter to each quart of milk. There is also a greater growth of carcass and an increased aptitude to fatten." We presume she did not give so much milk, or he would have mentioned it.

That the credit of this tribe of the combined Duchess and Oxford families has not lost strength, but rather gained among English breeders, notwithstanding their natural jealousies, is evinced by the most recent sales both public and private of this stock. At Mr. Hegan's sale which took place a year ago, at Dawpool, Eng., 17 of the descendants of Duchess 51st, brought £481 3s. each, as we usually

calculate, equal to \$2,405, which is by far the largest price ever brought, by a herd of Short-horns at public sale. The herd was small and very choice.

The heads of the Duchesses are quite peculiar, and are well represented in the engraving referred to. The whole poise of the head is peculiar; the dishing face, giving the marked prominence to the eyes and nose; the large, full eye; the clean jaws

Fig. 2.—POUCHED GOPHER.—(*Geomys bursarius*).— $\frac{1}{2}$ NATURAL SIZE.

The Oxfords originated in the Matchem cow, with which Mr. B. took the first prize at Oxford, and were used by him to cross with the Duchesses, and they have been so bred in with them that now-a-days Oxfords and Duchesses mean pretty much the same thing, and in this tribe also the family name follows the dam. Our readers should remember that by the common consent of breeders no cattle are now named Duke or Duchess, except those of that family. Nor is the name Oxford used except for animals belonging to the family of that name.

The reputation of Mr. Bates' herd has been long established, and many fine animals from it

and jowls, mark the family quite as distinctly as they do particular individuals.

What Constitutes Good Milk?

The quality of milk is a matter which concerns not only the consumer of the liquid as milk, but also those who make butter and cheese from it. Much has been said of late years concerning the reliability of the usual tests for the quality of milk, and the lactometer has been discarded by many as quite unreliable. Doct. Voelcker, chemist to the Royal Agricultural Society of England, has recently published, in the Popular Science Review, a paper upon "Milk and its Adulteration," in which he shows that for the purpose of detecting any amount of adulteration that would be profitable, the old method of testing is satisfactory. The article referred to comes from such high authority, and is withal so interesting, that we wish we were able to give it entire, but we must be content with making rather copious extracts.

"A variety of conditions affect materially the quantity and quality of milk. . . . Thus the season of the year and the amount and kind of food given to cows influence the yield and quality of their milk; again, the race or breed and size of the animal to a great extent affect the yield and quality of milk.

"Generally speaking, small races, or small individuals of the larger races, give the richest milk from the same kind of food. Where good quality is the main object, Alderneys or Guernseys unquestionably are the cows that ought to be kept, for they give a richer cream than any other kind in common use in this country; but of course Alderneys are not the most profitable stock for cow-keepers in towns, with whom the Yorkshire cow, essentially a short-horn, is the favorite breed, as it surpasses all others for the quantity of milk it yields. The milk, however, compared with that of the Alderney or Ayrshire cow, is more watery and less rich in butter, and therefore not well suited for dairies in which butter and cheese are made.

"In the spring of the year, and the early part of summer, milk is more abundant, and the butter made from it of a finer flavor. As the season advances, the supply diminishes, but becomes richer in butter. The influence of food on the quality of milk is very striking. A half-starved cow not only yields but little milk, but what it yields is miserably poor. On the other hand, the liberal supply of food, rich in nitrogenous and phosphatic elements of nutrition, tells directly on the milk.

"Nothing, therefore, can be more injudicious than to stint dairy cows in food.

"The finest flavored milk and butter, I need hardly say, are produced by cows fed in summer entirely on the grass of rich permanent pastures, and in winter on nothing else but hay made of fine short sweet grass. Eleven or twelve lbs. of grass produce about one lb. of milk, or a ton of good hay produces as nearly as possible one hundred gallons of milk. Few persons, however, having the opportunity of keeping cows for their own use, can afford to feed them in winter entirely upon hay. Turnips, mangolds, meal, brewer's grain, bran, or oil-cake, with more or less cut straw, in a great measure have to take the place of hay as a winter food.

"Turnips give a disagreeable taste to the milk, and moreover produce very watery milk.

"Mangolds are less objectionable, but should not be given to milch-cows without an allowance of three to five pounds of meal. Of all kinds of meal, none is equal in milk-producing qualities to bean-meal—a fact which finds a ready explanation in the circumstance that bean-meal

contains as much as twenty-eight per cent. of flesh-forming matters, or the same class of compounds to which the curd and albumen of milk belong, and that it is also rich in phosphates, or bone-earth. Pea-meal or Egyptian lentils closely resemble bean-meal in composition, and may be used with equal advantage as an auxiliary and excellent food for milch-cows. It is not a little remarkable that in leguminous seeds, which are always rich in flesh-forming matters, as well as in other articles of food, a large percentage of nitrogenous or flesh-forming compounds usually is associated with a large percentage of phosphates or bone-earth. There exists thus naturally an admirable provision in food, specially adapted for milch-cows, or young and growing stock, to supply the animal not only with the material of which the curd of milk, or the flesh of young stock consist, but likewise to supply bone materials, for which there is great demand when growing stock has to be maintained in a thriving state, or cows have to be kept in a condition in which they may be expected to yield much and good milk. Oil-cake produces much and rich milk, but seriously injures its quality by giving it a bad flavor.

"Bran, on the other hand, is a good food for milk. Indeed, nothing can be better as an auxiliary winter food for milch-cows than four pounds of bran made into a thin mash, to which should be added four lbs. of bean-meal. Along with this about twenty-five lbs. of mangolds, and about fifteen lbs. of hay, and fifteen of straw-chaff, should be given per day to each cow.

"Cows fed upon such a daily allowance of bran, bean-meal, mangolds, hay, and straw-chaff, during the winter months, yield much more milk of a superior flavor than cows fed upon turnips and most other kinds of auxiliary food.

"When brewers' grains can be obtained at a reasonable price, they will be found one of the cheapest and best foods that can be given to milch cows. Brewers' grains, I find, are much more nutritious than their appearance seems to warrant. Even in the wet condition in which grains are obtained from breweries, a condition in which they hold from 75 to 77 per cent. of water, they contain a good deal of ready made fat and flesh-forming matters. When air dry, brewers' grains, I have recently discovered, contain from 7 to 8 per cent. of oil and fatty matter, and in round numbers 15 per cent. of nitrogenous matters, and in this state are more nutritious and a more useful food for milch-cows than barley meal in the same state of dryness.

"During the last ten years I have made a great many milk-analyses, from which I select a few for the purpose of illustrating the natural variations which may occur in the composition of equally genuine milk. The results are embodied in the following table, showing the composition of four samples of genuine new milk obtained and analyzed by myself in the country.

Composition of 4 samples of new country milk.

	1	2	3	4
Water.....	85.20	87.40	89.96	90.70
Fatty matter (pure butter).....	4.06	3.43	1.99	1.79
Caseine (curd) and a little albumen.....	3.74	3.12	2.94	2.81
Milk-sugar.....	5.0	5.12	4.4	4.01
Mineral matter (ash).....	1.13	.93	.64	.66
	100.00	100.00	100.00	100.00
Percentage of dry matters.....	14.80	12.60	10.04	9.30

"The analyses of these four samples exhibit a wide range of variations, which I found in equally pure and genuine country milk. The first analysis represents the composition of a sample unusually rich in butter; number 2 shows the composition of milk of average good qualities; the third of poor, and the last of very

poor country milk. The richness of the first I ascribe to the extremely good pasture upon which the cows were fed at a season of the year when milk generally becomes richer in quality, but less in quantity—that is, in September and October, up to November. The last sample was also September milk produced on the Agricultural College farm, Cirencester. The cows were then out in grass, but the pasture was poor and overstocked, so that the daily growth of grass furnished hardly enough food to meet the daily waste to which the animal frame is subject, and was then not calculated to meet an extra demand of materials for the formation of curd and butter. The poverty of this milk thus was evidently due to an insufficient supply of food.

"It will be seen that the variations in the amount of curd and milk-sugar in good and watery milk are far less striking than those in the amount of butter. A very good judgment of the quality of milk may therefore be formed from the amount of butter which it yields on churning, or from the amount of cream which it throws up on standing. Instruments, adapted for measuring the quality of cream thrown up by different samples of milk, are called creamometers. These instruments are simply graduated glass-tubes, divided into 100 equal degrees, in which milk is poured up to the division marked 0, and is kept at rest for twelve hours. Although the creamometer does not furnish results which correctly represent the real amount of butter in different samples, it nevertheless affords a ready means of ascertaining whether milk is rich or unusually poor in butter, in other words, whether or not milk has been skimmed to a considerable extent. Good milk, of average quality, contains from 10½ to 11 per cent. of dry matter, and about 2½ per cent. of pure fat. It yields from 9 to 10 per cent. of cream. Naturally poor milk contains 90 or more per cent. of water, and less than 2 per cent. of pure fat, and yields only 6 to 8 per cent. of cream, or even less.

"Experiments on a large scale have shown me that the thickest cream does by no means give most butter, and that the cream which rises from different kinds of milk often varies greatly in composition. The indications of the creamometer, therefore, are fallible when samples of milk, produced under very different circumstances, have to be tested. Milk sent by rail is necessarily subject to a good deal of agitation, and throws up less cream than that which has been less disturbed.

"A great deal has been said and written about milk-adulteration. Sheep's brains, starch paste, chalk, and other white substances, which are said—on what authority nobody has ever decided—to have been found in milk, only exist in the imagination of credulous or half-informed scientific men. It is difficult to understand where all the sheep's brains should come from, and how they could be amalgamated with milk, nor is it at all likely that chalk, a substance insoluble in water, and not easily kept in suspension, should be employed for adulterating milk. As a matter of fact I may state that I have examined many hundreds of samples of milk, and never found any chalk, nor any adulterating material except an extra quantity of water, and that I never met as yet with a chemist who has found any of the clumsy adulterations which popular treatises on food describe as having been detected in London milk.

"The whole question of milk adulteration and means of detecting them, resolves itself into an inquiry into the character of good, bad, and watered or skimmed milk, and the mode of

recognizing these with expedition and precision.

"As the result of my own experience, founded on the examination of many samples of milk produced under the most varied circumstances, and purposely adulterated with known quantities of water, I may state that milk may be considered rich when it contains from 12 to 12½ per cent. of solid matters, 3 to 3½ per cent. of which are pure fatty substances. If it contains more than 12½ per cent. of solid matter, and in this 4 per cent. or more fat, it is of extra rich quality. Such milk throws up 11 to 12 per cent. of cream in bulk on standing 12 hours at 62° F., and has a specific gravity varying from 1.028 to 1.030.

"Good milk of fair average quality, as has been stated already, contains from 10½ to 11 per cent. of dry matter, and in this about 2½ per cent. of pure fat. It yields 9 to 10 per cent. of cream, and has a specific gravity of about 1.030.

"Poor milk contains 90 per cent. or more water, and has a lower specific gravity than 1.027. Such milk yields not over 6 to 8 per cent. cream.

"Skimmed milk throws up still less cream, has a bluer color, and is more transparent, and when undiluted with water has a slightly higher specific gravity than new milk.

"Good skimmed milk has a specific gravity of about 1.033; poor skimmed milk 1.028 to 1.030.

"Milk purposely watered yields only 5 to 6 per cent. of cream, and invariably has a lower specific gravity than 1.025.

"If milk is both skimmed and watered it yields less than 4 per cent. of cream, and possesses as low a specific gravity as 1.025 to 1.026.

"A great many experiments have led me to the conclusion that within certain limits the specific gravity is the most trustworthy indicator of quality, and that for all practical purposes an ordinary hydrometer float, by means of which the gravity of liquids can be ascertained with precision, and a graduated glass tube, divided into 100 equal degrees, constitute the safest and readiest means for ascertaining the quality of milk so far as it is affected by the relative proportions of the normal milk constituents.

"A set of such instruments or lactometers, one being a graduated glass tube for measuring the proportion of cream thrown up on standing, and the other a gravity float or hydrometer, with plain printed directions for use, can be obtained at the cost of a few shillings.

"A few years ago I made some accurate gravity determinations of pure milk before and after skimming, and of samples mixed purposely with 10 to 50 per cent. of water, and as the results may be useful in comparing them with others, I give them in the subjoined table:—

SPECIFIC GRAVITY OF WATERED MILK.

	Specific Gravity at 62° F. before Skimming.	Specific Gravity at 62° F. after Skimming.
Pure milk	1.0314	1.0337
" " + 10 per cent. water	1.0295	1.0308
" " + 20 " "	1.0257	1.0265
" " + 30 " "	1.0233	1.0243
" " + 40 " "	1.0190	1.0208
" " + 50 " "	1.0163	1.0175

Here follow analyses of milk from numerous localities in the richer and poorer districts of London, which show that the amount of cream bears a direct relation to the specific gravity of the milk. The author concludes from his researches that: "These facts afford a conclusive answer to the objection that no dependence can be placed on the gravity test. The fact is, cream, though lighter than skimmed milk, is denser than water, and any amount of water worth adding at all, can readily be detected in milk by the direct lowering of its normal specific gravity."

Perfecting Bees.

BY BIDWELL BROS., ST. PAUL, MINNESOTA.

A colony of bees in a natural condition consists of a queen or mother bee, many thousand workers, improperly termed "neuter bees," and during a yield of honey, several hundred, and at times thousands, of male bees, called drones. An examination shows the queen to be created for laying eggs, neuter bees for work, and drones for sires, and each for nothing else. All the workers, drones and future queens are bred from eggs laid by the queen. When we remove her from the hive, eggs cease, and on her return appear again. (That so-called fertile workers sometimes lay eggs is no exception, they are not workers proper, but imperfect queens.) On removing the queen, the following facts are ascertained: That those eggs in cells, in which workers are reared, all hatch in 3 days (as worms) and are then termed larvæ; they are fed honey and pollen and water, called jelly, for 6 days, during which they grow to be large white worms nearly the size of the cell. The cell is then sealed over by the bees, and subsequently the worm transformed into a perfect worker, emerges on the 11th or 12th day after sealing, or from 20 to 21 days after the egg is laid. If any drone eggs are in larger, or drone cells, they hatch in 3 days, are worms for 6½ days, and emerge as perfect insects on the 24th or 25th day from the time the egg is laid. If any queen eggs are in pendant cells, they hatch in 3 days, are 5 days in the larva state, and appear on the 16th day. They fly out to meet the drones usually on the 3rd day after leaving the cell, and if successful commence laying on the 2nd day thereafter, producing worker, drone and queen eggs, as either may be required. When a queen is removed, the worker bees, on ascertaining their loss, seek to replace her by enlarging a worker cell containing a worker egg or larva. These intended queen cells, if in the body of the comb, are altered by removing the worker cells adjoining the one selected, extending the base to increase the size, and are built out to clear the comb and hang down. If they are on the edge of the comb, they are built directly downward in the shape of a pea nut. The drone and worker cells are built horizontally, as observed in a piece of honey comb; the larger cells are those in which drones are reared, and the smaller or ordinary sized are those for workers. In the case of the drone and worker, they are fed water and honey, and polleu or farina, which is properly termed bee-bread, as it contains the principal elements that support all animal and insect life. The color of the food or jelly partakes of the color of the pollen; at times it is yellow, brown, or red, as that of the flowers from which it is gathered. To show that the pollen of flowers is similar to wheaten flour, we might state that early last spring, after our bees had eaten all their pollen stored, during a long and cold winter, 100 stocks consumed over two barrels of flour in brood raising, storing none, the stronger colonies necessarily using upwards of 10 lbs. each, which affected the color of the jelly—converting it to a whitish mixture.

The food of the intended queen is ascertained by analysis to be "a bread containing an albuminous compound," secreted by the worker bees in the case of a natural queen, or compounded from the worker eggs for a forced queen. The drone and worker bees lose time, so to speak, in assimilating their coarser food, while the queen gains time in her development by being fed a concentrated easily assimilated compound. The

eggs in hatching require about summer heat from the nursing bees, which must be maintained throughout their maturing, or until their internal organization is established to produce it. For this reason, Italian bees can mature more brood in colder weather, the organization being more perfect, and better able to produce heat, and withstand cold, and consequently they swarm earlier. We have observed that the difference of a day in the maturity of the drones, or of the workers may be caused by the difference in temperature. When the heat of the days is 76° F. or above, the shorter time is made.

It is not then the size, nor the shape of the cells—for small and imperfect drones, and small and imperfect queens (called fertile workers), are reared in small or worker cells,—nor is it the food, nor yet the oxygen of the air severally, which develops life, but all acting in harmony. The ample cell, the quantity of nutriment and oxygen, produces a fullness, and the quality, a perfectness of development. The identity of the character of the parent and offspring is shown to be dependent upon the continuation of certain influences acting harmoniously on the principle of life; hence, like produces like only under similar circumstances. In raising over 300 Italian queens from one last summer, we observed that during a continued spell of scarcity of honey, and hence of food, the queens were more deficient in vitality, and in protracted cloudy weather less bright in color, but where a superabundant harvest and extreme fair weather prevailed, the highest degree of excellence was attained, convincing us fully that natural queens were far superior to forced or unnatural ones. The influence of food in providing an uninterrupted supply of honey producing flowers in summer, will give an increased development to the reproductive powers of the queen, and quiet industry to the workers; and avoiding the climatic extremes of heat in summer, which wastes and exhausts the system, and cold in winter, which tends to barrenness, will add health and strength to the bees, effecting more or less uniform changes, producing definite characteristics, and marking them ultimately as a distinct and perfected race.

Get Out of Old Ruts.

The consumption of barley is increasing year by year, as the Teutonic element in our population increases in number and wealth, and impresses more or less upon the American people the liking for the mild brewed beverages of Germany. The sale to brewers is in fact so ready, that the raising of barley as food for animals is hardly considered. We learn that oats in several extended sections of the country are, for some undetermined cause, beginning to fail to produce what were considered good crops but a few years ago. This is particularly the case in some of the river counties in this State, and it would, perhaps, be profitable to drop oats and try barley, which will probably do well upon the same soils. Hoops are also recognized as very profitable, and like tobacco and other purely commercial crops, (those never consumed, but always sold), it may be cultivated so as to bring real advantage to the farm. It almost necessitates clean culture, and gives the farmer means to buy manure, do draining, etc. This following in old ruts of practice is one of the worst things a farmer can do, and an experiment with a new crop now and then is often the straight road to fortune. It should always be done after careful thought and investigation.

Kicking, Jumping, and Running Cattle.

Horses, cows and other cattle may be perfectly controlled from kicking and jumping by the arrangement which we figure. A description is sent to the *Agriculturist* by Wait M. Myers, of Oneida Co., N. Y., who has found it a sure remedy for the eccentricities named. We figure it as applied to a cow, but the same arrangement may be put upon a horse; and it interferes with no desirable motion. A stout strap 1½ inches wide goes around the neck, and is connected by a still stronger one, 2 inches or more in width, to a small pulley under the brisket, through which a rope is rove, each end of which is made fast to fetters, or to hobble-straps above the fetlock. A girt strap simply holds up the pulley. "When the animal stands square on her feet," says Mr. M., "the rope must be pulled taut; and when all is right, she can walk or trot as well as ever, but she cannot kick with one foot, nor with both, nor can she jump over a fence three feet high to save her life."

It is obvious also, that an animal in this harness cannot run, for both hind feet cannot be moved backward at the same time. This contrivance is not new, but has long been used for breaking colts and controlling their action. Such things, however, except in cases of inveterate and obstinate kickers, or runners, do more harm than good. If a colt can be influenced by kindness and so broken, he makes a much better horse than one controlled by main force. This affair will not prevent that kind of kicking which knocks over the milk-pail, but only that most disagreeable and dangerous kicking back and sideways which some cows do.

Fig. 1.—SECTION LENGTHWISE THE STALL

Plan for Horse Stall.

Mr. A. W. Darrow, a Maine farmer, sends to the *Agriculturist* the following, which he has in use, and recommends from his experience: "I enclose a sketch of a horse stall, which I have used in my stable for the last six months. The plan is original with me. It is not patented, and I hope the public will not appreciate it less on that account. [The following references to the diagrams will enable the plan to be readily understood, especially if the reader will apply a scale of one-quarter of an inch to the foot.—A, B, C, feed box; D, grate; E,

platform; F, hinges attaching grate frame to platform; H H, grate supports; K, frame in which the grate bars are set; M, M, sides of stall; N, head of stall; O, end-bars of grate immovably attached to K, K, and forming part of the grate frame; P, position of grate when elevated to remove the droppings.] The grate has 2-inch bars and 2-inch spans, and the bars are 6 inches deep, and 6 inches space is between them and the floor. The droppings go through the grate, leaving it dry and clean. I have had hardly a stain to remove from my horse since using it, and no litter has been used. The bars being but two inches apart are as easy to the hoof as a plain floor. The droppings may be drawn from beneath by a hoe or scraper, or the grate may be raised, as indicated in Fig. 1. I keep muck under the grate, and think I can better save both liquid and solid manure than

Fig. 2. SEEN FROM ABOVE. Fig. 3. CROSS SECTION.

by bedding in the common way. It requires several days for the droppings to fill up the space beneath the grate. Hence the muck may be well saturated before removal."

Chicken Medicine.

It is very distressing to see our farm yard dependents suffering under any form of disease, and much more so when we see one after another droop and pine and die, while we are powerless to alleviate or remove the malady. In regard to the larger animals we can, in a measure, compare their symptoms with our own when we are sick. We have the pulse, the secretions and excretions, the warmth, moisture or dryness of the skin, the breathing, and the various modes the terrestrial mammals have for showing acute suffering or dull disorder. With birds, however, the case is very different—they droop, hide themselves in dark corners, or in the bushes, go through to us meaningless and rather funny motions, walk sideways, twitch their heads one side, fall off their perches, grow lean, swell up about the eyes or head, gape, sneeze, take cramps—and so on—and as a general rule, no body can tell either the seat or nature of the disorder, any more than what will cure it. The importance of the poultry interest, and the daily increasing value of the stock in this country, leads us to call especial attention to this subject, so that poultry fanciers and breeders may compare notes and learn something about the diseases of poultry and their treatment. Whoever will contribute to our stock of knowledge, will place both editors and readers under obligations to him. Let the behavior of the fowls and all the symptoms be closely watched, as well as the effects of the treatment; observe also the character of the soil, if wet, dry, clay or gravelly, and

other surroundings. The disease described by a lady of Cambridge, Mass., in the following letter—for want of a better name we may call

VERTIGO.—"Being a great lover of a poultry yard, and having for many years kept hens, I have been troubled and grieved on seeing some of my best layers sicken and die, without being able to save them. Last summer, finding a hen that was perfectly well the day before, walking round and round, her head twitching, heart beating violently, skin hot, I thought I would try a new remedy, viz.: paregoric, of which I took a teaspoonful, a half teaspoonful of sulphur, half teaspoonful of Indian meal, and about four teaspoonfuls of water. I then put her in a basket of hay. Three times a day I gave her a little paregoric and water. The sulphur operated on the bowels, and the hen was well in a few days. In November, I had two hens taken in the same way, their heads twitching, hot, and drawn nearly over the back, I doctored them in the same way, and they got perfectly well."

THE PIP.—Mr. D. S. Kimball, Jr., of Bergen Co., N. J., writes concerning this and other ailments:—"I have cured a great many chickens of the pip in the following way: The pip being caused by a small dark swelling on the tongue near the roots, and sometimes on the roots, I take a knife and remove the swelling, and rub on a little butter mixed with ground black pepper. I give them no greasy food, and keep those attacked entirely away from all the others, as I regard the disease very contagious.

"*Lameness of fowls* without any apparent cause, is often occasioned by the caking of the oil sack. This is shown by a hard crust on the top. In such a case, wash the upper part of the rump with warm water and castile soap. In case of

"*Loss of feathers*, give fowls no warm food at all until they commence to cover again with down, and be very careful in their feed until recovered."

"**HEN LICE.**—Seeing Kerosene recommended for the prevention of lice in fowls, I would say that the oil is good if sufficiently pure, but as it is not pure in one case out of fifty, it is often very injurious. I have found that the only preventives not injurious, and all that is needed to raise and keep fowls both clean and healthy are, first, and most important, have the hennery both light, clean, and warm. Do not overstock with roosters, as it tends to keep all weakly and liable to disease. Give them plenty of good, sharp, clean gravel, warm food (not too warm), with a little animal food mixed with it occasionally, at all times fresh pure water, and lastly give them clean sassafras poles for their roosts."

Charles Embrey, of Washington Co., Md., writes on the same subject:—"During the last summer my poultry and poultry-house seemed to swarm with vermin (hen lice); I lost several sitting hens in consequence. I tried as remedies, whitewash, sprinkling of lime, smoke, etc., to little or no purpose, and concluded to try brimstone. I got a stick or roll of about half a pound, drove the fowls out of the house, burned the brimstone, smoking the premises well. The experiment proved a success, I have had no trouble with vermin since; all seemed to disappear both from the fowls and the house."

STIMULANTS have often a very good effect on fowls. Cayenne pepper and pepper corns, both are valuable mixed with their food, but ale and other malt liquor, or spirits, even undiluted, administered upon stale bread, have often a wonderfully good effect upon dumpish torpid birds, and upon those with colds, etc. Ale is best; and may be given alone in severe cases.

Coop for Hen and Chickens.

We give herewith, a very pretty design for a hen-coop, which, though a little late for the principal broods, will nevertheless, serve for a hint at least, if not a model for those who, having summer broods, would be likely to subject them to great discomfort, did they place them in the common close coops. The design is to have a box without a bottom, provided with a slatted and movable front as exhibited, and to have the whole covered by a movable roof of thatch, or any other convenient and cheap material. The roof affords shade and protection from the weather, and being placed against the south side of a wall, makes their quarters exceedingly comfortable, if not luxurious. For ourselves, we prefer a coop with a slanting roof, and with a slat door of one or two slats, that may be raised and lowered, instead of being obliged to raise or lower the whole front. The thatched shed, however, is particularly picturesque, and useful for protection in all weathers.

Ring-bone.

This distressing disease in horses is caused by over-exertion in pulling heavy loads, especially in up-hill work. It is, besides, hereditary in some cases, like spavin, which it very much resembles, and occurs sometimes without obvious cause. When ring-bone is established, it consists of a bony enlargement with or without anchylosis of the fetlock, or pastern, and coffin bones and joints, just as spavin is an osseous growth upon or union of the bones of the hock. It commonly occurs upon horses subjected to heavy draught, while spavin often comes in consequence of fast work, leaping, etc. The commencement of the disease is in an inflammation of the periosteum and investing ligaments of the joint, which is communicated to the bones and produces disorganization to some extent, and a deposit of bony matter which gradually increases in size, and is always liable to grow larger and more painful, though it often

Fig. 1.—HEALTHY BONES.

remains stationary for years, and does not unfit the horse for some kinds of labor. After the bony enlargement has actually taken place, there is no cure; but counter-irritants, blisters, etc., sometimes relieve the pain and the lameness it causes for a time. The only time when a cure can be effected, is before the disease becomes fixed, while yet it is only an inflammation of the joint. This will be indicated by tenderness, pain, heat, etc., and cooling appliances, such as cold water, soap and camphor, with a little laudanum, etc., may be used, giving entire rest, with green food or roots. Follow this by some convenient preparation of iodine, like an ointment of iodide of lead and lard, or an ointment of biniodide of mercury—either of which may be had of any good apothecary. Rub in the ointment well, and follow up the

treatment for several weeks, not working the animal. In case there is a considerable swelling, though not yet firm bone, it is worth while to try blistering with cerate of cantharides, continuing at intervals the use of the iodine, the object of which is to promote the absorption of the swelling. Or a treatment may be followed similar to that suggested for spavin in the March number of the *Agriculturist*, page 94.

The engravings which we present, show, in fig. 1, the bones of the leg from the hock down,

in a condition of health, and, in fig. 2, the hoof and pastern joint affected by a very severe ring-bone. This is taken from a specimen at the N. Y. College of Veterinary Surgeons, Lexington Avenue, in which the enlargement of the bone was so great, that it grew from each side around outside the great flexor tendon, forming a ring through which it passed. Ring-bone usually manifests itself by a hard swelling upon the top of the joint, but the osseous tumor may appear most prominent on any of the affected parts.

Musk-rat Traps.

Whoever has undertaken to maintain the tide-water embankments described in the present volume of the *Agriculturist*, pages 57 and 92, for shutting out the sea from meadows, or whoever for any purpose keeps up dams or embankments, must have been greatly annoyed by that most persevering, industrious and shy animal, the musk-rat. He is considered very hard to

Fig. 1.—MUSK-RAT TRAP.

trap, as he cunningly avoids any thing suspicious, and, except in the winter, will not touch bait of any kind, unless very rarely. The holes and works of the musk-rat are the chief obstacle the tide-water farmer has to contend with, who attempts to shut out the sea and reclaim for cultivation what are known as salt meadows.

P. M. Griswold, of New Haven Co., Conn., writes: "The best trap for musk-rats that I know of, and one that is used quite extensively here, is thus made: A box is made 8 x 10 inches in the clear, and 3 feet long (fig. 1); two gates are

made to fit it as shown in fig. 2. The holes for the gates are placed 1 inch from the top and 2 inches from the end. Each gate is made in the following manner: take a piece of hard wood 1 inch square, long enough to cut a shoulder on each end, and let them play easily in the holes in the box. Then take wire 1/8 inch diameter, cut it in pieces two inches longer than the box is deep, and insert these in the hard wood piece, as shown; then weave fine wire across them 2 inches from the bottom, to keep from spreading, and when the gates are ready, put the box together. The gates hanging so that any animal going in will lift them, and when in, they will drop and secure him a prisoner. When done, place the trap in the water where musk-rats live. The water must be deep enough to cover the box 6 inches or more. Put a stone upon it to keep it down; drive stakes each way from the box at each end, to keep the rats from going past, and to lead them towards it; set a board up across upon each end of the box to keep them from climbing over, and they will dive and swim into the trap, and will soon drown. I caught three at a time in a trap like this."

We find that our friend F., whose trout ponds we described some months since, uses similar traps. They are made of sheet iron, the gates being a little different, as shown in fig. 3. In summer they are set as above described, without bait, but in winter they are baited with parsnips and sunk through the ice or in open places in deeper water, with cords attached with which to lower them and haul them up.

The Sun Dial—Use and Ornament.

Good watches and clocks are common nowadays, and there is no longer the use for sun dials and noon marks, which existed only a few years ago. Nevertheless, on farms a few miles from villages and town clocks, how often does it happen that the time is lost except as we depend upon the sun for it? At such times a sun dial is a real convenience, if it be large enough to give tolerably accurate time. Sun dials are always interesting, and may be made ornamental, and are certainly very appropriate ornaments to private or public grounds. In those of the ordinary form the gnomon or style which casts the shadow, is a right angle triangle, set with the long side up, to make the shadow. This long side should point directly toward the north pole. So that the north star, provided it could cast a visible shadow, (and indicated the exact north,) would cast none. To do this, the angle of elevation must be the same as the latitude of the place, and it must be set pointing due north. A correspondent sends us a pasteboard model, of a sun dial with a butterfly for the gnomon, or style which casts the shadow, as a sample of the pretty and fanciful

made to fit it as shown in fig. 2. The holes for the gates are placed 1 inch from the top and 2 inches from the end. Each gate is made in the following manner: take a piece of hard wood 1 inch square, long enough to cut a shoulder on each end, and let them play easily in the holes in the box. Then take wire 1/8 inch diameter, cut it in pieces two inches longer than the box is deep, and insert these in the hard wood piece, as shown; then weave fine wire across them 2 inches from the bottom, to keep from spreading, and when the gates are ready, put the box together. The gates hanging so that any animal going in will lift them, and when in, they will drop and secure him a prisoner. When done, place the trap in the water where musk-rats live. The water must be deep enough to cover the box 6 inches or more. Put a stone upon it to keep it down; drive stakes each way from the box at each end, to keep the rats from going past, and to lead them towards it; set a board up across upon each end of the box to keep them from climbing over, and they will dive and swim into the trap, and will soon drown. I caught three at a time in a trap like this."

We find that our friend F., whose trout ponds we described some months since, uses similar traps. They are made of sheet iron, the gates being a little different, as shown in fig. 3. In summer they are set as above described, without bait, but in winter they are baited with parsnips and sunk through the ice or in open places in deeper water, with cords attached with which to lower them and haul them up.

ful devices which may be used. He describes also the manner in which he made his gnomon of iron, and taking a piece of marble for the dial plate, and a short iron column, which was the body of a stove, for the standard, constructed a sun dial which, with a little paint, was made quite ornamental. For a simple noon mark, one of the best gnomons is a flag pole, not very high, set so that the shadow will fall at noon exactly in the middle of a walk, upon a row of small white stones, perhaps. Any such pole or tall staff offers another means of telling when it is noon, namely, by the *shortness* of the shadow, for it is shortest when the sun is highest, and he is highest when he passes the meridian—which is noon.

Turnips—Kinds and Culture.

Like peas, turnips can not endure the heat of our summers. They survive, but do not do well, the crops being corky and light, they are therefore sown late in the season, so that the roots shall fill out and mature in the cool weather of the autumn. Those sown early for the table, so that they may mature sufficiently for use before July, do well also. The usual time for sowing turnips for the main crop is after the last of July, and before the middle of August. Those sown very late, that is, after the first week in August, should not be risked on any but warm, light, and rich ground, not over moist. In some of the elevated counties of Central New York, where the land is heavy and hard, turnips must be sown as early as the middle of June or first of July, to make a crop, but such locations are the exception.

The soil for turnips should be mellow and well enriched, but not with rank manure. It is best if the soil is deep, but deep plowing for the crop, without previous deep culture, is not the thing. However, any good 4-inch soil, not choked with weeds, will give fair returns. The best flavored turnips for the table are produced on light, sandy loams in good heart, but in which the manure has disappeared from sight.

For field culture, when the crop is to be marketed for table use, the Golden-ball, Snow-ball, and Purple-top Strap-leaved, are among the very best, yielding well and being excellent for the table, and good keepers, the seeds may be had of most seedsmen, as they are old standard varieties. One pound of seed to the acre is the rule, but much less will do if the drill be properly set, or if it be mixed with sand or earth, so that the whole field may be evenly sown broadcast. It is best to sow in drills, 20 inches apart, and to thin with the hoe to the breadth of the hoe blade apart. Thus the ground may be kept clean, and while a much better crop is gained, the soil has most of the benefits of a summer fallow.

Ruta-bagas, or Swedish turnips may be sown as late as the first week in July, and upon land in good tilth, give good crops. If the soil is shallow, turn the furrows together in pairs, and sow on the top of the ridges, covering the seed a little deeper than if sown on the flat. Wet land may be treated in the same way. The *ruta-baga* needs a richer soil than is necessary for the English turnips, and has a much heavier, firmer, and more nutritious flesh. Late sown crops are smaller, for the roots do not get so large, as they must be harvested before they get their growth, nevertheless, they are better for the table, and find a readier market than if very large. The chief value of both these crops, however, is for affording succulent fodder for

stock during the winter. The turnips being consumed in the autumn and early winter, and the *ruta-bagas* toward spring. The best kinds of *ruta-bagas* to sow are, perhaps, Skirving's Purple-top, a yellow fleshed variety, and the Purple-top White, which has white flesh. Sow in drills like turnips, 20 to 24 inches apart, and thin to 10 inches apart early in the season, but later let them stand a little closer.

For our own use, we prefer *ruta-bagas* to turnips for every purpose, and would sow them upon all land that we can get in order in time, but they require so long a season that it is rarely possible to use them as a second crop, even in the garden. The turnips, therefore, have to be used generally after or among other crops, to follow and take possession of the soil. *Ruta-bagas* may be drilled in between the rows of onions and take possession, when they are harvested in August or September, but even for this, turnips are better. Turnips may be sown among corn, and the seed hoed in at the last hoeing, they follow early potatoes well, and do well after winter grain. They ought seldom to be allowed to occupy land upon which late cabbages would grow profitably, unless the labor which cabbages would require prevent their cultivation, for we know no crop which, on soil adapted to it, will produce more food.

Raise Your Own Clover Seed.

"Raise your own clover seed and sow it with an unsparing hand," like nearly all agricultural precepts, needs qualification. On a wheat farm it is not easy to grow too much clover, provided it is all consumed on the farm, or plowed in as a green manure; but it is quite easy to raise too much clover seed. Clover is, perhaps, all things considered, the best *renovating* crop that can be grown on a wheat farm. Like peas and beans, clover is a leguminous plant, and draws a considerable quantity of ammonia from the atmosphere, while its deep roots penetrate the subsoil and bring up potash and other ingredients of plant-food. It is admirably adapted to our climate, and as yet "clover sickness," which is so troublesome on the light soils of England, is known in but few localities in this country.

Whether it is best for farmers to raise their own seed is a question which deserves consideration. We have urged them to do so because we think they will be more likely to *sow* more if they have plenty of seed of their own, than if they have to purchase. But it should be borne in mind that the main object of sowing so much clover is to enrich the land, and it is undoubtedly true that letting clover go to seed changes it from a *renovating* to an *exhausting* crop.

John Johnston, in a letter now before us, says he has frequently sold from \$700 to \$1000 worth and over of clover seed, in a year. He thinks it one of the most profitable crops a farmer can grow, but he adds, "I have known a crop of clover seed exhaust the land more than a crop of wheat." The conclusion is this: Clover is a great *renovating* crop when grown for hay, for pasture, or for plowing under, and should consequently be sown liberally. On the other hand, raising seed is highly profitable, but somewhat *exhausting* to the land. Raise clover seed, but use the money obtained from its sale to *enrich the land*. A bushel of clover seed will usually buy six or eight bushels of peas or beans, and these fed to stock on the farm will restore to the soil, in the form of manure, six or eight times as much plant-food as the crop of clover seed removed. Do not try to cheat the soil. Do

not induce it to give you a good crop of clover seed, and then refuse it a share in the profits.

In raising clover seed, cut the first crop early—say in this latitude, the first or second week of June. It is also important that the first crop should be mown as *evenly* as possible that the plants may start equally, and the future crop of seed ripen all at the same time. It is desirable to get the seed early, say the first or second week in September. Occasionally a large crop will ripen in October; but at that season the weather is usually unpropitious, and a large number of the heads when ripe are apt to drop off in wet weather, both before and after they are cut. A large growth of foliage is sometimes obtained by sowing gypsum on the clover after the hay crop is removed, but in a cool, growing season, the seed in this case is apt to ripen poorly.

The largest crops are obtained, other things being equal, from land seeded with nothing but clover—and in this case the seed should be sown pretty thickly, say six or eight quarts per acre. This thick seeding has a double advantage: You get a finer quality of clover hay, and the plants being thick on the ground the crop is not so apt to lodge, and can be mown more evenly. Six bushels per acre is sometimes grown on good land when clover alone is sown, but three or four bushels is a full average. The expense of growing, harvesting, and hulling is very little, and the seed is practically nearly all profit.

Let not the farmer who neglects and starves his land think that he can get rich by growing clover seed. The profits are not for him. There is no better indication of good land and good treatment than luxuriant crops of clover. The land that will produce good clover will produce good wheat or other grain—and the negligent farmer deserves neither one nor the other. Let him give the soil good tillage and liberal treatment, and it will prove grateful, but if he starves the soil the soil will starve him.

Cows Long in Stripping.

To the Editors of the American Agriculturist.

Doubtless the fault is more with the milker than with the cows—they will learn bad habits, but usually need to be taught them. If they are properly milked—so as not to give them discomfort—they seem to enjoy the operation, and usually part with their milk freely.

I keep ten cows, and always do the milking; raised them all, besides some that have been sold—have bought but one in ten years, and got cheated in the operation—and have never had a kicking cow, a "stripping" cow, or a cow with sore teats. Now let me prescribe for Mr. B. Always milk with clean hands; and if your hands are hard and rough, keep a cup of grease—goose or hen's oil, lard or fresh butter is good—at the stable, and once a day, before milking, rub a little on the inside of your hands—just enough to make them feel smooth. Some of this will adhere to the teats and prevent sores and cracks, and all together will make smooth work. Rough hands are a "nuisance" to a cow's teat, and will prove a nuisance to the milker, in "long stripping." At the time of milking, take a small pail, which is the most convenient, with a little water in it, and a sponge about two-thirds as large as your fist, or a woolen rag will answer, and the first thing to be done after sitting down to the cow, is to wash the bag after this manner, squeeze the sponge a little so that the water will not drip from it, and rub the bag all over, teats and all—keeping the milk pail out of the way, of course; this will insure

cleanliness, is grateful to the cow, and will promote the flow of milk. Now begin to milk, not with a short, quick, jerking motion, which is very unpleasant to the cow, and helps to form the habit, but with a steady, and with sufficient pressure of the teats, with a slight downward pull, to expel all the milk every time; don't let half of the milk that you have drawn into the teats fly back into the bag, but force it all into the pail. Milk the teats you first start with clean, or as long as the milk will flow from both; but if they do not milk even, leave the unfinished one and milk the other two; then go back to the first, and finally milk the unfinished ones together. Never milk with one hand, but manipulate the bag with both hands, even if you do not get milk with but one hand. Strip the bag perfectly clean. During the process of milking, and when the bag is partly emptied and becomes somewhat pliable, let the hands work well up on to or against the bag, this will keep up the flow of milk until the bag is emptied, and "stripping" will not be a "nuisance." Milk fast, but not in such manner as to cause uneasiness to the cow; if you do, you will teach her the habit, and you will have to "strip." A fair milker should be milked clean in five minutes, if she gives a good mess of milk. A steady, even motion, filling the teat with milk at every pressure of the hands, is the most rapid way of milking, and the most agreeable to the cow. Treat your cow with perfect kindness, speak to her as you would to a child, and when milking let that be the only business on hand. Try the above and see how it works. I practice what I preach. J. L. R., Jefferson County, N. Y.

is no doubt that it has a value as a pasture grass, in the South, and though it would be of little use where better grass will grow, it has a tenacity of life that enables it to endure hot summers,

up stems which bear the foliage and flowers. These upright stems are slender, and the leaves are narrow and delicate, but they are produced in such abundance as to make a dense turf.

The small flowers are produced in spikes which radiate from the top of the stem. In its manner of flowering, it resembles the common Finger, or Crab-grass, though the flowers of the two differ very much in structure; but this is a point only of interest to botanists. In its strong prostrate stem, and the readiness with which each joint will become a plant, this grass bears a strong resemblance to Couch-grass (*Triticum repens*), and these are qualities which at once adapt it to form a turf with great rapidity, and also render it very difficult to exterminate when it is once established. The seed is not down in our catalogues, and it is doubtful if it produces seed as a general thing. Plants that are so abundantly provided with other means for multiplying themselves are usually shy about seed bearing. As every joint of the prostrate stem will make a plant, cuttings of it are used to form a pasture or lawn. The plant may be chopped up and the pieces scattered broadcast, and then rolled, or sets made by dividing a plant may be put in hills.

It is sufficiently hardy in most Southern localities to give grazing during the winter, and though it will grow where more valuable grasses will not, it flourishes much better on fertile soils, where it even becomes large enough to cut for making into hay. It should be carefully kept from spreading into cultivated fields, as it is difficult to extirpate.

SCHRADER'S BROMUS.—*Bromus Schraderi*. (?)—This grass is the *Brome de Schrade* of the French, and the agricultural journals of that people seem to be as wild over it as if they had found a new Chinese yam. We notice that they have dropped the name of "Rescue," under which it went a few years ago, and now designate it as *Brome de Schrade*. Just what this grass is, we will not attempt to determine until we have grown some specimens, but we have suspicions regarding its botanical character. If it is the old Rescue grass, the name first given it in Europe, it is unworthy of consideration, but if, as is now claimed, it is what was formerly called *Ceratocloa breviaristata*, from the N. W. coast, it may possess value and be worthy of trial. In France, it is stated that its excellence as a pasture grass, its productiveness, its endurance of cold, and its everything wonderful, will completely revolutionize their agriculture. But they are great on revolutions in France, and we content ourselves with calling the attention of Southern agriculturists to these statements, and suggest that this grass is, if half the foreign talk be true, worthy of trial by them. It must be borne in mind, however, that none of the species of Bromus, have, as yet, been favorably decided upon by a jury of intelligent cows, and if this one should be found to their taste, it will be an exception. Of course, cattle will eat the different species of Bromus, but they do not afford a very nutritious food, and they prefer other when it can be had. Both figures are given of about half the natural size,

Fig. 1. SCHRADER'S BROMUS.

and to flourish in sterile soils—qualities that also render it, when uncontrolled, a troublesome intruder. To answer several letters, we give a figure and description of it. The most striking thing about Bermuda grass, is its strong stems or runners, which extend upon or just below the surface in every direction, and are often four

Pasture Grasses for the Southern States.

One great cause of the running down of Southern lands has been the want of suitable grasses for both hay and pasturage. Now that the system of husbandry will be in a great measure modified from that of former years, the question, what are suitable grasses, will become a still more important one. We give a brief account and figures of two that are now attracting attention as valuable pasture grasses.

THE BERMUDA GRASS.—(*Cynodon Dactylon*.)—Our first acquaintance with this grass was made in Texas. After traveling all day over a prairie on which the verdure was browned in a September sun, we stopped at a planter's ranch and found his front yard clothed with its turf, the freshness of which was in marked contrast with the scorched aspect of other plants. Since then we have seen it in other Southern States, regarded as a weed to be avoided rather than as a plant to be cultivated. There

or five feet long. At intervals of about two inches, this stem throws down roots, and sends

THE EMIGRANT SHIP IN NEW-YORK HARBOR. — Drawn by Granville Perkins for the American Agriculturist.

One of the most interesting sights in the world, and one of especial concern to American farmers, is that of which we present the above beautiful engraving. The picture was taken at our request by one of our favorite marine artists, and presents a scene which may be witnessed almost every day in the year from the wharves or from the Battery, or from any point giving a view of the upper harbor of New York. A large sailing ship has arrived crowded with its living freight of emigrants all anxious to place their feet upon the shore of their adopted country. The bay is very beautiful, with its green shores enlivened by the country seats of the wealthy, and sprinkled with a score of villages with church spires showing on every hand above the tree tops; it is interesting from numerous fortifications, whose great guns command every part of the channel for miles before reaching the city, and it is always enlivened by the foreign shipping, coasting crafts and the hundreds of passenger steamers, and tug-boats. No one is ever disappointed with the first view of the new world who enters at this port. So the immigrants are usually cheerful and happy.

At the present time when a ship arrives it is boarded by health officers some twelve miles below the city, and if any contagious disease is

found, the ship with its passengers is detained in quarantine; otherwise it comes directly up to its anchorage near the city. The emigrants were formerly the prey of keepers of boarding-houses and all kinds of villains. Now no one is allowed to communicate with them, except perhaps relations of known respectable character.

The Commissioners of Emigration are officers of the State of New York. They occupy Castle Garden, an old round casemated fort, situated on one side of "The Battery," a park, at the southern extremity of the city. It is covered by an immense tent-shaped roof. The emigrants are brought here with their baggage, upon a barge, or the small steamer, which is seen in the picture, and after being registered, they are furnished transportation tickets, at the lowest prices, to any part of the country to which they wish to go; their money is exchanged at Wall-street rates as reported hourly, and they have opportunity to buy bread, milk, and other simple food. Here too, before any are allowed to go out or to see anybody from outside the building, they are addressed in their own language, and told the dangers they run in the city, and by the way, from all sorts of bad persons. Those who are sick, moneyless, or detained from any cause, are

taken care of; the rest are forwarded as rapidly as possible to whichever point they wish to go. It is chiefly those of intolerable stupidity who are very badly victimized after leaving Castle Garden. Sometimes great numbers arrive in a single day, as for instance on Monday, May 28, the arrivals were 4,500, which indeed was the largest number that ever came in in one day.

Last year about 200,031 arrived in all; 129,021 being from British, and 67,000 from German ports. The destination of these people was as follows: To the Eastern States, 13,511; Middle States, 129,141; Southern States, 3,419; Western States, 51,054; Pacific States, Mexico and South America, 1,000, and to the British Provinces, 1,534. The influx at the present time is much larger; so far this year more than double that of the same months last year; 40,300 came in May.

These strong muscles and willing hearts are greatly needed to subdue our soil and to carry on our improvements in agriculture, road and railroad building, etc., etc., and these people, in the hard laborious life which they lead, are making for themselves and for their children homes and a country. Let Americans, native or naturalized, so meet them with fairness and honorable conduct, that they will soon become intelligent, respectable and worthy citizens.

Our Native Violets.

We have growing wild in the Northern States, some seventeen species of Violet, and it is very seldom that we see one of them in cultivation. Perhaps their general lack of fragrance has something to do with this neglect. We are so accustomed to associate the delightful odor of the European species with the name of Violet, that there is a feeling of disappointment when we find ours scentless. Still we have several species which are really pretty, and would no doubt repay the trouble of any one who should endeavor to improve them by careful cultivation and selection. Some of them show a disposition to sport in color, in the wild state, and it is not rare to find white flowered specimens of several of our blue flowered species. The Bird-foot Violet (*Viola pedata*), is our showiest wild species, and quite handsome enough to merit a place in the garden. It has delicately cut, clean foliage, and very large flowers, which stand up well above the leaves, and have a fine lilac purple color. Occasionally a remarkable natural sport is found, in which the two upper petals are of a deep rich purple, and of the velvety texture of the Pansy. We are indebted to Mr. W. W. Denslow, of this city, for the specimen from which our engraving is taken. This was found upon the upper end of Manhattan Island, and some years ago we had a similar one from near Baltimore. On one of the flowers, the side petals were partially marked with the same dark color, and no doubt cultivation would develop flowers which would be velvety throughout. Mr. D. also finds a white variety. This species, which is a quite hardy perennial, grows naturally in poor soils, and when transferred to the garden should have a light sandy spot, where there is a partial shade.

Slugs and Snails.

Slugs and snails are so much alike, as far as the animal is concerned, that the snail may be considered as a slug with a shell, and a slug as a snail without a shell, or one so small, rudimentary, and hidden from sight, that it usually escapes notice. Both animals move in a slimy track by means of their contractile foot; both have four tentacles or "horns," capable of extension and retraction, in front of the head, and both produce their young from eggs.—Slugs are a great pest to the European gardener, and sometimes to us. Being unprotected by a shell, their slimy bodies are unable to endure a dry atmosphere, and the intense heat of our summers prevents their increasing here as they do in Europe. Still, in spring they are often destructive to lettuce and early cabbages, and in a moist autumn, we have seen late cabbages completely riddled by them. They are also more or less destructive to young and tender plants generally. The slug belongs to the genus *Limax*, of which there are several species. Our most common one is only about an inch long, but we have seen, rarely, a species 4 or 5 inches in length, and as large as one's little finger, which

is probably the European *Limax cinereus*. During a dry time they hide in the earth, but when there is the proper amount of moisture present, they come out to feed. In some parts of France, where slugs are troublesome, ducks are kept for the purpose of destroying them. These birds are said to be so fond of slugs that they will

common land snails, and is easily seen when on the plants. They are readily picked off by hand. Both this and a larger species are eaten in some parts of Europe, where they are considered not only as a valuable food for invalids, but they are also highly prized as a delicacy.

BIRD-FOOT VIOLET, (Variety.)

touch no other food while any are to be found. Slugs may be readily trapped by laying lettuce or cabbage leaves upon the ground. If these be taken up early in the morning great numbers of slugs may be captured and fed to poultry. Lime-water, tar-water, and diluted gas liquor, are all said to be efficacious in destroying them.

Snails are less troublesome with us than are slugs. We have never known any of our many native snails to do any appreciable injury, but the European horticulturist finds several species that he counts among his enemies. One of the European snails has long been known in Maine and Massachusetts, where it was early introduced, and we were interested last year at discovering it on Long Island, where it seemed completely naturalized in the vineyard of a friend. The increase of this animal in our or-

Fig. 2.—SNAIL.

chards and gardens is not to be desired, and we give a figure that will allow it to be recognized. This is what has been called *Helix hortensis*, but we believe that naturalists now consider it a variety of *Helix nemoralis*. It is much brighter and more handsomely marked than any of our

Insects and Plant Fertilization.

SECOND ARTICLE.

The Iris flower, illustrated in our former article upon this subject, (see *May Agriculturist*, p. 186,) is only a striking and well marked case of what occurs in hundreds of other blossoms. Admirable as the adaptation here is for fertilization by insect aid, and plain as it is, when once pointed out, that the Iris could hardly ever seed at all unless visited by bees or such like insects, yet this has never been anywhere noticed in print before, that we know of. If this is the case with such a common flower, we may be sure that there is yet very much to be learned about the relations of flowers to insects, and of insects to flowers. Many other flowers, however, have long been known to botanists as requiring the aid of insects, and as evidently intended to be so aided. But the question which abruptly closed our former article, still presents itself and demands an answer. *Viz.*: Why should insects be called in to do that which, by a little different arrangement, would be done by the flower itself, and which is done by many hermaphrodite flowers? And can we believe that a hermaphrodite flower like the Iris, was ingeniously constructed in this fashion in order that the pollen, however near by, should not fall upon the stigma of itself, and then that, by an equally ingenious arrangement, a bee or butterfly should be enticed to the flower, and made to do the work of carrying the pollen from the anther to the stigma?

The solving of this enigma has been left to our times, and is one of the capital hits of that sagacious investigator, Mr. Charles Darwin. The key to the solution of the riddle he found in the principle, recognized by breeders, that close breeding tends to sterility and debility, while cross-breeding among different individuals of the same species obviates this tendency. If breeding in-and-in has this tendency,—and it is pretty well understood that it has, in the animal kingdom and in the human race, and moreover, we could show upon general grounds that it is what ought to be expected—then cross-breeding or wide-breeding (as we may term it) must be essential, in the long run, to the perpetuation of any species. Now, this fertilization of a blossom by its own pollen is the closest kind of breeding in-and-in. And in contemplating this, Mr. Darwin was led to infer that even hermaphrodite blossoms should not be fertilized by their own pollen, at least for generation after generation. Those that were so would be weaker and less productive after a while, and if so would certainly die out at length, unless artificially protected, to make room for the stronger races.

This neatly explains the whole thing. Wide-breeding, i. e., crossing between different individuals of the same species, is obviously provided for in the many cases where the male and female blossoms are on different plants, and al-

most as well where they are on different branches of the same plant, the action of wind and of insects being considered. And it now becomes evident that hermaphrodite blossoms enjoy a similar advantage. In our Iris and Aristolochia, at least, it is now clear enough that it is not intended that the pollen shall reach the stigma which lies so close to it, and that is the reason why the anther and the stigma of Iris face away from each other: but the pollen is intended to be applied to some other stigma of the same species; and that is the reason of this curious arrangement of the parts, and why an insect is called in to do the work. A bee can not take the honey from an Iris flower without carrying off on its rough head some pollen from the anther it must rub against. It can not well take the honey from the next flower of the sort it flies to without depositing some of this pollen on that stigma as it seeks its feeding place.

The Dutchman's Pipe never set any fruit in our garden for 25 years, except once, and then only a single pod, evidently because it does not get the needful help; for in its native haunts in the mountains of Virginia and Carolina, it seeds freely. There some small insect, probably a coleopterous bug, that can enter the narrow orifice, doubtless visits it, attracted by the odor, and feeds on the scanty secretion at the very bottom of the flower. It can hardly fail to crawl over one of the anthers on its way out, and get its legs or chest powdered with pollen. Some of this pollen may be left on the stigma of the same flower, but is more likely to be deposited on the stigma of the next flower the insect enters. We hope to show that this provision for cross-breeding, which is so very complete in these two cases, and in several others we have yet to mention, is not confined to certain extraordinary instances, but is so common in some way or other, that it must be regarded as the rule among flowers.

A. G.

Something About Budding.

Were the horticultural department of the *Agriculturist* made up solely for accomplished gardeners, we should devote it mainly to recording the progress of horticulture. But as it is for the people at large, to whom as a general thing, the simplest operations of the gardener are mysteries, we are often obliged to go back to first principles, and treat of things which, to some readers, are as simple as A B C. Our correspondence is a fair index of the wants of our readers, and as we have now several letters asking us to say something about budding, we give such directions as will enable any one to perform the operation.

Budding consists in removing a bud from one tree and planting it, so to speak, in the stem of another. The things required are: buds; stocks, as the tree to be budded is called; a knife; and some tying material.

Buds.—Look at a shoot which has grown this year, upon any fruit tree. When it ceases to grow in length, it commences to form buds, which are to be developed and continue the growth next year. There will be a terminal bud at the end of the shoot, and others along the side, at the base of each leaf, called *axillary* buds. These last are the kind used in budding, and there will be a difference in these. Those nearest the end of the shoot will be the largest, while those farthest down will be very small and sometimes hardly perceptible. The shoots are cut when the buds are well formed, the time varying with the kind, and somewhat with the

season, just below the last plump bud. If the buds on the upper end of the shoot appear un-

Fig. 1.

ripened, cut them off; then cut away the leaves, but let the leaf stalk remain, and we then have what nursery men call a "stick of buds," (fig. 1) which may be used at once, or kept from drying in damp moss, or other material, and be preserved a week or two in a cool place.

Stocks.—Budding is usually performed on young stocks. Peaches are worked the first year from the seed. Pear, apple, and other stocks are grown one year from the seed, taken up and heeled-in for the winter, and set out in the spring in nursery rows, and are usually ready to bud the following summer or autumn.

Knife.—Any sharp thin bladed knife will answer, where there is but little budding to be done, but for continuous work, as in nurseries where buds are put in by thousands, a proper budding knife is used, the form of which depends much upon the fancy of the operator. Sharp and round pointed knives are made for the purpose, with a thin piece of ivory or bone at the end of the handle for lifting the bark. Some rapid operators lift the bark with the knife blade.

Tying Material.—Bass bark or matting is the best material, though in absence of this, woolen yarn, cotton wicking, or even a narrow strip of cotton cloth may serve as a substitute.

Time for Budding.—Stocks can only be budded while they are growing, and the bark "runs" or parts easily from the wood. Plums usually stop growing the soonest and are the first to be budded. The season for budding extends from July, with the plum, to September, with the peach, the time for each variety being modified by the season and location. When the buds are well ripened and the bark lifts easily is the proper time.

Operating.—Remove a bud (fig. 2) from the stick by cutting from below, inserting the knife about three quarters of an inch below the bud, and coming out half an inch above, taking as little wood as possible. The bud is usually held between the lips while an incision is made in the stock. Select a smooth place on the north side of the stock, as near the ground as possible, especially if budding on the quince or other dwarfing stock. Make a cross cut quite through the bark down to the wood, and then a longitudinal one extending from this down, as shown in fig. 3. Lift the corners of the cut portion without wounding the bark, and insert the bud, holding it by means of the leaf stalk,

and crowd it well down into place. A portion of the bark of the bud will project above the horizontal cut, this must be cut off even with the cross cut, so that the bark of the bud and that of the stock will fit nicely together, as in figure 4. The bud is now to be securely tied: commence winding below the bud and bind securely to exclude air and rain,

finishing the winding above the bud, as in fig. 5. In a fortnight, if the buds appear plump and sound, the union has taken place; if they have shrivelled, the operation may be repeated, if not too late in the season. In about a month the tying may be removed, but the buds should be looked to before this, and if from the growth of the stock, the string is so tight as to cut into the bark, it must be loosened. Some propagators always remove the portion of wood beneath the bud, while others leave it in. Where it parts readily from the bud, it may be removed, but where it adheres firmly, it is best to leave it in, as there is great risk of injuring the bud in trying to remove it. Mr. H. Unger, of Logansport, Ind., who was formerly engaged in the nursery business, sends us a form of budding knife which he found so satisfactory, that he wishes others to have the benefit of it: "Take a wide bladed budding knife, and grind a bevel on the point three-fourths of an inch long; this prepares the knife for the operation. Now, make your cross cut on the stalk so as to flare the bark out a little, place the knife as shown in the engraving, fig. 6, bear on sufficiently hard to cut through the bark, make a quick right and left motion with the upper or heel of the bevel, keeping the point fixed. This makes the perpendicular cut and opens the bark at once so that the bud can be inserted and shoved down to its place without any difficulty. This mode does away with all devices for opening the bark, all of which are more or less calculated, in their use, to rupture the tender inner surface of the incision, a thing that should always be avoided, as it militates against the sure and speedy union of bud and stock. I will venture to say that a smart man with some one to tie the buds for him, can set at least three thousand buds per day by using the above described knife."

Fig. 3. A drawing of a vertical stem with a cross cut and a longitudinal cut, showing the bark being lifted.

Jerusalem Artichoke.—(*Helianthus tuberosus*.)

Every one recalls the "Artichoke," which as a boy he used to dig out of the old garden, and which, as boys will eat everything that will yield to their teeth, he used to crunch and consider good. This old plant, which is occasionally seen, has now turned up in France, as something wonderful, and the journals are as enthusiastic over it as only Frenchmen can be. This is nothing like the true Artichoke, which is a thistle-like flower, the leafy scales of which are eaten. The Jerusalem Artichoke is a species of Sunflower, which bears tubers somewhat like a small long potato. These tubers are eaten when cooked, and as a salad, and from their resemblance in flavor to the Artichoke, they have received its name. The origin of the name "Jerusalem," as applied to this plant, is a little curious. As already stated, the plant is a species of Sunflower, which in Italian is called *girasole*, turn-sun. The word *girasole* easily run into Jerusalem, a name now firmly fixed upon the plant, and does not, as many suppose, indi-

cate its origin, which is really South American. The plant is just now lauded by the French writers as being even more valuable than the potato. Its tubers furnish food for man and beast, its leaves are excellent forage for cattle, its green stems are good as manure, while the dried stems are of great utility as stakes for making fences. Then, of course, follow figures showing the great profit per acre, which we forbear to give. Notwithstanding the extravagant view the French have of this plant, it probably merits the attention of our Southern and Western friends as a food for swine, and some of them will do well to test its real value by planting it and allowing the hogs to root it out.

Growing Water Cresses.

Among the salad plants of early spring, none are more highly prized than Water-Cresses. Judging from the high price at which they are sold in our city markets, their culture must be very profitable, inasmuch as a plantation once established yields a regular income every year. The water-cress (*Nasturtium officinale*), a member of the Mustard Family, is a native of Europe. It is, in many of the older settled parts of the country, naturalized in the ditches and streams. Though we have often collected the cress from the places in which it grows spontaneously, we never cultivated it, and as we can not draw upon our own experience, we give the following directions for its cultivation from the London Gardener's Chronicle, asking those who can suggest any modification of the mode of culture to do so. "Their cultivation is easy where there is a command of a gently flowing stream, and a depth of from 3 to 6 inches of water can be secured. If the bottom is of mud it must be removed and a new bottom of gravel substituted. The best time to form beds is May and June, for autumn use, and September and October for spring use, at which time select strong, well-rooted cuttings, and fasten them to the bottom of the stream on the gravel, by means of a stone placed on each cutting. The rows in shallow water should be 18 inches apart, but if the stream is very deep, 4 or 5 feet is not too much. Care should be taken, in gathering the crop, not to disturb the plants; hence it is always best to use a knife instead of breaking them off." The Bitter-cress, (*Barbarea vulgaris*), is sometimes sold in our markets. It is greatly inferior to the Water-cress, has less rounded divisions to the leaves, and its flowers are yellow, while those of the Water-cress are white.

Increasing the Size of Fruit.

That a dozen fine specimens of any kind of fruit are better worth having, than double the number of half grown and poorly ripened ones is too obvious to require argument. Thinning the fruit is one of the most ready and effective means to secure its full development, but there are other aids which will be mentioned presently. Thinning is often omitted through negligence, but more frequently from timidity. Indeed it does require some courage to remove half the young fruit from a tree, until one has experienced its utility. Not only do the remaining fruits acquire greater size, but a degree of perfection never found in an overabundant crop. One of our principal growers of the Isabella grape, whose success is generally credited to his favorable location, attributes very little to this circumstance, but thinks that his almost certain

crop of well-ripened fruit is due more to his severe thinning—taking off three-fourths of the berries—than to anything else. The largest pear growers of our acquaintance thin severely. The amount to be removed in thinning will depend upon the variety and vigor of the tree; with trees in full bearing, from one-third to one-half the fruit may often be removed with advantage. The earlier it is done after the fruit commences to grow, the better, except with stone fruits, which are allowed to remain until the stone is formed. Where very large specimens of fruit are desired, growers resort to other expedients or tricks, some of which, such as "ringing" the bark, we can not commend, while others, such as shading the fruit during its period of growth until the time of ripening, are harmless. Supporting the fruit so as to relieve the strain upon the stem, and supporting it right side, or blossom end up, are both said to aid in augmenting the size. Some horticulturists in Europe go so far as to inarch a leafy shoot upon the fruit spur, and thus bring to the fruit a greater supply of sap than it would otherwise get; and a solution of sulphate of iron (copperas), 20 grains to the pint of water, is applied by the French gardeners. The fruit is wetted with this two or three times during its growth, and it is said to increase its size and improve its beauty by preventing fungous spots. But these are refinements that few of our readers will care to practice: thinning, added to good culture, will give all that need be desired.

Protection from Late and Early Frosts.

The direction given by Cromwell to his soldiers to "trust God and keep your powder dry," implies that Providence helps those who help themselves. Much of our horticulture is carried on with a blind trust in Providence, and a general neglect of the powder. Many of our growers scout the idea of protecting anything, and think that whatever is not perfectly hardy is not worth cultivating. Now, all cultivation is artificial; we give certain plants advantages which they do not possess in a state of nature, and anything that tends to assist the plant to its best development is legitimate; the limit to artificial aid being the extent to which it will pay. Nothing can be further from nature than a hot-bed; yet every gardener considers it legitimate, even necessary, to give his seedling plants artificial heat and protection. The very general destruction, late in May last, in some localities, of tomatoes, grape shoots, and other

PROTECTION FOR GRAPE VINES.

things, to the total loss of the crops, should lead us to consider whether some protection would not pay. We do not every year have such killing late frosts, but we do, almost without exception, have late in May, or early in June, a cold spell, in which several chilly nights give plants a check from which they are slow to recover. Then in autumn we have a few early frosts

which nip the tender things, dahlias, etc., just as they are in perfection, and usually after this, weeks of glorious weather, in which those plants that escape the first attack seem to fairly revel. It is surprising how slight a covering will protect plants. By a judicious use of sticks and newspapers, we have had dahlias bloom, and tomatoes continue in fruit, long after those of our neighbors were blackened and dead. In Europe, where horticulture is more developed than with us, protection is as much a part of the gardener's duties, as propagation, or pruning. How far it will pay is a matter that we have yet to learn. We find that it pays to cover strawberries by the acre, and in France, it pays to arrange vineyards of many acres with *paillassons*, for protecting the young growth, and covering the ripening fruit. Those who have small gardens and who cultivate as much for the love of it, as for the products, will be willing to take any pains to help their pet trees and vines. A sheet thrown over a vine when a frost is anticipated, will often save the season's crop. We some time ago (Feb. 1863) gave directions for making straw mats, which are always handy to have. Screens made of laths filled in with straw are very useful; these may be laid over plants, or two put together roof-wise, and give ready protection. We give a cut from Guyot on the vine, showing how protection is afforded in vineyards on a large scale. The vines are planted against ridges, which are 8 or 10 inches high, and trained low, much after the plan shown in figures 1 and 2, on page 224, of the June *Agriculturist*, except that the vine is planted slanting toward the stakes, for the purpose of allowing the protection to be used. A straw matting, supported by stakes and wires, is placed over the whole row of vines, and it is so arranged that it may be turned up vertically to afford protection against the prevailing winds. We have not space now to give minute details of this method of culture, but simply give these suggestions which no doubt some of our wide-awake cultivators will carry into practice.

Collecting and Studying Plants.

A number of persons ask us to say more about wild flowers, and to give illustrations so that they can identify the common plants they meet. We can not devote a large space to any one subject, and though some may like to have more said about wild flowers, there are others who care nothing for them, but wish fruit, field crops, garden vegetables, etc. We try to gratify all and neglect none. To those who notice flowers, we can not too thoroughly commend the study of them. Figures—mere portraits of plants—help the superficial observer to find the name, but this gives him little idea of the structure of the plant, or its relationships. A dozen plants well studied, and of which the structure is well understood, will be a greater help to a knowledge of plants in general than a volume of nicely made portraits. We can not do our flower loving readers a better service than to advise them to study Gray's *Lessons*, to get an idea of plant structure in general. We know of no work which presents the subject in such a popular, and what is equally important, thoroughly correct manner as this. A novice can read it and understand it, and the advanced botanical student will, from its perusal, get new light upon his science. The general structure of plants being understood, the determination of any particular one is easy. For this purpose we have no works, which, for completeness and

accuracy, will compare with Gray's Manual for the Northern States, and Chapman's Flora for the States south of Virginia. Our friends on the Pacific Coast must wait a year or so for Prof. Brewer's Flora of California, which will include nearly all the plants not contained in the other two works. So much for books. In collecting, it is a too common fault to have regard to the flower and nothing else, and those who commence collecting plants spend a year or two in drying "snips" from the tops of plants, to be thrown away when they have learned to make better specimens.

A specimen should be a complete representative of the plant—not only the flower, but bud, fruit, or seed, all its various kinds of leaves, and in small plants, even the root. With some plants these can all be represented in the same specimen, but with others it is necessary to collect specimens both in flower and in fruit. Shrubs and other woody plants have usually the same kind of leaves throughout, but with herbaceous plants the leaves near the root are often very different from those near the stem, and in collecting this should be kept in mind, and both kinds of leaves secured. In preserving plants, they are to be thoroughly dried, and as newspaper is usually the handiest, this may be used, though any unsized paper, brown is as good as any, may be used. Two sorts of paper are required: *folds* and *dryers*. *Folds* are simply pieces of paper folded once, just like a sheet of writing paper. The *dryers* are made of six or more thicknesses of paper, with a stitch through them to keep them together. Having folds and dryers prepared, lay down one or two dryers, then a fold, containing the plant nicely laid out, then another dryer, another fold, and so on, until all the plants are disposed of, observing to use two or more dryers above and below those folds which contain very juicy plants. When all the plants are in, put a board on the pile, and on this large stones or other weights. The pressure should be just enough to keep the plants from wrinkling—and not crush them—50 to 100 pounds, according to the number and nature of the plants. The next day, at least, the dryers must be changed. The pile is to be rebuilt with fresh dryers. Put down a dryer, on which place a fold from the pile, without opening it or disturbing the plant, then another dryer, another fold, and so on. Spread out the dryers from the first pile to dry, (the drier they are the better,) and then they will be ready to use in another change. Plants when first put in should have the dryers changed at least once a day, and if they are very succulent, still oftener. It is to be understood that the plants are not to be taken out of the folds until they are quite dry, and when the change of dryers is made, they are to be undisturbed. When quite dry, the plants may be put away into the collection or herbarium. Any arrangement that will keep together plants nearly related, will answer. We must defer a description of the usual form of a herbarium until another time. We would remark that it is best for all collec-

tors to adopt the standard size for their drying paper, about 11 × 16 inches, and all specimens should be bent or cut to conform to this size.

American Cowslip.—(*Dodecatheon Meadia.*)

Those who are familiar with foreign books and papers on floriculture, will have noticed the high estimation in which this plant is held abroad. Last spring, one of the English horticultural papers offered a prize for the best lists

country the not inexpressive name of "Shooting-star." The flowers are of a beautiful rose purple color, yellowish in the throat, and the general effect is heightened by the bright yellow of the stamens, with brown filaments. There is a white variety which is less showy than the ordinary color. The plant is found growing wild in the rich woods of Pennsylvania, and further South and West, and is quite hardy in cultivation.

It does best in a cool and somewhat shady situation. The foliage dies soon after the flowering is over, and the stools may be divided when the plant is in the dormant state. Seeds are sold at the seed stores, from which, with proper care, the plant may be raised. The seeds are very fine, and like other small seeds, are best started in boxes. The name "Cowslip" is in some parts of the country applied to the *Caltha*, a yellow flower related to the Buttercup. This plant belongs to the same family as the true Cowslip—the Primrose family—one which gives us the Auriculas, Polyanthuses, Cyclamens, and other beautiful plants.—The botanical name *Dodecatheon*, means *twelve gods*; its application to this plant is not obvious. We hope to see increased attention given to hardy herbaceous plants, which have well nigh disappeared before the rage for bedding flowers, and among those we would commend to the notice of lovers of beautiful flowers is the *Dodecatheon*.

Horticultural and Botanical Congress.—Europe and America.

On the 22d of May last, there assembled in London, The International Horticultural and Botanical Congress. International so far as Europe was concerned, for though an American here and there may have been invited, American horticulturists as a body were ignored by those having the matter in charge. We are not at all surprised at this, as it is of a piece with the "British neutrality" which has persistently refused to acknowledge the existence of horticulture in America.

Probably there never was an assemblage like that which convened at the time and place above mentioned, for the number of eminent horticulturists and botanists brought together, and while we regret that some representative man of our own country was not present, we rejoice

that so many of our trans-Atlantic brethren convened, and look for the report of their doings with much interest. We mention this foreign Congress as introductory to calling attention to a body of quite as much importance that is to meet in St. Louis, Mo., on the 4th of September next. To be sure this meeting is only that of the American Pomological Society, but it is as important to us as that of the International Congress is to Europeans. It will bring together cultivators from as widely different climates as did that Congress, and if we may not be as strong in the array of great names, we at least shall have men of large experience, whose deliberations, if properly conducted, will be of benefit to the cause of horticulture.

AMERICAN COWSLIP.—(*Dodecatheon Meadia.*)

of fifty herbaceous plants. Many lists have been published, and we find the *Dodecatheon* in at least half of them. Though so popular abroad it is seldom that we find it in cultivation here, except in the gardens of those who cherish these less fashionable plants. Our engraving is from a plant from a friend's garden, and to save room, one below the average size was selected. What can be prettier than this? A graceful stem arises from a cluster of leaves, and bears at its top a number of flowers upon long stems. The flowers are exceedingly quaint in their form, the corolla being turned sharply back, somewhat like those of the nearly related green-house Cyclamen. This peculiar shape of the flower has given it in some parts of the

At these meetings too much time is usually devoted to general desultory debate, and perhaps the same thing can not be avoided this year, but let us endeavor to have the next meeting conducted differently. Let the business be arranged beforehand, and committees be appointed for each fruit, and all communications be written and presented through them, and then a limited debate be allowed on the papers, confining the discussions to *things* without inuendoes concerning persons, or flings at localities. If papers were written and read, we should be spared loose talk and going over the same ground several times, as is the habit of many speakers. This Society is called the *American Pomological*; let us see that its future meetings are of a character that will reflect credit on the name, and that its proceedings shall be of a value that will make them sought for as exponents of our present pomological knowledge, and indices of our progress.

HOUSEHOLD.

What is Vanilla?

"Lemon or Vanilla?" is the question usually asked when one orders ice cream, showing the great popularity of these two flavors. Of the many who are fond of this peculiar and, to most persons, delicious aromatic, probably but few know anything more about it than that it is a sort of bean, as the article is known in commerce under the name of "Vanilla beans." Vanilla is one of the few economical products of that remarkable family of plants known as Orchids, or *Orchidaceae*, so prized by the florist for the great beauty of its flowers, and so interesting to the botanist for the wonderful modifications of structure the flowers present. We have a number, such as the Lady's Slippers, Orchises, etc., which are all terrestrial, or grow in the soil; but in the tropics, where they abound, most of them grow upon the branches of trees, and draw all their sustenance from the air; hence when these plants are cultivated in our hot-houses they are popularly known as "air plants."

The Vanilla differs from most other orchids in being a climbing vine, such as we have shown in the engraving, clothing a dead trunk of a tree. It throws out great numbers of aerial roots, by which it clings, and produces very thick shining leaves. The flowers of the Vanilla are not as showy as those of most of the family, and are produced in clusters that are succeeded by bunches of long slender pods, which are the "beans" of commerce. In May last an account was given of the way in which insects conveyed the pollen from the stamens of the Iris and other flowers to the pistils, and more is said on the same subject on p. 257 of this number. It is worthy of note that the flowers of the Vanilla are in like manner dependent upon the help of insects, or they will produce no fruit. In tropical America, the native home of the plant, there are insects which understand how to do this, but in the East Indies, where the plant is cultivated, there are either not the right sort of insects, or they are less acute than the American ones, as the Vanilla produces no fruit unless the flowers are fertilized by hand. The pods are some 6 or 8 inches long, narrow, three-sided, and if allowed to remain on the plant, finally burst into three valves or parts, and scatter the minute black seeds. The pods are gathered when fully developed, dried in the sun, and afterward rolled up in parcels where they undergo a sort of fermentation, or sweating

process, to develop the odor. It is said that the fruit allowed to dry without this treatment possesses very little aroma. The pods are afterward oiled, done up in bundles, and sent to market. The best will be found to be frosted with minute crystals which are the aromatic principle. The name of the plant is *Vanilla aromatica*; Vanilla is a Spanish word, meaning a little pod. The Tonqua Bean, Sweet-scented Vernal-grass, Seneca-grass, Mellilot, and some other plants, have an odor resembling that of Vanilla, and contain the same or a very closely related aromatic principle. Indeed, the Tonqua bean is often substituted for Vanilla in flavoring, and the "Extracts of Vanilla" are frequently wholly, or in part made of it. The Tonqua bean is much less expensive than Vanilla, but the substitution can only deceive those who are not familiar with the flavor of the two. Not only is Vanilla largely used to flavor ice cream, but for

VANILLA.

custards, Russes, cakes, and many other delicacies. Probably a *reliable* extract is the handiest form in which to use it. The best way to use the bean itself is to beat it in a mortar, with sufficient loaf sugar to finely divide and powder it, and to absorb all the oil. This is to be kept closely stopped.

A Talk About Preserving Fruits.

In no other department of housekeeping has there been so great progress, during the past dozen years, as in the preservation of fruits. It is now practicable to have a supply all the year, nearly as good as the fresh picked. Instead of the dried apples, peaches, cherries and currants, and the concentrated costly jars of preserves to be brought out only for "company," or special occasions, it is now easy, and economical in money as well as in health, to have a daily supply of good, naturally flavored, almost fresh pie-plant, strawberries, cherries, blackberries, raspberries, peaches, pears, huckleberries, apple sauce, etc. The fruit thus kept, is healthful, and with high-priced butter a cheap bottle of nice fruit upon the tea-table, is economical, as it furnishes both nutriment and condiment.

There are various contrivances and methods for accomplishing the object, and each season brings out from half a dozen to two dozen new de-

VICES. In what follows, we speak wholly from home experience, remarking that we have latterly been almost uniformly successful in securing a full supply of various fruits, that have been agreeable to the home circle as well as to visitors. The chief requisites, after the fruits, are: Some good, convenient form of bottles or cans, a cooking vessel, and sugar.

The Fruits.—Fruits of all kinds are easily preserved, as are also rhubarb or pie-plant, and tomatoes. The main supply of fruits proper for the year consists, in the order of abundance: 1st, of peaches, when plenty; 2nd, strawberries; 3d, cherries, when plenty; 4, pears; 5, raspberries and blackberries; 6, huckleberries, etc. Apple-sauce is put up plentifully at different seasons, usually in the bottles first used for other fruits. Pie-plant and tomatoes, are preserved in large quantities, so as to have an abundance whenever wanted, until they come again. Indeed, all the fruits are put up in supply to last until a new crop of each, and in a season of special abundance, a two years' stock is laid in. We seldom find much difference in bottles of fruits opened after one, two, and sometimes even three years.

Bottles and Cans.—We have used a dozen different kinds, and succeeded with most of them, but have latterly settled down upon a simple form of glass bottle, usually quart size, for everything but tomatoes, and in part for these. Our chief failures have been with some tomatoes carefully put up in glass bottles, which fermented; yet we shall continue to use these, expecting that further experience will secure unfailing success. We have never failed with tomatoes in sealed tin cans, large and small, and they do not seem to act upon the tin at all. Glass is always preferable, however, for all preserved fruits, etc., as unpleasant effects may sometimes result from corrosion. Any kind of glass bottles will answer, if the neck be large enough to receive the fruit handily, and of such form as to admit of tight corking,—if soft corks of good quality can be obtained to fit them. If the corks are softened in hot water, pressed in firmly, and covered tightly with wax and cloth tied over, or with a well waxed cloth tied on, they answer. A corked bottle inverted into a little tin dish or patty-pan, or in a saucer,

containing a spoonful or two of cement, is effectually closed, if care be taken not to leave any air bubbles around the edge. The cement used is, $1\frac{1}{2}$ ounces of tallow melted with 1 pound of common resin, in a tin or iron vessel. Make in quantity, and heat it up as often as needed; every melting improves it. The only care required, in using wax for closing the bottle mouths, is to have the necks wiped clean after the fruit is put in, so that the wax will adhere firmly to the glass.

We now mainly use some kind of the patented bottles with covers closing upon an India rubber ring, which dispenses with wax. Any form that will *absolutely shut out all access of air*, will answer every purpose. We use most of the "Baker," or "Potter & Bodine" Jar, which is a wide mouthed quart bottle, with a tin or glass cover upon an India rubber ring, and held by a half oval clamp that is pressed down by turning it into a half screw swelling or projection upon the outside of the bottle neck. These are quickly put on and taken off. Any good form of bottles, though costing most at first, will in the end be the cheapest, as they will last for many years, with an occasional renewal of cheap rubber rings. We seldom break more than one or three bottles in a hundred, in a year's use.

The Cooking Vessel.—The best is the iron-porcelain kettles, now quite common, which are very

convenient for many cooking purposes. They are iron vessels coated on the inside with porcelain, or white earthen-ware, glazed. One holding five or six quarts will answer. Wide flat ones are preferable. Copper or even brass vessels, if well cleaned, will do; or a tin pail or pan can be used.

The Sugar.—For very nice preserved fruit, as white peaches and pears, the best Refined A sugar is desirable, and for all kinds, we think sugar as good as the Refined B sugar is best, and even cheapest on the whole. For apple-sauce, put into cans for general family use, C, or the best light brown, will answer. —Our rule is, to use just sugar enough to fit the different kinds of fruit for the table. Some families like more, and some less; hence no definite rule can be given. For the sweeter fruits, strawberries, peaches, sweet pears, huckleberries, and the like, we use 4 to 6 lbs. of sugar to the gallon of water, or $\frac{1}{2}$ to $\frac{3}{4}$ lb. to the pint. For more acid fruits, as cherries, plums, sourer pears, currants, crab apples, etc., about 1 lb. to the pint, more or less, according to the acidity, and ripeness.

Selecting and Preparing the Fruit.—As a rule, choose fully ripe fruit, but not that over-ripe. A soft or decaying spot may injure the flavor, and tend to decay the whole. If too green, the flavor will be inferior. The berry fruits are to be sorted, defective ones rejected, stems and hulls removed, and carefully but quickly washed if soiled, though this is always to be avoided if possible, as it injures the flavor, especially of raspberries and strawberries. Peaches, pears, etc., need paring. Some scald peaches, to aid in removing the thin skin, but they are better pared. They may be preserved whole, but are better cut in halves and the pits removed.

Cooking the Fruit.—Three methods are used: Some place the fruit in bottles with sugar added, put on the covers nearly tight, set the bottles in warm water, and heat to boiling, and after time is given to heat the fruit through, the covers are fastened down closely. We prefer, as being much less troublesome, to first cook the fruit in the porcelain or tin vessel, and then dip it hot into the jars, which must have been previously warmed to prevent their breaking, as noted below. For the nicest preserves, the fruit may be cooked in a syrup first, then dipped out into the hot jars, and a new syrup be filled in hot. The cooking syrup may be used for several successive batches of fruit, and finally for poorer kinds of fruit, or making common sauce. For ordinary preserving, the fruit and the syrup used in enoking it, may be dipped together into the bottle. *The amount of cooking is important.* Too little hazards the keeping, and too much, not only mars the appearance, but it greatly injures the flavor. In all cases have the syrup boiling hot and over the fire when the fruit is first put into it, and it will then heat through without becoming soft or losing its flavor. Only fruit enough to fill three or four bottles should be cooked at a time, or some will be overdone.

Strawberries should cook but 3 or 4 minutes before dipping them into the bottles, which should be previously all ready and hot. With this precaution they retain their natural form and flavor.

Peaches, being larger, require a little more time to heat through, but when fully ripe, 5 to 7 minutes is long enough, and the same is true of well ripened pears, especially the Bartlett's, and Virgilians, which, by the way, make a most delicious preserve.

Quinces, and hard pears, may cook 10 to 15 minutes, or more, for they should become tender.

The general rule for cooking, is, to have the soft fruits just heated through to the center, as quickly as may be after they go into the syrup, and then get them into the bottles immediately, giving no time for the escape of the aroma.

Tomatoes, well ripened, are scalded to skin them easily, then put into just water enough to prevent burning, and carefully cooked $\frac{3}{4}$ to a full hour, thus reducing their bulk materially. A very little salt is added, but no sugar. They can be seasoned and sugared when wanted for use.

Rhubarb or Pie Plant.—Cut the stems in small pieces, as usual. Cook with only a few spoonfuls

of water to keep it from burning before its own juices are at liberty. Boil $\frac{1}{2}$ hour, or so, or until ready for the table, and bottle without sugar added. This is excellent for winter and early spring use as sauce, and in making pies. It may be used in various ways. With crackers a pie very closely resembling apple pie, can be made.

Bottling.—Have all needed bottles, corks, covers, wax if used, etc., ready before beginning to cook the fruit. Have a kettle of hot water on the stove, and the last thing before cooking the fruit, dip a bottle rapidly in and out of the hot water until heated through, then fill it with the hot water and let it stand, and so with all the bottles needed for one batch of fruit. When that is cooked, pour out the hot water, and dip full of fruit and syrup, or, if new syrup is used, as noted above, fill with the hot fruit skimmed out, and pour in the new syrup last. For soft or nice fruits, dip in carefully, with the jar inclined, to avoid bruising or breaking. Let the bottles stand about two minutes, jarring them to facilitate the escape of air bubbles; wipe the tops carefully clean with a damp hot cloth, then pour in enough more syrup to fill them, if there is much settling. Now apply the caps, and clamps, or other covers, or corks, and close the bottles as closely as may be—or air-tight. One point is, to have little if any air left in the fruit. As there is always a little, often enough to produce a tuft of mouldiness on the top, which does not injure the mass in the bottles, if not mixed with it in handling, it is well in opening a bottle, to always remove a thin film from the top. Store the bottles on shelves in the cellar or other cool place, where they will not be exposed to great changes of temperature.

Boiling Eggs—Sundry Ways.

Messrs. Editors.—The writer is fond of boiled eggs—very. Soft boiled and hard boiled, but not par boiled. The readers of the *Agriculturist* may know exactly how to boil an egg to perfection, but if they do, they are an exception to the people I meet with away from home. Call "time"; plump the eggs into a sauce-pan of boiling water—in three minutes, "time," again, and the eggs are done. Half a minute more makes them too hard, and half a minute less leaves them glairy. So eggs are usually boiled, except at restaurants, where, if you are so indiscrete as to ask for soft boiled eggs, they are not cooked at all, but barely heated through. The eggs so cooked have their whites hard and tough as leather, their yolks barely cooked at all. I do not like them so, and hope your readers will try my plan, which is indeed not mine, but old enough.

How to Boil Eggs without Boiling them.—Scald out a dish that will hold the eggs and twice as much water. Wash the eggs clean; put them in the dish and fill it with boiling water; set it in a warm place for 5 minutes; then pour off the water, add as much more (boiling) and send at once to the table. Within 2 or 3 minutes the eggs will be cooked enough for those who like very soft boiled eggs; a little while later they will be done through, the white as soft as curd, yet well done, and the yolks will be cooked. The quantity of water should be in proportion to the number and size of the eggs, and if the water be poured off and a third time boiling water added, the white will not be tough and leathery.

To Boil Eggs Hard, put them into warm water and let it come to a boil, and boil 10 or 15 minutes. The yolks will then be crumbly.

To Poach Eggs—first prepare toast, taking pieces as large as one's hand, buttered, salted and made soft with warm water, or use hot milk with the butter and salt in it. Cover the bottom of a frying pan with $\frac{1}{2}$ to $\frac{3}{4}$ an inch of water, and when boiling, break into it carefully the eggs, one after another, not putting too many in at once, and remove them as fast as the whites are cooked. Take care not to break the yolks and lay each egg upon one of the pieces of toast.—A friend states that the eggs may be dropped in muffin rings laid in the frying pan, which is an improvement in the looks at least of the dish. Poached eggs are vastly better than fried, even with fried ham. X.

Cooking Cabbage.—Boil until tender, in clear water, or with other vegetables as may be convenient, then chop fine. To one medium sized cabbage head add two tablespoonfuls of thick cream, a bit of butter half as large as a small hen's egg, salt and pepper, or add vinegar to suit the taste.

For other Household Items, see "Basket."

BOYS & GIRLS' COLUMNS.

How to Play Base Ball.

(Continued from page 229.)

The players having taken their proper places, the pitcher delivers the ball for the first striker. He must pitch, not throw nor jerk it. With practice, this can be done both straight and swiftly, and experienced pitchers acquire a way of giving the ball a peculiar twist as it leaves the hand, making it more difficult for the striker to hit it squarely; this may prevent his giving it a full blow and driving it far into the field. The pitcher must deliver the balls fairly, so as to come within good range of the striker. If he fails to do this repeatedly, the umpire after warning him, calls "one ball," then "two balls," and if he calls "three balls" in this way, the striker has the privilege of going unmolested to the first base, and any batsman who may be occupying bases, may also walk one base further.

The striker watches for a good ball, and when it comes, tries to strike it with his bat as far into the field as possible, and also to drive it in such a way that it may not be caught by the fielders. He may do this by forcing it beyond them, or by making it go low, or by sending it between the fielders, if he see a good opening. As soon as he has struck, he drops the bat and starts for the first base, which he must touch with his foot or otherwise. Meantime the fielders endeavor to touch him with the ball while passing from base to base. The ball must not be thrown at the striker, but he must be touched with it while it is in the hands of a fielder; if the fielder, while standing on the first base, can get the ball before the striker reaches that point, the striker is "out." The striker watches his chances to run from the first to the second base, then to the third, and finally "home," without being touched by the ball while passing from one base to another, or when standing without touching the base. If he succeeds in doing this he is credited with one "run" by the scorer. When a player sends the ball so far that he runs around the whole course touching each base, without being put out, it is called a home run. This, however, counts no more than an ordinary run. [We think it would be an improvement to have it count two.—Ed.] The strikers take their turns in regular order, each trying to make a run in the manner described above. At each innings after the first, the next player to the last one put out, takes his turn at the bat. In running, the striker must keep within three feet of a direct line from base to base; otherwise he is counted "out." If the ball when struck, first touches the ground, or any other object behind the range of home and first base, it is "foul," and must be so declared by the umpire. In such case, the striker must return to the home base and try again, and any player having started to run from base to base, must return to the base which he left. He may be put out while doing this; the striker is exempt while returning to the home base after having struck a foul ball.

The striker is out if a foul ball is caught before touching the ground, or upon the first bound; or if three balls are struck at and missed, and the last is caught before touching the ground; or if a fair ball is struck and caught in the same manner. If three balls are struck at and missed, and the last one is not caught either flying or upon the first bound, the striker must attempt to make his run, as though he had struck a fair ball. When a fair ball has been caught before touching the ground, players running the bases must return to the places whence they started, and they may be put out while so doing in the same manner as a striker running to his first base; but players when balls are so caught, may run their bases immediately after the ball has been settled in the hands of the player catching it. If a player refuses to strike at fair balls, the umpire should call "one ball," and if he continues to refuse in the same manner, then "two balls," "three balls," and at the third call, the player must run as though he had struck.

Players must make their bases in the order of striking; and when a fair ball is struck and not caught flying, or on the first bound, the first base must be vacated, as also the second and third bases, if they are occupied at the time. Players may be put out on any base under these circumstances, in the same manner as the striker when running to the first base. Any player who shall intentionally prevent an adversary from catching or fielding the ball, shall be declared out. If the player is prevented from making a base by the intentional obstruction of an

adversary, he shall be entitled to that base, and not be put out. If an adversary stops the ball with his hat or cap, or takes it from the hands of a party not engaged in the game, no player can be put out until the ball has first been settled in the hands of the pitcher.

If a ball from the stroke of a bat is caught by an adversary, except as stated in the previous rule, and without having touched the ground more than once, the player is out. If two batsmen are already out, no player running home at the time the ball is struck can count a run if the striker is put out. When three of the batsmen are put out, the fielders take the innings, exchanging places with the former. A match game consists of nine innings to each side, and the side scoring the most runs, wins the game. If the number of runs should be equal, the play is to be continued until a majority of runs is made by one side upon an equal number of innings.

Awards for the Prize Puzzles.

This announcement we expected to be able to make last month, but the Committee to whom the contributions were referred, were not quite ready to report when the paper was sent to press. A very large number of communications were received, many of them excellent in their way, some of which will appear from time to time in these columns. The unsuccessful competitors should not feel that their efforts have been thrown away. The thought, attention, patience, and care, necessary to construct a puzzle, give pleasant and healthful exercise to the mind, combining both work and recreation, and thus some good has come from trying. Failures may be made beneficial if they stimulate a person to try again

In any laudable undertaking; many who have sent puzzles, can, with a little effort, bring out something worthy to be published—keep on trying.

The following are the decisions of the Committee:

1st.—*The Best Mechanical Puzzle.*—Most of those received had not enough originality to claim attention; of the others, none were deemed of sufficient excellence to merit the prize as puzzles. The nearest approach to it was a piece of very ingenious workmanship made by Paul Frick, of Jonesboro, Ill., an engraving of which is given above. It is a fanciful piece of wood work, the different parts neatly finished and joined together by pins and cords, and the whole is enclosed in a glass bottle. The stopper is secured in its place by a cross-piece

running through its lower part. The puzzle about it is, how was it put into the bottle. The maker assures us that the whole was introduced into the bottle's mouth, and put together by means of a knitting needle. This curious article is now on exhibition at the office of the *Agriculturist*, and attracts much attention from visitors. The twenty dollars were awarded to Mr. Frick.

2nd.—For the best *Arithmetical Problem*, ten dollars, to Josiah Keep, Paxton, Mass.

3d.—For the best *Hieroglyphical Rebus*, ten dollars to Charles Darwin, Cambridgeport, Mass.

4th.—For the best *Riddle or Enigma*, five dollars to Mrs. J. P. Ballard, Cambridgeport, Mass.

5th.—The best *Conundrum.*—To the surprise of the Committee, none of the original contributions were deemed worthy of publication, and therefore no prize is awarded.

The Prize Problem, Rebus, and Enigma, will be found under "New Puzzles" in the next column.

The Soldiers' Dogs.

Not long since a dog named "Toutou," came to Paris with a regiment of Zouaves which had returned from Italy. The soldiers were all greatly attached to him, for he had passed safely through a singular adventure which deprived them of all other dogs belonging to the regiment. When the war commenced the Zouaves embarked for Genoa; but as they were going on board the ship, they saw a formal order forbidding the entrance of all dogs upon the vessel. As they were very much attached to their dogs, they were stricken with grief. It was not easy to deceive the sharp lookout kept, for every soldier advanced along the narrow gangway, one by one, as his name was called. Necessity is the mother of invention. The drummers unscrewed their drums and the best dogs of the regiment were concealed in the drums which were screwed up again. When regiments embark no music is played, but on this occasion the Colonel determined there should be music. He ordered the trumpets and drums to take the head of the column, and to play a lively tune. The face of the drummers—every one of whom had a dog in his drum—grew very long! The trumpets sounded; the drums were all silent. The Colonel got angry and bawled to know why the drums did not beat. There was but one thing to do and that was to beat. The moment the drums began to beat, innumerable dogs began to howl and to bay, to the astonishment of everybody but the Zouaves. Everybody looked right, left, backward, forward—no sign of a dog anywhere; and yet, the more the drummers beat, the more the dogs howled. At last a spaniel fell out of a drum, rolled over and over on the ground, got up and took to his heels, howling louder than ever. Roars of laughter greeted this explanation of the mysterious howls. The drummers were then ordered to advance on board, one by one, and each to roll the drum as he came. If a barking was heard, the drum was unscrewed, and the dog put ashore. Only one dog got on board; this was Toutou, who kept quiet through all the rolling.

Early Days of a Noted Chemist.

Mr. Michael Faraday, now living in England, one of the first chemists in the world, distinguished especially for his brilliant discoveries in Electricity, was the son of a poor blacksmith. He was early apprenticed to a book-binder and bookseller, and while learning his trade amused and improved his leisure by making a small electrical machine and other philosophical apparatus. His master, pleased with the boy's talent, mentioned his acquirements to a customer who was a member of the Royal Institution. This gentleman took young Faraday to hear some of Sir Humphrey Davy's lectures. The apprentice made careful notes of the lectures and wrote them out fairly in a neat volume. He disliked his trade and desired to become a scientific man, and at last took the bold step of writing to Sir Humphrey Davy, expressing his wishes and the hope that he might be favored in his views. With the letter he sent his "notes of the lectures." The great chemist was struck with the knowledge displayed in the notes, as no one could correctly report a chemical lecture without knowing something about the science. He invited the boy to call on him, procured him a situation as assistant in the laboratory of the Royal Institution, and afterward associated him with himself in his travels, studies and experiments. He industriously improved his ample opportunities and thus succeeded in rising to the front rank of his profession.

Getting the Worst of it.

"Do you want any berries ma'am?" said a little boy to a lady, one day. The lady told him she would like some, and taking his pail from him, she stepped into the house. He did not follow, but remained behind whistling to some canaries hanging in their cages on the porch. "Why do you not come in and see that I do not cheat you?" asked the lady. "I am not afraid," replied he; *you would get*

the worst of it ma'am."—"Get the worst of it, what do you mean?"—"Why ma'am, I should only lose my berries, and you would be stealing; don't you think you would get the worst of it?"

Answers to Problems and Puzzles.

The following are answers to the puzzles, etc., in the June number, page 229. No. 210. *Illustrated Rebus.*—Wood u c k lamb eye t ass o c eight with fools but two s cape rep roach a band on vicious o o's i e t, or: Would you see calmly associate with fools; but to escape reproach abandon vicious society.... No. 211. *Illustrated French Rebus.*—*J'ai traverse par i sans sou liers*; which may be translated, I walked through Paris barefooted.... No. 212. *Illustrated Rebus.*—*Above, below, around, within, I wander in my dreams*.... No. 213. *Mathematical Problem.*—The squirrel went *nine* times to the box; each time he carried away one ear of corn, and his own two ears, making *three* taken at each journey!.... No. 214. *Enigma.*—All mankind are born free.

The following have sent correct answers up to June 4th: Orrie Wadley, S. P. Howland, C. M. Derwent, J. Dexter Andrew, Jael M. Reeves, Daniel Perrin, Beckie K. Morse, George Fern, Jennie Fletcher, W. B. Phelps, John T. Yarrington, Chauncey Wise, James D. Brewer. Many other names are omitted for want of room.

New Puzzles to be Answered.

No. 215. *Prize Rebus.*—Very good advice.

No. 216.—**Prize Enigma.**

The sage that heads above the tome
In mystic cypher found
Seeks for my *first*, quick uses it,
Then throws it all around.

The Artist links it with his fame
In pictures new and old—
The miser likes it least of all
Among his bags of gold.

My *second*, whether rich or plain
Is but a valued casket,
Its treasured gems no gold could buy,
Nor diamonds should you ask it.

My *whole* was made to send my *first*
Further than could be done without it,
And saves my *second* from the gloom,
Its *lack* has often thrown around it.

No. 217. *Illustrated Rebus.*—A very good wish.

No. 218. *Prize Arithmetical Problem.*—Contributed by Josiah Keep, Paxton, Mass. Two locomotives, A and B, on a straight and level track, are approaching each other. A, is moving at the rate of 10 miles an hour. B, at the rate of 20 miles an hour. When the whistle of A, is 3 miles from the engineer of B, it is blown for $\frac{1}{2}$ minute. What will be the distance of the engineer of B, from the whistle when he ceases to hear the sound, supposing sound to travel 1130 feet per second.

THE FORTUNATE GIRL.

That is the way it used to be with children in old times—at least some people thought so. According to their belief, a great many “little people,” as they were called, lived all over the world. They were said to be very strange creatures—some of them so small that they could easily creep through the cracks of the doors, and so active that they could catch a bird on the wing. Very few could say they had ever seen them. Once in a while a man would tell wonderful stories of how they appeared to him; but it usually happened that he was tipsy at the time, or something else disturbed his brain, so that he could not give a very creditable account of them. But almost every one was ready to tell what they had done. One said they twisted the grass, so that she stumbled, fell, and spilled a pail of milk; another declared that the edge of his ax was blunted by them, and many were sure that the little people stole the milk from their cows in the night time, in short, whatever mischief was done, the little people were sure to be blamed for it. Now, if there were such sprites, that was just the way to make them mischievous, for I never knew any body to be made better by continual fault-finding, and no praise. But in some fortunate places, good little people were said to make their homes, and then every thing prospered. The cows gave plenty of rich milk, the grain grew finely, the lambs all lived, and there was peace and plenty. You can see by the picture how they busied themselves with the children. Notice how that boy’s face is drawn out of shape by the little furies that are tormenting him. Poor boy! What would he do if he could see and catch them. Would he not show as little mercy to them as you would to a mosquito or flea? But the sweet little girl has fallen into good hands. Perhaps her sunny face attracted the pleasant little people, and they like to help her smile.—Since the little people have been driven away from the earth by the noise of steam engines and printing presses, children can no longer blame these creatures for mischief, nor expect their help in being good; the spirits which aid in doing right or tempt to do wrong are very different from any such beings. They

THE UNFORTUNATE BOY.

know how to find the way to the thoughts, but they will give little trouble to those who do not encourage them. So Master Charlie, and Miss Katy, take good care and govern yourselves right, and let sunshine from your hearts make your joyous faces bright.

A Little Boy’s Experiences.

April 10th. At last we have finished plowing for a while at least, and I am glad of it; for I am tired of driving oxen. Brother Charlie says I have been talking to the team, hallowing “whoa”! “back”! “haw”! almost every night. My mind kept “marching on,” while my body was sleeping. I don’t know much to write, that happened last week. We plowed up a field-mouse’s nest one day. There were four young ones and their mother. The old one started to run at first, but came back to defend her family. I couldn’t help feeling sorry when Jumper killed her with one bite. At first he went smelling about the nest, as though he wanted to play with the little mice, but the old one flew at him, and fastened her teeth in his nose, and then he gave her a sharp snap. At another place, the plow ran through a large red ant’s nest. It made a great commotion among the inhabitants of that underground city. There were streets all through it, and the ants ran up and down in wild confusion. There were hundreds of white eggs, which the ants picked up in their mouths and twice carried away out of danger. There were also baby ants, nearly white, which the older ones took up. We stopped to watch them a while. Pretty soon I felt sharp stinging bites on my legs, and at the same time, Jumper who was also looking on began to whine and caper about, and roll, in a very frantic way. The ants had attacked us, and we found them able to inflict considerable pain. The bites soon got well. I think I should not like to live in Africa where the ants are plenty and very powerful. They raise hills as high as a man’s head, and they can gnaw through wood. Missionaries living there say that they destroy clothing, books, and even houses.—I have

already begun to train my calves. I believe they know me, for I feed them every day, and they will let me handle them. I expect to halter-break them so that I can lead them about.—A pair of blackbirds are building their nest in a gourd which I hung up against the house near my bedroom window. It is pleasant to watch them as they go in and out with bits of straw. They keep up a merry warbling, and seem very happy in getting ready for housekeeping. They seem to have a great deal of consultation together, about their furniture, although they have only one bed-room to fit up.

April 12th. I had a quarrel with Charlie this morning about the garden. Father said we might each have a bed to raise what we pleased. We both wanted the same corner, and we both got angry. He is two years younger than I am, and I am ashamed that I was so selfish. Father would not decide between us. He said we must settle it in some way pleasantly, before either of us could have any garden. Charlie went off to school, and I helped father mend fence. After thinking it all over I thought I would tell Charlie, as he was the younger, he could have the corner. When he came home the first thing he said to me was, “Fred, you can have the corner, you are older than I am.” Then I told him what I had been thinking of, and we finally agreed to go in partnership, and both take the corner and work it together. Father liked this, and said he would give us some Japan melon seed to plant. If we raise good melons we can have the pleasure of eating them, and also get a good price for the seed, as they are not very plenty yet. I’m glad our quarrel is all over, for it made us both feel very unhappy.

A GRAVE QUAKEA once, passing through a bad street, was astonished to see his son emerge from a den which no decent person would frequent. The graceless youth drew back, hoping to escape observation. “Nay, Isaac,” said the sad, astonished parent, “never be ashamed of coming out of that sort of place; but be especially careful nevermore to go into one.”

(Business Notices \$2.00 per Agate Line of Space.)

LOCK-STITCH SEWING MACHINES.

Highest Premium, Fair of American Institute, 1865. CELEBRATED REVERSIBLE FEED MOVEMENT. UNIFORM SELF-ADJUSTING TENSION, FOUR SEPARATE DISTINCT STITCHES, WILL GATHER AND SEW A RUFFLE AT ONCE. OFFICES OF THE COMPANY.

505 Broadway, N. Y., and 97 Cheapside, London, England. PRINCIPAL AGENCIES.

WHEELER & WILSON

SEWING MACHINES.

"WOMAN'S GREATEST BOON."—We would advise a man to forego a threshing and thresh wheat with a flail, rather than to see the wife wear her health, vigor and life away in the everlasting 'stitch, stitch, stitch,' when a Sewing Machine can be obtained. The WHEELER & WILSON is an invaluable aid in every household. We have had several different kinds on trial, and after a six year's service, the WHEELER & WILSON has taken the precedence as the best, where all kinds of sewing are to be done in a family."

[American Agriculturist, Jan. 1865.]

THE GREAT FAMILY SEWING MACHINE.

HIGHEST PREMIUM Elastic Stitch SEWING MACHINE.

495 Broadway, New York.

THE YANKEE BLADE.

- 1st.—It is a Patent Sewing Ripper which takes out a seam faster than a sewing machine can make it. 2nd.—Button-hole Cutter for any size wanted. 3d.—Gathers Scratcher; just the thing for it. 4th.—Paper Cutter and Folder, always handy. 5th.—Eraser for removing blot, errors, &c. 6th.—Letter Opener for men of Business. 7th.—Nail Cleaner and Trimmer for everybody. Price only 35 cents; or, three for \$1, \$3 per dozen. Liberal Discount by the gross. Ask your Storekeeper for it, or send price and receive it by mail.

MONEY TO BE MADE.

I will give a Town Agency, except where there are over 10,000 inhabitants, to first person buying one gross of the Yankee Blade. Send price for sample, and Circular. Address W. A. FITCH, 151 Nassau-st., New York.

Come and See Wilson Early Blackberries, including the Old Original Plant in fruit, from the 1st to the 10th of July, at JOHN S. COLLINS' Small Fruit Farm, 8 miles East of Camden, and 1 mile S. west of Moorestown, N. J.

B. T. BABBITT'S LABOR-SAVING SOAP.

This Soap is made from clean and pure materials, contains no adulteration of any kind, will not injure the most delicate fabric, and is especially adapted for woollens, which will not shrink after being washed with this Soap. It may be used in hard or salt water. It will remove paint, grease, tar and stains of all kinds. One pound warranted equal to two pounds of ordinary family soap. Directions sent with each bar for making three gallons handsome soft soap from one pound of this Soap. Each bar is wrapped in a circular containing full directions for use, printed in English and German. Ask your grocer for "B. T. Babbitt's Soap," and take no other.

B. T. BABBITT, Nos. 64, 65, 66, 67, 68, 69, 70, 72, and 74 Washington-st., N. Y.

NEW VOL! JULY NO. READY! Subscribe for ILLUSTRATED PHRENOLOGICAL JOURNAL now. Only \$2 a year; \$1 for 6 months; 20 cents a number. Address FOWLER & WELLS, 89 Broadway, New York.

NEW VOLUME

Begins with July.

Let all the Children Subscribe Now.

The Best Children's Paper in America.

Fighting against Wrong, and for the Good, the True, and the Beautiful.

A First-Class Monthly Paper, of 16 Pages, for BOYS and GIRLS. \$1.00 a Year in advance.

Specimen Copy sent for Ten Cents Address,

ALFRED L. SEWELL, Publisher, Chicago, Ill.

Forney's Philadelphia Daily Press says of it: "THE LITTLE CORPORAL is destined to become the great children's paper of America."

THE LITTLE CORPORAL is the most interesting and instructive monthly in the Union.—Louisville Democrat.

THE LITTLE CORPORAL is universally admitted to be the best juvenile paper now in existence.—Dubuque Daily Times.

It is the cleverest thing of its kind yet realized in America.—Roxbury (Mass.) Journal.

After a careful examination, we can cheerfully say OF THE LITTLE CORPORAL, that it deserves all the praise that has been lavished upon it by the press everywhere.—Philadelphia Episcopal Recorder.

The Little Corporal for one year will do your children more good than a Quarter's Schooling.

Agents Wanted TO SELL

Address GEO. E. & F. W. WOODWARD, PUBLISHERS AND DEALERS IN Agricultural and Architectural Books, 37 Park-Row, New-York.

BOOKS FOR FARMERS and OTHERS.

[For sale at the Office of the Agriculturist, or they will be forwarded by mail, post-paid, on receipt of price.]

Table listing various books for sale, including titles like 'The Dog, by Dinks, Mayhew and Hutchinson', 'Allen's (L. F.) Rural Architecture', 'American Bird Fancier', etc., with prices listed.

Table listing books for sale, including titles like 'The Dog, by Dinks, Mayhew and Hutchinson', 'Frank Forrester, 1 vol.', 'The Dead Shot, or, Sportsman's Complete Guide', etc., with prices listed.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for a month, ending June 12, 1866, and the exports of Breadstuffs from this port thus far, since January 1:

Table showing transactions at the New-York Markets, including Receipts and Sales for Flour, Wheat, Corn, Rye, Barley, and Oats, with prices and quantities.

Table showing Current Wholesale Prices for various commodities like Flour, Wheat, Corn, Rye, Barley, and Oats, with prices for May 15 and June 11.

Gold advanced during the past month to 146 1/2, influenced by unfavorable financial and commercial advices from Europe, and the consequent heavy exports of specie from this port.

depressed. There has been increased activity in Corn, with free purchases for export,—the market closing with a downward tendency, under large arrivals from the interior.

New York Live Stock Markets.—

Beef Cattle.—The supply for a month past has been fully an average one, after allowing for a natural increase over the previous year, but prices have been fully sustained and advanced a little last week.

The calves are worth about \$10 each, on the average, making the cows cost the purchasers \$55 @ \$65. Cows giving 11 to 13 quarts per day bring \$70 to \$80 with the calves; those giving 14 to 16 quarts, \$85 to \$90.

Advertisements, to be sure of insertion, must be received BEFORE the 5th of the preceding month.

TERMS—(cash before insertion): Ordinary—\$1.25 per line of space, each insertion.

New York State Agricultural Society.

IMPLEMENT TRIAL TO BE HELD AT THE CITY OF AUBURN.

Commencing on the 10th day of July With the trial of Mowers, and will continue until all the implements shall be tried.

Trial open to all the States and Canadas.

Entries to be made at the Secretary's Office, Albany, at least one week previous to the 10th of July. Entrance fee \$15.00, for each implement in each class.

A programme of the Trial, with a list of implements to be tried, and a list of Judges will be furnished on application to the Secretary.

IONA and ISRAELLA
GRAPES.

These two kinds greatly surpass all others in their assemblage of excellences for all purposes, and my attention in propagating will hereafter be chiefly devoted to these.

My establishment which was heretofore the most extensive as well as the oldest in the country, has been greatly enlarged and improved this season, for the express purpose of producing the best possible Vines to meet all of the various wants in planting.

Persons interested are invited to visit the Island, and inspect the Vines during every stage of their growth, and note the manner of producing them.

A New Edition of the MANUAL will be published in July, and also a new Price List and Descriptive Catalogue.

My assortment, in addition to the above mentioned, comprises all of the valuable varieties, including remarkable fine plants of Allen's Hybrid, Rogers' Hybrids, Delaware, Diana, Adirondac, etc.

The Vines of the Iona Establishment have generally been acknowledged to be the **Cheapest, quality considered,** as well as the **Best** that have been produced, and the present stock gives promise of more than maintaining their former superiority.

For full account of these new Vines and their history and advantages, see Pamphlet, which is sent to all applicants for two-cent stamp.

C. W. GRANT, Iona,

(near Peelskill), Westchester Co., N. Y.

VINES

of a superior quality are grown at the Canandaigua Propagating Establishment. Dealers and Planters are invited to call and EXAMINE our Vines or send for Price List.

F. L. PERRY, Canandaigua, N. Y.

VINELAND

FARM AND FRUIT LANDS, in a mild and healthful climate. Thirty miles south of Philadelphia by Railroad, in New Jersey, on the same line of latitude as Baltimore, Md.

The soil is rich and productive, varying from a clay to a sandy loam, suitable for Wheat, Grass, Corn, Tobacco, Fruits and Vegetables. This is a great fruit country. Five hundred Vineyards and Orchards have been planted out by experienced fruit growers. Grapes, Peaches, Pears, &c., produce immense profits. Vineland is already one of the most beautiful places in the United States. The entire territory, consisting of forty-five square miles of land, is laid out upon a general system of improvements. The land is only sold to actual settlers with provision for public adornment. The place on account of its great beauty as well as other advantages has become the resort of people of taste. It has increased five thousand people within the past three years. Churches, Stores, Schools, Academies, Societies of Art and Learning, and other elements of refinement and culture have been introduced. Hundreds of people are constantly settling. Several hundred houses are being constructed, and it is estimated that five hundred will be built during the summer. Price of Farm land, twenty acre lots and upward, \$25 per acre. Five and ten acre, and Village lots for sale.

Fruits and Vegetables ripen earlier in this district than in any other locality north of Norfolk, Va. Improved places for sale.

Openings for all kinds of business, Lumber Yards, Manufacturing, Foundries, Stores, and the like.

For persons who desire mild winters, a healthful climate, and a good soil, in a country beautifully improved, abounding in fruits and possessing all other social privileges, in the heart of civilization, it is worthy of a visit.

Letters answered and the Vineland Rural, a paper giving full information, and containing Reports of Solon Robinson, sent to applicants.

Address CHAS. K. LANDIS, Vineland P. O., Landis Township, New Jersey.

From Report of Solon Robinson, Agricultural Editor of The Tribune: It is one of the most extensive fertile tracts, in an almost level position and suitable condition for pleasant farming that we know of, this side of the Western Prairies.

SUPERIOR FARM LAND.—20,000
Acres, Franklin Tract, at Newfield, Gloucester County, New Jersey, on the Railroad running from Philadelphia to Cape May, 30 miles South of Philadelphia—adjoining the Vineland Tract, and 2 miles North of the Vineland Station—for sale at low prices and on easy terms, in lots to suit purchasers. Circulars, with reports of Solon Robinson, Hon. William Ferry, and others, with full information, sent to applicants free. Address JOHN H. COFFIN & CO., Newfield, Gloucester Co., N. J. Improved Farms also for Sale.

600 Maryland and Virginia Farms and Timbered Lands.

Catalogue of Maryland and Virginia Lands, with Geographical description of Maryland, for sale by R. W. TEMPLEMAN & CO. Land Agents, 87 Lexington-st, Baltimore City, embracing a description of the soil and products of Maryland. Sent 25 cents for a copy of Catalogue.

NEW STRAWBERRIES.

Ripawam.—At the great Strawberry Show, of the American Institute, held last June, in this city, the new Seedling **Ripawam**, took the first prize, over all other varieties, for the large berries. The exhibit consisted of over 100 varieties. The Agriculturist was shown in great perfection, but the committee of judges consisting of Charles Downing, of Newburgh, Isaac Buchanan, of Astoria, L. I., and Prof. Huntsman, of Flushing, L. I., decided that the **Ripawam** was entitled to the first prize. In this remarkable Seedling seems to be another advance toward a perfect berry. The plant is very strong and hardy, and wonderfully productive, over 500 berries have been counted on a single plant, the berry of monstrous size, a brilliant scarlet color. It will bear carriage better than any variety I know of, and will not change its beautiful scarlet color for days. It is believed that this variety will surpass all other kinds for market purposes. I shall be ready to deliver plants in rotation as ordered, after the first of August, at the following rates: 12 plants, \$2.00; 50, \$6.00; 100, \$10.00; 1,000, \$90.00.

Ella.—A new Seedling of promise, ripening its fruit before any other kind, fruit large, very sweet, plant vigorous and productive, plants \$3.00 per dozen, or \$10.00 per hundred.

Huntsman's Emily.—A very large and productive, and beautiful variety, a Seedling of Prof. Huntsman, it should be in every good collection, plants \$2.00 per dozen; \$10.00 per hundred.

Golden Queen.—A monstrous berry, 6 inches in diameter, beautiful color, plant vigorous and very productive, the fruit commands a high price in market.

Knox's 700 has proved fine this season, plants \$1.00 per dozen; or \$5.00 per hundred.

New Jersey Scarlet.—This is a very early, and promising kind, fruit large and productive, plants \$1.00 per dozen; or \$2.00 per hundred.

Ida.—The productiveness of this variety is astonishing, fruit scarlet and showy, it will pay well for market purposes, plants \$1.00 per dozen; \$3.00 per 100; or \$30.00 per 1000.

Agriculturist.—This variety has given good satisfaction this season, the berries even larger, and more productive than before, unquestionably one of the best market varieties, plants \$1.50 per 100; or \$10.00 per 1000. I have a large stock of plants of this variety.

Mead's Seedling has fruited very finely this season, berries very large, and of the finest quality, plants \$1.00 per dozen; or \$5.00 per hundred.

Victory.—A splendid new Seedling, fruit very large and very productive, color, bluish, distinct from all others, a valuable kind, plants \$1.00 per dozen; or \$5 per 100.

Lenning's White.—Very large, the best White berry grown, plants \$1.00 per dozen; \$3.00 per hundred.

100 other varieties, embracing many new ones from France and Belgium.

Address WM. S. CARPENTER,
156 Reade-st., New York.

OUR NEW DWARF CELERY

Has proved so much superior in flavor, ease of culture and hardiness, that for the past 5 years we have grown it to the exclusion of all others. We plant 40,000 per acre, averaging even in the markets of New York, \$3 per 100.

Strong plants now ready. Price \$1 per 100; \$7.50 per 1000; \$30 per 10,000. Carefully packed to ship to any part of the United States. Plain printed directions for its culture and winter preservation accompanying each package.

HENDERSON & FLEMING,
 Market Gardeners and Seedsman,
 67 Nassau-st., New York.

FISH GUANO,
FISH GUANO,
FISH GUANO.

The cheapest and best Fertilizer in the world. Fish Guano is composed wholly of the Flesh and Bone of Fish, and contains a larger proportion of Phosphate of Lime and ammonia than any other manure. In many parts of the country it has entirely superseded the use of Peruvian guano. Where its remarkable effects upon the growth of vegetation become known, it is the article most sold to promote the growth of Tobacco, Grass, Potatoes, Corn, and all kinds of cereal grain. It is an indispensable Fertilizer for gardens and Nurseries. It is manufactured by the MYSTIC OIL COMPANY, and sold in quantities to suit purchasers.
 Price, \$30 per Ton for Dry, in Barrels at the Factory, or delivered on the Cars.
 " \$35 per Ton for Green, do. do. do.
 " \$30 per Ton for Green, in bulk at the Factory.
 All orders promptly attended to by
 E. W. BRIGHAM, Mystic Bridge, Conn.

BONE

For Sale by the Manufacturers. Pure Bone Dust and Fresh Bone Superphosphate of Lime. Address

A. LISTER & BROTHER,
 Ceres Mills, Newark, N. J.

AMMONIATED PACIFIC GUANO.

The attention of Farmers and Agriculturalists is called to this article, as superior to anything else offered in the market. Equal to Peruvian Guano, and costing much less.

We offer this fertilizer in lots to suit all purchasers. A liberal discount made to the Trade.

Pamphlets with copies of Analysis by Dr. Liebig, of Baltimore, and Dr. Jackson, Massachusetts State Assayer, and testimonials from Agriculturalists, showing its value, and directions for use, can be obtained from

J. O. BAKER & CO., SELLING AGENTS,
 131 Pearl-st., New-York.

A Plain Talk.

By the use of a poor Cane Mill, persons often lose enough in a single season to pay for two good Mills.

1st.—By not pressing out the juice thoroughly, and
 2d.—By breakages in the Mill, causing vexatious delays in the height of the season.
 All this can be avoided by using

THE VICTOR MILL,
 MANUFACTURED BY THE
CLARK SORGO MACHINE CO.,
 116 MAIN-ST., CINCINNATI, OHIO.

Thousands of them have been tested in eighteen different States. At seven State Fairs and many County Fairs it has received the **FIRST PREMIUM**, and among them last fall was the Illinois State Fair, where there were 22 competing first class Mills. It has lapped gearing which enables us to dispense with the "dumb return," thereby saving one-third the power, and avoids choking. MASTER ROLL FLANGED, DIAGONALLY BRACED, OIL-TIGHT STEP BOXES, MOVABLE SWEEP CAP, SPRING SCRAPERS, JUICE CHANNELS IN BOTTOM PLATE, PERFORATED FALSE PLATE FOR PREVENTING BAGASSE FROM DIPPING UP THE JUICE.

Send for Sorgo Hand Book. Early orders will insure attention.
 CLARK SORGO MACHINE CO.

PLANT MORE SORGHUM.
SORGHUM SUGAR.

HUNT'S Patent Sugar Separator, will separate from 5 to 7 pounds good sugar from granulated Sorghum Syrup.

Price \$50 and \$60 each.

For particulars, Address

JAS. L. HAVEN & CO.,
 Cincinnati, Ohio.

Circulars free to all applicants. For ten cents will send post-paid, a sample of sugar, or for 25 cents, will send a pound by express, you to pay freight when delivered to you.

WANTED—\$500,000,

For which we invite orders for PORTABLE or STATIONARY ENGINES, CIRCULAR SAW MILLS, FEED'S & BECKING'S PATENT PORTABLE FRENCH BURR GRIST MILLS and BOLTS, SUGAR-CANE MILLS and SUGAR PANS. Our works are the oldest and most extensive in the country. All of our machinery is of modern construction and guaranteed.

Our portable mills are so complete and perfect that our millwrights erect and set them to sawing in two days' time. Orders promptly filled, and deliveries made in any of the principal cities of the United States.

For information or illustrated circulars, address
 C. & J. COOPER,
 Mount Vernon, Ohio.

A. N. WOOD & CO.
EATON, MADISON CO., N. Y.,

Continue to manufacture their Improved

PORTABLE ENGINES,

For Farm and Mechanical purposes. They are particularly adapted to driving Threshing Machines, Circular Saws, Mills of all kinds, Printing Presses, Wood or Iron Lathes, Machinery in Cabinet or Wagon Shops, Boring Artesian Wells, Pumping Water, Corn Shellers, &c., &c.

We warrant our Engines to be what we represent them, and to give unqualified satisfaction in all respects.
 A. N. WOOD & CO.

First in the Field,

First in merit, and First in the estimation of all scientific Sorgo Cultivators, is

COOK'S SUGAR EVAPORATOR.

It has been before the public since 1833, has endured every conceivable test, and where the accompanying directions have been followed, has NEVER BEEN FOUND WANTING. Of

12,000 IN USE!

all fully warranted, not one has been returned.

Sorgo Conventions recommend it.
 State Fair Committees recommend it.
 County and local Societies recommend it.
 Agricultural Editors recommend it.
 Those who have used it, recommend it.

It is the most rapid Boiler. It saves fuel.
 It saves time. It saves money.
 It defecates thoroughly. It requires no chemicals.
 It may be portable. It may be stationary.

It has taken the First Premiums at 40 State Fairs; 2 United States Fairs, and at County Fairs without number.

As the hurried season is just upon us, those who would not be disappointed in procuring an Evaporator, should order immediately, as by their own delay hundreds of late orders yearly remain unfilled.

Sorgo Hand Book sent free.

\$100 will buy a Brick-Machine, which is capable of making 15,000 bricks per day of a better quality than by hand. Address FRET, SHECKLER & CO., Bucyrus, Ohio.

SKINNER'S PATENT

SORGHUM MACHINERY,

MANUFACTURED BY

E. W. SKINNER & CO., Madison, Wis.

(S. D. HASTINGS, E. W. SKINNER, AND O. S. WILLET.)

THE ONLY REALLY ADJUSTABLE CANE MILL!

Long Tried and Well Liked!

FIRST PREMIUMS AT ALL NORTHWESTERN STATE FAIRS

HIGHEST ENCOMIUMS

FROM PRESS AND PUBLIC EVERYWHERE!

THE BEST IS THE CHEAPEST!

THE LEVER PRINCIPLE IN OUR MILLS IS the only practicable and reliable mode yet applied for giving adjustability to Sugar Cane Crushers, and the lever and weight is, and must always be, the simplest and most unvarying power. With it the cane is pressed drier with less power and less liability of breakage than by any other mode. These Mills have been before the public for several years; they are extensively used throughout the entire sorghum growing sections of the country, and wherever used have invariably given entire satisfaction. They have been much improved for the present season, and now embrace points of excellence, aside from the leading feature of the lever, which of themselves place them far ahead of any other Mill in use. We build Mills of different sizes, geared to run by steam, water or horse power; also premium Horse Powers, very simple in their construction and of great strength; also an Evaporator of our own planing, equal if not superior to anything now in use; and in fact, every article required by Sorghum Manufacturers.

OUR SORGHUM HAND BOOK, containing full descriptions and illustrations of our different sized Mills and Sorghum Machinery, and embracing a treatise on the growth and manufacture of Sorghum, sent free on application.

Parties wanting our machinery should send in their orders early, as towards the close of the season we receive more orders than we can possibly fill. Address E. W. SKINNER & CO., Madison, Wis.

THE PREMIUM MACHINE.

Best in America.

The Railway Horse Power that is unequalled for ease of team, amount of power. The Combined Thresher and Cleaner that Cleans equal to any Fanning Mill, fit for Mill or Market. The Lamb Knitting Machine.

The Lamb Knitting Machine Company, Springfield, Mass., hold the exclusive right to manufacture, sell and use this Machine in the following States: New York, (all East of the Counties of Cayuga, Seneca, Schuyler and Chemung,) Maine, New Hampshire, Vermont, Rhode Island, Connecticut, New Jersey, Pennsylvania, Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia and Alabama.

The Machine manufactured by this Company received the highest premium, A GOLD MEDAL, at the Fair of the American Institute, in New York, and at the Exhibition of the Mass. Mechanic's Charitable Association, Boston. It has also taken the highest premium at all the various State and County Fairs where it has been exhibited, eclipsing all others.

It is really the only Family Knitting Machine invented, as no other has a range of work that entitles it to be called a Family Machine.

For Stockings, as it knits the heel and narrows off the toe, making any size required, it is the greatest labor-saving Machine ever brought before the public, being in this respect far in advance of its great rival the Sewing Machine.

It knits any and everything in the way of Fancy and Staple worsted articles that the ingenuity and taste of the operator can devise. Every Machine warranted perfect.

PRINCIPAL OFFICE AND SALESROOM, UNION BLOCK, Main-st., Springfield, Mass.

Address BRAUNSON BROTHERS & CO., Office 131 West 5th street, Cincinnati, Ohio.

DOTY'S

Clothes Washer

is easy to operate—sitting or standing—injures no garments, and does its work to perfection in from two to four minutes; is durable, and is the only washing-machine that is LIKED THE BETTER THE LONGER IT IS USED. Recommended as the VERY BEST,

by Solon Robinson, Orange Judd, Prof. Youmans, and many other prominent men.

Prices, Family Size, \$14. Hotel Size, \$16. A sample will be sent free of freight on receipt of retail price. R. C. BROWNING, General Agent, 32 Courtland-st., New York, (opposite Merchant's Hotel).

The Universal

Clothes Wringer,

WITH

COG-WHEELS,

Fits any wash-tub, wrings clothes almost dry with little labor, and will save its cost in clothing every year.

The Washer and Wringer have taken the first premiums at the great fairs of Europe and America. Send for wholesale and retail terms, also descriptive circulars.

Exclusive right of sale given to the first responsible applicant from each town.

R. C. BROWNING, General Agent, 32 Courtland-st., New York, (opposite Merchant's Hotel).

A Sample will be sent free of freight, on receipt of retail price, \$3.50.

UNION MOWING MACHINES.

The Union Mower is pronounced by those who have used them to be the best in use.—All Machines warranted. Agents wanted for the Union Mower, Clement's Improved Horse Hay Fork, Whitecomb's Wheelbarrow Hay Rake, and other implements. "Quite simple; extremely useful,—does double duty."—Scientific American. (See engraving in June Agriculturist.) Rights for sale. Send for Circular. H. C. FOOTE, Patentee, 15 Light-st., New York.

RUPTURE CURED.

BY SYDNEY, New South Wales, Feb. 19, 1866. Messrs. MARSH & CO., No. 2 Vesey-st., New York:—

GENTS,—In April, 1864, suffering much from a rupture of three years' duration, which made life a burden to me, I was entered on your books as a patient, not over sanguine as to the results, owing to the repeated and costly former failures in this part of the world. Gratitude demands of me a report of the success which has followed the scientific application of your RADICAL CURE TRUSS in my case. I followed your instructions for three months, and ventured to discontinue the use of the appliance with perfect impunity. Since that time I have enjoyed a return to perfect health and strength, and can follow my calling with pleasure and satisfaction. I don't part company with the Truss, for fear of another mishap, seeing the Australian colonies have no mechanical appliances to compare with it. It is the perfect cure. Trusting you will excuse my tardy but heartfelt acknowledgment. I am, gents, yours, most gratefully, W. A. BELL, age 33, Miner.

Dr. S. N. MARSH'S Patent Radical Cure and all other kind of Trusses, Shoulder Braces, Supporters, Elastic Stockings, Suspensory Bandages, Apparatus for Spinal Curvature, Club Feet, Bow Legs, and all other Physical Deformities, made and accurately fitted at the Radical Cure Truss Offices of MARSH & CO., No. 2 Vesey street, Astor House, opposite the church, and S. N. MARSH, CORLISS & CO., No. 3 West Fourth street, Cincinnati, Ohio.

Tingley's Patent Churn.

This Churn is the Barrel Churn, perfected, and is destined to become the Standard Churn of the country. Farmers pronounce it the best ever yet produced. The Patent Rights for the Western States for sale, or manufactured on a Royalty. Dealers supplied with Churns.

SAMUEL MACFERLAN, 71 Chestnut-st., Philadelphia.

H. W. JOHNS,

Manufacturer of

Improved Roofing, Preservative Paint, &c.

78 William-st., New York.

THE STORM KING!

Plastic Slate for Roofing and other Purposes.

The discovery has been made, that pulverized Slate rock being mixed with viscous matter and spread upon any surface exposed to atmospheric action, solidifies and slowly recedes into the perfect state, without shrinkage or expansion. That from the moment it is spread it is non-absorbent and impervious, non-combustible and unweaving, and therefore is the best possible covering for roofs, Vessels, Vaults, Walls of Stone, Brick, Mortar, or Timber, in the water, the ground, or the air.

This discovery is patented and worked by the **PLASTIC SLATE JOINT STOCK CO.**, Office 157 (room 19.) Broadway, N. Y., which has licensed the following Persons and Companies, to operate in the Territory designated.

- MAINE.—E. Harmon, of Saco, for York and Cumberland Counties.
- " S. P. Hinks, of Bucksport, for Hancock, Penobscot, and Waldo.

- NEB.—A. Osborn, of Raritan, Illinois, for the Territory.

Persons thus marked, make and sell State-Flour and Felt.

American Roofing Company.

One of the best articles of Roofing ever introduced, consisting of a stout material made WATERPROOF, by a compound of INDIA RUBBER, covered by a coat of METALLIC PAINT.

It is designed for STEAMBOATS, DWELLINGS, BARNs and SHEDS, and can be laid down by any sensible working man. Circulars, with testimonials and samples can be seen at the Company's Office, 4 Cedar-st., New York.

HENRY SMITH, Agent.

The American Paint

Consists of a mixture of OXIDE of IRON and LIME STONE CEMENT, ground with our PATENT INDIA RUBBER COMPOUND, ready for use, and may be made of any consistence with boiled Linseed Oil.

It is especially designed for TIN ROOFS and all out-door work, such as DWELLINGS, BARNs, PLAZZAS and FENCES.

Its tenacity, durability and surface covering capacity are unequalled; it hardens by exposure without cracking or blistering of which there is the fullest testimony.

For sale at the Company's Office, 4 Cedar-st., New York. HENRY SMITH, Agent.

Squire's Patent

THE MOST SIMPLE AND Fruit preserved with The only Glass Jar for This Jar has secured

The Perforated Elastic Rubber Feet or Pedestals

Fruit Jar.

EFFECTIVE JAR MADE. out the aid of Sugar, preserving vegetables, to it by Letters Patent Glass Cover. Fastenings. on bottom of Jar.

A combination of advantages that renders it emphatically the most desirable jar for family use; for by this the fruit can be cooked in the jar, the jar sealed while cold, completely filled to the total exclusion of all air—is in no danger of breaking from fermentation, or from heating or cooling in use, and can be opened with scarcely an effort.

Directions for preserving fruit and working, accompany each jar. Dealers will do well to see this before ordering—as it is the newest and best jar out. Send for a Circular.

100 YEARS.

Centenary Pictorial, or Pictorial History of Methodism, edited by Dr. Cunry, assisted by the first men and women of the church. We want an agency in every town in the United States and Canada, to sell ONE MILLION copies. It is the most useful, curious, popular, and cheap publication of the Centenary year.

Its attractions:— Article on Camp-Meetings; Itinerancy; Class Meetings; One Hundred, or a Centenary of Anecdotes illustrating Methodism all along the Century; A Fac-simile of the Diary of Mr. Wesley's Mother, 150 years old; A Fac-simile of a skeleton of a Sermon by Rev. John Fletcher; An Article in which the striking traits of one hundred men are presented, making a centenary of men in a centenary of years, as representative men of Methodism; The Noble Women of our Church, by Mrs. Olin; and other articles and incidents of great interest, making the reading of a \$1.50 book.

PICTURES.

A picture of Methodism:— 1. Mr. Wesley's little class; 2. An itinerant scene; 3. An immense congregation of every nation and costume listening to the Gospel; 4. A happy death-bed scene; 5. Mr. Wesley in the centre, surrounded by a cloud of light, making a most attractive centenary picture. The largest picture of a camp-meeting in full operation ever made. Both these pictures will make beautiful parlor ornaments, and either of them worth more than the cost of the whole work. And numerous pictures of our representative men and women. Historic scenes, as the graves and homes of our fathers; Sister Hock breaking up the card party; first meeting places, etc., etc.

PRICE, POST-PAID, 35 CTS.; WITH COVERS, 50 CTS. Send to N. TIBBALS, 145 Nassau-st., New-York.

Send us 25 Cts. for a copy, to examine and to canvass with. Large discounts to Agents. Ladies and Children can act as Agents.

LUMBER AND LOG BOOK.

Scribner's Ready Reckoner.—This work comprises upwards of seventy pages, intended expressly for Ship Builders, Boat Builders and Lumber Merchants; being a correct measurement of Scantling, Boards, Planks, Cubical Contents of Square and Round Timber, Saw Logs, Wood, &c., comprised in a number of tables; to which are added Tables of Wages by the Month, Board or Rents by the Week or Day, and Railroad Distances, also Interest Tables.

This is the most complete and reliable book ever published on this subject, and has now become the standard book for measuring lumber all over the United States and Canada. Its sales now amount to nearly 400,000 copies. No Farmer, Lumber Dealer or Mechanic should be without the book. It is for sale, generally, by all booksellers. Price 30 cents; sent pre-paid on receipt of this sum.

WANTED--AGENTS EVERYWHERE

(BOTH MALE AND FEMALE)

To sell a new Print entitled

"HOME AGAIN."

Painted by McClary. Engraved by Fabroniar. A clergyman sends us the following notice:

"The return of the loved son, husband, and father, can not be more truthfully delineated than we see it in the reverent attitude of the good old mother, in the puzzled, anxious face of the wife, and the joyous looks of the children who, with eager delight, are escorting the war-worn hero into the surprised circle at home. Every item is true to nature."

SOLD ONLY BY SUBSCRIPTION.

Agents, competent to engage others, will be offered superior inducements. Address W. J. HOLLAND, Springfield, Mass.

FORTY THOUSAND INSTRUMENTS.—Since the establishment of the celebrated Organ and Melodeon establishment of Price & Co., at Buffalo, in 1846, over forty thousand of these excellent instruments have been manufactured and sold. These have been sent over the length and breadth of the United States,—to the Sandwich Islands,—South America,—to England,—France,—Germany,—to the East Indies,—and have even penetrated to the Kingdom of Assam. Wherever they have been sent they have been received with universal favor. And it is a singular fact that of these forty thousand instruments not one has ever been returned as unfit for use. The new Illustrated Catalogue of Price & Co., can be obtained free of expense, by addressing the firm at Buffalo, N. Y.

YOUNG MEN, should read the PHRENOLOGICAL JOURNAL, to learn what they can do best. Only \$3 a year; \$1 for 6 months; 20 cents a No. Address FOWLER & WELLS, 389 Broadway, N. Y.

AGENTS WANTED TO SELL BOOKS.—For particulars send stamp to FOWLER & WELLS, 389 Broadway, N. Y.

Family Wine and Cider Mill.

Convenient, Economical and Cheap. Makes Pure Home and Sweet Cider.

Saves all the Fruit.

Send for Descriptive Circular. Address PEEKSKILL FLOW WORKS, Peekskill, N. Y.

OR, G. E. HUTHCHINSON, Cleveland, Ohio.

Cider Mill Screws.

Whole length, 5 feet. Length of thread, 3 feet. Diameter of Screw, 4 inches. Weight, including nut, 210 pounds. Price, complete, \$15.00. Address PEEKSKILL FLOW WORKS, Peekskill, N. Y.

Italian Bees.

Kelley's Island Apiary. 7000 miles from native bees. Sent for a Circular to

W. A. Flanders & Co., Shelby, Ohio.

THE MODERN HORSE DOCTOR,

BY GEORGE H. DADD, M. D., VETERINARY SURGEON.

Containing Practical Observations on the Causes, Nature, and Treatment of Disease and Lameness in Horses, embracing the most recent and approved Methods, according to an enlightened System of Veterinary Therapeutics, for the Preservation and Restoration of Health.

WITH ILLUSTRATIONS.

NEW-YORK:

ORANGE JUDD & CO., 41 Park Row, 12mo. 432 p. \$1.50. Sent post-paid by mail.

NEW BOOKS.

QUINBY'S BEE-KEEPING. By

M. Quinby, Practical Bee-keeper. Fully Illustrated. Entirely new. The result of thirty-five years' of successful experience—with directions about Breeding, Hives, Pasturage, Apiary, Robbing, Feeding, Swarming, Queens, Pruning, Diseases, Anger, Enemies, Wax, Transferring, Sagacity, Wintering, Italian Bees, Purchasing, &c. Price \$1.50.

NEW BOOK OF FLOWERS.

By JOSEPH BRECK, Practical Horticulturist. Containing Chapters on the Utility of Flowers, Lilies, Seeds, Flowering Plants, Budding, Double Flowers, Colors, Bouquets, Protection, Training, Gardens, Lawns, Rockwork, Aquarium, Parlor Plants, Potting, Insects, Bulbous Roots, Perennials, Annuals, &c. Beautifully Illustrated. Price \$1.50.

MINIATURE FRUIT GARDEN.

By THOMAS RIVERS. Illustrated. Or, how to raise many kinds of fruit on small trees, with full directions for Training and Culture. Pyramidal Pear Trees on Quince Stock. Summer Pinching. Compact Pyramids. Root Pruning. Pear Trees as Bushes. Pears adapted to Bush Culture. Protectors for Bush Pear Trees. Cordon Pears on Trellises. Espalier Pears on Quince Stocks. Pear Tree Hedge. Planting and after Management. Bush Pear Tree for a Market Garden. How to Store Winter Pears. Pyramidal Apple Trees. Apples as Bushes. Twenty Desert Apples good from July to June. Twenty Kitchen Apples fit for use from July to June. Pyramidal Plum Trees. Cherries as Pyramids. Filberts and Nuts. Figs on Bushes. Double Grafting. Peach Tree Borders, etc., etc. Illustrated. Price \$1.00.

SAUNDERS' DOMESTIC POULTRY

Book. By S. M. SAUNDERS. New Edition Revised and Enlarged. Containing Articles on the Preferable Breeds of Farm-Yard Poultry. Their History and Leading Characteristics, with Complete Instructions for Breeding and Fattening, and Preparing for Exhibition at Poultry Shows, etc., etc., derived from the Author's Experience and Observation. Very fully Illustrated. Golden Rules.—Never over feed. Never allow any food to lie about. Never feed from trough, pan, basin, or any vessel. Feed only while the birds will run after the feed, and not at all if they seem careless about it. Give adult fowls their liberty at daybreak. Never purchase eggs for hatching purposes until a hen is ready to sit. For seven or eight days before hatching, sprinkle the eggs with cold water while the hen is off. This will prevent the frequent complaint that the chicken was dead in the shell. Price, paper 40 cts., cloth 75.

MY VINEYARD AT LAKEVIEW;

Or, Successful Grape Culture. The Suggestion, Making a Change, Going West, Getting Settled, First Experience, Varieties, Planting a Vineyard, Propagation of the Vine, Soil and Situation, Preparation of Soils, Manures, Pruning and Training, More about Training, Autobiography of a Vine, Brief Expositions. Price \$1.25.

IN PRESS A NEW BOOK ON

PEAT, AND ITS USES.

By Prof. S. W. JOHNSON, Yale College.—Part I. Origin, Varieties and Chemical Character of Peat. Part II. On the Agricultural Uses of Peat and Swamp Muck. Part III. On Peat as Fuel.

Published by

41 Park Row, New-York.

Sent post-paid on receipt of the price. For sale by Booksellers generally.

THE GREAT AMERICAN TEA CO.,

Have selected the following kinds from their Stock, which they recommend to meet the wants of Clubs. They are sold at Cargo Prices, the same as the Company sell them in New York, as the list of prices will show.

All goods sold are warranted to give satisfaction.

PRICE LIST:

- YOUNG HYSOON, 80c., 90c., \$1, \$1.10, best \$1.25 per pound. GREEN TEAS, 80c., 90c., \$1, \$1.10, best \$1.25 per pound. MIXED, 70c., 80c., 90c., best \$1 per pound. JAPAN, \$1, \$1.10, best \$1.25 per pound. OOLONG, 70c., 80c., 90c., best \$1 per pound. IMPERIAL and GUNPOWDER, best \$1.25 per pound. ENGLISH BREAKFAST, 80c., 90c., \$1, \$1.10, best \$1.20 per pound.

Our Black and Green Mixed Teas will give universal satisfaction, and suit all tastes, being composed of the best Foo Chow Blacks and Mayone Greens.—English Breakfast is not recommended, excepting to those who have acquired a taste for that kind of Tea, although it is the finest imported.

These Teas are chosen for their intrinsic worth, keeping in mind health, economy, and a high degree of pleasure in drinking them.

COFFEES ROASTED & GROUND DAILY.

GROUND COFFEE, 20c., 25c., 30c., 35c.—best 40c. per pound. Hotels, Saloons, Boarding-House keepers and Families who use large quantities of Coffee, can economize in that article by using our FRENCH BREAKFAST and DINNER COFFEE, which we sell at the low price of 30c. per pound, and warranted to give perfect satisfaction.

Consumers can save from 50c. to \$1 per pound by purchasing their Teas of the

GREAT AMERICAN TEA COMPANY,

- Nos. 31 and 33 VESEY-ST., corner Church-st. POST-OFFICE BOX, 5,643 New York City. No. 610 BROADWAY, corner Bleecker-st. No. 503 EIGHTH AVE., near Thirty-seventh-st. No. 299 SPRING-STREET. No. 205 FULTON-ST., BROOKLYN, corner Concord-st.

Country Clubs, Hand and Wagon Peddlers, and small stores (of which class we are supplying many thousands, all of which are doing well), can have their orders promptly and faithfully filled; and in case of clubs, can have each party's name marked on their packages as directed by sending their orders to Nos. 31 and 33 Vesey-st.

Our friends are getting up Clubs in most towns throughout the country, and for which we feel very grateful. Some of our Clubs send orders weekly, some not so often, while others keep a standing order to be supplied with a given quantity each week, or at stated periods. And in all cases (where a sufficient time has elapsed) Clubs have repeated their orders.

Parties sending Club or other orders for less than thirty dollars, had better send Post-Office drafts, or money with their orders, to save the expense of collections by express; but larger orders we will forward by express, to collect on delivery.

We return thanks to parties who have taken an interest in getting up Clubs. And when any of them come to New York, we shall be pleased to have them call upon us and make themselves known.

Hereafter we will send a complimentary package to the party getting up the CLUB. Our profits are small, but we will be as liberal as we can afford.

The following letter tells its own story:

BROODHEAD, Green Co., Wis., May 8th, 1866.

To the Great American Tea Company, 31 and 33 Vesey-street, New York:

The package of Tea I ordered of you came safely to hand. All are highly pleased with their Teas. Your best is superior to what our merchants call their best, and sell for \$2 to \$2.50. The Oolong is far better than what they sell at \$1.70. I herewith send another order amounting to \$131. I could send you a much larger one, but many of our farmers are so afraid of being humbugged. They say that if you give us good satisfaction this time as you did before, they will then

"go in." Send the goods by United States Express, with bill for collection, as before. Also bill by mail for myself. You will hear in a larger way from this section next time. Mark the box to my address.

Respectfully yours, W. B. MACK. ORDER No. 2.

Table listing various tea types and prices, including Oolong, Imperial, Gunpowder, and Young Hysoon, with prices ranging from 50c to \$5.00.

Total.....\$131.00

P.S.—Send 4 lbs. of your best green Java Coffee, with price, to W. B. MACK.

Our second order from Mr. R. H. Harrison, of Pittsburgh, Fort Wayne and Chicago Railway Shops, Fort Wayne, Ind., embraces a Club-order comprising over 200 names of gentlemen engaged in the above manufacturing works.

P.S.—All manufacturers, where a large number of men are engaged, in CLUBBING together, can reduce the cost of their Teas and Coffees about one-third by sending directly to the

GREAT AMERICAN TEA COMPANY, 31 and 33 VESEY-STREET, corner of Church. Post-Office Box, 5,643 New-York City.

The Charter Oak Life Insurance Co., of Hartford, Conn.

"Every one should insure his life."—See page 129, April 1866 issue, of the American Agriculturist.

Insure this year in THE CHARTER OAK LIFE INSURANCE COMPANY.—See page 135, of the same Journal.

The Charter Oak Life Insurance Company has no superiors among the Life Ins. Co.'s of this country.—Its Assets April 1st, 1866, are, \$1,770,167.63, being an increase of nearly \$200,000 in three months. Its business is increasing with unparalleled rapidity.—Its expenses are less than the average of Life Ins. Co.'s.—Its losses are less.—Its dividends are greater.—It pays annual dividends commencing with the second premium.—It originated the system of annual dividends.—Its business is confined to the healthy and thoroughly settled portions of the country.—For further information concerning the Company, see April No. of the American Agriculturist, page 135.

OFFICERS.

He also mails, post-paid, the Novelty Microscope, for the examination of living insects, flowers, seed, &c., for \$3.00.

THE UNION WAR CHART.

A great success. Shows at a glance the facts of the Rebellion, Worth a dozen Histories! Every soldier and every family must have it. Endorsed by Lieut. Gen'l Grant, Gen'l Hancock, Gen'l Howard, and all the leading officers of the Union Army. Agents Wanted in every County. Wide-awake men can make fortunes. Price \$2.00. Address, immediately, LORENZO DOW & CO., Publishers, 7 Broad-st., New York.

HINTS TO HORSE-KEEPERS,

A COMPLETE

MANUAL FOR HORSEMEN.

BY THE LATE HENRY WILLIAM HERBERT. (FRANK FORESTER.)

Beautifully Illustrated.

HOW TO BREED A HORSE.—

CHOICE OF STALLION.—National Value of the Horse.—The best class of Horses the cheapest for all purposes.—What constitutes excellence.—Blood: what it gives; should be on the side of Sire.—Breed not, not down.—Diseases and Defects Hereditary.—General Rules.

CHOICE OF THE MARE.—Size, Symmetry and Soundness more important than Blood.—Points of the Brood Mare.—Diseases Hereditary.—Condition of the Mare.—Should have moderate work when with Foal.—Food and care during gestation.—Health and temper.

MUTUAL ADAPTATION OF SIRE AND DAM.—First consideration in Improvement of "cold" Blood.—Relative size of Sire and Dam.—Defects in either Parent.—How Remedied in Progeny.—Bloods which "hit."

CANADIAN BLOOD.—The Canadian originally the French Norman.—Characteristics.—Hardhood.—Speed.—Mode of Improvement.—Crossing with Thorough-bred.

NORMAN BLOOD.—Origin and History of the Percheron Norman.—A pure race.—Characteristics and Points.

MODERN ARAB BLOOD.—English and American Thorough-breds derived from Oriental Blood.—are now superior to the Modern Arabs.—Nolan Arab.

PONIES — DIFFERENT BREEDS, CHARACTERISTICS AND UTILITY.—Origin.—Different Breeds.—Shetland and Scots.—Gallopways and Narraganetts.—Mustangs and Indians.—Froth of raising Ponies.

HOW TO BREED MULES.

Value of Mules.—Their History and Natural History.—The Mule and Hinney.—Thorough-blood wasted in the Dam for Mules.—The Mule in the United States.—Large size not desirable.—Varieties of the Ass.—The kind of Mares to be selected.

HOW TO BUY A HORSE.

Of whom to Buy it.—Extraordinary Cheapness and Extraordinary Excellence not consistent with each other.—Points to be regarded.—How to Examine the Eye.—Broken Wind.—Roaring.—Whistling.—Broken Knees.—To examine the Legs.—Splints.—Damaged Back Sins.—Spavins.—Ringbones.—Curbs.—How to tell the Age of a Horse.

HOW TO FEED A HORSE.

Consequences of Improper Feeding.—Different Food for different conditions.—Food for the Brood Mare.—for the Foal.—For Working Horses.—Green Food.—Carrots.—Corn.—Feeding Horses in Training.—While Travelling.—Summering Horses.—The Best Method.—Management of Omnibus Horses in New York.

HOW TO STABLE AND GROOM A HORSE.

Requisites for a good Stable.—The economy of Proper Arrangements.—Ventilation.—Grooming; its necessity for all descriptions of Horses.—How Performed.—Clothing.—Treatment when brought in from Work.

HOW TO BREAK, AND USE A HORSE.

What is required in a well-broken Horse.—His education should commence when a Colt.—Biting.—Putting in Harness.—How to Use a Horse.—Travelling.—Working.—Pleasure Horses.—Punishment.

HOW TO PHYSIC A HORSE.—

SIMPLE REMEDIES FOR SIMPLE AILMENTS.—Causes of Ailments.—Medicines to be given only by the order of the Master.—Depletion and Euring.—Spasmodic Colic.—Inflammation of the Bowels.—Inflammation of the Lungs.—How to Bleed.—Balls and Purgatives.—Costiveness.—Cough.—Bronchitis.—Distemper.—Worms.—Diseases of the Feet.—Scratches.—Thrush.—Broken Knees.

FARRIER, ETC.

Castration.—Docking and Nicking.—Blood-letting.—Treatment of Strains and Wounds.—Galls of the Skin.—Cracked Heels.—Clipping and Singeing.—Administering Medicines.—Diseases of the Feet.

HOW TO SHOE A HORSE.

Unskilful Shoers.—Anatomy of the Foot Illustrated.—The Foot of a Colt.—Preparation of the Foot.—Removing the Old Shoe.—Paring the Foot.—The Shoe.—Fitting the Shoe.—Nailing.—Number of Nails.—Diseases of the Foot.

BAUCHER'S METHOD OF TRAINING HORSES.—

What Constitutes a Well-trained Horse.—To make him come at your call.—The Philosophy of Training.—Flexions of the Jaw.—Flexions of the Neck.—Flexions of the Croup.—Backing.—The Paces.—Leaping.

HOW TO RIDE A HORSE.

The Saddle.—The Girths.—The Stirrups.—Saddle-Cloths.—The Crupper.—The Martingale.—The Bridle.—Spurs.—Mounting and Dismounting.—The Seat.—The Hands.—The Legs.—The Paces.—Hints for Special Cases.—The Art of Falling.—Riding with Ladies.

LADIES' RIDING—WRITTEN BY

LADY.—Learning to Ride.—The Side-saddle.—The Girths.—The Stirrup.—The Bridle.—The Martingale.—The Bit.—The Dress.—Mounting and Dismounting.—The Position.—The Hands.—The Leg and Whip.—Accidents.

HOW TO DRIVE A HORSE.

The Art of Driving.—Pleasure Driving.—How to Hold the Reins.—Driving a Pair.—Four-hand Driving.—Driving Working Horses.—Plowing.—Three-a-driving.

RAREY'S SYSTEM OF HORSE-TAMING.

Rarey's System a New Discovery.—Previous System.—Principles of this System.—Instructions for practicing Rarey's Method.—To Stable the Horse.—To Approach the Horse.—Tying up the Leg.—Laying the Horse Down.—Final.—Vices and Bad Habits.—Bearing.—Kicking.—Balking.—Pulling on the Halter.—Shying.

VETERINARY HOMOEOPATHY.

Principles of the System.—Table of Remedies.—General Directions.—Treatment of a Sick Animal.—Diet.—Remedies for Specific Cases.—Glossary of Diseases.

SWANS IN BROODING TIME.—ENGRAVED FOR THE AMERICAN AGRICULTURIST FROM A DRAWING BY EDWIN FORBES.

Every one who visits New York City of course goes to the Central Park. The beauties of this pride of New Yorkers culminate in a large lake, spanned by airy bridges and margined by picturesque banks. The beauty of the scene is enhanced by the numbers of swans which glide along the surface, arching their necks with all the grace that we have seen represented in pictures. One in seeing a swan for the first time, is not disappointed, for in this case, at least, the real thing equals our preconceived idea. Nothing adds so much to the attractiveness of a piece

of water as these birds. The pure whiteness of their plumage, the majestic leisure of their movements, and the always graceful carriage of their long necks, have made them everywhere favorites. To see these usually meek and gentle birds, in other aspects, one should watch them at brooding time. The female chooses some isolated place for her nest; an island is usually preferred. The nest is a rude affair, built of straw, reeds and the like, and in this from five to eight eggs are laid.—The mother bird sits for six weeks, and during all this time the male or

Cob keeps most vigilant guard. From being a quiet and peaceful bird, he is the one of the most pugnacious, and always on the look out for a fight. Our artist has taken his picture just as the young brood is hatching, and has admirably given the motherly expression of the female as well as the fierce and war-like attitude of the male. He is constantly sailing around in the vicinity of the nest, and is ready to attack any other who approaches his domestic circle. The young swans are at first of a slate color, and it is three years before they get their full plumage.

AMERICAN AGRICULTURIST.

NEW-YORK, AUGUST, 1866.

Agricultural operations, especially out-of-door work, depend to a great extent upon the weather. In the early part of the season field labor was much interrupted by rains and cold storms, which prevented the early working of the land, and crowded work very much into June, so that whatever could be postponed until July was so put off, in many parts of the country. The result is, that while grain has generally been promptly harvested when in the best condition, a good deal of grass has been left to get over ripe and wirey before being cut. To the careless farmer there is a gain in this delay, for the older the grass the quicker the hay will make; but few realize how much poorer the quality is. There is reason still to expect great heat, such as we experienced in the last of June and the first of July, and if so, the provisions made for soiling cattle will be of great value. We cannot too often insist upon the practice, now happily becoming much more common than formerly, namely, that of sowing corn, sugar-cane, millet, and perhaps also other summer crops, like ruta bagas, or rape, to be used for this purpose when pastures run short. There are several things that can be sowed for fall feed now, which may come in most opportunely—such as oats, rye, sorghum, ruta-bagas, etc., sowed thick for leaf only. The pasturage may also be "pieced out" to good advantage, by feeding some dry hay which will ordinarily be relished by all kinds of stock, especially if it be cut up, salted a little, a handful or two of meal or oil-cake for each animal, sprinkled over it, and the whole moistened well with water and allowed to stand a few hours.

The dry season gives opportunities to get into the muck and peat swamps, which in the lull of field work upon the staple crops should not be neglected. The recent perusal of Prof. Johnson's admirable work on Peat and its Uses, impresses us more perhaps than ever before with the great stores of fertility locked up in our swamps and quagmires, waiting only enterprise to develop and to enrich with them the exhausted acres which on thousands of farms lie closely adjacent. The system of operations is first to find the lowest place and best outlet; then to dig trenches to drain the swamp, or part of it, making first the main ditches, open and flaring, then the lateral ones, leaving the muck which is thrown out exposed to the weather until it becomes dry and crumbles, unless the sun bakes it into too hard cakes, in which case, when partially dry, beat it to pieces and lay it up in compost heaps, with lime slaked with old brine. Such muck will be dry and ready for use in the stables as an absorbent in winter. That which is not so treated, will be disintegrated by frost for use in the spring.

It often happens that the work of this season is such that it may be left a good deal to the hired men, and thus the time gained for a few days of relaxation. Nothing is more beneficial. A trip to the sea-side, when a few neighbors make up the party, and enjoy sea bathing, fishing, clam bakes, and chowders; even a day of fishing and out-of-door sports in the woods with one's family and a few friends is worth a great deal for health and good spirits. We often hear it said that we make too little of holidays and have too few in this country, and it is true. Farm work will go better and one's interest in his farm, his family and in life itself is heightened, and made generous and healthy by occasionally giving up a few days to enjoyment, and having a real good time.

Not the least reason for occasional relief from the pressure of business and labor may be found in the sanitary condition of the country. There is no little anxiety at the time we write in regard to the cholera, which seems to be held off, under God, only by the strong sanitary police regulations maintained at our ports of entry. It is therefore the bounden duty of everybody to keep himself so far as possible in a condition of health, not to over-work or get exhausted in body, or foolishly anxious.

The women of the farm who, in the generosity of their hearts, often bid city cousins welcome to the best they have, and slave themselves almost day and night to serve them, are in more danger of over-working than anybody else, and husbands and fathers should quietly regulate this matter by planning excursions or visits, which shall break up the too long stay of labor-making guests, and give their wives and daughters pleasure and relief from the severe burdens of their confining duties. Perhaps you have never been invited to spend a fortnight in January with your consins in Boston, New-York, or Philadelphia, who visit you so gladly every August. At any rate you owe no one hospitality which will endanger the health of your family.

Hints about Work.

Bushes and Weeds.—August is a season for the most effective and deadly onslaughts upon weeds and bushes. The nature of most weeds is in the first part of the season to make tops, and afterwards to concentrate their energies either upon the production of seed or maturing their roots, so as to live through the winter. If cut in this dry hot weather, it is usually certain death. Even Butter-aud-Eggs (*Linaria*), that most showy and detestable of weeds, is sometimes killed by thorough hoeing up in an August drouth. As for bushes, once cutting up, and then letting the sheep browse off the young shoots, will make an end of the worst, even wild roses, and blackberry bushes. Do not let any weeds go to seed. The season has been particularly favorable to crops of weeds, and without proper diligence it will take years to do away with the harm that may be done, if they scatter their seeds.

Seed Grain.—Look out early for a good supply of clean plump seed, especially for that to be used this season. Clean it thoroughly from all shrunken kernels and weed seeds by repeated winnowing, using if possible the arrangement described on page 138 (April), which is applicable to all kinds of grain and grass seeds.

Buckwheat may be sowed now and make a good mass of green manure, to be plowed under in time for sowing rye, or for enriching the ground for spring crops, and with a chance for a crop of grain.

Timothy sowed alone will, on good soil quickened with a top-dressing of bone, guano, or any fine rich compost, usually catch well, and sooner make a good sward than that sown with spring grain, or upon winter grain in the spring.

Wheat.—If the soil be dry in winter and in good heart now, plow early, and giving a top-dressing of some good fine compost, or special manure, drill in the wheat. It is poor policy to risk winter wheat on soil which, from lack of draining, barely allows the plants to struggle through.

Oats.—Harvest before too ripe, and thus have much better straw, more and plumper grain.

Corn.—It is a great temptation sometimes to sucker corn for the sake of getting green feed for cows. We do not believe in suckering corn at all, though with some kinds it may have no evil effects. With many varieties we feel sure that the suckers are important to secure the proper filling out of the tips of the ears, the tassels coming into flower a little later than those of the main stalks, the later maturing tip kernels of the ear, are thus fertilized. Pull weeds among corn, but do no hoeing after the ground is shaded.

Tobacco begins to ripen for cutting by the middle of the month, if properly topped and suckered. When about 12 to 16 leaves have formed, and the flower stalk begins to push up rapidly, clear of the mass of large leaves below, then it should be broken off. The height will vary with the vigor of the plant, and the earliness or lateness of the season. The leaves increase rapidly in size after this, and suckers will start from the base of each, which must be broken off. The worming must go on all the time; and so vigorously do the suckers grow, and so active are the worms, that a few acres will give very steady work during this month to several

Post-Office Money Orders—Improvement.—The new law allows \$50 to be sent in one Order. The charge is ten cents for any sum up to \$20, and 25 cents for any sum over \$20 up to \$50. For over \$50 it is merely necessary to take more than one order. New Order Offices are being established. This system is of great value to the whole country, and amounts to positive safety in transmitting moderate sums of money by mail, by paying about 1/4 of one per cent.

hands, even after all haying is done. When the leaves have their full growth, and have that turgid and mature look and feel, difficult to describe, cut up at the roots in the middle of the day, turn frequently till wilted enough to handle without breaking, and then hang in airy sheds.

Cotton Picking is an important labor at the South this month; too great importance can not be given to clean picking, and leaving the bolls light and soft. There has been a machine invented for picking cotton, and we are inclined to think that here is a particularly good opportunity for the profitable display of mechanical ingenuity, if it can hardly be that the first machine will be any nearer perfection than the first sewing or mowing machine.

Stacks.—If hay or grain stacks settle, re-top them, building them up square and guard against rain.

Water.—There is no more important subject than the supply of fresh and pure water for the stock in the pasture and in the yards, the lack of it cannot be made up by the best of feeding and other care. It is very bad to be obliged to drive cattle far for water. Young calves and cattle are often seriously stunted by a short supply of water in August.

Weaning Young Animals.—Colts, lambs, and calves, left to take their regular allowance of milk naturally, should be weaned about this time, say when 3 or 4 months old. The colts being put in enclosures away from their dams, and allowed to suck at first twice a day, then once a day, then less often, and finally once a week for once or twice, thus they will be weaned quietly and without falling off in flesh through running to and fro in their anxiety. Lambs must be weaned abruptly, and to make it easier for both parties, separate them beyond the sound of each other's bleating, leaving the lambs in the old pasture. Give the ewes very dry feed, and milk those whose udders appear distended and tender. Put two or three old tame ewes or wethers with the lambs as leaders, and to make them manageable. Calves are very easily managed, being allowed to suck only while the cow is being milked, and that but once a day after a few days. The milker can restrict the allowance of milk that the calf gets at his discretion.

Cows.—Use all diligence to prevent the cows drying, giving good pasturage, extra feed if necessary, and plenty of pure water. Farrow cows to be fattened this fall, should be dried off before September, and kept in good flesh, being fed so as to be on the gain all the time.

Oxen.—Be careful not to over-work and exhaust working cattle. If put to hard labor, feed dry hay, and bright straw with bran upon it, in addition to what they pick up nights in the pasture.

Horses need careful treatment, and if kept up should have an armful or two of grass daily, and if worked hard, cut feed and dry hay. Cold water is perhaps the best application for galls by the harness; and do not forget that for all kinds of stock

Salt and Pure Water are essential to their health.

Pigs.—Keep them making manure; weeds and all sorts of rubbish which will decay, should be thrown to them to work over. Peas may be fed unthreshed, using such as may have been somewhat damaged, and thus the hogs will be in prime order when corn is fit to feed.

Sheep.—Keep far upon their noses to keep off the bot-fly, which causes grubs in the head; examine rams about the horns and heads and elsewhere for wounds, which soon become maggoty if neglected. Wash them out and apply very warm pine tar.

Poultry.—Give all kinds a share of the daily waste, butter-milk, lopped milk, etc. Collect eggs daily, keep in a cool place in close boxes, set on the points, and packed in Indian meal, bran, or slaked lime, inverting the boxes every two or three days. In the moulting season hens cease laying. Keep chickens well fed, and growing rapidly. Give scalded cracked corn, wheat screenings, Bronnus grains, etc., with free run for green food and insects. See that fowls have clean and deep dust baths, in which a little quick-lime or wood ashes occasionally thrown will be fatal to lice. Whitewash roosts and nest boxes. See basket item about hen lice.

Manure.—Employ any spare time in looking about the neighboring villages or factories for valuable refuse that will pay for hauling. Leather scraps, woolen waste, slaughter-house offal, horn piths, hops and sprouts from the breweries, soapy and oily water from the cloth factories, which may be absorbed by muck or led out upon the grass. Save any choice finer manure from the bottom of compost heaps in the yard for wheat.

Tools that have been in use during the summer should be thoroughly cleaned, the steel parts painted with linseed oil, and set away.

Turnips.—Sow till the middle of the month in most places below latitude 40°, on ground well cleaned of weeds by repeated harrowing.

Wells.—When springs are low, it is the best time to dig wells. Have everything ready to dig, stone up and curb at once.

Orchard and Nursery.

There appears to be a good promise for apples and pears, but a general failure of peaches. We can not hear of any Eastern peach region where there is likely to be even a moderate crop. What shall we do for peaches? The peach region has been pushed down into Delaware and Maryland; must we look to Virginia and the Carolinas for our supply? It is not only the borer, the curl, and the yellows, but the rigor of our winters, and uncertainty of our springs baffle the cultivator. We have given several plans that have been proposed for protecting trees during their season of rest. Whoever hits upon a system of protection, easily applicable on a large scale, will find his account in it.

Marketing of early apples and pears will require care. Regular market growers know that a little time expended in preparing fruit for market will be repaid. It generally pays to make two qualities, to which may be added a third, fit only for the pigs. Establish a reputation for fair dealing, by having the baskets or barrels run of even quality throughout. Pick the fruit before it softens, but not before it is fully developed. Allow no beating or other rough usage of trees in order to get the fruit off. A self supporting fruit ladder is very useful, or a common ladder may be stayed by guy ropes.

Insects will still demand the attention. Fruit that has fallen because it contains the larva of some insect should be gathered up and given to the pigs, or those animals be allowed the run of the orchard. Late caterpillars' nests must be removed, and the borers treated as recommended in May, on p. 187.

Budding is to be done whenever the bark runs freely and well ripened buds can be had. See directions last month. Round off stocks budded last year.

Trees set last spring without mulching will often show signs of failing this month. Removing the soil around the roots, and giving a thorough watering, will often save them. After replacing the earth, put on a mulch.

Seed Beds are to be shaded as heretofore directed.

Layer wood of this year's growth as soon as it is firm enough. The soil into which layers are put should be rich and well worked.

Pruning should have been finished last month, but if any needs to be done it is not too late yet.

Evergreens with proper care to keep the roots from drying, and watering the holes if not already moist, may be successfully removed during this month. Select a damp time for the operation.

Weeds.—Keep them down everywhere, especially in nursery rows.

Kitchen Garden.

One should not in the enjoyment of the abundant products of the garden forget to provide for next year, in the way of seeds. This is often thought of too late, and after the best of the yield has been used upon the table. We have so often insisted upon the earliest and best for seed that it is unnecessary to repeat it. Some kinds of seed are best raised by large growers, but there are many sorts that every one can as well save for himself.

Asparagus will now only need to have the coarse weeds pulled up. If seed is wanted, collect it from the best plants. Some English cultivators strip off the flowers as they appear, believing that the root will be stronger if not allowed to bear seed.

Beans.—Plant some of the bush sorts for salting.

Beets.—Thin and use the hoe freely. A slowly grown beet is of poor quality.

Cabbages and Cauliflowers.—If slugs are troublesome, use lime or set traps, as suggested last month. Caterpillars are easily disposed of when they first hatch and before they scatter. Use the hoe frequently. Set plants for the latest crop.

Carrots.—Hoe and thin, and if young carrots are wanted, sow the Dutch Horn variety.

Celery.—Earth up the early plants. Set out for latest crop. Keep that set out in flat culture free of weeds by running the cultivator between the rows—and towards the middle or end of the month commence to draw the earth up to the plants.

Corn.—Select the finest and earliest ears for seed. Destroy the worm that feeds on the silk.

Cucumbers.—Gather for pickles when of small size.

Egg Plants.—Keep the fruit from the ground by putting a handful of hay or straw under it. If holes appear in the leaves, look under for caterpillars.

Endive.—Set out plants a foot apart each way. Tie up the older ones to blanch.

Herbs.—Continue to gather as they come into flower. Dry and put out of the way of dust.

Lettuce.—If sown during hot weather, should have the benefit of partial shade.

Melons.—Remove those set too late to ripen. If a vine is allowed to carry only three or four melons, the fruit will be all the larger and finer.

Onions.—When a majority of the tops fall over, commence harvesting. If the onions are to be stored for winter, dry thoroughly.

Potatoes.—Leave those wanted for seed until ripe.

Radishes may be sown, especially the Chinese Rose-colored Winter, which is tender and well flavored, and will keep as well as a turnip.

Squashes.—Continue to deal with insects as suggested last month. Save seed of early sorts. Let the running vines root at the joints.

Tomatoes.—Keep those grown upon trellises tied up. Thin out crowded branches. Look out for and destroy the caterpillar or "worm."

Turnips.—Thin ruta-bagas, and sow the round sorts in places left vacant by other early crops.

Weeds.—Use the hoe rake, bayonet hoe, push hoe, or some other weeding implement. A heavy steel rake is capital for loosening the surface, and if used often, will keep down the weeds.

Fruit Garden.

In the rapid ripening up of small fruits allow none to go to waste. Raspberries, currants and blackberries may be preserved in any kind of bottles or jars, with mouths barely wide enough to admit the fruit. Drying may also be resorted to.

Blackberries.—Stop the growth of rampant canes at a convenient height, else they will grow out of reach and bear less fruit.

Dwarf Trees.—Continue to thin the fruit. A little pinching now and then of shoots inclined to push unduly, will keep the tree in shape.

Grapes.—We have given in this and previous numbers all the proposed remedies for mildew. Provide some kind of bellows and be prepared to use sulphur or other dusting material. Keep tied up to the trellis or to stakes.

Raspberries.—Select the young canes that are to fruit next year, and give them the advantage by removing all others.

Strawberries.—Runners may be rooted in small pots and set in beds, where they will bear a moderate crop next year. Keep the runners clipped when close culture is followed. We have elsewhere described and illustrated the leading varieties.

Flower Garden and Lawn.

Keep the soil stirred this hot month; it will be found more beneficial than watering. Observe neatness, not only in keeping ahead of weeds, but in tying up plants that need it, removing spent flower stalks and all unsightly matters.

Dahlias will need tying. Remove imperfect buds. Fuchsias—The summer sun is hard on many varieties, and if any drop their foliage, prune them closely and they will push anew when the heat is less severe.

Propagation of shrubs by layers may be continued. Cuttings of the new growth, shaded and kept moist, will take root. Make cuttings of such bedding plants as are needed.

Gladiolus stems are apt to fall over, and it is best to keep them tied to neat stakes.

Botted Plants need extra shade and water. Do not allow the earth to fill with weeds or moss.

Roses are apt to be infested by insects. Use the syringe freely, with soap suds or tobacco water. Make layers. Keep the new growth of climbers properly trained up.

Coeus.—This brilliant "foliage plant" produces a much finer effect when grown compactly. Shortening the growth by a judicious cutting, will make it thicken up.

Seeds.—Select only from the best flowers, and gather as soon as ripe. All which burst their pods suddenly, like phloxes, pansies, etc., are to be taken before they are dead ripe, or many will be lost. Label every variety as soon as gathered. Seeds of perennials and biennials are generally best sown the same season in a reserve bed. They will give a stock of plants for next year's flowering.

Green and Hot-Houses.

Shading the plants that remain in the house, watering, and ventilating, must not be neglected. Provide for winter flowering plants by making cuttings and sowing seeds. Look to the stock now out of doors, and see that it does not suffer from dryness or from violent winds.

Cold Grapery.

When the fruit commences to ripen, watering is discontinued. Prevent sudden changes of temperature, as they will interfere with the proper ripening, but give free ventilation. When the crop is ripe, the upper ventilators may be kept open at night. In warm and damp weather, mildew is to be feared, and sulphur must be used as directed last month, and the air kept as dry as possible.

Apiary in August.

Some of the bee keepers who read the Agriculturist will find that their bees, having had many flowers and favorable weather, have filled not only all the combs where honey should be stored, but the proper breeding combs too, more or less. This will be almost sure to interfere with maintaining strong stocks for winter.

Boxes filled with clover honey must be removed before buckwheat comes in blossom, for if sealed with a thin layer only of the dark honey on the surface, it will all sell as buckwheat honey. The moths will be very active this month, and should be trapped and caught in every way.

removal, and they may be discovered by little mealy streaks upon the combs, fill the boxes with fumes of burning sulphur.

As soon as buckwheat comes in bloom, give fresh surplus boxes; good stocks will often store 20 to 30 pounds. Remove boxes as soon as filled, or when the bees cease storing honey, and especially if they begin to carry it away. The comb grows darker the longer it remains on the hive. Do not leave on empty boxes, in which the bees do no work; they only soil the glass and smear up the interior with propolis.

Examine all stocks with reference to the healthiness and ability to winter well. Drive out sickly ones, giving the bees to weak stocks. Queenless hives may also have their bees, brood and stores divided, or be supplied with a queen, or brood comb, or both from other hives. Equalize stocks by changing hives from one stand to another, as frequently before described.

It is often desirable to breed Italian queens late in the season, because the drones are all killed off in common hives, and a supply of Italian drones being provided at home, the young queens will to a certainty be fertilized by them. To have a supply of late drones, remove the queen from a strong stock in a large movable frame hive, place in the live drone comb containing grubs or sealed larvae from other hives, and remove after 8 days any queen cells that may be formed.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for a month, ending July 13, 1866, and the exports of Breadstuffs from this port thus far, since January 1:

Table with 4 main sections: 1. TRANSACTIONS AT THE NEW-YORK MARKETS. 2. Comparison with same period at this time last year. 3. Exports from New-York, January 1 to July 13. 4. Receipts at head of tide water at Albany, each season to end of June.

Gold advanced early in the month to 169 1/2, owing to the money crisis in London and the heavy exports of specie in May and the first two weeks in June. Subsequently, it declined to 146 3/4, rallied again to 157 1/2. It opened yesterday (July 12,) at 149 1/2, and advanced to 151 1/2. Influenced by the rise in gold, an improved inquiry prevailed for the leading kinds of Produce and Merchandise, partly on speculative account, at advanced prices. The break in the Erie Canal temporarily aided holders to work up quotations to a higher range, especially for Breadstuffs. Since the canals have been repaired, produce has come forward largely, and as gold has fallen off, receivers have been forced to make some important concessions. Corn is arriving in enormous amounts (reaching in some days 700,000 bushels, and seldom less than 500,000 bushels,) and is finding eager buyers, in part on speculation. It is coming into market in remarkably good condition. Rye and Oats are also being moved to the seaboard in large amounts, and are meeting a ready market, but at declining figures. Flour and Wheat are not plenty, and are held with comparatively more firmness. Sundry lots of new wheat have been received and sold,—the latest and choicest were disposed of yesterday to a city miller. It was a lot of about 1000 bushels very choice new amber Jersey, which brought \$3 a bushel. There is a great scarcity of prime wheat which embarrasses matters very much indeed. Provisions have been in less active demand, and have been depressed in price. Butter and Cheese are plenty; the former is dull and drooping, and the latter is wanted

partly for export and for southern use, at steady figures. Cotton has been unusually quiet at reduced prices, closing 35c@37c per lb. for middlings.—The available supply now here is estimated at 125,000 bales; and at all the shipping ports of the country, at 297,000 bales. Wool has been in more request for manufacturing purposes, at full prices. Hay, Hops, and Tobacco, have been in moderate demand at uniform rates.

CURRENT WHOLESALE PRICES.

Table with columns for Gold, Flour, Super to Extra Southern, Extra Western, Superfine Western, Rye Flour, Corn Meal, Wheat, All kinds of Rind and Amber, Corn, Yellow, Miscellaneous, Oats, Western, State, Rye, Barley, Hay, Lodge, Straw, Cotton, Middlings, Hops, Feathers, Live Geese, Seed, Timothy, Flax, Hemp, Sugar, Molasses, Coffee, Tobacco, Seed, Wool, Domestic, California, Tallow, Oil, Pork, Prime, Beef, Lard, Butter, Cheese, Beans, Peas, Eggs, Potatoes, Apples.

New York Live Stock Markets.

BEEF CATTLE.—We are using about 500 more cattle per week this year than last, and the increased demand has been more than met during a month past, resulting in lower prices, though they have been higher. This week, good to first quality cattle have sold at 15 1/2c@17c, per lb. dressed weight, a few of the very best or extras, at 17 1/2c@17 3/4c; Medium to inferior, 15c@14c; Poorest, 13 1/2c@13c. MILK COWS.—Small receipts, and still smaller demand. Prices \$2 to \$5 per head below the detailed figures given last month. Cows are worth more in the country than here, in this weather at least. VEAL CALVES.—Receipts down to 1,200 per week; prices, which have been lower, are now 12c@12 1/2c, per lb. live weight, for lots taken together; selected and extras, 13c@13 1/2c; inferior, 11c@9c. SHEEP AND LAMBS.—Receipts 15,000 to 18,000 per week; this week, 14,795. Prices of sheep have run down gradually to 6 1/2c@7c, per lb. live weight for the best lots, and 6c@5c, for common to poor lots. Fair lots bring 6c@6 1/2c. Lambs are in demand at 11c@13c, per lb. live weight for poor to very good, and 13 1/2c@14c, for extras. LIVE HOGS.—Receipts have been very large for the season, 12,500 to 15,000 per week, but the high rate of gold, and foreign demand for pork, on account of the European war, have kept prices up well; present rates, 10 1/2c to 11 1/2c, per lb. live weight, for poor to best corn-fed.

The Fairs.—We go to press so early in July, that it is impossible for a full list of fairs to be prepared; in fact, at this date, the announcement of the time of holding most of them has not been made. We hope to present an unusually full list for our September number, to which additions may be made if we have the information as early as the 10th day of August.

- The Fair of the New England Society, in connection with the Vermont State Agricultural Society, will be at Brattleboro, Vt., September 4 to 7. Meeting of the American Pomological Society, St. Louis, Mo., September 4. The Ill. Implement Trial will be at Mattoon, Sept. 4. The N. Y. State Fair is to be at Saratoga Springs, September 11 to 14. The New Hampshire State Fair at Nashua, Sep. 18 to 20. The Pennsylvania State Fair, at Eaton; the Wisconsin State Fair at—; the Ohio State Fair at Dayton; the Illinois State Fair at Chicago, take place on Sept. 25 to 28. The Indiana State Fair, at Indianapolis, October 1 to 5. The Kansas State Fair, at Leecompton; the Minnesota State Fair, at Rochester, and the Kentucky State Fair, at Paris, all October 2 to 5. The Oregon State Fair, at Salem, October 17 to 20.

New Horticultural Books.

ORANGE JUDD & Co., Publishers, announce the following new and important works, which will be issued as soon as practicable:

American Pomology.—Part I. The Apple. By Doct. J. A. Warder. The announcement that the first installment of Doct. Warder's long promised work on Pomology is already in the publishers' hands will be received with pleasure by all fruit growers. Our present fruit books are all behind the time, and a work that shall put up our present state of knowledge concerning them, especially with regard to the apple, is much needed. Our pomologists will agree that Doct. Warder is of all others the man to supply the want, and will be glad to learn that the results of his large experience and extended observations are to be made accessible to others.

Barry's Fruit Garden.—The work bearing this title, by P. Barry, of the Mount Hope Nurseries, Rochester, N. Y., has long been the standard, and indeed the only work of its kind. It will be entirely revised with such additions as the progress of horticulture may require.

Practical and Scientific Gardening.—By Wm. N. White, Editor of the Southern Cultivator, Athens, Ga. This is a completely re-written work, upon the plan of Gardening for the South, by the same author. While especially adapted to the States south of Virginia, its utility will not be confined to that section of the country. It will include all the various departments of gardening. Now in hand.

The Small Fruit Cultivator.—By A. S. Fuller, Woodside Nursery, Ridgewood, N. J. The practical and scientific character of Mr. Fuller's Grape Cultivator caused it to take at once the position of a standard work. The other small fruits will in this book be treated in the same manner, and we predict for it an equal popularity.

Market and Family Gardening.—By a New Jersey Market Gardener. This work was briefly announced last month. There is no book in the country upon managing a garden for profit, and we are glad to be able to meet a long existing want, by presenting one from one of our most clear and practical writers and experienced and successful cultivators.

It is with much satisfaction that we announce these contributions to horticultural literature. We have others in contemplation which we are not yet prepared to name. These works will all be fully illustrated and produced in a neat and serviceable style. We do not propose to issue works of reference for practical men, in fancy paper, binding, and price, which put them beyond the reach of all but the wealthy, but to give good substantial books, to be used rather than to be looked at, illustrated with engravings which shall aim to be correct, as well as artistic, and at a price that shall render them accessible to the general public.

Barometers Useful to Farmers.

At the "N. Y. Farmers' Club," the Barometer has been condemned, first, by one farmer who thought the barometer was something designed to *make* weather; 2d, by a reporter who pronounced the rules and observations of all really scientific men as "all utterly fallacious," and 3d, by another reporter who talked much about experience, and observation, but who by his own confession, had never tried a good mercurial barometer. So much for the opinion of the *farmers* of the Club. On the contrary, we have the united testimony of all the leading scientific men of this country, and the world over, that the barometer is exceedingly valuable to indicate approaching changes in the weather, which it does with a great degree of certainty. A sea-captain would be considered as utterly incompetent, who should go on a voyage without a barometer to indicate approaching storms, and these are governed by similar laws on land and sea, not always the same. The Smithsonian Institution is constantly having recorded, in all parts of the country, the fluctuations of the barometer, and the tens of thousands of observations thus gathered, show the intimate connection of the rise and fall of the mercury, and variations of the weather.—We have watched the barometer for many years, and seldom if ever knew a change from wet to dry, or the reverse, that was not indicated by a rise or fall of the mercury. And most of these changes are governed by definite rules, upon which all scientific men have agreed. There are local or general exceptions to these rules, as when the atmospheric pressure is modified by the direction or velocity of the wind. But these are only exceptions, which careful observers must necessarily learn partly by experience, and must take into account. We assert positively and without fear of successful refutation by the "Farmers' Club," or others, that any careful, observant man, who will rightly watch a good barometer, will soon learn to predict the approach of wet or dry weather, from two to twenty hours in advance, in a very large majority of cases. A watch is useless to a

savage who can't tell the time. We repeat unhesitatingly, that a barometer is of very great value to every farmer or other person, on land or sea, to whom it is important to be forewarned of the immediate approach of a storm. To be most highly useful, it must of course be carefully observed. The novice may, and probably will, sometimes fail, and the careless man will often do so, owing to the occasional exceptions to general rules which he may not have learned to provide for in his calculations; yet with this drawback, it will be of great use to any one who is willing to devote the slightest care and attention to the instrument.—It will be useful to others, if such of our readers as have used barometers will send us an account of their successes and failures in relying upon them. We would like the opinion of a real "Farmers' Club," that is, of our agricultural readers who can speak from actual experience. We have no personal interest in any particular form or manufacture, but we have latterly commended and placed in our premium list those made by Charles Wilder and called "Woodruff's Mercurial Barometer," because its particular form renders it so portable and convenient, as well as for its general good make, and we shall do so again. The Aneroid is still more portable, and we continue the use of one at home with satisfactory results. But owing to complaints that its spring depreciated in elasticity in some cases, we ceased to commend it to general use. The permanent character and portability of the Woodruff instrument, impels us to place that above all others of similar cost for common use.

Containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Sundry Humbugs.—Some 300 letters, received recently, refer to 28 different swindling concerns, of which half or more have been already described by us, directly or indirectly. Too many correspondents request answers by mail to admit of replying in that way. Suffice it to say that when no answer by letter is received, put down the thing inquired about as a humbug. Pray don't send us so much money to try these humbugs with. We have returned large amounts,—all that has come. If anybody must try any promising concern, just send the tickets to us and we will advance the money, if for a good thing, and then send for it when we get the prize, for such grand prizes as are offered will surely be securely enough to us. This will save risk of sending money both ways in 999 cases in 1000. . . . When one asks, is such and such an enterprise a humbug, our silence means "Yes," in our opinion at least. . . . One swindler is trying to bother us by writing from different points, under assumed names, that he has recently forwarded us \$5 to invest in his concern, and asking us to return the money or the prize. "Old birds. . . Chaff. . ." That bogs "Merchants' and Manufacturers' Depository," is still troubling a good many people's quiet, by writing that they have drawn a "\$150," and upward, and asking merely the "\$5" for the ticket; a big swindle! . . . Rev. E. Wilson, has a twin brother in Brooklyn, Dagnall by name. . . . Among new humbugs, we find Sarah D. Lambert; Morehouse & Co.; Thos. H. Scott; and particularly Mackey & Co., who in two sets of tickets offer several of our subscribers articles valued at near \$400.00, all for less than \$30 in cash! We have plenty of their tickets of similar import. . . . But space fails to describe a lot more of similar character, or to speak of the old ink, vinegar, and other recipes, selling as something new and valuable; of Lindsay & Co., Bain & Co., and Haber & Co., the San Francisco operators, etc., etc. See items under this head in our previous half dozen papers, which explain the various swindling schemes.—P. S.—July 13th. We can't find Mackey & Co., to-day.

The N. Y. Independent on Cabbage Seed.

—The *Independent*, in its desire to supply an "agricultural column," has published far too much trash and error for a journal of its high standing and aims, even on agriculture and horticulture it can not afford to be independent of accuracy and reliability. We have referred to one or two of its items, and several intelligent correspondents, who read both papers, have written us quite sharply about the *Independent's* defects, desiring us to correct them. We can not afford the space required to keep the agriculture of that paper straight. Its responsible editors, if not practical cultivators, are liable to be imposed upon by pretentious, uneliable penny- liners.—As a moral and religious journal however, we suggest that the editors of the *Independent* should not, on their own account, allow these scribblers to stoop to

low slurs, and to dishonest garbling. Take an example from its issue of June 14. Omitting its slang, which far more concerns its own editors than us, we give parallel quotations from our language and from the *Independent*, as it pretends to quote us. To caution people against the *Independent's* advice to plant only cabbage stumps for seed, we said:

June Agriculturist:
"If there is any seed that needs care in raising, it is that of the cabbage, as this plant is ar removed from its natural condition and will revert to it, more or less, with the least neglect. Therefore don't follow this wise man of the *Independent*, [and plant stumps only.] but use only the best developed and be t kept cabbages, with the head on the stump, for seed raising, and then allow only the central flower stalk to grow. Any other course will surely degenerate the variety."

Independent, June 14.
"As the seed of apples, pears, peaches, and squashes is found within the fruit, or vegetables, the editor [of the *Agriculturist*] reasoning from analogy, concludes that the seed of cabbages must be enclosed within the head of this vegetable! . . . It [the *Agriculturist*] says: 'Put out the cabbages with the heads on the stump, and select the seed from the sprouts that spring from the center of the head!' If this is not the most illustrious piece of stupidity that a gardener ever read of! . . . The editors of that journal [the *Agriculturist*] state that the sprouts from the center of the head are the only ones that produce seed suitable for propagating cabbages."

We italicise the word *head* in the quotation from the *Independent*, to show more definitely what it aims at. The reader has before him, in the left half column, just what we did say. Here is a deliberate and labored attempt to make the readers of the *Independent* believe that the editors of the *Agriculturist* were so "illustriously stupid," as to think that the seed springs from the head of the cabbage, and our language is *misquoted* to favor this end. Was that sheer ignorance on the part of the writer, or malicious falsehood?—We at first put in type the entire article of the *Independent*, its slang, bad grammar, and all, but concluded it would not only deface our own columns, but would be too severe upon the responsible editors of the *Independent* themselves, who are personally our friends, and whom we would not hold directly responsible for what has *hitherto* appeared in its agricultural department. We will simply hint that they will do well to make a little inquiry into the previous history and *animus* of their "agricultural writer," before they allow him the free use of their columns from week to week.—To our correspondents, who have written on the subject of this and other items in the *Independent*, we say, before being anxious about what they see quoted in that paper as from this journal, they will do well to first consult the original.—In respect to the question at issue, we reiterate our former caution: "Use only the best developed and best kept cabbages, with the heads on the stumps, for seed raising, and then allow only the central flower stalk to grow." The retention of the head to nourish the seed stalks has been found by experience to be necessary to the production of perfect seed that will propagate the original well. Our best seed growers use the largest and best heads entire on the stalk, for producing seed No. 1, and seed from anything but the best whole cabbages is marked No. 2, or inferior. We speak not only from our past knowledge, but from recent inquiry of large seed growers, as Mr. Brill, of Newark, and others.

The Great Implement Trial, at Auburn, is in progress as we go to press, and is to continue for an indefinite time. The valuable results arrived at will be duly placed before our readers.

Practical and Scientific Fruit Culture.

—By Charles R. Baker, of the Dorchester Nurseries, Boston: Lee & Shepard. This is a work, the appearance of which has been looked for by pomologists with no little interest, as it was supposed, from the author's relations with the Hon. Marshal P. Wilder, it would embody many of that gentleman's ideas upon fruit culture. The preface relieves Mr. Wilder from any sponsorship, and the work stands on its own merits. It can only be considered as an industrious compilation of the views of writers on horticulture, and subjects having a relation thereto, such as meteorology, geology, etc. We never saw a book so full of quotation marks, and one looks over page after page filled with extracts of old and familiar writers—mainly Europeans by the way—in search of what the author has to say for himself. We do not object to a judicious use of quotations, but when thirty or forty pages are taken bodily out of the book of another and put in Mr. Baker's, some other name would be more appropriate than quotation. A book should either present old facts in a better form than had been done before, or add to our knowledge by giving us new ones. This work does neither, but only serves to add to the size of a horticultural library without increasing its value. Price by mail \$4.

Barn Yard Manure—A Request.—In order that agriculturists may be able to reason correctly in regard to the affairs of farmers in different parts of the country, several important elements should form a basis for such reasoning. The markets we all consider—that is, the ease with which crops, animals, or animal products may be sold or realized upon. We have every fluctuation in the markets reported daily, and every farmer finds it to his interest to be as well posted as he can be about prices of pork, beef, butter, corn and flour.—But there is another element which the farmers of the Eastern and Middle States at least know how to value, and which is almost always taken into their calculations when thinking about buying or bettering a farm, viz.: manure—the ability to make it, or to buy it. In all the older settled parts of the country barnyard manure has a market value. We are desirous of learning what the value of it is in all parts of the country, and will thank any of our readers who can conveniently do so, if they will give us the price at which they can buy good stall or yard manure of mixed dung and litter from common farm-stock. Manure is usually sold by the load, which means a load for a pair of oxen or horses, but for accuracy we will call it half a cord, 64 solid feet. The price within our own knowledge varies from \$6 to 50 cents. Those sections where farmers move barns to get them away from the accumulated manure are gradually growing less in number. That the comparison may be the more accurate, we ask also that the price per bushel of shelled corn or corn on the ear, by weight, on the farm, shall also be given. A collection and classification of answers to those questions will be interesting and valuable.

Ashes for Manure in Illinois.—“L. E. R.” says, there is a steam mill near his farm where they burn coal and wood, and that he can have all the ashes he wants. His question is whether they will pay to haul and put about fruit trees, etc., on a yellow clay soil? We think it will pay, especially if the ashes are clean, free from clinkers and slag. Coal ashes would be of doubtful utility alone, but mixed as we infer they are with wood ashes, the value of the mixture depends chiefly upon the wood ashes. If there is much wood burned, it might pay even to sift the ashes (provided they can be easily run through a common coal screen), in order to remove the slag and clinker.

“Flour of Bone.”—In April, page 129, we gave a general caution in reference to all fine ground fertilizers. The Agents of the “Flour of Bone,” (advertised elsewhere in this paper,) inform us that certain interested dealers quote our remarks as specially applicable to their manufacture. That can hardly be possible, for the case of fraud referred to, was distinctly stated to have occurred two years ago—or before the Boston Company’s “Flour of Bone” was heard of. We have had no reason to doubt that the “Flour of Bone” advertised by them, is pure bone, except the 5 per cent. salt added, which they claim to add, especially if furnished direct by the Company, or their authorized reliable agents. Our only controversy with them has been in regard to the price, and whether the “floured” material is as cheap as the lower priced coarser ground. That was the main point alluded to in April.

The Convenient Farm Gate described in the June No. (p. 219), is said by several correspondents to be claimed as a patented article and rights offered for sale. We know of its having been in use several years, and never before heard that the principle had been patented. Whose patent is it?

Trouble with Squashes.—Several complain that they are obliged to give up Winter Squashes on account of the borer. One writer finds a borer in the root. This is a new trouble, or one new to us. The ordinary borer we have had attack the stems, and have sometimes dug him out and saved the plant; but the mischief often gets beyond remedy. The parent insect which lays the eggs to produce the borer has an orange-colored body, with black fore wings and transparent hinder ones, and long fringes on its hind legs. It lays its eggs upon the vine, near the root, from June to August. If any such moth is seen about the vines, it is quite sure to mean mischief, and it should be caught. They are not very numerous, and it is probable that they may be headed off, if sufficient care be taken. Vines killed by this insect should be burned, or, at any rate, the grub should be killed, to prevent its increase.

The Practical Entomologist.—We have before alluded to this monthly, devoted to popular entomology. It was commenced as a gratuitous publication, and its projectors soon found they had their hands full. They now propose to issue it at the very moderate price of 50 cents a year, provided 5000 subscribers are

obtained. Otherwise the publication will not be continued after September. We trust those interested in insects will give it the very moderate support required.

Insects and Fertilization.—The lovers of the curious in nature will not fail to read the papers under the above title, contributed by Prof. Asa Gray. Most of the facts mentioned in these articles are for the first time given to the public, and while they are presented in a style so popular that every one can comprehend them, they are a very valuable contribution to science.

Unfermented Wine.—A Michigan clergyman, whose reputation induces us to respectfully consider his communication, takes exception to our statement that there can be no such thing as “unfermented wine,” and informs us that it is an “important Western production,” and quotes us the Hebrew name for it. While we admit that the reverend gentleman is right as to his Hebrew, we insist upon our English. The only two English dictionaries we have at hand are Worcester and Webster, both of whom give the definition of wine “the fermented juice of the grape.” Until we get some better authority in English, we shall use the word *Wine* with the meaning above quoted, and *Must*, for the unfermented juice, which is no more wine than dough is bread.

The Agriculturist Strawberry is shown at a disadvantage on page 288, as the engraved specimen was taken as the average size of a large lot raised in the field and sent to market; while of some others, the largest specimens were the only ones at hand to be engraved from. The application however of a measure to the engraving of the Agriculturist, will show it to be very large for field fruit, grown on young plants.

The International Horticultural Exhibition and Botanical Congress.—The recent English journals are filled with accounts of the great show and gathering which took place in London in May last, and to which we alluded in our June issue. A friend who was present writes that the exhibition was a great success, and the display of plants probably never before equalled. The Botanical Congress he describes as having been a rather dreary affair, as it well might have been with botanists of several different nationalities, each reading papers in his own language. Of course there were guinea days for the nobility and shilling days for common people, and great dinners and tedious speeches, as is the custom with our friends over the water.

The “Golden Queen” Strawberry.—After our notes on varieties were made up, we had sent to us specimens of a strawberry called “Golden Queen,” by Mr. J. B. Cline, of Rochester, N. Y. We have had an engraving made of one which will show its shape, and the average size of the specimens exhibited. The fruit is firm, bright scarlet, of a very aromatic flavor. It was stated in the summer meeting of the Fruit Grower’s Society of Western N. Y., that this was the same as Trollope’s Victoria. It certainly has some characteristics of that fruit, but we can not decide on their identity without comparing the two. Should this prove to be the Victoria, it will add another synonym to that variety.

The Butter won’t Come.—Ella M. is in distress about her cream, and is half inclined to think it is bewitched. No amount of churning brings butter. It happens so sometimes in good dairies. Change the diet of the cows if you can, especially give them salt, but begin gradually if they have not been salted regularly, and keep it always where they can get it. Take good care of the cream, keep it cool, and begin churning at the temperature of 55° to 60° Far. (or 15° C.)

Cancer Quacks.—Of all classes of quacks, those who make a specialty of cancers are probably the worst. A case has fallen lately under our notice which we will record for the benefit of others. An estimable lady, in mature life, had been for some years under the care of a thorough, attentive and excellent physician, and suffering with a cancer, which was only the obvious development of cancerous disease, existing in that part of the system where it was situated. She might have lived for several years under the good treatment she was receiving, but was frankly told by her physician that the malady would in time prove fatal. By the illjudged advice of friends she visited New York, submitted herself to a notorious cancer quack, submitted to a most excruciating operation, after which she rapidly sank away and within 3 months was in her grave. The quack’s fee was \$300, in addition to some 3 weeks board in the city which must have cost \$100 more, money which, though willing paid, cost no small sacrifice to the family. These rascals are all alike; they are the cannibals of civilized society, actually devouring not only widow’s houses, but

letting not even their patient’s lives stand in the way of their gain of lucre. Avoid, as you would death, any man who advertises his cures. The successful cures of the “Cancer Doctors” are usually not cancers, but sore glandular tumors of some kind.

The “Frost Flower” of Russia.—Under this head the N. Y. Christian Advocate quotes from a “Boston journal” a story of a wonderful flower that bursts “from the frozen snow on the first day of the year, it grows to the height of three feet, and flowers on the third day, remains in flower for 24 hours, and then dissolves itself into its original element—stem, leaves, and flower being of the finest snow.” And a great deal more of the same sort. Can our readers wonder that we “pitch into” newspaper science, when stuff similar to this is found in a paper in which we look for truth? The Advocate quotes from another journal, but it is no more true than if it had quoted from the Arabian Nights or Baron Munchausen. What thing may have served as a foundation of this story we cannot guess, but as the matter as presented in the article, it is just ridiculous. What there is in the constitution of daily and weekly newspapers to make them pervert or get at the wrong end of all matters of science, we cannot understand.

“The Great American Paint Company.”—“Excelsior Paint.”—An advertisement of this, marked for 3 months insertion, appears in several papers, and many inquire of us about it. From the name and claims, one might expect to find an immense establishment. We found a small third-story room, with one desk in it, as the office; but did not find the “head man” in. We sent one dollar, however, through other parties, and got the receipt, marked “copyright applied for.” The recipe sold for \$1, proposing to make an “excelsior paint,” seems to provide only for a lime white-wash, as the principal element is lime. Perhaps the sugar and salt added, may be of advantage. We shall try it. If on further examination and trial, it be found to be any improvement, and if the “Secretary” can show us any right he has for discovery, etc., we will help him sell it; otherwise, we will publish the recipe, and what it amounts to, in our next.

Silver’s Patent Broom.—This is a novelty, certainly. By means of a cap and screw, the brush can be removed at any time. We have no broom corn at hand to test the removal of the old brush and the putting in of new, but we do not see why it can not be readily done by any one, and farmers thus raise a little plot of broom corn and make their own brooms, after buying a patent handle. The one we are using has a superior elasticity.

The “Lightning Apple Parer” is the name of a new machine—partly we suppose to indicate the great rapidity of its work, and partly because all the other striking names have already been appropriated by the thousand and one apple-parers before the public. However that may be, we like the “Lightning parer” for its simplicity and good work, two important requisites in every machine. It is described in an advertisement.

The “Laub” Family Knitting Machine.—We examined the machine made by this company with some care at the last fair of the American Institute, and are satisfied that it is a most valuable invention, being comparatively simple, exceedingly rapid in operation, and adaptable to a great variety of work.

“Grand National Concert” at Washington.—Sundry circulars for the above come in just as we go to press, and have not opportunity to verify them. From the looks of the thing, we should have called it a gigantic “Gift enterprise” of exceedingly doubtful character, but these circulars are apparently franked by respectable members of Congress. Wonder if they saw the “pins,” “ear rings,” “sleeve buttons,” “spoons,” etc., offered? At best it is a disreputable affair, and is no better than a huge lottery, to say the least. The end not a whit sanctifies the means.

A Year of the Rinderpest in Great Britain.—June 22d completed the first year of the disease in England. Excluding the unreported cases, the official Report gives: 248,965 Cattle attacked; of which 124,187 died, 50,597 were killed, 32,989 recovered, and the results of 11,192 cases are not given. 51,343 cattle exposed, were slaughtered before being attacked. More than 1 in every 20 of the cattle in Great Britain were attacked; and of these, about 561½ in every 1000 perished. Of Sheep, 4,463 were officially reported attacked by the Rinderpest; of which 4,002 died or were killed and 461 recovered. 22 counties remained unvisited by the disease.—During the last week, the attacks numbered 666. The average weekly attacks during the year were 4,778.

Walks and Talks on the Farm.—No. 32.

We have been trying our hand at Cheese Making. It has long been a favorite theory of mine that we can make as good cheese in the wheat region as they do in the dairy districts. I think so still, but a few days' dabbling at cheese making, with no conveniences, may well deter any one from adopting it as a business.—First we wanted a cheese hoop. I was sent to the city to get one, but found it no easy task. "Have you any Cheese Hoops," I asked at the store where it was said they would most likely be found. "Yes, Sir," and thereupon they handed me—a peck measure with the bottom knocked out! This was the nearest approach to a cheese hoop that could be found in Rochester. I went to a cooper who it was said made them. But it seems he got up half a dozen five years ago and could not dispose of them, and gave up the business in disgust. He had none and would not make me one. So I took the peck measure, and started for home with pleasing anticipations of eating some nice home-made cheese next fall with a good old fashioned apple pie, made in a deep dish with no crust at the bottom!

Now for the cheese. Here is the milk, here is the rennet, and there is your hoop. But where is the cheese tub? The thrifty Scotch say, "keep a thing seven years and you will find a use for it." Some six years ago I got a Metropolitan Washing Machine, which has been in the lumber room ever since. It was voted to be just the thing for a cheese tub. So it was brought down, cleaned and sealed, the night's milk skimmed and poured in, and the morning's milk added. This made the temperature 74°. The rennet was added, and in about an hour the cheese "came"—sweet and tender as could be desired. We were jubilant.

Next the curd had to be cut, in order to allow the whey to separate. In the dairy districts they have a nice knife with six or eight long, narrow blades set half an inch or so apart, which, being drawn slowly through the curd, accomplishes the object in a few minutes. In the English dairies they use a tin hoop, about eighteen inches in diameter, with wires stretched across, and a wooden handle in the center. This is pressed down very gently and cuts the curd into small pieces. But we were obliged to use a long carving knife and a tin skimmer, with a free use of that original implement, the hand. We managed to get the curd partially separated, and dipped off carefully a portion of the whey; then cut the curd of one half the tub and placed it on the other half, and in this way got off more whey. Slowly the work progressed, but at last nearly all the whey drained off.

It was then placed in a cloth and put under a small lever press and pressed gently for an hour. It was then taken out, broken up fine and salted. Now for the hoop. The curd more than fills it! What is to be done? A tin fillet is put round the cheese and inside the hoop. This is the English way. As the cheese is compressed, the tin fillet slinks down inside the hoop and the curd is pressed. So far so good. But thinking that our hand press was not powerful enough, and recollecting that Dr. Voelcker in his analyses of English and American cheese, found that one trouble with our cheese was that the "whey was not sufficiently extracted," we put the cheese under a cider press. This brought out the whey; but putting on a little more pressure, the so-called hoop, or peck measure, burst, and the fat was in the fire!

Another peck measure was got, and using less pressure the cheese was finally made. I have no doubt that the cheese will be good, but the shape is not quite orthodox. It is ten inches in diameter and eight inches high, and weighs 27½ lbs.

This is from one day's milk of 10½ cows. (We keep 11 cows, but one of them is a farrow.) And you must recollect that the night's milk was skimmed. Last week, before we commenced to make cheese, we got 79½ lbs. of butter—actual weight, not guessed at. This is a little over 11 lbs. a day. Now we get from a day's milk 27½ lbs. of cheese, and probably four or five lbs. of butter besides

from the night's milk—or say 192 lbs. of cheese and 30 lbs. of butter per week. At the present relative price of butter and cheese it certainly must be more profitable to make cheese than butter. But cheese making will not become general in the wheat region, until we have a good cheese vat, proper hoops, presses, and good arrangements for doing the work expeditiously. Those who judge of the labor of ordinary cheese making from a single trial with one or two cheeses, with no conveniences, will not be likely to go into the business.

Determined to give the matter a further trial, and feeling dissatisfied with the peck measure, I went again to the city and succeeded in finding a good cheese hoop. But it was sixteen inches in diameter, and if we made a cheese every day they would be too thin. So we "set the curd" one day and made it, together with the curd of the next day, into a cheese. We make the curd the first day precisely as if we were going to make a cheese, press it a little under a hand press and let it lie till the next day, when it is mixed carefully with the new curd, put in the large hoop and pressed. This gives us a cheese 16 inches in diameter and about 8½ inches high, weighing about 56 lbs. This is not a bad shape, and it is less labor than making a cheese every day, and besides, it gives you the use of the press for two days, which is undoubtedly better than pressing for only one day.

Our cows give fully one third more butter this year than last, due solely to good feeding and warm quarters in the winter. They were cows I bought with the farm. They looked well, but proved to be poor milkers. They had been suffered to go dry about the 1st of November, under the impression that milking them in the winter would seriously injure them the coming summer. And I have no doubt that there is considerable truth in this idea, provided the cows in the winter have nothing but corn stalks and straw, and are not stabled. But if they are fed liberally, they may be milked, not only without injury, but with positive advantage. It favors the habit of secreting milk. Till within six weeks or two months of calving, a good cow, with plenty of rich food, can give four or five quarts of milk per day, and will still be able to secure milk enough for the calf. She will eat and assimilate more food, and will get the habit of secreting more milk. I believe there is no better way of restoring the milking qualities of cows that have degenerated from poor management. I gave my cows three quarts each of corn meal a day, and an abundant supply of corn stalks and straw. Instead of letting them go dry in November, I kept them stabled in cold weather, and they gave more milk, or rather they made more butter, after we commenced to feed grain, in November and December, than they did in August and September. I milked some of them till within six weeks of calving. This is perhaps too much—ten weeks would be better. The cows, after we stopped milking, fleshed up rapidly, and many were the predictions that the corn meal would spoil them for milk. But it did not. They give more milk than ever before, and it is certainly very much richer. The prospects now are that for the year commencing the 1st of last November till the 1st of next November they will give as much again butter as they ever gave in a year before. So much for good feeding in winter. We weigh every pound of butter made, and I feel confident that this opinion will prove correct. I have not yet fed meal this summer, but shall do so the moment there is any indications of a falling off in butter. In fact I should feed meal now if I had my buildings conveniently arranged for the purpose. I have not the slightest doubt that it would pay to give each cow two quarts of corn and pea meal a day. If twenty bushels of corn a year will double, or even add one third to, the amount of butter and cheese made by a cow, it is easy to figure whether it is profitable or not. I do not say they will not eat as much grass and fodder as if they were not fed meal. The more food they will eat the better, provided it is turned into butter and cheese.

Mr. Judd of the *Agriculturist* came home with me yesterday from the S. S. Convention at Rochester.

He is a man of untiring energy, and like others of his temperament is rather inclined to apply the spur to those of us who are of an easier disposition and move slower. "Why don't you pull out the wild mustard from the barley," he asked, as we approached the field that I had underdrained and sowed so early. It is certainly the best crop of barley ever raised on this farm, but these few yellow heads of charlock annoyed him as much as a blotch of ink would on one of the beautiful engravings in the *Agriculturist*. "When he was a boy on the home farm, they went over large fields and pulled up every dock and cut off every thistle in the growing grain, and in a few years scarcely a weed was to be found on the farm." I do not doubt it. But it is one thing for the farmer or his sons or with cheap help to do such work, and entirely another to pay \$1.25 a day to do it. It is an argument in favor of small farms. The high price of labor meets us at every step, and moulds our agriculture. I have over thirty acres of barley, and it would take some time to go over it and pull out every weed. This work must be done the year previous when the land is in corn, and if the land is not thoroughly clean, plant it to corn again, and two crops of corn in succession thoroughly cultivated will go far to destroy all the weeds. Then if any escape, it would doubtless be well to go over the field when in grain the next season and pull out the few weeds that have escaped. But with much other work pressing—with planting, cultivating, hoeing, and a thousand and one little matters to attend to, I plead for gentle criticism if a few things are neglected.

One of my neighbors hearing that Mr. Judd was coming, wanted to see the editor of the *Agriculturist*, and asked me to drive him over. "Tell him," he said, "that I will show him the best seventy-five acre farm he ever saw." Is not that a happy disposition? Many people are just as well satisfied with themselves and their farms, but are not so outspoken. He and the Doctor have great times when they get together. We won't call it boasting, for what they say is strictly true. "I have got a hog that will dress seven hundred by next Christmas," says the Doctor—and he has. He gives it corn meal and sour milk, and stirs it with a red hot iron. He thinks this very important. He is raising a calf that he feeds in the same way, and it is really astonishing how fast it grows. In reality, however, it is not so astonishing after all, for plenty of good food, comfortable quarters, regular feeding, and daily petting, will make any well bred young animal grow. I like to see a man pet an animal. He can hardly fail to feed well, and in nine cases out of ten the heifer calves raised by such a man will prove to be good milkers. It is certainly a great mistake not to feed calves well. Push them forward for the first year as rapidly as possible. Let them come in at two years old. Feed high, and if well bred, you are almost sure of getting a "deep milker."

A farmer cannot make a greater mistake than to starve or even stint a young animal. But it is very common. If I were buying young pigs I would give double the price for a litter at two months old that had been well fed and gradually weaned than I would for a litter that had been neglected. As I told you last month, I bought two litters of young pigs. One litter was half Suffolk and quarter Chester White, the other was "Native." Both litters had received ordinary treatment—that is they were half starved! I paid nearly as much again for the half-bred Suffolks as for the others, for the sake of the experiment. I fed both litters alike, giving them sour milk and a little corn meal. So far, the "Natives" are decidedly ahead. My own half-bred Suffolks, that were fed with rich food from the day they were born, Peart, the butcher, pronounced "the best pigs he ever saw," and he offered me 12 cents per lb. for them dressed weight. Not wishing to dress them I offered to take \$30 a piece for them, and he took me up! I have not yet learned how much they dressed, but I have no doubt the whole litter will average 250 lbs. dressed weight. They were not eight months old! I think it would not be easy to make a litter of common pigs do as well. The reason that the half-bred Suf-

folks I bought do not thrive as well as the Natives is undoubtedly owing to their not having good feed while young. The Natives will stand neglect and starvation better than a well bred pig. But feed them well from the start, and the latter will thrive the best. The reason why so many people get disgusted with thorough-bred stock is, that they do not feed high. The remark that "the breed goes in at the mouth" is partly true. No amount of breeding will enable an animal to make flesh out of air, or fat out of water. All that good breeding can really do is to lessen the amount of offal, and enable the animal to extract the largest amount of meat and fat from the food consumed.

The Doctor has been lecturing me for not sowing some corn to cut in August and September for the cows. He thinks there is nothing equal to it for keeping up the flow of milk, at a season when the pastures are apt to fail, and I wrote to a gentleman in Connecticut who has had much experience in raising different crops for soiling cows. The object was to ascertain whether I could sow rye in the fall, and cut it in the spring early enough to enable me to plow up the land and plant corn—and thus kill the red root. He writes:—"I cannot answer all your enquiries about rye as a soiling crop. In my own experience I found it poor feed—not enough on the ground—and that it paid better to let it grow for grain." Of course, this would not answer the object. If allowed to go to seed, it would be no better for killing red root than winter wheat, which with us pays better. He continues:—"I hear of its being used, but I never found a man who used it and liked it. Still I do not doubt that something might be done with it. Almost always, both rye and barley, are left too long and become hard—all straw and head—and cattle will not eat it. Barley is much better than rye, but as soon as it heads and has a beard (and this takes place almost immediately after the stalks attain any size) it is bad—the barbed beards stick in the cows' throats. Clover comes so early, or orchard grass, or the mixture, that it does much better every way. The cows eat it better than anything else; it yields heavily; continues in season well (by having some more manured than other pieces) and it makes milk." (I have no doubt that clover is one of the best soiling crops that can be grown. By top dressing it in the fall it will produce a heavy crop and much earlier than if not manured.) "If I should sow rye," he continues, "I would sow it very thick, say five bushels per acre." (I suppose with heavy manuring and thick seeding we should get a larger and earlier growth, and finer in quality. He sows as much as six bushels per acre of oats and barley for soiling. Barley he thinks one of the best late crops for soiling, as first hurts it but little.) "After clover," he says, "I use oats and peas, sown in drills—1½ bushels of peas and 1 bushel oats. If they come up poorly, you may need more peas. On rich land they do very well indeed, and are relished almost as well as clover."

Monuments to Deceased Soldiers.

Such monuments serve a double purpose. They indicate the gratitude of the people to those who served their country in its hour of trial, and are gratifying to the surviving soldiers as well as to the friends of the deceased. They cultivate in the young a spirit of patriotism and love of country. Any enterprise enlisting the united efforts of all classes is useful in fostering a public spirit. Prominent natural or artificial objects make any place more attractive.—Beautiful churches and school-houses, and other public buildings, well arranged lawns or squares and cemeteries, and even a fine "liberty pole," all add to the attractiveness of a village or town, and increase the saleable value of property. Every dollar raised to improve streets, and to build neat public structures of any kind, is at an early day returned ten-fold in the increased aggregate value of real estate. Structures like the one here described, become fixed in the memory of children, and however far they wander, they will often turn back in thought and heart to these objects in the home of their childhood. If our sons, who will people the far West, leave behind them such revered monuments, or other like things, they will be far less disposed to secede from the land of their nativity. So, from every consideration, we think the building of monuments, or other commemorative structures, is to be encouraged, and to this end we present this subject and illustration here.

The Flushing Soldiers' Monument is of Quincy (Mass.) Granite. The base stone is 9 feet square, standing on a solid stone and cement foundation 10½ feet deep. The foundation is raised 3½ feet above the ground, with a grass covered mound around it. The top of the shaft is 37 feet above the general ground surface. The form and structure are shown by the engraving. The general inscription is on the east side of the base, and on the other three sides are to be engraved the names of about eighty deceased soldiers. It is suggested to cut the portrait of President Lincoln, as the Nation's martyr of the war, on the side opposite to the star. The cost complete, including fencing, etc., is about \$4,500.

The enterprise was originated last year, and a general committee appointed. A Special subscription of over \$2000, in sums of \$5 to \$500, was subsequently raised, which has since been increased by lectures, concerts, etc., including over \$600 from a Strawberry Festival. The balance is being collected in Dollar Subscriptions, each subscriber receiving a beautiful tinted engraving of the monument, having on it a certificate of membership. The Committee are: Messrs. J. B. Brewster, Orange Judd, Fred. A. Potts, Lendal F. Pratt, L. Bradford Prince, Chas. A. Roe, Maj. Jacob Koerner, Hon. Morris Franklin, Chairman, Joseph T. Moore, Treasurer, and Benj. W. Downing, Secretary, who will furnish any desired particulars. Any one sending \$1 to the Treasurer at Flushing will receive a certificate of membership, including also a tinted engraving suitable for framing.

SOLDIERS' MONUMENT—FLUSHING, QUEENS CO., (L. I.) N. Y.

R A B B I T S.—FROM A STUDY BY ROUSSEAU.—(COPYRIGHT SECURED BY M. KNOEDLER.)

Rabbit Breeding.

It was one of the joys of boyhood to keep rabbits, and though we never made much use of them as food at that time upon the home table, our friends were glad to accept the present of a fat pair now and then; and some little profit, which, to boys amounted to a good deal

were studied with an interest which impressed facts upon our minds that have been useful ever since—not that we boys pursued deep investigations in the theory and practice of breeding, but we certainly got some very good lessons. Others, however, have used rabbits for scientific investigations into principles which they have applied to their flocks and herds with great advantage; among them we may mention the late Col. Jacques, of Worcester County, Mass., and the lamented Col. F. W. Rotch, of Otsego County, in our own State.

Fig. 2.

however, came from the sale to companions of the surplus of our flock. It was not for profit, nor to give them away, that rabbits were kept, but they were enjoyed as pets and companions. Almost every one had a name, and the mysteries of pairing, nest making, suckling, etc.,

Rabbits do not require expensive houses or yards, but may be bred in health and to excellent advantage, in the simplest kinds of boxes and hutches. It is best usually to have a pen, with a roof over the whole. A part of an open shed is a favorable place, and this should be laid with boards or paved with bricks or stones, to prevent their burrowing out and doing mischief in the garden. Ambitious to imitate nature so far as possible in accommodating our pets, we made a contrivance which is described and

figured because we had so good success with it.

First a pit fully 3 feet deep was dug, and a box (A, fig. 2) set in it, open at the top and at one end. The box was about 3 feet long, 18 inches wide, and of the same height. A board passage (B) having a bottom and sides only, was then made from the open end of the box up to the top of the ground. The whole was then loosely filled with soft sandy soil, with a few stones as heavy as the rabbits could move.

Fig. 3.

Then we nailed barrel staves (D, D,) over the box and the passage, and scattering some shavings on the staves, filled up the pit with earth—not, however, before we had driven barrel staves (G, G,) in a row all around the box and passage-way, coming up to the surface and

meeting the pavement. Our reasoning was, that when the doe had dug out her nest in the box, (which we were sure she would do if we started the hole a little for her,) then it should have the natural ventilation of the open earth, and not have a close box cover, and close pavement over it; and yet the loose earth above the box should be so enclosed that other rabbits could not dig down and work galleries beyond the limits of the pen. The does would dig out their burrows in these boxes just as contentedly as if they were at work in the open ground, and when one began to make her nest before bringing forth her young, we would turn a box, with no bottom and a slatted top, over the mouth of the hole. In this box the feed was placed, and hay and straw for the nest. Thus the doe was left entirely to herself and her family, and could not well be interfered with by curious persons, or even by the owner himself. When the young ones are old enough to be taken from the mother (say 4 or 5 weeks old,) they should be removed—certainly in time for the next family, which may come in 5 or 6 weeks.

Such a sunken box or burrow is not necessary for the successful breeding of rabbits; but with a few boxes like fig. 2, and good care, success is quite certain. This box is of about the same size as the buried one in fig. 1, viz: $1\frac{1}{2} \times 1\frac{1}{2} \times 3$ feet. One end is of stiff fixed wire rods, one rod being inserted close to the wood on each side, to prevent gnawing. There is a partition across the middle of the box, with a corner cut out for a door, and there should be an outside door as shown. The top lifts off, or is hinged and locked down. This box may easily be cleaned out, and is big enough for a pair of young rabbits, or one breeding doe.

Young rabbit breeders should remember not to let bucks and does run together, after they are 5 or 6 months old; not to feed too much green food, nor any wet food, but to give plenty of hay, with some oats, barley, or other small grain, in connection with green food, clover, grass, young lettuce, cabbages, roots, etc. Celery leaves are good occasionally, and so are any other sweet herbs they will eat. They need no water, and are usually better without it, if they have some green food daily. We have kept rabbits all winter on nothing but hay, with no water, and they did finely. A doe, 6 or 8 months old, should be left one day with a buck, and she will probably have young ones 31 days after. Old bucks are very apt to kill the young if they can, and two bucks will generally fight and often kill one another.

How to set a Bar Post.

"Any fool can do that," said neighbor Tucker, as I got the hole dug out to plant mine for the fifth time. "Just chuck your post into that 'ere hole, and pound the dirt in well, and it will stay till it rots. Dirt packs a great deal solidier than stone," said Tucker by way of a clincher.

"Not so fast, neighbor Tucker," said I. "There is gumption needed in setting a bar post as much as in setting a hen. I used to do it in your way until I found out a better. You see if you pack the dirt in solid there is no chance for the water to run off quick, and the soundest wood will rot off just below the surface of the ground in a very short time. I have had 'em spoiled in three years so that I had to put in the other end. That bar post has been in service at least 35 years, and if you examine the wood, you will see it is about as sound where it has been under ground as it is above.

"I dig a good sized hole to begin with, and then put in a good sound post of chestnut or white oak stripped of the bark. The butt should be at least eighteen inches below the lower hole in order to hold well. I pack in around the post stones of any convenient size, and pound them in sung with a crowbar. This leaves room for the air to circulate all round the bottom part of the post, and it is kept about as dry as if it were above ground. A post set in this way is good for an ordinary life time. I have some posts of forty years standing, and they are good yet. The frost of course will move the stones, and they will need resetting occasionally, but no oftener than those packed in dirt."

"How much, do you suppose, you have saved by that operation," asked Tucker with a sneer.

"No contemptible sum," said I, "as you can easily calculate. Bar posts set in dirt will last say five years; in stone forty. If they are worth 2 dollars a pair I save seven pairs in forty years, or fourteen dollars, not counting the interest for every bar way. I have forty on my farm, quite too many I admit, but that makes a saving of \$560, which is worth looking at."

It is by attention to small things that the farmer makes his money and his fortune. A penny saved is as good as a penny earned.

CONNECTICUT.

More About Wild Oats.

In February last, we published an account from a correspondent in Wisconsin, of the occurrence of the Wild Oat (*Avena fatua*), in his vicinity. The writer gave an account of its supposed occurrence by a degeneration of the cultivated oat. This statement has brought out several letters in reference to the oat. Mr. G. C. Hill, of Fond du Lac Co., Wis., says that he has known the oat for ten years, doubts its being a degenerate cultivated grain, but thinks the seeds were probably introduced from California, with seed wheat. He says: "Wild oats are a great pest in a wheat growing country. They are hard to eradicate by tilling, because only those seeds that are near the surface will vegetate, while those plowed under deep will produce a crop in after years. My plan is to seed down and mow or pasture."... F. V. Morrison, of Ulster Co., N. Y., states that a few years ago, in Brown Co., Wis., the wild oat "would over-run and nearly destroy cultivated oats and spring wheat." On the other hand, James Cass, of Sacramento Co., Cal., wonders that we consider the appearance of the wild oat in Wisconsin, as something to be regretted. He says: "If I were in Wisconsin, and knew as much about the wild oat as I do now, I should be delighted with its appearance."... "In curing it for hay, it must be cut as soon as the top seeds are turning, and put into cock as soon as you can give a handful a wring and not produce sap, and it should not have more than one dew, by any means, as the least dampness sets the seeds to crawling out. As a hay, it is unsurpassed in this State, and brings the highest price in our markets. I cut from 40 to 75 tons yearly..." These statements show how differently the same plant is regarded in widely dissimilar climates. In reconciling them, it should be recollected that there are but few portions of California in which our most valued meadow grasses will succeed. The wild oat is the best grass that grows there. With regard to the alleged identity of the wild and the cultivated oat, the principal proof lies in the experiments of Prof. Buckman, formerly of the Royal Agricultural Col-

lege, England. He, by planting and selecting those specimens that showed a tendency to lose their wild character, and continuing this for several years, succeeded in producing a plump grain, destitute of hairs, and having the general characters of the variety of oats known as White Tartarian. A portion of the original bed was continued by allowing the plants to seed the ground in the natural way, while the selected seed was kept out of the ground until spring. Prof. B. has made many interesting experiments in "ennobling," or improving plants from their wild state, and attributes great importance to the keeping the seed out of the ground from the time it matures until the time for sowing. This is one of the conditions in which most cultivated plants differ from wild ones, of which the seed falls at maturity, and generally lies all winter in the earth.

How the English destroy the Hop Aphid.

The hop crop of this country has been greatly damaged in many sections—almost destroyed, for three years past by the hop-louse or Aphid.

These little insects multiply so as to be particularly observable during the month of July, and soon cover the entire vine with mildew-like green masses of life, sucking its juices, and destroying the crop. Some patents have been issued for preventing this destruction, but we are not familiar with the means employed. There are a number of substances, which, if they can be applied, will kill Aphides and not harm the plants upon which they live. Tobacco smoke, and tobacco water are both used in green-houses upon tender plants with success.

Mr. F. W. Collins of Rochester, the inventor of the horizontal hop yard plan, which has been described in this Journal, and in our hop book, spent last summer abroad looking into the modes of hop culture. He writes us, that the English hop growers use almost universally one or the other of the following washes:

1. A mixture of strong soap suds, to which salt and saltpeter are added, so that a brine is made about half as strong as common beef-prickle, and to this one pound of copperas to five gallons of liquor is added, dissolved in warm water.

2. Tobacco water made about as strong as for sheep dipping: that is, a strong decoction made by boiling a pound of tobacco in a gallon of water. The stems and refuse parts of the leaf are usually employed.

Mr. Collins says: "They raise hops in England on a much larger scale than we do in this country. Gardens of 50 to 100 acres are quite common, and 200 to 300 in one plantation are occasionally seen. They are strictly watched, and as soon as the vermin begin to appear on the vines (or *bines* as they are called there), they go through between the rows with a machine, like a little fire engine, carrying a tank containing the liquid and a force pump. There is a hose with a sprinkling nozzle attached, by which the liquid is thrown in fine but strong jets to the tops of the highest poles, in such a way as to strike the leaves upon the under sides where the lice for the most part collect. We can easily apply the preparation to our smaller yards with the green-house syringe or the garden engine, especially, if the economical system of training on short stakes and twine be employed. This brings all the vines within 7 feet of the ground, and so within reach. This is an advantage of the horizontal system perhaps not heretofore appreciated, and it will be still more

valued should the mold or mildew appear here. In England this disease causes a thickening of the parts affected, the stems and leaves, and attacking the burs or immature hops, stops their development. To prevent this, they dust on sulphur with a machine for the purpose.

The hop crop is the most paying crop, both in Europe and America, taking any ten years together for 40 years past. In this country its culture is rapidly increasing. We have now about 16,000 acres devoted to hops; England has 50,000, Austria 150,000. Our hops are nearly 30 per cent. stronger than those grown in England, and fully equal to the Belgian hops.

Peat and its Uses.*

The great war from which this Nation recently emerged with all its woes and terrible suffering, financial crises, and political overturning, not only worked great changes in the domain of State craft, but it also inaugurated equally startling movements in the economies and industries of the country. Among all the various subjects that have claimed the attention of the public, and appealed to capital for development, which we may regard as directly or indirectly the fruit of the war, the development of our *peat resources* is prominent. The rage for speculation in stocks and gold having most wickedly extended to the necessities of life, bread-stuffs, meats, coal, etc., the stores of fuel in our immense deposits of muck and peat, naturally attract the attention of enterprising men. They find a material, differing greatly in quality and in accessibility, but existing almost everywhere in the country; but they find also many not unexpected difficulties in the way of its rapid or general introduction as fuel. Though many kinds burn well, simply cut and dried, yet the smoke is disagreeable and a strong prejudice exists against it among those who have been accustomed to more convenient fuels—wood, coal, coke, etc. In other countries much thought and labor have been expended upon peat to bring it into compact and convenient forms, but the American way is, not to follow, but rather to strike out new paths; so the ingenuity of men has been taxed to dry and press peat into the driest and densest masses possible, and of convenient size, so that it may be used like coal. The results, satisfactory as they are in many particulars, are not yet proved to be thoroughly economical. The condensed peat is excellent fuel, but the pressing machinery is expensive, the manipulation and drying is costly, and the new fuel must yet find a market.—The work of Professor Johnson, the title of which we use as a heading to this article, is very full upon the most successful methods of preparation of peat fuel in use both in Europe and in this country, describing them, illustrating the machines, and giving the economical results, in a way to enable us to compare the expenses of doing the work here with those abroad.

It is not alone in the furnace that the uses of peat, etc., are discussed in this valuable work; for to the farmer the subject has an especial interest and value. This we have often considered in these columns, but it is a matter always important, and upon which every new fact should be sought and applied. A consider-

able portion of the book is devoted to the consideration of its employment in agriculture, embodying the results of a very thorough investigation of the peats and mucks of Connecticut, made by the author some years since, in which many of the best farmers of that State cooperated with him in the investigation so far at least as to furnish many samples for analysis, and to describe minutely their ways of making composts, and the effects of the manures thus made, upon various crops. Whether therefore we regard the book from a purely scientific stand point, or with relation to its bearing upon mechanical and domestic economies, or upon the most important of all industries, agriculture, it is one of the most valuable works recently issued from the American press.

Chicken Medicine.—Charcoal.

Under this general title we continue a subject discussed on page 252 (July,) and include here a statement of a Springfield, Ill. correspondent, about the wonderful effects of charcoal upon a diseased and dying lot of turkeys, prefacing his letter, however, with a word or two about charcoal as a preventive of, and a remedy for disease in almost all our domestic animals, and not less in man. The most convenient form in which to administer it, is as the "prepared charcoal" of the drug shops. This is simply soft wood charcoal, which, being thoroughly and carefully burnt, is finely pulverized. It is the best cure we know for bad breath, indigestion, ulcers, etc. It may be given internally mixed with food, or clear, as the bird or animal prefers, and we know of no need of caution against excessive doses. It is conveniently made by covering soft wood embers with ashes, and when the heap has done smoking, and is a mass of live coals, open it and sprinkle water upon the mass. The coals, and if some of the ashes are attached it is just as well, may then be powdered to fine dust. "J. S. D's" experience is as follows:—

"I have thought that some of my 'dearly bought' experience, if communicated through your columns, would be instructive to many of your readers. In 1847 I took up my residence in a small county town in that portion of Southern Illinois, named 'Egypt,' (probably by unsuccessful speculators—perhaps from its great fertility and mild climate, but more likely from the supposed ignorance and mental darkness of its population.) We were seventy-five miles from St. Louis, the roads to which city, although excellent in summer, were during the open, constantly freezing-and-thawing winters almost annually impassable to wagons. I kept a country store, and one day in January, a customer drove up to my door, with about one hundred turkeys. A sudden thaw, accompanied by rain, had set in, and any further traveling was impossible. He wanted me to take the whole load for 31 cents each, and I finally reluctantly yielded. The turkeys were turned into a good-sized lot, in which was a house for shelter, and abundance of gravel, sand, water, and corn, costing only 15 cents a bushel, to feed them.

One would suppose this to be a very paradise for turkeys, but it was soon found to be their grave-yard. Notwithstanding our care and abundant food, they drooped, sickened, and commenced dying. We changed their food, gave them oats, corn meal, fresh meat, procured fresh gravel, but all to no purpose, the sickness and mortality increased and continued. It was clear that they had contracted some disease

while cooped on the wagon, and that four or five weeks freedom, and abundant and pure food appeared to only aggravate it. What was to be done? Everything had been tried within our knowledge. Old ladies, familiar with 'Turkey,' were solemnly consulted, but their nostrums and opinions were as useless and valueless as our own experiments, when, accidentally, the remedy presented itself. There was a smoke-house in the yard in which the turkeys were confined; the fire, made in a pit extending the length of the house, was extinguished with water every night. A considerable quantity of charcoal was there made, which was cleaned out every morning. The first thrown out into the yard brought the turkeys; they eat every piece of it and continued to eat it daily for three weeks—the time consumed in smoking. Then an English poultry butcher, who was on the 'tramp,' butchered and dressed them, placing the livers under one wing, and the gizzards under the other, ran two handsome skewers through each of them, and decorated them with ornamental white and colored paper. They were pronounced the finest lot of turkeys ever seen in St. Louis' market."

Gas Tar for Posts.

A correspondent says: "The complaint is sometimes made that gas tar does not prevent rot in posts. Whenever it fails to do this, it is probably because the posts were green when it was applied. Of course, when they afterward became season-cracked, the moisture entered the cracks and decay went on rapidly. The only way is to use seasoned posts. The tar is generally applied with a coarse brush. Experience is now showing that the best of all ways is to heat the tar in a deep vessel, and when it is boiling, set in the lower ends of a few posts at a time, keeping them in about half an hour, so that the tar will fairly boil into the pores of the post. This requires time and patience, but it is worth the while, because posts so treated will last half a century. The gas tar coating should extend up a few inches higher than the surface of the ground." It is settled also that if the freshly tarred posts be covered with sand or sandy soil, the highest good effect is secured. The experiments detailed in the *March Agriculturist*, page 94, showed the best result from applying hot gas tar with sand twice, at intervals of three days.

Horse Carts, or Wagons?

Where the roads are smooth and level, and where but little field work is to be done, the horse cart is endurable, if made light and handy. But as a general rule, they are the most cruel machines ever made for horse-flesh. For farm-work, they must needs be made strong and heavy. The requisite harness weighs from forty to fifty pounds. When the cart moves on level ground, it bears heavily on the horse's back; when on a descent, it is still worse; if toiling up hill, it pulls upward on the belly; if one wheel falls into a rut, it whirls the thills suddenly to one side, and tends to upset the horse, and at best strains him. The unwieldiness of a cart is seen in the fact that it is almost impossible to make a horse trot in one. Not so, however, with a four-wheeled wagon. We advise our readers not to invest in horse-carts, without thinking the matter over carefully. There are many handy dumping wagons made now-a-days,

* PEAT AND ITS USES; its origin, varieties, and chemical characteristics; its applications in agriculture, and its preparation, value and use as fuel: by S. W. Johnson, M. A., Professor of Agricultural Chemistry at the Sheffield Scientific School, Yale College.—Fully illustrated.—Orange Judd & Co., New York. 163 p. 12mo. Price \$1.50.

Stacking Hay or Grain.

The use of the horse fork in unloading hay and grain is all but universal nowadays, but there has always been a difficulty in using it for stacking, so much apparatus was required. The use of a simple pair of shears has been recommended, and we have suggested it to our readers. A correspondent sends us a sketch, from which we make the accompanying engraving, to illustrate his way of accomplishing the end cheaply and easily. He selects two strong poles, so long that when bolted together at the tops, the pulley suspended between them will be about 24 feet from the earth. This pulley block is hooked on to an eye bent in an iron rod, which is shaped as in the enlarged part of the figure, and sprung over the bolt. Another block is attached to the foot of one of the legs of the shears, a pin being run through it. The engraving shows how the rope is rove through these blocks, and how the horse is attached. If the ground is hard, the end of the pole against which the horse draws is secured from slipping, by driving stakes into the ground. The shears are held in place and given any desirable amount of play back and forth, at the top, by two guy ropes. The load is driven quite close to the shears at one side, and when a forkful is raised and swung over the stack, the shears incline that way, being allowed to do so by the slackness of the guy-rope that passes over the load. This plan seems feasible, and has the merit of simplicity.

About Farm and Orchard Ladders.

Our correspondent, Gilbert J. Greene, of Hudson, who has given us so many practical hints, offers some upon ladders, which, in the main, strike us as excellent. There are numerous patent ladders made very light and strong, of white pine or white-wood, some of which we have used with great satisfaction; but these are not within the convenient reach of all, and besides, it is always better to use one's spare hours in making such things, rather than one's spare change in buying them. Mr. G. says:—

"The ladders in use about the farm are often heavy, clumsy affairs, often requiring the strength of two men to carry or put them in position. Soft wood will make a stiffer ladder than hard-wood, one more easily made and handled, and less liable to be broken if thrown down. A ladder with the sides of 1 $\frac{1}{4}$ inch pine, 2 $\frac{3}{4}$ inches at the bottom, and 2 inches at the top, and 18 feet long, with oak rounds about 21 inches long at the bottom and 15 at the top, will weigh only

about 28 pounds. It can be readily handled by a boy, and will sustain a weight of 200 lbs., placed at any angle. Second-growth basswood is the best timber to make ladders of, because it is the stiffest light timber grown in this country. A ladder, 26 feet long, 3 inches at the bottom and 2 at the top, and 1 inch thick, will weigh about 32 pounds, and will sustain a weight of 150 pounds placed in the centre, the ladder lying in a horizontal position, and sustained only at the ends; (of course, it will sustain a heavier weight if set in any other position.) The rounds of a ladder (to use a contradiction of terms) should be flat, 1 $\frac{3}{4}$ inches wide, and $\frac{5}{8}$ inch thick, and the mortise $\frac{3}{8}$ inch wide. About every fourth round should have a dovetail, made upon the upper side of the tenon, the mortise cut to fit it, and a wedge driven in beside the tenon to fasten it. In this way the ladder is securely fastened together, and the outside is smooth.

A ladder should not be left exposed to the weather, but should be well painted, and placed under shelter when not in use. Fig. 1 represents a light ladder, from 10 to 12 feet in length, to be

Fig. 1.

Fig. 2.

used about the fruit garden or orchard, where a longer ladder is not necessary, or might injure the trees. A brace, *B*, is hinged to the upper part, and can be so placed as to give the ladder any desired angle; a single brace is much better than a double one, because it is more easily constructed and handled, and the ladder will stand square on any uneven surface. Such a ladder, 12 feet long, of pine or basswood, weighs about 23 pounds. [We very much prefer two independent braces, instead of one. They must each swing free, and be firmly hinged upon the upper round or near the top of the ladder, as shown in fig. 1. Two independent braces will hold a lad-

Fig. 3.

der very firmly, but if they are united by a stiff cross-brace, they are much less secure. ED.]

Fig. 2 is an extension ladder, which possesses some merit. It is composed of two ladders, so

arranged that one can be drawn above the other to any desired height. The ladders can be of any length; they should be of the same

Fig. 4.

width at each end. They are held together by a strap of flat iron, as *A*, fastened upon the top of the first ladder and on the bottom of the second; they should be loose enough to admit of their sliding freely upon each other. The second round in the lower ladder is turned with shoulders, this passes through the sides of the ladder, with a small crank upon one end. A rope, twice the length of the ladder, is attached to this round, which passes up on the back side of the ladder. A small iron pulley is attached to the top round, and thence the rope passes down the front to the bottom round of the second or upper ladder; turning the crank to wind up this rope draws the second ladder above the first to any height. The ends, however, should always be allowed to lap upon each other, at least twelve to twenty inches. The top ladder is kept at any desired height, by fastening a hook, as *B*, fig. 2, to the bottom round of the second ladder, and hooked on any round it will reach in the first ladder. The iron straps, holding them together, should be fastened with screws, so that the ladders can be taken apart and used separately if desired. With this design in view, it would be a good idea, perhaps, to have the ladders of different lengths." The construction of figures 3 and 4 is readily seen.

Hints About Hen Roosts.

In the treatment of our domestic animals, there is no guide so reliable as nature. If we keep our eyes open and observe the habits and inclinations of our dumb dependents, we will gain insights into their natures so that we may be able to do much for their health and comfort. The following hints about hen roosts illustrate and suggest this idea. "X," of Green Bay, Wisconsin, sends the following communication to the *American Agriculturist*:—"In some of the more northern latitudes, where the mercury falls to zero, and below, it is difficult to preserve poultry from freezing their feet, and I shall be glad if my experience in preventing it will be of any value to others. If you will observe the habits of poultry during the year, it will be noticed that in warm weather they prefer to roost on poles, the edges of fences, boards, etc.; while in cold weather they seek out flat places, where their toes may be kept up among the feathers. The favorite place which my fowls found in the winter, was the top of an unfinished harness room, where they found the flat surface of a 2x4 scantling, with its broadest side up. In the summer, they go back to the roosting poles, which are probably cooler.

I have devised a plan to accommodate them winter and summer, which I have tried to make plain by the accompanying rude sketches. Scantlings, 2x4, are made into oval shape, as

HEN ROOSTS.

shown enlarged, with a pin in each end, so that they will turn on the supports. A number of them are then fitted in inclined supports, as is shown, and can be adjusted with their broadest or narrowest surfaces uppermost. In this way the careful and humane poultry keeper may give his fowls, without trouble, such roosts as they prefer through the varying seasons, and secure them against frozen feet in the severest weather.

The plan of inclined supports for the roosts seems to be the most economical as regards room. Each row of fowls is a little behind and a little above the one in front, and they are out of the way of each other. The past is the first winter during which my fowls have not frozen their feet more or less, though the mercury has been as low as 28° below zero."

Feeding Boxes for Chickens.

Authorities disagree somewhat about the desirableness of feeding boxes for chickens, but it is often a matter of convenience when fowls are confined in close quarters. It makes fowls lazy when they are wanted to forage for their own food and pursue insects, if they have all that they want to eat at home. We give drawings of two styles of feeding boxes, which are very easy to make, and very good. Take any small box, such as a candle or soap box, knock it to pieces carefully, and put it together again after cutting the pieces where necessary, and preparing other pieces for the bottom, or for the slanting pieces as may be needed. Fig. 1 shows a sectional view of one form, in which the food is exposed on the outside of the box; and this is the best form for indoor use. In this arrangement there is provided a slanting false bottom coming to the bottom about an inch or less back from the front, and the front comes to within about half an inch from the bottom. This leaves a space across the entire front for the grain to flow out, and it is prevented scattering by the edge which is nailed on the projecting front of the bottom. The top of the box is made to lift off, and is also strengthened by cleats on the underside, which are so placed as to prevent the sliding of the covers. This plan is very similar to one sent us some time since by J. A. H., of Scarsdale, N. Y., which

Fig. 1.

suggested the form which we describe, and which in practice is found to work admirably. The other form, fig. 2, has the advantage of keeping the grain away from the rain, so that the box may stand in the yard. The whole front is open, and the birds may walk in, or standing outside reach in, according to the depth of the box. A convenient size for this style of box is 2 feet high, 3 feet long, and 1 foot deep. The false bottom comes, as seen in the figure, within about an inch of the back angle, and a cleat is nailed 3 or 4 inches in front of where the grain pours out. These boxes should be set up a little above the ground, or they may be hung up on a fence or partition, upon nails passing through holes in the back.

Fig. 2.

Another Farm Gate.

We have presented within a few months past several excellent forms of farm gates. Some are very cheap, and some less so, but more convenient. The plan which we now give was sent some time since to the *Agriculturist*, by Roswell Cook, Wayne Co., N. Y., and is durable and convenient. The only parts liable to especial wear being easily removed. He says of it: "I have used such an one at my barn-yard for eight years without any trouble or expense, except the removal of one pin through the wheel." "They may be made of light or heavy lumber as you please—I use hemlock. I take three pieces 2x4 inches for uprights; one bottom board is 8 inches wide, the other boards are 5 or 6 inches wide. On the opposite side I put a board at the bottom to hold the wheel pins, and one at the top so that the uprights will clear

FARM GATE.

the stakes when the gate is run back and forth. The gate runs on two wheels, cut from hardwood plank, a little thinner than the uprights, so that they will turn freely between the boards. They should project 3 or 4 inches below the bottom boards. The wheels run on 1 1/2-inch pins. The stakes or posts at the side by which the gate slides, should be 5 inches apart. It is well also to have two similar stakes for the gate to run into to give it firmness. I use no fastener, if any one wishes this he may nail a block upon the track plank which the wheel will roll over when it shuts. This will hold the gate where you want it." [Our engraving varies a little from the description at the latch end, but it will be understood. The objection to this arrangement is that in winter the wheels may be obstructed by snow or ice. A modification of the plan might be to have the axils of the wheels run through the posts, and the bottom-board run upon them.—Ed.]

Hints About Fences.

We have given elsewhere in this volume of the *Agriculturist* the views of several practical men about the cheapest fences that will turn common stock, several of their plain patterns were not ill-looking. Yet their good looks were no recommendation, utility being the only thing sought. We seek beauty in our horses and cattle, in our mowing machines and farm wagons even, and farm fences need be no exception. We have had this subject in mind for some time, and have taken a good look at any neat fence patterns we may have seen, and made a sketch now and then, the result of which we now give our readers. The cost of these fences we cannot state with any accuracy, and if we could, it would be of but little advantage, for the price of stuff and labor varies immensely in different parts of the country. The posts are supposed to be made all of good seasoned stuff, tarred and sanded, set fully two feet in the ground. The rails, either of sawed 2x3-inch, or 3x4-inch stuff, according to the span of the lengths, or the desired strength of the fence. They may be made, also, of 3 or 4-inch poles with the back one split in two pieces. The

Figures 1 and 2.

paling and ornamental pieces are best made of red cedar, though almost any of our common woods will answer. These are nailed to the rails and to each other, or they are bound on where they cross one another with galvanized

iron wire. Figures 1 and 2 are simple and easily made, as indeed are 3 and 4, but figures 5 and 6 are a little more complicated, yet stronger in proportion, and would exclude pigs and geese, and perhaps other poultry very well. There is general complaint that rustic work, and fences of this kind, soon fall a prey to dry wood borers of two or three kinds. One of the most successful makers of this kind of work in this neighborhood in-

forms us that he soaks all his wood for use with the bark on, in sulphuric acid (oil of vitriol), diluted, but still quite strong. This entirely prevents the damage by insects. We think a solution of sulphate of copper or blue vitriol, espe-

Figures 3 and 4.

cially if the wood were long soaked, or if the solution were hot, would be as good to keep out borers, and it would kyanize it and thus defend the wood better against decay. It can

hardly be expected that fences of this description will be used very extensively upon the farm, but made immediately adjoining the house,

Figures 5 and 6.

they will improve the appearance, and thus add to the salable value of the place, besides giving much pleasure to the owner.

Dry Earth as a Deodorizer.

It is very seldom that one finds a privy in the country which is not a nuisance. Those who are careful and neat about most matters, generally utterly neglect this necessary appendage to their premises. It is well known that the pondrette which is made and sold in such large quantities is only night soil, deodorized by mixing it with the dredgings of a canal and drying it. It is commonly supposed that some particular kind of earth is necessary, and in the absence of that, none at all is used. Any kind of earth, well dried, and all the better if sifted, will answer to mix with the night soil. The Rev. H. Moule, of England, states, that he finds that the earth after being used once and then thoroughly dried, is equally as efficacious as at first, and that he was using the same earth for the fifth time, the resulting compound being so perfectly odorless, that a person unacquainted with its composition would not suspect what it was. Aside from considerations of comfort and health, this plan is worth adopting for the value of the resulting manure. He says:—

“A farmer and several laborers to whom I mentioned the following simple plan at once entered into it: the present vault is to be discontinued, and in the place of it there is to be under the seat a small enclosure of brick or stone, six or nine inches deep. To preserve the full value of the manure for the garden, the enclosure should be paved, or have a flat stone for its bottom. It would, of course, be closed with a door. On one side would be a small rough shed, capable of covering and keeping dry a cart-load of earth for the purpose of mixing, and on the other side a similar shed into which the soil so mixed would day by day be thrown, for the purpose of drying. When dry, this would be used again, and the uses of the two sheds be reversed. By thus repeatedly using it, and shifting it backwards and forwards from one shed to the other, one load of earth will be found sufficient for five persons, certainly for six months, and, I believe, for twelve. This is the simplest, but by no means the least offensive mode of applying this remarkable agent.”

Willow Hedges.

The vexed question of living Willow fences, is thus treated by our correspondent G. G. Greene, of Hudson:

I have heard much complaint from persons who have undertaken to make hedges of willow, that they were unable to make them grow, or that they died out in places after having started.

The soil at times may have been too dry and poor, or they were not properly put out or cared for: the following plan which I have followed with very great success, will, I think, ensure a hedge in almost any soil, and at almost any season. In cutting or trimming up old willow trees, I take the limbs varying from two to six inches in diameter, cut them up in pieces as long as they will cut tolerably straight, say four, six, or ten feet long. I plow a furrow if practicable, just where I desire the fence, or dig a shallow trench, placing these pieces in the trench in a straight continuous line, and cover them up with earth; if the soil is wet, I leave the tops exposed, if dry, I cover, say an inch in depth: the sprouts spring up very rapidly, much thicker than they can be grown in any other way, and they will make as much growth in one season as they will in two years by the ordinary mode of planting. They make a better hedge than can be grown of willow in any other way, for these reasons:

They are sure to grow; the sprouts come up so thick as to admit of being trimmed the first season, and they grow more rapidly than in any other way; their roots are one continuous mass and the fence can not be pulled up or blown down; they do not die out in places; they can be grown on any kind of soil; they will make a fence cheaply and effectively, which can not be said of half the willow hedges I have seen.

In the fall a furrow should be turned up against them, and at the proper season they may be trimmed to suit the owner's views.

Along water courses, where the soil is in danger of washing away, they answer an excellent purpose planted in this way, as their roots penetrate the soil rapidly, and soon link it together in a firm mass.

The Mole-Cricket.—(*Gryllotalpa borealis*.)

A correspondent sends us a specimen of an insect found in his potato ground, and wishes to know what it is. It is the American Mole-Cricket, and as it is an interesting and not very common insect, we have had its portrait taken, to enable others to see what it is like. The scientific name, *Gryllotalpa*, means Cricket-mole, a name which the peculiar structure and habits of the animal readily enough suggest. The engraving is of the natural size; the animal is covered with fine velvety hairs, and is of a drab

MOLE CRICKET.

or fawn color. The wings are so short as to be insufficient for flying; but what the insect lacks in this means of locomotion is made up to it in the size and strength of its enormous fore-legs, which are especially adapted to its favorite mode of travel—that of burrowing through the ground like a mole. By means of these excavators, the Mole-Crickets push long galleries through the soft earth, and where they are numerous, do much damage. With us, the insects are not sufficiently abundant to be troublesome, but in Europe a related species is one of the pests of the garden, especially in the warmer countries. While Harris states that they live upon the tender roots of plants, the recent French authors say that their food is entirely insects and their larvæ, and that the damage they do to plants is only in cutting off the

roots of such as come in the way of their underground engineering. In some parts of France they are so destructive in hot-beds, that it is necessary to drench the manure with hot urine before making up the beds.

More About "New Peas."

In May last, we gave some account of the trials of new peas by the London Horticultural Society. A venerable Connecticut correspondent thus recounts his trial for the *Agriculturist*:

“Carter's First Crop of Peas.”—I hope he may never raise a second crop of peas, or any other seeds. I think the real value of them by the bushel would be from \$1.25 to \$1.50. I was so foolish as to pay \$1.50 per quart. I had them planted very early, intending to beat my neighbors, who planted the good old kinds. The result is a monstrous crop of vines, seven feet high, and still growing. They remind of the story my good mother told me 70 years ago, of Jack the Giant Killer's Bean, which grew up to the moon. About three weeks after the Carters were planted, and well up, I planted a few rows of Dan O'Rourke. The result is, the O'Rourkes are in full bearing, while the Carters are just beginning to show small pods, which look as if they might have a few peas in them some time. The originator of the fraud ought to be indicted for swindling, and every dealer that bought of him ought to refuse to pay for them, if he has not already got his pay; and if he has, to follow him up, and make him refund the money if possible. I bought from seedsmen in good repute; but seedsmen in good repute do very wrong to sell seeds of any kind that they know nothing about, and to advertise them to be two weeks earlier than any other kind, and 2½ feet high, when they are four weeks later, and mine will, undoubtedly, be ten feet high or more. I do not care for the money spent, but I do for green peas.”

More About Mildew.

In June last we gave an account of the uses of sulphur, for stopping the ravages of mildew. Since then we have seen in the *Floral World* a letter from P. Lazaris, Athens, Greece, in which he gives an account of his experiments with sulphur, a highly sulphurous earth and common clay. Mildewed vines seemed to be equally benefited when dusted with either of these, while vines along side of those thus treated, but to which nothing was applied, were injured by mildew. Mr. L. thinks that the sulphur exercises no specific influence upon the mildew beyond that of any other powder, and attributes the whole curative effect of sulphur or any other powder to its power of absorbing moisture from the mildew fungus, and thus destroying it. We think Mr. L.'s views worthy the attention of grape-growers, especially as we have somewhere recently read—where, has escaped our memory, or we would give credit—of a grape-grower who, falling short in his supply of sulphur, used lime and ashes, and thought them more efficacious than sulphur. In some parts of Europe road-dust was used, some years ago, with alleged efficacy in preventing mildew. If these several experiences in using dry powders are reliable, we must then conclude that sulphur may prevent mildew in two ways; 1st—by its emanations when used, as it often is under glass, sprinkled on the ground and on the flues; 2d—by acting as an absorbing powder when dusted on vines out-of-doors. This is an inter-

esting question, and one which, we hope, our grape-growers will settle, using very dry and sifted clay or road-dust, in comparison with sulphur, and report the results.

Notes on Strawberries.

A hard winter, and a cold spring with late frosts and cold cutting winds, have made the strawberry crop as a whole, a failure. Here and there a field has yielded well, but these are exceptions. We attended the recent Pittsburg meeting of the Penn. Fruit Growers' Society, where, besides Pennsylvanians, there were gentlemen present from New Jersey, New-York, Ohio, Indiana, Illinois, and Missouri, all of whom told the same story, and variously estimated the present year's crop, at $\frac{1}{2}$ to $\frac{1}{4}$ the usual amount. In the extensive grounds of Mr. Knox, the crop will not exceed $\frac{1}{4}$ of that of former years.

With regard to varieties, we are no nearer any definite result than before; and it is not possible to say, what one, or what dozen varieties are best for all soils and localities. The difficulty in making up select lists of fruits which shall answer for a wide range of country, becomes manifest when we bring together the experiences of cultivators in widely separated localities, not only in our own country, but abroad. An instance of this is found in the list of 25 strawberries, recommended last year by the Imperial Horticultural Society of France. Ever since the appearance of the list, the journals of that country have been full of criticisms, so severe that one is almost induced to believe that the Society had proposed the twenty-five worst instead of the twenty-five best varieties.

Wilson's Albany is the variety more generally cultivated than any, perhaps than all others; yet, in some places, it is perfectly worthless and quite given up. The "Agriculturist," in Southern New Jersey, is likely to be the leading variety. Indeed, the only really good crop of strawberries we have seen in quite extended tours, was of this variety, in the grounds of Mr. William Parry, of Cinnaminson. Its yield there is something so remarkable, that he and his neighbors speak of it in terms of the greatest enthusiasm, and will plant very largely of it; and we have similar reports from some other localities. Yet this same variety, in the grounds of Mr. Knox, near Pittsburg, has a very poor show of fruit. These facts demonstrate the value of local experience. The strawberry is so easily multiplied, comes in fruit so soon, and the varieties are so numerous, that it is an easy matter for each large grower, or for each local society, to soon find out, by actual test, what kinds are best suited to their conditions of soil, etc.

In the methods of cultivation, we also find diversities of opinion. In some parts of Illinois, the plants are set and allowed to cover the ground; they get very little attention, and when they cease to yield, they are plowed under. In Southern New Jersey the plants are allowed to cover beds three and a half or four feet wide, with two feet alleys between—the bed receiving in early winter a dressing of fine stable manure, but no mulching of straw. These beds bear one and two years. In hill, or stool culture, as extensively practised by Mr. Knox, the plants are set 18 inches apart, in rows 18 inches from each other. In autumn the ground is well mulched with straw, and the plants lightly covered. In spring the straw is opened directly over the plant, but is not removed. As the runners appear, they are pinched off; or, if allowed to get too strong for pinching, they are cut

with a knife. The weeds that appear near the plants are pulled by hand, and those that come up through the straw between the rows, are removed by the hoe. But few weeds make their way up through a heavy mulch, and these are destroyed very easily. The hills keep in bearing three or four years, and the mulch is kept on all the time, replacing each year the annual waste from decay, which amounts to a fourth or a third of the original quantity. That this careful culture with many varieties, especially those of European origin, will give better results than allowing the plants to run, there is no doubt; but, that it is the best for all kinds, we are by no means certain. We have nowhere seen the Agriculturist producing as well when kept in stools, as where it is allowed to cover the ground with its vines, and, we may say, with its fruit.

Unusual Ways of Fruit.

We are so accustomed to see flowers depart from their natural form, that the deviation does not strike us as anything remarkable. Indeed our most beautiful double flowers are as far from the natural condition of things as possible. A monstrous fruit is more rare than a monstrous flower, and we sometimes meet with cases in which the departures from the usual way are curious and interesting. A strawberry was sent us by a correspondent, which bears upon its upper end, or the one farthest from the calyx, a tuft of leaves. We do not recollect to have ever before seen a similar instance, yet it is just what we might expect would occasionally occur. Though we call a strawberry a fruit in

Fig. 1.

common language, it is not so in the strict sense of the word. The fruit proper is those little grains that we usually call seeds. These are minute one-seeded nuts distributed all over or sunken into the surface of the enlarged and fleshy end of the flower-stalk or stem. As the strawberry then is a bit of stem, very much changed from the way

Fig. 2.

in which we usually see stems, and made to serve a certain office, it is not so very strange that it should sometimes sport, and that its real nature should manifest itself by bearing leaves as in the case before us. Another sport, perhaps not so striking, but to us still more curious, is the double cherry, fig. 2, one of some dozens brought us by Mr. Thompson, of West Farms. It is the usual way of the cherry to have a single pistil which ripens into a single fruit. It is not unusual for cherry flowers to become double, by an increase in the number of petals, but when they do this the pistil becomes abortive. In the present instance, as near as can be judged from examining the fruit, and without seeing the blossoms, it would appear that two pistils were produced in the place usually occupied by one. Sports like these are not only curious, but they are of great interest to the botanist, as they often give him an insight into the real nature of parts.

Urine as a Liquid Manure.

A writer, in the *Gardener's Chronicle*, (Eng.,) finds urine a most valuable fertilizer, when used in the following manner:—Human urine, free from other slops, is allowed to get quite stale, which in a moderate temperature it will do in about a week. In this condition it is strongly alkaline, and will turn red litmus paper blue. To the urine in this condition, sulphuric acid (oil of vitriol) is gradually added until it is slightly acid, which is known by its turning the blue litmus paper red again. The amount of acid required, is about two ounces to each gallon of urine. To neutralize any excess of acid, add about 2 ounces of ground chalk to the gallon. Of the liquid thus prepared, one pint, after stirring it thoroughly to diffuse the settlings, is diluted with one or two gallons of water, the latter proportion being strong enough for most plants, and applied at once. This manure has been found very serviceable on grass plots in England, and may be applied wherever guano or other ammoniacal manure would be admissible. The litmus paper is paper colored with an infusion of litmus. It is blue or red, according as it has been subjected to the action of an acid or an alkali. The paper, or the litmus itself, may be had of any good druggist.

Stopping the Bleeding of Vines.

Though too late for use this year, we give two methods recently proposed. A correspondent, "C.," writes, that having to move an old vine, he cut it back and covered the wounds with copal varnish with success, and that he has since used the varnish when obliged to prune in spring, and finds it stops the bleeding. A writer in the *London Journal of Horticulture*, wipes the end of the vine dry, and covers it with a stiff paste of cement (hydraulic lime). The application is repeated two or three hours after the first one, and the bleeding effectually stopped.

The Introduction of the Verbena.

The following notes in relation to the introduction of the *Verbena* into this country, are from Mr. Amory Edwards, of Elizabeth, N. J. It will interest the admirers of this now very common and popular plant to know something of its early history.

"The *Verbenas* are natives of Buenos Ayres, and were first noticed by John Tweedy, who was collecting plants for the Conservatories of the Earl of Derby, and a firm in London.

In 1834 and 1835, I frequently accompanied Mr. Tweedy, a Scotchman, and a hearty lover of flowers, who was then about sixty years of age, in excursions around Buenos Ayres, and as I was about sailing for New York, he gave me a plant of the *Verbena Tweediana*, [now called *phlogiflora*.—Ed.] (red) and a fragrant white one, together with some seed of the Scarlet *Petunia*. These plants I gave in Sept. 1835, to the late Thos. Hogg, who then had a garden near the House of Refuge, now Madison Square, and he told me that they were the first *Verbenas* ever in this country, and the first Scarlet *Petunia*. A white *Petunia* had been received before.

Grant Thorburn, in 1837, received a plant of *Verbena Tweediana* from London, where he told me that it cost him two guineas.

Most of the stock now in the gardens in the United States is from these plants, originally there were but two colors of each—red and white."

SOME OF THE LEADING VARIETIES OF STRAWBERRIES—NEW AND OLD.

Cedar Apples.—(*Podisoma macropus*.)

Those who have been much acquainted with the Red Cedar (*Juniperus Virginiana*), must have noticed the peculiar excrescences which are often seen upon the small twigs, and which are known by the popular name of "Cedar Apples." They are of an irregularly rounded shape, at first very small, but increasing in size until they reach that of an inch or two in diameter. They are often found completely encircling a small twig. Externally they are covered by a brownish purple rind, or skin, which has its surface thickly covered with circular or obscurely angled markings, with an elevated or embossed center. Upon cutting the mass, it is found to have about the consistence of a green apple, is whitish within, and a careful inspection with a good magnifier will show here and there some exceedingly minute white fibres traversing its substance. These cedar apples are by most persons thought to be of the same nature as "Oak Apples," and other galls, and to be caused by the presence of an insect. All excrescences upon plants are not the work of insects, and this, and the black knot upon plum and other trees, are instances in which parasitic plants are the cause of the abnormal growth. If, during a warm and long continued spring rain, one visits the trees where cedar apples are plenty, he will be surprised at the change that has been wrought. The apples will appear more than twice as large as before, and of so beautiful a color that they might well be called "Cedar Oranges." A closer inspection will show what has caused this change. Each one of the little elevations of the surface, before mentioned, will be found to have burst, and from the opening protrudes a thick orange colored string, an inch or more long, translucent, and quite gelatinous in consistence. A brilliant orange colored dust will often be noticed upon the surface of the strings and also sprinkled around on the neighboring leaves, branches, etc.

A few hours of hot sun, and the strings wither, become brown and inconspicuous, and finally drop off. They may be made to develop artificially by placing the apples in a moist atmosphere. The one from which the engraving was made, was brought out by suspending it in a large bottle over water, and setting it in the sun. The one figured does not show the twig passing through the apple, as it commonly does, nor does it show the threads in their most swollen state; with abundant moisture they become so large as to completely hide the central portion or "apple." The microscope shows the threads to be the *sporidia*, or seed vessels, (fig. A,) of a fungus—*Podisoma macropus*—united into a mass by means of a gelatinous substance. And the dust above spoken of is the exceedingly minute spores, or bodies answering, like seeds, to reproduce the fungus. The fungus, or plant itself, lives within the apple in the form of the minute fibres which ramify through its substance, forming what botanists call a *mycelium*, and which corresponds ex-

actly to the spawn in the mushroom bed, while the showy orange colored threads answer in nature to the mushrooms themselves. The presence of this parasitic plant growing within the tissues of the cedar twig, causes it to take on an unusual growth, and makes the swelling or apple, in a similar manner that the presence of a foreign body of another kind, the egg of an insect, causes the growth of a gall. We have seldom known these to be so abundant as to ap-

pear for quite different characters; with the market man flavor is nothing. If a berry produces well, carries safely, and is showy, he knows that it will sell, be it as sour as crabs, or flat and insipid. The amateur puts quality before everything else, and rejects those fruits that upon the palate break the promise they have made to the eye. For the market garden it is best to have the crop ripen up rapidly, so that it can be taken in a few pickings, while in the family garden

it is desirable to have a variety continue long in bearing and give a moderate supply through as long a time as possible. We mention these points in order that our readers may understand one reason why different people give such discrepant accounts of the same fruit. In many of the larger kinds of strawberries we find imperfect fruit. Often the apex, or that part farthest from the stem, is not filled out, and is very seedy. Though the flowers are perfect, the pistils seem out of proportion to the stamens, and there does not appear to be sufficient pollen produced to fertilize the central pistils, and we have on this account an imperfect development of the fruit. This difficulty is obviated by taking care to set the sorts in which it occurs in the vicinity of those kinds that produce an abundance of well developed stamens.

For the engravings given on the opposite page, we have endeavored to select specimens of medium size, and not above what may be expected in ordinary field culture. It would be easy to represent much larger berries of each variety, but our wish is to

CEDAR APPLE.

parently injure the tree, and they are quite ornamental during the damp weather of spring. If they are too numerous, cut off and burn them. Observers differ as to the duration of the fungus; we are inclined to think that those who say that it lives several years are right. The Black-knot is very similar in its nature and manner of growth to the cedar apple, except that the fruiting portions are minute, black and inconspicuous.

Strawberries—Notes on Varieties.

At the close of the season of strawberries, it will be expected that we follow our usual custom and give some notes on varieties. The task is not an easy one, and to give an opinion about strawberries becomes yearly more and more difficult. Varieties of this fruit are so easily multiplied that some cultivators number their seedlings by thousands. Among these numerous seedlings a great many will be apparently too good to throw away, and yet no better than those we already have, but the partiality of the raiser will induce him to see superior qualities in them, and they will be put upon sale, to increase our list of kinds, and possibly replenish the pockets of the grower. There are many who consider size a prime requisite in a strawberry. We think it one of the least importance, beyond a certain limit, and the chief advantage in large size, is facility in picking. We do not object to size, but hold that quality and productiveness are far more important. The amateur and market grower look

give the characteristic shape and average size.

The following notes on varieties are given in the order in which we find them in our memorandum book. A number of old sorts are included, for in our desire to keep pace with novelties, we do not wish to overlook the merits of the older kinds. In speaking of some of the newer kinds, we are not, perhaps, as enthusiastic as those who are interested in them may desire. We speak of the fruits as they seem to us. Those who are engaged in introducing new varieties usually take care that the public shall know their views of them through the medium of their own catalogues and advertisements.

New Jersey Scarlet.—II. A medium sized conical fruit, of a lively scarlet color. Very early, and as a market fruit, is much prized on the light soils of Burlington Co., where it originated. The fruiting period was nearly over when we saw it, but we are convinced that it is a very early and productive market variety.

French's Seedling.—II. An oval berry, often of large size, light scarlet, very productive and of fair quality. Good for a near market, but too soft for distant transportation. One of the standard varieties in Southern New Jersey.

Ward's Favorite.—P. Small to medium, globular or depressed; seeds very numerous, sunken; rich crimson, and when fully ripe, very dark; flesh firm, solid, colored throughout, not very juicy; sweet and high flavored. An old variety introduced by Doct. I. M. Ward, of Newark, N. J., and has the reputation of being a poor bearer, but with good culture it yields very fairly

and is worthy the attention of those who prefer quality to quantity.

Ladies' Pine.—*P.* Fruit small, round, pale orange scarlet, not very firm; sweet and of the most delicious flavor. Despite its small size and unpleasant color, this is the very best berry, as to flavor, with which we are acquainted; unfortunately it is not productive, and it commends itself only to those amateurs who prefer a quart of good fruit to a bushel of poor. It is well to have a bed of this as a standard of flavor, and very few varieties can stand its test.

Burr's New Pine.—*P.* A medium sized, conical, light scarlet berry, very early and producing well with good culture. Mr. Knox regards it as his most valuable early variety. This is in most collections under the above name, but Ohio pomologists declare that this berry is not the true Burr's New Pine, which is a much lighter colored fruit, and is now, as far as they know, lost to cultivation. Whatever the berry may be that now goes by the name of the "lost tribe," it is a fruit of great excellence for the family garden or for early marketing.

Agriculturist.—*H.* This variety was fully described, and some of the larger specimens figured in August, 1863, and we now engrave an average specimen from a basket put up for market, from a bed which had been allowed to run. We have no interest in this variety, other than that which naturally comes from the fact that we were instrumental in introducing it, and in disseminating it free, more widely than any other variety was ever distributed. We of course wish it may do elsewhere as well as it has done with us. That it would do so everywhere, was not to be expected, with this or any other fruit. In some places it has not borne well, but in the majority of instances, it has proved valuable, and there is, perhaps, no one variety that may be planted at a venture more safely than this. The only very large crop of strawberries we have seen this season, was at Mr. Parry's, Cinnaminson, N. J., of this variety. We saw good crops of it at Mr. Pullen's, Hightstown, N. J., E. S. William's, Montclair, N. J., a fair one at F. Brill's Newark, N. J., and a poor one at Mr. Knox's. It is perfectly hardy and fruited this year where the Wilson failed.

Green Prolific.—*P.* Fruit large, depressed globular; seeds slightly sunken; pale orange scarlet; flesh solid, colored, soft, very juicy, acid and not high flavored. As a fruit this can not rank as first class, but it has an unequalled vigor of foliage, great productiveness, large size, and showy color, and is altogether a variety of remarkable character, and will commend itself to those who do not look for high quality. This is one of the parents of the Agriculturist which is a cross between this and the next.

Peabody.—*H.* Fruit medium to large, of a rich crimson color, and with a long distinct polished neck; flesh solid and colored to the center; sweet, and of excellent flavor. This is an old variety, which originated in Georgia. It is a poor bearer, and we only mention it by the side of the Green Prolific, as being the other parent of the Agriculturist. We have examined several hundred seedlings of the Agriculturist and found many plants with fruit which seemed quite like that of one or the other parent.

Durand's Seedling.—*H.* Fruit large, of a peculiar oblong shape, and flattened; seeds but slightly sunken; color, a peculiar light bright scarlet; flesh firm, solid, nearly white; juicy and well flavored. This we have only seen in the grounds of Mr. F. Brill, Newark, N. J., where

it seems to be an abundant bearer, and to produce fruit a long time. From what we have seen of it, we regard it as a variety of great promise for family and market purposes.

Perry's Seedling.—*H.* Fruit medium to large, nearly globular, with a slight neck; seeds depressed in well defined cavities; color bright crimson; flesh colored, but not uniformly so; moderately firm, sweet and with a rich sprightly flavor. Introduced by Geo. Perry & Sons, Georgetown, Conn. We have seen the fruit only of this variety, and it appeared to be like McAvoy's Superior (unwarrantably called Buffalo). It is sufficient praise to say that it is as good as the McAvoy, and we have the assurance of the proprietor that it is perfect, hardy, and very productive. To be looked after.

Mead's Seedling.—*H.* Fruit conical, often flattened, and with an obtuse apex; seeds prominent, and when fully ripened, much darker colored than the lively light crimson of the surface; flesh very solid and firm, juicy, and of a sprightly, but not very high flavor. This variety originated with Peter B. Mead, Esq., and has merits which should not be overlooked. We have not seen any but recently set plants, and can only quote others who say that it produces well.

Jueunda, 700.—*H.* Fruit large, conical, regular in shape and size; bright crimson; flesh firm, white, hollow, juicy, and of a flavor that will please those who like Triomphe de Gand. This variety has been described by Mr. Knox, as well as by horticultural editors and committees, and we feel a little hesitation in giving an opinion after so many distinguished persons have put themselves on record. In this disastrous year it is the best producer Mr. Knox has upon his grounds, and with his system of culture, has a good crop. The fruit is large—very large—showy, of good shape, and carries well, as we know from the state in which we found a basket which reached home on the fourth day after picking. These are all good qualities, but its flavor is not to our individual taste, it being much like but hardly equal to that of the Triomphe de Gand, which is not a favorite with us. On good soil, and with close culture, it produces a great crop of large and very showy berries.

Golden Seeded.—*H.* Fruit medium to large, bluntly conical, and flattened, crimson, with prominent yellow seeds. This was produced by Mr. Read, the originator of the Ladies' Pine, and is not generally cultivated. Mr. Knox regards it as one of his best early varieties, and it is productive and showy, and a valuable market variety with him. Not esteemed at the East.

Lennig's White.—*H.* Globular or depressed, white with a fine blush; flesh solid, buttery, and of excellent flavor. This variety is called White Pine Apple, and by several other names. It is a specialty with Doct. Hexamer, of Westchester Co., who raises it in great perfection. It is really a fine fruit, very productive, and the best of all the white strawberries.

Lady Finger.—Elongated conical, sometimes broadly so; seeds sunken deeply in well defined depressions; color brilliant scarlet; flesh solid, remarkably firm, somewhat colored, not very juicy; sweet and of good flavor. This variety originated in Burlington Co., N. J. Mr. Williams of Montclair, N. J., states in his catalogue that it combines more good qualities than any other berry that he grows. It is certainly a most handsome fruit on account of its brilliant color, and beautifully honeycombed surface, has a firmness that is unusual, and with good culture produces fair crops. Scott's Seedling, a very different fruit is sometimes sold for it.

Scotch Runner.—Under this name there are brought to the N. Y. market great quantities of a small berry, much like the Lady Finger as to color and surface, but much smaller, and more acid. It is a more generally elongated fruit. It is also called "Pine Apple" and Scarlet Runner, and probably has other synonyms. It is small, very showy, of a good strawberry flavor, and an esteemed market variety.

Fig. 1.—A magnified flower of a common green Orchid, called by Botanists *Platanthera orbiculata*; front view. a—One of the two pollen-masses with its stalk and sticky disk.

Insects and Plant Fertilization.

THIRD ARTICLE.

If there ever was a flower made for being fertilized by moths or butterflies, and absolutely dependent on their aid, it is one like this Orchid, fig. 1, a flower from the larger Green Orchid, called in strict botanical language, *Platanthera orbiculata*. The same may be said of most Orchids, although the ways, or contrivances, as we must call them, are different in the different sorts. Four years ago Mr. Darwin published a most interesting volume "On the various Contrivances by which British and Foreign Orchids are fertilized by Insects," which opened up this whole subject. This Green Orchid will show in a general way what takes place in all our Orchises, although some are arranged to be served by insects of a certain sort or size, and some by another. Take this, then, as a specimen.

The greater part of the centre of the blossom, Fig. 1, consists of the anther, the two cells of which, splitting down lengthwise, show the pollen within, and are continued forward into the two widely separated horns. Each horn bears at its tip a miniature button (the disk), the face of which is very sticky and will adhere to the finger or whatever you touch it with. As you remove the finger, you bring away, sticking to it, this little button or disk and all that belongs to it, viz.: the whole contents of the anther-cell, fig. 1, a. The button, it appears, is borne on the end of a slender stalk; and the large mass at the other end of the stalk is the pollen, not here a light powder, as in most plants, but its grains are stuck together in little masses or coarse grains, and these grains strung together and tied fast to the main stalk by threads as

delicate as spider-web, and as elastic as India-rubber. The surface just under the anther and in the angle between the horns is the stigma. This is quite as sticky as the disks are. Now

fully an inch-and-a-half long, actually do visit this flower, we have undoubted proof. They have been captured with something queer hanging from their protuberant eyes, sometimes one from each eye; when brought to us for examination, we have identified the strange body (by a peculiarity not represented in the figure a), to be the pollen-mass of this very Orchis, or of another species very like it. Then, on bringing the head of this butterfly, or any other of similar size, over the orifice of the honey-tube, just in the position it must occupy when the long proboscis is thrust down to the bottom of the tube, each eye comes in contact with one of the sticky disks. Withdraw the head after a few seconds interval, and the disks stick fast, bringing away with them the attached pollen-masses, leaving their cells empty. On inspecting a spike of flowers, we shall be apt to find that most of the blossoms towards the bottom, which have been longest open, have lost their pollen-masses. We see how they must have been carried off. It is very unlikely they could fall out of

by which winged insects are solicited to do the work for sedentary flowers.

Different Orchids show very different but equally effectual arrangements for the same end. In our pretty *Arethusa*, for example, the

Fig. 2.—Flower of Yellow Lady's Slipper, *Cypripedium pubescens*, of the natural size.

we should remark that our figure, made from a drawing many years old, when these nice adaptations were unthought of, is not quite correct; the horns do not diverge so much, and the sticky buttons face forwards and a little inwards, nearly a quarter of an inch apart, one on each side of an open orifice, just between the stigma and the long and narrow front petal. This is the orifice of the spur, a long and narrow sac, the bottom of which contains honey or nectar. The plain object of this is to attract honey-feeding insects. The honey-bearing sac in this instance being from 1½ to 2 inches long, with the nectar dripping to the bottom, the only insects which can make it worth their while to visit this

their place; it is next to impossible that one would ever fall upon the stigma, near by as it is, if the flower were let alone; while no butterfly or moth, with head about a quarter of an inch broad across the eyes, approaching it from the front—where the dependent narrow petal offers a favorable landing place,—could here drain the cup without showing the marks of it about his eyes. Suppose, after rising with one of these appendages fixed to either eye, the insect were to settle back again into the same position,—which is not likely. If the stalks of the pollen-masses remained stiff and motionless, obviously nothing would come of it. But, on manipulating with a butterfly's head, or with the point of a pencil as a substitute, we find that the stalk of the pollen-mass bends downwards and forwards within a few seconds after extraction (by a very peculiar movement), so that the two become parallel, or even converge instead of diverging as at first. If now the head be brought again over the orifice, the broad ends of the pollen-masses, one or both, will hit the stigma, will adhere to its sticky surface, and as we pull away, either the disk will separate from the insect's head, leaving the whole pollen-mass on the stigma, or more commonly only those portions of the pollen-mass which had actually stuck to the stigma are torn away by the rupture of their elastic connecting threads, and left behind.

pollen is rather powdery, the grains loosely held together by delicate threads, and contained in a helmet-shaped anther which is inverted on a shelf, the underside of which is stigma; and the anther is hinged at the back, and may be raised like the lid of a coffee pot; its front edge, the visor of the helmet, just projects a little beyond the shelf, as the lid of a chest does beyond the body, for the convenience of lifting; and when raised, the pollen tumbles out. Now a bee, entering the mouth of the flower over the crested front petal, sucks out a little nectar from the bottom of the narrow cup, which is over-arched

by the upper petals and the long curved style carrying on its apex the stigma and the anther as above described,—Pyramus and Thisbe very near each other, but with a solid wall between, so that communication is quite hopeless. The bee is not likely to help them directly. But as it backs out of the flower, and raises its head to fly away, it knocks up the lid by hitting the projecting rim, and catches some of the loose pollen on its rough and bristly forehead, enters with this into the next flower, where, when it retreats, it can hardly fail to dab this pollen on to the sticky face of the stigma, the instant before it raises that anther-lid and takes a new supply of pollen from this sec-

Fig. 3.—A partial section of the sac, stigma, etc., of the Yellow Lady's Slipper; anther; one of the anthers.

flower are those furnished with a proboscis of nearly this length. Such are butterflies and moths, the former flying by day, the latter by night. That such insects, with proboscis

In this way it is certainly possible that a stigma should get the pollen of its own flower; but not probable, for when the insect had drained one flower it would fly to a fresh one, and give to that some or all of the pollen taken from its neighbor, taking away its pollen in turn, and so from plant to plant. To cross the flowers of the species is plainly the object of the whole contrivance, and an admirable contrivance it is,

Fig. 4.—Section of the slipper, stigma, etc., of the Stemless Lady's Slipper, *Cypripedium acule*, natural size. a, Anther; b, Sterile Stamen; c, Stigma.

Fig. 5.—Magnified section of a part of the stigma of Lady's Slipper, cut lengthwise, showing the short and stout little bristles or projections, like the teeth of a rasp or of a card, all pointing forward.

ond flower to the third flower, and so on.

Cypripedium, or Lady's Slipper, (fig. 2) although of the Orchid family, and equally dependent upon insect aid, gets its work done by a different class of insects and in a different way. The front petal, to which the honey-tube in *Orchis* belongs, here forms the great sac or slipper, and is the only showy part, the other leaves of the flower being dull greenish, or purplish. The slipper, which in shape might suit the taste of a Chinese lady, is open at the instep; and there the edges are rolled in, after the fashion of the entrance to a rat-trap. The central part of the blossom, which curves downward and is partly thrust into the slipper, consists of stamens, style, and stigma. The spade-shaped, petal-like body which covers the stigma, and is nearly all that is seen from the front, takes the place of a stamen, but has no pollen; underneath it is the broad stigma, which faces to the heel of the slipper, as is best seen in the partly sectional view, fig. 3, and in fig. 4; and just back of the stigma are the two anthers, one on each side. The back, or as we may say the sole, of the slipper, is lined with long hairs or soft bristles, and these appear to contain something attractive to insects. There is no honey in the slipper. The anthers are so placed that the pollen can never of itself fall on the stigma, nor be thrown upon it by the wind. Indeed, the pollen does not fall of itself; for, although of the appearance of a damp powder, or so moist in the yellow species as to be almost pulpy, the surface is covered with a thin film of sticky varnish. When touched with the finger, the varnish adheres, and brings away with it a layer of the pollen, of the size of the adhering surface.

Now, as to the fertilization. The flower left alone would be hopelessly sterile. Although we have never seen an insect spontaneously enter the slipper and do the work, we are about as sure that the work is done in this way, as if we had seen it. Probably it is visited by nocturnal insects. The slipper may be entered by the orifice in front, which, in most species, offers the readiest access; or, from behind, by crawling under either anther, and thence under the stigma into the main sac. A large fly, or a coleopterous insect of corresponding size, entering from behind, would probably hit the back of his head or eye against one of the anthers, and as he crept under the stigma, might lodge some of it there. Feeding upon the hairs as he passed on, the front orifice would be before him for egress; but its incurved border would interpose some obstacle. It offers none to entrance; and we presume that the insect enters at the front, and passing onwards, departs by the back door. In so doing, whether he turns to the right or the left, he must rub his head against an overhanging anther, and carry off a plaster of pollen. If he then passes to another flower of the same species, and enters it by the front orifice, as he proceeds towards the most practicable exit he must crowd under the stigma, upon which he will hardly fail to deposit some of the pollen brought from the neigh-

boring flower. Now, that this is really the way of it, that it is intended the insect shall enter at the instep and emerge at the heel of the slipper, and so bring the pollen of one flower to the stigma of another—is as good as demonstrated by the peculiar character of the surface of the stigma in this flower. It is not glutinous as in other Orchids, but only moist, and is rough to the touch. Under a magnifying-glass the roughness is seen to arise from the whole surface of the stigma being covered by sharp projecting points, or what would be rigid bristles

last anniversary of the society, and which sets forth its objects and progress. We notice this to give the Society our best wishes for its success, as well as to call attention to the utility of such institutions. Natural History Societies and Clubs are springing up all over England, an old country, which one would suppose had been so thoroughly explored, that there remained little to reward the naturalist. Yet this is not the case, for industrious workers are constantly developing there some new facts of interest. In a new country, like our own, there is greater inducement to the student, and there should be in every considerable village or town a museum of its natural productions of all kinds. These local collections have an interest to the community in which they are made, and are of great value to science, as they not only furnish important data upon the distribution of plants, animals, etc., but they preserve specimens of many things that are rapidly disappearing as the population becomes more dense. Such collections always increase with astonishing rapidity where a nucleus is once formed, and their utility in giving direction to the tastes of the young is incalculable.

House-Leeks and Stone-Crops.

There are some plants so very common that their beauty is unappreciated. The well known House-leek is one of these, and to us who like plants, even if they have not flowers upon them, this much neglected and even persecuted individual is a great favorite. The healthy green of its leaves, their symmetrical arrangement in beautiful rosettes, its tenacity of life, growing where scarcely any thing else will live, defying frost and drouth, but bright and cheerful under the most adverse circumstances, are qualities that commend it. To be sure it seldom flowers, but then its clusters of leaves are handsome enough to answer for flowers; they are much like green camellias. The botanical name is *Sempervivum tectorum*. *Sempervivum* means "always living," or "live-forever." The specific name *tectorum*, is from the Latin for roof, in allusion to its growing upon houses; and our common name, House-leek, refers to the same thing. It is an exceedingly useful plant for Rock work.—Another favorite of ours is a very old green-house species, *Sempervivum arboreum*, which we now rarely see, it having been crowded aside

TREE HOUSE LEEK.—(*Sempervivum arboreum*.)

if they were longer; and *these all turn forwards*, so that the apparatus may be likened to a rasp, or to a hand wool-card of the olden time; and one cannot resist the conclusion that it is *intended to card off* and to retain the pollen brought upon the head of an insect entering at the front, and on its way to get out at the back part of the flower.—A more ingenious and effectual contrivance for crossing the flowers of a species by the help of insects, could hardly be devised.

A. G.

THE LINNÆAN SOCIETY of Lancaster, (Pa.) City and County. We have received an essay by S. S. Rathvon, Esq., which was read at the

by novelties that are often inferior to it. We were so much pleased to see a fine engraving of our old friend in the London Gardener's Magazine that we have reproduced it. The plant is of the easiest culture, and when well grown, makes a fine show. It needs to be kept in the house in winter. We have found to our sorrow that mice are very fond of this plant, seeming to prefer it to all others. There are several varieties, one with purple leaves, one in which the leaves are edged with red, and another in which they are beautifully striped with yellowish white. The whole family (*Crasulaceae*) to which these plants belong, is deserving more attention than it now has.

The Crassulas, Rocheas, Echeverias, and the large genus of Sedum, make up a vegetation peculiar in its aspect, and while many of them flower finely, they are interesting at all times. Among the Sedums, *S. Sieboldii* is a most interesting species. Its foliage is of a peculiar glaucous hue, it is hardy, and flowers profusely. Mr. Hogg has sent home from Japan a variety of this with mottled foliage, which will doubtless, if it proves hardy, be a popular favorite.

THE HOUSEHOLD.

A Home-made Lamp Bracket.

The following explains itself, so we offer no comments:

Mr. Editor.—You said you admired the lamp brackets you saw at our house the other day, and as that pleases me well, I send you a description of how they were made, and, if you will excuse the egotism of my saying so—I must add that I admire them myself, not so much for their beauty,—you may pass judgment upon that—but for their utility. Well, then, you must know I have been trying a long time to get father to saw me out some semi-circular pieces of board, with brace pieces, to make them of, but it has been busy time with him and all the rest of mankind, so I could do no better than help myself. Fig. 1.

Fig. 1.

piece A, fig. 2, was made of a portion of the head of a nail keg, part being split off and the corners sawed square, and the sides thus formed rounded into the curve of the head as best I could with a hand saw. B, represents the brace, a triangular piece of 3/8 inch clapboarding. Fig. 3 shows how the two, with one nail to hold them together, were nailed to the wall; one nail going through a gimlet hole at the notch in the brace piece, and another driven slanting through the top. I was lucky in striking studs in the wall. Before this, however, the cloth covering was tacked on to the top. This covering I made of plain muslin-delaïne (if striped, the stripes to run up and down, it looks very well,) cutting a piece a little wider than the brace piece is long, and long enough to allow for a frill at the top. This piece was hemmed on the top and a thread run 3/8 of an inch from the edge to draw the frill by, and it was drawn so as just to go round the top piece which was covered with the same material. A thread was also "caught in" at regular intervals along the bottom edge of the cloth so as to draw it into regular plaits, and then this cover was tacked to the top, the gathering thread being covered by a fancy braid 1/2 inch wide. Then the bracket was nailed up, the bottom gathered and tied to the front of the brace, and a rosette was made and pinned on. Thin stuff requires a lining to prevent the light showing through, for which brown paper will do. As you saw, I made a pair and placed one on each side of the mirror at the toilet stand, so high that lamps set upon them will shed a good light upon the head of a person before the glass.

Fig. 2.

Fig. 3.

the bottom gathered and tied to the front of the brace, and a rosette was made and pinned on. Thin stuff requires a lining to prevent the light showing through, for which brown paper will do. As you saw, I made a pair and placed one on each side of the mirror at the toilet stand, so high that lamps set upon them will shed a good light upon the head of a person before the glass.

A Very Pretty and Cheap Tidy.

An especial interest in those articles of feminine contrivance called "Tidies," was awakened in us a few days since, by our sitting down (in bachelor's quarters, of course,) in a very comfortable rocking chair with a high back and inviting arms. The day was warm and damp, and the chair was a drowsy one, so we were very quiet for some minutes, and when finally aroused, found that we were held fast, Abas-lom like, by the hair of the head. That was a "sticker," and the increased regard for tidies will doubtless stick by us as long as the recollection. One of our lady friends lends us a neat tidy for a pattern, of which we present an engraving. It is made of simple "Swiss" or "Book muslin," which is cut square and hemmed with a narrow hem, and then "braided" with narrow white linen braid in any pretty pattern. That of the one we present is simple, yet pleasing. In forming the points of straight parallel lines; braid of two differ-

ent widths is used, with pretty effect. Finally, the tidy is bordered with a narrow white linen fringe, which may or may not have an open heading. These little affairs wash and "do up" very easily, so the ladies say, and are just as pretty as if they cost five or ten dollars. They may be made of different sizes to suit the backs of chairs or the arms of lounges; and if there are two or more used, it gives a pleasing variety, even if they are made alike, to arrange some with the points down, and others horizontally. It is a useful practice, and quite a test of taste and ingenuity to devise pretty original patterns for the braiding.

All About Mens' Shirts.

[If there is anywhere a woman who has had "supervision of" a husband's wardrobe for a dozen or more years, without having had any experience similar to that so faithfully recorded below, we would be glad to find her out; she would doubtless be able to contribute to the Household Department of the *Agriculturist* valuable information on other "vexed questions" we think of.—Ed.]

A long time ago I undertook the supervision of a set of shirts, including, of course, their wearer. It was the height of my young ambition that the man should be exactly fitted by his shirts, concerning which he began to make complaints just one moon after I took him in charge. "What is the matter with them?" I meekly inquired. "There isn't a single one that fits me."... Totally unconscious of the inherent wickedness of the article concerned, I flattered myself that the difficulty would be easily remedied. So I ripped here and basted there, pulled up this shoulder and pulled down that, until I thought I had got it.—Mistaken mortal! it would not fit!—I made another series of experiments with equally futile results. Then I consulted one or two friends, and felt sure I had at last discovered where the shoe—I mean the shirt—pinched. I applied a cure, but the thing wasn't cured. Next I employed a tailor to try his skill. Not one whit better. The man was getting—and I was getting—desperate.

As my *dernier resort*, I summoned a council of

sewing-society women, and we went into a committee of the whole. For hours we expended our united wits on a single shirt, often subjecting the luckless owner to successive trials of the garment. "Don't that now fit your neck exactly?" asked the head of the conspiracy, as for the forty-fifth time we gathered around our victim. "Why, yes," with a charming smile of relief, and twisting his head about experimentally.—"Really, I can't suggest any improvement."... "Oh! be joyful!" exclaimed I, clapping my hands. "Suppose," said one of the wise women, looking at me over her glasses as if some important idea had struck her, "suppose we cut out a new shirt on the improved plan, and if that suits, we'll take a pattern from it."... "Agreed," cried I, quite jubilant, and ran to a chest for the cotton. "So we cut, basted, and tried on—sewed and tried on—starched, ironed, and tried on.... "Capital!" affirmed our representative of the lordly sex. "Not a thread amiss. It is the first time in my life that a shirt has exactly fitted me."

As a grateful memorial, I made up six new ones after that identical pattern. We entered on our triumphal epoch.... Woe worth the day! Must I own that before forty-eight hours had passed, that "exactly fitted" individual called me aside, and pointed with cruel significance to his neck. "I am very sorry," with the blindest air in the world. "I suppose your mistake came from your great desire not to choke me."... "Mistake! choke you!" echoed I, convulsively, a little tempted to try the latter.... "Don't be troubled. It requires only a slight alteration—a trifle cut out of the binding, that's all. You see its rather large."... "Why couldn't he have found it out before?"—to myself.—Then aloud with great dignity: "Tell me precisely how much to cut out."... "Well, I should say just about an inch."... "Just about an inch," muttered I sarcastically, adding, "I believe the mischief is all in your neck, which dilates and contracts on purpose to torment me."... He smiled kindly on my wrathful tears, and I—well—when the shirt was "rough-dry," I dutifully cut out the inch, basted the binding, and tried it on again.

"That is just what I wanted. It does very nicely now, you see," working his chin up and down.... "Yes, I see. I did before."... "Practice makes perfect, and this time you hit the nail on the head."

When the change was completed, he once more tried on the shirt, and unequivocally assured me "it fitted to a T." So I made the same alteration in the other five, and sat down to take a bit of comfort.

Can you imagine what next happened?—In the course of a fortnight, the man gave me an invitation to ride with him, which I was only too happy to accept. How extremely gracious and agreeable he was! I might have suspected something was coming. From one thing to another he led the conversation, until finally he approached the old hateful topic, (he had on one of his new shirts.)... "I don't mind my vexation," remarked I innocently, "now that you are at last suited." Then, supposing the matter forever at rest, I turned to a pleasanter subject. But coming back to the shirts again, his face assumed such a deprecating look, that I exclaimed in alarm: "Nothing ails them now, I hope."... "Only a very little thing, and easily altered. In your fear of getting them too large, they are a trifle too small—only a trifle."... My heart swelled but I uttered not a word.

When we reached home I made him measure off on his forefinger exactly how much he wished inserted. The shirt he had on happened to be the identical one I had first altered. I was fortunate enough to discover in my work-basket the very piece I had cut out. And I was malicious enough to exult at its proving the exact measure of the addition wanted. So I sewed it in again, repeating to myself all the while, "Oh the crochetyness of man!" Will you believe me when I whisper it confidentially, that after all this, for many years, I alternated between cutting out and putting in the self-same piece—the man's neck invariably playing me false. Of late, however, I have dropped the labor of sewing, having discovered that *pinning over* one week, and unpinning the next, answers all the pur-

pose. The victim of this perpetual change silently acquiesces in the inevitable arrangement; and what is better, he has learned to do the thing himself. There is a shirt hanging over a chair in his chamber at this moment. I have had the curiosity to go in and examine it, as I have been writing. I find it is the *pinning over week*.—*Hours at-Home*.

Information Given.

[In June, page 228, under "Information Wanted," 28 questions were given. We begin with some of the answers received, asking others to respond. No one writes about questions 1, 2, 4, 8, 13, 14, 17, 19, 22, 23, 26, 27.—Ed.]

Original Contributions to the American Agriculturist.

No. 3.—TO COLOR KID GLOVES.—CLEANING THEM. (a) Put $\frac{1}{2}$ ounce extract of logwood into a 2 oz. phial, and fill up with good brandy. This dye will keep for years if well corked. Put the gloves on the hand, sand with a small swab (a piece of sponge tied to a stick is best,) apply the dye evenly all over them. Then rub one hand with the other, smoothly and firmly, until the gloves are dry—a few minutes only, as the spirit soon evaporates. More logwood gives a nearly black color; less produces a delicate lilac.—*Mrs. S. J. Wood, North Madison, Ind.*....(b) Dissolve India ink in water and apply with a camel's hair brush.—A fine brown may be obtained by rubbing lightly with a strong decoction of tea.—(c) Gloves may be cleaned thus: Wrap a fine cloth around your finger, dip it in new milk, then rub on fine soap, and rub the glove lightly. In all the above operations, the glove must be on the hand.—*E. M. H., Grand Rapids, Michigan.*

No. 5.—TO GET RID OF FLIES.—When the flies settle on the ceiling, as they usually do at night, reduce the light in the room so you can just see them, and take a tumbler, or wider vessel, two-thirds full of warm soap-suds, and place it quickly over each group of the flies, when they will fall into the suds. With a chair or form to stand upon, you can soon clear a whole room, entirely destroying the pests. I have caught a pint of them thus in a very few minutes.—*E. D. Gibson, Ashburnham, Mass.*

No. 6.—CEMENT FOR KNIFE HANDLES.—(a) Lay a piece of alum on the stove, and when melted roll the knife shank in it and immediately thrust it firmly into the handle. It will soon be ready for use.—*S. M. Parker, Wilton, N. H.*....(b) Fine brick dust stirred into melted rosin and used hot will fix knife and fork handles firmly.—*Farmer's Daughter, Richmond, Indiana*....(c) Mix equal parts of wood ashes and common salt, with water enough to make a mortar. Fill the handles with this, and then drive in the shank, and let it dry. I also fixed a stove spud in this way, and it is very tight.—*Joel H. Suttenton, Orleans Co., N. Y.*

No. 7.—PORK BRINE.—(a) The "best pork I ever ate" was the unsolicited compliment paid by many who ate of the pork I put up as follows: For 200 lbs. pork, $\frac{1}{2}$ gallon of sorghum syrup in the bottom of barrel, and a good layer of salt sprinkled into it. Pork packed as usual, well salted with rock salt, and covered with strong brine containing an ounce of saltpetre and sweetened with sorghum.—*L. A. Gildersleeve, Wilmington, Ill.*....(b) To have good sweet pork, first, have the cask sweet and clean; second, the meat must not be frozen; third, use plenty of salt, rock salt is best. Put in a layer of salt, then one of meat packed in as closely as it can be; then alternate layers of salt and meat, until the cask is nearly full. Cover with about 3 inches of strong cold brine, always keeping the meat under brine.—*N., Shelter Island, N. Y.*

No. 9.—GOOD HOME-MADE INK.—(a) Take $1\frac{1}{2}$ ounces nutgalls, fine ground; 1 oz. gum arabic; 1 oz. copperas (sulphate of iron); 3 gills rain water; $\frac{1}{2}$ gill elder vinegar. Put the nutgalls, water, and vinegar in a quart bottle; let it stand 2 or 3 days, shaking it well several times each day. Strain the mixture, rinse the bottle, return the strained liquid, and add the gum and copperas. Two or three pieces of crushed sugar, the size of a hickory nut, will give the ink a gloss. [Much sugar will make it sticky.—Ed.] This letter is written with ink

made by the above recipe. [It is beautiful.—Ed.] The ink is not jet black at first, but becomes so on exposing the bottle to the sun a few days.—*N., Shelter Island, N. Y.*....(b) Take 6 ozs. finely powdered nutgalls, 4 ozs. gum arabic, 4 ozs. copperas, and 3 pints rain water. Put all into a bottle and shake often for a week. This letter is written with ink, made by the recipe, 8 years ago, and it is as good as the day it was made.—*Erie Co., N. Y.* [The ink shows very clear, but is not quite so brilliant as (a) which is the same except the vinegar added.—Ed.]....(c) To make a good black ink, that flows well, that will not corrode a steel pen, will not cast a precipitate, or grow gummy; is not injured by freezing: To one gallon of hot rain water add one ounce extract of logwood; $\frac{1}{4}$ ounce gum arabic, and $\frac{1}{8}$ ounce of bituminate of potash, and heat in an iron kettle. The first part of this letter is written with some of the ink thus made, which was frozen half a dozen times last winter. The second part is written with some new made. [Both are good; we see no difference.—Ed.]—*Americus, Perry Centre, N. Y.*

No. 10.—EXTRACTING WHEEL-GREASE FROM UNWASHABLE GARMENTS.—(a) Use kerosene with a sponge or flannel, putting a clean cloth under the greased spot. It is necessary to change sponge and under cloth several times. "—*Shelter Island, N. Y.*"....(b) Coal oil, similar to the above.—*Farmer's Daughter, Richmond, Ind.*....(c) Rub the grease spot faithfully with a cloth wet with Benzine, if necessary wetting the spot with Benzine also. This is good for other grease and paint, for coat collars, etc.—*S. M. Parker, Wilton, N. H.*....[Benzine is very good for extracting grease of any kind. Wheel grease varies, but the chief difficulty is the iron worn off into it from the wheel boxes, which is troublesome to remove, though the above directions will usually take most of it out.—Ed.]

No. 12.—PRESERVING BACON OR HAM IN SUMMER.—(a) Cut in slices, half fry it, pack in stone jars, cover with the fat fried out, or if that is not enough, add sweet lard. I have tried it for 2 years. A few have failed from not putting it down early enough, and especially from not completely covering every piece remaining after removing a portion for a meal.—*Mrs. S. J. Wood, North Madison, Ind.*....(b) Similar to (a) above.—*E. M. H., Grand Rapids, Mich.*....(c) On a fine dry day in April or May, wrap each piece in paper; then put in bags, 2 or 3 pieces in each, tie them tightly, and hang in an airy place.—*Shelter Island, N. Y.*....(d) Sprinkle the flesh side with black pepper from a box; hang in the smoke house, and flies will not trouble the bacon.—*W. A. Harold, Moline, Ill.*....(e) Salt and smoke early, before flies appear; coat well with black pepper; pack in tight boxes, filling in around, and 3 or 4 inches on top, with clean, fine ashes.—*Samuel C. Wilson, Fairmount, Ind.*....(f) I have seen hams kept successfully through the summer, in Alabama, by rubbing them thoroughly with ground black pepper, when taken out of the brine, after draining, previous to smoking. The brine was sweetened with brown sugar, and cleansed by boiling and skimming. No flies or bugs ever troubled them. Never ate better hams or pork than the above. When smoked, the hams were hung up without canvas or further treatment.—*L. I. Gildersleeve, Wilmington, Ill.*....(g) Some one (name lost) suggests packing the half salted hams in a heap or box of dry salt....(h) Having hams that appeared hardly salt enough to keep through summer, I cut them in slices and cooked them through thoroughly in a dripping pan in the oven; then packed the pieces in a stone crock, and poured over the fried-out fat, and they kept in excellent order. There is the convenience also, that you always have cooked ham ready for an emergency.—*Mrs. E. Perin, McLean Co., Ill.*

No. 13.—SOAP, AND WASHING FLUID.—*Chemical Soap.*—Pour 2 gallons of boiling water over 3 lbs. sal soda and $1\frac{1}{2}$ lbs. unslaked lime; stir up carefully and let it settle some little time. When clear drain off the lye into a brass or copper kettle, and add 3 lbs. clear grease, and boil $2\frac{1}{2}$ hours, stirring it most of the time. Try some with a little water,

and when done enough fill up the kettle as full as when you commenced boiling, with a weaker lye made by adding another gallon of boiling water to the dregs after turning off the first lye. It should turn thick and soapy, when a tablespoonful of salt is to be stirred into it, and then turn it into moulds—drippers answer nicely. When cold, cut up into bars and lay them in a place to keep when they will dry slowly. It improves with age. When dry it is superior to the "German Chemical soap," I think, and costs only about 4 cents a bar.—*E. M. H., Grand Rapids, Mich.*....WASHING FLUID.—Put into a kettle 1 lb. sal soda, $\frac{1}{2}$ lb. unslaked lime, and pour over them 1 gallon boiling water. Let it settle and pour off into a stone jug.—Soak dirty clothes over night in just enough strong suds to thoroughly wet them, and in the morning put your boiler over $\frac{3}{4}$ full for boiling suds, and heat to boiling point. Wring out your clothes, sorting them, and add to the boiling water 1 teacupful fluid and soap enough to make a good suds; throw in the clothes and boil from ten to twenty minutes according to grade, drain well so as to save boiling water; rub out of the sudsing water, and rinse thoroughly.—*E. M. H., Grand Rapids, Mich.*

No. 16.—TO COLOR COTTON AND FLAX CARPET WARP, GREEN.—The following has been often tried with success; will not color woolen: Put in a bag 1 lb. Fustic, with $\frac{1}{2}$ lb. chip logwood, and soak over night in 6 gallons rain water. Then boil one hour, and add 1 ounce of blue vitriol (sulphate of copper), skimming carefully. The clothes or carpet warp are to remain in this a short time, constantly stirred.—*Farmer's Daughter, Richmond, Ind.*

Butter Making.—To "Novice," Montgomery Co., Pa. Most people making butter from one cow have, at sometime, found the same difficulty in getting good butter, and even in getting it all, especially in summer. The mixture of cream gathered in each of six or seven successive days, and of different degrees of sourness, does not work well. The only remedy we can suggest, is to keep the daily cream as cool and sweet as possible to prevent the first gathered from too great souring; then mix it all well and raise the temperature to about 65°, when beginning to churn.—Do not churn too fast. Churning twice or thrice a week will help matters. The trouble will probably cease when cool weather arrives. "Novice" writes so pleasantly, and is so observant withal, that we doubt not she will find many things in her new country life experience, that we shall be glad to hear about.

"Pain Perdu."—Which for an English name we may call *bread secrets*. (The French name means *lost or hidden bread*.) It is an exceedingly delicate dish for tea, and served hot with hot wine sauce with Zante currants, makes a most delicious desert dish. Take half a common loaf of stale bread and cut off all the crust. This crust is put into a slow oven and dried, and then crushed and rolled to fine crumbs with a rolling pin. Cut the bread into slices 1 inch thick, and these into 2-inch square pieces. Take 2 cups of milk, and add to it 2 teaspoonfuls of sugar, and 1 well beaten egg. In this, dip the bread and allowing it to moisten through uniformly, dip it into the crumbs of the crust, then drop into boiling lard and brown like doughnuts; while hot, dust with rolled white sugar and a little ground cinnamon, and eat at once.

Safe from the Second Commandment.—The ladies, and those of the other sex who are accustomed to go into extasies over a "love of a bonnet," are often in danger of breaking that clause of the second of the Ten Commandments, which prohibits "bowing down to anything made in the likeness of anything in the heaven above, in the earth beneath, or in the water under the earth." Those who adore the present latest style of bonnets, may rest assured that they do not thus infringe upon this commandment.

For other Household Items, see "Basket."

BOYS & GIRLS' COLUMNS.

The Sun Seen at the Poles.

To a person standing at the north pole, the sun would appear to sweep horizontally around the sky every twenty-four hours, without any perceptible variation in its distance from the horizon during its circuit. On the 21st of June it is 23 degrees and 38 minutes above the horizon—a little more than one-fourth of the distance to the zenith, the highest point that it ever reaches. From this altitude it slowly descends, its track being represented by a spiral or screw with a very fine thread; and in the course of three months it worms its way down to the horizon, which it reaches on the 23d of September. On this day it slowly sweeps around the sky, with its face half hidden below the icy sea. It still continues to descend, but after it has entirely disappeared it is still so near the horizon that it carries a bright twilight around the heavens in its daily circuit.—As the sun sinks lower and lower, this twilight grows gradually fainter until it fades away. On December 20th the sun is 23 degrees, 38' below the horizon, and this is the midnight of the dark winter of the pole. From this date the sun begins to ascend, and after a time his return is heralded by a faint dawn, which circles slowly around the horizon, completing its circuit every 24 hours. This dawn grows gradually brighter, and on the 20th of March the peaks are glided with the first level rays of the six months' day. The bringer of this long day continues to wind his spiral way upward until he reaches his highest place on the 21st of June, and his annual course is completed. The same appearances are presented at the south pole, only at opposite dates, the 21st of June being midnight and midwinter there, while the north pole is having its summer sunshine.

Two Fights and a Victory.

Bently, formerly a well-known Massachusetts clergyman, one night at a late hour heard a rattling sound near his house. He looked from the window and saw a woman fill her apron from his wood pile, and hastily go away. Shortly after this was repeated, and he returned to his study, sad with the thought of her destitution which led her to the sin. Not long after he was startled by a heavy crash of falling wood, and again looking from the window he saw the poor woman shaking the very dust of the wood from her apron. She swiftly turned away and soon returned heavily laden with wood, which she threw upon the pile in a most determined manner. The doctor's compassion and curiosity were now intensely excited, and leaving the house, he cautiously followed her until he found where she lived. Early the next morning he ordered a wood dealer to send her a half cord of his best wood, sawed and split, but by no means to let her know from whom it came. The teamster happened to overhear the order, and when the poor widow eagerly asked who sent it, he told what he had heard. The conscience-stricken woman hastened immediately to the Doctor's house, and with deep humility and bitterness told him of the temptation to which her poverty had brought her. "Sir," said she, "though my house was dark and cold, though my heart was wrung with anguish at the sight of my poor shivering little ones, I could not keep the wood, my conscience would not let me."—"Say no more, my dear Madam," said the good man, "I saw it all.—I saw you conquer the devil in two fair fights."

Nicknames.

Somebody has collected together the following list of nicknames given to the citizens of the different States, and the by-word titles of several of the different cities:

Maine, foxes; New Hampshire, granite boys; Vermont, green mountain boys; Massachusetts, bay state boys; Rhode Island, gunflints; Connecticut, wooden nutmegs; New York, Knickerbockers; New Jersey, blues or clam-catchers; Delaware, muskrats; Pennsylvania, Penhamites or leather heads; Maryland, clam humpers; Virginia, beagles; North Carolina, tuckoes; South Carolina, wensels; Georgia, buzzards; Alabama, lizards; Mississippi, tadpoles; Florida, fly up the creeks; Louisiana, creoles; Texas, beef-heads; Arkansas, tooth-picks; Kentucky, corn-crackers; Ohio, buckeyes; Indiana, hoosiers; Illinois, suckers; Wisconsin, badgers; Michigan, Wolverines; Minnesota, gophers; Iowa, hawkeyes; California, gold hunters; Nevada, sage hens; Oregon, hard cases; Nebraska, bug-eaters; Kansas, jayhawkers; Colorado, rovers; Dakota, squatters; Utah, Brighamites; New Mexico, Spanish Indians; Idaho, fortune seekers, or cutthroats; Nova Scotia, blue noses; New Brunswick, fish heads; Canada, canucks.

Nicknames of some cities and towns:

Quebec, the Gibraltar of America; Montreal, Ila, Cudhes city; Kingston, the Limestone Quarry; Portland, Hill City; Lowell, Spindle city; Boston, Modern Athens, Literary Emporium, City of Notions, and, Hub of the

Universe; Providence, Roger Williams' city; Hartford, Insurance city; New Haven, Elm city; Brooklyn, city of Churches; New York, Commercial Emporium, Gotham, and Metropolis of America; Philadelphia, City of Brotherly Love, city of Penn. and Quaker city; Baltimore, Monumental city; Washington, city of Magnificent Distances, and Federal city; Troy, Ilium; Albany, Sturgeondom; Syracuse, Salt Works city; Schenectady, Durip; Rochester, Aqueduct city; Buffalo, Queen of the Lake; Richmond, Cockade city; Savannah, Forest City of the South; St. Louis, Mound city; New Orleans, Crescent city; Louisville, Falls city; Nashville, Rock city; Cincinnati, Queen of the West, and Porkopolis; Cleveland, Forest city; Detroit, city of the Straits; Indianapolis, Railroad city; Chicago, Prairie or Garden city; Milwaukee, city of Brick; Kenkuk, Gate city; Leavenworth, Cottonwood city; Atlanta, Gate city of the South; San Francisco, Golden Gate; Denver, city of the Plains; Salt Lake City, Mormon city; St. Paul, North Star City.

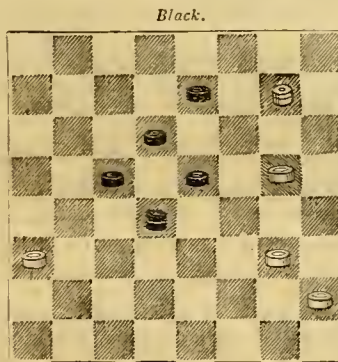

How an Owl was Caught.

Arthur Sexton, Wellington, Ohio, gives an account of his singular capture of a large horned owl. The bird, not content with its usual diet of mice and wild birds, visited the farm-yard to secure the extra daintiness of a young chicken or two. It came to a coop where a hen was covering her brood, and boldly entered. The hen at once retreated from the unwelcome visitor, taking her chickens with her, and in passing out, knocked away the prop, which held up the door or lid of the coop; down it came, making the owl a prisoner, and leaving the hen to finish her night's rest undisturbed. The owl was secured in the morning, and is now suffering captivity as a penalty for his misdeeds. If we had room for him we would be pleased to accept Master Arthur's kind offer to send him to the *Agriculturist* Office.

Mixing the Pronouns.—We clip the following choice specimen from the New York Independent of June 21: "Did you ever know a person to read how David—even when he was a country boy too—slew the lion and the bear, when they commenced their carnage on the flock that he was watching, without feeling as if they would like to hold the boy in their lap, and give him a loving squeeze and a kiss?" We have no doubt the lion and the bear would have enjoyed giving David a loving squeeze, as the above sentence intimates, perhaps they would have kissed him after their fashion, but as to holding him on their lap, that would have been very awkward if not impossible. Be careful, boys and girls, not to mix the pronouns; it sometimes makes queer work with a sentence.

The Game of Checkers or Draughts.

White wins.

(*) Is so named by Anderson, because the first move of the second side is played from the one double corner toward the other. (a) 14 to 18 draws, (b) The losing move. (c) Position No. 6. (See June No., page 229.)

Answers to Problems and Puzzles.

The following are answers to the puzzles, etc., in the July number, page 263. No. 215. *Prize Rebus.*—A band on a sinking ship o'er the waves, clothes over her, or: Abandon a sinking ship before the waves close over her.... No. 216. *Prize Enigma.*—Light-house.... No. 217. *Illustrated Rebus.*—1 long two e w hat ear b (tied on mountain) hill and plane, four eye r (round the) hole world (wide) good will two man kind rain, or: I long to see whale'er beside on mountain hill and plain, forever round the whole world wide, goodwill to mankind reign.... No. 218. *Prize Arithmetical Problem.*—Ans. next month.

The following have sent in correct answers to puzzles: Maggie A. McCabe, Lottie E. Worth, A. W. Morton, Catskill, Peggy, Jennie Cooper, Wm. R. Price, Maggie J. Scott, Lewie Rorebeck, Wm. Kay, Mr. and Mrs. J. W. Scott, L. Stone, C. A. Parsons, II. R. Stanley, Mary E. Brigham, Martha L. Newlin, S. G. Robbins, Frank L. Kilmer, Fred. C. Parmenter, Mary N. Charlton, John Fergus, William Hunter, Lucy A. McCoy, Nelson G. Hull, John T. Binkley, Joseph A. Barnes, J. C. Gopen, Nancy Patton, Maria Patton, Henrietta Titus, A. M. Beecher, S. S. Meservey, Silas Bice, Minard R. Bice, John Price, A. J. Myers, Cassia, (please send on the puzzles.) E. Prevost, Harry N. Smith, Daniel Frohman, Henry A. Young, Ida R. Tood, Willis Fair, Wm. Pipkin, C. W. Bailey, C. S. Wise, Willie V. Cloag, Diantha Roads (no answer came with your rebus), Scott Jenks, Sarah J. Brown, R. Bosworth, H. S. Kraz, Frank Gilderleeve, Eva Littlejohn, S. W. Kleinschmidt, John M. Culver, Charley Ray, Samuel Shawd, H. W. Bateman, Dr. M. D. Leichter, Etta Wilson, Helen M. Bushnell, M. R. Trumbower, George B. Shapley, Walter Lewis.

No. 219.—A Scripture Riddle.

Take the name of a Jew who reigned long o'er his land, And who for one sin drove a Queen from command; Who in life, and in death no small honor could claim, Which backward and forward will spell just the same.

Then the name of a Jew, only known by the fame Which his son nobly earned, spelling each way the same; And the time of the death of a person (whose name Though not found in the Bible, still knows Bible fame), And which time, back and forward remains just the same. Of a Jew who had sinned, and reformed, take the name, (Which is all that we know of his honor or shame), And which backward and forward is ever the same.

Place these four initials together, and frame Of one wise, old, and good, the brief scripture name, Which backward and forward is still just the same.

No. 220. Illustrated Rebus.—Dear to all Americans.

No. 221. *Mathematical Problem.*—During the time that the shadow on a sun-dial, which shows true time, moves from 1 o'clock to 5, a clock which is too fast a certain number of hours and minutes strikes a number of strokes equal to that number of hours and minutes; and it is observed that the number of minutes is less by 41 than the square of the number which the clock strikes at the last time of striking. The clock does not strike 12 during the time. How much is it too fast?;

No. 222. Illustrated Rebus.—Good advice to all.

No. 223. *Farmers' Enigma.*—I am composed of 24 letters. My 13, 7, 10, 15, 11, is raised by farmers. My 5, 3, 12, 24 is eaten by farmers. My 23, 2, 8, 14, 19 is worn by farmers. My 1, 6, 4, 5 is used by farmers. My 9, 15, 21, 16, 20, 18, 4, 14 is received by farmers. My whole is the farmer's friend. What is the word?

No. 224. *Enigma.*—My last is made of my first, my first is kept in my whole. What is the word?

A PARADOX.—When a shoemaker is going to make a boot, the first thing he uses is the last.

"YOU HIT ME."—FROM A DRAWING OF C. E. BETTCHEER.

If these two little boys could be properly trained they would make splendid fighters. They look strong, hardy, resolute, and full of pluck. The world needs plenty of just such men as these may become. They are wanted to meet and conquer danger and difficulty in thousands of places; to fight the great waves of the ocean and to make them bear ships safely to port; to level mountains that are in the way; to force the earth to give up its precious ores; to compel barren fields to yield plentiful harvests; to restrain the winds, guide the lightnings, and make a slave of steam; to struggle against error and wrong; to endure persecution; in short, to win triumphs by making the world better, wiser, and happier. For all these great works, just those qualities are needed, which, when wrongly trained, make men brutal bullies. See in the picture how the dog enjoys the prospect of a fight; the boys are putting their combativeness to a wrong use. They may win applause from dogs, and dog-like people, but how much nobler to use their fighting powers in the way God intended, and thus secure the approbation of all the good. *Fight* boys! there are plenty of battles to win, but be sure to fight in the right way.

The Right Road.—"It was a first command and counsel of my earliest youth," said Lord Erskine, "always to do what my conscience told me to be a duty, and to leave the consequence to God. I have always fol-

lowed it, and I have no reason to complain that my obedience to it has been a temporal sacrifice. I have found it, on the contrary, the road to prosperity and wealth, and I shall point out the same path to my children."

Something About the Toad.

The toad is a homely little hunchback, with a rough warty skin, and seems at least deserving of pity. But like many other unfortunates, he has been judged a villain from his looks, and fallen a victim to prejudice. No more harmless animal lives; he can not bite, scratch, or inflict other injury, yet long chapters of his supposed vices and crimes have been written. One writer says: "If he burrows near the root of a tree, every one who eats a leaf thereof will die, or if he only handles it he will be struck with sudden cramp." The cause of this poison was said to be its liver "which is very vicious, and causeth the whole body to be of an ill temperament." Fortunately, however, toads were said to have two livers, and "although both of them are corrupted, yet one is full of poison, and the other resists poison." An effectual remedy for toad poison was said to be composed of "plantain, black hellebore, powdered crabs, the blood of the sea-tortoise mixed with wine, the stalks of dogs' tongues, the vermet of a hare, the quintessence of treacle, and the oil of a scorpion mixed." But even in the

days when this prodigious prescription was invented, some good was acknowledged to exist in the toad. It was said to have a precious jewel in its head, and also to have great power to stop the flow of blood. Says one, "If any one fall and knock his nose against a stone, he can stop the blood, if he hold a dried toad, in his hand; because the horror and fear constrain the blood to run into its proper place, for fear of a beast so contrary to human nature." Such nonsense as this is now scarcely heard, except in some ignorant districts in Europe, where people know little more than what their ignorant parents handed down to them. The toad certainly can not be praised for his beauty, although his eye is as bright as a jewel; but like many other homely creatures he has rare virtues. He does no harm. He may live in the garden among the most tempting berries and flowers, but not one will he pluck; his taste does not run that way. But let a fly, a bug, or a worm show himself within reach, and the dull stupid looking toad instantly appears like another being; he is all animation, and his eye glistens with excitement; his tongue is shot from his mouth like a flash, and the insect disappears down the throat of the happy toad. His tongue is admirably contrived for this use. Its base or root is fastened at the entrance of the mouth, the tip end when at rest pointing down

the animal's throat. It is covered with a sticky slime, to which the insect adheres if hit; and then the victim makes a very rapid journey to the toad's stomach. Gardeners will do well to encourage the visits of these insect killers. Entomologists may also procure many rare specimens by killing the toad and examining the insects which he has swallowed. The next time you find a toad, try his expertness with a few bugs and worms; observing his habits will give much pleasure. Perhaps by becoming well acquainted with him, you may chance to see him change his coat and pants, which he does occasionally—curiously enough, when he takes off his old skin, he rolls it into a ball and swallows it!

An Auctioneer was selling a library at auction. He was not very well read in books, but he scanned the titles, trusted to luck, and went ahead. "Here you have" he said, "Bunyan's Pilgrim's Progress; how much 'm I offered for it? 'Tis a first-rate book, gentlemen, with six superior illustrations; how much do I hear? All about the Pilgrims by John Bunyan! Tells where they come from, an' where they landed, an' what they done arter they landed! Here's a picter of one of 'em going about Plymouth peddlin' with a pack on his back!"

A MAN proves himself fit to go higher, who shows that he is faithful where he is.

WHEELER & WILSON

**ROTARY HOOK
 SEWING MACHINES.
 625 BROADWAY.**

"WOMAN'S GREATEST BOON.—We would advise a man to forego a Thrasher and thresh what with a flail, rather than to see the wife wear her health, vigor and life away in the everlasting 'stitch, stitch, stitch,' when a Sewing Machine can be obtained. The WHEELER & WILSON is an invaluable aid in every household. We have had several different kinds on trial, and after a six year's service, the WHEELER & WILSON has taken the precedence as the best, where all kinds of sewing are to be done in a family."
American Agriculturist, Jan. 1865.

Price of colored sheets, 40 cents; mounted on rollers, 75 cents. Size, 28x38 inches, is ready, in English and German.

**H. H. LLOYD & CO., PUBLISHERS,
 21 John-street, New York.**

AGENTS WANTED!

EVERYWHERE TO CANVASS FOR THE
 Official Southern History of the War,
THE LOST CAUSE,

By E. A. POLLARD, of Virginia.

Complete in one large royal octavo volume, nearly 800 pages, with 24 fine steel Portraits—giving a full and authentic account of the rise and fall of the late Southern Confederacy—the Campaigns, Battles and Incidents of the most gigantic struggle of the world's history.

There are already in the field no less than eighteen Histories of the War, arranged by Northern writers; and correctly understand the great struggle through which we have passed, we must have the facts and figures as presented by a Southern Historian; for we can only arrive at the truth by a knowledge of the events as seen by both parties to the struggle.

It comes to the work with the encouragement and authority of Generals R. E. LEE, J. E. JOHNSON, BEAUREGARD, "DICK" TAYLOR, FITZ-HUGH LEE, Ex-Gov. WISE, and other distinguished Confederate leaders.

Why Should I Buy It?—Every family, for without it the History of the Great Civil War is incomplete.
How to Get It?—Apply to the Agent in your locality or address the Publishers.

E. B. TREAT & CO., 651 Broadway, New York.

**EMPLOYMENT, "PLEASANT AND PROFIT-
 ABLE."** Agents wanted to sell New Physiognomy,—1000 Engravings, price \$5.—and other illustrated standard works. Send stamp for terms to FOWLER & WELLS, N. Y.

 Pages, for BOYS and GIRLS.
 \$1.00 a Year in advance.**

Specimen Copy sent for Ten Cents.
 Address,
**ALFRED L. SEWELL,
 Publisher, Chicago, Ill.**

Forney's Philadelphia Daily Press says of it. "THE LITTLE CORPORAL is destined to become the great children's paper of America."

THE LITTLE CORPORAL is the most interesting and instructive monthly in the Union.—Louisville Democrat.

THE LITTLE CORPORAL is universally admitted to be the best juvenile paper now in existence.—Dubuque Daily Times.

It is the cleverest thing of its kind yet realized in America.—Roxbury (Mass.) Journal.

After a careful examination, we can cheerfully say of THE LITTLE CORPORAL, that it deserves all the praise that has been lavished upon it by the press everywhere.—Philadelphia Episcopal Recorder.

The Little Corporal for one year will do your children more good than a Quarter's Schooling.

**USING B. T. BABBITT'S
 Pure Concentrated Potash**

OR
READY SOAP MAKER.

Warranted double the strength of common Potash, and superior to any other saponifier or ley in the market. Put up in cans of 1 pound, 2 pounds, 3 pounds, 6 pounds, and 12 pounds, with full directions in English and German for making Hard and Soft Soap. One pound will make 15 gallons of Soft Soap. No lye is required. Consumers will find this the cheapest Potash in market.

**B. T. BABBITT,
 Nos. 64, 65, 66, 67, 68, 69, 70, 72, and 74 Washington-st., N. Y.**

**B. T. BABBITT'S
 STAR YEAST POWDER.**

Light Biscuit or any kind of Cake may be made with this "Yeast Powder" in 15 minutes. No shortening is required when sweet milk is used.

Nos. 64 to 74 Washington-st., New-York.

**B. T. BABBITT'S
 BEST MEDICINAL SALERATUS.**

Bread made with this Saleratus contains, when baked, nothing but common salt, water and flour. Nos. 64, 65, 66, 67, 68, 69, 70, 72 and 74 Washington-st., New York.

**B. T. BABBITT'S
 LABOR-SAVING SOAP.**

This Soap is made from clean and pure materials, contains no adulteration of any kind, will not injure the most delicate fabric, and is especially adapted for wooleens, which will not shrink after being washed with this Soap. It may be used in hard or salt water. It will remove paint, grease, tar and stains of all kinds. One pound warranted equal to two pounds of ordinary family soap. Directions sent with each bar for making three gallons handsome soft soap from one pound of this Soap. Each bar is wrapped in a circular containing full directions for use, printed in English and German. Ask your grocer for "B. T. Babbitt's Soap," and take no other.

VICK'S

Illustrated Catalogue of Bulbs,
and Guide in the Flower Garden for 1866,

will be published by the middle of August. It will contain descriptions of the best **Hyacinths, Tulips, Crocuses, Lilies**, and other hardy Bulbs for fall planting, with plain directions for culture.

It will be illustrated with a fine **COLORED PLATE** and numerous wood-cuts.

This Annual is published for the instruction and benefit of my customers, and to all whose names are on my books it will be sent free as fast as it is possible to mail them. To all others, price 10 cents, which is not half the cost.

Address **JAMES VICK,**
Rochester, N. Y.

TURNIP SEEDS.

We desire to remind **DEALERS IN SEEDS** of the near approach of the season for sowing Turnip and Ruta Baga. We shall be able to offer a large supply of all the approved varieties, and let it be observed,

EVERY GRAIN THE PRODUCT OF BLOOMSDALE.

We have not in store, and shall not have an ounce of imported seed.

Our **TURNIP SEED CIRCULAR**, with particulars of interest to those who deal in SEEDS, issued May 25th, will be mailed to all dealers who apply.

Planters, Farmers, and private families generally are invited to supply themselves at the stores of our wholesale customers—when their residence is remote from such, supply may be had by mail or Express.

DAVID LANDRETH & SON,
Nos. 21 and 23 South Sixth Street,
PHILADELPHIA, PA.

Turnip Seed—New Crop.

Purple-top Flat, and White Flat Dutch, Strap-leaved; Ruta Baga; Yellow Globe; White Norfolk; grown from selected and transplanted roots, forwarded by mail (pre-paid), at 10 cents per ounce; 80 cents per pound. Address

H. A. DREER, Seedgrower,
714 Chestnut st., Philadelphia, Pa.

SEEDLING POTATOES.

Having twenty-three acres planted with the Early Goodrich and Harrison potatoes, I am now ready to receive orders for fall delivery. The seed was procured directly from the farm of the late Rev. C. E. Goodrich, of Utica, N. Y., who propagated them from a seed ball of the Cuzco. The stock of these valuable potatoes is limited, and persons desirous of obtaining them must send their orders early.

Price for Harrison, per dbl. of 165 lbs., \$12.50.
do. Goodrich, do. do. \$9.00

Discount for large order.
JAMES THORNTON, Byberry, Philadelphia, Pa.

A Remarkable Strawberry.

THE GOLDEN QUEEN.

The above shows a fair average sample of berries of this new variety exhibited at the Agricultural Office, July 5th. It is of beautiful bright scarlet color, of very high flavor and enormously productive, many berries each measured 6 inches in circumference. It ripens 15 days after the Wilson, and is thus most valuable as a late berry, for family use or marketing. Plants \$1 per dozen; \$5 per 100; \$30 per 1000. Cash orders filled in rotation. Address
J. B. CLINE, Rochester, N. Y.

Durand's Seedling Strawberry.

A new variety produced from a combination of Boyden's Green Prolific, Thomple de Gand, and Peabody's Seedling. The plant is very hardy and vigorous, has stood entirely unprotected the past three winters. The foliage, which is large, and of a rich glossy green, is sufficient for shade, though there is not a superabundance to absorb the nourishment which belongs to the fruit, and it is never affected by sun blight. The blossoms are perfect; the fruit is very solid, large, and uniformly so throughout the season, color scarlet, flesh firm, flavor excellent, equalled by very few Strawberry varieties and surpassed by none. It is very prolific, ripening with the earliest, and continuing to bear fine fruit full two weeks after all other varieties are gone. It is emphatically the best Strawberry out, and from its intense solidity, productiveness, fine flavor, attractive appearance, and many fine qualities combined, it must take precedence over all others for family, and more especially as a market fruit. It has been seen in our grounds the past season by many of the prominent Horticulturists of the country, and notwithstanding the fact that our fruit was grown and exhibited under very unfavorable circumstances, the season here having been very cold and wet, yet all pronounced them to be very remarkable, and under more favorable circumstances undoubtedly very superior. Those who saw them in 1865, in Mr. Durand's garden, were astonished, and all pronounced them the finest they had ever seen.

We stake our reputation upon the veracity of what we say of this wonderful Strawberry, and advise all fruit growers, and especially those who sell plants to secure a stock, for as this fruit becomes known, the demand for plants will be enormous. We received subscriptions for these plants during the past spring and many subscribers upon seeing the fruit increased their orders, several from one hundred to one thousand. Circulars containing further particulars of this Strawberry, reports of Committees and individuals who have seen it, and also a general list of nursery stock furnished to all applicants.

The Durand's Seedling will be ready for distribution about August 15th. We will send out strong plants only, at the following rates: One plant, 5 cents; five, \$3.25; six, \$3.00; twelve, \$5.00; fifty, \$15.00; one hundred, \$25.00; one thousand, \$3.00; carefully packed, and small lots sent pre-paid by mail. In ordering, give your name, town, county and State, in full, and be particular to state whether to send by Express or mail. If by Express, give the name of the one having an office at your place.

We have the entire stock of this Strawberry, therefore all orders must be addressed to us, and must in all cases be accompanied by the cash, and where such can be had, send Post Office Money Orders. Address
FRANCIS BRILL, Newark, New Jersey.

IONA and ISRAELLA VINES,

These two kinds have been found, after extensive trial, greatly to surpass all others for every purpose.

Under consideration of their importance, I have made the propagation of these a specialty; and have endeavored by all the means and advantageous care within my knowledge from long experience, to produce the best possible plants for early bearing and constant abundant productiveness in garden and vineyard.

"Attenuated production of vines from imperfect wood, causes thousands of disappointments."

My plants are produced from the best wood of vines of mature age, carefully grown for the purpose, without forcing by manure or any other means, which is a very important consideration in respect to all of the most important qualities of the plants.

As heretofore, all persons interested are invited to call at Iona, to see the plants in every stage of growth, from the first setting of the eyes for the production of new plants, to the full establishment of the vines in bearing.

My stock is very large, and the plants at present are more promising in quality than in any former season.

I shall be happy to entertain orders most favorably for any number, from single plants to tens of thousands. My plants are chiefly grown in open ground with sufficiency of room for their full accommodation. But I have for those who may prefer them, many thousands grown in large pots that are better than can be produced in open ground.

My general stock of the leading kinds is of excellent quality, and I invite especial attention to the plants of Delaware, Allen's Hybrid, and Adirondac.

Prices and Terms will be found to be very liberal and advantageous for all who desire to buy to plant, and also to dealers.

The Club arrangements which have been in very extensive operation the past three seasons, have been highly advantageous, enabling buyers to obtain their vines in the most cheap and satisfactory manner.

For Price-Lists, Club-propositions and Pamphlet, containing the history and full account of the IONA and ISRAELLA vines, with engravings of both these kinds in bearing, send two-cent stamp.

"THE MANUAL OF THE VINE, eighth edition," is sent for Fifty cents.

The Pamphlet is designed to furnish such information as those proposing to purchase would wish to obtain, including "The Present and Future of American Grape Culture and Wine Making." And the Manual is intended to be the most thorough and comprehensive practical treatise on the vine in the language.

C. W. GRANT, Iona,

(near Peekskill,) Westchester Co., N. Y.

Cromwell's Patapasco Nurseries, One Mile South of Baltimore.

The Subscriber offers for the coming Fall and Spring, a large and well grown stock of Dwarf and Standard Pears, Peach, Plum and Cherry, Evergreen and Ornamental Trees, Strawberries, Grape Vines, &c., in large or small quantities. Our Collection of grapes consists of all the old as well as the last new varieties, including Rogers' Hybrids, and can now be seen in the bearing condition, and all who may feel interested, I invite to visit the Nursery. Catalogues sent to any address. Office 46 & 48 Light st., Baltimore, Md. **RICH'D VINCENT, Superintendent.**

FOR SALE 120,000 PEACH TREES, OF which 40,000 are Hales' Early. Also a complete stock of other Nursery Trees. Agriculturalist and other Strawberries, Blackberries, Raspberries, &c. For Circular, Address **ISAAC PULLEN, Hightstown, N. J.**

\$5 PAYS FOR 75 AGRICULTURIST, 50 IDA, 50 Russell's, 50 Monitor, 75 Brooklyn Scarlet, 50 Ellsworth, 50 Fillmore, and 50 Lennig's White Strawberry plants. Three of each variety for \$2, post-paid. Wilson's \$5 per thousand. Send for a Circular. **P. SUTTON, Box 338, Pittston, Luzerne Co., Pa.**

WANTED.—The address of some Western growers of Broom Corn that want to deal direct with the Manufacturer's, thereby saving Commissions, &c. Direct to **STEELE & CLARK, New Hartford, Conn.**

GRAPE VINES AND ROSES.

PARSONS & CO.,

offer for the Fall Trade, **600,000** Grapes of all the best varieties, including **Delaware, Iona, Israella, Concord, Hartford Prolific, Diana, Creveling, Adirondac,** and many other fine sorts.

Among them is the **IVES SEEDLING**, a grape which is now being planted about Cinclinnati, on a very large scale. It neither rots nor mildews, and during the last year, on our own premises, its leaf was always fresh and clean.

By many it is preferred to **NORTON'S VIRGINIA**, of which we have also a fine stock.

All these different varieties will be sold at their usual low prices by the hundred, lower still by the thousand, and yet lower where ten thousand are taken. They also offer for delivery in the Autumn,

ROSES of the various classes at

\$20.00 per 100; \$150 per 1000.

These Roses are grown from cuttings, and are not grafted or budded on the root or otherwise.

They include **REMONTANT, MOSS, TEA, CHINA** and **NOISETTE**, with the largest proportion of **REMONTANT** or **HYBRID PERPETUAL**.

Only the finest well known sorts of each class are furnished.

For Catalogues, Address

PARSONS & CO., at FLUSHING, N. Y.

WILLIAM PERRY & SON,

BRIDGEPORT, CONN., are growing a few more of those splendid **Concord Vines** that **E. A. Thompson**, an extensive planter of Cinclinnati, O., and numerous dealers say are the "**BEST Vines they ever saw.**"

Allen's and Rogers' Hybrids, Creveling, Maxatawney, and Hartford Prolific, are grown at Bridgeport, Conn.

Iona, Israella, Adirondac, Delaware, Diana, Norton's Virginia, Ives Seedling, Union Village, &c., &c., &c., are grown at our Branch Establishment, Canandaigua, N. Y. Call and examine our Vines, or send for Catalogue.

Address, with stamp,

F. L. PERRY, Canandaigua, N. Y.

JUST ISSUED,

"**An Abridged Manual of Grape Culture,**" giving an outline of the different modes of training and culture. Illustrated by numerous cuts specially prepared for the work, together with the

Annual Catalogue of Small Fruits of "Pomona's Home Nursery," where all varieties of Small Fruit plants are grown and sold at the lowest living price.

Three acres of Concord layers. Half an acre (10,000) Delaware layers.

The above is the most complete work of the kind ever issued. *Send for one; sent free.*

P. S.—Annual Price List in Sept. Agriculturist.

J. H. FOSTER, JR., Box 660, West Newton, Westmoreland Co., Pa.

VINELAND

FARM AND FRUIT LANDS, in a mild and healthful climate. Thirty miles south of Philadelphia by Railroad, in New Jersey, on the same line of latitude as Baltimore, Md.

The soil is rich and productive, varying from a clay to a sandy loam, suitable for Wheat, Grass, Corn, Tobacco, Fruits and Vegetables. This is a **great fruit country.** Five hundred Vineyards and Orchards have been planted out by experienced fruit growers. Grapes, Peaches, Pears, &c., produce immense profits. Vineland is already one of the most beautiful places in the United States. The entire territory, consisting of forty-five square miles of land, is laid out upon a general system of improvements. The land is only sold to actual settlers with provision for public adornment. The place on account of its great beauty as well as other advantages has become the **resort of people of taste.** It has increased five thousand people within the past three years. Churches, Stores, Schools, Academies, Societies of Art and Learning, and other elements of refinement and culture have been introduced. Hundreds of people are constantly settling. Several hundred houses are being constructed, and it is estimated that five hundred will be built during the summer. Price of Farm land, twenty acre lots and upward, \$35 per acre. Five and ten acre, and Village lots for sale.

Fruits and Vegetables ripen earlier in this district than in any other locality north of Norfolk, Va. Improved places for sale.

Openings for all kinds of business, Lumber Yards, Manufacturing, Foundries, Stores, and the like.

For persons who desire mild winters, a healthful climate, and a good soil, in a country beautifully improved, abounding in fruits and possessing all other social privileges, in the heart of civilization, it is worthy of a visit.

Letters answered and the Vineland Rural, a paper giving full information, and containing Reports of Solon Robinson, sent to applicants.

Address **CHAS. K. LANDIS, Vineland P. O., Landis Township, New Jersey.**

From Report of **Solon Robinson, Agricultural Editor of The Tribune:** *It is one of the most extensive fertile tracts, in an almost level position and suitable condition for pleasant farming that we know of, this side of the Western Prairies.*

NEW STRAWBERRIES.

Ripawan.—At the great Strawberry Show, given by the American Institute in this city, the Ripawan took the first prize, over the Agriculturist, and all other varieties, for the largest berry. For particular description of this remarkable strawberry, see my advertisement in July number. Plants \$2 per doz.; \$6 for 50; \$10 per 100; or, \$90 per 1000.

Ella.—A new Seedling of promise, ripening several days earlier than any other kind. Fruit large, productive, and fine flavored. Plants \$2 per dozen; or, \$10 per 100.

Golden Queen.—A Seedling resembling Trollope's Victoria, but more productive fruit very large and fine, \$1 per dozen; \$5 per 100.

Knox's 700.—Plants \$1 per doz.; or, \$5 per 100.

Ida.—This Seedling is enormously productive and fine flavored. \$1 per doz.; \$3 per 100; or, \$30 per 1000.

Huntsman's Emily.—A very large, productive, and beautiful Scarlet berry. \$2 per doz.; \$10 per 100.

New Jersey Scarlet.—A promising new variety, very early, and productive. \$1 per doz.; or, \$2 per 100.

Agriculturist.—I have a large stock of this fine variety, at \$1.50 per 100; or, \$10 per 1000.

Mead's Seedling.—This is one of the best berries in cultivation. \$1 per doz.; or, \$5 per 100.

Lennig's White.—The best of all the White berries, fruit very large and beautiful. \$1 per doz.; or, \$3 per 100.

For further particulars, see my advertisement in July No of Agriculturist. All orders addressed to

WM. S. CARPENTER, 156 Reade-st., New York.

FLAX BRAKES, &c.

MALORY & SANDFORD'S Improved Flax and Hemp Brakes have been called, from the first, the best in market. They are now greatly improved, being made with less parts, of superior iron, and very strong and not likely to give way or break like the old pattern machines. They must be seen to be properly valued. Many are giving up other machines and using these. They occupy about 5 feet square, weigh about 1000 lbs.—require one to two horse power, and one man and boy to work them.—break from 20.0 to 300 lbs. flax straw in ten hours, taking out 65 to 70 per cent. of the woody matter. If a good Brake is wanted, there is nothing that will do so much work, do it so well, and is so cheap. It will save 120 lbs. to the ton of flax above any other machine in the world, and this would pay for it in a short time. It has six rolls and will break both straight and tangled straw. We have an entirely new TOW SHAKER and PICKER, that does the work fast and first-rate. Those who have seen it and ought to know, say "It will do the work quicker and better than any other in market." We know of nothing as clean and good. Also a New Tow Catcher, taking the tangled tow after passing through the Brake and producing rapidly a fibre free from shive, yet fine and straight as line flax, and adapted to carding and spinning. These machines we show in operation, at the Company's Office. JOHN W. QUINCY, Treasurer, 98 William st., New York City.

To Sorghum Growers.

Vertical and Horizontal Sweep and Power Cane Mills,

with self-adjusting Rollers, combining immense strength, and great efficiency.

Strong Sweep Horse Powers, Evaporators.

The best and cheapest Cane Machinery in the world. Manufactured and for sale by the

The SORGO HAND BOOK sent free to all applicants.

CIDER PRESS SCREWS.—Five feet long, four inches diameter. These powerful screws bring out a third more juice than portable presses. Send for a Circular. Made by THOMPSON & CARPENTER, Philadelphia. (Successors to L. M. Arnold) Poughkeepsie, N. Y.

Repair your Leaky Roofs

WITH

Compound Mineral Cement.

Applied with a common trowel it will fill up crevices, and stop leaks around chimneys, dormer windows, &c. Price 5 cents per pound in 50 and 100 pound boxes.

H. W. JOHNS,

Manufacturer of

Improved Roofing,

Preservative Paint, &c.

78 William-st., New York.

American Roofing Company.

One of the best articles of Roofing ever introduced, consisting of a stout material made WATERPROOF, by a compound of INDIA RUBBER, covered by a coat of METALLIC PAINT.

It is designed for STEAMBOATS, DWELLINGS, BARNs and SHEDs, and can be laid down by any sensible working man.

Circulars, with testimonials and samples can be seen at the Company's Office, 4 Cedar-st., New York.

HENRY SMITH, Agent.

The American Paint

Consists of a mixture of OXIDE OF IRON and LIME STONE CEMENT, ground with our PATENT INDIA RUBBER COMPOUND, ready for use, and may be made of any consistency with boiled Linseed Oil.

It is especially designed for TIN ROOFS and all out-door work, such as L WELLINGS, BARNs, PLAZAS and FENCES.

Its tenacity, durability and surface covering capacity are unequalled; it hardens by exposure without cracking or blistering of which there is the fullest testimony.

For sale at the Company's Office, 4 Cedar-st., New York. HENRY SMITH, Agent.

For Merchants, Druggists, Hospitals, small Job Printers, &c. Address ADAMS PRESS CO., 26 Ann-st., New York, and No. 35 Lincoln-st., Boston. Specimen Sheets of Type, Cuts, &c., Ten cents.

WOOD & MANN STEAM ENGINE CO'S CELEBRATED Portable Steam Engines,

FROM 4 TO 35 HORSE POWER. ALSO PORTABLE SAW MILLS.

We have the oldest, largest and most complete works in the United States, devoted exclusively to the manufacture of Portable Engines and Saw Mills, which, for simplicity, compactness, power and economy of fuel, are conceded by experts, to be superior to any ever offered to the public.

The great amount of boiler work, fire surface and cylinder area, which we give to the rated horse power, make our Engines the most powerful and cheapest in use; and they are adapted to every purpose where power is required.

All sizes constantly on hand, or furnished on short notice.

Descriptive circulars with price list, sent on application.

WOOD & MANN STEAM ENGINE CO., Utica, N. Y.

Branch Office, 96 Maiden Lane, New York City.

BABY JUMPER and WALKER, Coldwell's patent, received Silver Medal N. Y. State Fair, price 85c. Sent for Circular to L. P. TIBBALS, 478 Broadway, near Broome-st., N. Y.

SILVERINE.

A new and genuine preparation of **PURE SILVER,**

for cleaning and polishing Silver and Silver Plated Ware, and for Silver Plating articles of Copper, Brass, German Silver, &c., by the use of which every one can give the appearance of solid Silver to all articles made of above metals, which they will retain permanently with an occasional application. It restores the plating where worn off, by a single application, and will be found one of the most valuable articles ever produced for the many thousand articles to which it can be applied to advantage.

This article is different from all others ever produced for similar purposes, as it does not contain Mercury nor any acid, nor any property injurious to metals or the hands.

FOR SALE EVERYWHERE. DIXON, CLARKS & HALLETT, Gen'l Agents, 119 Chambers-st., New York.

MENDENHALL'S IMPROVED SELF-ACTING HAND-LOOM

Is the most Simple, Durable and Reliable Loom ever invented, and is the ONLY Self-Acting Loom that has NEVER failed to give entire satisfaction. It makes as OPEN a SHED as any other Loom, and will weave goods on Woolen Warps equally as well as on Cotton Warps.

For descriptive Circulars and samples of weaving done on the Loom, address, with stamp,

GREENWOOD LOOM COMPANY, CINCINNATI, OHIO.

Or, **A. B. GATES & CO.,** PHILADELPHIA, PA.

THE LIGHTNING APPLE PARER.

A thorough trial of this Machine last year established the fact, that it is the best PARER in market. It will pare smooth apples as well, and rough or bruised apples better, easier and quicker than any other Machine ever produced. It can be found at the Wholesale Agricultural and Hardware stores in all the principle cities in the United States and Canadas.

FARMERS AND FRUIT GROWERS, call for the LIGHTNING PARER and accept no other, and when you have tried it, recommend it to your neighbor and let the people know that the world moves. We submit a few, of a multitude of strong endorsements, which we might offer, from parties who have given it a thorough trial.

St. NICHOLAS HOTEL, New York, July 11, 1866.
We have been using the LIGHTNING APPLE PARER for some time past, and we consider it a very superior machine—being more simple in construction, rapid in operation and perfect in its work than any other we ever saw.

Signed
GEO. PIERIS, Steward.

We are using the LIGHTNING APPLE PARER. We consider it a perfect machine in all respects.

Signed
METROPOLITAN HOTEL, New York, July 10, 1866.
SIMEON LELAND & CO.

We are using the LIGHTNING APPLE PARER and consider it the most perfect and useful of any we have ever used.

Signed
REVERE HOUSE, Boston, 12th June, 1865.
BINGHAM, WRISLEY & CO.

We are using the LIGHTNING APPLE PARER and consider it the best of any we have ever used.

Signed
PARKER HOUSE, Boston, Feb 7th, 1866.

No. 1.

WOODRUFF'S IMPROVED PORTABLE BAROMETER.

No. 2.

The Barometer is now becoming an instrument of universal use among intelligent farmers and others engaged in outdoor pursuits. Foretelling accurately impending changes in the weather from six to thirty-six hours in advance, by its use, hay, grain, and other valuable crops may be secured uninjured, when much damage and loss might otherwise ensue from exposure to storms. In busy seasons much valuable time may be saved by its use. Often in cloudy, foggy mornings, the farmer is at a loss to decide whether to cut down grass or grain, and much time is lost "waiting for the weather to clear up," when the Barometer would instantly and unerringly decide the case. As a general guide for the conduct of out-door operations which would be affected by the weather, it is invaluable. Operating upon infallible natural laws, no change in the weather can occur without being plainly foretold by the Barometer. By the invention of this instrument, the great difficulty attending the transportation of the Barometer has been obviated, and WOODRUFF'S Barometer can be as safely transported by ordinary express carriage, as any ordinary glass ware, to any part of the country. Its construction is such that temperature changes do not affect its action, a feature possessed by no other Barometer. No materials come in contact with the mercury, that can be at all affected by its corrosive action, so that the instrument is durable for a century. Its construction is perfectly simple and plain, making it impossible to get it out of order by ordinary use. By simply turning a screw it is rendered instantly and perfectly portable. In all the essential points for a Barometer for general use; accuracy, portability, durability, simplicity, and sensitiveness to slight atmospheric changes, it is without a rival. Upon any one or all these points combined, we challenge competition with any Barometer in the world. None but the best materials are used, and most careful and skillful workmen employed in its construction. By a systematic division of labor and an extensive sale, we are enabled to produce a perfect instrument at a price much lower than any other reliable Barometer has ever been sold. It is offered to farmers and others interested in out-door operations, as an instrument of real, sterling, practical value and utility, from the study and observation of which they will derive both pleasure and profit. During the past five years we have sold many thousands of these instruments, and not an instance has been reported where it has failed to give perfect satisfaction in the hands of intelligent, practical men, while we have many hundreds of voluntary certificates of its great

value and utility from farmers and others having them in practical use. Unsolicited testimonials of its value are received almost daily. It is cased in Walnut, Oak, Cherry, Maple, Mahogany or Rosewood, and forms a very beautiful and ornamental article of furniture, in addition to its scientific and practical value. Every Barometer has a metallic scale, with Vernier slide, by which variation in the Barometer may be read to the hundredth of an inch, and a neat and accurate Thermometer. Dr. Henry, of Smithsonian Institute, estimates that five per cent, on all crops might be saved by the universal use of Barometers by farmers, thus effecting a total saving to the country of *Eighty Million Dollars* annually. To all desirous of procuring a good Barometer we offer this instrument in the full confidence that they will find it all they desire or expect, and that they will never regret its purchase. Farmers who believe in Mowers, Reapers, Threshers, improved plows, and other farm machines, will find their value greatly enhanced by the use of the Barometer to tell them when it is safe to operate their machines. We believe it is perfectly safe to say that the thousands of Barometers we have sold in the past five years have saved already to the purchasers an average of *five times their cost*. We have a record of a well authenticated case where more than *One Thousand Dollars* was saved in a single instance, by the use of one of Woodruff's Barometers. And have a large number of voluntary certificates from persons who have saved their cost in a single case, or a single season. The *American Agriculturist* gives it unqualified approval, the *Country Gentleman*, *Boston Cultivator*, *Iowa Homestead*, *Journal of Agriculture*, *Ohio Farmer*, *Ohio Cultivator*, *Valley Farmer*, *Journal of Health*, *Mothers' Journal*, *Christian Instructor*, *Scientific American*, *Agricultural Chemist*, *Boston Journal*, *Boston Traveller*, and a large number of agricultural and miscellaneous papers endorse and recommend it from practical experience.

Combining a real practical value that soon repays its cost, often manifold, an elegance of design and beauty of finish that please the taste, with a scientific value that instructs and interests, the Barometer has become an instrument whose use contributes equally to the self interest as an economical labor saving implement, to the love of the beautiful, and culture, refinement, and instruction of the purchaser.—Probably no article manufactured in the country has gained for itself a more widespread and permanent reputation than Woodruff's Barometer. Not alone among the farming community, but everywhere in homes of elegance and refinement, has it come to be considered a valued and essential part of the household treasures. In some of the cities of the country its use has become so universal that not only many private dwellings are furnished with Woodruff's Barometer, but also public edifices, halls, and public rooms, as well as banking, insurance, express and railroad offices, hotels, stores, &c. There is hardly a department of labor or occupation in life where a good Barometer will not sooner or later repay many times its cost.

Description of Instruments.

No. 2 is put up in neatly turned cases of Maple or Cherry, varnished. Length, 40 inches, diameter, base and top, two and one-half inches, shaft tapering slightly, about one and one-fourth inches in diameter, semi-circular glass face, and mounted with metallic plates, Vernier scale and thermometer. Price, \$12.00.

No. 1 has a large tube, is cased in finely finished and polished Black Walnut. Length, three feet; width of top and base four inches—of shaft, two inches; depth, one and three-fourths inches, with pedestal two and one half inches deep. Mounted with metallic plates, Vernier scale, thermometer and index. Glass door over the face. Price, \$18.00. Same in Mahogany, \$19.00.

No. 1—Ornamental. Form similar to No. 1 with ornamental top, door and mouldings, and spiral thermometer, Cased in Oak. Tube very large. Price, \$21.00.

No. 0.—Extra Rosewood. Style similar to No. 1 ornamental, with a large spiral thermometer, having a Fahrenheit and Reaumur scale, covering front of shaft. Double metallic scale, Vernier and index, and extra large tube. Price, \$30. Same in Oak or Black Walnut, \$26.00.

Weight of either style, from 4 to 6 pounds.

Sent to any address carefully boxed and packed on receipt of price. We want a *reliable Agent in every Town or County in the country*, where agencies are not already established, and will make liberal terms. Circulars containing full particulars of terms to agents sent on application with stamp enclosed.

FIRST PREMIUMS

Have been awarded us for the best Barometers and Thermometers at Thirteen State Fairs, two New England Fairs, and Fair of Mass. Charitable Mechanics' Association. They have never failed to take the highest premium over all competing instruments.

THERMOMETERS.

We manufacture in all styles of tin and copper cases. Also mounted on Walnut, Satinwood, Mahogany, Ebony, Rosewood, and other fancy woods. Also a very neat and pretty style of *Portable Thermometer* for travellers' use. Thermometers for Brewers, Dyers, Chemists, Manufacturers, and all other purposes for which Thermometers are used, of any size, shape or description, made to order at short notice. In this branch of business as in Barometers, we aim to make the *Standard work of the Country*. We make more than one hundred varieties of Thermometers. Price Lists sent on application.

The following extracts from our files of letters from persons using the Woodruff Barometers will show the estimation to which it is held.—*Every one is purely voluntary and unsolicited.*

I have for some time past been urging farmers to use Barometers. I would not be without one for a hundred dollars, so great is its value as a "weather teller."—*Orange Judd of Agriculturist.*

Aurora, Ind., Aug. 10, 1864.

The experience of the last year has convinced our farmers of the utility and accuracy of your Barometers. A little over a year ago I distributed a number among intelligent and enterprising farmers here, and they express themselves well satisfied with their utility and accuracy.

R. C. SAWDON.

The Barometers I sold last Spring give complete satisfaction, and have created a demand for more among the neighbors of those who bought them.

GEORGE SMITH.

Cookshire, Canada East, Sept. 23, 1865.

The Barometer you sent me last year proves to be very reliable. I would not be without it on any account.

R. H. WILFORD, P. M.

The Woodruff Barometer you sent me I can say with truth is a good one, and if I could not get another one I would not take \$100 for it. It has told every time before it rained. My neighbors feel very anxious to get them.

SIDNEY SQUIRE.

The Barometer you sent me through Mr. Judd came to hand. I sold it to a neighboring farmer who says it has already more than paid for itself.

ENOS ARMS.

Your Barometers have given satisfaction.—Mine has afforded me much pleasure, beside being of much practical value.

FREDERICK H. BARTLETT.

Neosho, Wis., May 11, 1865.

I saw one of your Woodruff's Barometers at Hastings, Minn., last Summer, and had a favorable chance to test its accuracy during a six months stay, and every rain was indicated for many hours before it fell. I want one for my own use.

J. STRAIGHT.

We know them to be good, and the best quality and make. From our own experience and observation, we are certain that the Barometer will save many times its cost to a farmer, and indeed to every person whose business or pleasure depends at all on being able to predict the weather. *Woodruff's is the best Barometer*, and is a thing that will pay to have in every house.—*American Agriculturist.*

Warren, Iowa, Nov. 8, 1865.

I have one of your Barometers in my room which is so entirely accurate, not being affected by temperature, that I would hardly take \$100 for it.

J. F. HUNT.

Crestline, O., Feb. 8, 1864.

Having bought a Barometer of your agent here, I find it very reliable. I think I can sell many of them.

WM. McCULLY.

Bridgewater, Vt., Nov. 2, 1863.

I think the Barometer is the thing for foretelling the weather. I have but two acres of land, but have saved the expense of the Barometer in securing my hay and corn, even on that small amount.

NELSON W. DAMON.

Philad., 2d mo., 18th, 1864.

I had an opportunity last summer of observing one of thy Woodruff Barometers, and found it a superior instrument.

J. JENKINS.

Maytown, Pa., July 10, 1865.

My partner, Mr. Hely, having had charge of our Barometer lately, says it has been of great advantage to him. Recently, when there was no appearance of foul weather, the Barometer indicated rain. Mr. H. accordingly got in all his grain and saved it by the means, for in the evening a heavy storm came on. Mr. H. says the Barometer never fails.

S. L. YETTER.

From Messrs. Munn & Co., of the *Scientific American*:
"From the construction of this instrument, as well as from the ample testimonials, both of practical farmers and men of science, we are satisfied that it is really a good, practical, portable Barometer."

Bucyrus, O., Sept. 9, 1865.

I have had one of your Barometers more than a year, and could hardly get along without it.—This wet season, with the help of a mowing machine and watching the Barometer, I put up fifty-one acres of hay and grain, and got but eight cocks wet.

DENTER BACON.

Blackberry Station, Ill., Jan. 25, 1865.

Farmers here were at first disposed to look on Barometers as a humbug, but my predictions have been so correct with regard to the weather, that they begin to think they can be relied on.

J. P. BARTLETT.

St. Paul, Minn., Feb. 2, 1864.

After ordering the twenty Barometers the 27th ult., I thought I would not take any more orders until those were received. Since then I saw Capt. Sibley's instrument, and although the Captain was absent, Mrs. B. spoke so highly of the Barometer, I concluded to resume taking orders. Accordingly, in about two hours I sold eight more. Gov. Miller, Gen. H. H. Sibley, Ex. Gov. of State, R. H. Nelson, U. S. District Judge, Ex-Mayor John S. Prince, Hon. Ed. Rice, and others of our most distinguished citizens purchased. Accordingly, you may send another dozen immediately.

D. A. ROBERTSON.

Ex-Mayor City St. Paul, Minn.

I have used the Woodruff Barometer for more than a year, and I would not be without one on any account.

JAMES EDGARTON, Barnesville, Ohio.

Ets. Country Gentleman.—I recently ordered for myself and friends a dozen of Woodruff's Barometers of Mr. Wilder, the manufacturer—all of which work entirely to our satisfaction.

A. M. HAINES, Galea, Ill.

CHARLES WILDER,
PETERBOROUGH, NEW HAMPSHIRE.

THE GREAT AMERICAN TEA CO.,

Have selected the following kinds from their Stock, which they recommend to meet the wants of Clubs. They are sold at Cargo Prices, the same as the Company sell them in New York, as the list of prices will show.

All goods sold are warranted to give satisfaction.

PRICE LIST:

YOUNG HYSON, 80c., 90c., \$1, \$1.10, best \$1.25 per pound.

GREEN TEAS, 80c., 90c., \$1, \$1.10, best \$1.25 per pound.

MIXED, 70c., 80c., 90c., best \$1 per pound.

JAPAN, \$1, \$1.10, best \$1.25 per pound.

OOLONG, 70c., 80c., 90c., best \$1 per pound.

IMPERIAL and GUNPOWDER, best \$1.25 per pound.

ENGLISH BREAKFAST, 80c., 90c., \$1, \$1.10, best \$1.20 per pound.

Our Black and Green Mixed Teas will give universal satisfaction, and suit all tastes, being composed of the best Foo Chow Blacks and Mayone Greens.—English Breakfast is not recommended, excepting to those who have acquired a taste for that kind of Tea, although it is the finest imported.

These Teas are chosen for their intrinsic worth, keeping in mind health, economy, and a high degree of pleasure in drinking them.

COFFEES ROASTED & GROUND DAILY.

GROUND COFFEE, 20c., 25c., 30c., 35c.—best 40c. per pound. Hotels, Saloons, Boarding-House keepers and Families who use large quantities of Coffee, can economize in that article by using our FRENCH BREAKFAST and DINNER COFFEE, which we sell at the low price of 30c. per pound, and warranted to give perfect satisfaction.

Consumers can save from 50c. to \$1 per pound by purchasing their Teas of the

GREAT AMERICAN TEA COMPANY,

Nos. 31 and 33 VESEY-ST., corner Church-st.
 POST-OFFICE BOX, 5,643 New York City.
 No. 610 BROADWAY, corner Bleecker-st.
 No. 503 EIGHTH AVE., near Thirty-seventh-st.
 No. 299 SPRING-STREET.
 No. 205 FULTON-ST., BROOKLYN, corner Concord st.

Country Clubs, Hand and Wagon Peddlers, and small stores (of which class we are supplying many thousands, all of which are doing well), can have their orders promptly and faithfully filled; and in case of clubs, can have each party's name marked on their packages as directed by sending their orders to Nos. 31 and 33 Vesey-st.

Our friends are getting up Clubs in most towns throughout the country, and for which we feel very grateful. Some of our Clubs send orders weekly, some not so often, while others keep a standing order to be supplied with a given quantity each week, or at stated periods. And in all cases (where a sufficient time has elapsed) Clubs have repeated their orders.

Parties sending Club or other orders for less than thirty dollars, had better send Post-Office drafts, or money with their orders, to save the expense of collections by express; but larger orders we will forward by express, to collect on delivery.

We return thanks to parties who have taken an interest in getting up Clubs. And when any of them come to New York, we shall be pleased to have them call upon us and make themselves known.

Hereafter we will send a complimentary package to the party getting up the CLUB, of \$30 and over. Our profits are small, but we will be as liberal as we can afford.

The following letter tells its own story:

VIRGINIA, Cass Co., Ill., June 6th, 1866.
 To the Great American Tea Company, New York City:
 GENTLEMEN,—The package of Tea I ordered came safely to hand. All are well pleased with their Teas, as the cost is nearly \$1 per lb. cheaper than they have been paying for Teas no better than we have bought from you.

I herewith send you another order, which you will please send the same way—by the United States Express Co.—to my address
 JAMES NEEDHAM.

P.S.—I thank you for the complimentary package in the other box.

\$71.75

N.B.—All towns, villages, or manufactories, where a large number of men are engaged, by CLUBBING together, can reduce the cost of their Teas and Coffees about one-third by sending directly to the GREAT AMERICAN TEA COMPANY.

*** If we needed any endorsement of our reliability, the complimentary notice we received in the editorial columns of the July number of this paper, would be sufficient, as all its readers are fully aware of the entire reliability of the American Agriculturist. Address

GREAT AMERICAN TEA COMPANY,

31 and 33 VESEY-STREET, corner of Church.
 Post Office Box, 5,643 New-York City.

THE EMPIRE SHINGLE MACHINE

IS acknowledged to be, by all odds, the best Shingle Machine in America. With only one horse power 3000 ELEGANT SHINGLES per hour are easily made. The machine is built entirely of iron, very compact and easily transported. It works VERNERS, SPRAYS and BOX STUFF, and out of the same number of bolts of timber, one-third more Shingles are manufactured than can be done by the Sawing Machines. All the saw-dust is saved by the Empire and goes into the Shingles.
 ABRAM BEQUA, Gen'l Agent, 141 Broadway, New York.

BRICKS.

The NATIONAL BRICK MACHINE is a clay tempering machine, and with only

TWO HORSES MAKES

30,000 GOOD BRICKS PER DAY.

If the machine does not do this, it will be TAKEN BACK AND THE MONEY REFUNDED. For Rights and Machines Address ABRAM BEQUA, General Agent, 141 Broadway, N. Y.

THE ILLUSTRATED PIRENOLOGICAL JOURNAL, with Portraits, Biographies and Characters, Monthly, at \$2 a year. Address FOWLER & WELLS, N. Y. Sample No's by first post, 20 cents.

WANTED—AGENTS in all parts of the United States, to sell a *New National Work*, by Rev. JOHN S. C. ANNOTT. For particulars, Address
 B. B. RUSSELL & CO., Boston, Mass.

Downing's Landscape Gardening and Rural Architecture. Price, \$6.50.

The most complete and valuable work ever issued on Landscape Gardening in North-America, for the Improvement of Country Residences; containing full Directions for every thing connected with Laying out and adorning the Rural Home, the Grounds, the Gardens, the Buildings, the Trees and Plants, etc., with principles of taste so stated as to adapt the work to all classes. Splendidly Illustrated with many Steel and fine Wood Engravings. By the late A. J. DOWNING. New Edition, Enlarged, Newly Illustrated and revised, with Supplement, by HENRY WINTHROP SARGENT. Octavo, 531 pp. Extra cloth, gilt, beveled eds.

ORANGE JUDD & CO.,

41 Park Row, New York.

SENT POST-PAID ON RECEIPT OF PRICE.

Fuller's Grape Culturist. Price, \$1.50.

This is the latest and most practical work issued on the Culture of the Hardy Grapes, with full directions for all departments of Propagation, Culture, etc., with one hundred and five excellent Engravings, illustrating the various operations of Planting, Training, Grafting, etc. By ANDREW S. FULLER, Practical Horticulturist. Cloth, 12mo., 262 pp.

ORANGE JUDD & CO.,

41 Park Row, New York.

SENT POST-PAID ON RECEIPT OF PRICE.

Warder's Hedges and Evergreens, \$1.50.

This is the only book wholly devoted to the cultivation, pruning, and management of plants suitable for American hedging, especially the Maclura, or OSAGE ORANGE; illustrated with engravings of plants, implements, and processes; to which is added a *Treatise on Evergreens*, their varieties, propagation, culture, etc. By J. A. WARDER. 12mo, 291 pp.

ORANGE JUDD & CO.,

41 Park Row, New York.

SENT POST-PAID ON RECEIPT OF PRICE.

NEW BOOKS.

QUINBY'S BEE-KEEPING.

By M. QUINBY, Practical Bee-keeper. Fully Illustrated. Entirely new. The result of thirty-five years' successful experience—with directions about Breeding, Hives, Pasturage, Apiary, Robbing, Feeding, Swarming, Queens, Pruning, Diseases, Anger, Enemies, Wax, Transferring, Sagacity, Wintering, Italian Bees, Purchasing, &c. Price \$1.50.

NEW BOOK OF FLOWERS.

By JOSEPH BRECK, Practical Horticulturist. Containing Chapters on the Utility of Flowers, Lilies, Seeds, Flowering Plants, Budding, Double Flowers, Colors, Bouquets, Protection, Training, Gardens, Lawns, Rockwork, Aquarium, Parlor Plants, Potting, Insects, Bulbous Roots, Perennials, Annuals, &c. Beautifully Illustrated. Price \$1.75.

MINIATURE FRUIT GARDEN.

By THOMAS RIVERS. Illustrated. Or, how to raise many kinds of fruit on small trees, with full directions for Training and Culture. Pyramidal Pear Trees on Quince Stock. Summer Pinching. Compact Pyramids. Root Pruning. Pear Trees as Bushes. Pears adapted to Bush Culture. Protectors for Bush Pear Trees. Cordon Pears on Trellises. Espalier Pears on Quince Stocks. Pear Tree Hedge. Planting and after Management. Bush Pear Tree for a Market Garden. How to Store Winter Pears. Pyramidal Apple Trees. Apples as Bushes. Twenty Desert Apples good from July to June. Twenty Kitchen Apples fit for use from July to June. Pyramidal Plum Trees. Cherries as Pyramids. Filberts and Nuts. Figs on Bushes. Double Grafting. Peach Tree Borders, etc., etc. Illustrated. Price \$1.00.

SAUNDERS' DOMESTIC POULTRY.

By S. M. SAUNDERS. New Edition Revised and Enlarged. Containing Articles on the Preferable Breeds of Farm-Yard Poultry, Their History and Leading Characteristics, with Complete Instructions for Breeding and Fattening, and Preparing for Exhibition at Poultry Shows, etc., etc., derived from the Author's Experience and Observation. Very fully Illustrated. *Golden Rules*.—Never over feed. Never allow any food to lie about. Never feed from trough, pan, basin, or any vessel. Feed only while the birds will run after the feed, and not at all if they seem careless about it. Give adult fowls their liberty at daybreak. Never purchase eggs for hatching purposes until a hen is ready to sit. For seven or eight days before hatching, sprinkle the eggs with cold water while the hen is off. This will prevent the frequent complaint that the chicken was dead in the shell. Price, paper 40 cts., cloth 75 cts.

MY VINEYARD AT LAKEVIEW;

Or, Successful Grape Culture. Contents: The Suggestion, Making a Change, Going West, Getting Settled, First Experience, Varieties, Planting a Vineyard, Propagation of the Vine, Soil and Situation, Preparation of Soils, Manures, Pruning and Training, More about Training, Autobiography of a Vine, Brief Expositions. Illustrated. Price \$1.25.

PEAT AND ITS USES.

By Prof. Samuel W. Johnson, Yale College. —Part I. Origin, Varieties and Chemical Character of Peat. Part II. The Agricultural Uses of Peat and Swamp Muck. Part III. Peat as Fuel. Illustrated. Price, \$1.25.

Published by

GROUP OF HIGHLAND CATTLE. — FROM A PAINTING BY ROSA BONDHEUR.

It is perhaps not too much to say that Rosa Bonheur stands at the head of the animal painters of the world, especially as a painter of domestic animals. Her tour through the Highlands of Scotland a few years since brought the picturesque cattle of that wild region to her notice, and she has made several striking pictures, one of which we copy, as the best representation we can find of this breed. These West Highland cattle furnish the best beef that is brought to the London market. It is best,

because the fat and lean are so intimately mingled, the best parts being thoroughly marbled, and because the choice cuts are large in proportion to the size of the animal. They are brought from the coarse feed and hard pastures of the mountains and fatten rapidly in the low lands, which is one cause of their excellence. We believe a few of them have been imported to this country, but as yet they have made no mark. Their fitness for the rough country of northern New England, New

York and Canada has never been proved. They are, however, good in the yoke and fair for milk. This spirited picture shows the fine forms of these cattle, their rough and shaggy yet soft coats, and their great vivacity, which comes naturally from their half-wild character. Their carcasses are deep, well ribbed out, round and full; their bones and heads small. It is morning in the highlands; the mists just clearing away; and the sense of frostiness, which pervades the original, is well preserved in our engraving.

AMERICAN AGRICULTURIST.

NEW-YORK, SEPTEMBER, 1866.

September comes with the promise, and almost the full fruition, of abundant harvests of all kinds of crops. The summer harvests were reported variously from different sections, but on the whole, we believe, the amount of wheat, oats and barley is fully up to the usual average, as well as to just expectations. The hay crop is a little short on an average, and in some sections it will be imperatively necessary for farmers to make the most of the straw and corn fodder, and while we refer to an article on page 321 on corn fodder, let us drop the hint that it is easier and cheaper to buy straw at this season than at any other, especially if the buyer will take it away as fast as it is thrashed. Corn fodder is best bought at husking time, especially if the husking is done at the shocks in the field.

This month and the first part of October is the time for Agricultural Fairs. Every day, "Sunday's excepted," from the 4th of September to the 20th of November is devoted in some place or places to an agricultural fair. It is particularly unfortunate that so many are held upon the same days, so that people are in straight as to which to attend and which to neglect. This might all be obviated by a little correspondence, or if the Secretary of the United States Agricultural Society, which we believe has existence enough to meet and elect officers, would take the matter in hand. We can hardly urge too strongly upon farmers to plan to go themselves at any rate, and take one or more of their sons, to one or two of the best county fairs near their homes, and if possible to go to the State fair also. There is a great deal to learn, the knowledge of which will make a man a better farmer, help put notions of leaving the farm and going to the city to be a merchant out of the boys' heads, giving them an interest in their own profession, and an ambition to raise as fine grain, fruit and vegetables as they see, and to have improved implements and well-bred stock.

We know that there are men who would rather not have their boys get such notions, and think that the old ruts are smooth, easy going, and good enough, but these are men who think in ruts as well as work and run the farm in them. The boys will think, and read and see, and it is harder to keep them in the ruts than the old fogys think.

There is a great deal of work to be done in September, but it is not all of that driving, hurrying kind like much of the summer and spring work.

Hints about Work.

The crops that now require especial attention are :

Buckwheat, which must be cut before frost hurts it, and if put up in neat gaves, the tops being bound to shed rains, will go on filling out, so that, though very few grains may have been fully formed at the time of cutting, there will be few not filled out at the end of a few weeks,—and

Tobacco, which is hopelessly damaged by a slight frost. If tobacco has grown well, the greater part of it will have been cut before the end of the first week in September. See hint about harvesting given last month. The way of hanging most economical of space of any we have ever seen, was described in March, 1864, and is well worth the attention of tobacco growers.

Root Crops may generally at this season receive some attention. Weeds should be pulled when they appear, and the ground kept clean. The soil may often be stirred, especially among carrots, to great advantage, and the best way is to run a sub-soil plow midway between the rows. Turnips need hoeing and thinning, and cabbages constant hoeing.

Potatoes.—The decay of the vines indicates the maturity of the potatoes, and early sorts may be dug and housed at once; but if there is any appearance of rot, leave them in the ground. It makes less work to dig only the sound ones, and the decaying will be chiefly over before the last of October; however, it may pay to dig and market early.

Corn, which promised so very little in July, probably never looked better in August than this year. It is only a little late. Do not top it so as to expose the ears to the frost, certainly not until it is thoroughly glazed. Read an article on page 321 on corn fodder. Go through the best pieces to

Select Seed Corn.—Trust this to no hired man, but do it yourself. Select by feeling ears a little above medium size (no monstrosities), close, firm, well tipped over, tight and full at the butt. Mark these in some way, as with a dab of paint, or by tying a string around the ear. Then in the husking these may be unhusked, or broken off and then husked, leaving the husks attached. Finally select from these the well ripened ones, and those with fewest irregularities, false or short rows of kernels, and braid them up in strings for thorough drying.

Sorghum.—See article on page 316.

Seeding to Grass.—Grass seed may be sowed alone on good soil, on which fine compost has been harrowed in, and, if the ground is not both poor and clayey, will stand the winter well and do much better than if sowed with winter grain. Oats and buckwheat are occasionally sown as a protection to grass. The grain should be sparingly sown. It dies in the winter, but affords the grass a mulch.

Soiling.—Wheat and rye are sown this month for early soiling crops. Next spring, as soon as the rye is fit to be mown, its feeding daily will produce a very great difference in the yield of milk. This is the earliest crop. Wheat follows soon, then very late sowed rye, then spring sowed oats, corn, etc. The rye and wheat will be off the ground in time for summer crops, and as they do not seed, do not exhaust the soil perceptibly. It should be in good heart and tilth, however.

Wheat.—Sow wheat early. The soil should be well worked—not plowed below its natural depth. If sowed upon clover turned under, work in a liberal dressing of fine compost with a Shares' barrow, cultivator, or harrow. Guano, well mixed with fine muck or peat, brings forward rapidly that sown a little late, and causes it to tiller well this fall. By all means drill in the seed, if the ground be of even quality and consistency. If it is hard and clayey, and sandy or light in spots, sow by hand.

Weeds.—Burn every weed that has gone to seed. If fed to hogs, you fill the manure with the seeds.

Stacks of either hay or grain should be watched, and if they settle unevenly or the tops become disarranged by the gales, brace them and retop them. See article on page 277, last vol. (September, 1865.)

Vermin.—The granaries should be early freed from vermin, which will generally collect as soon as grain is stored. Insects must be removed before the grain is put in, when the bins, etc., should be most thoroughly cleansed and whitewashed inside and out. Rats are easily disposed of by using liberally the phosphorous paste. This has also some effect on the mice, but not so much, because, though it is poison and kills them, the mice do not go in communities as rats do, and can not be "stampeded." The paste gives some of the rats a severe colic and they alarm the rest, and so all are cleared out. This paste is very fatal to fowls.

Drainage.—The better the ditcher, the narrower does he make his ditch; broad ditches are only made by green hands. A ditch 3 feet deep should not be more than 14 inches wide, and one 4 feet deep (which is the best for common tile drains) not more than 2 or 3 inches wider. To do this, a set of good ditching tools is needed. Use round tiles if you can get them. Drainage water may often be used upon meadows lying on lower lands for

Irrigation.—The water of brooks, springs, etc., (the more permanent, of course, the better,) may be made the vehicle of untold fertility upon grass lands properly arranged to receive it. The water must never stand, nor flow over the soil, but through it, if benefit would be derived from irrigation. This is a source of wealth, as great as that which lies in the peat swamps, and one quite unbedded.

Neat Stock require no especial attention this month other than good care and good feed to prepare them for winter. None should be allowed to run down. Though cows coming in late for winter milking

should not get fat. Beef stock, which are to be finished off for market during the fall and winter, should have an increase of feed.

Hogs for fattening should be penned and fed old corn, ground and cooked. Let the pigs have the run of the orchards. "Taming" hogs by cutting a gash across the snout close to the rooting gristle, so as to make it powerless, is better than putting rings in their noses, and much more easily done.

Sheep.—Give good pasturage with water, salt and shelter from long storms. Fattening sheep should be making flesh fast, and "stores" kept improving.

Manure.—Collect all kinds of waste vegetable matter for increasing the manure heap; put into it no weeds having seeds. The hogs will work over an immense amount of weeds, sods, potato tops, etc., and convert the whole into excellent manure. An old farmer used to say, "he would give more for a cob that a hog had *breathed* on than for a shovelful of yard manure." The bulk and quality of hog manure, or any other kind, are greatly increased by having it all under cover.

Muck and Peat.—Secure as much as possible for use in mingling with manure, or under the stock in the stables this winter. Compost it with lime, if it be not now in a crumbly condition, for it should be dry and fine. Get out as much as you can, and leave it exposed for the action of the frost in winter. This is work for the whole autumn and winter when it can be done.

Orchard and Nursery.

Whoever sends fruit to a distant market, is obliged to pack it in barrels, baskets, or crates. It would pay those who dispose of the products of their orchards near home to take more pains than is usual. In our large towns and villages it is a common thing to see the body of a wagon without springs, filled with apples, pears and peaches, to be peddled out with no more care than potatoes. If those who dispose of only a moderate amount each year will place their fruit in bushel baskets or crates, and put in only good fruit, they will get an increased price that will in a short time more than pay for the packages. Fruit is too great a blessing to be treated in the careless way we often see. Fruit should be picked, especially if to go to a distance, while yet firm, but still fully developed. The old peach basket is now replaced by slatted crates, with two compartments of $\frac{1}{2}$ bushel each.

Dried Fruit.—Commence with the autumn apples and peaches. If the sun is depended upon, take pains to keep bees and flies away. It is better to have some kind of a dry house. One was described in June last. A room kept hot by a stove will answer better than no drying apparatus.

Budding is to be continued with all varieties, in which the stock and bud are in proper condition. See directions given in July. Look to those budded earlier, and if the bud has taken, loosen the bandage. If the first attempt has failed and the bark of the stock will lift, it may be rebudded.

Nameless Fruits.—A fruit without a name is much less valuable than if it had one. In almost every orchard there are more or less varieties of which the name is lost. In such cases, instead of inventing a name, as is too often done, take good specimens to the fair, or to some competent pomologist, and get the correct name.

Labels will be needed to mark rows as they are budded in the nursery, and to label trees as they are sent out or are set this autumn. These can be made on rainy days, or may be ordered of those who make them by machinery.

Planting.—If trees are to be set in autumn, do it early. Draining, manuring and plowing may be done this month. Select the varieties and order trees early. Attend all the fairs and pomological meetings, and learn the local success of varieties.

Seeds.—Gather seeds of trees and shrubs as they ripen. Pits of peaches and plums are best if not allowed to dry. Bury them in earth or sand.

Insects.—Wind-falls should be picked up and given to swine, and thus destroy the grub within

them. Pick off cocoons and all kinds of nests as soon as discovered. Borers, in working their way into the trunk, often show their tracks in the form of saw-dust or borings. When a borer is once in, use a knife and a wire or whale-bone probe and crush him, but it is best to prevent its going in by some of the appliances recommended in May last.

Weeds.—Keep the nursery rows clean by use of the plow and cultivator.

Kitchen Garden.

As soon as a crop of anything is off, gather up the rubbish and take it to the compost heap, or feed it to animals, if suitable. Leave no cleaning up until spring, which may be done in autumn.

Beans.—Limas are to be shelled and dried for next winter's succotash, and string beans, prepared as for cooking, are to be packed down in kegs or jars with alternate layers of salt and beans.

Cabbages and Cauliflowers.—The only way to get them early is to keep plants over winter in cold frames. Seed of the early sorts may be sown in the open ground this month, to furnish plants for this purpose. Keep the late crop well hoed, and if slugs appear dust with lime.

Corn.—Dry for winter. Save best ears for seed. When early sorts are gathered, remove the stalks.

Cucumbers.—Those for pickles need picking every day, or they will get too large—put them in brine strong enough to float an egg.

Celery.—Earth up, whether growing in trenches or on the surface. In earthing up bring the stalks together with the hand, and keep the earth out of the "heart" of the plant.

Endive.—Hoe growing plants, and when they are a foot across blanch them. Any way that will exclude the light and not stop the growth of the central leaves, will answer. The old way is to tie up the outer leaves over the center; another is to gather and cover with a flower pot. The usual plan in market gardens is to cover it with a mat.

Kale.—Sow hardy variety, called German Greens.

Manure.—The compost heap should increase from the abundance of garden refuse. Act on what has been said in this and previous numbers upon utilizing the contents of privies.

Melons.—Turn to ripen both sides. When fit to pluck, the stem parts with a slight pull. Put the fruit on ice for a few hours, before it is sent to the table.

Onions.—When the tops fall down, harvest them. Let them dry thoroughly before storing and spread them thinly in a cool dry place.

Radish.—Sow the Chinese Rose Colored Winter early this month. It will keep all winter.

Spinach.—Sow in drills 15 inches apart, and thin and weed as soon as the plants are large enough.

Sweet Potatoes.—Some of the larger roots may be carefully taken out, and smaller ones left to grow.

Squashes.—Keep on the lookout for insects. Allow the vines to root at the joints. The Hubbard, when green, is better than any summer squash.

Tomatoes.—Cut away superfluous growth. The larva of the Hawk-moth, a large green "worm," will be abundant this month, and it makes a clean sweep of leaves and fruit. Its presence is betrayed by its droppings. When these are seen, search for the enemy. Preserve plenty of tomatoes in bottles and jars for winter, and make catsup.

Turnips.—Sow the round sorts early in good soil. Give Ruta-bagas frequent hoeing.

Winter Cherry.—The hulls turn yellow when they are ripe; gather and keep in a dry place. They make a most excellent sweet-meat, and are often called strawberry tomato, from their fruity flavor.

Weeds.—Let none seed in out of the way corners.

Fruit Garden.

The suggestions as to preparing for autumn planting, about insects, weeds, etc., under Orchard and Nursery, apply equally to the Fruit Garden.

Blackberries.—The strong shoots for next year's fruiting should be shortened at the height of 4 to 6 feet. This will cause fruit branches to be thrown

out, which may also be stopped if making a very rampant growth. Remove old canes when the fruit is off. Two or three canes are enough to a stool.

Grapes.—As the early varieties ripen, the birds will find it out. We believe nothing short of powder and shot is found effectual in keeping them away. It is a hard remedy, but the choice lies between that and no grapes. The fruit may be sent to a near market in shallow boxes, about six inches deep. Pick with a long stem and handle carefully, so as not to injure the bloom. See p. 223. Enough was said on mildew in previous months.

Pears are to be gathered as soon as ripe and before they mellow. A little experience will determine when to pick. If taken from the tree too early, they will shrivel instead of ripening. Spread upon shelves in the fruit room to ripen.

Raspberries.—Keep the soil free of weeds, and allow only two or three canes to grow to the stool. Remove the old wood, if not already done.

Strawberries.—Early this month is the best time for autumn planting. For culture see last month.

Flower Garden and Lawn.

The cool nights, and less severe heat of the days, will allow many things that were burned in mid-summer to take a new start; the garden should now be brilliant with these and late blooming varieties.

Bulbs.—Hyacinths, Tulips, Crocuses, etc., should be purchased as soon as the dealers offer their stocks, as the best ones are soon disposed of. Set them the last of this or early next month.

Bedding Plants.—As a general thing it is much better to start new plants from cuttings, or layers, than to take up old ones. Yet there are some shrubby ones, as Lantanas, Fuchsias and Heliotropes, that it is desirable to keep. They should be potted before the weather gets too cool.

Chrysanthemums.—Do not allow them to become too crowded; thin out the weaker shoots. They are very fine for house decoration, and last a long time in flower in a cool room. Some for flowering in-doors may be potted this month.

Dallias.—Cut out all imperfect buds, and remove flowers as soon as they begin to wane. Continue to stake and tie whenever needed, else a strong wind will make short work of the plants.

Lawns.—Pull out coarse weeds, re-seed bare places, and give an occasional mowing.

Perennials and Biennials.—If seed be sown early this month, plants will be had strong enough to winter over and bloom next year—Columbines, Campanulas, Lackspurs, Pentstemons, Phloxes, etc.

Pits.—A flower pit will allow of saving many half hardy plants. A pit 6 feet deep, with the sides boarded up and covered with sash, and shutters, will answer as well as a more expensive structure. It should be well drained and the mice kept out.

Seeds.—Save from the best and earliest flowers, and label as soon as gathered.

Violets.—To have them early in spring, they should be set in a frame early this month. A common plank frame with sash, is set in a sheltered and well drained place, on well manured fine soil. Set out the violets, and keep the sash off until frosts come. Then cover the plants lightly with leaves, and put on the sash and cover with mats on cold nights. They may be started into bloom at any time after midwinter, by removing the leaves and giving them plenty of sun.

Green and Hot-Houses.

If repairs, cleaning and painting have been put off until now, have the houses made ready at once, as they may suddenly need to be occupied. Indeed many of the more tender plants had better go in this month at any rate.

Sow Annuals and plant Cape bulbs, Oxalis, etc., for winter blooming.

Callas.—Divide and repot. It is always well to have an abundance of them; they are so useful in decorating the green-house or dwelling.

Camellias.—If the flower buds are so thick as to crowd, remove a portion. Clean the foliage with a damp sponge, and repot if needed.

Bringing in plants from out of doors will be governed by the locality. Take in the more tender ones first. Clean the pots thoroughly, and renew the surface soil. Remove dead leaves, trim and stake those needing it, and renew defaced labels.

Cold Grapery.—The fruit is now generally ripe, except perhaps some very late varieties, and the atmosphere of the house is to be kept dry. Ventilate freely in fine weather, but close up during a storm. Keep a look out for rats and boys.

Apiary in September.—Weak stocks at this season simply waste honey, and tempt other bees to rob them. While buckwheat is in blossom, there will be little robbing, but as soon as it fails, there will be several hives emptied very quickly, unless watch is kept, and the weak stocks strengthened or protected. Leave no honey where bees can get at it. When bees can protect the entrance of their hive, they will do so, hence make the fly-holes of weak stocks very narrow. When bees are robbing and a stock succumbs, the conquered party turns about and helps the victors remove the spoils. If a stock is found with abundant supplies of honey, yet weak in bees, it may be strengthened by placing it upon the stand of a strong hive when many of the bees are out. If a queen is wanting, a frame of brood comb with fresh eggs may be supplied, in case the drones are not all killed, or a weak colony with its queen may be united with the queenless one. Very few bees furnish the strongest indication of queenlessness. Stocks which have honey, and which it is decided not to winter, should not be broken up until all the brood is hatched and matured. The bees may then be added to other stocks, and the clean empty combs set away for use another year. Surplus honey boxes should be taken off as soon as bees cease to store in them, or they will empty them soon.

Agricultural Fairs for 1866.

American Pomological Society.—

Postponement—Just as we are going to press we receive the following circular, signed by the Hon. Marshall P. Wilder, President:—"Whereas, The American Pomological Society was ordered to be convened at St. Louis, Mo., on the fourth day of September next, for the purpose of holding its Eleventh Session; and, Whereas, the existence of Cholera in several of the cities of the United States has become manifest, thereby creating more than usual precaution in regard to visiting places distant from home; Therefore, in consideration of this fact, and also of the fact that there is a small crop of fruit in many parts of our country, the undersigned, by and with the advice of the Executive Committee and other leading Pomologists, does hereby postpone and defer the meeting of said society to the year A. D. 1867, when due notice will be given for its assembling, in the aforesaid city of St. Louis.—This will carry disappointment to a great many, and we think the action is hardly based on sufficient reasons. In New York we too have cholera, and don't mind it at all. It is a disease of the poor and miserable only, and to postpone an important meeting on so slight an excuse, strikes us as something particularly absurd.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for a month, ending Aug. 11, 1866, and the exports of Breadstuffs from this port thus far, since January 1:

1. TRANSACTIONS AT THE NEW-YORK MARKETS. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. 24 days this m'th, 233,500 36,300 3,820,000 115,000 23,000 1,292,000

SALES. Flour, Wheat, Corn, Rye, Barley. 24 days this month, 181,000 447,000 3,867,000 153,000 18,300

2. Comparison with same period at this time last year. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats. 24 days 1866, 332,500 363,000 3,820,000 115,000 23,000 1,292,000

SALES. Flour, Wheat, Corn, Rye, Barley. 24 days 1866, 181,000 447,000 3,867,000 153,000 18,300

3. Exports from New-York, January 1 to Aug. 11: Flour, Wheat, Corn, Rye, Oats. 1866, 589,300 167,036 7,548,273 187,189 894,602

4. Receipts at head of tide water at Albany, to Aug. 7: Flour, Wheat, Corn, Rye, Barley, Oats. 1866, 114,400 1,490,500 10,435,600 473,000 105,300 4,194,000

CURRENT WHOLESALE PRICES.

Table of current wholesale prices for various commodities like flour, wheat, corn, rye, and oil, listing prices for July 13 and August 11.

Gold has been declining in price, during most of the past month. Within a week it has been as low as 146 3/4, as against 151 1/2 at the date (July 13) of our last review. It opened to-day @ 148 1/2. The demand for the principal kinds of breadstuffs during the month has been less active, and under urgent efforts of holders of both flour and grain to realize, prices rapidly receded.

New York Live Stock Markets.

The supply during the past four weeks has been very good for this season of lowest demand, as here shown:

Table showing weekly average for beef cattle, milch cows, and veal calves, listing weeks ending from August 7 to July 17.

The weekly average for beef cattle, milch cows, and veal calves is just about the same as for all of last year, while this is the season of least demand; sheep, including lambs, 2000 higher, and live hogs 3700 less. The generally increased consumption has kept prices well up. Beef Cattle were materially higher last week, but this week sell about the same as a month ago.

WANTED FOR 1867,

200,000 Subscribers!

Or, Better Still,

One More from each Present Subscriber.

HOW WE PROPOSE TO GET THEM.

A Splendid Paper for All; Great Premiums for Clubs; Extras to New Subscribers.

Everybody Read The Following:

The great success of the present year encourages the Publishers to renewed effort for the coming year, and to begin the work in advance. They propose to secure at least 200,000 Subscribers for 1867.

1st.—The present Volume speaks for itself. Our readers know how much, and how valuable matter has been given so far—how many thousands of Hints, Suggestions, etc. And aside from the reading matter, every Subscriber, at the expense of only \$1.50 or less, receives in this Volume Engravings which alone cost about Eight Thousand Dollars!

to make it even much better, just as we are making this Volume better than the preceding one. So every subscriber for 1867, new or old, may confidently expect a great deal for the little currency it will cost.

2d.—The Publishers will Pay every

Person Well, who will take the little trouble and time required to bring the Agriculturist to the notice of those who do not now read it, and obtain their subscriptions. To do this in the simplest manner, without the trouble of correspondence, and to give everybody an equal chance, they will offer a large and valuable General Premium List of good and useful articles, from which each one sending a club of subscribers may select just such articles as he may desire, such as Seeds, Vines, Plants, Trees, Implements, Machines, Books, Melodeons, Pianos, extra plated beautiful Tea Sets, Pitchers, Castors, etc., etc.

3d.—What every new Subscriber

during September will Receive: Any new subscriber sending in this month the regular subscription price will receive the Agriculturist for all of 1867 (volume 26), and the last three months of this year FREE.

N. B.—This offer applies to all new subscribers received in September, whether single names, or members of ordinary clubs, premium clubs, or otherwise. Thus: \$5 will pay for four subscribers for 15 months (October 1866 to December 1867 inclusive), and so of all other club rates.

Sufficient time will be given after September 30 for responses to this offer to come from the Pacific States and Territories, and other distant points. Will our readers please show this offer to friends and neighbors, and invite all to embrace it?

The Implement Trial at Auburn.

The officers of the N. Y. State Agricultural Society have undertaken to conduct a trial of Mowers and Reapers, which would fairly test these machines in such a way, and in so many different ways, that after their report is before the public, every one giving careful attention to it may be able intelligently to review every step of their progress, and pass a fair judgment upon their conclusions.

The trial commenced upon the 10th of July, with the understanding that the committee would stick to work as long as was necessary. The Society was ready on the day appointed, but the exhibitors were most of them behind hand, causing fully 24 hours delay, and no small annoyance and expense to those who came from a distance. The names of the judges are as follows:

HON. JOHN STANTON GOULD, *Chairman*, Hudson, N. Y.
 Col. B. P. JOHNSON, Albany, N. Y.
 SANFORD HOWARD, Esq., Lansing, Michigan.
 E. R. POTTER, Esq., Kingston, Rhode Island.
 Prof. PIERCE, Harvard University, Cambridge, Mass.
 HON. ELISHA FOOTE, Esq., Washington, D. C.
 HENRY WATERMAN, Esq., Hudson, N. Y.
 HON. EZRA CORNELL, Ithaca, N. Y.
 HON. SAMUEL CAMPBELL, New York Mills, N. Y.
 HON. A. B. CONOER, Haverstraw, N. Y.
 T. L. HARRISON, Esq., Morley, N. Y.

They are gentlemen who are so well known and respected, that no one will think of such a thing as charging intentional partiality to any one of them. The competitors are, we think, perfectly satisfied that the committee mean to deal fairly by them. The Dynamometer (the instrument used for testing the draught), employed is a triumph of mechanical ingenuity, and is the invention of Mr. Waterman, a member of the committee who has successfully used a larger one several years in testing the draught of locomotives. The instrument acts independently of jerks, equalizing and measuring their force, it records the distance traveled over, and the power expended, so that after a load, or machine has been moved any distance, it may be seen at a glance how many feet the same outlay of power would have lifted 1000 pounds perpendicularly, if it had been so applied. We hope soon to give our readers a description of this interesting machine, with illustrations.

There were 57 entries of Mowers and Reapers, including several entries from the same parties in each of the different classes, as for instance, the same exhibitor would show his machine as a mower, as a self-raking reaper, as a hand-raking reaper, as a combined mower and reaper, and as a one-horse mower—presenting of course as many different machines.

The writer was present the first days of the trial, but could not remain throughout. The field work commenced on the 11th, and was continued for more than two weeks. The mowers were tried first in a piece of badly lodged clover, each cutting an acre, and starting four at a time. The Kirby was the only 1-wheeled machine we saw, and there was one. The Eureka, of novel construction, which struck us as having some very good points. The wheels are set as wide apart as the length of the 5 or 6 foot cutter bar which is between them, and the horses travel 6 feet or more apart, one close to the grass and the other in the standing grass. The grass, if heavy, is left nearly erect. All the most popular machines were represented, and the work done, both in the field mentioned, and in others, in grass of diverse quality, was prevalently excellent. The dynamometer tests have not been made public.

In the grain fields, so far as cutting went, of course all the machines did well. The great interest centered in the modes of disposing of the cut grain. *Hand-rakers* worked well, why should they not?—Some of the *Self-rakers* did well, but not up to the mark. The *Droppers* merited and obtained considerable attention and favor. These receive the cut grain upon a series of long fingers extending backward at right angles to the finger bar, and when a sufficient quantity has been accumulated for a sheaf, the fingers are dropped and the stubble pressing up between the fingers sweeps the gavel off, while by a simple contrivance the falling grain is caught and held, until the dropper is brought into its place again. This plan has the merit of cheapness and great simplicity. There was also a very interesting machine exhibited before the committee, but not placed in competition, upon which two binders riding, bound the grain as fast as it was cut. It is the invention of C. W. Marsh, made by Stewart & Marsh (Plano, Kendall Co., Ill.). Stewart, an exceedingly rapid and expert binder, rode alone and bound the wheat for a short time as fast as cut, when the machine was driven very slowly. On the whole, the hand-rakers are regarded as a thing of the past, the droppers will probably take their place, and people will not be satisfied with self-rakers which do not deliver to binders upon the machine. The trial was a very tedious one, much more so than was necessary. Some members

of the committee evidently lacked practical sagacity: and the committee needed a good foreman, one who would do no work himself, but simply direct others and make things go with spirit. Still we have no doubt of the great value of the results, which will be quite as great for the manufacturers as for the purchasers. The report is not looked for before the State Fair, and we presume it will hardly be given in full at that time.—During the mower and reaper trial, other implements, hay tedders, hay forks, presses, horse-forks, hay loaders, etc., were exhibited, and after the trial they were examined and tested by the committee.

Containing a great variety of items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each, for less than four copies; Four to nine copies, \$2.25 each; Ten to nineteen copies, \$3.00 each; Twenty copies and upwards, \$1 each. An extra copy to the sender of a Club of Ten or more (if no other premiums are taken). The papers are addressed to each name furnished.

GIVEN AWAY—Three Months' Subscription for Nothing!—By reference to the preceding page will be seen that the Publishers offer the *Agriculturist* for the last three months of this year free to all new subscribers for 1867 received at any time in September.—We respectfully request all our readers to make this offer extensively known, and to invite their friends and neighbors who are not now subscribers, to embrace this opportunity to become so. They will get the paper **15 months for one year's subscription price**. Clubs can now be made up, at club rates for next year, embracing old and new subscribers, and the new subscribers will all get the extra numbers free, **provided the new names be so marked**.—In making this offer, the publishers have several ends in view: 1st, The extra offer is an inducement to many persons who ought to read a paper of this kind, but who hesitate to subscribe; 2d, Every one who reads this journal for a month or two will doubtless be ready to influence still others to subscribe at the opening of the new volume; 3d, Every name, new or old, received now, can be entered and properly arranged on the mail books while our experienced clerks have leisure, and by so much lessen the pressure of business towards the close of the year, when more than a hundred thousand renewals are to be attended to. This last item will partially pay the expense of the extra numbers. So we solicit the kind offices of our friends in swelling the list of new subscribers this month. The extra numbers free will go far in deciding the question of subscribing with many persons, if some one will inform them of the offer.

GOOD PREMIUMS for all who Desire them.—This Month a good Time to begin.—The publishers are preparing a list of excellent articles to be given to those who make up clubs of subscribers for 1867. The list is delayed to make it as complete and valuable as possible. It will be completed during this month with full descriptions, and be sent free to all desiring it. It will contain many valuable articles one or more of which will be specially desired in every family. Any one can begin at once to make up a list of subscribers, and then choose the premium afterwards when the list is made as large as possible. Old and new names will count in the premium clubs, but the extra offer to new subscribers, noted above, will aid in securing new names this month. The extra numbers are given to new members of premium clubs, the same as to others. **N. B.**—Every list of names designed for a premium club must be so marked when sent in, and it will then be credited to the sender in the premium book. Send the names along as fast as obtained, so that the subscribers may begin to receive their papers. To avoid error, and save keeping wrong accounts, let the exact subscription money accompany each list of names. The best mode of remitting money is by Post-office money orders, or drafts on New York Banks, payable to order of the publishers.

Start the Premium Clubs at the Fair, Elections, etc.—These annual gatherings afford a good opportunity to those who wish to secure one or more of our good premium articles, to begin the work. Last year many persons collected names enough to secure premiums worth from \$10 to \$60, by a single day's work at the fairs.

Government Land and Land Offices—We have a good many letters asking where the best Government lands are located. We privately could

not express our own preferences without getting a flood of letters assuring us that the lands and prospects in a dozen other sections were equal or superior. In most of the new States, and those recently the seat of war, the people are anxious to have settlers from the old States come among them, and a letter to the Governor or Secretary of State, of the State preferred would receive attention, and reliable information would be given.

Trouble with the Grape Leaf.—A. F. Gillett sends us a grape leaf, upon which are many rough protuberances, asking what the trouble is. If he cuts these open, he will find a minute larva within. We have seen this several times, but never where we could watch its development and ascertain what the perfect insect is.

Saratoga.—This resort of fashionable people and invalids, who crowd its hotels and one another from June to October, seeking health in its saline waters, or amusement in the society they there form and find, this year offers an attraction to the farmers in having secured the State Fair. The fair promises to be of unusual attractiveness, and there are many things to interest and entertain outside the fair grounds, of which we are pleasantly reminded by the "*Views of Saratoga*," published by J. Nelson & Son, New York, with an historical and descriptive sketch by Wm. L. Stone. These are a dozen colored lithographs, and form not only a pleasant souvenir, but a guide book to Saratoga, which will be of value to visitors.

"The Might of the Republic."—Wm. O. H. Oldroyd, of Columbus, O., a soldier during the whole of the late war, has prepared an interesting sheet. He secured *carte de visites* of 110 of the leading public men of the past half dozen years, including military men, statesmen, divines, etc. Upon these were secured the actual autographs of the individuals themselves, and then the whole were arranged together, and copied in a large photographic picture, on a sheet 20x24 inches. Framed and hung in the parlor it is a neat and valuable ornament, giving us the pictures and autographs of each of the 110 men at a moderate cost—\$3, or \$6 if placed in a neat walnut and gilt frame and glass.

\$1.50 pays for a copy of the *Agriculturist* for all of 1867, and a new subscriber sent this month will receive the paper free the last three months of this year.

\$5 pays for four copies of all of 1867, and each new subscriber will receive the rest of this year free. The same rates for five, six, seven, eight or nine copies.

\$12 pays for ten copies for all of 1867, and each new subscriber will receive the remainder of the year free. The same rates for any number of subscribers up to nineteen. A free copy to the sender of the club.

\$20 pays for twenty copies for all of 1867, and each new subscriber will receive the paper the remainder of this year free. The same rates for all copies over twenty. A free copy to the sender of the club.

Hog Cholera.—I. Plaquet, Ills., F. S. Haskell, Mass., S. B. Peck, Mich., and others.—The following will answer your queries, in regard to a remedy concerning which many theories are better known than how to cure it.

Many names have been applied to this disease, it being known in various parts of the world as "Blue Sickness," or "Blue Disease," "Pig Distemper," "Red Soldier," and "Hog Cholera," and veterinarians have theorized much on its nature. It first affects the digestive organs; the blood undergoes changes favorable to transudations, which occur in different parts of the body.

Symptoms.—The first thing that generally directs attention to the disease is the sudden death of one or more pigs. On a closer inspection the animals are noticed to be dull, caring neither for food nor water, creeping beneath the straw or into some dark place; the head is held low, and the ears drooping. Signs of abdominal pain are often well marked, and, as a rule, there is a disposition to lie on the belly. The animals are under some circumstances wild, frantic, or quite unconscious. There is occasionally violent retching or vomiting of food or mucus, and bile. In the early stage, the feces are of normal consistence; urine, pale; later, diarrhoea sets in, excrements becoming dark and fetid. The pulse beats from 100 to 120 per minute, the action of the heart being barely perceptible. A staring look, tendency to press on the abdominal organs, rolling about, inability to stand, etc., are indicative of increasing pain. There is a singular jerking or spasmodic breathing in all cases, complicated by congestion of the lungs. A marked weakness of the hind quarters is observed from the commencement of the attack. The animal staggers, its limbs cross each other, and at last are paralyzed. It can not squeal or grunt, and there is a sublethal hacking cough. Blood settles in the skin more or less over the whole body, discoloring the skin and mucous membranes sometime before death; this gave origin to the name "Blue Disease."

The red-lash or purplish color disappears wherever the skin is pressed; an eruption is apt to appear, and the skin becomes scurfy. Death occurs in from three to six hours.

Post mortem appearances.—The skin black and blue; the capillaries, veins of the skin, and subcutaneous tissue are dark-colored and gorged with blood. A yellow serum is apt to accumulate wherever there is the ramified redness. The serous and mucous membranes are studded with ecchymosis (patches where blood settles), which are most developed in the organs of the chest. The intestine is stopped occasionally with solid material. The liver and spleen are full of blood, and the lungs also may be much congested. The blood is dark, serous, fluid, and coagulates very slowly and imperfectly.

Prevention and Treatment.—Wholesome vegetable diet, a sparing allowance of only well cooked animal food and cleanliness, with clean and dry bedding, are the best preventives. When the disease breaks out, send for a well educated veterinary surgeon or a physician. If one is not to be had, an emetic in the first stage of the disease may be given, followed by a gentle purgative or clyster; well-made gruel should be the only diet.

Clover.—"P." Laconia, N. H., says his clover has run out, and he does not wish to break up the sward. If he can get it in again without. We would try sowing clover seed, then harrow, sow plaster, and roll, or drag it all over with a heavy bush harrow if you have no roller.

Grass for a Grove.—"F. J. C." writes to sow grass seed in a grove of Chestnuts and Black Oaks, 25 to 40 feet apart, and some nearer together.—He can not do better than to break up the old soil and sow Blue grass, or Blue grass and Orchard grass mixed.

English Seeds.—Seed dealers will not fail to notice the advertisement of the house of James Carter, Dunnett & Beale, upon page 333 of this paper. The name of Carter as connected with the seed trade is familiar to all who read English Agricultural and Horticultural papers, and their reference to well-known dealers here shows that they have established a good reputation upon this side of the water. They are alive to their own interest in selecting a medium through which to become widely known to the American seed trade.

Thanks to Cyrus W. Field.—August 14th 3 o'clock P. M. We are now realizing the transactions in London and Paris, of *To-day Noon!!!*

Extra Size.—This number, like all but two of the previous numbers of this year, has several extra pages. It now looks as if we should be obliged to "keep doing so all the time."

Sundry Humbugs.—The swindlers are having a hard time of it. The *Agriculturist*, and the talk it has raised, meet them in every corner of the land. Then the N. Y. City Post-Office shut down on them, and after July 1st none of the known or supposed fraternity of rascals could get a P. O. Box. This of course compelled the chaps to call in person and prove their identity, or to have an actual place of business to receive letters from the carriers—a fatal thing to the greater portion of them, as they had hitherto dodged detection by having only a nominal place of business, and a P. O. Box. We are glad to learn from the Post-office here, that the letter business of these operators has fallen off to less than a tenth of what it was a few months ago. We have ample proof that in its warnings, and its exposures of these swindlers, the *Agriculturist* has saved to the people the present year, at least five times as much as its entire subscription has cost. We shall try to be faithful in this respect in the future, and we solicit a copy of every circular or scheme that comes out hereafter. Not much need be added about particular cases this month. . . . D. Miller, of the "Depository of the Mechanics and Manufacturers' United Stock Company" has been operating somewhat. His "\$150," "\$165," "\$300," etc., prizes have been scattered around freely. We have a score or two of them on hand. For the \$5 paid for these he sends, as prizes, some poorly printed "certificates" of a great many shares in the "Sandy River Petroleum Prize Company." What's that, and where is it? We have some of these certificates—one for 390 shares sent to Ross County, O., as the "\$300 prize" drawn by Mr. —; another for \$165 (165 shares in the S. R. P. P. Company) sent to a Massachusetts Legislator, etc. As we said last month, this is "a rig swindle." . . . We have lots of tickets, issued by different operators, for watches "valued at" \$18 to \$750, and have by proxy called on all the parties that could be found (not one-fourth of them are where their circulars and tickets say they are), and not one of the watches was worth the small sum asked for the tickets. The same of other articles of jewelry, etc., etc. . . . The "honey manufacturer" is a humbug; \$5 is asked for a recipe, which we published several years

ago and condemned. . . . Humbug "Mackey & Co.," and M. Morphy & Co. issue precisely the same circulars, except the heading and names, both printed from the same type! . . . The sewing machines offered by tickets, and the "English Time Keepers" are worthless. . . . The Washington "Grand National Concert," as stated last month, was a simple pure "lottery," operating upon the benevolence of people. . . . Westbrook & Co., of N. Y. City, send three different schemes in one envelope. They say their "Manufactory is not accessible until further Notice." Will they not hurry up that "notice" and let us in to see the grand things. They offer "Phot's of 50 voluptuous Female Beauties!" . . . Parkinson & Co., in the "ticket" line of business, feel dreadful bad at being refused a Box in the N. Y. P. O., and issue a "smashing" circular against said Office. Parkinson & Co. must be splendid fellows, and wonderfully rich and generous. . . . too, for in one of their circulars we find 128,000 articles, valued at \$6,800,000, or \$53 each, all offered for \$5 each! or less than one-tenth of their value." Why! they offer at \$5 each, "500 solid gold hunting watches valued at \$300 to \$750" a piece, and another "500 watches valued at \$250 to \$500" each! We found their magnificent establishment to be a small upper room, and could but wonder where they keep the 3500 watches, the 1000 music boxes, the 1000 silver dining sets, the 1500 silver tea sets complete, the 2000 silver urns and salvers, the 2000 richly framed oil paintings, the 3000 mammoth photographic albums, etc., etc. That little upper room of their's must be a wonderful place. Wish we could see something beyond that "talking hole" in the partition, through which they do business with callers. We would give the price of several \$5 tickets to have one look at half the things they claim to be distributing; it would be a bigger sight than all Paris affords. We strongly endorse the advice of Parkinson & Co.'s, (*alias*, Hubbard, *alias* Gaughan.) as in their circular they say "we [P. & Co.] beg of you not to make any remittances by mail."

About Pickles.—With pickles for family use there is no difficulty, but many who raise cucumbers on the large scale for profit, there is a doubt as to how they shall dispose of their crops. Many have gone into the raising of cucumbers for pickles, from reports of the large returns of some few cultivators. Those who within our knowledge have made pickle-raising the most profitable are those who, living within easy distance of the great pickle factories, could find a ready sale for their crop. The putting up of pickles and canning tomatoes, and the like, is a regular business, and is prosecuted by those who have the experience and capital, on so large a scale, that it is not advisable for small operators to attempt to compete with them. Growers of cucumbers, tomatoes, and the like, who are near these large establishments, meet with a ready sale for the raw material. There is another class of growers who live within a few days by rail, who find a market for their cucumbers by slightly salting them. These put up their cucumbers in tight barrels, with a half peck of salt, then fill the barrel with water and bung it up. In this weak brine the cucumbers will keep a week or two, but if allowed to remain much longer they will get slimy. This is the way in which growers send the cucumbers to not very far distant factories. To put up cucumbers to last for a long time, instead of four quarts of salt to the barrel, at least a half bushel should be used. A brine of this strength, in tight barrels, will, as we are informed by an old pickle maker, keep them for an indefinite time. For family use, when small picklings are made daily, it is as well to dry salt the cucumbers. They will give out their water to make a brine and will shrivel, but when soaked for putting in vinegar they will acquire their plumpness. Use a plenty of salt, as no more will be dissolved than is needed.

Architecture.—The book of designs, etc., which we noticed in July (p. 245) meets with such general favor from practical men (carpenters, etc.) that we call attention to it again. It is advertised on page 349.

How much Hay will an Ox Eat a Day? that is, what proportion of his own weight; supposing he is in good "store" order from first to last, has a good stable in winter, and is required to do no work?

Another Report on Peas.—"H. W. B." writes from Peekskill, N. Y. "A correspondent in your August *Agriculturist* is indignant over 'Carter's First Crop Pea,' and slaughters Carter, and seedsmen generally. My experience is far happier. I bought of Thorburn, in New York, the same pea, (which is sold also under the name of Sutton's Ringleader.) It came on finely, and on June 14th we gathered the first mess. The vine is early, very productive, and the pea the best early pea that we have yet tried. Another pea tried this year for the first time is 'McLean's Little Gem.' It is very early, a dwarf, growing but about 14 inches high, quite productive, and of a flavor nearly equal to the Champion

of England. It is the only wrinkled dwarf pea that I have ever seen. The peas on which I shall rely for another year, are: For very early, Carter's First Crop; for early, McLean's Little Gem; and for main crop, Champion of England."

Cooking Egg Plants.—"L. M. R.," and others, ask how to cook the egg plant, or rather egg fruit. Slice the fruit half an inch or more thick, peel and place for an hour or so in salt and water; then drain and dip in thin batter, or preferably in egg, and then in pounded cracker and fry brown. They are sometimes fried without batter or egg, but then they soak up fat and become too greasy. The rind is sometimes left on to make the pieces hold together, but when they are covered as above this is not necessary. There may be other ways of cooking this fruit, but the above is the only one we have tried, and is good enough.

The New Potato Bug—The 10-lined Spearman.—Numerous specimens of this fearful pest have been sent us this year from Iowa and Illinois. Last

Fig. 1.

year we had it from west of the Mississippi, and as it seems to be progressing eastward—according to Mr. Walsh in the *Practical Entomologist*—at the rate of over 50 miles a year, we reproduce our engraving of the beetle and its larva, in order that it may be recognised and "stamped out" on its first appearance in any locality.

The insect is known to entomologists

as *Doryphora decemlineata*, and is represented in its perfect state, fig. 1, of twice the natural size. It is yellow, with 10 black stripes. It lays its eggs on the leaves of the potato; they are yellow, placed endwise in clusters, and hatch in about six days.

The young larva is nearly black, but when full grown, fig. 2, (enlarged,) is orange colored with black markings. In seventeen days it goes into the earth,

Fig. 2.

where it takes on the pupa state, and in thirteen days comes forth as a perfect insect. These dates are from a very interesting series of observations communicated to the *Practical Entomologist* by Henry Shimmer, M. D., of Mount Carroll, Ill. This destructive insect has some natural enemies among insects, but the only practical way thus far known of treating them is to hand-pick, or knock them off into a pan and destroy them. Mr. J. Malony, Jr., Dubuque Co., Iowa, sent us a particularly fine lot which came alive, and we have taken good care that they shall not increase here, except in print.—Since the above was in type, we notice a report that this destructive insect has appeared in Maine. If this is true, it is greatly to be regretted, and we trust that it will prove that some other insect has been mistaken for it.

A Mine in the Muck Swamps.—

It is hard to make people believe that in those dark, black, sedge-growing, mosquito-hatching, ague-breeding, snakey, musk-ratty nuisances of peat bogs, and muck-swamps, which have been eye-sores and abominations, they are to find their Eldoradoes—their gold mines—and Anthracite mines. The material which shall warm them in winter, and cheer them in summer, which shall carpet the landscape with green and gold, make smiling harvests and heavy purses. Notice the advertisement of Prof. Johnson's new work on "*Peat and Its Uses*," on p. 339.

S. S. Question Books.—The series, entitled "*Lessons for every Sunday in the Year*" embrace

four numbers, each containing 32 lessons, viz: **No. 1**, The period from the Birth of Christ to the End of Acts; **No. 2**, The rest of the New Testament; **No. 3**, From Adam to Elijah; **No. 4**, From Elijah to Christ. The plan in each book is: the selection of lessons to be learned of about 7 verses each, and connecting them with a history, so that while the lessons are landmarks in order of time, the connecting history gives the pupil a clear idea of the events of each period in the order of occurrence. The questions and answers, direct or by references, aid both teachers and scholars to thought, and are especially valuable to the great mass of teachers who are not supplied with abundant commentaries and reference books. These books seem to have met a decided want among Sabbath School people, as between three and four hundred thousand of them have been called for, we believe, almost equally from all denominations of Christians. Editions are issued by several publishers, one of which is supplied at the *Agriculturist* office. Price 15 cents each, \$1.44 per dozen, or \$12 per 100 copies, for any of the numbers. If sent by mail 4 cents each must be added for prepaid postage, or 3 cents each in packages of ten or more. Four sample copies (**Nos. 1, 2, 3, and 4**) will be sent post-paid to any address for 65 cents.

Chimneys in Hay Stacks.—It is a common practice in England, where it is frequently difficult to get hay well cured, to make a chimney in the hay stack. This is done by filling a large four bushel sack with cut straw and placing it upright in the middle of the stack, and stow the hay around it. As the stack rises, pull up the sack and proceed as before, until it is finished, and you have a chimney that will carry off the heat, gases, moisture, etc. A butter firkin with a handle to it or a rope answers the purpose. When hay is stacked in a barn, especially a tight boarded one, this chimney is of still more importance, and care should also be taken to have rails underneath, so arranged that air can circulate under the hay and get into the chimney.

Seventh Volume of the American Short-horn Herd Book, which has been for some time promised, is now on our table. It contains the pedigrees of 1086 bulls, and 2400 cows, owned by about 400 breeders. This is the 7th of a series of volumes, edited and published by Hon. L. F. Allen, of Buffalo, which are of inestimable value to Short-horn breeders. We can not better express our own appreciation of this work than by quoting and endorsing the following from the preface: "No one need suppose that he can become a successful breeder, and command sales and prices, unless he be familiar with all the blood, and strains, and crosses of Anglo-American Short-horns. They must be his study. Without this knowledge he goes gropingly to work. Some breeders may suppose that in possessing the volume containing the pedigrees of their own stock, their herd book necessities are supplied. Not so. The best, and most successful breeders, whose herds are most sought by intelligent purchasers, are those who possess and study the entire series of the work."

The Use of Scrub or Grade Bulls.

—This practice can not be too severely deprecated. There are plenty of thorough-bred bulls, Ayrshires and Alderneys especially, probably also Devons, which are for sale at very low prices; calves for \$50 to \$75—yearlings, \$100 to \$200. Quite often, bulls of name and fame, 3 years old or so, which have been used as long as their owners desire upon their own herds, and which are still as good as ever, may be bought very cheap. Certainly no farmer who raises his heifer calves should ever use a scrub or grade bull, and those who raise veal should use good blood Short-horns or Ayrshires.

Preventive of the Pleuro-pneumonia.

—In the 2d Report of the Royal Commissioners on the Rinderpest, "Col. the Hon." Wellington Patrick Chetwyne Talbot and his advisor, who is bailiff of Lord Granville, state in their testimony that as a preventive of the diseases to which close kept cows are subject (Pleuro-pneumonia, etc.), the following articles are given to the cows in Col. Talbot's and Lord Granville's milk stables, viz: 1 oz. nitre every other day to each cow in 1 pint of water, (probably on the feed.) 1 pint of prepared charcoal between two cows on the feed, every morning. This changes the odor of the breath in a few days.

Caked Bag following a Thunder Storm.

—W. L. Benedict, Orange Co., N. Y., communicates to the readers of the *American Agriculturist* the following interesting facts: On the afternoon of the 27th of June it was exceedingly hot and a thunder storm passed over, preceded and accompanied by cold wind and rain. He says: "My cows were in the pasture during the shower, which was very heavy. They were brought up to be milked at 6 o'clock, when I found three of them with their udders very much swollen, badly inflamed, and so sore that it was difficult to milk them. But little milk, and that clotted, could be drawn from the parts affected. I put them in the stable with plenty of dry straw for bedding, and bathed the parts freely with cold water. This seemed to afford much relief, and I repeated the application in about two hours. The next morning the swelling had somewhat subsided. Cold water was again applied freely, as also the succeeding evening, when the cure seemed complete. Some years since I had two cows affected the same way, one of which lost one of her teats, and the other dried up for the season, but then I had not learned from the *Agriculturist* to put my cows immediately in the stable and give them a dry bed."

Woodchuck Medicine.—From your suggestion some months since, to smoke out woodchucks with a rag dipped in melted sulphur, I took the hint of another method. This is my recipe: Blasting powder, 1 lb.; saltpeter, powdered fine, 1 lb.; flowers of sulphur, 2 lbs. (Total cost 85 cents.) Mix well, not breaking the grains of powder. Some rainy day roll a half newspaper on the broom stick, tie up one end of the tube so make it fill 6 or 8 inches with the medicine, insert 10 inches of blasting fuse (price 3 cents a yard), tie snugly, and re-

peat, until you have a rocket for each woodchuck, and one to spare for the boys when they want a Roman candle, and you can't afford one. (Some dark evening lash it firmly to an arrow near the head, and when the fuse has burnt short, let it fly 100 or 150 feet in the air and they will shout.) Put the rest in a raisin box, cover with a shingle, and detail an artillery guard to carry the caisson in the day of battle. Order the regiment under arms, send skirmishers in advance to report on woodchuck holes, let the corps of sappers and miners close the upper opening, if one is higher than the other, and prepare sods and dirt for the lower; light fuse, insert rocked as far as may be, charge shovels and stop the hole when the fire becomes a roar, and see how the smoke will force its way through the ground in various places to show the course of the tunnel. Repeat until the caisson is empty. My woodchucks do not dig out again. *

Hen Lice.—Try the following. (Where the idea comes from we do not know, but we have little doubt it will work well; an alum wash kills lice on cattle, why will it not on hen roosts): Dissolve alum in cold water, or better in hot water, adding enough water to keep it all in solution when cold—about 2 pounds of alum to 12 quarts of water; and apply this thoroughly to every part of the hen house, and perhaps also to the hens. It tans the lice, as we suppose.

Marking Chickens.—It is often a desirable thing with breeders of fancy poultry to be able to mark them so as to readily identify individuals in the flock, in order to keep a register, on the principle of a herd-book, or so as to be able to recognize the age of hens at a glance. In the great poultry shows of England and France, it has been found very difficult to separate birds of the same breed should they by any accident become mixed, and we have seen a French suggestion that fowls should be marked by notches filed upon the toes. This might do for a year or two, but it is very awkward, and we suggest thin copper labels the size of an old three cent piece, wired upon one leg (above the spur in cocks). Such labels may be of several different shapes—square, round, oblong, triangular, oval, and all the chickens of one year receiving their labels at six months old might be adorned with those of one shape, while those of another year receive another shaped label, and so on.

Curing and Packing Hams.—F. Kessler, of Great Salt Lake City, Utah, writes his method of curing and packing hams as follows, and though we do not like his pickle very well, the way of packing is new to us and may be very good: "I pack my joint meat in barrels as close as I can, make my brine strong as possible with boiling water, letting stand until cold, and then for every 100 lbs. of meat add one teaspoonful of saltpeter to the brine, stirring all well together. Cover the meat well over with the brine. If the weather is very cold and the hams large (say 40 lbs. weight), they should remain 6 weeks; if the weather is mild, or the meat kept in a warm place, 4 weeks will be sufficient. Rub the bony parts well with a strong decoction of red pepper. Hang up the meat for smoking, the hocks down; this prevents drippage; smoke to taste with green hickory or sugar maple. The smoke house should be roomy. When sufficiently smoked, I pack in boxes or barrels in clean new wood ashes, where the hams will remain in perfect safety until needed for use. I have kept my hams and shoulders in this way for years past with entire satisfaction; no vermin of any kind will trouble them in the least. I have never known the first piece of meat treated as above to become rusty or old tasted, but it retains its freshness until used up."

Pickling Beef and Tongues.

—**Burlington Recipe.**—Rub slightly with fine salt and let them lie 24 hours. Then cover with the following cold pickle: For 100 lbs. meat, 6 gallons of soft water, 6 lbs. fine salt, 1½ ounces saleratus, 3 ounces saltpeter, and 1½ lbs. of sugar. Beef for drying to be left in this brine nine days; Tongues three weeks.—*City Subscriber.*

How to Train a Shepherd Dog.—Will somebody answer "One who wants to know?"

Dogs for Sale.—The picture in a recent number brings numerous inquiries about Black and Tan and Bull Terriers. There are people in all the cities who make a business of buying and selling, or breeding dogs. They would be able to sell a good many of such as would be servicable ratters, etc., if they would advertise. Good shepherd dogs are frequently inquired for.

The Sliding Balance Gate not Patented.

—J. S. Rogers, of Marengo, Ill., answers one question in the June number about the gate as follows: "There is no patent on the gate that I know of, but Mr. Joel Lee, of Galesburg in this State, has made an im-

provement on it, for which he has obtained a patent. It consists of an iron roller working on a swivel, which is placed on a cross-piece under the second board from the top. The gate rolls back until it balances, and is then easily swung around. His agent has been through this section, selling rights to use the rolls, for \$3 to \$5, according to size of the farm, and leaves a supply of the cast rollers at some hardware store, where they are retailed at 25 cents, the buyer being required to show his papers. Almost every farmer buys a right, for the gate is cheaper, easier made and every way better than a 'pair of bars.'"—See description of gate on page 219.

Where to Locate?—Numerous letters come to us, asking advice where to locate for farming, fruit or market gardening, etc. We are obliged to decline answering such applications for obvious reasons, one of which is that they come mainly from those who should first ascertain whether they should locate at all. Gardening of any kind is only successful when the individual has skill, perseverance and industry. One with a stock of these may locate anywhere near a market and do well, while one without them, no matter how favorably he may be settled, will soon fail. We try to give general hints from time to time; but to give judicious individual advice, we should need to know so many things about the querist's circumstances, experience, natural tact, capital, family, etc. (without knowing all of which we might advise wrongly), that many hours or days of correspondence, and thought on the subject would be required. No one could decide such a question for himself even, without much meditation and inquiry. This statement of the case will explain why we do not answer many letters. Our time can not of course be devoted to individual cases, or we should have none for the public, or for ourselves.

Look Out for the Pronouns.

—A careless use of pronouns often spoils sense. We try to keep them straight, but sometimes fail, and it is worth while to make a mistake now and then if we can get taken up so sharply and pleasantly withal, as we are by J. A. Delano, Mazonia Co., Ill., who writes: "I have read the *Am. Agriculturist* with satisfaction and profit for several years, and generally find its teachings 'stand to reason.' Now I am in a quandary, the thermometer indicating 95° in the shade. On page 279 of August number of *Agriculturist* I read the Doctor's treatment of his pinguitudinous porker. 'He gives it corn meal and sour milk, and stirs it with a red hot iron.' Cannot some less ardent persuasive to obesity be substituted during the present 'heated term?' Is it not possible to induce sufficient agitation by those less objectionable (in extreme hot weather) appliances, the 'sharp stick,' or the 'long pole?' How often does the Dr. 'stir' his adipose pet? Might not chloroform or other anæsthetic be employed during the process perturbative? Does not the Dr. render himself liable to an action on a charge of 'cruelty to animals?'"

Tile Drains vs. "Timber Drains."

"J. R." of Marion Co., Ind., asks: "How do earthen tiles do for draining land?—Do the drains last many years? With us many drains laid with timber are falling after about 8 or 10 years use—the wood rots."—It is such a settled thing in our own minds, that there is no material so good for drains as well baked earthen tiles, that perhaps we have not dwelt upon it enough of late. Properly laid in any soil, except in quick sands, or on other unstable bottoms, well baked tiles will last indefinitely long. Nobody has ever known such a drain to fail from the giving out of the tiles. A drain may fill up, or the earth wash and some tiles drop out of place, but placed below the influence of frost, the tiles suffer no perceptible change, except from the wear of the water. Soft tiles will sometimes be crushed by the pressure of the soil above, or crumble by the action of frost, or perhaps by some other influences, and occasionally one soft tile in a line of hard ones gives out and makes trouble.

Japanese Striped Maize.

—In the notice of this new ornamental leaved plant given last March, we were rather cautious in our praise, as we feared that it might forget the "kink," and fail to reproduce its peculiarities from seed, outside of Japan. We have seen plants this year raised from seed grown by Mr. Hogg, and sent out through the enterprise of B. K. Bliss, the well known seedsman, of Springfield, Mass. These plants are as beautifully striped as those we saw last year from Japanese seed, and we see no reason why the peculiarity should not be permanent. The plant has met with great favor in Europe, the horticulturists both in England and on the Continent selling specimens in pots. Moreover, at the recent International Horticultural Exhibition, it received a prize, and has had honorable mention at other European shows. We are glad to be able to give so good an account of a novelty that we were the first to illustrate and bring prominently into notice.

Poudrette from New York to Ohio.

—“A. C.,” four years a soldier, saved his money and bought a farm 22 miles from a R. R. station in Ohio. He lucks manure, and asks if it will pay to get poudrette from New York to make corn. No, indeed! It will not pay to cart poudrette as far as you say, if you could have it for nothing. Guano, bone-dust, a good superphosphate, or even ground plaster are of sufficient value to haul so far. If your carts come back from the station empty, it might pay to bring a light load of poudrette, but not if you could get either of the other manures mentioned; that is, if plaster (or gypsum) has a good effect on your soil. Make your own poudrette. See article on p. 319.

Charcoal for Manure.—James Ferguson has at command a large lot of charcoal dust, which he would like to apply to his land, if advisable. Charcoal does not act largely as a fertilizer. Its chief value is as an absorbent, and it may be used in the stables if it be frequently removed and mixed in a muck or earthy compost. Charcoal first absorbs and then decomposes organic gases. When spread on the land it will produce an immediate beneficial effect. There is always more or less ashes in such dust, which would act beneficially.

Fertilizer for Wheat.—“W. W.,” of Southern Indiana, has his choice between poudrette, Peruvian guano, and flour of unburnt bones, for his wheat land, which is of clayey soil. Poudrette for field crops we do not believe in, except home-made poudrette. Peruvian guano, if pure, is very good, especially if properly mashed and mixed with 3 or 4 times its weight of dry fine muck or peat. This compost may be much improved by adding twice as much bone dust, and as much ground plaster (gypsum) as guano—say 150 lbs. guano, 150 lbs. gypsum, 300 lbs. bones. This mixture may be sowed on and harrowed in, or mixed with as much fine muck as you please, and applied evenly.

Animal Carcasses.—Cover up with loamy soil, or muck, work them over a few months after the temperature has become such as will allow fermentation, and mingle again more soil or muck, using as much plaster as you please.

Woolen Waste.—“F. O. W.,” of Black Stone, Mass., can have all the “picker waste” he wants from a woolen mill. It is oily and can not be wet, it is dry and might be used as bedding for horses, but he has tried it and “it spoils the manure” (!) “Left in a pile through the summer, it heats so that one can not hold his hand in it.” We advise F. O. W. and anybody else who is troubled with *too strong* manure to treat it exactly as they would *too strong* tea or coffee—namely, *dilute it* to suit his taste. You add water to strong tea; add soil or swamp muck, or straw to the waste, and make it just the strength you want, first heaping it until it begins to heat.

The Fence Nuisance.—The Legislature of New York overhauled and amended extensively the fence law of the State. The more laws and amendments we have, the worse off we are and the farther from equal justice, until “the People of the State of New York, represented in Senate and Assembly, do enact” that all owners of cattle of all kinds shall be responsible for them, and all the damage they do; and in case they do trespass, wandering from the high way or from their owner's land, or elsewhere upon the premises of other proprietors, it shall be regarded as a misdemeanor of the owner, for which fines and punishments shall be awarded.

How to get in Timothy Grass.—“C. F. S.,” writes: “I have an 8-acre lot, once seeded with timothy, which has now run out, and grows nothing but a wild grass, having its rough prickly seed growing on the blades and not at the top of a stem. How shall I kill this grass? The meadow is overflowed several times a year, and is nearly flat.” There are 10,000 farmers who have each just about such a piece of ground. It needs draining, and the way to do it is to begin when the land is dry, and dig narrow straight ditches 30 feet apart, and 3 feet deep, usually uniting in a main ditch or two dug so as to get the best fall possible. The ditches should be as nearly level as possible and still have a distinct fall. Small drain tile should be laid in the ditches; and 4-inch tiles would generally be large enough for the main drains. After the draining is done, plow in the spring, raise a crop of corn, and follow with spring grain, seeding to Timothy. We suggest summer crops and spring plowing, supposing that the overflowing would interfere with other practice. This meadow offers an excellent chance to irrigate after the plan suggested in August 1864, page 236.

Pinching Grapes.—C. Thurston, Bradford Co., Pa., objects to our directions to stop bearing canes at 3 or 4 leaves from the last bunch, as “agin

natur,” and suggests that “thorough trimming in the fall, with *judicious pinching off*, is according to my experience the best course.” Now friend T., we should like to ask if thorough trimming is not “agin natur?” As to “judicious pinching,” we directed just that same, on the supposition that the vine had been properly trained at the start. Ranbling vines in rich garden soil, will have pretty much their own way, whatever you do with them.

What is it on the Pear Tree?—C. C. Phillips, Cumberland Co., Pa., says: “My dwarf pear trees have almost been stripped of their leaves by a slimy, sticky, snail-like worm. What is it?” We try to anticipate such common troubles as this in our “Hints about work.” Under the head of Fruit Garden, in June, it is said: “The disagreeable slimy slug which appears on pear and other trees is killed by a dusting of air slaked lime.” We would not seem to take our friend to task for not reading each paper from the heading to the last advertisement, but use his query as a sample of many for which we have already provided in our Hints about Work. That portion of the paper is made up with a great deal of care, and though many things must of necessity be repeated from year to year, it is always re-written and many new suggestions from letters, etc., worked in.

Beans for a Name.—“P.,” Franklin, N. Y. Those in the green paper are apparently the White Runner, and the others are Lima.

Grafting “Thorn Apples.”—“G. B. S.” By “Thorn Apples,” we suppose you mean some species of Thorn, of which we have several. The pear will grow when grafted upon the thorn, but the trees thus produced are usually short lived, and inferior to those grafted upon quince.

Flies on Cherry Trees.—“Mrs. L. C.,” writes to know why flies gather on her cherry trees, and she notices that the leaves are covered with what she takes to be their eggs. The supposed eggs are undoubtedly aphides, or plant lice, which are very common on cherry trees. These lice exude a sweetish liquid, or honey dew, which attracts flies and other insects in great numbers. Tobacco water will kill the lice, but its application is not very practicable upon the large scale.

Thanks to Whom they are Due.—A delegation of the American Institute Farmers' Club, visited Hammoncton, N. J., in strawberry time, and were splendidly entertained by the people of that enterprising place. For some reason not clear to us, it was supposed that we should be there, and at the festival a fine bouquet upon the table was dedicated “To the Editor of the *Agriculturist*.” We are sorry that we did not get the bouquet, but are glad we didn't go, as we should have been obliged to make a speech, which is the horror of our life. Still, the lady or ladies who were so thoughtful will accept our thanks for the compliment.

Degeneration of Strawberries.—M. Korff, asks if the statement made in the report of the Department of Agriculture for 1863, to the effect that the use of side runners in propagating strawberries causes the varieties to degenerate, has any foundation in fact. We never met any one but the writer of the article alluded to who believed in or practised its teachings. One good healthy runner is as much a representative of the original plant as another, no matter from where it starts, and will perpetuate the variety as perfectly as will a bud taken from any part of a tree. The two cases are perfectly parallel, and the strawberry plant may be regarded as a tree with branches too weak to stand upright.

Derivation of “Weigelia.”—W. Peters, New Haven Co., Conn. The proper word is *Weigela*, and it comes from the name of Weigel, a German botanist of the last century. In Latinizing names of other languages, they follow the usual rules of Latin pronunciation, and in this case the *g* would be soft. The plant is now referred to an older genus, *Diervilla*, which is its proper botanical name, while *Weigela* will serve for its English name.

Propagating the Blackberry.—L. Grafton, Pulaski Co., Ind., was unsuccessful in propagating the Lawton or New Rochelle blackberry. Many who have it in their lands would be glad to know what he did to kill it. We do not know how it is in Indiana, but here the smallest root will make a plant. It is too late for peanuts—sweet potatoes will be noticed in season.

“Golden Currant.”—A. Mitchell, Macoupin Co., Ill., sends us specimens of a currant of a bright yellow color. He considers the fruit as excellent for tarts. It appears to be a variety of the Missouri Currant, and is known but not valued with us.

Angle Worms.—J. H. Luttenton, Orleans Co., N. Y. You will find a brief account of the history of the angle worm, with an engraving of its eggs, in the *American Agriculturist* for January, 1863.

A “Rose” on an Apple Tree.—E. W. Knight gives an account of a “white semi-double rose” found on an apple tree, and asks if we have “previous to this, knowledge of a double rose blossoming on the apple?” No—but we have several times seen very handsome double apple-blossoms, which look remarkably like small double roses. They usually appear after the general blossoming is over.

Thorn Seeds.—“N. W. W.,” Peacedale, R. I., says that the seeds of one of our wild thorns will come up the first year, even after being kept dry all winter. Will he oblige us with a leaf or two, that we may know the species.

Out-door White-wash—A Colored Wash.—Having recently erected 1500 feet of rough picket fence, we adopted the following wash, which seems to stick well, and appears very well. About a peck of lime at a time was put in a tub, and over this was poured two pailfuls of water, in which a large double handful of salt was previously dissolved. As soon as the lime began to boil up well, we added about $\frac{1}{2}$ lb. of coarse grease from the fat-tryers, and stirred it in *thoroughly* while the whole was hot. It was then used on the pickets, rails and posts, stirring it often, and diluting as needed. For the running bottom boards we mixed nearly a barrelful of white-wash, in quantities of a peck at a time, with grease and salt, as above. $3\frac{1}{2}$ lbs. of lamp black were then ground or mashed; then thoroughly stirred in 3 quarts of sweet milk and strained into the barrel and well stirred—the stirring being repeated every time a pailful was to be taken out, and that in the pail frequently stirred while using. This applied carefully to the bottom board, gives a fine very dark lead color, that contrasts well with the white. Both the white and colored washes were applied very freely, $1\frac{1}{2}$ barrels of fresh lump lime being used.—The posts and rails were washed *before* nailing on the pickets, and the pickets were also washed on one side, so that there is a coat of lime between the pickets and rails. The whole job is satisfactory, and the fence looks like one planed and painted. We expect the lime will add much to its durability.

Deep vs. Shallow Pans for Milk.—There is a general impression that cream rises more freely when milk is set in shallow pans than in deep ones. It seems, however, that the Orange County butter makers, at least in the factories, use deep pans or pails, and think they get just as much cream and of better quality, as there is less exposure to the atmosphere and consequently less liability to its crusting over. X. A. Willard and others in Herkimer Co. have made some experiments which seem to prove that there is no advantage in putting the cream in shallow pans. If such proves to be the case, it will be a great saving of labor (in scalding, etc.), to use deeper pans, as we shall need fewer of them, and this at the present cost of pans is no slight advantage.—Much must depend upon the cow, the season of the year, that is the temperature, and the length of time the milk will keep sweet and in the best condition for cream to rise. A few years ago the subject was discussed, and we know of numerous experiments which led us to consider it a settled fact that shallow pans gave the most cream, and we have little anticipation that this decision will be reversed.

The Glory and Shame of England.—Several years ago Mr. C. Edwards Lester wrote a book with the above title. Since the war, during a portion of which he was in Great Britain and upon the Continent, he has re-written it, or rather we may say, put forth another work with the same title, in two volumes. Mr. Lester looks upon England's power and England's weakness as an American may now-a-days be expected to do, making few allowances, and applies to her the measures which she delights to apply to the rest of the world. He has furnished a book of many statistics, and statements in regard to the condition of the agriculture and of the agricultural population of Great Britain; and in his discussions of politics, religion and society, of the condition of Ireland and of India, and of the aristocracy, he furnishes a mass of matter which will be read with great satisfaction by at least some American people in their present frame of mind. Mr. Lester does not forget the love we bear to England as the mother country, and the home of our poets, philosophers and historians, nor the warm brotherly affection we entertain for the working men and the liberal statesmen of England, and the work is one which will exalt the appreciation and love of his own country in the heart of every American. It is in 2 vols., small 8vo., 364 pages each, price in muslin \$4.

Two Tons of Clover per Acre. (or rafter what would make that amount after cutting and drying for hay.) plowed in green. Dr. Warder tells us he thinks is fully equal to 10 cords of ordinary barn yard manure. Manure costs the farmers in the vicinity of New York, on an average, delivered on their farms, fully \$6 per cord. To spread and plow it in costs about the same as plowing in the clover. Now the cost of raising these two tons of clover, allowing \$10 per acre for rent of land, cannot exceed \$20, if over \$15 on the average. It would then require the addition of a little bone dust, guano or some salts to make it equal in general quality to barnyard manure, which would add to its cost. The question now is whether it is not cheaper to plow in clover, buckwheat, turnips, or some green crop, than to purchase city stable manure at a cost of \$6 per cord, delivered on the farm? In deciding this matter, it must be recollected that the city manure is exposed more or less to the weather when unloaded on the dock, and its wastage and deterioration are often considerable.

Ashes on Orchards.—F. Ruteliff, of Henry Co., Ind., asks: "Will ashes be good to bring up an old orchard; if so, when and how shall I apply them?" Adding: "There are plenty at a saw-mill 1½ miles from our farm." There is nothing better, as a general rule, for old orchards than a liberal dressing of unleached wood ashes. It would be hard to tell how much it would not pay to apply; a barrel or two in each tree, spread as far as the outmost boughs, plowing 4 to 6 inches deep, will probably rejuvenate the orchard, provided there is any soundness left in the trees. Lime is nearly as good. It should be spread freshly slaked, after plowing, and be harrowed in; or a light dressing, say ½ of the whole, may be first spread and plowed in, and the rest put on the surface after plowing, and then harrowed in. Calculate to put about 3 bushels to each tree, though more would do no harm; make the application in the autumn.

Lime on Wet Land.—"J. W.," New London, Ct., has a piece of wet land which lacks only drainage to be excellent meadow. He has drained as deep as he can, but to drain the piece, his neighbor below must deepen his drains also—which he will not do. Mr. W. has legal right to go on and deepen his neighbor's drains, or to lay a tight drain across the piece, and so benefit himself only, but does not want to do it yet. "Will lime help the land?"—We think it will, where the ground can be plowed in time for corn or potatoes, but not much elsewhere. Apply after plowing, and harrow in.

Death to Canada Thistles.—David Newport, of Evergreen (no State), "actuated by the desire to do good and communicate," says: "I would inform the readers of the *Agriculturist* that I have succeeded in destroying two considerable patches of Canada thistles, by the persevering use of small quantities of coal oil applied to each plant."—If Canada thistles are cut in the summer, after they throw up their flower stalks and before they bloom, perhaps also at other times, and a pinch of salt is dropped into the hollow stem, they die. When they are cut frequently with a spud just at or below the surface, they will rapidly disappear. The application of coal oil will kill any weed, or any other plant, it comes in contact with, and may prevent growth of any vegetation on the same spot for a considerable time. So be careful.

White Willow Fences.—The public have heard the growls of the dissatisfied and humbugged people through the press, while those well satisfied with their willow fences, that is, those who obtained the genuine article and took good care of the fences as they grew, we seldom hear from. It is therefore worth while to read such a letter as this now and then. Levi Smith, of Story Co., Iowa, writes to the *American Agriculturist* as follows: "In the June number of the *Agriculturist* you make some inquiries about the white willow. James Smith is the man who first introduced the white willow in Illinois, in 1843. He there tested it successfully. There is a fence on the old farm in Illinois twelve years old, for which the owner refused \$8 a rod for the trimmings some years ago, it was to be cut high enough to leave an everlasting live fence. I have known it to form stems in one season 1½ inches in diameter. Designing men have procured such samples, and with them have canvassed the country and obtained orders, which have often been filled with a spurious article easier to procure. Our farmers have been so shamefully humbugged with worthless trash, that they are of opinion that all willow is alike worthless. I have now six miles of it, three and four years old, and it is a substantial fence, ready to turn and defy any stock. I consider it worth more to-day than the land it encloses. For fuel I grow five times the amount I can consume. Every year I can cut enough poles to fence 2000 acres of land, and still leave me a substantial live fence when they were cut. You may say

to the readers of the *Agriculturist* that the white willow is no humbug, and if any of them will call, I will show them six miles of fence, which will settle the question."

Putting Straw Among Clover in Stacking is an English practice. The straw absorbs the juices from the clover, and arrests all tendency to injurious fermentation. The hay is sweeter, and cattle eat the straw with avidity. If you have a heavy crop of clover, that is a little green, put thin layers of bright straw between the layers of hay, and there will be no danger.

Plow for Deep Work.—"B & B," Adamsville, Ohio, ask, "What is the best plow to break up the ground 14 inches deep, and throw up the subsoil?" There are as many patterns of the "double Michigan," or "sod and deep soil" plows, as of single plows. The plowman must suit himself as to shape and price. We described and figured the operation of these plows on page 145, of the last volume, (1865). The sod and deep soil plow is like any other large strong plow, with a small plow, called the skimmer, attached to the beam. The beam is subject to severe strains and should be strong accordingly. Such a plow will do the work required, burying the sod either in the bottom of the furrows if the slice is thin enough, or folding it like a book and setting it edgewise, while the big plow follows and covers it up.

The Water Carrier Improved.—B. C. Dodge, Washington, D. C., writes to the *Agriculturist* suggesting an improvement upon the Water Carrier, described on page 218, (June). He says: "Instead of the number of posts and the wooden track or rail there used, a good strong telegraph wire may be substituted to great advantage. A strong wire, firmly secured at each end and stretched tight, may be thus used for a distance of from one to two hundred feet, without any intervening posts or supports. If a longer line is required than can be thus used, it may be made of any required length by the addition of an occasional post—care of course being taken to so arrange the arm that supports the wire, as not to form an obstruction to the passage of the pulley, which is easily done. A common iron pulley can be used on the wire. I have seen two such devices in use, one about 100 feet, and the other nearly 200 feet long, at an angle of fully forty degrees, without any support except at the ends, and they worked admirably and had been in use for years. One is in Wisconsin and the other in Minnesota, and both raise water from fine springs situated in deep hollows, summer and winter.

Convenience and Practical Utility of Frame Hives.—On May 31st we swarmed—and arranged ready for work—32 swarms of bees in 5½ hours, by simply lifting out the combs, and shaking ¾ of the bees together with the queen into a new hive. While under the practice of drumming, it required a whole day to drive even 20 swarms. Bidwell Bros., St. Paul, Minn.

New Peas Again.—"A Lady Gardener" writes: "I am tempted to give you my experience with Carter's First Crop. I sent for a package of them with other seeds last spring, had them planted when the garden was made (which is not, in the north part of Worcester, Mass., usually "very early.") I had peas fit for the table July 4th, leaving a portion of the vines untouched for seed. The vines so left grew about 2 feet high, the peas ripened and were planted again on the same ground, and now, July 23th, I have a second set of vines growing for late ones. Those vines from which I plucked the peas green are some of them still growing, but none more than 3 feet high. We threw out the Dan. O'Rourke years ago as poor in quality, and poor bearers. There's a difference somewhere. I sincerely sympathize with your venerable correspondent in his care for the green peas, but still think that those I bought under the style of Carter's First Crop are a good pea." We have had other letters speaking well of "Carter's First Crop Pea," and doubtless our correspondent, whose letter was published last month, got the wrong sort.

Plants Named.—"New Rochelle": No. 1, *Salisburia adiantifolia*, the Japan Ginkgo, and not rare in cultivation. No. 2, *Periploca Græca*, often called Virginia Silk, but not a native of this country. . . J. M. Wooley, Ogdensburg, N. Y. No. 1, *Robinia hispida*, Rose Acacia. No. 2, *Cytisus Laburnum*, the Golden Chain, or Laburnum. No. 3, *Spiræa prunifolia*. . . M. R. Allen, York Co., Me. No. 1, *Oenothera pumila*, Dwarf Evening Primrose. No. 2, *Tiarella cordifolia*, False Mitre-wort. . . Miss E. Goss, Wellington, O. *Thalictrum dioicum*, Early Meadow-rue. You were puzzled with this because it is dioecious, and for the same reason R. G. Fuller, Kent, Conn., could not make out *Chamaelirium luteum*, the Blazing Star. . . R. H. McCarty, Mottville, *Spiræa opulifolia*, Nine-bark, a shrub worth cultivating. . . A. W. Tabbut, Columbia Falls, Me. No. 1, *Ledum*

latifolium, Labrador Tea No. 2, *Juniperus communis*, Common Juniper. . . C. W. Beanis, Holliston, Mass. The shrub with yellow flowers and bladd ry pod is *Colutea arborescens*, Bladder-senna; the other is *Amorpha fruticosa*, False Indigo. . . J. J. S., West Point, O. *Dicentra spectabilis*, the Bleeding Heart; the other a Phacelia, but not enough of it to determine which. . . W. S. Van Doren, Kansas. We cannot undertake to tell double roses from dry specimens. . . "Subscriber," Baskingridge. The Scarlet Lychnis, *Lychnis Chalcedonica*, a very old garden plant. . . J. Johnson, Camden, N. J. No. 1, *Rhexia Virginica*, Deer-Grass, No. 2, *Polygala sanguinea*. . . Mrs. O. D. Frost, Neosho Co., Kansas. *Sabbatia angularis*, one of the species of American Centaury; and something of the Mint Family, but no flowers to determine it by.—We have a number of other specimens which will be determined as soon as we have time.

Strawberries in Iowa.—J. Bouland, Winneshick Co., Iowa, has tried several varieties, and they all failed. He does not say whether they were covered in winter. Plant in spring and when the weather is cold enough to freeze the ground, cover with straw, corn stalks, or leaves. Wilson's Albany is perhaps as safe as any, but it is no harder than the *Agriculturist* and many others.

Fruit in San Francisco.—Mr. T. Hart Hyatt writes, that apricots and green corn appeared in the markets of San Francisco on May 20th, and at the date of his letter, June 29th, ripe fresh figs have been on sale for several days.

Setting Osage Orange Hedges.—J. T. McLain, Morrow Co., O. It will not do to set Osage Orange plants in autumn. The yearling plants are very tender, and need to be taken from the seed bed and protected through the winter, by setting them in boxes of earth in the cellar, or by stacking them up out of doors and covering sufficiently with earth to prevent freezing.

Pinks and Pansies.—J. Bouland. If your pinks are carnations they should have been layered when in bloom. If they are of the China, or other biennial sorts, you must rely upon seed. Pansies strike readily from cuttings taken early in the season from near the bottom of the plant.

Ants in the Garden.—"H. W." We never had much success in fighting ants, but have not tried Mr. Rivers' preparation, which is: boil 4 oz. quassa chips for 10 minutes in a gallon of water, and add 4 oz. soft soap. This is poured into the holes and sprinkled about in the places where they congregate.

Peaches in Niagara Co.—We are glad to learn from a Lockport correspondent, that the promise of peaches was never better than it is at present.

Preserving Celery in Cellars.—R. Reed, Wayne Co., N. Y., asks the best way to preserve celery in cellars, as he finds his to rot by January 1st. The best way to preserve celery is to keep it out of the cellar altogether. Make a trench in a dry place, a foot wide, and as deep as the celery is tall. Set the plants upright in the trench, packed close together, and leave them until severe weather comes, when straw or other litter is to be thrown over, putting it on gradually as the weather gets colder, until it amounts to a foot in thickness.

The Wilson's Early and Kittatinny Blackberries.—The experience of another season shows the great superiority of these varieties. The Wilson's Early is especially valuable as a market fruit, being early and ripening rapidly. We have seen fine specimens from Mr. John S. Collins, of Mountstown, N. J., and shall have more to say of this variety at another time. The Kittatinny has this year more than sustained the high praise we have heretofore given it. It is a little later than the Wilson, and the sweetest and most delicious fruit of any variety that we have seen in cultivation.

A "Mare's Nest" in Vineland.—The Vineland people have discovered that their Wilson's Strawberry plants are mostly "bogus"—a variety we have not heard of before. A committee has been appointed by the Agricultural Society to visit the plantations and point out the true and the "bogus" Wilson. This committee find from three-fourths to one-eighth of the plants to be "bogus." The singular thing about it is that the committee consists of two dealers, who have strawberry plants for sale and benevolently pull up "bogus plants," if paid for it, and also furnish the true for a compensation. This is as a correspondent states, and according to this, it looks like a rather smart operation.

Ferrets and Weasels vs. Rats and Gophers.

The discussion which has taken place in the *Agriculturist* about Gophers, called out a communication from a Western Subscriber, who says he has used the common ferret with great success against the striped Gopher, and suggests its use in exterminating the common Pouched Gopher. The idea is a very good one, and considering that the "common ferret" is one of the most uncommon of our domestic animals, we figure and describe it. To save correspondence we will say that we know not where there are any for sale, but that if our readers want to buy them and see none advertised, they may bear it in mind when they next visit some large city, and then inquire for them of those people who import and sell dogs, singing birds, etc., for they generally keep them.

The ferret is an animal of the weasel kind, only much larger and stronger. It is known in Europe and America only in a state of domestication (but not of tameness), for its native country is Africa, and unless protected in winter in northern regions it will perish from the cold.

This species so resembles the European polecat or fitch that it was regarded by Buffon as a variety of the same species. And it is said that the two animals breed freely together; so that the breeders of ferrets practise crossing them to increase the size and constitution of the ferrets. It seems probable that the color of the ferret, which is commonly a dingy white with pink eyes, is a result in part of domestication, for its natural colors are light brown, sometimes dark brown or even black, the color being more or less in spots. The albinos appear, however, to be most common, and their red, fiery eyes are most remarkable. The ferret is about thirteen or fourteen inches long, the tail being about five inches more. It has great strength and boldness, and when attacking its prey it exhibits astonishing ferocity and nervous excitement.

These animals are bred and used extensively all over Europe, to hunt rabbits, rats and other

small animals. Their natural instincts are so strong that they require no training, though of course they improve by practice, which is called training; the only desirable quality which they may be taught seems to be to allow themselves readily to be caught. They are always muzzled when let out or hunted with, for when one gets

\$10 to \$25 a pair. This makes them rather expensive, especially as they are not long lived as a general thing, being peculiarly subject to disease. We have, however, several native animals of the same family which may be obtained at less cost, and would probably do very good service, if domesticated and trained like ferrets.

The Mink (Putorius vison) is larger than the ferret, and it is said to be easily tamed; doubtless also it would breed in captivity, and, if so, might easily be trained to hunt muzzled and return, or allow itself to be caught, to get its food. It is of the same fierce disposition, and is an implacable enemy to the smaller quadrupeds and birds.

The little Weasel (Putorius pusillus) is most common, although the larger one, known as the *New York Weasel (Putorius*

Novboracensis, De Kay), or *Ermine Weasel (P. erminea, Linn)*, is common, and probably a better rat catcher. The former is 7 or 8 inches long, with a tail of two inches; its color is the same summer and winter, namely, chestnut brown above, and growing darker to the tail, which is black at the tips. The belly is yellowish white, and white beneath the throat. It is readily recognized by its size, and muzzled would hardly drive a fierce rat. The *Ermine Weasel* is a much more powerful animal, having a stouter, thicker body, larger head, jaws and legs, of very much the same color in its summer dress, but in its winter dress pure white, with sulphur-yellow flanks, and a black tipped tail. Its ferocity is equal or superior to any of its congeners, except the ferret perhaps, and it will attack without hesitation animals much larger than itself. We have no doubt it would make, with only a little training, an excellent

Fig. 1.—THE FERRET—*Putorius furo*.

off its muzzle it is almost surely lost, for it will catch its victim, suck its blood, and then go to sleep. From this sleep or stupor it will not arouse until it has digested its repast, and wakes hungry and fierce for other prey, and where its game is plenty nothing more will be seen of it; but it will perish when winter comes on. Kept muzzled, however, it will return after its hunt to be fed; while the animals are driven from their burrows or holes into nets or snares of some kind.

Fig. 2.—THE ERMINE WEASEL—*Putorius erminea*.

The ferrets, in common with their congeners, the polecat and the weasels, possesses the property of emitting a very disagreeable skunk-like odor when they are irritated or attacked by a superior animal. This makes it necessary therefore to handle them with great care. Their bite is also severe and hard to cure.

The price asked for ferrets in this country is

rather, and equally effective destroyer of gophers. Like the rest of their genus they are nocturnal in their habits, and prone to periods of stupor after gorging themselves. The engraving which we give is of the *Ermine Weasel*.

The weasels are well-known destroyers of rats and mice, and a pair will soon rid barns and granaries of these vermin. Many a farmer

hardly grudges the eggs and chickens that he loses for gratitude for the great favors they do him. Field mice in immense numbers, and also small birds are destroyed by them. In their hunts they exercise no little cunning, which is very like reason sometimes. A friend narrates to us the following as a fact, of which he was cognizant. A pair of tame weasels were kept at the house, and used to hunt the rats with great pertinacity. One rat was too much for the weasel in a fair fight, and would turn and chase it, the weasel running frequently through a certain hole. At once the weasel seemed to be at work filling up the hole; then he dug through, leaving a hole just big enough for himself to pass. Here, the next time the rat chased the weasel, he was brought up all standing, while his little enemy, executing a rapid flank movement, attacked and dispatched him in the rear.

Tim Bunker on the Cotton Fever and Emigration Down South.

MR. EDITOR,—I was a good deal taken aback by my talk with John, about which I wrote you in my last. You see Mrs. Bunker and I had never thought of any thing else for him than our own home in Hookertown, and that he would want to live and die in the house in which he was born. We had not considered what a change three years was to make in him. He went away a boy, he came back a man with notions of his own, and the reasons to back 'em. There was no disguising the fact that it was something more than a boyish freak that he had taken, to carve out for himself a new home in the sunny South. I turned the thing over in my mind, and I could not get round the argument. I had had my chance in Hookertown, and made my own home and fortune without any boasting. Why shouldn't he have his chance in a spot of his own choosing? He has seen the land and tried its climate, and was capable of judging for himself. If he could not stay at home without a feeling of constraint, why the sooner he was off the better. A contented mind is a continual feast, and without that a man must be a drudge anywhere.

So we give up arguing, and conclude that John had quite as good a right to dispose of himself as we had. If he felt he had a mission down South it might be as sacred as any other, and it didn't become us to stand in the Lord's way. Perhaps he had something better in store for John than Hookertown. They say old people, and some that are not quite so old, come to think that they live exactly in the center of creation, and that there is no spot quite equal to their town and their part of it. Even Mr. Spooner preached his new-year's sermon on being "Content with such things as you have," and undertook to show that the western hemisphere was the best part of the world, that the North American Continent was greatly superior to the South, that the United States was the best part of the Continent, that Connecticut stood head and shoulders above all the other States, and Hookertown was the cream of the land of Steady Habits. I don't want to stir up the jealousy of Boston, or any other respectable village, but I endorse Mr. Spooner's opinion—I thought all the while he was a preaching that he had a squint toward the folks who were so fast for going down South—and he owned as much afterwards. But preaching won't save a man who has got the cotton fever. You might

as well undertake to preach total depravity out of him. It will work out.

"D'yc 'spose, Squire, there's any chance to make money in this cotton business?" asked Jake Frink this morning.

"Certainly," said I. "Growing cotton is just like any other business. Some men who have capital and skill will go into it and prosper, and others will fail for the same reasons that they would fail in any thing. It does not require any more intelligence to manage a cotton plantation than it does to work a northern farm, and hardly so much. It has always been done by the rudest kind of labor. There is no doubt that the skill acquired in growing the dozen or more crops we raise here in Hookertown, will come to a good market in the South."

"How much capital is required to raise cotton?"

"Just as much as to raise corn or potatoes, and the more one has the better he can make it pay, up to the point where he can command all the labor he can see too. There is no difficulty in growing cotton in a small way, if you are where you can use another's gin and press. But the better way is to have a large plantation and use your own gin and press."

"I like the notion of using your own gin, Squire, for I don't think I should stand much of a chance of borrowing unless folks down there are different from the Hookertown people."

"Very likely. But the gin you have in mind won't help the cotton harvest any more than it does the hay."

"Well I don't see," said Jake despondingly, "as there's going to be any chance for me down there. Kier is going, and pretty much all the folks in the White Oaks, and I thought I might as well go along, but if it takes such a heap of money I shall have to give it up."

I could not encourage neighbor Frink to join the expedition, for he and the class of men to which he belongs will not succeed either North or South. They are a good way past their prime, and their habits are bad.

But young men of good habits need not hesitate to go, even though they have small capital. Skillful labor will for a long time command a good price there, if labor is all that one has to put in to the market. The unfriendliness of the climate to the white laborer is greatly overestimated. This story has been industriously circulated by interested parties, as an apology for slave labor. When I took Mrs. Bunker down to New Orleans seven years ago, I found the most of the labor about the wharves and cotton presses was performed by men of European birth. Irishmen and Germans were plenty as laborers and mechanics, and they suffered as little inconvenience from the heat as Africans. When I went up on to the cotton plantations, I found the planters employing Irishmen to ditch and drain where they would not put their negroes. I found Scotchmen and New Englanders settled there, and enduring the climate perfectly well. It is well known that multitudes of Germans and Hungarians have gone into Texas, still further South, and there raise cotton quite as safely and more economically than it could be done by slave labor. Our soldiers have stood the climate well, and it is my private opinion that labor in a cotton field isn't any harder or more dangerous than fighting. That's the opinion of the boys who have spent two and three years there in places where they couldn't always take care of themselves. I guess it will do to risk them when they can build houses of their own, and have the comforts of northern homes around them. The fact is, climate has

the credit of a good deal of mortality that really belongs to whiskey. Of course in clearing up a new country there will be exposure to malaria and sickness. But when the forests are cleared and the swamps are drained, as they will be by northern skill, the risk of health and life will deter no one from going South.

Capital will be the great want of the emigrant to the South. There is plenty of cheap land to be bought, and plantations enough to be cheaply leased. Money must be had for this, and for stock and labor. According to John's figuring, a man wants forty-four dollars for every acre in cotton. If he was going in for 500 acres of cotton the outlay would be

For stock, seed and implements.....	\$ 6,305
Supplies for 60 hands—say 1,200 bushels of corn, 120 barrels corn meal, 84 barrels pork, 15 bushels of salt, 10 months wages at 15 dol- lars a month, and incidentals.....	14,875
For rent of land at 10 dollars per acre.....	5,000
	\$26,180

The stock and implements would be worth three-fourths their first cost or more at the close of the year, and this amount may be deducted for the second year's operations. Sometimes the cotton can be sold by Oct. 1st, and the money realized go to pay the expenses of the year.

The returns for such an investment will of course vary with the yield and the market price. The average crop, as planters estimated it under the old system, was—one bale upon alluvial, two-thirds of a bale upon "hard bottom lands," and half a bale upon upland. With free labor this yield would probably be exceeded. The bale is rated at 400 pounds. At a bale per acre, and cotton at 30 cents, the crop on 500 acres would be worth \$60,000. At a half bale per acre it would be worth \$30,000. The lowest estimate gives near fifty per cent. profit. The highest near three hundred.

Here is great temptation for northern skill and capital. With any thing like a fair chance, money must be made at it. It isn't strange that the cotton fever rages and carries off our people. The boys have all started, and I suspect the girls will—be sent for.

Hookertown, Aug. 16th, 1866. } Yours to command,
TIMOTHY BUNKER, Esq.

The Sorghum Syrup Crop.

We know of no other crop ever having been introduced among agriculturists which grew so rapidly in popularity as has the Sorghum. Many circumstances have conspired to render the product more valuable than could have been expected when it was first introduced, and now, after 10 years experience, we have seen it grow constantly in favor and its culture so extend, that in many districts, in widely different parts of the country, it is regarded as one of the staple crops, ranking with corn, potatoes, wheat, etc., in importance. The profits per acre, at the present prices of sugar, are larger than those yielded by any of the staple crops, except perhaps tobacco and hops. We have never known any one who began to raise it and who possessed a mill and evaporator, or could easily get his cane to them, who gave it up.

The syrup—gained by simply boiling the expressed juice, skimming off the feculent matters which rise as scum to the top—is often of very good quality; and under other circumstances of soil, manuring, maturity of the cane, etc., it is very poor, acid, and colored; still the poorest qualities may be purified and refined, so it all has a market value, especially in those parts of the country where it has been most grown. The improved evaporating pans, of which sev-

eral claim the favor of the public, enable a common hand with a modicum of good judgment to produce clear well-flavored syrups in most cases, which sell as high as, or higher, than good W. I. molasses, and answer all the purposes for which that is used in our kitchen economy. The prospects now are, if the weather continues favorable, that the yield of syrup this year will be vastly greater than ever before.

Within a year or two the discovery has been announced, and to a good degree confirmed, that the earlier the cane is cut, the more sugar is obtained in a crystallizable form. We have always held that the quantity and quality of the sugar separated from sorghum syrup was such, that it was much better not to aim at its production, but rather to produce syrup. What we have seen, with the exception of a few samples, was gummy, lacking in sweetness, and not as thoroughly crystallized as good sugar should be. However, if it be a fact that cane cut and worked early will yield a paying percentage of good sugar, it may greatly alter both the product and the profits. It must be remembered that green cane abounds in feculent matters.

In harvesting the sorghum, it is primarily necessary to cut it before hard frosts and to have it housed or protected from them. It is immaterial probably whether the topping and stripping be done at once, or later, and practice differs. The stripping is conveniently done by the hands, which must be protected with leather mittens, or what is better, square pieces of kip skin, to cover the palms, in which a fold may be sewed for the thumb to go in, and if necessary a strap may be sewed upon the back to go over the two middle fingers. As the cane stands, it is stripped from top to bottom at one motion, the leaves being laid between the rows. After this is done, upon as much ground as it will take several hours to cut, the stalks are cut at the ground, and laid between the rows in gavels, resting upon the leaves to keep them out of the dirt. The tops, with about three feet of stalk, are cut at the same time, so that the gavels of cane may be bound at once. The bundles should be of a size convenient to handle, and bound with two bands, which may be made of the leaves if not too dry. The tops are also bound in sheaves to be cured and fed out in the bundle or threshed. The leaves make very good dry fodder, being considered superior to corn fodder, of which, however, we have some doubt, for we value corn fodder very highly. These operations are laborious and tedious, so much so that at the West, where the relative value of labor is high, some farmers do not strip, but pass both stalks and leaves through the mill, even at a loss of considerable juice in the more bulky bagasse. The cane is best when the bundles are at once removed to the shelter of a roof of some kind; but when this is not practicable it should be piled up like cord-wood, and covered by a course of boards laid edge to edge and battened, or laid to break joints thus , or in some other way, protected from the weather and from freezing. It may be worked any time before hard freezing weather.

The time to cut the cane is said to be when the seed begins to turn brown, that is, when it is in the milk. At this time certain changes are going on in the stalk, which are not perfectly well understood; this much, however, is certain, that some cane sugar exists there together with a considerable portion of grape sugar, that the former is converted into the latter in the process of ripening, and that as the ripening pro-

gresses, a considerable portion of the grape sugar is converted into starch and woody fibre. It is probable also, that at an early stage much fruit sugar exists in the sorghum. This differs from grape sugar in being much sweeter and never assuming the crystalline form. Cane sugar crystallizes very readily, as we all know, for this is the common sugar, brown and white, which we use, derived from the Southern cane, from the maple, from the beet, etc. Grape sugar is much less sweet, 5 parts sweetening only as well as 2 parts of cane sugar, or of fruit sugar, which is as sweet as cane sugar. Honey contains both grape and fruit sugar. That portion which solidifies when honey becomes candied, is grape sugar. When grape sugar crystallizes, it usually forms fine needle-like crystals, grouped in such close masses that no crystals can be seen. It attracts moisture from the air, and becomes a pasty mass. Most of the sorghum sugar we have examined is a mixture of cane sugar crystals which are very distinctly seen, together with the gummy mass of grape sugar, and more or less molasses. When cane sugar is subjected to the action of a ferment or any acid, it changes rapidly into an uncrystallizable sugar, which in its acid and more or less impure state we know as molasses, and which is very similar if not identical with fruit sugar. The juice of the sorghum contains more or less acid, a green substance which promotes fermentation, also an albuminous substance which is a very active ferment in its natural state, and which, on being changed by boiling if any be left in the syrup, gives it a disagreeable flavor.

It is important that the canes be bundled and kept so that they will not be bruised, whereby air would come in contact with the juice and corrupt it. They should be thoroughly ground as it is called, that is, passed between rollers, so as to express all the juice possible at one operation. The juice should be exposed in the least possible degree to the air, and if delay is unavoidable, a very small quantity (1 or 2 pints to 100 gallons) of bi-sulphite of lime should be added, the operation of which is to arrest any incipient fermentation. The juice should be boiled down in flat pans as rapidly as is consistent with thorough skimming. If it is very acid, milk of lime is added, using seldom more than a pint to 30 gallons. Towards the latter part of the operation, the syrup should not boil, for the albuminous gummy substance will rise like cream upon the still surface, and may be removed. If the boiling continues rapid, it will not rise, but remain floating in minute particles through the syrup. The syrup is evaporated until it has, on cooling, the thickness of molasses.

There are several excellent evaporators of well-established reputation, with which, as we have said, any one of common sense can make good syrup, and if the juice contains cane sugar, this may also be obtained. To this end the syrup is evaporated considerably more than the consistency named, namely, to 38° or 40° of Beaumé's Sacharometer, while 25° to 30° is a sufficient density for syrup. On cooling and stirring, the sugar forms, and may be separated in a crude state by draining off the molasses.

THIN OUT AND HOE THE TURNIPS.—Success with any root crop depends upon keeping down the weeds and keeping the ground open and mellow. We charge our readers to remember that a turnip plant within two, or three, or six inches of another, is just as much a weed as a mullein or ragweed. It is no place for any plant, where it will interfere with the

full development of a more valuable one. Turnips never ought to stand nearer than eight inches apart, ten or twelve on an average in field culture is about right. Those which being crowded are checked in their growth do not yield nearly so much per acre, and they are stronger in flavor, and more pithy in texture.

Northern Men for the South.

It is true that the South is now open to Northern capital and labor, and that there are very good opportunities offered for Northern men with little capital, to do very well for themselves and their families, in many parts of the Southern States. A good many men are going thither, who are steady, industrious, good men; some men who have been unlucky and have not succeeded exactly at the North, either from bad judgment or sloth; a few others, restless spirits, go because they think there is a chance to speculate and get money by not working hard for it. No one goes expecting to take a similar position to that which he has at home—he aims at something better. Our Southern correspondents who write us enquiring about the chances of getting Northern men to come to take charge of their farms and plantations, and to do the labor upon them—to manage their dairies—and do all sorts of things, seem to realize only that Northern folks are not afraid to work, and that they will do any kind of honorable labor if they are well paid for it. This is true, but it is also true that intelligent men, such as they want and would be satisfied with, are a good deal more intelligent and *smarter*, to use a common expression, than many, if not most of the men and women who want to hire them. They may not all be able to write as good a letter, though many of them will better. They would not appear as well in an evening party, perhaps, but for the real business of life are their equals. These men and their families go South expecting to become land owners, to take positions in society equal to anybody—to carry their principles with them, whether they are Democrats, Republicans or Radicals, to sell their labor, their knowledge, their abilities to whoever they make agreement with; but to be bound to nobody, except, for mutual advantage, they be *mutually* bound. If Southern landowners want such men they may advertise for them, or secure them in any way; and if they will give them a fair chance, no doubt they will gain the services of good farmers, dairy folks, etc., and good, moral, substantial, freedom-loving citizens.

Some such chances are afforded. There are, besides, fine lands in Virginia, Tennessee, Missouri and Arkansas, and indeed in every other Southern State, offered for sale cheap; and if Northern men would associate themselves and purchase farms in the same districts, so that they would be a moral aid, if necessary, a physical support to one another, there appears to be for single men, or families desirous of emigrating, no more favorable prospects anywhere else.

Any class of men who are kind to the negroes, get them to labor for them freely; but those planters who attempt to control the labor of the plantation in the old way, find no end of difficulties. Among this class newly arrived immigrants will and do find profitable employment; and, as at the West, habits of frugality and industry will soon be rewarded by competence, and the immigrant will surround himself quicker than he could in New England with land and home of his own. It must not be forgotten that the difference between these two

classes of settlers is, that the New England emigrant leaves a competency, home, land and all, and moves to *do better*, while the European immigrant comes to this country to *make his home*, and a home for his children after him.

Chicken Medicine.

We continue our discussions of the subject of chicken ailments, because we hope to give our readers information by which they may profit, and to receive hints from them, and so, by and by, get facts enough to enable breeders to successfully study and treat the diseases of poultry.

Parasites. — Lice, are among the most annoying of the troubles which the poultry raiser meets with, and remedies quite successful in one yard fail altogether in another. The reason doubtless is because there are several kinds of lice which occur in our poultry yards, and the remedy entirely efficacious for one may not affect the others.

We published some time ago the statement of a correspondent who drove the lice out of his nest boxes by raking up the leaves of the button-ball tree raked up in the fall. The following from G. T. H., of Beverly, Mass., gives another similar remedy, and one which may be employed at any season of the year.

"For a number of years past I have kept from 20 to 50 hens, and they used to be much troubled with hen lice; and though I kept my hen house (as I thought) pretty well whitewashed, at times it was overrun. I was told if I made roosts of the Sassafras wood, it would surely drive the lice off. Not being able to get that kind of wood for roosts, I set about devising a substitute. One day I came across a large bed of common tansy. I gathered a good quantity, took it to my hen house, and made several nice nests. This was done in the summer of 1864. Last season I renewed the tansy. When the lice left I know not, but this I do know, I have not seen a louse, or the sign of a hen louse, about the premises for more than a year, and I have examined the hens pretty often and thoroughly."

In order that our readers who are interested in this subject may investigate the parasites more understandingly, and specify the kind of louse which certain remedies drive away or destroy, we give pictures of four kinds which are the only ones figured, as found upon the domestic fowl, by Mr. Henry Denny, in his work on the lice of Great Britain, called *Monographia Anoplurorum Britannia*. We know of no English names, and for convenience coin some.

The Big-bellied Hen-louse (*Goniocotes holo-gaster*), fig. 1, is an eighth of an inch long; its head, thorax and legs, are of a pale yellow color, with pitchy black marginal bands, and its very large abdomen is girt with pale ash-colored bands (*fasciæ*), bordered with black.

The Big-headed Hen-louse (*Goniodes dissimilis*), fig. 2, has a length of a little over one line ($\frac{1}{12}$ of an inch.) It is tawny, smooth, shining,

somewhat downy or hairy; head large, with prominent temporal angles, abdomen large.

The Long-bodied Hen-louse (*Lipeurus variabilis*), fig. 3, is $\frac{2}{3}$ of a line long, of a dirty white color, margined with black. The head is dome-shaped, pale yellow, with a black spot on each side behind the eyes. The abdomen has an interrupted (broad and narrow), dusky band running lengthwise down the centre.

The Pale Wandering Hen-louse (*Monopon*

so, virtually, making the fence by so much the higher. This plan, on soil upon which it will stand, has several merits, which we think are worthy the consideration of even those farmers who are so well pleased with their own plans. We have not yet heard particulars from Mr. McLean, but taking the simple statement above, it is evident that the walls stand. The reason is, that no water can stand near the wall, and so the heaving of the earth by the frost affects earth, foundation and wall, all alike.

"R. S.," of Norfolk, Conn., writes, quoting the statement referred to: "If you would see the best stone fences you can build perfectly prostrated in 8 or 10 years, build them upon a ridge thrown up 18 inches high, and my word for it you will not be disappointed. If, on the other hand you desire good and permanent fences, take six inches from the surface and plant good substantial stones in at the

bottom; (see fig. 1.) then build the remaining part well, and you have a fence that will be with you and in good shape most likely during your sojourn here. Thirty-five years' experience in wall-laying confirms me in this belief."

"A Subscriber," of Tingsboro', Mass., details his own experience as follows:

"I dig a ditch (see fig. 2,) or trench, where I wish the wall to stand, as wide as the foundation of my wall, and as deep as the soil is suitable for making manure, (I think the soil thus obtained pays for the labor of throwing out);

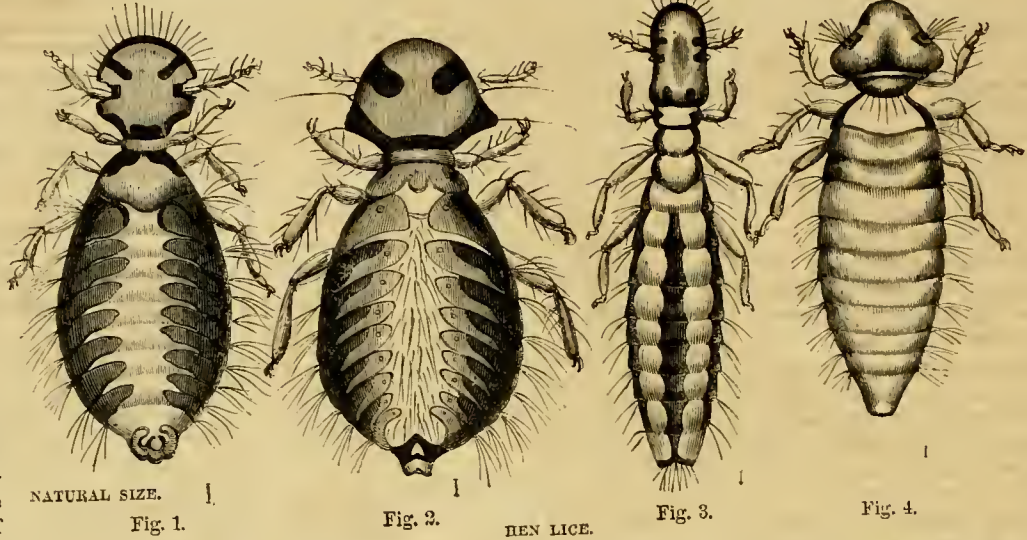

Fig. 2.

then I pick up and cart to the line of the wall all stone large enough to be in the way of the scythes or the mowing machines; thus clearing my mowing land, and furnishing a material for a foundation on which a wall, no matter how heavy, will stand for years. My father has walls upon his farm built twenty years ago, upon the same plan, from which not a stone has been thrown by the action of the frost. The plan is adopted by many farmers in this vicinity, and well liked."

These plans will both answer well upon certain soils and situations, but not upon all. R. S's plan, for instance, does not secure a dry foundation in clayey ground, and we know many a piece of land on which such walls would surely fail. Nevertheless, they are economical, lasting on soils where water will not stand. The second plan is better, for the small stone foundation affords drainage, which would leave the wall dry if there were only a slight inclination of the ground. There should be provision for taking off the water from the low parts on the line of the wall.

The plan of building a wall over a good stone drain is approached in this case, and where the soil is not full of water, the shallow drainage thus provided for would answer a good purpose

NATURAL SIZE.

Fig. 1.

Fig. 2.

HEN LICE.

Fig. 3.

Fig. 4.

pallidum), fig. 4, has an elongated body of a pale straw color, shining and smooth. The head is slightly hollowing on each side, with pitchy black spots. It is from $\frac{1}{2}$ to $\frac{3}{4}$ of a line long, and is found in great abundance in neglected henneries upon the roosts, etc., and usually first noticed by its running over the hands, from which it is difficult to brush off on account of the smoothness of its body, and the tenacity with which it clings with its sharp claws.

The use of mercurial preparations is always dangerous, unless conducted with extreme care. These are always fatal to lice of all sorts, but can only be used upon the polls and necks of adult fowls (where they can not reach with their beak), for, in drawing the feathers through their bills in pluming themselves, they would be surely poisoned. Dixon recommends the use of white precipitate dusted upon the heads of young chickens, three or four days old. Greasing fowls is a temporary relief, but it does not clear the lice out of the nests or from the roosts, and unless the application be followed up, there is no security. The grease is applied any where; but under the wings and upon the poll and breast is best, for here the lice are usually found.

All other varieties of poultry, and wild birds besides, have each their distinct kinds of lice.

Stone Fences.

The statement made in regard to Hon. John McLean's stone walls on page 130 (April), has elicited several letters of dissent from farmers who also rejoice in having their stone walls stand well. It will be remembered that Mr. McLean's walls are built on ridges of earth thrown

Fig. 1.

up 12 to 18 inches high, the ground used for the ridge being taken from each side, and

Fig. 3.

as stated by "A Subscriber." The best walls we have seen were built over broad and deep stone drains, which were brought to the surface, and really formed the foundation of the walls. A few weeks since we saw a good wall upon the farm of a friend in Hartford County, Ct. It was very simply laid up, the foundation stones being the largest ones, of course, and being barely bedded in the soil, but on a formation of ground where water would not stand. The peculiarity of construction consisted in "tying" the wall with pieces of fence rail, cut of suitable width, and laid up athwart the wall, with the stones as indicated in fig. 3, by *a, a*. These tie pieces were arranged in two lines or rows, about midway of the height of the wall, and 2½ to 3 feet apart in each row. This wall has stood very even and firm for many years, while a wall of an adjoining proprietor, built of the same kind of stones, and in the same way, omitting the ties, has been in spots nearly shaken down by the frost, and stones are misplaced throughout its whole length.

The Needed Reform.

It may be remembered that in the *Agriculturist* for January there was an article on a "Needed reform and its profitable practice," which described a way by which all the contents of the privy were saved for manure in an entirely inoffensive form. The method there suggested of saving this exceedingly valuable manure (to mingle it with well-dried peat or swamp muck) is excellent, and can hardly be improved, except, perhaps, in the use of artificially dried soil, as in the earth closets alluded to in the last number, p. 286. Very dry muck is probably better than earth, though we have no experiments showing which is best, and as peat has a considerable value for fuel in England, soil has been used, and its virtues perhaps unduly exalted. "B. C. F.," of Port Jervis, sends us a plan of a drawer for a privy which may, with little expense, be attached to almost any one, and so the contents be easily removed to the compost heap, or where it can be immediately utilized. He writes as follows: "The accompanying diagram will explain this, and give an idea of how the difficulty may be overcome, and at the same time have a conveni-

Fig. 1.

ent situation, as I have, with a good Grape Vine screen; in fact it is ornamental as well as useful. The diagram (fig. 1) shows a drawer made

of inch boards, 5 feet long, 5 feet wide, and 2 feet deep, of a shape to extend under the seats. Under the outside edges are two hard wood sticks, with grooved wheels let in, which are nailed to the drawer. This drawer moves on a hard wood frame 10 feet long and 5 feet wide, with strips of half round iron screwed down, forming a track for the wheels, and by this means you are able to pull the drawer with ease clear of the building, and remove its contents. The depth of pit should be 3 feet, and filled in with gravel to the required height for the frame. The building should stand at least the width of two bricks above the ground to preserve the sills, and the foundation should be set in mortar or cement. Cover the 5 feet space in the rear with a trap-lid with rings, or hinges screwed to a frame."—With formations of ground, as would admit of it, this would be the best plan perhaps, but we have seen another form of drawer or box used, which is preferable when the ground has a slight slope. The box (fig. 2) is supposed to be, say 5 feet long and 2½ feet high. It is made of inch stuff, and set on a pair of 4 inch blocks, or a single pair of wheels. The shape of the box is such that it will tilt forward unless braced up as shown in the engraving, or at least may easily be tilted forward. This enables a man to shovel over the contents and add fresh muck or soil. When full, two men will move it anywhere on hard ground, or it may be pulled out and the contents shoveled into a cart or upon the compost heap. In these cholera times when people's minds are dwelling so much upon sanitary measures, there is hardly a more important subject than clean, neat, odorless privies, that can receive our attention.

Fig. 2.

It is hardly necessary for farmers to attempt to dry and work over the muck or soil several times, though, should they do so, the compost, "poudrette," or whatever it may be called, would be so much the stronger. Yet the manure made by once using the muck is strong enough for most purposes—fully as strong as good barnyard manure, and the working it over would involve to most farmers as much or more labor, as obtaining an equal quantity of fresh material, muck or soil, of proper dryness.

Yet Another Bag-Holder.

Yes—Another Bag-holder—the simplest yet, and one of the very best as well as most easily obtained. Many a man would rather go half a dozen miles, and then buy what he can make himself perfectly well in half the time, just because he never can make any thing to suit him. So as most of the bag-holders we have described require a little ingenuity to make them, no doubt many go without the convenience. Here, however, is one ready made, a barrel with both heads out, and a few nails driven in between the staves and hoops at one end. The sketch is sent for the benefit of *Agriculturist* readers by "Michigander," of Hastings, Mich., and as we have tried it and found it to answer, we present it to our readers. A common grain bag in most parts of the country is longer than a barrel, and may be hung over four nails in the top of a barrel, and still be slack, touching the ground. The bag is spread and hung over the

BAG-HOLDER.

nails as shown. The measure may be rested upon the chine of the barrel, if desirable, and when the bag is full, the barrel may be lifted off.

Cows for Milk and Butter.

That the milking qualities of cows are hereditary no one will deny. They come from both sire and dam, and it is claimed, not without some foundation, that heifers take after their sires' dam in regard to milking qualities oftener than after their own dams. This may be true in some cases, but not in all, and especially not in crossing bulls of pure breeds on common milking stock. We often have letters like this: "Will you have the kindness to give me some information about cows for milk and butter purposes. I want to breed especially for milk and butter for family use, and want nice cows, with a good supply of good rich milk and butter. I want to establish a herd of this sort for home use, and to supply the country demand. What breed shall I select from?"—Buy the best common cows you can, which are good rich milkers. Use upon them a pure blooded bull. If you use an Alderney bull you are very sure of rich milk, but small size in the progeny. If you use a Dutch bull, you will get large frame and probably much milk of medium quality. The Ayrshire cows will give a medium quantity of milk of fair richness, while the Short-horn cross will be likely to produce stock giving a good quantity of milk, the quality variable. The tendency to give much milk is increased in heifers by letting them have calves very young, milking three times a day, and giving succulent, rich, milk-producing feed.

The Mississippi Levees.

Our readers are probably aware, that during periods of high water in the Mississippi, a large part of Louisiana was once entirely submerged, especially that portion lying south of the mouth of the Red River. The channel was incapable of carrying the water, and so it overflowed, making other channels to the Gulf, and deluging the adjacent country. The Atchafalaya and Plaquemine are the principal of these channels, and these have been throughout their whole extent, nearly, carefully embanked. When the river bursts through the embankments, the break is called a "crevasse." Through these torrents flow, doing unspeakable damage, tearing up the land and depositing earth and sand in bars here and there. Where the water remains with little motion, deposits of rich soil are made. Enough sediment is brought down the Mississippi River every year to cover 125 square miles, 1 foot thick with solid soil. The entire area of the Delta of the Mississippi is about 14,000 square miles. As the population increased, planters,

who at first occupied the higher ground, began to secure themselves against the overflows by low embankments, raised just high enough to turn the water off from their own property. As the number of these "levees" increased, of course the river rose higher and higher in its bed, and so the levees had to be raised and made stronger, until finally it came to pass that the governments of the parishes and of the State took hold and regulated the matter.

The U. S. Government had an elaborate survey made of this whole country, by which a vast amount of information was gathered, and the foundation laid for proceeding understandingly with one of the most important agricultural public works which any government ever undertook. Congress has recently refused to pass a bill to reconstruct the levees which have broken down more or less in consequence of the war. This is well perhaps, for the subject had hardly been sufficiently considered either by the Congress or by the people. Millions of acres of the very best farming lands in the world are rendered entirely unproductive by the danger or by the reality of overflow. The lands might properly be assessed to pay for the works and their maintenance. Levees alone are not what is wanted, but a system of canals by which the surplus water may safely be drawn off and conducted into the Gulf, should form an important feature. With proper engineering, the overflowed lands of the Southern Mississippi would become the very garden of the world. Corn and sugar cane, are the staple crops. Figs, oranges, pecan nuts, etc., for which the markets of the world are open, grow almost wild—while sweet potatoes, yams, peanuts, melons, and almost all sorts of garden vegetables are produced with a luxuriance, which a Northern man will only believe when he sees. Is not the redemption of these lands a work for the Government? The poor, bankrupt rebel States can not think of appropriating the money to it, while private enterprise can only work on the old plan and strengthen its own levees.

Walks and Talks on the Farm.—No. 33.

Last year we raised a nice lot of yellow Danvers onions, and sold them to a man to take to Canada. We took them to the steamboat landing and got there just as the vessel was seized for smuggling whiskey. Of course, I had nothing to do with that part of the business! But I had to bring the onions home—a hundred bushels or more, and before the men got back it rained heavily and wet the onions. I had no convenient place to store them, and the only thing I could do was to set them out for seed.

I had no experience in raising onion seed, and determined to do the work as expeditiously as possible. I marked out the land with a corn marker, then ran a plow along the marks, turning up a shallow furrow, and then set the onions six or eight inches apart, and covered them with a plow. The work was soon done, and I concluded that if the onions failed the loss would not be very great. This spring I ought to have gone over them and removed the earth just as the onions were starting, but as it was merely an experiment I did not feel willing to incur the expense. Well, many of the onions died, and I have rather a spotty piece of seed. But I planted beans in the vacant places, and on the whole shall probably get pay for the labor. The land was in prime condition, and the onions being thin, the heads are very large, and I think we shall have some splendid seed.

One of our largest seed-growers was here a few days ago, and thought, "I should not grow any more onion seed." I told him that he was greatly mistaken. The fact that I had not succeeded very well in the first attempt, was precisely the reason why I should not abandon it. I have read an anecdote somewhere of the Mother of the Wesleys. She did not teach them their letters until they were five years old, and all of them but John learned the alphabet in a single day. But John was stupid. He could not remember his letters. It seemed as though he was destined to be the dullard of the family. At length the discouraged mother told her husband that she would have to give up John. She had tried and tried to teach him his letters, but he could not learn. It was no use trying any more. "But, my dear," he said, "if you give it up now, you will lose all you have done." She tried again, and that time John succeeded and gave his mother no further trouble.

One of my neighbors took a lot of cattle to New York, and the market happening to be a declining one, he lost a thousand dollars by the transaction. "But," said he, "I told those fellows down there that I had merely lent them a thousand dollars and that they would have to pay it back with compound interest." He believed in "looking for money where he had lost it." I don't know whether he has succeeded or not. "Sam has been sick" a good many market days since then, and possibly the money is still at interest. But the principle is a correct one. If you fail, try again.

"Not raise any more onion seed." I should feel ashamed of myself. That man will make a poor farmer who abandons a crop on account of a single failure. One failure at the outset will teach him more than a dozen successes.

"But," said my visitor, "I should think you would not like to have a poor crop close by the road, where everybody could see it—and you, an agricultural editor!"

"As an agricultural editor, judge me by what I write.—As a farmer, by what I practice. Don't mix things up. Perhaps I ought to write better for being a farmer, but I don't see how I should farm better for being an editor."

"Those who preach, should practice. You give advice to others; ought you not to follow it?"

"I do not 'give advice.' I state what I think the best methods, and if they are the best, and others act upon them, I do no harm. If I do not adopt them myself, it is my own loss—not theirs."

This seemed to him an entirely new view of the matter. Of course, I do the best I can. But where is the farmer that is always able to do just what he thinks ought to be done—and at just the right time?

Yesterday I was drawing in wheat. We had had several heavy showers, but the wheat was finally dry, except at the bottom where it stood on the damp soil. About nine o'clock, after the dew was off, I set the men to pull over the shocks so that the butts would be exposed to the sun. The day was perfect, and we pulled over the whole field of fourteen acres. By eleven o'clock the wheat was in prime order, and we commenced drawing in with three wagons. We got in five loads, the men worked with a will, and in five or six hours the whole would have been in the stack. "But see that dark cloud! Is it possible we can have rain on such a day as this?" The Deacon was appealed to, but thought it would not rain. The barometer fell a little, and presently a clap of thunder was heard in the distance. But the cloud is passing

off to the North and we shall escape. Shall we? The cloud took a short tack, and in less than three minutes it poured such a flood of rain upon us that it was only by quick work that we could throw straw enough on the stack to keep it from being soaked to the bottom.

Of course, my critical neighbors say I was foolish to pull over all the shocks and get caught in a shower. Perhaps I was, but I would rather have grain spoil in the field than in the barn, and had the shower held off four or five hours I should have hit it—as it was, I missed it.

But no matter, I was more fortunate with my clover. I got in thirty-three acres without a shower—or at least without one that did any harm. And what is better the clover was heavy, and I have three noble stacks that ought to fatten a good many sheep next winter. It looks now, too, as though I should have a good crop of clover seed. The rain which has interfered with the grain harvest helps the second growth of clover. The potatoes, too, grow like weeds.

The Deacon says I hit it with my potatoes. I plowed the land in the fall and spread some well-rotted manure on the surface early in the spring, and cultivated and harrowed it in, and then planted the potatoes without plowing. A finer growth of vines I never saw—and while you sometimes get vines without tubers, you never get a big crop of potatoes without a good growth of vines. They should be thick and strong, not long and spindling. Some of them may be a little too rank, but we shall see.

There is one thing I should like to know: When you let clover go to seed, does it weaken the plant so much that you cannot look for a good crop the next season? I have had no experience, and do not recollect seeing the matter alluded to in any of the agricultural books or papers. But from what I know of the habits of the plant, I should think, that after it has once perfected its seed, it would make only a feeble growth the next season. Ordinarily, timothy is sown with the clover, and the year after the clover seed is grown, the next crop is principally timothy with only a little clover. But in my case I sowed nothing but clover, and if this fails I have nothing to occupy the ground. If it does fail, I suppose the fact can be ascertained early enough in the spring to allow the field to be plowed up and planted to corn.

I am not sure if this would not be a good system of rotation. We might need more manure than most of us can command to carry it out to the best advantage at first. But when the land was once in good heart, it would not be difficult to keep it up. We should have, say wheat seeded with clover; the clover mown for hay the next season, and for seed in the fall. Then, if you can spare it, top-dress with manure. This would probably give a good growth of clover that could be turned under immediately before planting. I would plow it well and harrow thoroughly, and then drill in the corn every day as fast as the ground could be got ready. This cannot be done if the corn is planted in hills. You must wait until the whole field is finished before you can plant a kernel. The plowing need not be done until the weather is right for planting. The ground would be warm, and a clover sod of this kind might easily be made as mellow as a garden. The corn would be soon up, and the cultivator could be run through the rows as soon as you could see the corn. You can drill in corn with a machine that takes two rows at once, much straighter than it can be planted by hand, or at

least straighter than it usually is planted. On such a clover sod, nearly all the hoeing can be done with the cultivator. The clover will decay and furnish food for the corn, and if thoroughly cultivated, a noble crop will be obtained. After the corn is off, plow the land in the fall, and the next spring run a three horse cultivator through it once or twice, harrow and drill in barley. Follow with wheat in the fall, and seed down with clover again in the spring.

If we are ever able to get Peruvian guano, or some other equally good artificial manure, at a reasonable price, it would pay to give the wheat a dressing of two or three hundred lbs. per acre in the fall. It would help the wheat a good deal, and would greatly increase the growth of the clover. The barley, too, would be much benefitted, especially if sown early, by a similar dressing of guano or other good fertilizer.

As soon as we were able to afford it, I would top-dress the young clover in the fall, after the wheat was off, with some well-rotted manure. This would give a heavy growth of clover for hay early in the season, and in addition to this it will insure a good crop of clover seed.

"You have no timothy." No. We cannot afford to raise it on the upland portions of the farm. It impoverishes the soil as much as a crop of wheat. Raise it on permanent meadows on the low land. Such land, if drained, will give great crops of hay, and this fed out on the farm will make manure for the upland. We have no crops that we can raise to sell that will injure the land less or pay better than wheat, barley, and clover seed. The clover hay, and the corn and fodder will, of course, be fed out to stock in winter. This rotation may be easily varied without throwing it out of gear. For instance, you might plant potatoes instead of corn, and follow with barley just the same. But as the potatoes are sold, the enriching effect of the rotation would be weakened. They are, however, usually a profitable crop, and if we used more artificial manures, the land could be kept in heart equally well. I know of no ordinary farm crop to which a good artificial manure can be applied with as much profit as potatoes. The reason of this is not that the manure benefits potatoes more than other crops, but simply that we get a better price for potatoes than we do for ordinary grain crops. For instance: An average crop of wheat without manure, would be about 15 bushels per acre; and an average crop of potatoes 100 bushels. Now a manure that would add one-half to the wheat would also add, probably, one-half to the potatoes. In other words, it would give an increase of 7½ bushels of wheat on the one hand and 50 bushels of potatoes on the other. The wheat at \$2.00 a bushel, would be worth \$15, while the potatoes at 50c. a bushel, would be worth \$25. And in this section wheat is much more frequently below \$2.00 than potatoes are below 50c.—on the farm. I say "on the farm," because the labor of storing and marketing potatoes is considerable.

The Deacon always shakes his head when I talk about artificial manures. "You have raised one good crop," he said the other day, "but we shall see." He alluded to my wheat. I have not yet thrashed, and of course cannot tell how it will turn out, but as the pomologists say of a new fruit, "it promises well." If I could buy Peruvian guano containing 16 per cent. of ammonia, and 25 per cent. of phosphates, for \$90 per ton, I would put 300 lbs. on every acre of my wheat this fall. By the time

it was on the land this would cost say \$15 per acre. In England, 5 lbs. of ammonia give an extra bushel of wheat. According to this rule, 300 lbs. of such guano would give an extra yield of about 10 bushels per acre. If we got \$1.50 a bushel, the account would just balance. But we should get a greater growth of clover the following year. And even if all the guano is used up by the wheat and clover, the extra growth of clover roots would serve to enrich the land, and this with the extra crop of clover hay and seed would afford a profit—"not gorgeous," as the author of "My Farm of Edgewood" says, but still a profit.

I see that the editors of the *Agriculturist* ask its readers in different sections of the country to inform them of the price of manure. This is a good idea. I think it will astonish those who have thought little on the subject to find how much it costs to manure an acre of land. I was talking to a farmer who draws considerable manure from the city, and he told me that he believed it cost him \$100 an acre. He does not raise ordinary farm crops. If he did I do not believe it would pay. As a general rule, the more labor a crop requires to grow it, the more profitable will manure prove. That is awkwardly expressed, but you get the idea? This is the reason why market gardeners, seed growers, and nurserymen can afford to pay so much for manure. If they can double the crop without increasing the labor, they can well afford to pay a high price for manure, for the price of the product is usually in proportion to the labor and skill required to produce it.

The Doctor says he sowed oats this spring on land that was plowed last fall, and simply harrowed in the spring without another plowing, and he raised a splendid crop. He thinks harrowing is better than cultivating, as oats, like wheat, seem to prefer a firm soil.

Last spring I drilled in some of my barley, and sowed the other broadcast. We are cutting it to-day (July 28), and Dutch Peter, who was cradling round the field to make a path for the reaper, remarked, "You sowed the barley with a machine?" "Yes," I said, "Part with a machine and part by hand." I showed him the place where the drilled barley ended, and remarked that the broadcast seemed the best. "Ten times better than the machine," he said. This was a slight exaggeration! Peter, of course, is prejudiced against all machines. But it would seem to be a fact in this case that the broadcast barley was the best. Still it is so much more convenient to sow with a drill—you never have to stop on account of a high wind—that we cannot afford to be without one.

Speaking of the prejudice against machines, I heard one of my men tell Jacob, who drives my reaper, that if we had another man who could cradle as fast as he could, they could cut more wheat in a day than he could with a machine. This was in the morning, before we commenced to reap. I told Jacob not to mind their taunts, but to drive steady. The horses were disposed to be a little frightened at the reel. But I knew all the bolts were tight and everything snug, and that there was not much danger of breaking one of Wood's best reapers. "Keep 'em straight Jake, and let 'em go"—and away they went round the field as fast as they could walk, and sometimes a little faster. But the machine stood it. The wheat was pretty heavy, and there was no need to put

the break on the self-raker. The sheaves came off thick and fast, and the five men who were binding, were soon left behind and I had to put on another hand, and even then they thought they had to work hard. Now, we ask the opponents of machines, where are the two cradlers that can keep six men busy to bind after them?

Topping Corn and Corn Fodder.

We are in little danger of over estimating the value of well-cured, or only tolerably well-cured, corn-fodder. As feed for milch cows it is hardly surpassed by very good upland hay, and has to encounter only one serious drawback, namely: it must be cut up fine, salted and wet up with a little meal, bran, or oil cake of some sort, in order to get the full benefit. The necessity of spending so much labor upon it detracts from its value, so that while in New England a farmer may perhaps afford to pay two-thirds what he would have to pay for hay, at the West, where fair hay may be had for the cutting and hauling, its value is less in proportion. Still, fed whole, it is highly relished by all kinds of stock, and constitutes the chief living of the young stock in winter over a large portion of the Northern States. At the West the great corn-fields, upon which the stalks are left standing after the ears are picked, afford winter feed, poor and weathered though it is, which helps many a herd through that might perish otherwise in the hard winters.

When the corn-stalks are very large, it is hardly worth while to attempt to cure the big butts and cut them up for fodder. There is probably a small gain in the weight of the grain, if after the kernels glaze well the corn be cut up at the ground, rather than topped above the ears. Yet where the great dent corn is planted, we incline decidedly to the opinion that there is a decided advantage gained when it is topped, and the tops and suckers (earless side-stalks) are well cured.

The practice at the South of breaking out the suckers together with the lower leaves of the corn, while yet it is green and the ears not glazed, certainly affords a very excellent fodder, and if enough of the strong growing suckers, which would make good male flowers, be allowed to stand to fertilize the tips of the ears, it is probably economical. Where the small kinds of corn are grown as throughout Canada, New England, and New York, we regard it as poor policy and a loss of fodder to top corn for the sake of getting a kind of fodder which the cattle will eat up clean if not chaffed. With a little pains and labor, but a very small portion of the stalks are refused by the stock.

Dr. R., of Hartford Co., Conn., had a corn-stalk stack accidentally put up too green, (or perhaps, it got thoroughly rain-soaked,) so that it heated, and the interior came into a condition of very active fermentation. The result was, that he thought it mostly ruined, and as soon as he could, threw off the unhurt portions to save them, and thus opened what appeared to be a mass of corruption beneath. The butts were the only parts of the stalks which retained their form, all the rest was a brownish or black mass, smelling, however, not unpleasantly. The cows showed their preference at once by rejecting the sound stalks, and eating the others, the softened ones, with great gusto. The fermentation had proceeded just so far as to form the famous "brown hay," the stalks being soft, sweet and flavorful. The Doctor has, we believe, repeated the operation with success.

ORNAMENTAL GROUP OF AQUATIC PLANTS. — Designed and Engraved for the American Agriculturist.

Aquatic Plants for Ornamental Ponds.

The term, Aquarium, has of late years been so exclusively applied to the glass tanks in which plants and animals are grown, that we forget there is an older, and quite as legitimate use of the word, viz., its application to ponds or enclosures of water in which aquatic plants are grown. A body of water, fed by springs or a living stream, is always desirable in grounds of moderate dimensions, while a mere pond, depending upon rains and drainage of the adjoining land, for a supply of water, is always a nuisance.

Those who possess a proper body of water, have the means of cultivating a number of aquatic and marsh plants that could not otherwise be grown. While some plants need a certain depth of water, others grow well if their roots are merely placed in the moist margins. Our artist has represented some of the more striking aquatic plants that may be employed for ornamenting bodies of water. In the centre of the picture we have the Water, or Pond-Lily, (*Nymphaea odorata*), which may deservedly rank as first in importance. The fine floating leaves, the pure white of its flowers, as well as their delicious perfume, make this the most desirable of water plants. This Lily has a large and fleshy root, as large round as a man's arm. It

grows in two or three feet of water, and is rather difficult to get up. When the root is obtained, sink it, by means of stones tied to it, and it will soon make itself at home. There is considerable difference in the size of the flowers, and some of them have a pinkish color. The Yellow Water-Lily, (*Nuphar advena*), is less elegant, but may be introduced to make up a variety. The tall aquatic on the left hand of the picture is our largest wild flower. It is the Yellow Nelumbo, or Water Chinquapin, (*Nelumbium luteum*). The leaves are often two feet or more across, and the pale yellow flowers, which are six or eight inches in diameter, are succeeded by a peculiar top-shaped fruit. This plant grows at Lyme, Conn., at Philadelphia, Penn., at Big Sodus Bay, Lake Ontario, and in the waters of the Western and Southern States. It bears tubers from which it can doubtless be propagated. Our native *Calla palustris*, much like the green-house Calla, but smaller, may be introduced in shallow water. This is shown in the engraving in the foreground on the right of the centre. To the right of this is the Arrow-head, (*Sagittaria variabilis*), of which the arrow-shaped leaves present a great variety of forms. Another common plant, with an arrow-shaped leaf, and a spike of purple flowers, not shown in the engraving, is the Pickerel-weed, (*Pontederia cordata*), and is found in almost every pond.

The banks of such a piece of water afford an admirable locality for the curious Pitcher Plant, figured in May last, as well as for the brilliant Cardinal Flower, (*Lobelia Cardinalis*), and many others. Nor should the less showy but curious aquatics be forgotten in planting. The common Cat-tail, (*Typha latifolia*); the Reed, (*Phragmites communis*); the Wild Rice, (*Zizania aquatica*), should not be omitted. Indeed, our own waters furnish enough species, which, judiciously planted, will produce a pleasing effect. We have noticed only some of the most conspicuous of our native water plants. Any one can, with a little care, transfer to his pond the attractive plants he finds in his rambles, and there are besides a number of exotics worth growing.

THE HOLLYHOCK AS A BOUQUET-FLOWER.— We are so accustomed to see the Hollyhock used as a stately ornamental plant that it is one of the last that we would think of using in a bouquet. Yet after the abundance of roses is over, Hollyhocks go largely to make up the showy bouquets sold by the flower-girls in the streets of New York. The improved varieties are very double and neat in form, the texture of their petals is delicate, and they present a great variety in color, from pure white to almost black. Some of the shades of straw and

rose colors are as fine as need be. When these flowers are used in a bouquet, they are placed singly, on artificial stems. The outer, or "ray petals," as florists term them, are removed, an operation which leaves the flower in such an altered condition that it would not at first sight be recognized as a Hollyhock. With plenty of lively green, and here and there a Tuberosa, or bit of Heliotrope to give fragrance, they produce a most pleasing effect, and have a delicacy and brilliancy which one would hardly suppose the Hollyhock capable of showing.

Packing Grapes for Market.

Scarcely any fruit depends more for its price upon the way it is packed than do grapes. They are so easily knocked from the stem, and the berries so readily broken, that it is not practicable to transport them for a long distance in large packages. The favorite package in the New York market, is a box holding five pounds. Ten pound boxes also come, but have a less ready sale. The boxes have light top, bottom and sides, and strong ends, and are made in the grape regions at a very cheap rate. The grapes are packed with the top nailed on the box, and the bottom removed. Some growers put a piece of paper in the box before putting in the fruit, but this is not essential. First, a layer of fine bunches is put in, then smaller bunches, until the box is full. The bottom of the box is then nailed on, taking care to have the berries packed as closely as possible without crushing them. When the fruit is to be kept for some time, the boxes are filled a little heaping, and allowed to stand for several days before closing. During this time the fruit shrinks somewhat, and the skin becomes tougher, so that the bottom can be put on with considerable pressure. All grapes should be picked when perfectly dry, and those that are to be retained for a later market should be kept as cool as possible.

The Philadelphia Raspberry.

The original plant of this Raspberry was found growing wild near Philadelphia some twenty odd years ago, and is probably a marked variety of our common red species, *Rubus strigosus*. Though it has been so long in cultivation it has not been extensively grown out of Southern New Jersey. We give an engraving of a fruit cluster, from Fuller's Small Fruit Culturist, now in preparation. It will be seen that the fruit is only of medium size; it is of a dark, or purplish red color, firm, and of fair quality. Those who take Brinckle's Orange or even the Fastollf as their standard of quality, will not rank the Philadelphia as first class. Still, upon the light soils of New Jersey it is much more valuable than the finer varieties, and possesses qualities which make it the leading market variety and one of the most profitable fruits of that section. In a market fruit, productiveness is of the first importance, and this the Philadelphia has in a high degree. We regarded the stories told of

its productiveness as extravagant until we saw the plants in bearing. It is stated, upon good authority, to yield over 200 bushels to the acre. It is perfectly hardy, and requires no laying down, and has so sturdy a habit of growth as to require no stakes. The plant does not sucker very freely—a desirable quality in some respects, but one which prevents its multiplying as rapidly as may be desired by those who sell plants. Upon the whole we are greatly pleased with all we have seen of this berry, and shall be glad to hear that it has proved itself as valuable elsewhere as it is in the vicinity of Philadelphia. We believe in having a high standard of quality in all fruits; we also believe in having fruit in plenty, and if we cannot get an abundance of the best, let us have the best we can get. The Philadelphia

PHILADELPHIA RASPBERRY.

is among Raspberries, what the Concord is among grapes, not a fruit of the highest known excellence, but a sure and abundant bearer.

Since the above was in type, we notice a report in the Northwestern Farmer that this variety has given good results in Indiana. Mr. A. Furnas says: "The Philadelphia has fruited twice with me, and thus far, has been apparently as full of fruit as it could hold. Indeed, the canes were weighed down with their load of fruit. This raspberry has proved to be entirely hardy thus far. The berry is of a pale red color, quite firm, with what some pronounce a slight touch of the pumpkin flavor, which with some amounts to an objection, while with most its quality is much admired. This is a late variety, just coming in as Doolittle is going out, and thus lengthening the season of this wholesome and delicious fruit."

Monthly Roses—How to Preserve During Winter.

BY PETER HENDERSON, SOUTH BERGEN, N. J.

The question is asked me many hundred times every season, "What kind of Roses shall I plant?" I invariably recommend the "Monthly," rather than the so-called "Perpetual" varieties, which, with very few exceptions, sustain their "Perpetual" character by only once flowering freely, in June, with occasionally a few scattering flowers throughout the summer and fall. While with the monthly varieties, we have not only a monthly, but an almost daily supply of flowers, embracing far more variety of

color, from June till November. There is no plant sold which, for the first season at least, is so unsatisfactory to the buyer as the Perpetual Rose; the purchaser, in good faith believes that its name indicates a perpetual flowering character, and is

Fig. 1.

wofully disappointed to find that the flowers or flower buds that are on it when purchased, are nearly the last that are seen on it for that season. True, its entirely hardy nature, sustaining it unscathed through the winter, compensates for the first year's disappointment by a gorgeous bloom in June, but this is all; for the remainder of the season there is little ornamental about it. While on the other hand, the Monthly Rose, the original types of which are natives of China, are evergreen and ever-blooming, if not arrested by severe frosts,—for in the milder latitudes of our Southern States, they grow and bloom without cessation the entire season, unless perhaps for a month or two in extremely dry and hot weather in summer. But now comes the question, are these monthly roses hardy in our Northern States? They are certainly not so by ordinary treatment, but my object in writing this paper is to explain a very simple process by which they can be preserved in as good condition during winter as the hardest Perpetual or Prairie Rose. The success of the plan, however, depends greatly on the condition of the soil in which they are growing. If it is naturally dry, having a gravelly or sandy subsoil, it is certain to succeed; but if wet and undrained, they cannot be saved by this or any other process. The operation is to remove three or four inches of soil from one side of the plant close up to the roots, and of length and width proportioned to the size of the bush, as represented by figure 1. The plant is next bent down into the excavation, and held in place by

Fig. 2.

a few pegs, as shown in figure 2. It is next covered entirely, root and branches, by sods, placed grassy side upwards, and presents when finished, a little hillock in appearance like figure 3.

There is one very important condition to success, which is: the time at which it is done. Few of our rose amateurs have any idea of the amount of freezing that the most tender Tea Rose even, will sustain without injury, and would in consequence be apt to hurry to put them under their winter covering on the appearance of the first slight frost in October. This would most certainly prove fatal to the Rose by causing it to rot during the still warm autumn weather. We usually have frost in this part of the country to injure most green-house plants that are exposed in October.

Fig. 3.

Yet I have never seen it severe enough to injure Roses of any kind before the middle of December, to which time the covering up

should be delayed. Covering the ground, however, around the bushes with three or four inches of straw or leaves, to prevent the earth from being frozen, should be done a month earlier; this little precaution will allow of excavation at the time of covering with the sod. The time here given for the operation (the middle of December) is that best suited for the latitude of New York; sections to the North or South must be varied accordingly. Perhaps the best rule that can be given is, to delay the operation until the ground can no longer be plowed or dug with the spade. The covering of sod may be removed as soon as vegetation fairly starts in spring—for this section, say the middle of April—the plants raised to the upright position and closely pruned. It will be understood that in the process of bending down, the roots are only disturbed slightly on the side that has been excavated, consequently they have nearly the full vigor of an undisturbed root, and the plants will grow in a way that will amply repay the little trouble given them. Every plant saved over in this way has a value four-fold of anything that can be planted in spring, for the obvious reason that it has not had its roots disturbed by removal. This plan is a great improvement on that sometimes practised of digging them up and burying them in the fall, to be unearthed and again replanted in spring, for this cannot be done without mutilation of the root, and consequently diminished growth the next season. Plants of different kinds vary much in their ability to recuperate, after planting, and few suffer more than the Rose, hence the necessity of practising the method recommended, in preference to that of digging them up. But a still worse plan is, for amateurs in gardening to lift their Rose plants and pot them in fall, and attempt to keep them in the house or cellar in winter; in nine cases out of ten they never live to spring, and if they do, only linger on a miserable and diseased existence. Roses are often expensive, and always valued plants, and we can well imagine how natural it is on the approach of cold weather to lift and pot them, and place them in the window of a warm sitting room or parlor; but this kindness is killing to them, for they are not a kind of plant that desires heat at this season, or in this condition of their growth. It is still more delusive to think that they can be lifted from the ground in fall and potted so that they will bloom during winter; perhaps by such treatment as can be given in a cool greenhouse or frame, they may be got to bloom by February or March, but they should never be forced into bloom earlier, unless they have been grown in pots during the summer previous.

Striking Cuttings in Sand.

A correspondent writes: "In the June *Agriculturist*, (p. 297,) you gave a process of rooting cuttings in sand as practised by Mr. Henderson and others with success. The following plan, which I adopted some years since, answers the purpose in a small way. I had some tin basins made in the following manner: three inches in depth, ten inches in diameter at the bottom, and eight inches at the top. These were painted black and varnished, filled with fine sand, and kept constantly wet. The cuttings were from three to four inches in length, and placed in the sand about half an inch apart. They were placed in a sheltered spot where the sun could shine on them all day. At night they were removed to the house. The sides being

sloping and black, the sun acted with powerful effect upon them, and kept the sand quite warm, and I found that I could grow anything which could be grown from a cutting in any propagating house. They were very useful, simple, and cheap."

Insects and Plant Fertilization.

FOURTH ARTICLE.

We described in our last article the ways in which insects are made to fertilize two or three of our wild Orchids, taken as specimens of the whole tribe. Orchids exhibit the greatest diversities and the strangest forms in tropical countries, and the contrivances by which some of these are fertilized are, if possible, still more wonderful than those which we have attempted to describe. Take, for example, the case of *Coryanthes*, a large-flowered Orchid of Trinidad. We can not describe it more briefly and graphically than in the following abstract by Mr. Darwin:

Fig. 1.—A flower of *Kalmia latifolia*; the stamens of which are out of their sockets, having done their work.

"This Orchid has its labellum or lower lip hollowed out into a great bucket, into which drops of almost pure water, not nectar, continually fall from two secreting horns which stand above it; and when the bucket is half full, the water overflows by a spout on one side. The basal part of the labellum curves over the bucket, and is itself hollowed out into a sort of chamber with two lateral entrances, within which and outside there are some curious fleshy ridges. The most ingenious man, if he had not witnessed what takes place, could never have imagined what purpose all these parts served. But Dr. Crüger saw crowds of large humble-bees visiting the gigantic flowers of this Orchid in the early morning, and they came, not to suck nectar, but to gnaw off the ridges above the bucket; in doing this they frequently pushed each other into the bucket, and thus their wings were wetted, so that they could not fly out, but had to crawl out through the passage formed by the spout or overflow. Dr. Crüger has seen a 'continual procession' of bees thus crawling out of their involuntary bath. The passage is narrow, and is roofed over by the column, so that a bee, in forcing its way out, first rubs its back against the viscid stigma, and then against the viscid glands of the pollen-masses. The pollen masses are thus glued to the back of the bee which first happened to crawl through the passage of a lately expanded flower, and are thus carried away. Dr. Crüger sent me a flower in spirits of wine, with a bee which he had killed before it had quite crawled out of the passage with a pollen-mass fastened to its back. When the bee thus provided, flies to another flower, or to the same flower a second time, and is pushed by its comrades into the bucket and then crawls out by the passage, the pollen-mass necessarily comes first into contact with the viscid stigma, and adheres to it, and the flower is fertilized. Now at last we see the full use of the water-secreting horns, of the bucket with its spout, and of the shape of every part of the flower."

Fact is here stranger than fancy; for no one

would have beforehand imagined such an arrangement. *Catasetum*, another large-flowered Orchid of the same region, is equally visited by bees, for the purpose of feeding on the substance of the labellum or sac of the flower. "In doing this they inevitably touch a long, tapering, sensitive projection, or, as I have called it, antenna. The antenna being touched, causes a certain membrane to rupture through its own irritability, and this sets free a spring by which the pollen-mass is shot forth, like an arrow, in the right direction, and adheres by its viscid extremity to the back of the bee. The pollen-mass is thus carried to another flower, where it is brought into contact with the stigma, which is viscid enough to break certain elastic threads, and to retain the pollen-mass which then performs its office of fertilization."

This brings to mind the flower of Barberry. Every one knows that the six stamens around the pistil stand, bent a little backwards, one under each of the over-arching petals; and that when the base of the filament is touched on the inner side, it starts forward by a sudden movement of irritation. With our vision now enlightened we can see the use of this to the plant. The anther opens, in an unusual way, by a sort of trap door, one on each side, hinged at the top; these doors when the blossom is open stand ajar, or are at length uplifted; so that when the stamen springs forward at a touch, the pollen rattles out into the bottom of the flower. Now as the flowers are visited by small winged insects which seek for nectar at the bottom of the flower, we may be confident they will touch the sensitive base of the filaments, and consequently get powdered with some of the discharged pollen; they will carry this pollen to the next flower they visit, and as they enter it they can hardly fail to rub some of it on the button-shaped stigma. We have not watched the operation in the case of the Barberry, but we hope some of our readers will do so next year, and report the result. We have, however, admiringly seen the thing done in a somewhat similar way, although by a different mechanism, in the flowers of our common *Kalmia*, or American Laurel. Here, in all the species, there is an ingenious contrivance, in which elasticity is made to do the work which in the Barberry is done by a vital irritability.

Fig. 2.—Section of a flower-bud of *Kalmia latifolia*.

ly to fall out of the anther at all; for, instead of splitting open from top to bottom, in the common fashion, or opening by trap-doors, as in the Barberry, each of the two anther-cells here opens only by a little hole at the top. How then is the pollen to get out, and how is it ever to reach the stigma of the same, or of any other flower? Most people, who are accustomed to look at flowers, know that the corolla has 10 pouches or pockets, and that an anther is stuck into each. Fig. 2, is a section of

a flower-bud, cutting through two of these pockets, and showing the anthers enconced therein. Fig. 3 shows the half of a flower just expanding; and in so doing it has carried the anthers outwards and downwards, bending their filaments. When the flower is wide open the filaments are bent backwards still more, with considerable tension, like that of a bent bow. Pull the filament a little, or gently lift the anther with the point of a pin, so as to disengage it, and the bow straightens itself with considerable force, throwing the pollen out of the anther

Fig. 3.—One half of an opening flower of the same, showing 6 of the 10 anthers in their pouches.

with a momentum which carries it far over the stigma. In fact, this stamen is on the plan of, and acts like, a boy's pea-shooter, or rather like a double pea-shooter,—two quills upon one bit of whalebone. So the pollen is shot at the stigma; and out of ten shots some may hit the mark. But we may well believe this elaborate contrivance was not got up for such a purpose. On enclosing a truss of flowers in gauze, so as to keep off flying insects, we find that the anthers remain in their pouches till the flowers wither, or till the filaments lose their elasticity and become flabby. Evidently the anthers are to be set free by insects. Now bees and wasps visit the *Kalmia*-flowers abundantly, chiefly in early morning. A bee on the wing poises himself directly over the centre of the flower, and usually rotates around, his fore-legs hitting or even pulling at the filaments in succession, while his proboscis is searching the bottom of the flower on every side; and the anthers, one after another, discharge their pollen upon the bee's chest and abdomen, the very parts of the body which, during the operation, are continually rubbing against the stigma.

We ought next to describe the curious flowers of the common Milkweed, in which the pollen coheres to form a waxy mass, and these masses are connected in pairs to a sticky gland; much as in the *Orchis* family, otherwise very different; and these glands, with the pollen attached, stick to the legs of bees and butterflies, by which they are conveyed from flower to flower. But we have not room for the description and for the figures which would be needed to make the account intelligible.

Fig. 4.—One of the stamens, more enlarged.

There is no need, however, to restrict our view to flowers of extraordinary structure, such as *Orchids* or *Kalmias*, or endowed with extraordinary irritability, like the *Barberry*-blossom. Most of our common brightly colored blossoms, and many that are not at all showy, plainly reveal on inspection their adaptation to cross fertilization by the aid of insects. Look into the corolla of a *Foxglove*, and see the four an-

thers and the two-lobed stigma pressed against the upper side of the tube, about half way down; but, the style being a little longer than the filaments, the stigma projects beyond the anthers. As the flower hangs mouth downwards, it might be supposed that the pollen would fall on the stigma; but, the stigma facing forward, so as to prevent that, the pollen must fall useless to the ground. Now the flowers are much visited by bees; and it is interesting to see either a *humble-bee* or a *honey-bee* crawl into the flower: alighting on the projecting border or lip on the lower side, he turns over so as to face the stamens and stigma, catches hold of the curving filaments to aid in the ascent, and works his way upwards until the proboscis reaches the nectar at the very bottom of the flower. In so doing he brushes his chest and belly, first against the stigma, bringing to it the pollen from the previously visited blossom, and then against the anthers, thus receiving a charge of pollen for the next flower.

We need not multiply examples. Every garden and every field offers equally good examples,—lessons which anybody may read and understand, if he will only open his eyes, and be convinced that the familiar ditty of our childhood has a more extended application than the good old *Dr. Watts* ever dreamed of. When the "*Hymns for Infant Minds*" are brought up to the present state of science, we shall read:

"How doth the little busy bee
Improve each shining hour
By carrying pollen day by day
To fertilize each flower,"

and the lesson of disinterestedness will carry a worthier moral than the praise of selfish accumulation. A. G.

Dutch Bulbs.

The superiority of *hyacinths* and *tulips* as grown in *Holland*, over these raised in this country, has been so long insisted on that there must be some truth in it. All gardeners who have bought fresh imported bulbs know that for the first year they are very fine, the next year less so, and so on for a succession of years. At least, it requires extraordinary skill to keep up their original excellence. Perhaps our hot and dry summers, with our stimulating manures, has something to do with this deterioration; but we can not believe that good bulbs are an impossibility here, if we attend carefully to the condition of the soil. A writer in the *Gardener's Chronicle* gives us an account of the nature of the soil in which the best Dutch bulbs are grown. The land about *Haerlem* is composed chiefly of sand and decaying shells, combined with considerable vegetable matter. This is dressed every year with a liberal supply of cow-dung, and nothing else. Where bulbs are to be grown, the land is trenched two feet deep and heavily dunged. The ground is not yet ready for *hyacinths*: the manure when first applied is too rank for the healthy culture of such roots. Accordingly, the ground is devoted the first year, to some hoed crop, such as *potatoes*; after these are harvested, the ground is again plowed and harrowed smooth; and then, say in *October*, the bulbs are put in. They are set about 4 inches deep, and when frosty nights set in, the ground is covered with reeds, 4 or 5 inches thick. So managed, the bulbs form strong rootlets before winter, and in spring shoot up vigorously.—It is added that great pains are taken during the summer to ensure a healthy growth of leaves. As soon as the flowers fade, and even before, the flower stalks are cut off,

both to strengthen the roots and to prevent these stalks falling down and bruising the leaves. Perhaps we in this country mistake by cutting off the leaves before they are fully ripe. At any rate, the foregoing are the *Dutch* facts; let us speculate upon them and profit by them.

The Wine Question.

Grapes will, in many localities, be ripe this month, and it will be expected that we shall say something about wine making. To those who intend to make any considerable quantities of wine, we cannot do any better service than to commend to them *Mr. Husmann's* excellent treatise on *Grapes and Wine*. In *October, 1864*, we gave the process as followed in a small way, and we very briefly recapitulate it. Let the grapes be thoroughly ripe, pick out all decayed ones, and grind them in a mill that will not crush the seeds, or pound them in a barrel. The pulp is allowed to stand from one to three days, according to the desired quality of the wine. The longer it stands the more color and astringency it will acquire; for light wines, one day is enough. The juice is then to be pressed from the pulp and put into a perfectly clean cask to ferment. The cask being filled, it is closed by a bung, which has fixed in it a tin or glass tube bent into the form of a siphon, or twice at right angles. The open end of this tube dips under the surface of water in a cup or other vessel, and allows the gas produced during fermentation to escape, while it completely excludes air from the contents of the cask. When active fermentation has ceased, the cask is bunged tightly, and left for two or three months, or until the wine becomes clear. The wine is then carefully racked off from the lees and transferred to a clean cask. Usually another, but less violent, fermentation sets in the following spring, and after this is over the wine may be bottled. This is a rough outline of the process, which should in every part be conducted with the greatest care and cleanliness, using no casks or other vessels that can impart any flavor to the wine. This is the process of the best makers, to produce wine from the fermented juice of the grape, without any addition. We headed this article the "*wine question*," as there is a question that has been discussed by our western vintners, with more or less acrimony on both sides. One side holds that wine should be the fermented natural juice of the grape and nothing else. The other side maintains, that in some seasons the grape does not contain sufficient sugar to make wine, while it has all the necessary acids and other constituents. They have a process of testing—which it would take too long to describe here—by which the amount of both acids and sugar is ascertained, and when there is a deficiency of sugar they add enough to make up the quantity to that of normal must. This is the case stated in brief, and the question, whether this is a proper procedure, is one which is likely to make still more discussion among wine makers. There are good arguments for both sides, and we are not yet prepared to express an opinion, except so far as to say that the claim that grape sugar makes wine, and that cane sugar makes rum—has no foundation in fact. Perfectly pure cane sugar, and pure grape sugar in fermentation will yield alcohol precisely the same, and it is only the associated matters that make wine of one and rum of the other. We know that it is not safe to advocate the doctoring of wines in any way, as in bad kinds it is liable to abuse.

We know, on the other hand, that our people are paying large sums for imported and California wines that have been treated in this very way, and even worse, as some of the so-called California wines are vile compounds, fortified with brandy. As it is likely that we shall be a wine-making people to a considerable extent, it is important that we come to some understanding upon this matter, and if only the product of unsugared grape juice is to be considered wine between the Atlantic and the Rocky mountains, let us have it so arranged that wines made otherwise elsewhere shall not be allowed to be sold.

A Fine Columbine.—(*Aquilegia glandulosa*.)

With the increased attention now given to hardy herbaceous perennials, we are glad to see that the Columbines are not overlooked. The old garden Columbine, *Aquilegia vulgaris*, sports into a great variety, and a bed of this, in its different colored double flowers, is very beautiful. But there are other species which are to our taste more pleasing than *A. vulgaris*; they are not double, it is true, nor is it necessary that every flower should be double; there are some, the grace and simplicity of which would be spoiled by any multiplication of parts. Our common wild Columbine, *A. Canadensis*, which was figured in May 1865, is much valued in European collections, and should be seen in our own gardens oftener than it is. When introduced into the border it takes on a vigorous growth, flowers profusely, and seems to do its best to repay the attention of the cultivator.

We recently saw in the grounds of Mr. Henderson, at South Bergen, among other choice herbaceous plants, a Columbine, *Aquilegia glandulosa*, which seemed such a gem that we had an engraving made of one of the smaller specimens. The finely cut foliage makes a tuft close to the ground, and the stems are a foot or less high, bearing very large flowers. The calyx and horns of the petals are of a most pleasing blue color, while the upper portion of the petals are of a pure white, the two making a striking and charming contrast. The species is hardy with Mr. H., but Mr. Breck says that he lost his; the plant being a native of Siberia, any want of hardiness is probably due rather to changes of temperature than to excessive cold.

Hedges and Hedge Plants.—1st Article.

THE HONEY LOCUST.

That hedges form the most available enclosures in many places, and the most beautiful in all, is generally conceded. Where there is a great abundance of timber, or where the land abounds in stones, these materials are not likely to be superseded by the live fence. In ornamental grounds, they form the most appropriate enclosures, but in small gardens they often occu-

py more ground than is desirable. Whoever sets a hedge, for whatever purpose, must make up his mind to take care of it. A neglected hedge is as ugly as a well kept one is beautiful. Nothing gives a place a more dilapidated appearance than a hedge, as we often see it, a mass of foliage propped up on long and naked sticks. To have a perfect hedge, it must be begun in the

native of Illinois, Pennsylvania, and southward, but is hardy all through New York State. It forms a fine large ornamental tree, with light feathery foliage, and has numerous sharp thorns which often become very large and branching. The flowers are in small clusters and not showy; but the pods which succeed them are long, flat, and wavy, and contain brown seeds, of the size of a large bean, imbedded in a sweet pulp. One of the objections that have been proposed to the use of this as a hedge plant is, that in its natural state it is a large tree. This objection will equally apply to the thorn, which we have seen twenty or thirty feet high. That a tree left to itself will attain a large size is no proof that it cannot be dwarfed by cutting, and its habit completely altered. The best specimens of a Honey Locust hedge within our knowledge are to be seen at the nurseries of David D. Buchanan, at Elizabeth, N. J. These hedges were set about 20 years ago by William Reed, the then proprietor, and are well worth a visit by those who would like to see a perfect hedge. The plants in these hedges are set at a distance of about six inches. This is much nearer than has been advised. Warder, in his work on hedges, suggests three feet, which would appear too far. Probably a foot would be found a better distance than either. At any rate, these old hedges show no signs of decay from overcrowding, are furnished with branches quite to the bottom, and present a barrier impassable to man or beast. The seeds are to be bought of the seedsmen, or may be collected this autumn. If kept in earth through the winter they will germinate without difficulty, but if they have been kept dry they will need to be scalded before planting. Sow in drills as soon as the ground is warm, and keep clean and well cultivated through the season. The seedling plants are perfectly hardy, and unlike the Osage Orange, stand the winter without protection. In the spring the hedge is set, first shortening

AQUILEGIA GLANDULOSA.

right way, and when well established, kept in the proper form by regular clipping. Leaving the matter of setting and forming a hedge to another article, we wish to call attention to some of the suitable hedge plants. In the matter of hedges, as in other agricultural and horticultural affairs, the early attempts in this country were close copies of European practice, without taking into account differences in climate. The universal Thorn of England is a general failure with us, and so with the Privet and other plants. It was only when attention was turned to our native shrubs that we made any progress in hedging. Among the plants that have had a varying reputation as hedge plants, is our Honey Locust, which has now been sufficiently tested to confirm all that has been claimed for it, and in many localities it may be regarded as our most valuable plant. The Honey Locust, often called Threethorned Acacia, (*Gleditschia triacanthos*) is a

the plants to about three inches. Plants suitable for setting can be purchased at the nurseries.

The Golden Dwarf Peach.

This is a comparatively new variety of peach that is a natural dwarf, growing only four or five feet high. The trees we have seen have a remarkably compact habit, and very healthy foliage. We have not seen the ripe fruit, but have seen it when nearly full grown. It is of fair size, and terminated at the end opposite the stem by a very distinct point. We saw fruiting trees in the orchard house of Mr. Isaac Pullen, of Hightstown, N. J., who is disposed to think well of the variety. Aside from the curiosity of the thing, this variety has an economical importance, if it proves to be all that is claimed for it. Peaches have of late years been such a precarious crop, as to discourage their cultiva-

tion in most places. The Golden Dwarf may prove to be the founder of a race of peaches of such humble stature, that they may be protected as easily as raspberry bushes, and thus allow peaches to be raised in localities where it is not now practicable. It is well known that the peach is more nearly reproduced from seed, than any other of our cultivated fruits. It would be interesting to know if this dwarf habit is inherited by any of the seedlings of this variety.

THE HOUSEHOLD.

Something About Indigo.

It is well known that linen and other white fabrics will not be perfectly white, no matter how thoroughly they may be washed. They acquire a yellowish tinge which is counteracted by diffusing a small quantity of Indigo through the rinsing water. This is about the only common domestic use of Indigo, and though the amount consumed in each household is small, it in the aggregate amounts to a large sum annually. Indigo is a remarkable product, usually obtained from species of *Indigofera*, shrubby plants of the Pea Family.

The engraving shows the general aspect of the plant, which grows from three to six feet high, and has compound leaves much like those of the locust tree. The flowers are small, blue, and have the general shape of the pea blossom; they are followed by a small pod. The plant is cultivated in various warm countries, especially in the East Indies. The foliage of the Indigo plant is green, and no one would suspect it capable of yielding such a dark blue coloring matter. Indeed indigo, as such, does not exist in the plant, but is contained in juices in a colorless and soluble form. To obtain indigo, the plants are steeped in water, and the liquid, or tea thus obtained run off into vats where it is stirred and beaten with rods for the purpose of bringing the air freely in contact with the liquid. By this treatment, the oxygen of the air combines with the colorless and soluble matter, and converts it into blue and insoluble indigo, which is allowed to settle, and is then made into cakes. The product of different countries varies considerably in hardness and intensity of color, but all of it when rubbed by any hard substance, such as the finger-nail, takes on a peculiar metallic luster. Indigo is soluble in strong oil of vitriol, and in this condition it is the "sulphate of indigo," or liquid blue of the

druggist and dyer. In the common way of dyeing with indigo, it is first changed from its blue and insoluble state. There are several substances that effect this change; a mixture of lime and copperas is often used in setting the vat. Fabrics immersed in this solution of colorless indigo and then exposed to the air become dyed by the change of the indigo, back to its blue condition. It has been found that turnips contain a principle (pectine) which converts indigo into the soluble form, and in France, turnips are largely used by the dyers.

Remember

1st.—That before food can be of any benefit to the body, it must be dissolved in the stomach, so that it can be absorbed into the blood in a liquid state, and be thus carried to the parts of the body needing to be nourished or strengthened, or renewed by it. *Remember*

2nd.—That the human stomach is not like the gizzard of a fowl—a hard, tough membrane, filled with gravel-stones, to break or grind up the food—but that it is a soft bag, so to speak, which merely holds the food and shakes it about, so that the gastric juice can better dissolve and work it into a liquid state; therefore, *Remember*

3d.—That nothing should go into the stomach which has not first been masticated (chewed) *very fine*, or cut or mashed fine before it is taken into the mouth, so that it can be easily dissolved. Lumps of potato, or of fruit not well ripened and mellow, pieces of meat as large as chestnuts, lumps of dough or new bread, small fruits with skin unbroken, etc., etc.—anything that will be slowly dissolved—causes an uneasy feeling, and often irritates and inflames the stomach itself. Further, if they are not fully dissolved, these things pass down through the whole twenty-five feet or more of the alimentary canal, causing pain, colic, diarrhœa, and often dysentery. *Remember*

4th.—That the saliva of the mouth mixed with the food, greatly aids the dissolving or digestion of the food in the stomach, and that even soft food should be chewed or worked over in the mouth, until well mixed with saliva. *Remember*

5th.—That children can not appreciate the importance of masticating food, and that great care should be taken, either to see that they do masticate it well, or that it be so thoroughly prepared for them that it can not go into the stomach in an undigestible form. Proper care in this single thing would save the lives of half the children that now die young, and a very large proportion of all "pains under the apron," the diarrhœas, and bowel complaints, that children, and grown people as well, suffer. *Remember*

6th.—That, as all food after going into the stomach must either be properly digested, or produce injurious results, it is the height of folly to crowd down into the stomach two or three quarts of food and drink, and expect that organ to work it all up readily. Suppose that for every article you eat at a meal, you put, or imagine you put, precisely a similar amount into a dish—the meat, bread, potatoes, vegetables, tea, coffee, or water, and the pie or pudding—what a mixture you would have both in kind and bulk; yet that is what is given the stomach to dissolve, or try to dissolve. *Remember*

7th.—That the stomach keeps at work while it has any undissolved food in it, and that if you "lunch" or "piece" between meals you give that organ no time to rest, and it will in time be weakened if it do not give out. *Remember*

8th.—That sleep is far more quiet and refreshing, if the stomach sleeps with the rest of the body, and that it is better to eat nothing which can not be digested before retiring to rest. Children, who retire early, or ought to, should have only light suppers of simple, digestible food.

Cheap Sponge Cake.—1 cup sugar, 1 cup flour, 3 eggs, 1 teaspoonful cream tartar, $\frac{1}{2}$ do. of soda dissolved in a little milk. Mix all together and bake 20 minutes in a quick oven.—*A Friend.*

Original Contributions to the American Agriculturist.

"Information Given."—(See page 294.)

No. 9.—**HOME-MADE INK.**—(d) The kind I use altogether, and it is better than any I can buy, is made by boiling maple bark in water for sometime, then straining it off through a cloth and boiling down until thick enough for use. To make it black enough, I add a little pulverized copperas (sulphate of iron).—*Isaac H. Page, Ottumwa, Iowa.* [Mr. Page's letter is certainly written with good ink.—Ed.]... (e) Into one gallon of soft water put 2 ounces extract of logwood; boil ten minutes, and then add 24 grains bi-chromate of potash, and 12 grains of prussiate of potash, stirring a few minutes while over the fire. The ingredients cost 25 to 30 cents. I have used it exclusively for 4 years.—*P. O. E., of Schodack.*—[The ink appears well on the letter. Would not some gum arabic improve it?... In a prescription from Foxboro, one of the figures is blotted out.—Ed.]

No. 10.—**EXTRACTING WHEEL-GREASE, ETC.**—(d) I have cleaned wheel-grease from a nice silk thus: Laying the silk on a clean sheet folded to 8 thicknesses, I rubbed the greased part with a soft cloth dipped in lard, moving the silk to a new spot frequently. After a time the wheel-grease all went through, leaving only clean lard. This was then cleaned out in the same way, by rubbing it with some nice soap and alcohol, using a clean cloth to rub with, and frequently changing to a new spot on the under-lying sheet. The silk was then laid on a clean cloth, and rubbed dry with a soft cloth. A friend cleaned a white Canton Crape in this way, and you can not find the place where it was greased.—*S. M. Healy, Trempealeau, Mo.*

No. 15.—**TO REMOVE MILDEW FROM MUSLIN.**—(a) Put the muslin on an earthen platter and pour over it a strong soap suds, to which a teaspoonful of soda is added. Set it in a strong sunlight three or four days, or longer if needed, adding more suds to make up the evaporation, and turning once or twice a day to expose all parts of the fabric. I have used this with great success for a number of years.—*Mrs. S. J. Wood, North Madison, Ind.*... (b) Stir $\frac{1}{4}$ lb. chloride of lime in a gallon of cold water. After settling an hour, pour off the clear liquid, and soak the mildewed cotton or linen in it two hours; wash well and expose to the sun.—*Farmer's Daughter, Richmond, Ind.*

No. 18.—**OLD BRINE.**—Eight years' experience convinces me that old brine which has not soured, if taken in spring, or before hot weather, and well boiled and thoroughly skimmed, is as good as new, when cold.—*Z. P. L., Erie Co., Ohio.*

No. 20.—**HOME-MADE TOILET SOAP.**—Boil together 3 lbs. soda ash, 1 lb. unslaked lime, and 4 gallons of water. When hot, strain it, return to the kettle, add 6 lbs. clean grease; boil slowly but constantly three hours, and let it cool. Next day take off the hard soap from the top, and put it in a clean kettle, adding $\frac{1}{2}$ lb. borax, and any kind of perfumery you like; let it melt, stirring it well together, and pour into a wooden mould or box that has been previously well soaked in water. Let it remain 24 hours, and then cut it into any convenient or fancy shaped cakes desired. Dry these a day or two, taking care to bring in at night. When dry enough, pack away for use.—*Mrs. S. J. Wood.* [Meeting's adjourned, only.—Ed.]

No. 21.—**PREPARATION OF PICKLES.**—For 200 pickles of moderate size, take 2 gallons of cider vinegar, or enough to cover them, 1 ounce whole cloves, 1 oz. allspice, 2 oz. mustard seed, 2 oz. alum, 6 oz. horse-radish, and $\frac{1}{2}$ pint salt. Put all together and heat in a brass or glazed kettle to near a boiling point, and pour it on the previously washed cucumbers; cover them with cabbage leaves and put on a weight to keep them down. If they do not look green enough in two or three weeks, pour off the vinegar, heat it, and return it. Heat it a third time if necessary to make the pickles green enough. To prevent a white scum on the vinegar, cover the

cabbage leaves with a flannel cloth. Pickles thus prepared, keep a year well.—*Writer's name unknown.*

No. 24.—**LARD AND ROSIN.**—Some 12 or 14 years ago, the late Prof. Olmstead, of Yale College, read a paper before the American Scientific Association, describing the great value of a mixture of lard and common rosin melted together, for covering metals liable to rust. Just lard enough is added to the rosin to make it soft or semi-fluid at common temperatures. This may be applied to any metal surface, and, if desirable, be wiped off nearly clean, yet the thin film left will prevent rusting or oxidization. It is cheap, and useful for all farm and household implements, as well as for the most delicate philosophical apparatus. The mixture can be kept, ready for use, for a long time. We do not remember the best proportions. Can any one give them? Almost any proportion not too soft, but that will be fluid enough to apply without heating, will answer the purpose.

No. 25.—**TO KEEP SAD IRONS SMOOTH AND FREE FROM RUST.**—Rub the flat-iron on a paper, and when this is hot, rub it with beeswax. The same paper may be used several times.—*E. M. H.* [With care, the film of beeswax may be so thin that it will not come off to any troublesome degree at the next ironing. The lard and rosin mixture, No. 24, applied and wiped off, will still leave coating enough to prevent rust. "Cousin Marion" writes, "Keep the irons in a dry place and they will not rust." Poor sad irons will rust anywhere, in damp, foggy weather.—*ED.*]

Moisten the Air.

It is important to remember, at all times, when artificial warmth is needed, that heating the air has the peculiar and remarkable effect of causing it to take up and secrete a large amount of water. Air that at the freezing point is damp, when heated to 70°, or a comfortable condition, so hides away all the moisture, that it is unpleasantly dry; it then absorbs the moisture from our bodies, and from our lungs, and produces a feeling of uneasiness. It sucks out the moisture of the furniture, causing it to warp or crack, if not fall to pieces. When it comes in contact with the cold glass, and is reduced in temperature, it gives up the hidden vapor, and thus cold windows and walls tend to still further dry out the air. To make the atmosphere healthful, as well as agreeable, always keep upon the stoves, or over the heating furnaces, a full supply of water in wide open-top or loosely covered vessels, to constantly evaporate moisture to saturate the air. This is equally important for all living organisms in a room, for plants as well as animals, and in churches and school-rooms, as well as in private dwellings.

Hints on Cooking, etc.

Recipe vs. Receipt.—Many writers, including some editors, use these words indiscriminately. Though Webster gives the authority of Dryden and Arbuthnot for this custom, it would seem preferable to confine the use of the word "receipt" to its proper sense, the receiving of something, or the acknowledgment of its reception, and use "recipe" only for directions for making compounds in cooking and medicines.

Cream Beer.—Prepare a syrup thus: Into 3 pints of water, put 2½ lbs. white sugar, 2 ounces tartaric acid, the juice of half a lemon, and boil together five minutes. Then stir into it ½ cup of flour previously mixed up with some water. When nearly cold, add the whites of 3 eggs well beaten, and ½ ounce essence of wintergreen. Put into a bottle and keep in a cool place. It is ready for use at once, but improves with age. To use, dissolve 2 tablespoonfuls of this in a tumbler of water, and stir in ½ teaspoonful of soda. Always shake the bottle well before using the syrup.—*M. L. B.*—[A little white of egg beaten and added to the com-

mon soda-water syrups gives a peculiar foaming or froth-like consistence to the fluid when the gas water is drawn in. We saw the directions for adding the egg sold in the West a few years ago, at \$1 to \$5 each to owners of soda water fountains.—*ED.*]

Wedding Cake.—(Pronounced excellent at a great many weddings, says the contributor, whose name is not on the sheet with this and sundry other recipes kept for publication as we have room): 1 lb. flour, 2 lbs. raisins seeded and chopped, 2 lbs. currants, ¾ lb. citron, 1 lb. sugar, ¾ lb. butter, 10 eggs, 2 wine glasses brandy. Stir sugar and butter to a cream, add yolks of eggs, then spices, then the flour in which has been rubbed 2 teaspoonfuls cream of tartar and 1 of soda; then the fruit, and lastly the whites of the eggs beaten to a froth. The spices are, 1 tablespoonful ground cinnamon, 1 grated nutmeg, and 1 teaspoonful cloves. The loaves require from one to two hours baking.

Jelly Cake.—Mix 2 cups flour, 1 cup of milk, 1 cup sugar, ½ cup butter, 2 eggs, 1 teaspoonful soda and 2 of cream of tartar. Divide into six parts, and spread each as thin as possible in pans of uniform size. Bake about 3 minutes; when done, lay together with layers of jelly between; cover the upper layer with plenty of sugar sprinkled on, or with a thin frosting.—*Contributor's name not given.*

Bachelor's Pone.—Stir well together 1 quart sweet milk or sour milk with soda, 2 tablespoonfuls lard, 2 eggs, 4 teacups white corn meal, or enough to make a moderately stiff batter. Bake in a loaf in a quick oven.—*Subscriber, Kent Co., Md.*

Soft Gingerbread.—Two cups molasses, ¾ cup water, ½ cup butter or lard, 1 teaspoonful soda, ginger and salt as desired; mix thin with flour.—*Housekeeper, Worcester, Mass.*

"Hasty Pudding."—A housekeeper directs: "Nine tablespoonfuls of flour, six eggs beaten light, one quart milk; have a hot oven, and bake 20 minutes. Eat with sauce; butter and sugar rubbed to a cream, and flavored to your taste, is very nice."—Such a hasty pudding must be nice, if one has plenty of cheap eggs. We should want some sugar in it. Our home manuscript book calls this recipe "Sunderland Pudding."

Indian Meal Pudding.—Put a teacupful of meal into a quart of hot milk. Add 3 beaten eggs, ½ tablespoonful ginger and cloves, butter half the size of an egg. Boil 2 or 3 hours in a boiler.—*Miss Belle, Catskill, N. Y.*

Best Corn Bread.—I think none of all the good corn bread recipes printed in your invaluable *Agriculturist*, are quite equal to ours, made thus: Make a thick batter of 1 quart of sweet milk and 1 quart of butter-milk, 1 tablespoonful of saleratus and 1 of salt, 1 teacup molasses, 2 teacupfuls of wheat flour (or shorts), and corn meal enough to thicken it. Bake two hours in an oven a little hotter than for wheat bread.—A loaf still nicer, especially for poor teeth, is made by using half the above quantity, steaming it three hours, and then baking enough to just brown the top nicely.—*"Laura," Cooper, Mich.*

Brown Bread.—Mix 3 cups corn meal, 3 cups rye flour, ½ cup molasses with a teaspoonful of soda dissolved in it, with a sufficiency of cold water. Bake in a covered dish, about 3 hours, in a slow oven.—*A Friend.*

Corn Dodgers.—Salt and scald sifted corn meal. When cool wet the hands in cold water and mould into cakes like biscuits, but not very thick. Bake rather slowly, on a griddle, in hot fat, browning first one side and then the other. Split open and eat while hot, with butter or syrup, or with meat and gravy.—*Contributor's name not given.*

Preserving Green Corn.—To E. F. Green, Kalamazoo, Mich. We have tried various methods of bottling and canning green corn, but never with satisfactory results. We have also eaten that put up by those who make a business of canning fruits and vegetables, but the corn was always poor, to our taste. We know of no way to put up

green corn successfully, except to cook it on the ears, then shave off and dry it in a strong sunlight, or by the fire, or in the oven. Preserved in this way it is very palatable at a season when green vegetables are scarce.

Meat Balls.—A good way to use bits of cold meat. Cold beef or pork, chopped very fine, put into a dish with an egg to each ½ lb., crumbs of bread soaked and mashed fine, 2 onions [if liked] chopped well; season well with salt and onion, and with pepper. Make into small cakes and fry in plenty of lard.—*M. L. B.*

Carrot Sauce.—Scrape and thoroughly clean the carrots, slice in very thin round pieces, boil tender, and then cook dry. For each quart of slices pour over a cup of sweet cream, season with salt and pepper and let them boil up for a moment. Serve hot. Thus prepared they will be relished highly, even by those who do not like carrots any other way.—*Mrs. M. Ingalls, Muscatine, Iowa.*

Heating Bottles for Fruit.—"Subscriber," of Columbus, N. J., writes that she washes and wipes the jars dry, and then sets them in the oven until too hot to handle without a cloth. As wanted they are taken out, set on a warm board, and the hot fruit poured in. In this way she has broken only one bottle in three years. By the hot water plan, described on page 202 (July), we have not broken one in putting up the last four hundred.

Claret Wine Stains.—A Wilbraham (Mass.) subscriber says that these may be removed from a table cloth by rubbing the spot, as soon as made, thoroughly with common salt. When washed, the stain will entirely disappear.

To Color Scarlet.—For one pound of cloth or yarn, mix in warm water, ½ ounce cream of tartar and 1 ounce pulverized cochineal; add 2 ounces muriate of tin. Stir until it scalds, then put in the cloth or yarn.—*Housekeeper, name unknown.*

Red Ants.—After our safes, cupboards, etc., are washed and wiped as dry as they can be with a wrung out cloth, we sprinkle on salt and rub it well into the wood and all the cracks and crevices with the same damp cloth, and have found it effectual against the ants.—*E. Carr, Camden, N. J.*

A Ready Answer.—That eccentric preacher, Lorenzo Dow, was once stopping at a hotel in New York, kept by a man named Bush. Among the guests was a General Root. They occasionally made themselves merry at Lorenzo's expense. One day General Root began upon him thus: "Mr. Dow, you tell us a great deal about heaven. Now, I want you to tell me plainly what sort of a place heaven is." With imperturbable gravity, the preacher replied: "Heaven, gentlemen, is a smooth, rich, fertile country; there isn't a bush or a root in it, and there never will be." The Root and Bush subsided, and Mr. Dow wasn't further troubled.

AN OLD FELLOW of the ultra-inquisitive order asked a little girl on board a train, who was sitting by her mother, as to her name, destination, etc. After learning that she was going to Philadelphia, he asked: "What motive is taking you thither, my dear?" "I believe they call it a locomotive, sir," was the innocent reply. The "intrusive stranger" was extinguished.

HOUSEHOLD NOTE (by a Cockney).—What to do with cold mutton. Heat it.

LITTLE three year old Susie was playing very roughly with her kitten—carrying it by the tail. Her mother told her that she would hurt pussy. "Why, no I won't," said she, "I'm carrying her by the handle."

SUBILITY IN HUMILITY.—The soul goes highest when the body kneels lowest.

A SCOTCH clergyman did not satisfy by his preaching a certain portion of his flock. "Why, sir," said they, "we think you dinna tell us enough about renouncing our own righteousness." "Renouncing your ain righteousness!" cried the astonished doctor, "I never saw any you had to renounce!"

THE MAN who can make his own fire, black his own boots, carry his own wood, hoe his own garden, pay his own debts, and live without wine and tobacco, need ask no favor of him who rides in a coach and four.

BOYS & GIRLS' COLUMNS.

"Where do the Weeds Come From?"

Many a boy has asked this as, for the fourth or fifth time in the season, he has bent over the onion or strawberry bed, and taken out every one that showed its head above the surface. But they won't stay pulled up. In a few days another crop is ready to try the industry and patience of the young gardener. No wonder many people have thought weeds were in some mysterious way created in the soil. But we know that every one comes from a seed which in some manner has found its way into the earth, and waited, sometimes for years, for a favorable time to sprout and send up a plant to provide another supply of seeds. It is wonderful how these inanimate things, having no power to carry themselves, manage to travel to new homes, even to emigrate to new countries. The dandelion, the thistle, and other seeds furnished with downy appendages, ride upon the wind, and may be carried miles before finding a resting place. Some seeds, like those of the burdock, and coekle, have strong little hooks ready to lay hold of the first man or animal that brushes past them, and are thus transported to other fields. Some seeds are good swimmers, or rather floaters, and the currents in the streams and even of the ocean bear them safely to foreign lands. The seed pods or vessels of some plants are made so that they fly open with a snap when the seeds are fully ripe, and scatter them over the ground. The seed of the Sand Box Tree, described in the *Agriculturist* of June, 1865, is contained in a sort of spring box, which explodes with a bang like a musket, and sends the seeds flying in every direction. Some seeds are strongly affected by moisture and dryness, when dry they are curled up, when wet, they straighten out; this gives them a rolling motion which moves them at almost every change of weather. The animated oat, and the species of geranium called "Stork's bill," are examples of this kind. The birds swallow many seeds, and deposit them uninjured in new places; in this way some plants find their way to distant islands. When we find so many ways in which seeds may be carried about, and when it is remembered that many of them may be for years buried in the soil, and yet retain their life, we need not wonder that they spring up almost everywhere. If the boys will pull up all the weeds in the garden before they go to seed, they will not only keep their own premises pretty clear, and have less such work to do each year, but they will also help their neighbors, and thus be doing some good in the world.

One Way to get an Autograph.

A correspondent of the Boston Advertiser tells the following story: I have seen an album which contains the following inscription on one of its pages: "*Treason is the greatest crime.*"—WINFIELD SCOTT. *Washington, D. C., August, 1861.*" The name is written in the stiff characters so well known, but the motto is traced in a much bolder and more forcible hand. The album is the property of a New York lady, who visited the city at the extra session of Congress in 1861. She was very anxious to get the old General's autograph, but soon learned that it was not an easy thing to do. She, however, hit upon the expedient of sending her little girl, of about ten years, right to his office during business hours.

The child told the orderly that she must see General Scott—and she would not be put off with any plea of business, but waited half an hour, till her request was finally taken to the Adjutant. Of course, she was admitted to his presence, though he had no intention of allowing her to see the General. She persisted, however, and said she must see him. The officer finally pointed out the door which led to his room, and told her that she could go in if she dared. She took him at his word, and in an instant stood within the door. Speaking of it afterward, she said she was afraid when he first looked up, "but when he saw it was only me, he said right pleasant, 'Well, little girl, what do you want?' and I told him my ma wanted him to write his name in her book; and he looked sharp at me, and then smiled a little bit, and then shook hands with me, and asked me who my ma was, and I told him, and I told him my ma was in the army, and my ma was all alone with me; and then he just kissed my cheek and wrote in ma's book, and said 'Good morning,' to me, and I came out, and nobody didn't hurt me at all."

New and Useful Sport.

A subscriber to the *Agriculturist*, Mr. Alexander Gordon, Woodbury, Conn., has just described to us his way of catching flies, which we think may furnish lively sport to the children—almost as good as fishing or catching butterflies. Make a bag of millinet or mosquito netting, about three feet long, the upper part just wide enough to fit nicely to the flat hoop of a flour barrel; the lower part is narrowed down to a point, making the

whole funnel shaped. Tack it securely to a hoop, and fasten the hoop to an old broom handle or other convenient stick. Now you have a net which you can sweep around in the rooms and take nearly every fly. When caught with a rapid motion they will fly to the narrow end, and when enough are taken, give it a twist to confine them, place them in a basin, and a little boiling water will instantly convert them into good chicken feed.

An Amusing Play.

Let two or more boys each take a stick—an old broomstick is just the thing, and place it under their knees, with their arms passed under it, and hands clasped in the position shown in the engraving. Each is then to try and push his neighbor off his feet, the hands remaining clasped. The effect is quite comical, and makes much sport. A clean grassy spot should be chosen for this.

The "Crook."—"My dear friends," said a returned missionary at one of the late anniversary meetings, "let us avoid sectarian bitterness. The inhabitants of Hindoostan, where I have been laboring for many years, have a proverb that 'though you bathe a dog's tail in oil, and bind it in splints, yet you cannot get the crook out of it.' Now, a man's sectarian bias is simply the crook in the dog's tail; which cannot be eradicated; and I hold that every one should be allowed to wag his own peculiarity in peace!"

A Dutchman's Temperance Lecture.—"I shall tell you how it was. I put mine hand on mine head, and there was von pig bain. Then I put mine hand on mine pody and there vas anoder. There vas very much pains in all mine pody. Then I put mine hand in mine pocket, and there vas noting. So I jined mit de temperance. Now there vas no more pain in mine head. The pains in mine pody was all gone away. I put mine hand in mine pocket, and there vas twenty dollars. So I shall sthay mit de temperance."

Puzzle for the Eyes.

We present herewith another puzzle picture in which our young readers will be pleased to discover the different figures, and find out what they are doing. Those who have examined our previous pictures of this kind will probably readily see what is intended, as the solution of one is a key to all similar designs. As we only print the names of those sending answers to the problems, etc., in the "Puzzle Column," our young friends need not tell us when they succeed in making this out.

An old fellow, who took part in the late great rebellion, was one day boasting in the village tavern to a crowd of admiring listeners, of his many bloody exploits, when he was interrupted by the question:—"I say, old Joe, how many rebs did you kill during the war?"—"How many did I kill, Sir? how many rebs did I kill? Well I don't know just 'actly how many; but I know this much—I killed as many of them as they did 'o me!"

Answers to Problems and Puzzles.

The following are answers to the Puzzles, etc., in the August number, page 295. No. 219. *Scripture Riddle*: Asa, Nun, Noon, Aziza, Anna. No. 220. *Illustrated Rebus*: First in war, first in peace, and first in the hearts of his countrymen. No. 221. *Mathematical Problem*: 3 hours, 23 minutes too fast. No. 222. *Illustrated Rebus*: Beware, indulge not over much in sleep, for fear penury over take you. No. 223. *Farmers' Enigma*: The American Agriculturist. No. 224. *Enigma*: Wood-house. No. 218. *Prize Problem*, July number, page 263. Answer. 13918 ¹⁴³³⁸/₁₇₃₉ feet.

The following have sent in correct answers to puzzles: Daniel Frohman, Mattie Rankin, T. Spoon, Esq., Rufus H. Roys, Frank A. Lawrence, B. J. Hammer, B. Jones, J. C. Brantigan, C. E. Amidon, Harry J. Meixell, L. A. Dale, Levi Capp, Emily L. Adams, J. H. Barr, C. A. Hege, Carlle F. Hedges, E. L. Bouton, George M. Hunter, S. C. Ware, Herman, Lizzie and Jennie Cook, Hessian E. Reynolds, J. L. Purdy, Isaac F. Tillinghast.

New Puzzles to be Answered.

No. 225. *Word Puzzle*.—The name of a distinguished rebel contains five letters. From the letters of his name may be formed. 1st, his occupation; 2d, his character; 3d, his offspring; 4th, his first victim; 5th, how he obtained this victim; 6th, the sentence pronounced upon the victim and himself. Who was the rebel?

No. 226. *Illustrated Rebus*.—A very popular proverb. No. 227. *Word Puzzle*.—Worth 20 shillings, I measure 45 inches, and my name represents 500. What is the word? No. 228. *Conundrum*.—When is music like a vegetable?

PUZZLE PICTURE.—NO EARTHLY SWEET WITHOUT A STING.

(COPYRIGHT SECURED.)

A GRAND MUSICAL ENTERTAINMENT. — *Designed and engraved for the American Agriculturist.*

Our artist attended a cat concert a few nights ago, and has given the above spirited sketch of the scene. It was held on the roof of a shed near his window. He could not see the performers, for it was pitch dark, and so he was guided entirely by sound in making the picture. He says they sang in a very *felune* manner, though he could not understand the words. That, however, is fashionable—almost all opera singers perform in the same way, so that nobody can tell what they are singing about, and it is only now and then that church choirs talk English when they sing. Some may laugh at the idea of cats making music, but the cats themselves think it very fine; they are quite like most other singers in this also.

Spicy Letter about a Picture.

To the Editor of the American Agriculturist:

I was somewhat amused, but more vexed, to see the pictures of the "Unfortunate Boy," and the "Fortunate Girl," in the July number of the *Agriculturist*. I am a boy myself, 12 years old; have brothers and sisters—quite a number—and I attend a school, numbering sixty scholars, of all ages between six and fourteen,—boys and girls of course. I have observed that the girls as often have their faces drawn awry as the boys, notwithstanding we always give them the best places in the schoolroom, the smoothest part of the play-ground, and never go above them in spelling,—when we have a head and foot to the class, even if they miss all the words. In winter we draw them to and from school on our sleds, or shovel nice, broad paths for them. We are very happy to do all this and feel more than repaid when we receive a bright smile, or a pleasant "thank you" from one of these little ladies. But, Mr. Editor, what vexes me is the construction that will be placed upon such pictures by those

whose habits or tempers do not lead them to associate with children, and whose memory is so defective that they do not recollect when they were "Boys and Girls together." I am afraid they will judge that boys are always so bad as to invite all the imps of mischief around them, while the dear little girls are so sweet, that it employs all the angels to take charge of their goodness! How can that little girl help smiling with so many bright beings hovering near to whisper happy thoughts? And how can the boy, who is just as pretty and good as the girl,—when they are both left alone,—help breaking his toys, and screaming with real pain, when so many little imps are tugging at his eyes, nose and mouth, and blowing fire and smoke in his face? I believe they hurt him worse than a rousing ear-ache or a dozen whippings. I am sorry for him. If the boys were a *little worse* than girls it would be no wonder; for they have so much more to vex them. But they are not. They are often sent to bed, in a dark room, when in the best part of their story; they are made to wait when company comes, and if there is no pudding left for them, it is "no matter, they are only boys." They must run errands, give the sidewalk to any body, and if they have a pet in the shape of a dog or bantam rooster, whose attainments in vocal music are their especial pride, they are not allowed to exhibit them, but must put them in a coop in some out-of-the-way corner, while the girl can have her noisy canary or even a dirty kitten in the house. In short—the girls are petted,—the boys are *snubbed*. If your pictures were both boys, or both girls, I would not have troubled you;—as it is I am yours for

EQUAL RIGHTS.

[Our young correspondent is more than welcome to our columns—we like those who can think for themselves, and will allow all to have their "say," (if we have room) if they can say it as well as this lad. By his own account

of how he treats the girls, he acknowledges that he thinks a *little* more of them than of the boys, which is quite natural and pleasant, and he can hardly blame other people for doing the same thing—especially as boys have the best chance to push their own way through the world. Perhaps some of the girls, or some other boy would like to say a word on this question; we promise fair play.]

Something Besides Money Wanted.

A Frenchman of immense wealth fitted up a most gorgeous palace in Paris. A gentleman who obtained leave to visit it, relates, that upon entering the dining room he found a table magnificently laid out. "Your master," he observed to the *maitre d'hotel*, "makes wonderfully good cheer." "Alas, sir, my master never sits down to a regular dinner; a single plate of vegetables is prepared for him." "Here, at least, is food for the eye," said the visitor, pointing to the pictures. "Alas, sir, my master is nearly blind." "Well," resumed the visitor on entering another room, "he compensates himself by listening to good music." "Alas, sir, my master has never heard the music which is played here; he goes to bed early in the hope of snatching a few minutes' sleep." "But at all events he enjoys the pleasure of walking in that magnificent garden." "Alas, sir, he can not walk." In a word; for all purposes of enjoyment, the millionaire was the poorest of the poor.

A LITTLE GIRL, who made very frequent use of the word "guess," was told by her teacher to say "presume." Presently, one of Mary's little playmates coming up to her remarked: "I think your cape very pretty, and my mamma wants your mamma to lend the pattern, because she's going to make one like it." "My mamma has no pattern," was the prompt reply, "she cut it by presume."

MUSIC ABROAD.—Rev. Robert Nelson, at Shanghai, China, writes to Prince & Co., Buffalo, N. Y., "there are five of your Instruments here—and so fine and sweet an instrument for the parlour—and especially for sacred music, has never yet been brought to light. I have seen some of your Melodions at Niogpo, the port next south of this." Rev. I. J. Stoddart, at Assam, Hindoostan, says, "The six instruments I have ordered for myself and friends on the Bralimputra, have given perfect satisfaction. In fact they are the only instrument that at all stands the climate of Hindoostan. The instrument you sent me seven years previous is in perfect order." A. W. Smith, Surgeon, U. S. Army, at Cruces, New Mexico, says, "I am agreeably surprised at the volume, and sweetness of tone of the instrument." Send to Prince & Co., Buffalo, N. Y., for a copy of the New Illustrated Catalogue, which will be mailed free of expense.

Hudson River Institute.

Superior advantages in English, Classics, French, German, Piano Music and Painting. Lewis' Gymnastics for Ladies, and Military Drill for Gents. Eighteen Instructors. Term opens Sept. 10th. REV. ALONZO FLACK, A. M., Principal, Claverack, Columbia Co., N. Y.

POPULAR SUBSCRIPTION

In aid of the Memorial Church of Washington Irving, Tarrytown, N. Y.

This Edifice—the only Memorial to WASHINGTON IRVING ever begun in the village, now celebrated as the place of his residence and his burial—is located in the midst of scenes immortalized by his pen. Ever since it was commenced it has been the desire of its projectors to finish it without having a particle of debt to encumber it. That they may accomplish this end, as well as make it a Memorial which all the admirers of "Geoffrey Crayon" shall have had an opportunity to assist in erecting, they have determined to solicit

Contributions of One Dollar.

in order that they may speedily obtain the sum (\$10,000) they still need to render the Building fit for immediate occupancy. In return, as a memento of the offering, they will send by mail any one of the following PHOTOGRAPHS, that may be indicated by the contributor:

- 1.—WASHINGTON IRVING. (The only exact likeness ever taken.)
2.—SUNNY SIDE. (The Home of Washington Irving.)
3.—THE OLD DUTCH CHURCH. (Built A. D. 1699; where Ichabod led the Choir.)
4.—BRIDGE OVER THE POACANTIC. (Alongside of which the School-Master disappeared.)
5.—THE OLD MILL. (Built in 1686; a picturesque relic of the Elder Time.)
6.—IRVING'S GRAVE. (In the Sleepy Hollow Cemetery.)

For a contribution of Five Dollars, the complete Set of Six Pictures will be sent in return.

Direct MEMORIAL CHURCH OF WASHINGTON IRVING, care of either of the following Addresses: Rev. E. GULBERT, Rector, Tarrytown; A. D. F. RANDOLPH, 770 Broadway; W. H. KELLEY & CO., 533 Broadway; H. APPLETON & CO., 49 Broadway; HARPER & BROTHERS, Franklin-Square, New York.

Hints to Bee-Keepers. SENT FREE OF CHARGE to any address. This is a practical pamphlet. See June Agriculturist. Agents Wanted in all unoccupied territory, for the Improved Movable Comb Bee-Hive, "The Bee-Keeper's Text Book," and "Italian" Queens. Address H. A. KING, Nevada, O.

SPECIAL NOTICE TO THE AMERICAN SEED TRADE.

ESTABLISHED 1835.

JAMES CARTER, DUNNETT & BEALE,

SEED FARMERS AND MERCHANTS,

Offices and Warehouse, 237, 238 and 261 High Holborn,

LONDON, ENGLAND.

SEED FARMS, { East House Farm, Dedham, Essex.
Jupes Hill Farm, Dedham, Essex.
The Seed Farm, Sr. Orsyth, Essex.

Plant Nursery, Crystal Palace Nursery, Perry Hill, Sydenham.

J. CARTER, DUNNETT & BEALE, beg leave to announce to the AMERICAN SEED TRADE, that they have three large Farms in the County of Essex, England, specially devoted to the cultivation of

FARM, GARDEN and FLOWER SEEDS,

and that they are

THE LARGEST BONA FIDE SEED GROWERS IN ENGLAND.

From their position as Seed Growers, J. C., D. & B., are enabled to offer seeds of their own saving with a greater degree of confidence than a Merchant purchasing from Growers can possibly do. Their seeds are saved from carefully selected Stocks, and are proved to be of the best germinating quality before sending out.

J. C., D. & B., respectfully invite Buyers coming to England, to favor them with a call, and will be happy to send special quotations of prices by return Mail, on receipt of Business card.

TERMS:

The usual Trade credit if accompanied with satisfactory London reference, or cash with order.

THE ONLY PRIZE MEDAL FOR SEEDS

awarded to London Seed Merchants,

International Exhibition, London, 1862,

was granted to

JAMES CARTER, DUNNETT & BEALE,

for "Superior Excellence."

JAMES CARTER, DUNNETT & BEALE, have large growths of the following seeds:

PEAS.

Carter's first Crop. }
The earliest pea in cultivation }

Very early Daniel O'Rourke.

McLean's Little Gem.

A dwarf prolific green wrinkled marrow; habit similar to Beck's Gem or Tom Thumb, and is a first early. This Pea is a great acquisition, as the chief fault hitherto in early Peas has been want of flavor, and this valuable variety has all the sugary flavor of the late wrinkled Peas coupled with a first early Pea. Height one foot, and requires no stakes.

Advancer.

Beck's Gem or Tom Thumb.

Carter's Surprise Peas.

An improved blue Surprise, larger in sample, larger pods, and more prolific; a good useful Pea for market garden-work, and one that will come into general use.

Champion of England.

Veitch's Perfection,
and other leading sorts.

CABBAGE.

Early Dwarf York.

Early Large York.

Imperial Oxheart.

Winnigstadt.

Battersea.

Wakefield.

Red Drumhead, pickling.

Gibson's Flat Dutch.

Robinson's Champion Oxheart. }

Improved Drumhead. }

Green Curled Savoy.

Drumhead do.

And other sorts.

CARROTS of Sorts (Clean Seed).

CAULIFLOWER.

Carter's Dwarf Mammoth.

A very early hardy variety, of dwarf and compact habit, with a firm white head, larger than the Walcheren; stands dry weather, comes in before the ordinary early Cauliflower, and is fit to cut after the late variety; can be specially recommended as the best variety for forcing and general use.

And other sorts.

LEEK.

Large Musselburg.

LETTUCE

Of Sorts.

ONION.

White Spanish,

and other sorts.

PARSLEY.

Dunnett's Garnishing,

and other sorts.

RADISH.

Scarlet Olive Shaped.

"The French Breakfast Radish."

A new quick-growing variety of Radish; very much liked in Paris, and considered the best for early forcing. It is of an oval form, color scarlet, tipped with white; and for its good flavor and ornamental appearance it is decidedly an acquisition for salads and other purposes.

And other sorts.

SALSAFY.

TURNIP.

Improved Snowball,

and other sorts.

FARM SEEDS.

Carter's Imperial Hardy Swede,

and other sorts.

All the best sorts common Turnips, Whites and Yellows.
Mangel, Very select Stocks, &c., &c.

LANE'S PURCHASING AGENCY,
FOR PURCHASING

Articles of Merchandise, Implements for the Farm, Garden and Household, Good Fertilizers, Seeds, Vines, Trees, &c., &c.

Special attention paid to purchase of Books, and the selection of Private and Public Libraries.

H. E. LANE, 151 Nassau-st., New York.

VINELAND

FARM AND FRUIT LANDS, in a mild and healthful climate. Thirty miles south of Philadelphia by Railroad, in New Jersey, on the same line of latitude as Baltimore, Md.

The soil is rich and productive, varying from a clay to a sandy loam, suitable for Wheat, Grass, Corn, Tobacco, Fruits and Vegetables. This is a *great fruit country*. Five hundred Vineyards and Orchards have been planted out by experienced fruit growers. Grapes, Peaches, Pears, &c., produce immense profits. Vineland is already one of the most beautiful places in the United States. The entire territory, consisting of forty-five square miles of land, is laid out upon a general system of improvements. The land is only sold to actual settlers with provision for public adornment. The place on account of its great beauty as well as other advantages has become the *resort of people of taste*. It has increased five thousand people within the past three years. Churches, Stores, Schools, Academies, Societies of Art and Learning, and other elements of refinement and culture have been introduced. Hundreds of people are constantly settling. Several hundred houses are being constructed, and it is estimated that five hundred will be built during the summer. Price of Farm land, twenty acre lots and upward, \$35 per acre. Five and ten acre, and Village lots for sale.

Fruits and Vegetables ripen earlier in this district than in any other locality north of Norfolk, Va. Improved places for sale.

Openings for all kinds of business, Lumber Yards, Manufacturing, Foundries, Stores, and the like.

For persons who desire mild winters, a healthful climate, and a good soil, in a country beautifully improved, abounding in fruits and possessing all other social privileges, in the heart of civilization, it is worthy of a visit.

Letters answered and the Vineland Rural, a paper giving full information, and containing Reports of Solon Robinson, sent to applicants.

Address CHAS. K. LANDIS, Vineland P. O., Landis Township, New Jersey.

From Report of Solon Robinson, Agricultural Editor of The Tribune: It is one of the most extensive fertile tracts, in an almost level position and suitable condition for pleasant farming that we know of, this side of the Western Prairies.

Maryland Farms
"On the Eastern Shore,"

Ranging from 50 to 500 acres, in Talbot County, on or near the Salt Water Courses, and the "Maryland and Delaware Railroad." Send for Circular and for reference to parties lately settled among us.

GOLDSBOROUGH & HALL, Agents, Easton, Maryland.

Maryland and Virginia Farms.

The Subscribers have on hand, Farms from 50 to 1000 acres on all the chief Thoroughfares, Railroads, and Water courses, in Maryland and Virginia. Also Country Seats near and Residences and Building Lots in and around Baltimore and Washington. For Descriptions apply to

JOHN GLENN & CO.,
50 Second-st., Baltimore, Md.

SUPERIOR FARM LAND.—20,000

Acres, Franklin Tract, at Newfield, Gloucester County, New Jersey, on the Railroad running from Philadelphia to Cape May, 30 miles South of Philadelphia—adjoining the Vineland Tract, and 2 miles North of the Vineland Station—for sale at low prices and on easy terms, in lots to suit purchasers. Circulars, with reports of Solon Robinson, Hon. William Parry, and others, with full information, sent to applicants, free. Address JOHN H. COPPIN & CO., Newfield, Gloucester Co., N. J. Improved Farms also for Sale.

Farms in South Jersey,

Of all sizes and excellent quality, well improved, good buildings, fruit, etc., for SALE at \$35 to \$40 per acre. Also, excellent Timber Land at \$15 to \$20 per acre, near churches, schools, mills, also, railroad and navigation leading to Philadelphia and New York. Descriptive Catalogues sent free. Apply to T. HOYT, Manamusk, Cumberland Co., N. J.

FRUIT LANDS IN SOUTHEAST MISSOURI,

the *future Vineyard of America*.—For grapes, peaches, &c., not surpassed in the world, 40,000 acres at \$1.25 to \$1.50 per acre, in Tracts to suit purchasers. Send for particulars to T. O. W. MARSHALL & CO., Ironton, Iron Co., Mo.

BARGAINS, Grinnell, Iowa.—House and lot in city, \$800; 10 acres partially improved, 1/2 mile north, \$600; 10 acres 3 miles west, \$150. Religious and Educational advantages excellent. W. C. CONDIT, Grinnell, Iowa.

Colgate's Aromatic Vegetable Soap.

A superior Toilet Soap, prepared from refined Vegetable Oils in combination with Glycerine, and especially designed for the use of Ladies and for the Nursery. Its perfume is exquisite, and its washing properties unrivalled. For sale by all Druggists.

CANANDAIGUA PROPAGATING ESTABLISHMENT.

An imperfect cut showing vertical partition two feet in length, with Vines as they are transferred to the open ground Secured by letters Patent, March 27, 1894, to F. L. PERRY, Canandaigua, N. Y.

Grape Vines grown by my Patent process of propagating and transferring to the open ground, merit their superiority in size and vigor by the rapid growth allowed in the construction of my patent. It consists in the vertical partition separating the roots of each row of Vines, and by which means they are transferred to the open ground without checking the growth of vines, or disturbing the roots as is unavoidable in the ordinary way.

I am propagating by my method a large number of the most approved varieties, and am prepared to furnish vines singly or by the **Hundred Thousand**. Price List sent on receipt of stamp to pre-pay postage. It will pay those wanting Vines to consult my List before ordering elsewhere.

For full explanation of my patent and its advantages, impartial description of the leading and most profitable grapes for Wine or market, send two red stamps for Retail Catalogue, containing also cuts of Iona, Israella, Adirondac, Concord, Rogers' Nos. 15 and 19, and Testimonials of our former patrons.

I cordially invite all interested to call and examine my stock, or address

F. L. PERRY, Canandaigua, N. Y.

PARSONS & CO.,

offer for the Fall Trade, 600,000

GRAPE VINES

of all the best varieties. Among them are:

DELAWARE,

2 years, transplanted and unusually fine, \$35 per 100; \$275 per 1000.
1 year, No. 1, \$25 per 100; \$200 per 1000.
" " 2, \$20 per 100; \$150 per 1000.
" " 3, \$12.50 per 100; 100 per 1000.
Concord, \$12.50 per 100; \$100 per 1000.
Hartford Prolific, \$25 per 100; \$200 per 1000.
Diana, \$25 per 100; \$200 per 1000.

IONA,

No. 1, \$100 per 100; \$800 per 1000.
2, \$50 per 100; \$500 per 1000.
Israella, \$100 per 100; \$800 per 1000.
Ives' seedling, \$25 per 100; \$200 per 1000.
Norton's Virginia, \$10 per 100; \$300 per 1000.
Adirondac, \$10 per 100; \$300 per 1000.
Crevelling, \$10 per 100.
Rogers' Hybrids, \$40 per 100.

All the vines thus offered are grown without bottom heat, from single eyes of well-ripened wood, and in good, deep soil, not injured by extra manuring.

For list of other sorts, they refer to their Descriptive Catalogue of Vines and Roses.

They offer a large stock of very fine ROSES, mostly Hybrid Perpetuals and Moss, all on their own roots, at

\$20.00 per 100; \$150 per 1000.

Also, very fine Camellia Japonica, in large quantity, and very healthy.

For the Catalogue of a large assortment of the best TREES and SHRUBS,

Address

PARSONS & CO., at FLUSHING, N. Y.

T. C. MAXWELL & BROS., Geneva, Ontario Co., N. Y.

GRAPE VINES.

Iona and Israella, also Delaware, Allen's Hybrid, Adirondac, with all other valuable kinds.

In growing the above Vines, quality instead of quantity has been the object. By giving them such attention as they needed at all times, a superior class of Vines have been produced.

The Vines have not been forced by stimulants or any other means. The different varieties are offered as low as any other establishment will furnish Vines of equal quality by the Thousand, Hundred, Dozen or single. All Vines are warranted true to name.

For Price List, Address HOLTON & ZUNDELL, Haverstraw, Rockland Co., N. Y.

Sing Sing Grape Vines.

I offer to the Trade for the coming Fall the best lot of Grape Vines I have ever raised, all the new and leading varieties.

As I sell only Vines grown by myself, the demand for the last three years has been greater than I could supply, my stock this year is larger, but I advise my friends to send their orders early.

Prices the same as last year, and all vines warranted true to name. Send for Price List.

J. F. DELIOT, VINE GROWER, Sing Sing, N. Y.

Strawberry Plants for Sale.

Agriculturist, Ida, Lennig's White, Russell's, &c. Circulars free. P. SUTTON, Pittston, Luzerne Co., Pa.

Durand's Seedling Strawberry.

A new variety produced from a combination of Boyden's Green Prolific, Triomphe de Gand, and Peabody's Seedling. The plant is very hardy and vigorous, has stood entirely unprotected the past three winters. The foliage, which is large, and of a rich glossy green, is sufficient for shade, though there is not a superabundance to absorb the nourishment which belongs to the fruit, and it is never affected by sun blight. The blossoms are perfect, the fruit is very solid, large, and uniformly so throughout the season, color scarlet, flesh firm, flavor excellent, equalled by very few Strawberries and surpassed by none. It is very prolific, ripening with the earliest, and continuing to bear fine fruit full two weeks after all other varieties are gone. It is emphatically the best Strawberry out, and from its intense solidity, productiveness, fine flavor, attractive appearance, and many fine qualities combined, it must take precedence over all others for family, and more especially as a market fruit. It has been seen in our grounds the past season by many of the prominent Horticulturists of the country, and notwithstanding the fact that our fruit was grown and exhibited under very unfavorable circumstances, the season here having been very cold and wet, yet all pronounced them to be very remarkable, and under more favorable circumstances undoubtedly very superior. Those who saw them in 1865, in Mr. Durand's garden, were astonished, and all pronounced them the finest they had ever seen.

We stake our reputation upon the veracity of what we say of this wonderful strawberry, and advise all fruit growers, and especially those who sell plants to secure a stock, for as this fruit becomes known, the demand for plants will be enormous. We received subscriptions for these plants during the past spring and many subscribers upon seeing the fruit increased their orders, several from one hundred to one thousand. Circulars containing further particulars of this Strawberry, reports of Committees and individuals who have seen it, and also a general list of nursery stock furnished to all applicants.

The Durand's Seedling will be ready for distribution about August 15th. We will send out strong plants only, at the following rates: One plant, 75 cents; two, \$1.25; six, \$3.00; twelve, \$5.00; fifty, \$15.00; one hundred, \$25.00; one thousand, \$200; carefully packed, and small lots sent pre paid by mail. In ordering, give your name, town, county and State, in full, and be particular to state whether to send by Express or mail. If by Express, give the name of the one having an office at your place.

We have the entire stock of this Strawberry, therefore all orders must be addressed to us, and must in all cases be accompanied by the cash, and where such can be had, send Post Office Money Orders. Address
FRANCIS BRILL, Newark, New Jersey.

Strawberry Plants.

Jucunda or 700, \$1 per doz.; \$5 per 100; layered in pots, \$2.50 per dozen; \$15 per 100.

Agriculturist, La Constante, Triomphe de Gand, Green Prolific, Wilson, Russell's Prolific, Brooklyn Scarlet, \$1.50 per doz.; \$10 per 1000 Layered in pots, \$1.50 per doz; \$8 per 100; \$60 per 1000.

We beg to call the attention of those planting Strawberries to the great benefit derived from planting those layered in pots. Thus planted late as October, they will produce a full crop next season. Fresh Samples daily on hand.

Lilium Auratum.

New Golden Striped Lily from Japan.

Thus described by Dr. Lindley, in the London Gardeners' Chronicle. "If ever a flower merited the name of glorious, it is this, which stands far above all other Lilies, whether we regard its size, its sweetness, or its exquisite arrangement of color. From this delicious flower there arises the perfume of Orange blossoms sufficient to fill a large room, but so delicate as to respect the weakest nerves." It is quite hardy and deserves a place in every collection. Flowering Bulbs mailed to any address upon receipt of \$3.00.

Address **B. K. BLISS, Springfield, Mass.**

VICK'S ILLUSTRATED CATALOGUE OF HARDY BULBS, FOR THE AUTUMN OF 1866, AND FLORAL GUIDE.

BAUGH'S
RAW BONE
SUPER-PHOSPHATE OF LIME.

PROTECTED BY COPYRIGHT.
MANUFACTURED UNDER PATENTS AND GUARANTEED
By **BAUGH & SONS,**
Inventors and Sole Proprietors,
PHILADELPHIA, PA.,
under the ORIGINAL FORMULA, for 12 years past.

For WHEAT, RYE, TURNIPS and ALL CROPS and PLANTS.

The most highly concentrated, speedy, permanent, and cheap manure in the market, used by thousands of farmers in the Atlantic States, and endorsed by the most practical agriculturists in the country from twelve years actual use. See "Ten Acres Enough," Chap. 22, page 225. Local Dealers can furnish consumers in all parts of the United States and Canada.

BAUGH BROTHERS & CO.,
General Wholesale Agents,
No. 181 Pearl-st., and No. 4 Cedar-st., New York.
Just published—"How to Maintain the Fertility of American Farms and Plantations,"—12th Edition, 85 pages— for distribution free and mailed upon application.

BONE TA-FEU!!

Has been tested by thousands of farmers and found superior to any other manure for Fall and Winter grain, and for a top-dressing on lawns and meadows.

It is manufactured for and used as a substitute for Peruvian guano, and judged by many to be fully equal to it. It is sold at the low price of \$40 per Ton.
Manufactured only by the
LODI MANUFACTURING COMPANY,
66 Courtlandt-st., New-York,
to whom all orders must be addressed.

Mr. M. A. Bradford, of Rye, Westchester Co., N. Y., says of "Bone Ta-feu," that it is the very best compound I have ever used combining those principles which promote rapid growth and also permanent benefit to the land. I used it on gravelly soil, which had always been very unproductive, although well manured, the result was so marked as to attract the attention of all who witnessed it. An abundant crop of rye was produced measuring from 6 1/2 to 7 1/2 feet, followed by a heavy growth of timothy and clover. I have also used it in the garden and in every case it has given perfect satisfaction.

AMMONIATED PACIFIC GUANO.

The attention of Farmers and Agriculturists is called to this article, as superior to anything else offered in the market. Equal to Peruvian Guano, and costing much less.

We offer this fertilizer in lots to suit all purchasers. A liberal discount made to the Trade.
Pamphlets with copies of Analysis by Dr. Liebig, of Baltimore, and Dr. Jackson, Massachusetts State Assayer, and testimonials from Agriculturists, showing its value, and directions for use, can be obtained from

BENJ. HAINES, 27 Courtlandt-st., New York.

Greene's Patent Cylinder CIDER MILL,
For Crushing and Expressing the Juice from Apples, Grapes, and other Fruit, at one and the same operation.

The subscriber has invented and patented a Machine for crushing and expressing the Juices from Apples and other fruit, at a single operation, thereby dispensing with Screws, Levers, Presses, and other cumbersome machinery, and saving all the time and labor necessary to separate the juices from the fruit by the old process. This important result is attained by a novel arrangement of crushing and pressing cylinders together in one frame, entirely unlike any Machine ever heretofore constructed for such a purpose, and which must eventually supersede and do away with all known processes for extracting juices from fruit.

The subscriber claims, and is ready to demonstrate, that the following advantages are gained over all other Machines:

1st.—With the same amount of power, *three times the quantity of Cider or Wine* can be made in a day, than can be made by any other Machine.

2d.—That from 25 to 40 per cent. more Cider or Wine can be extracted from the same amount of fruit.

3d.—That it is more compact and simple in its operation, stronger and less liable to get out of order; is adapted to hand or other powers; is portable and can be transported readily from place to place; can be driven by any kind of power, and can be attached to any machinery.

4th.—Is cheaper in proportion to its capacity.

5th.—Is stronger, being constructed entirely of iron.

6th.—In being adapted for expressing juices from all kinds of fruit, including Apples, Grapes, Rhubarb, or Wine Plant, Currants and Berries of all kinds.

7th.—That it is superior to any Root Cutter known, for the purpose of crushing roots of all kinds, for feeding stock, quicker, easier and better than any other Machine.

8th.—That it expresses the juices from Apples or other fruit the moment they are crushed, wherein lies the great secret of making good Cider or Wine.

9th.—That it does not grind or break the seed of any kind of fruit; thereby doing away with a great objection, which is urged against all other Machines.

Enclose stamp for Descriptive Circular.

Address, **G. J. GREENE, Hudson, N. Y.**

WOOD & MANN STEAM ENGINE CO'S CELEBRATED Portable Steam Engines,

FROM 4 TO 35 HORSE POWER. ALSO PORTABLE SAW MILLS.

We have the oldest, largest and most complete works in the United States, devoted exclusively to the manufacture of Portable Engines and Saw Mills, which, for simplicity, compactness, power and economy of fuel, are conceded by experts, to be superior to any ever offered to the public.

The great amount of boiler room, fire surface and cylinder area, which we give to the rated horse power, make our Engines the most powerful and cheapest in use; and they are adapted to every purpose where power is required.

All sizes constantly on hand, or furnished on short notice. Descriptive circulars with price list, sent on application.

WOOD & MANN STEAM ENGINE CO.,
Utica, N. Y.

Branch Office, 96 Maiden Lane, New York City.

FLAX.

MALLORY & SANFORD'S IMPROVED FLAX AND HEMP BRAKES,

As now made, are the strongest and best ever used. They occupy about 5 feet square, weigh about 1,000 lbs., require one man and a boy, and one to two horse power to work them; breaks from 2,000 to 3,000 lbs. Flax straw in 10 hours, taking out 65 to 75 per cent. of the woody matter. This machine will save 120 lbs. to the ton more than any other machine in the world. It will break tangled straw as well as straight. We have also an entirely **NEW TOW SHAKER AND PICKER**, works perfectly and does its work quicker and better than any other machine, and prepares the stock for Rope. Also a **NEW TOW COMBER**, which cleans and straightens the tow, free from shive, rapidly making it fine and straight. Send for circular or see machines in operation at 93 William-st., New York. Address

GRAPE VINES AT IONA ISLAND.

Price Lists, including leading kinds, with description of the quality of plants for the Fall of 1906, are now ready.

Also, Club-propositions for those who desire to avail themselves of the great advantages of this method of purchasing.

The Iona and Israella a Specialty.

Lists of Iona and Israella Vines for Vineyard planting, and for those who wish to deal very extensively

The Terms for Club-Agents and Dealers are extremely favorable, and the quality of the plants and other inducements are worthy of particular attention this season.

MY STOCK OF THE IONA AND ISRAELLA VINES, BOTH GROWN IN OPEN AIR, AND UNDER GLASS, IS VERY EXTENSIVE, COMPRISING PLANTS SPECIALLY ADAPTED FOR THE GARDEN, AND ALSO FOR THE VINEYARD.

The past winter of great severity has added its weight of confirmation to the well-established character of the IONA and ISRAELLA, for hardy endurance and constancy of production.

There remains no doubt in the minds of the most judicious observers, that upon these two chiefly rests the promise of eminent success in American Grape Culture, for fruit and for wine. (See "Present and Future of American Grape Culture.")

"The IONA equals the best European kinds in richness, purity and refinement, and in the uniform melting quality of its flesh, which can not be said of any other American grape."

"It is unequalled for fine, rich, enduring wine; its centre being free from all unripeness, is an incalculable advantage over all other American kinds that have been used for that purpose. It is only with such grapes as this that we can equal the fine wines of Europe."

Those grown from single eyes are from the best of wood prepared for the purpose of making the most healthy and enduring plants.

I have also a fine stock from green-wood cuttings that are the best of their class, and very cheap by the thousand.

For many years I have sedulously prosecuted the purpose of producing the best possible plants of Grape Vines, and since the surpassing merits of the Iona and Israella became established, I have yearly added greatly to my means of propagation, always having chief regard to the quality of the plants for early and abundant bearing, and for hardy vigor.

My plants have been extensively disseminated throughout the entire Vine-growing region of the United States, and in other countries. Their unequalled excellence, as well as that of the packing, has been everywhere acknowledged, and the demand for the best quality of plants has greatly exceeded the supply. The present season my enlargements have been much greater than ever before, with important improvements for promoting the strength of the plants, which has been done without increase of price to purchasers, although the quality has greatly advanced.

The prices of IONA and ISRAELLA Vines of first garden quality are now so low that all who have ground in which to plant them can afford to obtain enough vines at once, to furnish an early and abundant family supply of the best of fruits.

All who are interested are invited to visit the Island, and inspect the vines. The Hudson River passenger trains all stop at Peekskill, where boats are in readiness to convey passengers to the Island, two miles distant, for a moderate compensation.

Samples of Garden-Vines of Iona and Israella, Nos. 1 and 2, three plants each, or the same of either number will be sent on receipt of the prices per dozen, with fifty cents additional for cost of sending. One dozen Vineyard Vines will be sent as above, at price per hundred.

To Dealers and those who desire to plant largely, I am

able to offer a number of lots that cannot well be represented by samples, at very favorable rates. Many who have called to examine as to quality have found my No. 3, better than they had expected to find No. 1, and have also found the purchase of special lots very advantageous.

Those who purchase by sample, will be assured of receiving the quality represented, and all will be guaranteed the safe arrival of the Vines in perfect condition at the Depot designated.

Manual of the Vine (comprising Illustrated and Descriptive Catalogues), a thorough and comprehensive treatise, in which every operation is clearly represented by engravings, 150 in number—sent for fifty cents.

Twenty-four page Pamphlet, containing a full account of the Iona and Israella, with their distinctive characteristics. "The Present and Future of American Grape-Culture," and other important matters, with engraving of Iona and Israella Vines in bearing, sent for two-cent stamp.

BOOK AGENTS

IN LUCK AT LAST.

J. T. TROWBRIDGE'S great work on the South is selling rapidly, is selling North, South, East, West, and in the middle. The old read it. The young read it, the children cry to see the pictures, men sit up nights to read it, until the women cry out, "Husband, ain't you ever coming to bed." Everybody wants to read about the pardon seekers at the White House.

Read About

The burning and sacking of Richmond, Columbia, Charles ton and Atlanta.

Read About

Visits to the graves of the gallant dead.

Read About

Terrible incidents of the battle fields, related by eye witnesses living on the ground.

Read About

What Andrew Johnson's neighbors down in Tennessee say about him. Guess they hit the nail on the head.

Read About

Persecuting the Union people shooting, hanging, burning their houses, driving them to the mountains, &c.

Read About

What two neighbor planters say about the Freedmen working, one says they never did better. I am getting along first rate. The other says the niggers won't work at all. One wants matters to go along smoothly, the other wants everything to go to smash. That's what the matter.

Read About

The poor white trash—Sand Hillers—Clay Eaters—Croakers, &c. Specimens of conversation. "I'm in my fifty one year old, and their's eight on us in the family, and tu horses."

Read About

Conversation of Freedmen discussing their political rights. (See the pictures too.)

Read About

What the common people say about the Davis Government, how the war was brought on, and how they were forced into it.

Read About

The aristocracy getting into Bomb proofs, how they got there, what the Bomb proofs were.

Read About

What the former slave owners say of the niggers, of educating them, their voting, &c.

Read About

The progress of the Freedmen in education, what they are doing to help themselves.

Read About

The Guerrilla's Davis' conscripting bands. Gen'l Wilson's great Raid through Georgia and Alabama.

Read About

The hummers and hangers on of General Sherman's army. Robbing defenceless women, children and negroes of every article of value, through a stretch of country for hundreds of miles, under every conceivable form of threat. The descent of the Yankees on the South was more terrible than the Goths and Vandals on Rome. No wonder they are a little out of temper.

Read About

The women during the rebellion how they urged and drove the men into the war, how they treated Yankee soldiers and Union prisoners.

Read About

The spirit and temper of a class of people showing itself in riots as at Memphis, New Orleans and other places.

Read About

What the aristocracy, middle class, poor whites and negroes think and say about reconstruction, the old government, Yankees, &c., &c., &c.

If you want to know what war means to the conquered party,

Read About

The general destruction, misery, and suffering through the length and breadth of the land, the result of four years war, cost the sacrifice of half a million of lives, and five thousand millions of treasure, including both sides. If people won't read Trowbridge's book on the South, they can't be induced to do anything. If Agents can't sell it they can't sell any book.

Agents wanting territory to canvass must apply soon, as those now in the field want more ground, more room to canvass, want to grasp the whole country.

For territory and conditions, address as follows: Ohio, Michigan, and States West, C. W. STEBBINS, Columbus, Ohio. New York, H. E. Goodwin, Syracuse, N. Y. Pennsylvania and Maryland, P. Garrett & Co., 702 Chestnut-street, Philadelphia, Penn. New Jersey, Connecticut, Western Massachusetts, and Vermont, L. STEBBINS, Hartford, Conn. Maine, New Hampshire, Eastern Massachusetts, Rhode Island, H. WENTWORTH, 119 Washington-street, Boston, Mass.

The Income Payer's Guide and Pocket Register.

Sent by Mail on receipt of 25 Cents.

This popular and rapidly selling little book contains the Income law as revised and amended, with the decisions concerning the same, &c. Also pages of writing paper with columned registers, to be filled up from day to day, showing a correct and itemized account of receipts and expenditures—of amounts subject to income or exempt therefrom, simply arranged and easily comprehended. Deductions allowed from hints in this book, if but amounting to \$100 more than would otherwise be secured, at 5 per cent, would be \$5 tax saved, while the price of book is but 25 cents. Commence with the 1st of January next, to itemize your income accounts. Address F. H. STAUFFER, Assist. Assessor

8th Div., 9th Dist., Mount Joy, Pa.

Farmers' & Stock Breeders' Advertiser.

A monthly Journal devoted to Farming and Stock Breeding, giving practical and reliable information as to the most profitable breeds of Horses, Cattle, Sheep, Goats, Swine, and Poultry, history and varieties of each. Where they can be obtained. Best modes of Breeding, Feeding, and General Management, Diseases, &c.

Only \$1 per year in advance, each number contains 32 pages of closely printed matter, plus other valuable engravings. As we shall print from 30,000 to 50,000 copies of the Oct., Nov. and Dec. numbers for free distribution, it will afford an excellent medium for advertisers.

Send stamp for a specimen copy and circular, with list of splendid Premiums to Agents. Address

By JOSEPH BRECK, Practical Horticulturist. Beautifully Illustrated. Price \$1.75.

MINIATURE FRUIT GARDEN.

By THOMAS RIVERS. Illustrated. Or, how to raise many kinds of fruit on small trees, with full directions for Training and Culture. Price \$1.00.

ORANGE JUDD & CO., 41 Park Row, New York.

SENT POST-PAID ON RECEIPT OF PRICE.

A political struggle, rarely surpassed in importance or intensity, has been precipitated on the country by the treachery of Andrew Johnson and some of his official or personal adherents to the great and patriotic party by which they were intrusted with power.

The aim of this treachery is to put the steadfast loyalists of the South under the feet of the "whipped but not subdued" Rebels, and to enable the latter to glut their vengeance on the former, whom they hate and curse as responsible for the most unexpected overthrow of their darling "Confederacy."

The recent wholesale massacres at Memphis and New-Orleans were but conspicuous manifestations of the spirit now rampant in the South, whereof the pro-Rebel triumph in Kentucky is a more recent example. The soldiers of Lee, Beauregard, Johnston and Hood, are now the dominant power from the Potomac to the Rio Grande; they elect each other to office in preference even to stay-at-home Rebels; they have supplanted nearly all others as policemen of Southern cities; they are organized and officered as State militia; and they ruthlessly crush every demonstration of loyal Whites or loyal Blacks in assertion of the Equal Rights of American Freemen. The school-houses of the Blacks are burned and their White teachers subjected to violence and outrage by unchanged Rebels, who relieve the work of murder and arson by cheers for Andy Johnson and execrations of Congress.

The purpose of forcing representatives of the Rebel States into Congress, in defiance of the loyal oath, by Presidential fiat and Military power, is openly avowed, with threats that those who resist it shall be treated as rebels, and a civil war thus kindled throughout the North and West.

It has thus become imperative that those who stand for Liberty and Loyalty—for the right of the Union to exist and of Man to be Free—should organize and work to strengthen the hands of Congress for the inevitable contest before us.

We must convince the South and the Copperheads that revolutions go not backward—that Emancipation is an unchangeable fact—that the glorious Civil Rights Act can never be repealed—that the rights of the humblest American are henceforth guaranteed and shielded by the Federal Constitution, and must be maintained against all gainsayers—that the days wherein Blacks had no rights which Whites were bound to respect have passed away forever.

We hold to-day the power in all the Free States of 1860, in West Virginia, and in Missouri beside. We must hold these in our ensuing elections, and add to them Maryland and Delaware—the former lost to us through treachery, otherwise Johnsonism. We must elect to the XLth Congress an overwhelming majority devoted to Loyalty, Nationality, and the inalienable Rights of Man.

To this end, let Light and Truth be systematically diffused to every neighborhood, every fire-side, throughout our broad country.

To this end, we propose an extra issue of THE WEEKLY TRIBUNE (identical in size and contents with the regular edition), which we will supply to all orders received prior to the 12th of September, the subscription to commence on receipt of the money, on the following terms:

9	copies for three months.....	\$1
12	" " " "	5
26	" " " "	10
60	" " " "	20
100	" " " "	30

Payable always in advance.

All friends of the cause are invited to form clubs; but we employ no traveling agents, and warn all against paying money to other than persons of known responsibility.

Nos. 31 and 33 VESEY-ST., corner Church-st.
POST-OFFICE BOX, 5,643 New York City.
No. 640 BROADWAY, corner Bleecker-st.
No. 503 EIGHTH AVE., near Thirty-seventh-st.
No. 299 SPRING-STREET.

Country Clubs, Hand and Wagon Peddlers, and small stores (of which class we are supplying many thousands, all of which are doing well), can have their orders promptly and faithfully filled; and in case of clubs, can have each party's name marked on their packages as directed by sending their orders to Nos. 31 and 33 Vesey-st.

Our friends are getting up Clubs in most towns throughout the country, and for which we feel very grateful. Some of our Clubs send orders weekly, some not so often, while others keep a standing order to be supplied with a given quantity each week, or at stated periods. And in all cases (where a sufficient time has elapsed) Clubs have repeated their orders.

Parties sending Club or other orders for less than thirty dollars, had better send Post-Office drafts, or money with their orders, to save the expense of collections by express; but larger orders we will forward by express, to collect on delivery.

We return thanks to parties who have taken an interest in getting up Clubs. And when any of them come to New York, we shall be pleased to have them call upon us and make themselves known.

Hereafter we will send a complimentary package to the party getting up the CLUB, of \$30 and over. Our profits are small, but we will be as liberal as we can afford.

The following letter tells its own story:

FISK'S CORNERS, Winnebago Co., Wis., June 23, 1866.

Total.....\$69.50

Our second package which we sent for, was received all right, and has given good satisfaction, and all are highly pleased. Many think that they don't keep as good tea in Oshkosh, as your 10s. tea's—their \$2 is certainly no better. I have taken pains to scatter as many of those circulars as I could, and I presume others will get up Clubs and get their tea from you.

Still there are some "knowing ones" left yet who still insist it is a "Swindle," "Sell," and such like expressions;

but I think time will convert them, and that they will consult their pockets before paying \$2, \$2.50 per pound for tea when they can get as good an article of you for ten shillings. You may send the Complimentary package in Tea.

I am Sirs, very respectfully,

SANFORD CORNISH.

N.B.—All towns, villages, or manufactories, where a large number of men are engaged, by CLUBBING together, can reduce the cost of their Teas and Coffees about one-third by sending directly to the GREAT AMERICAN TEA COMPANY.

*** If we needed any endorsement of our reliability, the complimentary notice we received in the editorial columns of the July number of this paper, would be sufficient, as all its readers are fully aware of the entire reliability of the American Agriculturist. Address

GREAT AMERICAN TEA COMPANY,

31 and 33 VESEY-STREET, corner of Church.

Post-Office Box, 5,643 New-York City.

Evidence after Eight Months Trial.

TREASURY DEPARTMENT, Fourth Auditor's Office, }
July 31st, 1866.

GREAT AMERICAN TEA Co., 31 and 33 Vesey-st., New-York :

GENTLEMEN,—Accompanying this, I send you our regular monthly Club list, which you will perceive is still increasing in proportions. We have now tried your Teas and Coffees for upwards of eight months, and have come to the conclusion that we get as good an article from your house, and at about half the price that we would be forced to pay our merchants here.

I congratulate your Company at the great success that has crowned its efforts in its endeavors to lighten the burden of high prices borne by our laboring people; and also congratulate our Club upon its good fortune in procuring these luxuries of life at prices so fair and reasonable. Hoping you will continue to receive a liberal share of public patronage. I am, sir, very respectfully yours,

L. CASS CARPENTER.

THE EMPIRE SHINGLE MACHINE

Is acknowledged to be, by all odds, the best Shingle Machine in America. With only one HORSE POWER 3000 ELEGANT SHINGLES

per hour are easily made. The machine is built entirely of Iron, very compact and easily transported. It works VENEERS, STAVES and BOX STUFF, and out of the same number of bolts of timber, one-third more Shingles are made than can be done by the Sawing Machines. All the saw-dust is saved by the Empire and goes into the Shingle. ABRAM REQUA, Gen'l Agent, 141 Broadway, New York.

BRICKS.

The NATIONAL BRICK MACHINE is a clay tempering machine, and with only

TWO HORSES MAKES

30,000 GOOD BRICKS PER DAY.

If the machine does not do this, it will be TAKEN BACK AND THE MONEY REFUNDED. For Rights and Machines Address ABRAM REQUA, General Agent, 141 Broadway, N. Y.

The American Emigrant Company

Furnishes labor, skilled and unskilled, for farms, factories, mines and railroads, in all parts of the country, on advantageous terms. Address

JOHN WILLIAMS,
General Agent for Emigration,
No. 3 Bowling Green, New York.

BY CUMMINGS & MILLER.

Carpenters, Builders, and Stone Cutters ;

Your attention is invited to a NEW and PRACTICAL WORK ON ARCHITECTURE, giving in detail on a working drawing scale, the exterior and interior of various classes of buildings—with 382 designs and 714 illustrations, containing street fronts, suburban houses, cottages, cut stone work, &c., &c. It is 11 by 14 inches in size, containing only practical work, designs and illustrations that separately would cost hundreds of dollars. Price \$10.

ORANGE JUDD & Co.,

41 Park Row, New York.

Fuller's Grape Culturist. Price, \$1.50.

This is the fullest and most practical work issued on the Culture of the Hardy Grapes, with full directions for all departments of Propagation, Culture, etc., with one hundred and five excellent Engravings, illustrating the various operations of Planting, Training, Grafting, etc. By ANDREW S. FULLER, Practical Horticulturist. Cloth, 12mo., 263 pp.

ORANGE JUDD & Co.,

41 Park Row, New York.

SENT POST-PAID ON RECEIPT OF PRICE.

NOTICE.

TO YOUNG MEN from the farms--- MIDDLE-AGED MEN who desire to better their condition in Life ---and to PARENTS who would make their Sons successful, useful Men.

I have suggested the best Course of Study and System of PRACTICAL Training for preparing Young and Middle-aged Men for active, successful life, ever adopted in this or any other country.

My course for Farmers' Sons is the best in the world, it being the most useful, the shortest and most comprehensive, and within the reach of all.

Such is the popularity of my System of Practical, Useful Education, that my College at Poughkeepsie, N. Y., on the Hudson, has become the largest Educational Institution on the Continent—enjoying patronage from all sections of our own country, South America, Europe, Cuba, Mexico, and the Canadas, and exerting more power and influence for Practical, Popular Education than all Commercial or Business Colleges in this country combined.

Such was the extended patronage from the West, that it became necessary to establish an Institution at Chicago,—under the Principalship of Prof. E. P. EASTMAN,—where this system of Education could be enjoyed, and its success has no parallel in the history of Schools and Colleges, it being to-day the largest Educational Institution in the West.

Young men from the Farms who can devote a few months to Study, Men of Middle-age who desire to change their present employment for something more remunerative, and others who desire lucrative, honorable situations in business, can enjoy advantages here not to be found elsewhere.

Parents who desire to educate their sons in the best manner, in the least time, and at the least expense, for useful, successful men, will please investigate the claims of this institution. Reference is given to the best Educators and Business Men in the country.

Graduates are assisted to such situations as they merit, through the College Agencies in the different cities. References are given to more than 200 in Government Departments, and more than 400 in the City of New-York alone, who owe their success to this Institution.

The prescribed Course of Study can be completed in three months, at a total expense for Tuition and board of from \$85 to \$100. The Institution guarantees the total expense not to exceed One Hundred dollars for three months, and receives Students for that sum. Those wishing to become members will be admitted any week day in the year. There are no examinations at commencement.

The Illustrated Paper of 16 pages, giving full information of the Course of Study, and the Eastman system of Training, is sent free of charge to all who desire it.

Applicants will apply in person or by letter to
H. G. EASTMAN, LL.D., Pres't.,
Poughkeepsie, N. Y.

Or, for Western Institution to
E. P. EASTMAN, Principal,
Metropolitan Hall, Chicago, Ill.

NOTE.

The Public will not confound this Institution with the many small—so-called—"Commercial" and "Business" "Colleges" that have sprung up in the different Cities. They bear no more comparison to this Institution than a common school does to Yale College. This Institution is the fountain of them all, and is exerting more power and influence for good than all combined. Some claim to have introduced practical instruction on the plan taught here. It will be understood that the Eastman System of Practical Training, was granted by law to this College, through Patents dated Sept. 6th, 1864, and Eastman College of Poughkeepsie, and Chicago, are the only Commercial Institutions in this country that conduct their operations practically. It is also the only Business Institution that has a regular system of Agencies, to procure situations for Graduates.

H. G. EASTMAN, LL.D., President.

THE ELK, OR WAPITI.—(*Cervus Canadensis*).—DRAWN FROM LIFE FOR THE AMERICAN AGRICULTURIST.

This most graceful and beautiful of the larger deers is a native of all the Northern United States, though in several of them it is now extinct. An old elk stag is a noble animal in his whole style and bearing. The poets of Europe, from early to the latest times, have been inspired by their stag, which is smaller and has less of forest-lord dignity than ours, though they are very similar. Mr. John Bell, the naturalist and taxidermist, has been filling a large order for the king of Italy, and seeing 17 of these elk at

his farm a few days since, we engaged our artist to sketch them for this engraving. The elk breeds freely in confinement, and when it is possible to fence them in, so as to enclose them upon recently cleared wood land, growing up full of under-brush and young wood they thrive, and may be reared for market with greater ease and at a less expense than beef. Such at least is the testimony of Mr. Stratton of Cattaraugus Co. Their natural food is about the same as that of cattle and sheep. The stag

sheds his horns annually in early spring, and gains them again during the summer. The flesh of the elk is delicate and highly esteemed in our markets; the hide makes buck-skin, and the horns furnish handles for cutlery, etc. It seems a pity that our rushing, money making, "march of empire" does not provide for the profitable culture of such beautiful and useful animals upon the rough mountain ranges on which they would thrive, and not drive them, with the red man, across the plains, and to ultimate extinction.

Two Months Free.

All new subscribers to the *Agriculturist* now received for one year, are at once entered in our books to the close of 1867. Thus, then, all new subscribers received in October for Volume 26, that is for all of 1867, will get the *Agriculturist* for November and December of this year without any extra charge. Note, that this offer is only for October, except for names from the Pacific Coast, and other points too distant to respond by the close of the month. N. B.—The above applies to all subscribers, whether singly or in clubs, or in premium lists, or from Agricultural Societies, etc.

AMERICAN AGRICULTURIST.

NEW-YORK, OCTOBER, 1866.

It is a great thing to be before-hand with one's work, so as to feel free to take a run away from the farm for a few days to attend a Fair or State Convention, or to give up a few days to politics. If we could only make those plodders and day-after-the-fair folks among our readers, work up and get ahead with their work, so as to stay so the rest of their lives, we might even advocate turning politician for a few days or weeks, now and then. There are a great many who will have the time to go to fairs, and see the neat stock and tools, get new notions, and seeds, etc.—it does them good the whole year. The October fairs make a long list, and we hope all our readers will be able to go to some of them. We go to press too early to be able to report about any of the September fairs, except those of the New England Society, and of the N. Y. State Ag'l Society. See p. 346. These fairs are, day by day at this time, developing the fact that the fruits of the earth are ours in most bountiful store this year. The few frosts in August did little damage, and we confidently anticipate that the corn crop will make good its early promise. Potatoes are rotting in some sections, but not very badly. Sorghum promises very well, and there is a great breadth planted. If severe frosts hold off until after our readers receive this paper, the critical period will have passed with almost every thing.

At this season farmers are more likely to appreciate the benefits of association than at most others, and we call attention to the formation of

Farmer's Clubs.—These are useful not merely for the purpose of holding discussions upon matters of agricultural theory and practice, as too many are apt to think who "pool" at a "debating society," but an especial use of the farmer's club is to learn about the markets, and to contrive methods of selling the produce of its members in the most advantageous way. The lone farmer gets "posted" about prices, and then runs his produce or stock off to meet the demand of some particular market, but says nothing about it until it is disposed of, and not then unless he has sold well. He keeps his information to himself, lest his neighbor should laugh at him, or in order to have the sorry gratification of seeing his neighbor, who has laughed at his mistakes the year before, fall into a trap which he has avoided. In the club all may work for one another's interest, and so advance their own. On specialties, into which communities of farmers often run, clubs have the ability to improve the products and the style in which they are marketed, so that the district shall gain a reputation for some particular articles, which will bring buyers to the place, or enable producers to realize considerably higher prices than otherwise. All such things are the legitimate objects of a farmer's club, and besides the circulating library of agricultural books and periodicals, the stated meetings for discussion, and those for social enjoyment, ought not to be omitted. We ought to have farmer's clubs all over the country, just as much as district schools. Men do not stop learning when they come to years of discretion, and there is no pleasanter school for grown up farmer folks than the farmer's club. The movers for such clubs often ask us for a constitution, and seem to be at a loss how to start without one. We have one in type, crowded out this month, which will answer a good purpose, and may be modified to suit the requirements of every club.

Hints about Work.

Perhaps there is no more important thing for a farmer to think of at this time, after he has harvested his crops for the most part, and begins to see his way clean through his fall work, than his

Buildings.—A little labor upon them now will tell. A board here and a nail there, and a few shingles newly set, will save many dollars' worth of loss or expense later in the season, when storms and winds do their work, and rain and snow pen-

trate. Warm close stables, with good ventilation, should be looked to. Make sheds to shelter manure if it is thrown out of barn windows and doors. No matter how good your barn-yard, the manure is a great deal better kept under cover. Even the hog-yard ought to be thus covered, though there should be space for the sun to shine in, and make a warm place during a good part of the day. Painting may be done in October to excellent advantage. Take time after a rain when surfaces are clean and when there will be no dust flying. And in connection with putting the buildings in order for winter above ground, do not forget the

Cellars.—Both house cellars and root cellars should be cleaned out, and well limed. If there is time, put in grouted cement bottoms, proof against rats, and mice, and water. Cement the walls also, first chinking them up, that is, filling in between the stones with small ones. A good cellar is not only a comfort, but if frost proof and rat proof, a great economy. Make cellars frost proof by banking up outside against the walls, if they are exposed, and by double doors and windows. We have discussed the subject of

Ice Houses on page 357, and have only to add here that it is worth all it costs to have a good supply of ice all the year round. The house we describe is more substantial, and hence more expensive, than is absolutely necessary, but we cannot counsel our readers to do half-way work, nor to make a poor thing. One 10x10 feet inside will pack 4 cubic yards of ice for each foot of elevation.

Live Stock at this season require the careful attention of the farmer, for it is now that the question of profits is really settled. The weather is not severe, yet bracing enough to give animals an appetite. There is an abundance to eat, and it is not difficult to get stock in good condition. The careful husbandman will husband those things which will keep best, and feed out those which are of a perishable nature. Soft corn, mubbins, grown grain, green pumpkins, and the fruits of the orchard, which are liable to decay, may be fed to cattle, or cooked for swine, and help to get them in first-rate order for winter, before the grass fails, and while it begins to afford not quite so good feed as is desirable. It is ruinous policy to neglect

Culves and Colts at any time, but especially give them a good start and let them face the winter with a coat of fat on their ribs, and if they look better than your neighbor's, you will be very apt to keep them growing, by grooming them now and then, and providing at least warm sheds for them.

Cows ought to be yarded at night at all seasons, but at no time is it more important than now. The nights are long, the cows need some extra feed, which is best given in racks or in troughs, or in the proper stalls, and the verdure they crop, consists largely of old leaves which are full of inorganic or ash constituents, hence their dung is of more value than usual. Keep up the flow of milk by feeding pumpkins (without the seeds), roots, soft corn, etc. Practice the same course of feeding for

Bees, for they lay on flesh very fast now, and will do as well on grass and the articles mentioned in liberal quantity, as on much richer food later in the winter. Leave only the *finishing* to be done by aod by, and secure the foundation of fat in this month and next. With

Hogs, the case is a little different. They should be putting on fat now for good, and have all they can eat of thoroughly cooked rich food. Keep them clean, giving them warm nests and plenty of litter. Most farmers lose half the hog manure—the most valuable of all made on the farm, except that of fowls. Hogs thrive so much better for being clean, that it pays to wash them. A watering can, aquarius, or syringe will make short work of it. Clean the troughs daily; have separate troughs for water and feed, and let there be a full supply of water at all times. A little salt in the food is good, perhaps essential. Let hogs have ashes and charcoal. They even like to root among coal ashes; and superphosphate and ashes, Mr. Harris says, they eat with avidity. Should any scour, give powdered chalk mixed in their feed.

Sheep.—For butchers' early lambs (March) use if possible South Down, Leicester or Coltswoold rams this month. The better the sire, the better the stock. Yard the sheep on frosty nights, and as grass fails, give extra feed. Those intended for fattening during the winter should have a little grain while still on grass; they will fatten much quicker for it when shut up for feeding—and will gain more this month than at any other period. Check scours by isolating those ailing, and feeding milk porridge made with fine wheaten flour.

Manure.—Watch the manure heaps with all jealousy. Get in stores of muck, leaves, and litter of all kinds, and either put it under cover in places convenient, or under any temporary roofing, which will turn the rain and keep it dry until needed for use. The yards should be frequently cleaned up, and all droppings thrown into heaps, and composted with litter or soil. Dust gypsum over the stable floors, and on fermenting manure wherever it is; bring to the hog yards potato tops, swamp grass, and any kind of vegetable matter which may be found, or fill low spots in the barn-yard with it. Stack coarse litter which the salt meadows or the upland swamps will cut for similar use during winter. Make provision to save liquid manure, and pump it over the solid manure as it is piled up, mixed with straw or other litter. This maintains fermentation, yet does not let it proceed too far and cause a loss of ammonia.

Soiling.—To have a full flow of milk earlier than the grass is fit for grazing, manure heavily, sow rye early, and again as late as you dare to and expect it to stand the winter. Unless the winter is a peculiarly open one, or unless the snow lies very heavy and long, there will be fully 10 days difference in the growth of the crops in May. This will afford the first green feed for the cows, and their milk will at once increase greatly, even though they have had roots: spring rye, oats and peas, etc., follow.

Winter Grain.—If not already done, spots in the wheat fields where the land is poor, may have a dressing of fine, well rotted manure, scattered on the surface. Rye may often be sown at the very last of the month, but much is risked by delay after the middle in our latitude. In the earlier part of October, wheat is often sown to advantage, but do not delay after the 10th, and even then there is great risk of a poor stand and of winter killing.

Fall Plowing should not be neglected from pressure of other work, but hire an extra hand or two and keep all the teams going. This year's corn ground intended for barley and oats next spring, should be plowed as early as possible. The stooks of corn should be set in straight rows, as far apart as possible, and the ground plowed between them, finishing after corn is husked, and stooks removed.

Draining.—As other work is disposed of or becomes less pressing, and as other farmers discharge their laborers, it is a favorable time to put a good force of men and teams at draining. With a little contrivance, and the use of long yokes or long eveners, the plow may be drawn in the ditches, the horses or cattle walking on each side, and thus the labor be greatly lightened as well as expedited. Narrow ditches, 3½ or 4 feet deep, (not less,) as nearly level as possible, and yet with a regular slight fall, are best whether laid with stones or tiles. Study the lay of the land and drain with system.

Corn should be husked as soon as cured, and not left in the shock, subject to the attacks of vermin and birds, and to damage by rain, causing mildew. Corn houses should be of open slats and rat proof. Before corn is put in bins, soft ears should be thoroughly sorted out, and all not sound should be cured by spreading thinly on the floor of a hot dry loft.

Corn Stalks bound in small bundles and set in stooks dry slowly, and ought to be taken down and re-stooked once in a week or ten days. When cured, stack near the yards, and top the stacks with straw.

Root Crops.—The treatment roots receive depends much upon the location. Dig potatoes when they have done growing. Turnips make their best growth in this month, so leave them to the last. Carrots are injured more easily than other roots, and so should be pulled early enough to be out of

the way of hard freezing. Ruta-bagas and Mangels must be gathered before the ground freezes. See valuable article on preserving vegetables, page 362, remembering that the season at Bergen is at least a month later than that of the Northern tier of States.

Apples and Cider.—Handle fruit without bruising. Lime barrels are excellent to pack it in. The best kept apples we ever saw were packed in barrels between layers of leaves raked up dry. Cider may be concentrated on any good sorghum evaporating pan, to a delicious jelly, which, without addition, keeps perfectly for years. We have seen some made last year on Cory's evaporator which is excellent.

Weeds.—Collect and buru, and cut so as to prevent their maturing seed.

Orchard and Nursery.

The promise of the spring's blossoms is not generally borne out by the autumn's harvest, and many an orchard that seemed good for a thousand barrels, will not give fifty. While we may not be able to say that fruit is scarce, it is certain that the supply is so inadequate that good prices must rule. Whoever has a moderate crop of fruit, should manage it so as to get the most from it. Careful picking, selecting, and packing are needed. If "a few scabby sheep spoil a whole flock," so a few badly developed mis-shapen apples spoil the looks of a barrel. Pick all the fruit by hand, take care that none is bruised in handling, and pack in clean barrels. For shipping, apples should be headed up under pressure. It is found that there are only a few of the top apples bruised when the head is pressed on, and the damage as a whole is much less than when the fruit is left loose enough to rattle, and all get more or less bruised. Several patent presses are sold for use in barreling fruit. They consist of a clamp to go over the barrel, and in the clamp is a screw for pressing down the head. Any ingenious man can, with a rail or bit of scantling, rig up a lever press to answer the purpose. Fruit should not be picked until it is "tree ripe;" that is, until it has obtained all the nourishment it can receive from the tree. This period varies greatly with different fruits, and nothing but experience can serve as a guide for the orchardist. Late sorts may be kept on the tree until light frosts come.

Autumn Planting is generally to be preferred for apples and pears, provided it can be done early enough. The soil of the proposed orchard should have been prepared in advance. Whether trees are to be planted in the spring or this fall, order at once and heel them in, as noted on page 363.

Drains are needed in many orchards, and if the operation was neglected at the time of planting, drains may be put now between the rows. Tile drains is the best, but where stones are abundant, it is often more economical to make good stone drains.

Drying of fruit should be continued, according to hints given last month, and

Cider may be made as soon as the fruit is ready Good fruit, and care, and cleanliness in all steps of the operation, are essential to the production of good cider. If the juice be fermented with the same care directed for wine, (see last month, p. 325) a superior article will be the result.

Buds set late, will, especially if the autumn should be warm and the stocks continue to grow, need to have their tyings loosened or removed.

Seeds for nursery stock are to be secured this autumn. Apple seeds are obtained by washing the pomace from the cider mill. Spread thin and dry, and keep in a cool place until spring.

Ornamental Trees.—Set the deciduous ones as soon as the leaves drop; the earlier the better.

For other hints still in season see last month.

Kitchen Garden.

This is an excellent time to prepare the ground; drains may be laid and the soil manured, plowed and sub-soiled. The way market gardeners put on the manure would astonish most cultivators. We were recently in the grounds of an amateur friend, who pointed to his manure heap with the exclamation,

"there is my head gardener."—Now is a good time to engage the "head gardener" for next year, and the size of the compost heap should show that a favorable engagement has been made. Not only stable manure, but brewer's hops, sweepings of the malt floor, bone, whalebone waste, and hair and animal matters of all kinds, may be made available; nor should home-made poudrette, from night soil, be overlooked. We have frequently described the preparation of this important fertilizer.

Preserving Vegetables for the winter. The article on page 362 gives useful hints. Small roots may be put in a cool cellar in bins and boxes with sand, or light soil, enough to keep them from drying.

Asparagus.—Cut the tops when growth ceases, and burn them. Cover the beds with littersy manure or leaves.

Beets should be taken up before the advent of hard frosts, else their sweetness will be impaired.

Cabbages.—Plants sown for wintering over, should be set in cold frames about 2½ inches apart; set deeply, and do not cover until cold weather. To winter cabbages, cover with earth, in the manner mentioned on page 362. We have had better success in this way than with setting them upright in roofed trenches. Savoys, and other late kinds, may be left out until the ground is crusted with frost.

Cauliflowers.—Treat young plants the same as cabbage plants. Old plants that have not headed, should be put in a cold frame, or a light cellar.

Celery.—This is best preserved out of doors in trenches a foot wide, and as deep as the plants are tall. The celery is packed closely in the trench in an upright position, and as cold weather comes on, the tops are to be gradually covered with straw, leaves, or other protection, adding to the covering as the weather becomes colder, until it amounts to about a foot in thickness. To be more readily accessible, a portion may be put in a box in the cellar, and packed in moist sand to keep from wilting. This will not do if the cellar be warm.

Hot-beds.—Gather a good heap of rich loam and put it under a shed, or cover it with boards, so that it may be got at in February and March, for use.

Parsnips.—As many of these may be dug as are required while the ground is frozen, and placed in the cellar or in pits; the rest are left as they grew.

Rhubarb.—Make new plantations by dividing the old roots, securing a bud to each portion of the root, any time before the ground closes. The richer the soil, the better. Cover beds with coarse manure.

Salsify is to be treated the same as parsnips.

Spinach.—Keep the late plantings free of weeds, and when hard frosts come, give a light covering.

Squashes will not bear frost without injury. Gather in time and keep at an even temperature.

Sweet Potatoes.—As soon as the vines are blackened by frost, dig on a bright day and let them dry before housing. Pack in cut straw or very dry sand; do not bruise them, and keep where the temperature does not fall much below 60°.

Tomatoes.—The green ones that will not ripen before frost, should be picked for pickles.

Fruit Garden.

Prepare the soil by draining, manuring and plowing or trenching. Most small fruits like a rich soil. Planting is to be done as early as possible.

Blackberries are set six feet apart each way, or in rows 8 feet apart, plants 4 feet distant in the rows.

Currants and Gooseberries.—Bushes may be set and cuttings made. See page 364. Training currant bushes to a single stem, like a small tree, is now abandoned, and 3 or 4 main stems allowed to grow.

Grapes for wine or for keeping are allowed to remain on the vines until there is danger of frost. For boxing see last month on page 323. To preserve them for use, put in small boxes and keep at a uniform low temperature. Vines may be set as soon as the leaves fall, and pruning done; if the wood is wanted for cuttings, bury it before it dries.

Strawberries.—New plantations may be set early this month; see notes given last August. Do not

cover too early. Better keep the covering off until the ground is slightly crusted with frost, than to cover earlier. Straw, leaves, or corn stalks may be used.

Flower Garden and Lawn.

This month we usually have grand weather for work, and it should be devoted to making improvements in the ground, laying drains, road and path making, etc. Those who enjoy the rich tints of the autumn foliage, should plant trees with a view, in part to the autumn effect, of their changing colors.

Annals.—Sow hardy kinds, such as Larkspurs, Gillias, and all those that do best when self-sown.

Bedding Plants.—Make cuttings at this time of all such plants as are not intended to be taken up.

Chrysanthemums.—Pot for blooming in-doors, and when in flower, mark those desirable to propagate.

Dahlias.—When the frost has blackened the plants, cut them down. Lift on a fine day and allow to dry off in the sun before being housed.

Gladiolus is to be treated the same as the Dahlias.

Lawns may be laid down this month. Draining, deep plowing, and thorough pulverizing of the soil, should be attended to. Roll after seeding, and just before the ground freezes, roll again.

Perennials.—Even the hardiest do all the better with a winter covering. Divide and re-set clumps.

Pinks and Carnations.—Pot rooted layers and set in cold frame, where they can be kept rather dry.

Pansies and Violets.—Put roots in a cold frame for winter blooming, as was directed last month.

Roses.—See article given on page 323, last month.

Tuberose, not done blooming, may be lifted with a ball of earth into pots or boxes. If they are set in a green house or room, they will continue flowering.

Transplant all kinds of deciduous hardy shrubs.

Green and Hot-Houses.—Take in tender plants before the cool nights check their growth. Have all the pots clean, and renew the top soil; remove dead leaves, cob-webs, and prune and stake where needed. The change from free air to the confinement of the house should not be too sudden, and abundant ventilation must be given whenever the weather is fine. Bring no insects into the house with the plants, but have every thing free from these pests before it is brought in.

Near cities a large business is done in forcing hardy herbaceous plants and shrubs, such as Dicentra, Lily of the Valley, Deutzia gracilis, Weigela, etc. Pot now and keep dormant until near spring.

Annals may be sown in pots for winter blooming, and bulbs may be potted. Towards the end of the month some fire will be needed on cool days and nights, and its management will require caution.

Cold Grapery.—The wood should be thoroughly ripened, and so leaves should be left on until they fall spontaneously. Avoid sudden changes of temperature, and as cooler weather comes on, keep only the upper ventilators open. Shut up entirely in cold and stormy weather.

Read the Premium Descriptions.

—Explanation.—We add several extra pages this month, to make room for our Premium List and descriptions. This will be found worth looking through, for though a business document mainly, there are numerous items of information scattered through the Descriptions, which will be interesting and often useful. —The list is quite extensive, and the articles offered of so great value, and so easily obtained, that we doubt not there will be one or more persons in every neighborhood, who can get some very desirable thing by the little effort required to raise a club of subscribers. We believe and know the *Agriculturist* is doing a good work of itself, and we aim to get it introduced into tens of thousands of families, where it will not chance to find its way unless it is brought directly to their attention by some one who will be well paid for his or her trouble, by the fine premiums here offered. The enlarged circulation thus obtained, so increases the value of our advertising department that the loss on subscription money is amply made up.—Many have already (Sept. 20) sent in clubs of new and old subscribers for 1867 and secured valuable premiums.

\$1,250.00 IN PRIZES.

I—Prairie and Western Farming.

\$500 IN PRIZES.

The immense Western regions brought under culture in recent years, and yet to be occupied, give great importance to that section. In order to call out and systematize as much practical information as possible, which shall be useful not only to those already at the West, but also to a vast multitude yet to go thither from the Eastern States and from the Old World, the Editors and Publishers of the *American Agriculturist* offer a

1st Prize of \$350, for the best practical Treatise or Essay upon *Western Farming* in general, and especially upon *Prairie Farming*, including the various particulars of selecting land, getting on to it, bringing it under Culture, Fencing, Crops, Animals and Fruits, their kinds and treatment, etc. In short to give a Clear Guide to beginners as well as to old cultivators; to tell what to do, and how, and when to do it best—in plain, simple language, just as one would talk from day to day to a new-comer who needed to learn all about farming.

2d Prize of \$100, for the Second Best Treatise.

3d Prize of \$50, for the Third Best Treatise.

The manuscripts to be ready March 1st, 1867, and at least 200 pages of Foolscap. See *General Remarks below.*

II—The Cultivation of Cotton.

\$500 IN PRIZES.

The great importance of the Cotton crop, the general interest in its improved culture, both among Northern and Southern men, and the little comparatively that is recorded in books or otherwise on the subject, induces the Publishers of the *American Agriculturist* to offer a

1st Prize of \$400, for the best Treatise or Essay giving full, plain, practical directions, all about Cotton Culture, from the soil and its preparation and cultivation, to the gathering, packing, and marketing of the crop—all so plainly stated as to aid not only the old routine cultivator, but also to be a guide to the new cotton grower.

2d Prize of \$100 for the Second Best Treatise.

The manuscript to be at least 200 foolscap pages, to be ready by January 1st, 1867. See *General Remarks below.*

III—Timber and Fencing for Prairies.

\$250 IN PRIZES.

The great importance of this subject to millions of Western cultivators, induces the Publishers of the *American Agriculturist* to offer the following:

1st Prize of \$150 for the best Treatise or Essay on the securing of Timber and Fencing material, for the timberless prairie regions of the West, including also Hedges, Wind breaks, etc.

2d Prize, \$75 for the Second best Essay or Treatise.

3d Prize, \$25 for the Third best Essay or Treatise.

The manuscript to be ready by or before February 1st, 1867, and contain at least 150 pages of foolscap. See *General Remarks below.*

General Remarks.—The above prizes are offered for the purpose of calling out more general and systematic information than can now be found in books or papers. The first and most important aim is to gather information useful in preparing the pages of the *American Agriculturist*, but it is the expectation that at least one of each class of Treatises will be worthy of issuing in a more compendious or complete book form.

The lowest number of pages in each case is named above. No maximum limit is fixed. Those essays will be most valuable which give the greatest amount of really practical information without useless dilution in wordy or high flown phrases and sentences. Compilations of other men's writings, or a rehash from Patent Office or other Documents, are not what is aimed at.—Drawings and Sketches will give additional value.

The several Essays will be submitted to Committees of the best Judges that can be obtained, among those who are practically acquainted with the several subjects.

The Essays receiving the prizes will be the exclusive property of the Publishers of the *American Agriculturist.*

Should there be nothing offered at all worthy of any one or more of these prizes, in the opinion of Competent and Impartial Judges, the prize will of course be withheld. Any one proposing to write for them, is requested to send for a printed slip, giving more full information than we have room for here. All communications of this kind will of course be strictly confidential.

About "Harris Brothers," Boston.

During the summer, a letter from Boston asked the terms for 10,000 to 50,000 subscriptions, to the *American Agriculturist*, to be used in building a Home for Disabled Soldiers. Our reply was, that we could give no answer until we knew something of the enterprise. Afterwards, two men called on the same business, giving their names as "Harris Brothers." Great inducements were held out to give us a splendid increase of circulation. The answer again was, that we could not do anything to forward any enterprise not known to be legitimate and proper, however it might benefit us. In answer to the question what our terms were, etc., the remark was made that we received subscriptions from any one, on our regular terms, when accompanied by the money. Nothing more was heard of it, until the following correspondence. (The letter was accompanied by proof-sheets of a circular and newspaper orders, such as have been recently distributed by Harris Brothers.)

Boston, Mass., July 19th.

Mr. CHASE, care *American Agriculturist*
Office, New York.

Sir:—A little over a month ago we called on you, and had some conversation in reference to an enterprise we were then starting. We have so far completed our plans, as to be able to submit for your inspection our documents and papers. We propose to carry out all we promise, and all we expect of you is, that you will furnish the "Agriculturist" to those who may order it, and we will pay the orders upon presentation, or will deposit an amount with you sufficient to cover what orders you might receive in a given time. We do not ask you to endorse our enterprise, but simply ask you to furnish the papers at as low a rate as you can; at any rate we expect to get the papers at the Club rates.—You are of course at liberty to investigate, and after you have perused, please write us, and tell us if a deposit is necessary, in order that our orders may be recognized when received by you. We shall advertise extensively, and certainly your subscription list will be largely increased.—Let us hear from you at your leisure, and any suggestions that you may make will be carefully considered.

Yours in haste

HARRIS BROTHERS.

[REPLY.]

New York, July 27, 1856.

Messrs. HARRIS BROS., 50 School-st., Boston.

Returning to-day from a week's absence, we find yours of 19th.—We do not see any essential difference between your proposed "National Distribution," and any other Lottery; and we must protest against your issuing tickets, etc., that give even the quasi endorsement of the *Agriculturist*, as your tickets and bills appear to do.—We cannot consent to receive the "Newspaper Orders" on any conditions, or to receive any deposit for them. The only answer given you by our Partner, Mr. Chase, was, that we received subscriptions sent in with the money, and at club rates from those who sent in enough to make up a club. He also objected to being in any way mixed up with your proposed plans, at least until we should examine and approve them—which has not been done.—Further, we shall deem it our duty to the public, to show up your scheme in its true colors, and warn people against it. We warn you not to issue any circulars, announcing that you have "made" any "arrangements" with us, for supplying copies of our paper, on any terms, to forward your enterprise. Yours respectfully,
[Signed] ORANGE JUDD & Co.

We supposed the above letter had ended the matter, so far as we were concerned, and we heard nothing more of it, until just after the the September *Agriculturist* had got well to press, when we began to receive from all over the country, copies of a flaming Circular, Orders for the *Agriculturist*, etc. The circular announces tremendous prizes, and, among other things, says:

"EVERY PERSON who invests FIVE DOLLARS in the NATIONAL DISTRIBUTION, receives, in addition to a chance in the Grand Dividends, one year's subscription to either the '*American Agriculturist*,' published in New York City, the '*Rural American*,' published at Utica, N. Y., or '*Balou's Literary Magazine*,' published at Boston, Mass. The Managers of the Distribution have made such arrangements with the publishers of these celebrated Rural, Agricultural, Horticultural, Floral and Literary publications, that they can give, as a gratuity to each purchaser of a Certificate, one year's subscription as above. Thus, every investment of \$5 entitles the investor to a chance in the Dividends, ranging from \$5 to \$30,000, a year's subscription to the Leading Agricultural and Literary Papers of America, and lastly, aid and encouragement to one of the most noble, patriotic and benevolent Institutions ever devised by man."

Any one can see, by reference to our above letter, that this is a downright IMPOSITION. Harris Brothers "Enterprise" is, neither more nor less, a Lottery Scheme, and we shall wonder if it is allowed to continue in Boston. We refuse all "certificates" coming from Harris Brothers. We find it impossible to answer otherwise than by this notice, the letters of inquiry about the concern, as they are so numerous.

Acknowledgments.—The unusual pressure upon our columns, notwithstanding we have added extra pages, crowds out a number of acknowledgments already in type. Those who have sent documents, catalogues, specimens of fruits, flowers, vegetables, etc., will understand that their favors are not unappreciated nor overlooked, but we are not able at this time to make a separate notice of them, simply for want of room.

Containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Mark All Subscriptions sent in, as New or Old.

For Market Report and List of Fairs, See Page 379.—The great press of matter, after omitting several pages prepared for this Basket, compels us to take out advertisements, and put the market and fair lists in an unusual place as above noted.

Our "Political Preferences" are inquired after by a few subscribers. Well, we exactly agree in sentiment with the man who is positively every way right and sound in his political views. Does any one disagree with us now? This is all we are allowed to say in a paper that has nothing to do with politics.

"Stop My Paper," says a subscriber, enclosing an advertisement of the N. Y. Tribune cut from our business columns, which we had not even changed to notice before.—"Stop my Paper" has been said by one or two persons every time we have inserted an advertisement of the Herald, World, Times, or Independent.—We advertise in many papers, of all political shades except those positively and professedly opposed to the Union. The more enterprising journalists, who know where to find a good medium, use our columns largely, and thus we get part of our money back. Journals so out spoken in their columns, and in their advertisements especially, as those above named, can deceive no one, and as they "have the ability and will to do what they promise to do in their advertisements," our rules in no way cut them off from using what space they pay for at full rates. Nobody is obliged to buy or read. If anybody "having the ability and will to supply them," should advertise to supply pigs, or panthers, as household pets, we might admit his card, without thus commending his animals for the use recommended by the seller.—We aim to admit nothing deceptive or immoral; how well we do this, our work must show. We can not, however, send around and ask permission of all our readers before admitting an advertisement.

Barometers.—Letters giving details of experience in using the barometer, and of its benefits, are coming to hand, and we solicit still more of them. Let us have a full report, at least from those who have had our premium barometers. We can not of course publish these long communications, but they are useful, and we will endeavor, by and by, to give a summary. So far these letters, with an exception or two, speak of good results. Some who have not been so successful in always predicting storms and fair weather with certainty, as they hoped to be, yet speak very favorably of the general accuracy of the instrument, and we judge that not more than one of them would be willing to part with his barometer on any consideration.

Valuable in Every State—Why.—

An Illinois subscriber writes that "the Editors of the *Agriculturist* should visit that State before they can get any idea of the magnitude of the West and what farming is there." Why, friend, the Senior Editor has traveled for observation, partly on foot, through at least thirty States, and the Canadas—including over 10,000 miles in Ohio, Michigan, Illinois, Wisconsin, Southern Minnesota, the eastern half of Iowa and Missouri, part of Kentucky, besides Tennessee, Arkansas, Mississippi, Louisiana, and all the Atlantic States from Maine to North Carolina. Another has traveled for the same purpose in all the Middle States East of the Mississippi, and spent a year in the Southwestern Country. Another leading Editor spent several years in the employ of the Government, making observations upon the country at the Southwest and up and down, and across the Continent to California and back. A fourth Editor devoted a season to examining the Sugar, Cotton, and Rice regions of the South. Constant observations and correspondence are received from every section of the country.—The prizes offered elsewhere in this paper (page 344) are only a small part of the expense and effort constantly put forth to gather general information.—But aside from the personal advantages enjoyed by the editors, and the other sources of information, the great principles of soil culture are the same everywhere. Animals, fruits, etc., need the same general rules and observations. The Household, and Children's Departments, and the engravings, are equal valuable in Nova Scotia, New York, Nebraska, Texas, Oregon, or Australia. We indeed write much about manners for the older States, but though there is

enough other reading for the newer West, we advise farmers there that some attention to this subject is worth their while, against a day of necessity—"A stitch in time, etc."—To show the adaptation of this paper to the West, we may mention, that a Western paper begged earnestly for home support on the ground that eastern papers were not at all adapted to that region—basing its remarks specially at this journal, which seemed to be a favorite in its bailiwick. The very same paper had only 21 columns of reading, and of these 15 were filled with articles that first appeared in the *American Agriculturist*; 7 columns were directly credited to this journal, and 8 were not credited!—A multitude of persons, residing in every section of the country, including several away on the Pacific Coast, have detailed to us, how single hints, derived from or suggested by reading this paper, have resulted in very great pecuniary value, often to the amount of hundreds and thousands of dollars in individual cases.

Picking Apples for Cider.—Mr. G. R. Green, Hudson, N. Y., finding hand picking too slow, and wishing to avoid the stones and dirt that will be mixed with apples when gathered from the ground, contrived the device shown in the engraving. It consists of a spread made of stout burlap, 20 feet square, bound on the edges. In the center is a hole large enough to encircle the tree, and provided with a drawing string to fasten it to the trunk. From this hole is an opening to one side of the spread, to allow it to be put around the tree, and the opening is afterwards laced up by means of a string running through eyelet holes. In each of the corners of the spread a strong eyelet hole is worked—or what is better, an iron eye may be inserted. The spread being placed around the tree, three of the corners are raised up and stretched out by means of slender poles, in such a manner, that the corner without a pole will be the lowest. Under this depending corner is placed a barrel, or wagon if the tree be a tall one. The apples are shaken down on to the sheet, and roll towards the lower corner, where they are caught. Though apples are but little bruised by this treatment, it is not recommended for those intended for long keeping.

Sundry Humbugs.—Aside from a large number of letters about "Harris Brothers," and J. D. Miller, our batch of letters about swindlers reaches only about a hundred this month, by far the smallest number for any month during a past year. We learn that the exposures of the *Agriculturist* have made the "Circular" and "ticket" business so unprofitable through the North, that the swindlers have turned their attention more to the Southern States, where they are now operating with all possible speed and diligence. We must try to get the *Agriculturist* circulating more thoroughly there, though it is already going that way pretty extensively. A few particulars will suffice here: Harris Brothers are noticed on page 344. J. D. Miller was shown up last month, and though not dead, is on the wane. J. D. Granger operates with the same circulars, sending letters pretending to have drawn \$130 to \$165 prizes for sundry people. The "prizes," like those of Miller, are shares in the "Sand River Prize Petroleum Company." The certificates for \$150 shares, more or less, are worth about one-twentieth part of one cent—for waste paper—and no more. All the Art Unions, the Soldiers' Unions, and other like Schemes, are no other than sheer lotteries, and dangerous to touch by any one who does not wish to gamble or throw his money away. No one of these has ever come up to its promises about drawing, etc. Usually when all the money is in, some one of the clique finds

it convenient to decamp with it, as at Milwaukee, for example. The Illustrated papers, and the respectable Daily and Weekly papers, are aiding in the swindles by publishing the advertisements. Pray do not be blindfolded by the array of names of bankers and other public persons, who are made to at least seem to favor these enterprises. They are springing up all over the country, but are all of a piece, villainous lotteries, dangerous because got up so plausibly, and so thoroughly sugar-coated. Our letters this month contain notices and circulars of 31 swindling parties and concerns, some of them already shown up, and others are the old parties under new names, but with the same circulars, etc. The most numerous circulars and tickets are from "Vincent, Willis & Co., Williamsburgh, N. Y." That is a large city, now united with Brooklyn, but its streets are systematically laid out and numbered. Why then did not V., W. & Co. tell people where they are to be found? It is bad for us, because a Pennsylvania friend has presented us with tickets for some magnificent prizes, all for \$2.60 each, an installment of 200 other lots, all sent "exclusively and privately" to persons in his town. Many others send us similar gifts.—Vincent, Willis & Co., you are myths—Humbugs!.....The European Pocket Time-keeper, and the "Silent Friend," are both gross humbugs. Julius Sinking and others, who offer these, should go into some honest business. Joseph T. Iman, and Madame Thornton, have both been already denounced, and those who advertise for them are helping them to victims among the ignorant and credulous. The following are Humbugs: "Grand National Gift Enterprise," N. Y. City.—"Errors of Youth" Recipe, N. Y. City.—"Great Closing Off Sale," do.—"Mutual Benefit Association," Quincy, Ind. Marcus Blair, Attorney, etc., of Oakland, Clinton Co., Ohio, who offers to lie \$500 prizes through for \$10 to \$50, and will lie to you—Dr. Freeman.—"Perfume of Love."—"Essence of Life."—"Radical Regenerator."—"Metropolitan Jewelry Association."—"New Jewelry Association."—"Great National Gift Concert for Benefit of N. Y. Soldiers' Monument Association," J. L. Jaynes, Manager.—"\$5 to \$10 Sewing Machines," under several names: not worth receiving as a gift.—"Great Gift Concert for Soldiers' Monument," Sidney, Ohio, etc., including some fifteen pretended sellers of splendid Jewelry, valuable Watches, etc., by tickets for from \$1.75 to \$12. Every such concern in N. Y., is a Humbug! E. E. Bryan, of N. Y., is too good looking a man to be engaged in the disreputable, villainous business he is in, that of supplying obscene, disgusting books, pictures, and instruments, marked cards, loaded dice, etc. He is ashamed of the business, or afraid of it, as he tries to dodge the law by pretending to be only an agent; he refused us even a circular at his office, saying he had not there anything he offered, not even a circular to supply to us—a pretended country peddler. We would not like to trust any money in his hands by mail, as he requires it sent. Give all such disgusting circulars as he sends out, to ashes as soon as possible; they will soil your hands even. We stop here for a month, for want of room.

Documents Acknowledged.—Transactions of the Worcester Co. (Mass.) Horticultural Society, from Edward W. Lincoln, Sec'y. Address of Hon. Henry H. Crapo, before the Central Michigan Ag'l Society, at their Sheep-shearing Exhibition, Lansing, May 21, 1866. Report of the Northern Ohio and Lake Shore Grape Growers' Association: to be had of Allen Pope, Treas., Cleveland, O. Transactions of the California State Agricultural Society for 1864 and 1865, a volume of over 400 pages. Trans. Pennsylvania Horticultural Society for 1865. Trans. Columbia Co., Wis., Agricultural Society for 1865. Indiana State Horticultural Society, Transactions 1865-66. Catalogue of School of Mines, Columbia College, N. Y. City. Trans. Essex (Mass.) Agricultural Society for 1865.—The following dealers have sent us catalogues of Hardy Bulbs: Brill & Kumerle, Newark, N. J.; James Vick, Rochester, N. Y.; B. K. Bliss, Springfield, Mass.; J. M. Thorburn & Co., 15 John St., N. Y. Catalogues of General Nursery Stock from J. W. Hinks & Co., Bridgeport, Ct.; Faulkner Nurseries, Danville, N. Y.; J. C. Williams & Co.; F. Trowbridge, New Haven, Conn.; Dutchess Nurseries, Ferris & Caywood, Poughkeepsie, N. Y.; Parsons & Co., Flushing, N. Y.; Bloomington, Ill., F. K. Phoenix; Genesee Valley Nurseries, Rochester, N. Y.; Frost & Co.; Washington Nurseries, Geneva, N. Y.; Bronson, Graves & Selover. Grape Catalogues from C. W. Grant, Iona, near Peekskill, N. Y.; Humboldt Nurseries, Toledo, Ohio; Pomona's Home Nurseries, West Newton, Pa.; J. H. Foster, Jr.; Canandaigua (N. Y.) Propagating Establishment, F. L. Perry, Proprietor. Price Lists of Strawberries, etc., from Reisig & Hexamer, Newcastle, Westchester Co., N. Y.; Francis Brill, Newark, N. J.; Willetts Bros., Buchanan, Mich. Catalogues of Vegetable Seeds, Henry A. Dreer, Philadelphia, Penn.; Brill & Kumerle, Newark, N. J. Report of the California Assembly Committee on the Culture of the Grape Vine; Thirtieth Annual Report of the Ohio Pomological Society, 1866.

Cabbage Queries.—W. R. V., Elkton, (where?) An ounce of cabbage seed will usually give about 2000 plants. See notes for Kitchen Garden this month, and article on Management of Cold Frames in March last, page 90, for answers to other queries.

Tomato Seed.—"W. R. V." The pulp is usually allowed to ferment slightly, when it will wash. A friend puts the seed in a cloth, and washes the cloth with the enclosed seeds in soap suds. We have not tried this.

Tilden Tomato.—Either we have not the right sort around New York, or it is not suited to this locality, as our own, and those we have seen in a half dozen other places, have been in no respect equal to the old smooth red; not as early, no more dwarf, productive, solid, nor better flavored than that excellent old sort. Has it been over-estimated, or have we the wrong seed?

Large Cauliflower.—Mr. Randall H. Green, of Wickford, R. I., sends us a cauliflower that measures 47 inches around and weighs 11 lbs. It grew in the black soil of a reclaimed bog. Pretty good for Rhode Island—or any other State.

A Prompt Settlement.—The Niagara Fire Insurance Company of this city, paid their losses, \$70,000 and upward, within one week after the great fire in Portland, besides paying \$1000 toward the relief of uninsured sufferers. Such promptness will increase confidence in an excellent company.

The New England and Vermont Fair.—The New England Agricultural Society, with the Vermont State Society, held a fair at Brattleboro the first week in September, at which we were able to be present a short time. The weather was all that could be desired, the grounds in fine order, and the attendance large. The show was remarkable for its uniform excellence in almost all departments, and the New England farmers, breeders, and mechanics deserve great credit, almost all of the N. E. States being well represented. As a show of live stock, there has rarely been a superior exhibition in this country. All classes of sheep were represented in goodly numbers. Mutton sheep, especially the Cotswells and Southdowns, were very fine, but the great show was that of Merinos, as was to be expected, and in this class it is claimed that all previous exhibitions were eclipsed by both the number and value of the animals shown. In the various classes of neat stock the show was fine also, the Short-horns greatly preponderated, though there were animals of all the favorite breeds. Among horses, Thorough-breds, Morgans, Black-hawks, and Hamiltonians divided the honors given to breeding stock. The same blood told its story on the trotting course, Ethan Allen, now 19 years old, making his mile in 2 min. 38 sec.—the best time made. Specimens of most of the valued breeds of swine were on exhibition, and the show was regarded as creditable. There was also a good show of poultry. To the departments of industry we had not time to devote much attention, but from the crowd, have no doubt the multitudes were gratified and instructed. Gov. Andrew's able address was listened to on Friday by a great audience, surrounding the stand and filling the seats, which were said to accommodate 3000 people. Listening was painful, and hearing quite impossible for all within the sound (and who was not?) of the continual yelling, auctioneering, shouting and declaiming of the keepers of a great number of disgusting side-shows, snakes, big woman, big dogs, peddler wagons, gambling stands, and what not, which were allowed to fill up a good portion of the grounds. A shame and blot upon the otherwise good management of the fair.

New York State Fair.—The Fair of the N. Y. State Agricultural Society, was held this year at Saratoga, a location which offered great inducements so far as concerns the comfort of both visitors and exhibitors, in the excellent grounds of the County Society, and the abundant hotel accommodations of the city. The weather was prevalently good, the first and last days only being rainy, and the attendance on Thursday was very large, so that it is safe to say the expenses were paid, and perhaps a snug sum laid by against a rainy day. The show was a very large and interesting one in several departments. The Fairs of this Society have been always good in the department of farm machinery and implements of all kinds—but this has, in our view, exceeded all previous ones in this particular, both in variety and excellence of the articles. The show of swine was the best we ever saw in this country, or perhaps we should say, it was a show of the best swine, for the number of different breeds was not very great. The Jefferson Co. breeders were there in full force, most with excellent swine. The show of cattle was small, but very good, the herds of Messrs. Cornell, and Sheldon,

were represented by as good Short-horn cows as ever took the Society's prizes, and the Alderney's were in goodly number, and unexcelled in quality by any we have ever seen exhibited together: we can not specify particular animals now. The Ayrshire and Devon stock had each good representatives, so that on the whole, the cattle department presented a most instructive exhibition. In the sheep class, there was also a very instructive show. The American Merinos, worth from \$500 to \$1,500 each, were in strong force; the Silesian Merinos, in smaller number, but of great excellence; their grades also of the first and second crossing were shown, demonstrating the great improvement in the quality of the fleece thus produced on common flocks. There was a good show of most excellent Long-wools, and some South-downs. The horse show was, on the whole, inferior to those of other years, and to what it should be. There was a very poor show of Dairy produce, and of fruits. The side-shows, whose name was legion, were kept outside. The management was excellent, and though many of the cattle and sheep, and horse-stalls were empty, yet, on the whole, the show was a very interesting and important one. The discussions held during the mornings were well kept up, and formed a valuable feature. There is much to interest a stranger in the town, and this visit to Saratoga Springs will be remembered with satisfaction by a great many people.

Awards of the N. Y. State Ag'l Society to Mowers, Reapers, Threshers, etc.

—The awards of the great trial at Auburn were announced at the N. Y. State Fair, as follows:

CLASS I.—*Mowers*, 18 entries.—The Gold Medal to the "Buckeye," Adriance, Platt & Co., New York.—2d Prize, \$25, to the "Clipper," R. H. Allen & Co., N. Y.

CLASS II.—*Reapers (Hand-rake)*, 2 entries.—The Gold Medal to the "Kirby," D. M. Osborne & Co., Auburn, N. Y.—2d Prize, \$25, C. Wheeler, Jr., Auburn, N. Y.

CLASS II½.—*Reapers (Self-rake)*, 5 compete.—Gold Medal to Seymour, Morgan & Allen, Brockport, N. Y.—2d Prize, \$25, to C. C. Bradley & Son, Syracuse, N. Y.

CLASS III.—*Combined Mowers and Reapers (Hand-rake)*, 7 compete.—Gold Medal to W. A. Wood, Hoosick Falls, N. Y.—2d Prize, \$25, to the "Eagle," E. F. Harrington, Rondout, N. Y.

CLASS IV.—*Combined Mowers and Reapers (Self-rake)*, 10 compete.—Gold Medal to the "Hubbard," Williams, Wallace & Co., Syracuse, N. Y.—2d Prize, \$25, Seymour, Morgan & Allen, Brockport, N. Y.

CLASS V.—*Combined (Hand and Self-rake)*, thrown out. CLASS VI.—*One-horse Mowers*.—Gold Medal to the "Clipper," R. H. Allen & Co., New York.

CLASS VII.—*Horse-Power Inclined Endless Chain*.—A Gold Medal to R. & M. Hardee, Cobleskill, N. Y.

CLASS VIII.—*Horse-Power Lever and Sweep*.—Dow & Fowler. Gold Medal recommended, [not awarded].

CLASS IX.—*Ten-Horse Thresher and Cleaner*.—Dow & Fowler, a premium recommended.

CLASS X.—*Two-horse Thresher and Cleaner Combined*.—Gold Medal recommended to R. & M. Hardee.

CLASS XIII.—*Horse Rakes*.—To Barker, Sheldon, & Co., Gold Medal, to A. B. Sprout, \$25. H. N. Tracy, and P. S. Carver, judged worthy of second premiums for Horse Rakes, with and without sulky attachments.

CLASS XIV.—*Hay Tedder*.—Herring's Tedder was judged worthy of a Gold Medal for the design, but it was refused because the workmanship was so inferior.

CLASS XV.—*Horse-Power Hay Forks*, 4 compete.—Gold Medal to J. Mansfield & Co., \$25 to Chapman, Hawley & Co., applicable to Barley and Oats. A 2d premium, is recommended for A. B. Sprout, for Harpoon Fork.

A New Grape Box.—Boxes for packing grapes are usually made of six pieces. We have been shown one patented by Smith & Doolittle, that is made of only three pieces. The ends are of pine, and the sides, bottom and top are made of one thin piece of white wood. This piece is cut part way through, so as to allow it to bend at the corners. That portion of the piece that forms the two sides and bottom is tacked to the ends. The top is about 2 inches wider than the box, and this portion lays over and fastens to the side. By taking the nails from this flap, the cover opens without splitting, and remains attached to the other side, as if it were hinged. The box is light and cheap, and if no fault is found in use, it will no doubt become popular with grape growers.

Blackberry Queries.—"Subscriber" complains that the new kinds of blackberries are too expensive to plant, and wishes to know if wild plants can be successfully transplanted, or shall he depend upon seed. All of the garden blackberries are accidental wild seedlings that have been taken up and propagated. Wild plants differ greatly in the size and shape of their fruit, as well as in productiveness and time of ripening. If "Subscriber" knows where to get wild plants, that in

their natural state have desirable qualities, they will be likely to do much better when put under cultivation. To put out a plantation of wild plants, taken at hap-hazard, would not be likely to be profitable. The matter of seedlings is one requiring some time and patience, and though some good sorts may be obtained, it will be much cheaper—if fruit is desired—to procure a few plants of varieties of known excellence and propagate from them. In good soil, blackberries multiply very rapidly—often too freely for convenience.

Manuring Orchards.—"Subscriber," Middletown, Mo. The best time to manure an orchard is just as the trees are making their growth in spring. It is usually more convenient to haul manure in winter when the ground is frozen, and there is more time for the work, hence it is frequently done at that time, though at some waste of manure.

Cooking Cauliflower.—"I. C. S.," De-Kalb Co., Ind., is not acquainted with cauliflower, and wishes to know how to cook it. If friend S. does not know cauliflower, he has a pleasure in store. Cut the heads before they become loose, and boil in water slightly salted—never with meat. When tender, which will usually be with 20 minutes cooking, take up and drain and cover with drawn butter, (white sauce made with butter, flour and water,) and serve hot. They are usually eaten without other addition, but some dress with pepper and vinegar—the same as they do cabbage.

Cooking Egg Fruit.—Last month we gave our manner of cooking the fruit of the egg plant. Since then we have received several communications upon baking the vegetable. "Hawk eye," of Burlington, Iowa, says: "Cut longitudinally, like opening a water-melon, scrape out the contents of both halves, mix well with dry bread crumbs, season with pepper and salt, replace in the hollow rind, and bake well in a hot oven. Try it if you wish a treat." Others direct that the fruit be parboiled before it is opened.

Good Home-made Ink—Humburg Recipes.—W. H. Bull, West Springfield, Mass., writes us with a beautiful jet black ink which he says was made thus: *Two ounces of Logwood and half an ounce of Bichromate of Potash* were dissolved in *one gallon* of rain water and strained, and *one-eighth ounce of ammonia* then added.—The ingredients can be bought of any druggist for less than 50 cents (probably for 25 or 30 cents). So many others recommend this or a similar compound, and send such good specimens of the ink used, that it must be good.—If we had not so thoroughly exposed the humbugs as to make their business unprofitable, we might soon expect to hear of a dozen of them privately offering by circulars, to send a valuable and "immensely profitable" recipe for only a "\$V." and then forward this very ink recipe, printed on a large sheet and marked "Patent," or "Copyright" "applied for." In our many investigations among this class of swindlers, we have paid 25c. to \$5 for recipes, etc., that we had already published in the *American Agriculturist*.

Gardening for Profit in the Market and Home Garden, by Peter Henderson." A few months ago we announced a work on market gardening as being in preparation, but did not give the name of the author, as he preferred it should not be announced until he had completed his work. The manuscript is now in our hands, and the book will be brought out as soon as the necessary illustrations can be prepared. To answer numerous applications, we state that orders cannot be filled until late in autumn or early in winter. While the work is written more especially as a guide to market gardening, its teachings are also adapted to small operations, and it will be, as those familiar with the practical character of Mr. Henderson's writing might expect, just the book that its title indicates.

The Pew Hat Rack advertised in this paper is a very neat and simple contrivance for keeping one's "best hat" safe while attending church.

The Death of Prof. John A. Porter of Yale College took place at New Haven on the 25th of August. Prof. Porter was known to many of our readers as having filled the chair of Agricultural Chemistry in the Sheffield Scientific School for some time, and subsequently that of Organic Chemistry. That very interesting, and to those who participated in it, instructive convention of agriculturists, by whom the so-called "Yale Agricultural Lectures" were delivered and listened to, was carried through in great part by his efforts, and identified him with the cause of agricultural progress. The Sheffield Scientific School, now so liberally endowed, owes its success to Prof. Porter in a great degree.

Manure from the Breweries—Rag-Weed.—“J. W. T.,” of Elliot, Me., asks: “Will it pay to put hops and malt refuse from the breweries upon grass land at two cents a bushel? We have a field that is full of rag-weed. What will kill it out? Some of the ground was laid down three years ago, and it is full of it now.”—The hops and malt manure will probably pay well. Compost it with loamy soil, sods or muck. It will heat quickly, and as soon as it becomes homogeneous, it may be applied. It is highly nitrogenous, and you must judge of its strength by the activity of the fermentation of the compost heap. . . . The way to get rid of rag-weed (*Artemisia*) is to put on hoed crops, manuring well, and keep them well hoed, not letting a weed go to seed for two years, then seed down with a small grain crop. A strong sward will keep down rag-weed, but this needs a soil in good heart. The plant is an annual, and the seeds usually not long lived in the soil.

Oyster Shells or Oyster Shell Lime.

—Morris Moses asks, in which condition oyster shells are most valuable as a fertilizer, burnt or ground.—In the first place they are more cheaply reduced to a fine powder by burning than by grinding; 2d, the powder of the slaked lime is infinitely finer than the ground; 3d, the lime is a very active substance, producing immediate and marked results, for good, usually, for evil, if improperly applied; 4th, the ground shell is an inert substance, decomposing very gradually and producing no ill effects, and good ones only in case the ground lacks calcareous matter, except so far as 1 to 1½ per cent. of animal matter and a trace of phosphoric acid will go. Many soils need calcareous matter, and 5 pounds of slaked oyster shell lime will go much farther to supplying this for a crop or two, than 50 of ground shells.

Clover for Green Manure.

—G. J. Gilbertson, Mitchell Co., Iowa, asks: “In order to improve our dry sandy prairie land, I wish to sow clover; what kind shall I get, and when shall I sow it?”—Plow at once, giving the land a dressing of gypsum (three to five bushels per acre), and sow twelve pounds of large red clover seed of good quality on a March snow.

Plaster and Hen-dung Compost on Potatoes.

—Daniel Edwards, of Allegany Co., N. Y., writes: “G. H. Case planted half an acre of potatoes last spring on a sward of Timothy and wild grass, with no manure. After they were up, he put on 2 bushels of plaster and hen manure, equal parts, leaving two rows undressed in the middle of the field. The two rows have been yellow and of small growth; the others have a deep, rich, healthy green, and are twice as large as those undressed, and indicate double the quantity of potatoes that there would have been, but for the dressing. I am near 70 years old, and never saw such a contrast produced by any kind or quantity of manure.”

Horse-racing—Agricultural Societies.

—The number of comments and complaints, not to say bewailings, over the prostitution of agricultural societies to the interests of horse jockeys is greater than usual, and shows either that the evil is growing worse, or that farmers are feeling it more. The fact is, that agricultural societies must be supported. Without the horse-races, which we dislike thoroughly, and consider demoralizing and only bad as generally conducted, the fairs too often do not pay expenses. The farmers have the thing all in their own hands; they may canvass the district before the annual meeting, elect officers who sympathize with their views, and then guarantee them the expenses and the premiums. In this way they will have the fairs to suit them. But will they do it? The farmers are slow, the horse-men are fast and free with their money. So they have things their own way, and the farmers may thank them, not themselves, that they have even \$10 offered for the best bull, and \$2 for the best mower and reaper. \$200 offered in merely agricultural prizes will hardly bring 50 people into the grounds, while for every dollar offered as a trotting prize, 50 people may seek entrance. This, unfortunately, is the way the thing works.

Sussex Co., N. J.

—The northernmost county in New Jersey is called *Sussex*, which might be wondered at in any State except New Jersey.—H. C. N. reports that, braving the scoffs of his neighbors, he introduced a corn planter this spring, with which he planted 6 acres a day, and also a horse corn plow with which he finishes each row at one plowing. So he saved himself fully half the labor of corn culture, and though the neighbors called them humbugs, the machines held their own. Old *Sussex* County is famous for milk and butter.

Questions not Answered.

—We do not wonder that many of our kind readers, who interest themselves for the *Agriculturist*, and who send us

questions, are disappointed at not seeing them answered, and it is but fair that we should occasionally explain. Our space is very far too small to allow us to give as much as 10 lines to each question. Often we are able to answer half a dozen in one. Frequently questions require study and investigation, which it is sometimes difficult to find time for before the season is passed for the current year. Then again there come questions which we can not well answer. Here, for instance, is one:

How to Make Sod Fence and Ditch.

—“How should a sod fence be built, or a ditch fence, or a sod fence and ditch?”—“J. B. C.,” Montgomery Co., Iowa. This question we are happy to propound to our readers, and some “old country man” will probably have to answer. Turf or sod fences, with or without ditches, are common in Europe, especially in Ireland, but rare here.

Setting Fence Posts.

—“N. C.” advises to set posts without preparation, but to apply “a large shovelful of wood ashes to each post just at the surface.”

A Dumping Wagon Wanted.

—“What is the best plan for a wagon, the body of which will tilt, to dump its contents like a cart?”

Leaky Tin Roof.

—“G. S. R.” When a tin roof proves itself good for nothing from any cause, rip it off. The plastic slate roofing is coal tar, mixed with slate flour, ground very fine. It is said to make a good roof if applied on a good felt, or wrapping paper.

Roofing.

—“V. H. E.,” and others. From our own examination, from what we hear, and from the nature of things, (but not from the rather extravagant statements made by the parties who have it for sale), we are inclined to think that the so-called “Plastic Slate Roofing” is equal to the best roof of its kind.

Sick Chickens.

—Mrs. “J. R. T.,” of Flemingsburg, Fleming Co., Ky., is very much distressed about her fowls. She has lost 200 or more of her young chickens, and 25 or 30 hens, 75 young turkeys and several old ones. They droop a day or two, seem to have sore throats, and “the scours,” then die. Of course we can only guess what may be the matter. We have known a similar trouble from fowls eating carrion and maggots, and would put them in a yard, feed softened grain, or better grain ground and scalded, mixed with fine charcoal, and wood ashes. We have checked scours by giving a wine-glass of ale with 10 or 15 drops of paregoric to full-grown fowls; sop bread in the ale, and put it down their throats.

Marking Chickens.

—“Progress” says: “When I wish to mark chickens as I take them from the nest, I cut the web between the toes. As there are 3 toes on each foot, there are 4 places where you can have life-long marks on the fowls.”

Witching or Switching for Water.

—“T. M. L.”—The only result that usually comes from following the witch-hazle-switch indications of water, is, that people locate their wells in very inconvenient places. If a man digs a well deep enough, he usually gets water, whether the hazle switch indicates it or not. Still, people who mean to speak the truth, tell very marvellous stories, which we have no wish to dispute. Only we will say, when a writer like one in an esteemed contemporary runs mad in his philosophy, and makes electricity do more wonderful things than talk across the Atlantic, we must protest.

Cheese Factory in Columbia Co., N. Y.

—We recently visited a new cheese factory just erected at Rider's Mills, Columbia Co., N. Y. The building is 100x30 feet, two stories high, erected in a very substantial manner. It is calculated to work up the milk from 600 cows. The location is an admirable one both as regards conveniences for manufacture, and excellence of the surrounding pasture, from which the very choicest butter has long been derived. The enterprise is a new one in that section, but it will undoubtedly pay, as it is intended to establish an A No. 1 brand in market.

Will Roots Enter Cisterns?

—“Christopher,” of Nantucket, asks, if the roots of grape vines planted near a brick cistern will interfere with it. They will not if the bricks are well laid in cement, and the cistern is water-tight to the top. Roots will penetrate a wall loosely laid, and do often go through common cellar walls, even though cement mortar may have been used, but they will not go where water cannot.

Cow with the Heaves.

—Wm. Wade, of Bristol, Ohio, has a cow which has had something very like the heaves in horses for 2 years. The heaves is similar to asthma, and we know no reason why cows should not have it now and then. If it is asthmatic in its

nature, it will be hard to cure, but probably may be alleviated by common heave remedies.

Sweet Potato Vines.

—Frank Parker asks, if it is absolutely necessary to lift the vines during the growing season. No. Neither is it absolutely necessary to raise sweet potatoes at all. The vines make roots throughout their entire length, and on these roots little potatoes will form, but never mature. On this account the vines are torn up from the ground, or cut off to stop their running now and then, and the strength then goes to perfecting the tubers in the hills.

Propagating Blackberries and Raspberries.

—M. Korff, Gray's Summit, Mo. These are propagated extensively from root cuttings. The roots are cut in pieces one or two inches long and planted in spring, with a slight bottom heat.

Beardless Barley.

—The beardless or bald barley does well in Canada, and that fact answers the question as to its bearing a northern latitude. The Nepal Barley is naked as well as bald.

How Much do People Weigh?

M. Queflet, of Brussels, Belgium, conceived the idea of ascertaining the average weight of people at different ages, with other items. To this end he weighed many thousands of persons of all ages and occupations, in different parts of Europe. The following is the result:

a.—Infants, at birth, vary from	2½ to 11 lbs.
b.—Infants, average weight	6½ lbs.
c.—Young men, at 20 years old, average	143 lbs.
d.—Young women, at 20 years old, average	129 lbs.
e.—Men weigh most at 35 years old, averaging	152 lbs.
f.—Women weigh most at 50 years old, averaging	139 lbs.
g.—Men and women together, at full growth, average	140 lbs.

* Boys, a little more; girls, a little less.

There is apparently some error in the last item, for with the average weight of men of full growth at 152 lbs., and of women at 139 lbs., the average weight of both taken together should be 145½ lbs. Probably the last figure refers to men and women of all ages taken together, for taking the given averages (c, d, e, f, above) the average is 140½ lbs., and allowing for the usual excess of females, the average of all would be reduced to about 140 lbs. It is noteworthy that men reach their greatest average weight at 35 years, and women not until 50 years of age. The figures refer to Europe; we think the average weight of women in the United States would fall below 129 lbs. at 20 years old, and 139 lbs. at 50 years.

Rats.

—The question how to get rid of rats meets with a ready answer from “J. C. F.,” Litchfield Co., Ct. He says: “My method is to catch a rat, and dip him all but his head in red paint, and let him go. The rest do not like his looks and so leave the premises.”

Preparing Sweet Corn.

—G. Manahan, Elkhart Co., Ind. The corn is boiled just enough to harden the “milk,” and then cut from the cob and dried. A machine has been invented for cutting the corn from the cob, which will soon be advertised.

Curing Meats.

—“Massachusetts Hams” writes: “I cure and smoke 50,000 to 100,000 pieces per year, and know my business. Meat cured in pickle made of water is not as good, and only used because more profitable and less laborious. The flavor of cured meats depends mainly upon the kind of molasses used. The best temperature is 40°. Frozen meat will not cure, and if above 50°, will be liable to taint. For 100 lbs. meat, take 8 lbs. salt, 1 quart best molasses or 2 lbs. sugar, ¼ lb. saltpeter, 2 ounces ground alum; mix and rub on the fleshy side of the meat placed in pans, so as to keep all the mixture; repeat the rubbing every three days, rubbing in thoroughly. For large pieces, and cold weather, 60 days will be required; if mild weather, 50 days, and 15 days less for small pieces. The skin and fat of hams should be cut clean from the face, as far down as the second joint, to allow the salt to enter. The recipe for keeping meat, viz., in ashes, given in September *Agriculturist*, is good. Smoking is of no benefit; it is only a quick way of drying. Most people would prefer drying without smoke. If you smoke, use only walnut or yellow birch wood, or mahogany saw-dust. Be sure your meat is well cooled off before salting; ten days after killing is better than ten hours.”

Home-made Ink—Correction.

—In some of the first printed copies of August *Agriculturist*, one of the ink recipes was spoiled by the use of wrong letters in a word intended to be *Bichromate* of potash, which is an abundant material, found in most drug stores. Many others have recommended similar preparations, and sent us specimens of writing with the ink, most of which are very good. See page 294 (August).

The Raccoon or Coon.

The Raccoon is one of the most interesting of the native quadrupeds of the United States, and claims our attention in the three-fold character of friend, foe, and household pet. The great naturalist Linnæus classed it in the same genus with the bears, (*Ursus*), but naturalists have since separated the genus, of which several species, all American, are recognized. The coon is familiar to all American farmer folks; it is of about the size of a large cat, of a compact build; the entire soles of its feet are bare, and standing, it rests upon its feet from toes to heels, flat, like a bear, but in walking it goes upon its toes only, like a cat. Its coat is very thick, composed of a soft, grey fur, and long glossy hairs, which are marked alternately with black and greyish white. The color therefore varies, as the spectator looks into it or across it, and according to the light, giving it a peculiar richness. The face has a dark band across the eyes, and a dark stripe down the nose, which are set off by light grey surroundings. The tail, full and bushy, is marked by 5 or 6 very distinct dark rings. The coon is easily tamed and becomes very familiar; is characterized by playfulness, fondness of attention, and for doing mischief. It is an omnivorous creature, eating almost every thing, but being especially fond of sweet fruits, green corn, honey, nuts, shell fish, eggs, birds, insects, all kinds of grubs, worms, etc. In the spring it does the farmer no little service in destroying the grubs and other insects of his field, but in the autumn he takes his pay by eating all the green corn he wants when it is in the "roasting ear" state. The boys know exactly when, and after the coon hunt, whether successful or not, they never forget to take pay for their good deed, or for their good will, as the case may be, out of the nearest corn fields. The bushel or two of nice ears roasted in the ashes of the fires which lighted them and their dogs in dispatching the poor coon, is more than a whole family of coons would damage in the entire season.

The Raccoon has a curious habit, which gives it its specific name, *lotor*, or washer. The Germans call it *wasch-bär*, or washing bear, from this peculiarity. Whenever it can do so, it takes its food and dips it in water, waving it to and fro. Coons visit poultry yards sometimes, and the fact may be known by the 5-toed tracks, showing occasionally that of the whole hind foot, like a miniature human foot print.

RACCOON—*Procyon lotor*.

They eat off the heads of poultry, usually leaving their carcasses. Their habits are chiefly nocturnal, and they may be taken in box traps, steel traps, or by fall traps, baited with sweet apples, etc. In autumn they become very fat, and they hibernate in winter. Their flesh is like bear's meat, and quite agreeable, and their skins have considerable value in the fall, or winter.

and white or yellowish white, black preponderating, and the fur is long, soft, though coarse, and very glossy. The tail is long, and might, with propriety, be called a "switch tail" from the length of the hairs. The white and yellowish patches are disposed irregularly upon the head and back, and white hairs and spots may occur on any part of the body. They are persistent enemies of grubs, and insects. They eat mice too, and display much skill in ferreting out mouse nests, for eating the young. They destroy the eggs of birds also, eat frogs and birds, and probably also snakes and snake's and turtle's eggs. If an occasional visit to the poultry yard puts them under the ban of the law, do not let the vengeance be extended to other than the guilty individuals. They are exceedingly peaceable, and mind their own business as well

as any animals we are acquainted with, but if it becomes necessary for them to defend themselves, their means of defence are so offensive and effectual, that neither man nor beast seeks a second encounter. There are two sacs, connected with secreting glands, which are filled with a yellowish oily fluid. These are situated beneath the tail, and by a muscular motion, the fluid may be ejected with great force in a very fine stream to a distance of 15 or 20 feet, and with considerable accuracy of aim. This is not urine, as has been supposed. The effect of this nauseous fluid upon a dog or a man, is to cause gasping for breath, and effort to obtain fresh air by running in an opposite direction to the enemy. The stench can be removed from clothing by the action of the soil, when buried for some weeks, but this is apt to cause it to mold and rot.

SKUNK—*Mephitis chinga*.

The Skunk.

The North American skunk is called by naturalists, *Mephitis chinga*. It is a well known animal, and one with which many have a too intimate acquaintance. It is of about the size of the Raccoon, but with shorter legs, and a longer body in proportion. The head is small, the end of the narrow snout blunt; the color is black

These animals often take up their abodes in house cellars, or about the under-pinning of barns, etc., but cause no inconvenience if not disturbed. They are best dispatched by a well directed shot. The flesh is delicate, and esteemed by those who can overcome their natural repugnance to it. Skunks are nocturnal in their habits, and very numerous. Their skins are valuable in proportion to their size and amount of black.

AMERICAN AGRICULTURIST.

ORANGE JUDO & Co., Publishers, 11 Park Row, N. Y. City.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies: Four to nine copies, \$1.25 each: Ten to nineteen copies, \$1.00 each: Twenty copies and upwards, \$1 each. Papers are addressed to each name.

SEVENTY-FIVE

Excellent Premiums.

Something for Everybody.

A first-rate Opportunity to get Good and Desirable Things, without Expense, and benefit others at the same time.—Every thing offered is new, and of the best quality and make.

Look all through the List and Description of Articles.

An extraordinary subscription list, exceeding the entire circulation of more than twenty-five other similar journals, enables the Publishers of the American Agriculturist to supply a very large paper, one most extensively illustrated and expensively prepared with practical, reliable, condensed information, at a very low price. One office, one corps of Editors and chief business men, one set of engravings, one setting of type, etc., answer for 150,000 to 200,000 subscribers, in place of the thirty or forty establishments that would be required if this number of subscribers were divided into the average circulation of 5000 or less. This explains why the Agriculturist is furnished so cheaply—only a few cents a year to each subscriber above the cost of printing paper. All subscription money received (and usually more) is expended in getting up and supplying the paper to subscribers.

Again: The large circulation necessarily brings a large and valuable advertising patronage, which furnishes the publishers a satisfactory income, besides a margin to pay for good premiums to those who collect clubs of subscribers. Thus, more subscribers bring more advertising receipts, and these again furnish premiums for still more subscribers—a satisfactory thing all round.

Every Publisher, by commission or otherwise, pays (or ought to pay) those who take the trouble to collect large lists of subscribers, new or old. Of course, many send the names of friends or neighbors without premiums, because they believe the paper will benefit them.

To save time, correspondence, etc., we appoint no agents, but offer as pay for doing the work of an agent, a fine selection of such articles as are wanted, or have been called for, by our canvassers. Any one so disposed can select the premium desired, and raise the required number of subscribers. By Wholesale purchases, by advertising arrangements, etc., we can pay much more in premiums than in cash. Every article is given at the regular price which it would cost any purchaser.

Each article offered is for a definite number of subscribers; every one thus knows just what is required. A premium is not dependent upon favoritism, or upon what some unknown person elsewhere is doing.

Over Eight Thousand Persons have hitherto received our premiums with great satisfaction; we have not heard of one in a thousand who has not been highly pleased.—It is a good work. The tens of thousands of persons persuaded by our canvassers to take and read the paper, have been benefited by so doing.

It is much easier to raise a club and get a premium than most persons suppose before they try it. The paper speaks for itself, is very cheap, and there are at least two million people in the country who would be benefited by it much more than its cost.—Many persons canvass where they are known, as a business. They sell the premiums, and so secure large pay for their time. Thus, one getting 10 subscribers a day for 52 days (two months), or only 5 a day for 1/4 of a year, secures a fine Steinway's Piano, to sell at \$625, at which price thousands are sold every year. And so of other articles of less value. Many have started to get one premium only, and before stopping have secured several.

Multitudes of Families have obtained some article wanted, by a little effort on the part of the man or woman, and often of a child. Clergymen have repeatedly secured the Cyclopaedia for their libraries by two or three days' work in raising a club of subscribers among their parishioners, who gladly help in such enterprises. Many congregations have clubbed together and secured a Sewing Machine, a Library, or a Tea Set, for their Pastor, or a Melodeon for the Church or Sunday School. Many Widows, and unfortunate persons, have been furnished with a good Sewing Machine by the efforts of a few individuals. Quite young Boys and Girls have, by their efforts at canvassing, obtained useful articles for those to whom they have been a great boon. Several Agricultural Societies have paid for a large club of subscribers, given away the subscriptions as prizes at their exhibitions, or supplied them to members, and sold the premium articles at auction for the benefit of the treasury. Scholars at school have joined their efforts and secured a Melodeon for their room, or some desired article as a gift to a Teacher. We put in the beautiful Ladies' Watches this year more especially for scholars, though any one can take them. Many gentlemen have secured premium sewing machines, etc., as presents to their companions at the holidays, or on a birthday. Our letter files contain a multitude of instances like the above. The Watches, Guns, etc., offered this year, will afford a capital chance to obtain valuable articles of these kinds.

We take so much pains to procure only good articles in all cases, that any one securing anything from our premium list, saves the risk usually run of getting poor or indifferent goods, when buying of unknown or irresponsible parties. Every thing we send out as a premium is guaranteed to be the best of its kind and price.

Our premiums are standard articles, and enough can be obtained to supply all calls for premiums for six months. Every canvasser can take abundant time, but

As fast as subscriptions are obtained, send them along, that the subscribers may begin to receive the paper; and when all the names that can be obtained are forwarded, select the premium, and it will be promptly furnished. To save mistakes and keeping accounts, send with each list of names, the exact subscription money (in Post Office money orders, drafts or checks on N. Y. City; or, if these can not be had, registered money letters.)

Every name designed for a premium list must be so marked WHEN sent in.

NOW is the best time to begin to raise a club, as every new subscriber for 1867, received in October, gets two months of this year free, as noted elsewhere.

Old and new subscribers count in premium lists, but a part should be new names, for it is to obtain such that the premiums are in part offered. Papers in Premium clubs need not all go to one Post Office. Of course the extra copy, usually offered to clubs of ten or twenty, will not be furnished when a premium is called for.

Specimen Numbers of the Agriculturist, Cards, and Showbills, as may be needed, will be supplied to Canvassers. These should be used carefully and economically, as each extra copy of the paper with postage (2c.), which must be pre-paid, costs about 12 cents.

Table of Premiums and Terms, For Volume 26.

Open to all—No Competition.

Table with 5 columns: No., Names of Premium Articles, Price of Premiums at \$1.50, and Number of Subscribers required at \$1. The table lists 75 items including Garden Seeds, Flower Seeds, Nursery Stock, and various household items like Sewing Machines and Watches.

Every article offered is new and of the very best manufacture. No charge is made for packing or boxing any of the articles in this Premium List. The forty-three Premiums, Nos. 1, 2, 6, and from 29 to 32, and from 40 to 75 inclusive, will each be delivered FREE of all charges, by mail or express, to the Post-Office or express office nearest recipient, to any place in the United States or Territories, excepting those reached only by the Overland Mail.—The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance that may be specified.

Description of the Premiums.

No. 1—Garden Seeds.—A valuable selection of 40 varieties of the best seeds for a family garden, each parcel large enough for a garden of ordinary size. The seeds are all fresh and good, of this year's growth. This premium and the next are put up for us by Messrs. J. M. Thorburn & Co., 15 John-st., N. Y., whose seed establishment is well known as one of the oldest and best in the country. (We prefer procuring seeds of this good house because the nearest and most convenient to our office—otherwise we would gladly select also from such good houses as B. K. Bliss, James Vick, Henderson & Fleming, and other reliable parties whose advertisements we admit from time to time.)—This premium will be of great value and convenience to many, especially to those distant from good seed stores, as we shall send the seeds post-paid to each one, the postage law allowing us to send seed packages of 4 lbs. each, at a cost of 32 cents, to any part of the United States (except to those points reached only by the "Overland Mail.")—In many cases the recipient will have enough in each package for his own use, and a considerable quantity to spare to friends and neighbors, or to members of the club.

No. 2—Flower Seeds.—Like No. 1, this is a valuable as well as beautiful premium, wanted by thousands of persons. It consists of 100 different kinds of flower seeds, all in separate papers, and includes not

only the finer common varieties, but many of the newer and rarer kinds that are costly when bought by the single paper. Each parcel contains the usual amount sold by seed dealers. The parcels are all packed together and delivered free, the same as No. 1. This premium will give quite an assortment to each of the members of a club if the canvasser of the club chooses to distribute part.

No. 3—Nursery Stock—Plants, etc.

—This premium can be selected in any thing desired, from the Catalogues of Parsons & Co., Flushing, N. Y., at the East, or of F. K. Phoenix, Bloomington, Ill., at the West. Both are well-known, very reliable parties, having extensive Nurseries, Green-Houses, Ornamental Trees and Plants, Grape Vines, Shrubs, etc., etc. Send a stamp direct to either of them, for their regular catalogues, stating that it is to look into the value of this premium, and they will be furnished free. Any one choosing this premium, can select to the amount of \$20, or a larger amount proportioned to the names sent us, and we will send an Order for the amount on either party named above. None but the best articles will be furnished, and whatever is ordered will be well packed without expense and forwarded as freight, or by express, or otherwise, as directed by the recipient. This premium will be sent this fall, or in spring, as desired.

No. 4—Iona Grape Vines (12).—This valuable new variety has been often referred to in our reading columns, and is becoming so well known that we need not describe it here. None but No. 1 Vines will be sent. They will be forwarded by express either this fall or next spring, or by mail to distant points, if so desired, and postage is furnished.

No. 5—Concord Grape Vines (100).—*"The Grape for the Million."*—This excellent, hardy, early, prolific grape, is popular almost everywhere, and though not so high flavored as the Iona and Delaware, its easy culture, vigorous growth, earliness, and productiveness, make it one of the best for general cultivation, especially where it will receive little attention. It is now so abundant that we can offer a large number of No. 1 Vines. They will be sent by express well packed, in fall or spring, as noted above for the Iona Vines. This is a good Premium for a club. The canvasser can offer one to each subscriber, and still have 35 or 81 left for himself.

No. 6—Japan Lily Bulbs.—A most beautiful flower, one of the few flowering bulbs that do well even when planted early in spring. Most kinds of bulbs require to be planted early in autumn. One can easily multiply his stock after getting a few to start with. The full directions for culture are given in the *Agriculturist*. We send them post-paid by mail to any place in the United States and Territories (except via Overland mail). They go as safely as potatoes. They are furnished to us for this premium, by Francis Brill, Esq., of Newark, N. J., one of the largest cultivators of them.

Nos. 7, 8, 9, 10, 11, 12—Sewing Machines.—We are glad to be able to offer this year a choice of the leading kinds of good Sewing Machines. (See list in the Table above.) They are all too well-known to require long specific descriptions. We can recommend any one and every one of them as of great value to every family not owning a machine already. Each of these six different machines has some peculiarities superior to the others. We have used them all at home during the last half dozen years, except the Tailoring Machine, and that we have watched carefully in the hands of tailors. One has been tried several months, and then another, and so round; and they are all so valuable that we prefer to recommend all, instead of in the slightest degree hindering the speedy introduction of this important household implement by even a comparative word of discredit to any one of them. We would not part with the last one of these, whichever it might be, and be without any Sewing Machine for \$500! Here are the reasons: The \$500 at 7 per cent. interest, would yield, less taxes, about \$32. Most families require at the lowest, four months of steady hand-sewing a year, costing, if all hired, not less than \$24 a month, board included, or \$96 a year. With a Sewing Machine a woman can certainly sew as much in one month as in four months by hand. Here is a clear saving of \$72, or of \$60 if you call the seamstress' work only \$20 a month, including board—leaving a net annual saving of \$30 to \$40 above the interest, while any good machine will wear a dozen years. Then a speechless and earless machine at work one month, is preferable to a live machine for four months. But far above this, and all questions of money saving, is that of health. The everlasting "Stitch, stitch, stitch," with form bended over the work, and the loss of sleep, have brought tens of thousands to early graves, broken down

millions more at an early age, and entailed an enfeebled constitution upon many millions of infants. We say to every man, get your wife a Sewing Machine, even if you have to sell a favorite horse, or an acre or two of land. A Sewing Machine costing \$55 to \$65, involves an interest of only \$3 or \$4 a year; it will, in the long run, save you five, if not a hundred fold, in Doctor's bills alone. Get the Sewing Machine any way. If you can get one through our premium list, well and good; it will help you, will enlarge our circulation, and benefit those you induce to read and think more; but get the machine. In previous years, a great number of premium machines have been secured for widow ladies, indigent tailors, and others, by the united efforts of a few persons in raising a club of subscribers. Several Post-masters have each obtained a machine for such an object. Many a wife has received from her companion a holiday or birthday present of a premium machine obtained from our office. Every machine given is boxed and delivered free to any railroad station, or express office, or other place in this city, and costs the recipient only the freight after leaving the city. They go safely as railroad freight. Full printed instructions go with each machine. Each of the machines is supplied with a Hemmer. Further particulars may be obtained by sending for circulars to:

Wheeler & Wilson Mfg Co., 654 Broadway, N. Y. City.
Grover & Baker Mfg Co., 493 Broadway, N. Y. City.
Florence Sewing Machine Co., 505 Broadway, N. Y. City.
Singer Manufacturing Co., 458 Broadway, N. Y. City.
Willcox & Gibbs Mfg Co., 503 Broadway, N. Y. City.
Howe Machine Company, 699 Broadway, N. Y. City.

The number of names required to obtain any one of these Machines, is given in our Table above.

No. 13—Washing Machines.—For a long time we have annually tried half a dozen or more new Washing Machines. Some of them have promised well at first, but no one has continued in so much favor as the "Doty's Paragon," which we have now used nearly three years. It is the only one the "help" will use without being required to do so. Some new improvements have been added within the present year. It is neat and compact, and convenient. Full Descriptive circulars can be had of R. C. Browning, 32 Courtlandt-st., New York, or of the Metropolitan Washing Machine Co., Middlefield, Conn. The machine packs in small compass, and can be sent cheaply as freight or by express, as desired, to any part of the country.

No. 14—Clothes-Wringing Machine.

—A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand, is hard upon the hands, arms and chest, and the twisting stretches and breaks the fibres with lever power. With the Wringing Machine, the garments are passed between two elastic rollers which press the water out better than hand wringing, and with no wrenching of the fibres. It is done as fast as the left hand can pick up the garments, while the right hand turns the crank. It is so easily done that a child of 10 or 12 years can quickly wring out a tub-full of clothes, dropping them from the machine set upon the side of the wash-tub directly into a clothes basket, ready to hang out. We offer the family size, "Universal Wringer," provided with Cogs which make the rollers turn together, and which we consider essential to prevent injury to the fabrics, loosening of the rubber, etc. We used a single one of these Wringers, one of the first make, several years without any repairs, and with the greatest satisfaction.—It weighs only 15 lbs., and can be readily carried by hand, or sent by express, or freight, to any part of the country, ready to be set upon any form of tub, and used at once. We have given over a thousand of these as premiums, with almost universal satisfaction. At least a thousand families may get one this year as a premium.

No. 15—A Tea Set.

—This premium gave the greatest satisfaction last year. One person was so pleased with it that he raised a second club and obtained a second Set to present to a friend. There are six pieces, viz.: A Coffee Pot, two Tea Pots (one for Tea and one for Hot Water), a Creamer, Sugar and Slop Bowls—all of beautiful, uniform pattern, and new style, with raised and embossed figure work. They are to all appearance equal to the best solid silver, and for all practical purposes as valuable, though costing not one-fifth as much, at the present price of coin. They are not the common silver-washed articles, but the heaviest plate, known as "Sheffield Plate," the foundation being white metal, so as not to show, even when the heavy silver-coating may chance to be worn off in any spot by long hard usage.—These Sets are made by Lucius Hart & Sons, of Nos. 4 and 6 Burling Slip, N. Y. City. Mr. Hart, "the veteran Sunday School man," has been in the same place and business for nearly a quarter of a century. We have known him and his work for many years, and take pleasure in commending and guarantee-

ing its value to be as represented. The amount of silver on plated-ware depends wholly upon the will and integrity of the manufacturer. We could give nearly as good looking plated-ware for less than half the money, but it would not be worth a tenth part as much. The Sets given as premiums will be boxed without charge, and sent to any place by express or otherwise as desired. (See remarks under No. 20 below.)

No. 16—Castor, and Fruit or Cake Basket, Combined.

—This is a new pattern, both novel and beautiful. It can be used as a large showy Castor, with six cut glass bottles, or be instantly changed into a complete Castor, with Call Bell, and a separate Cake or Fruit Basket, with a colored glass dish inside. Every one receiving it will be delighted. It is from the same maker as No. 15, and of the same metal, plating, etc., and will be sent in the same way. Many cheaper and less beautiful Castors could be obtained, but desiring only the best things in our premium list we selected this.—We introduce this and Nos. 17, 18, and 19, at the earnest request of many of our premium canvassers last year.

No. 17—Ice or Water Pitcher.—A

large and ornamental article, just such as we recently selected for a wedding gift to a near friend, and then a duplicate for our own use. It is of the same metal, plating, etc., and by the same maker as No. 15. For 35 subscribers at \$1.50 each, we will add a round Salver of pattern to correspond (value \$6) or, for 47 subscribers, a large 16-inch oval Salver (value \$14), large enough for two goblets with the Pitcher. And for 53 subscribers, the Pitcher, large Salver, and a pair of beautiful Goblets, silver-plated without, and gilded within (value \$38). This complete Set is exceedingly desirable, though the Pitcher alone, or that and the smaller Tray or Salver, will answer a good purpose both for use and ornament.

No. 18—One Dozen Teaspoons.—

These are of fine pattern, "figured tips," and of the same metal, plating, etc., and from the same maker as No. 15. They are far cheaper than any thing we have found at half the price.

No. 19—One Dozen Table Spoons.

No. 20—One Dozen Table Forks.—

The same description and remarks apply to these as to No. 18. We select as premiums only such articles as we can warrant every way in quality and price. As we explained in Volume XXV, page 147, a silver dollar can, by the galvanic process be spread over many yards of surface so as to deceive the eye completely. Plated ware is valuable when we can trust to the honesty of the manufacturer to put on a coat of silver of given weight and thickness, and to do it on a good white metal. As all the work is the same, the thicker the coat, the cheaper the article in the end, provided we get the silver-plating we pay for, and this is the chief merit we claim for these premium articles, though a good deal is to be allowed for their beauty of form and workmanship.

No. 21—Steinway Piano: SEVEN-OCTAVE, ROSEWOOD CASE; LARGE FRONT, ROUND CORNERS, CARVED LEGS AND LVRE; OVER-STRUNG BASE, WITH PATENT AORAFFE TREBLE, AND CONTAINING ALL MODERN IMPROVEMENTS.—Regular and only price \$625.

The finest premium ever offered! It is enough to say that it comes from the world-renowned establishment of Messrs. STEINWAY & SONS, Nos. 71 and 73 East 14th-st., N. Y. City, and is of their best make at this price. We have one of these instruments for our own use, and desire no better. And this premium is within the reach of a great number of persons. We expect to give six at least, from correspondence with previous premium canvassers, and will give fifty if called for. Only 520 subscribers are required to get one! This is only 10 a day for two months—or 5 a day for four months, while it will pay many persons for a year's steady canvassing. Why! a person could go to work and get this premium and sell it, and thus make high wages. Twenty young ladies at school, by gathering 20 subscribers each among their friends, can secure this premium as a present for a Teacher, or for a School or Society room. There are not a few young ladies wishing a first-class piano, who might well make it the year's business to raise a club and secure this premium. The personal effort would teach them business habits—to take care of themselves. There are more than 520 families in many single towns who would be benefited by the *Agriculturist*, and ought to take it, and would if brought to their notice. We aim at having this done, in offering such premiums. The premium club, however, is not confined to any one town, or P. O.—Railroad Conductors on local trains, can (as some have done) collect large lists of subscribers along their routes, and secure this premium and others.—Send to Messrs. Steinway & Sons for a free circular, describing this premium.

Nos. 22, 23—Melodeons.—These are excellent and desirable instruments, for the Home Circle, for small Churches, for Sunday Schools, for Day Schools, Academies, etc. Music is not only pleasing to the ear, but it exercises a healthful moral influence. Far better to give the children a Melodeon, and cultivate their finer feelings, than to leave them each an acre or two more of land. Instrumental and Vocal music in a school has a direct beneficial influence upon the pupils. We have seen the whole tone and character of the pupils of a school improved by the introduction of a Melodeon.—Set the pupils to work and they will raise a club of subscribers, and obtain this premium easier than they can get money subscribed for it. We offer Geo. A. Prince & Co's. Melodeons, for we know them to be good. A large one in our own Sunday School room has been in use for seven years, without a dollar's expense for tuning or repairs of any kind, and is to-day just as good as when first purchased, though used from time to time by a large number of persons.—Last year an unusual number of clergymen obtained this premium for themselves or their Churches, or Sunday School rooms. The premium clubs of subscribers were quickly raised among the members of their parishes.—But many others can get this premium for their own home use. We have given many of these instruments as premiums in the past few years, and we believe they have invariably been highly esteemed. Send a postage stamp to Geo. A. Prince & Co., Buffalo, N. Y., and get their illustrated descriptive circular, giving full particulars of forms, sizes, and prices. The premium Melodeons will be shipped direct from the manufactory at Buffalo, ready boxed for safe transportation by Railroad, Steamboat, or by Express, as may be ordered. They go just as safely by freight, as by express, and much cheaper, though not so quickly.

No. 24—Ladies' Gold Watches.—At the request of last year's canvassers, we add this and No. 25.—The Lady's Watch offered is one of the prettiest watches we have seen. It is in a "hunting" or closed case, beautifully engraved and inlaid with enamel, and is warranted a good time keeper by Messrs. Benedict Bros. (See No. 25, below.) This is a beautiful and appropriate present to a Teacher from the members of a School, who can easily divide among themselves the number of subscribers to be raised. It is also a very neat and beautiful gift for a companion. Not a few gentlemen can get this in time for a Holiday Present.

No. 25—A Good Watch.—For years past we have been urged to offer a good, reliable Watch, as a premium, and can now do so. We have arranged with Messrs. Benedict Brothers, of 171 Broadway, to supply us with two kinds at actual cost in gold—such watches as they will put in first-rate order and warrant. These Gentlemen we know to be every way upright and reliable men, governed in their dealings by Christian principles, and with their guarantee we unhesitatingly offer these premium articles with confidence. (As is generally known, Messrs. Benedict Brothers are entrusted with the keeping of the N. Y. City time, and they furnish time to a large number of Railroads and Steamers.) Every watch we send as a premium will be first thoroughly tested and put in running order by them, and warranted for one year.—No. 25 is in a plain hunting case of Coin Silver, and running work of excellent manufacture. This premium will give very many a chance to obtain a really valuable, reliable time piece, and at the cost of only a little effort.

No. 26—Double Barrel Gun: OR FOWLING PIECE.—Many subscribers have asked for such a premium, and we can now gratify them.—The guns offered are the genuine London "Twist" barrel, Patent Breech, Bar Lock, ebony ramrod, and every way a desirable piece for practical use. As a special favor they are furnished to us for this premium, by Messrs. Cooper & Pond, of 177 Broadway, know the world over as one of the most reliable and best houses in their line of business, and they highly recommend this particular gun, and guarantee it in every respect. It is from one of the oldest and most favorably known English manufacturers, and of a kind which Mr. Cooper assures us he has had so long, and found so good, that it is just the gun he should take if he were going out for a day's shooting. The price is not put on in fancy carving, and useless plating for show, but in the gun itself. We could get almost as good looking guns for half the sum, but we follow one general rule in this premium list, to offer only real, substantial, reliable articles, those cheap at the price named in our table. This premium includes the Gun, Powder Flask, Shot pouch, and Wad Cutter.

No. 27—Spencer Repeating Rifle.—If after chasing a Deer or Wolf all day, one gets a "crack" at him and fails, it is a consolation to be able

to try half a dozen more in as many seconds. If one meets a Bear face to face, he will send the first bullet with more precision, if he knows there are six more protests ready against an affectionate embrace. If within shooting distance of a herd of Buffaloes, seven chances at the fellows before they can scamper out of one's reach, while he is measuring out powder, would be quite agreeable; and so of any game to be brought down with a rifle only, seven shots in place of, and in the usual time of, one, is something desirable. And we may add, that a thief would be likely to give a wide berth to a house where he might be followed by half a dozen or more dangerous leaden policemen before he could have time to scale a rear fence.—Well, Premium 27, is one of Spencer's Repeating, Sporting or Hunting Rifles. It carries 7 charges inside of the stock, which are successively thrown into the barrel and fired, simply by pressing out the trigger guard, pulling it back, cocking and pulling the trigger itself. One can do all this, lying behind a log without rising to scare his game. The seven shots can be readily fired in less than half a minute, and then you have only to slip seven more ready made charges into the stock—in half the time you can load a common rifle once at the muzzle—to be ready to fire seven times more, and so on.—An exceedingly interesting statement of what this rifle has done during the war, and of what it is, and is capable of, may be obtained by addressing WARREN FISHER, jr., Treasurer of Spencer Repeating Rifle Company, Tremont-street, Boston, Mass.—We have abundant evidence of the great range, power, accuracy, and durability of this Rifle, and we take pleasure in offering it as a premium for only 70 subscribers. Our premium includes the \$45 Rifle, and \$10 more for the Globe and Peep sights, including 100 rounds of prepared ammunition, boxing and shipping. These are the Company's cash prices. The addition of the Globe and Peep sight adapts the gun for the longest ranges, for sharp-shooting, etc. Each charge contains powder, conical ball, and fulminate, all in a copper case, and is water-proof. No ramrod, no cap, and little or no cleaning of the gun barrel is required.—The regular size is: bore or calibre, 44-100 of an inch; length of barrel, 26 inches. Any one preferring a length of 25 or 30 inches, can have it for \$1 or \$2 extra.

No. 28—Chest of Good Tools.—Good Tools, always at hand, will save a great deal of time in running after repairs, and save buying of many articles easily made at home. Most boys, having a chest of tools, will stay out of bad company, and in the use of the tools will acquire skill, ingenuity, and self-reliance. (For example, our plants have been guarded from insects this year by fifty families of Wrens which took up their abode in as many bird houses, all constructed by a boy of ten years, in his out of school hours, and these are but a small part of his work in this line. He has just the chest of tools which we have selected for this premium.) We wish every boy in the land could be supplied with such a chest, or even one with half the tools in it. If a boy has no "mechanical genius," there is all the more reason why his skill in this line should be cultivated by every possible means. We think any boy will be far more likely to succeed in after life, if he acquires ingenuity and tact; and these are partly cultivated by the use of tools in constructing various articles.—We once tried to furnish cheaper premium sets of tools, but gave it up in disgust after using one of them awhile, and hearing complaints from others of the inferior quality, because they were cheap. For the present year, we have, through the special favor and assistance of Messrs. PATTERSON BROTHERS, of 27 Park Row, arranged for a few chests of the very first quality of tools of the kinds and prices named below. The same kinds of tools could be purchased for about half the money, but these are all A No. 1, and can not be procured at any less price. They are for practical use, and worth a dozen common articles. For this we have the word and guarantee of Messrs. Patterson, which is amply sufficient for us, and for all who know them. They make up assortments of these, or any part of them that may be ordered of them, at the prices affixed, and any one can purchase of them what they desire. We make up only a single premium, which contains a full assortment for all common purposes. The tools are of regular size, and but few additions would be required for a journeyman Carpenter. We add a Soldering Iron, which is exceedingly useful about the house. With a little practice, any one can stop leaks in tinware, and do sundry other jobs of tinkering, that will soon save quite a large outlay, besides the loss of the use of a thing until it can be carried to a tinner, and waited for, or sent after a second time. The assortment of our premium is as follows: Plain chest, 31x16x16 inches, with sliding compartment box, \$7; Jack Plane, \$1.60; Smooth Plane, \$1.45; Jointer Plane, \$2.25; Hand Saw, 22 inches, \$1.75. Compass Saw, 10 inch, 70c.; Compasses, 6 inch, 60c.; Warner's Hammer (adz eye), \$1.50; Hammond's Hatchet, 55c.;

Drawing Knife, \$1.25; Try Square, 6 inch, 55c.; Bevel, 8 inch, 70c.; Chalk Line and Spool, 45c.; Mallet, 25c.; Pair of Pliers (pinchers), 35c.; Sliding Tongs (pinchers), 55c.; Calipers, 3 1/2 inch, 55c.; Brace, 65c.; Augur Bits for Brace, 2 1/2 inch, 25c.; 3/4 inch, 45c.; 3/8 inch, 72c.; Center Bits, 2 1/2 inch, 25c.; 1 inch, 25c.; 1 1/2 inch, 35c.; 1 3/4 inch, 40c.; Six Glimlet Bits, assorted sizes, 90c.; Three Glimlets in Handles, assorted sizes, 35c.; Screw-driver Bit, 25c.; Flat Countersink Bit, 25c.; Rose do. do., 25c.; Small do. do., 25c.; Octagon Reamer, 30c.; Taper Bit, 50c.; 3-inch Screw-driver in Handle, 30c.; 6 inch do. do., 40c.; 5/8 inch Handled Gouge, 50c.; 3/4 inch do. do., 60c.; 1/2 inch Handled Chisel, 35c.; 1/2 inch do. do., 40c.; 1 inch do. do., 60c.; 1 1/4 inch do. do., 80c.; 3/4 inch heavy Framing Chisel, \$1.10; 1 inch do. do., \$1.25; 1 1/4 inch do. do., \$1.50; 3/4 inch Augur, 60c.; 1 inch do. do., 70c.; 2 inch do. do., \$1.30; Full set of Bradawls, \$1.35. Common 2 foot Measuring Rule, 30c.; File, 3-cornered, 20c.; do. do., 25c.; Flat File, 30c.; Wood Rasp, 50c.; Soldering Iron (copper), \$1.15; Solder, Nails, etc., \$1. Total \$44.50.—The Chest will be locked and sent by freight or otherwise, and the key sent by mail.

Nos. 29, 30—Mathematical Instruments, for Draughting, Drawing, etc.—Very convenient not only for Architects and Mechanics, but for farmers and others, and for Boys and Girls. These are neatly fitted in beautiful Rosewood Cases, having dividers with flexible joints, and points, semi-circles, pencil and penholders, rulers, etc., etc. All the pieces in No. 29, are finished in brass and steel; those in No. 30, are German Silver and steel. The pieces are the same in each, but No. 30 is of extra beauty and workmanship. They are useful in making drawings, plans of buildings, fields, etc. They are valuable to children, to cultivate a taste for, and habit of observing and sketching farms, plotting fields, orchards, buildings, for drawing, etc., etc. Such "playthings" not only keep them from "mischiefs" but develop their minds, and make them "handy." These premiums will be sent by mail, post-paid, to any place in the U. States and Territories.

Nos. 31, 32—Morton's Gold Pens: WITH EVER-POINTED PENCILS, IN EXTENSION COIN SILVER CASES.—Premium 31 contains Morton's best No. 5 Gold Pen; and No. 32, his best No. 6 Gold Pen. We have used many gold pens, and like those made by Mr. A. Morton, of No. 25 Maiden Lane, far better than any others we have ever tried. We have used no other for a long time past. No better gold pen is made. The No. 6 is considerably larger than No. 5, and on this account is preferable. We send them anywhere by mail, post-paid.—Those securing this premium should write whether they want a stiff or limber point, and what kind of writing they use it for most. If the flexibility in any case does not chance to suit the hand of the recipient, the pen, without the case, can be returned and exchanged for another, at a trifling expense for postage. Mr. Morton, as well as ourselves, desires every one receiving one of the pens to obtain a first-rate serviceable article.

Nos. 33, 34—Mercurial Barometer's.—WOODRUFF'S PATENT, made by CHAS. WILDER, Peterboro, N. H. These are the most convenient and portable Mercurial Barometers made. (Send to Mr. Wilder, for a circular giving engravings and descriptions of the instruments.) The peculiar form of Mercury cup invented by Mr. Woodruff, renders these far more portable than any Mercurial Barometer previously known. They are so easily carried, that Mr. Wilder guarantees the safe delivery of every Barometer given by us as a Premium, if not to be sent beyond the Rocky Mountains. The instruments are beautifully made, are about 3 feet long, and are packed and sent direct from the factory, with no expense save the express charges. We offer two forms, which differ mainly in the style of case, both being supplied with Thermometer and Vernier. The \$18 form is of course more ornamental, and the more desirable instrument, though either of them is highly valuable.—There is no disputing the fact that a Barometer is often very useful to any one having occasion to desire to know when a storm or fair weather is to be looked for. The mercury generally rises or falls with the changes in the atmosphere, which precede a change in the weather.—A Barometer is to farmers, or others on land, what it is to sailors at sea—an indicator of the weather to be looked for. There are many times every year when the indications of the Barometer in regard to the weather will often be of more value than its whole price (e. g. in the safely housing of a crop before a storm), while the interest on its cost is hardly a dollar a year.—Many who have received this premium from us in former years, have given us definite statements touching its great value to them. Like all things human, it is not infallible, especially to those who have not learned to observe and study the exceptions to the standing rules; yet, as a general thing, its indications are reliable, and often greatly useful. For examples: This very day (Aug. 28), we made a short journey which a rain would have prevented, and we even left our umbrella at home, though the sky very strongly indicated

rain, and we found everybody in the cars carrying umbrellas. We relied upon our Barometer which had risen during the night. Again, early in August we had a field of oats cut, and the bundles were spread out to dry in the forenoon by the men, because the sky was clear. Glancing at the Barometer we found the mercury had fallen $\frac{1}{8}$ inch, and was still falling. The men were ordered to stack the oats up immediately. They did so, and just saved the grain from a long, soaking rain that continued several days.—Aside from its direct utility, the habit of observation, and of scientific study cultivated in children, where a Barometer is used, is important.

No. 35—Buckeye Mowing Machine.

—The gratification expressed by those who received this premium last year, and the request of others who wish to get it this year, lead us to continue it on the same terms. The Buckeye Mower is so widely and favorably known throughout the country, that we need not describe it particularly. Any one writing to the Manufacturers, Messrs. Adrance, Platt & Co., 165 Greenwich-st., N. Y. City, will receive a circular giving full descriptions, engravings, etc. The experience of last year showed that many a farmer can easily secure this premium by a very few days, or odd hours and evenings, canvassing for subscribers. A few can unite their efforts, each getting a part of the subscribers, and then own the machine in common, if they do not each need the full time of a mower.—It would pay a man well to canvass for this premium, and sell it afterward. Ten subscribers a day for 15 days would secure the premium, which sells regularly for \$125.—Many can, at town meetings, fairs, elections, and other gatherings, or during the evenings, secure this premium club without much if any loss of time.

No. 36—Cylinder Plow (Allen's Patent).

—We hear very good reports from those who received this premium last year.—In May, 1861, we described some highly successful trials made with it, alongside of other first-class plows. During the war, like most other good implements, this was not brought much before the public. It is named from the peculiar form of the mold-board. Several improvements have been made upon it within a year or two past. It is an Ohio invention, we believe, but is manufactured by R. H. Allen & Co., of 189 & 191 Water-st., New-York City, to whom application may be made for further description, etc. There are several sizes and prices, with a greater or less number of attachments. The kind we offer for premiums, is the "Two-horse size, cutting a furrow 12 to 14 inches wide, and 5 to 8 inches deep." It is also provided with wheel, and with a "skim plow," that is a smaller plow attached under the beam, like the double "Michigan plow."

No. 37.—The Aquarius: OR, WATER-TANOVER.

—This is an excellent little portable hand force-pump, useful in many ways. One can take this instrument in his hand with a pail of water, and throw a considerable stream to a point where a fire may be breaking out, and do more to quench it, than he could with a dozen pailfuls dashed on, even if the fire could be reached. We have thrown water from the ground up against the third story windows of a house. The Aquarius is very useful for watering gardens, for washing windows, carriages, etc., etc. It is provided with rubber suction pipe, to draw water from a pail, tub or bucket, and an ejection pipe having both a nozzle for throwing a stream, and a rose or sprinkler. It has also an air chamber for giving a constant stream. It is a handy instrument for every household, aside from its use as a fire engine, with which many incipient fires have been stopped. Send to the manufacturers, Messrs. Wm. & B. Douglas, Middletown, Conn., for a descriptive circular, giving full particulars. The Aquarius packs into small space, and is readily sent by express or otherwise.

No. 38—American Cyclopaedia.—ARPLETON'S NEW.

—We can hardly commend this great work too highly. We wish it could be placed in every family in the country. Several were fortunate in securing it through our premium list last year, and we hope many more will do so this. For example, a clergyman, in a small church on Staten Island, began to canvass among his people on Monday morning, and in less than four days he obtained subscribers enough to secure the Cyclopaedia—to the great benefit of himself and parishioners. Scholars at our Academies and Seminaries, and members of Library Associations, can easily unite their efforts and secure this important work for their Libraries. Many young men ought to devote their evenings and spare hours to canvassing, and obtain this magnificent and useful work for their own use. The Cyclopaedia is a whole Library of itself, consisting of sixteen very large octavo volumes, well bound, averaging 800 large

two-column pages in each book, or in the whole, 12,804 pages! They treat upon over 25,000 different subjects. It is hardly possible to name any subject, any country, any person of note, in past or recent time, concerning which pretty full information may not be found in the Cyclopaedia. It embraces every topic of human knowledge, alphabetically arranged for convenient reference.—"Cyclopaedia" means the whole circle of instruction or knowledge. This is called the American, to distinguish it from the similar comprehensive works published in England and France. The British Cyclopaedia, though less comprehensive, and not coming down to recent dates, costs more than twice as much as our better American Cyclopaedia. To get this premium is worth a year's effort in raising subscribers. The lowest price is \$80.

No. 39—The Great Dictionary.—

WORCESTER'S LARGE PICTORIAL, UNABRIDGED EDITION, containing 1854 three-column pages, with a multitude of illustrative engravings. (The work is 12 inches long, 10 inches wide, and nearly 4 inches thick, and weighs nearly 10 lbs.) Many of the most thoroughly educated men of the country consider this as far the best Dictionary in the English Language. It gives the spelling and pronunciation of every word in the language, with full explanations, and as a source of general information stands next to the Cyclopaedia. The Dictionary can be called for at our Office, or be sent by express or otherwise, to any part of the country. We have given away hundreds of copies as premiums, many of them obtained by quite young boys and girls. It should be in every family. It is published by Brewer & Tileston, Boston.

Nos. 40 to 49—Volumes of the

American Agriculturist (Unbound).—These amount to a large and valuable Library on all matters pertaining to the Farm, Garden, and Household, and contain more varied information on these subjects than can be obtained in books costing three times the money. We have stereotype plates from the Sixteenth to the Twenty-fourth Volume complete, and will have Vol. 25, soon after Dec. 1st. From these plates we print as needed. The price of the volumes is \$1.50 each, at the office, or \$1.75 if sent by mail, as they must be post paid. They are put up in clean numbers, with the Index to each volume.—They are profusely illustrated, the Engravings used in them having alone cost about Twenty Thousand Dollars! Those obtaining premiums for from one to nine volumes, can select any volumes desired, from XVI to XXV, inclusive. For ordinary use, the sets of numbers unbound will answer quite well.—Many hundreds of these volumes are taken every year as premiums.

Nos. 50 to 59—Bound Volumes of

Agriculturist.—These are the same as Nos. 40 to 49 above, but are neatly bound in uniform style, and cost extra for binding and postage. Sent post-paid.

No. 60—Genesee Farmer Volumes.

—As is generally known, we recently purchased the entire establishment of the Genesee Farmer, and united it with the Agriculturist, at the same time engaging the exclusive Editorial services of Mr. Harris. This was one of the best Agricultural papers in the country, which was an inducement to make the purchase. The back volumes of that journal contain much material of great practical value, including the first two years of the "Walks and Talks upon the Farm," now continued in the Agriculturist by Mr. Harris. We have stereotype plates and back volumes of the Genesee Farmer for eight years past, 1858 to 1865, inclusive. The price of these, sent post-paid by mail, is \$1.25 per volume, in numbers, or \$1.75 bound in half leather. We will forward the whole eight years' numbers, post-paid, to any one sending 15 subscribers to the Agriculturist at \$1.50 a year, or 58 at \$1.00 each; Or, we will send the Bound volumes for 21 subscribers at \$1.50; or, 70 at \$1.00 each.

No. 61—Downing's Landscape Gardening, and Rural Architecture.

—This is a most beautiful Octavo volume, in extra binding, and will be an ornament to the best center table in the land, as well as be practically useful. It contains 108 fine engravings on Wood, Steel and Stone. It will be sent post-paid.

No. 62—Architecture: A NEW AND

PRACTICAL WORK ON ARCHITECTURE, containing Designs for Street Fronts, Suburban Houses, and Cottages, etc., etc., giving in detail Designs and Working Drawings for both the exterior and interior of buildings; also a great variety of Details not in the Designs. It is 11 by 14 inches in size, and contains engravings of 382 Designs, and 714 Illustrations, that would separately cost Hundreds of Dollars. By Cummings & Miller. Sent post-paid.

Nos. 63 to 74—GOOD LIBRARIES.

—In these premiums, we offer a choice of Books, for the Farm, Garden, and Household. The person entitled to any one of the premiums 63 to 74, may select any books desired from the list below, to the amount of the premiums, and the books will be forwarded, paid through to the nearest Post Office, or Express office, as we may find it most convenient to send them. We need not enlarge upon these premiums: every one knows the value of good books. Twenty-five or Fifty dollars worth of books on subjects pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to make their heads help their hands. Any good book will, in the end, be of far more value to a youth, than to have an extra acre of land, or coming to maturity. The thinking, reasoning, observing man, will certainly make more off from 49 acres, than he would off from 50 acres without the mental ability which reading will give him.—Our premiums will enable many a family to secure a larger or smaller Library. This is a good opportunity for the farmers of a neighborhood to unite their efforts and get up an Agricultural Library for general use.

No. 75—General Book Premium.—

Any one not desiring the specific Book premiums, 63 to 74, on sending any number of names above 25, may select Books from the list below, to the amount of 10 cents for each subscriber sent at \$1: or to the amount of 30 cents for each name sent at the (ten) club price of \$1.20 each, or to the amount of 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid by us.

BOOKS FOR FARMERS and OTHERS.

[For sale at the Office of the Agriculturist, or they will be forwarded by mail, post-paid, on receipt of price. All these are included in Our Premiums 63 to 75 above.]

GROUP OF CHESTER COUNTY WHITE SWINE. (COPYRIGHT SECURED.) PROPERTY OF J. ROYD HEARD, ESQ. MORRISTOWN, N. J.—(See page 354.)

G. H. HAYES, S.F.

Really Valuable Hogs.

There is a large farmer living in New Jersey, whose habit it has been for many years to get his information by going after it himself. He is what New England folks call "*forehand-ed*"—that is, he always has or can make time to do what he wants to. If he wants to build a barn, he and his son go about and see barns, take measurements, study all the fixtures and conveniences, and take notes; then, when ready, they draw their plans and build. They do just so about other things. A while ago they wanted to renew their stock of hogs, and as they had long favored a large breed, they set to work to find what they wanted.

Without commending their judgment in preferring the Chester County breed, we give the results. On an adjoining page are portraits of several very handsome swine. They are of the so-called Chester White breed, and were selected by our friends after visiting every herd of note in the county, and others outside of it. They found such animals as they wanted, and bought them, paying any price asked, and even tempting breeders' best stock away from them with the all-powerful greenbacks. Therefore, we say, if there is any such thing as a Chester White breed, they have it—and our readers have a picture of as true a lot of Chester Co. hogs as there are in the country. The artist has had his own way, and made pictures which represent them as accurately as possible. Their legs are not trimmed down to suit any-breeder's fancy—neither are their backs and bellies straightened and filled out, the heads and ears trimmed down, and all sorts of exaggeration employed to show them as somebody might think they ought to be, instead of as they are. The boar is 4½ months old, the sows 7, and the roaster, not a fortnight old, is the choice one of a recent farrowing of another sow, bought at the same time that the others were.

There appears to be two rather distinct kinds of hogs which go by the name of Chester Whites, and these have been mixed considerably, so that important characteristics of the hogs are not fixed. They are all large, but do not all grow to extraordinary size—nor have they all precisely the same shape. The ears of some lop forward, others incline outward, others still, stand up straight and pointed. Some ears are soft and silky, others fleshy and coarse. All these things indicate a lack of good breeding, which prevents these swine being recognized as a true breed. They have many good points, however; they are large, small boned, quick maturing, easy feeding, and well coated, but to compare them for persistently uniform characters with the Berkshire, Essex, Chinese or Suffolk breeds, is preposterous. The hogs which we picture are by no means fat, but simply in good breeding order, yet when we saw them a few days since, they struck us as so even and well-formed—so broad on the back, especially in the loins and shoulders, and so good all over that we wanted our artist to make a picture of them for their beauty, aside from the fact that they represent the choice of the Chester County herds. The dressed weight of 7 pigs 7 months old, of the same breed, all of one litter, killed last year by the owner of these, was respectively as follows: 238, 258, 237, 243, 283, 310, 240 lbs., which is considerably more than one pound for each day of their lives, (in one case over 1½ pounds. The same is true of some hogs 15 to 18 months old, killed at the same time, minus the weights of which we have mislaid.

Walks and Talks on the Farm.—No. 34.

What cold wet weather we are having! Corn is at a stand-still, and unless we have more sunshine the ears will be small. My corn is drilled, and I suppose will suffer more than that planted in hills—though so far, I think it is as good as most fields in this neighborhood. At all events, if we have no frost, I shall have plenty of fodder. The second growth of clover is splendid, and the prospect now is, that we shall have a great yield of seed. I plastered part of the clover on the second of June. We sowed it with a broadcast plaster drill. The clover was knee high, and when we had sown about eight acres, there came up a shower and the wet clover reached to the drill and clogged it, and we had to stop in the middle of the field. I could not see any marked effect of the plaster on the first crop, probably because it was sown so late—though there are those who think plaster does most good when sown on the leaves. But now, on the second growth of clover, you can see to an inch how far the plaster was sown. You can see it the whole length of the field, and also on the half breadth sown till the drill stopped. Nothing could be more distinct. There is of course danger of getting too large a growth. The seed may not mature. But I can hardly bring myself to believe that it is possible to make land on this farm too rich for any crop. I understood that one of my neighbors, when he heard last year that I was seeding down my wheat with clover, and that I had been obliged to pay \$17 a bushel for the seed, remarked "Well, he may sow it, but he will get no clover. That field never has raised any clover and it never will. It is run to death." But I had as good a crop on the whole field as I could desire, with the exception of about an acre. This was poor, and is comparatively poor now, though the difference is not so striking on the second crop as on the first. I believe I told you before why this was. When I bought the farm, three years ago, 14 acres of the field was in corn, and 18 acres in clover, so called—but there were far more thistles than clover. Well, the following spring I sowed the corn land to barley, and broke up the clover sod and sowed part of it with peas, and planted three acres with potatoes. The potatoes were manured with ammoniated Pacific guano, and gave me 200 bushels per acre. The peas had also some guano and plaster, and also part of them superphosphate; the barley had part bone dust and part superphosphate, and other artificial manures. An acre or so, in the barley and in the peas, had no manure of any kind. It is this land that gave such a poor growth of clover. And recollect it is two years ago last spring since the manures were used. The barley was sown late, and only yielded about 12 bushels per acre, and was of such poor quality that the maltsters would not buy it. The peas were a little better, but still very poor. The potatoes were good. The barley and pea land was sown to wheat, and produced a little over 15 bushels per acre. The potato land was sown with barley, and received another slight dressing of artificial manure, and gave a fair yield, and nothing more than fair—but the clover on this part is superb. "The husbandman waiteth for the precious fruit of the earth, and hath long patience for it." I have unbounded faith in good culture and manure, but my first two years' experience on this farm tried it sorely. But this year I feel quite encouraged. My crops are good.

The barley on the five acres of wet land that I under-drained, turned out better than I expect-

ed. When we were getting ready for "the threshers," William asked me where the barley was to be put. I told him we would put it in such a bin. "It will not hold it." I told him I thought it would. He has been on the farm six or eight years, and knew the size of the bin. "How much barley do you think you will have?" he asked. "I think we shall have a little over 20 bushels per acre." "Thomas and I," he said, "think this five acres in the bay will go 40 bushels per acre." "I told him he was as wild as a hawk; that I would bet him a hat it did not go thirty." Well, we commenced threshing, and soon had a hundred bushels in the bin, and then fifty more. "Two hundred" was the next report, and still the bottom not reached. "Two twenty," and considerable excitement in the barn. "Two thirty," hurrah! "Two forty." Clean up the floor. Whoa. "How much?" "Two forty-five. Forty-nine bushels per acre, and I don't believe there is over four and a half acres in the field!"

So much for under-draining, and the free use of the cultivator among the corn. About an acre of the field had a heavy dressing of superphosphate last year for corn. I could not see that it benefited the corn in the least. It was sown broadcast with a machine after the corn was up. I have usually applied it in the hill. But it is clear to my mind that superphosphate and other artificial manures, do comparatively little good on Indian corn in this section. I think one reason for this is that corn delights in a soil abounding in organic matter. Artificial manures do not supply this, while barn yard manure, peat, clover, and grass sod, furnish it in considerable quantity. Wheat and barley do not seem to need it so much as corn. Hence artificial manures should be applied to these crops rather than to corn. Put the barn yard manure on the corn land, either on the grass the previous year, or directly to the crop, as most convenient. Then, if artificial manures are needed, apply them to the following barley crop, with a little more on the wheat. This will give as good a crop of corn, barley and wheat, and the clover sown with the wheat will get the benefit of what remains in the soil. I should expect as heavy clover as could grow. My young clover, where I applied superphosphate and Laves' wheat manure to the wheat last fall, is a splendid color, and promises a great growth. And in renovating a farm, *the first aim should be to get good crops of clover.* Make sure of the clover, and you are sure of every other crop.

"You have great confidence in artificial manures?" Yes, provided they are good and can be obtained at reasonable rates. But I have still greater confidence in *thorough tillage.* Or, perhaps, it would be better to say that both should go together to get the best results. And make and use all the barn yard manure you can in addition—and be sure to make it as rich as you can by feeding the animals well, and preserving the manure from leaching. There is far greater loss from leaching than from evaporation. Many farmers let half the value of their manure run into the nearest ditch. If the barn yard is properly constructed, the buildings spouted, and you have the requisite number of open sheds for the stock, and then keep the yard well littered, there is no danger of loss either from leaching or evaporation.

Some time ago I read in an English paper an anecdote of a President of a County Agricultural Society. "At the last Annual Meeting," said he, "you awarded me a white hat for the dirtiest barn yard in the county. I have worn it a year, but I think Mr. Blank's yard is now

worse than mine;" and to the great amusement of the audience, he handed Mr. B. the hat.

For the first two years I should have stood a chance of getting the hat in Monroe County. And yet a dirty barn yard is my abhorrence. But I had no straw, and how can you have a clean yard, clean pig pens, and clean stables without straw? A year ago last spring I had to buy straw and draw it five miles to litter my horses. But the next harvest brought the long-looking for abundance, and I used it freely, but still had a large stock left over this spring. "Mr. S. and I have just been talking about your having so much straw on hand," said one of the best farmers in this section, as he rode past from the city. "I always like to work it up in some way during the winter." He is a man whose opinion I value highly, and I took the reproof meekly. Of course I could have spread it about the yards and trod it into manure. But I now find that I blundered into a far better practice, and I shall always endeavor in future to have a good stock on hand for litter, during wet weather in summer and early autumn. The cows stay in the yards at night, and by keeping them well littered it is perfectly astonishing how much manure is made. I really believe they make more than during the winter, when they are in the yards and stables all the time. Then, how much pleasanter it is to milk in such a yard, and how much more comfortable the cows are! When you have once got a good bed, it requires fresh litter but seldom. The pigs root it up and it soon dries, and by spreading this over the yard, it can be kept clean without much trouble.

But I probably should not make so much manure if I did not slop my cows. I was telling you sometime ago that I wanted to slop them, but could not do it, because we had no conveniences for feeding them. Where cows are milked in the yard you cannot feed them with a pail, as they will frequently pull it over, and in any case the other cows would disturb them. My cow stable has no space in front of the cows where you can carry the food to them, and we should have to carry the pail of slops between the cows. Both cows would try to get at the pail, and the harsh tones of the man, to say nothing of the occasional kicks in the mouth, would go far to counteract the benefit of feeding. But during the "heated term" my cows fell off from nearly 80 lbs. of butter a week to less than 60 lbs., and when cows once fall off in their milk, it is not easy to bring them up again. But I thought I would see what could be done.

We got a large trough, made of two-inch plank, that will hold forty or fifty pails of water. We set this under the pump in the yard, so that the cows can stand all around it. Into this trough, which is about two feet deep, we put a bushel of corn meal, and then pump in some water and stir up the meal. This should be done in the morning as soon as the cows are turned out to pasture, in order that the meal may have time to soak. Of course it is not necessary to fill up the trough till the cows are brought up in the evening, when they will like it all the better in hot weather if cold and fresh. When the cows get to the barn yard there is a race for the meal trough. And though they come fresh from water in the field, it is astonishing how much meal-water they will drink.

The weak spot in the arrangement is this: After the cows have drank the water, and they can get at the meal, the master cows will keep away the others, and eat the whole. The remedy for this is simply to have the trough large enough to hold more water than they can drink

during the night, and to fill it full the last thing in the evening, and pump in more, if necessary, the first thing in the morning. I keep a good many pigs, and feed them more or less corn meal all through the summer. The meal that is in the bottom of the cow-trough we take out before it gets sour, and throw it into the pig-cistern, so that we can, without loss, put a good deal more meal in the cow-trough than the cows actually eat, as it is all fed to the pigs, and is improved by the soaking. The only difference between this way of feeding meal, and the ordinary mode of giving them slops in a pail, is, that in the latter case the cows eat the whole of the meal, while in the former they get only the soluble portion and that held in suspension—and they are allowed all they can drink.

But, as I said before, the water must never be allowed to get so low that the cows can reach the meal. If you attend to it yourself, night and morning, this is an easy matter, but no ordinary farm man that I have yet met with can get the idea through his head, short of a month or six weeks. I attended to it myself for the first week, and all went right, but one Saturday night, not feeling well, I did not go to the yard, and the next morning I did not get there until they were just through milking. Sure enough the cows had got down to the meal, and two or three of the master cows were gorging themselves with it, while three men, the assembled wisdom of the farm, stood looking on. But see to it yourself for a month or two, until it becomes a matter of daily routine, and then you can trust it to any careful man.

Instead of corn-meal I am now feeding peas. Like all peas raised in this section, they are full of bugs, or rather of the grubs that produce the bugs. But if fed out soon after harvest, and before the grubs become bugs, they do little or no harm. But, at this season, the peas are not dry enough to grind up fine. The better plan is to put them to soak over night, and then boil them. They boil up quite soft in a couple or three hours, and can be mashed easily, making as nice "peas pudding" as can be desired. We have a steamer, and cook a barrel at a time. Last night I put a barrelful in the cow-trough, with say forty pails of water, and you would be astonished, or at least I was, to find what splendid pea soup it made. It was too strong, to allow the cows to have all they wanted, while the same quantity of corn-meal (uncooked) would have given only a very weak solution.

John Johnston writes me, that his Diehl wheat that he got last year from Indiana, gave him 105 bushels by weight from 3 bushels and 27 lbs. seed, on a little less than three acres of land—say 35 bushels per acre. Not bad for this season. His Witter wheat went over 33 bushels per acre, on land from which he had a crop of barley last year of over 40 bushels per acre. The Diehl wheat is a handsome white variety, and bids fair to prove a valuable acquisition.

Mr. J. threshes his wheat as he draws it from the field. Had I done so this year, it would have been greatly to my advantage, as the heavy rains damaged the top of the stack considerably. Had I postponed threshing a few days longer, the loss would have been very great. Johnston's plan is to thresh outside and put the straw in the barn.

Some of my potatoes on the low land are commencing to rot. I shall dig them as soon as they are ripe and feed all that are specked

with disease to the pigs. It used to be said in England that diseased potatoes, when cooked and allowed to ferment, would fatten a hog quicker than sound ones. And it is not improbable. I can see how the starch might be changed into sugar, and this by fermentation into alcohol. And without discussing the question whether alcohol is a food or a poison, it is a well known fact that a little favors the accumulation of fat. "Hog feed should be allowed to get sour," is an old agricultural precept. I presume it is not the acid that is beneficial, but the other products of fermentation which accompany the formation of acid. The "whiskey" produced by allowing corn meal to ferment, may check the growth of pigs, but increase their tendency to lay on fat. But will the pork be as good?

During the recent cold, wet weather in August, my young pigs did not thrive. I let them run in the barn-yard, and in the barley and pea stubble, and they had all the slops from the dairy they could eat, with a little corn meal mixed with it. I could not think what was the matter with them. But since the weather has become warmer, they begin to improve, and I have no doubt if I had kept them shut up in a warm pen during those chilly nights, they would have done much better. Pigs are very sensitive to changes in the weather, and cold affects them seriously. Unless you have warm pens, and perhaps give warm food, it is not profitable to fat hogs, so far as the accumulation of fat is concerned, much later than the first or second week in November. But of course it is desirable where hogs are fattened for market, to keep them until we have cold weather, as better prices are obtained from eastern packing establishments.

Last spring I planted my potatoes with Ives' Potato Planter. It is set to plant the potatoes in drills 3 $\frac{1}{2}$ feet apart, and to drop a set in the drill about every eighteen inches. I think with nearly all varieties, except the Peach-blow, a foot or fifteen inches would be better. With Nevin's Potato Planter the eyes only of the potato are used. They are gouged out, and the potatoes can afterwards be used for stock. The "sets" are but little larger than corn. These sets are drilled along the rows just as you would drill grain. I have seen a crop raised in this way that was, to say the least, as good as if whole tubers or ordinary sets had been planted, and the ground was remarkably clean, although nothing but the horse hoe had been used. Still, on the whole, I prefer to plant larger sets. If the potatoes are assorted, I believe Ives' planter will drop them as well as it is ordinarily done by hand, and it will plant five or six acres a day. It marks out the land, makes its drills, cuts, drops and covers the potatoes at one operation.

One of the Dutchmen who works for me occasionally was telling me to-day that he has just sold his cow. A farmer who wanted a cow, hearing this one was for sale, came to look at her and milked her. "She gave a pailful," said Jake, "and he handed over the money (\$65) in a wink." I told him that I would have given that for the cow. "She was old," he said, "and the milk was very poor. He only got two pounds of butter a week from her." Still I would have bought her. The cow ran in the road, and had nothing but what she could pick up. I would like to have tried her with a liberal diet of pea-soup. It is easier to increase the quality of milk than the quantity. A cow that gives a pail of milk twice a day, will make a pound of butter a day, if she has sufficient good food.

Fig. 1.—GROUND PLAN OF DRAIN TILE WORKS.

The Manufacture of Drain Tiles.

The demand for tiles for under-draining has increased every year since the early experiments in "burying crockery" were tried in this country—about 18 or 20 years ago—and it ought still to increase until every neighborhood is easily and cheaply supplied. The expense of starting a tile works is not great, and there is no mystery or secret about it. Tile makers, as might be expected, are not very communicative, under the mistaken notion that an increase in tile manufacture would hurt their trade. The contrary will be true. Were there ten times as many made and used, the steady demand, and the activity of their trade would more than compensate for a somewhat decreased price. Mr. J. W. Penfield, of Wiloughby, Ohio, has, at our request, prepared with considerable minuteness a description of his tile works, and of his processes. The sub-

Fig. 2.—GROUND PLAN OF KILN.

ject is too extensive for a single article, and this one will be followed by another. Mr. P. writes:

"*Clay for Tiles.*—Although tiles can be made of inferior clay, or such clay as many brick-makers use, yet it is very desirable to have the kind best adapted to the business. Such clay is known by the smooth, elastic manner with which it moulds, and the rapidity with which it can be dried without cracking. It is very seldom that clay is used for tiles that would be improved by the use of sand. Too much sand in clay makes it brittle, causes the tiles to run rough, and increases the difficulty of making large ones. The purer clay is, the better; much coarse sand, or vegetable matter, is always objectionable; black muck or loam is sure to make trouble in drying, as it causes the tiles to shrink too much and to crack. The roots of grass and other plants are sometimes troublesome. Some clays are hard to soak, being filled with dry lumps, and for this, exposure to frost and wet through the winter, is a cure. This promotes also the decay of the roots. Clay a little inclined to be sandy, should never be dug to freeze. Whiteness, toughness, elasticity and smoothness, are the most essential qualities of good clay, and such clay may generally be

found in all localities where there is much wet land. It is moisture that makes the particles of clay adhere; the amount required for different kinds of clay can only be determined by experience in using. When taken from moist beds in a rainy season, it frequently requires no additional water. Blue clay that has much sand in it should be worked comparatively dry, as in grinding it becomes softer; while as to close, fine, yellow clay, the more it is worked the dryer it gets. It improves any clay that needs moisture to soak twelve hours before moulding, and if dry when dug, this is positively necessary. A little experience in soaking clay, will enable any one to do it correctly; it is better to get it too soft at first, than too dry. Stony clay can not be used successfully, as stones interfere with moulding or fill the screen rapidly. Stones may be crushed with rollers, but the same expense would make tiles of good clay. Occasional stones $\frac{1}{2}$ an inch in diameter or less, will make but little trouble; larger ones will. When three or four such can be found in a shovel-full of clay, larger ones will be found. Many attempts have been made to use stony clay for tiles, but in every instance I know of, the cost exceeds that of clean clay. A little time spent in looking for good clay will be well rewarded in almost any township.

Construction of Sheds.—It is economy to work under cover. Where a machine is run by horse-power, a shed may be constructed as follows: Make it with ten sides, 40 feet in diameter, setting posts in the ground, 12 feet apart, sawed off, 6 feet high: spike on joists 2×8 edgewise against the outsides of the posts at top, and a main rafter running from each post to the center of shed at the proper pitch. This rafter should be 22 feet long, 3×3 at top end, 3×6 at the lower end. Short rafters can be cut in between these to suit the kind of roofing used. Either shingles or boards may be used. Strips of 2-inch band iron, 1 foot long, should be spiked on the outside of the girt-plates, over the joints to prevent spreading. The drying shed

Fig. 3.—ARCHES AND FLUES.

may be 14 feet wide, 180 long, posts 6 feet high set in the ground, 4×4 scantling for plates, 2×4 for rafters. Fig. 1 shows the ground plan of the shed, giving the location of the tile machine, clay pit, horse track, etc., and from this

the drying shed with two rail tracks in it going to the kiln. There is a switch at each end of the drying shed, but only one is shown for lack of space. Many cars are used, on which the green tiles are laid, and remain until dry enough to go into the kiln, each car holding 1000 2-inch tiles.

Construction of Kiln.—The size of kiln, a partial plan of which is here shown (fig. 2), is 14×16 inside; the walls are 16 inches thick in addition, and the firing flues project, forming a platform at each end. Four flues 20 inches wide, run the long way of the kiln; benches or spaces between the flues are 26 inches, and the side benches 4 inches wide. The flues for firing should be 4 feet long, 12 or 13 inches wide, extending out from the kiln. The structure as shown in fig. 2, should be built one foot high, and then it is ready for turning the arches. The arches, shown in fig. 3, are turned over the flues, as indicated by the dotted lines in fig. 2.

Fig. 4.—FLOOR OF KILN.

The shape of the arch should be higher than wide, or more than half a circle, if not they are apt to flatten and fall in. If too high, they will fall in at the sides. Each course of arches is built independent of the other, except being tied together on the center of each bench, which makes a partition between the flues from the bench up to the kiln-floor. This is shown at G, G, fig. 4. The arches are as wide as the length of one brick (8 inches), and the space between, the width of a brick (4 inches). Fig. 4 shows a portion of the floor finished, which is done by laying bricks (2) flatwise across the spaces between the arches, and a course (1) lengthwise, on the center of the arches. The bricks should be closer over the fire than over the benches, and more space should be allowed at the corners and around the sides than elsewhere, this is important for the purpose of drawing the heat to the corners and sides. It is better to use fire-brick for the floor, and to turn the arches, as they are more permanent, and keep the floor smooth and even. The openings in the floor should vary from $1\frac{1}{2}$ to $1\frac{3}{4}$ or 2 inches between the bricks, and 3 inches along the sides of the kiln. The height of the kiln should be governed by the length the tiles are cut, and the number of courses to be set. Eight courses of tiles, cut $13\frac{1}{2}$ inches long, would make it necessary to have the kiln ten feet high above the floor. In fig. 4, dotted lines running from A to B, indicate the course of the arches under the floor. The tops of the arches being seen at F. The course of the flues under the arches is shown by the dotted lines at right angles to the arches, running from D to E, while the dotted lines C to D show where the firing flues go through the wall; 1, 1, 1, are bricks lying upon the arches, and 2, 2, 2, bricks crossing from arch to arch, and forming the spaces up through which the fire comes."

Ice Houses—North and South.

With the wane of the summer, as usual, come inquiries about Ice Houses.—There is nothing like necessity to drive us up to action, and the extreme heat of the past summer causes ice to be regarded, more than ever perhaps, as a necessity as well as a luxury. The topic is not a new one for us to discuss with the readers of the *Agriculturist*. In October, 1864, there is a plan and elevation of an ice house, given with considerable minuteness of detail, but at the risk of a little repetition, we must answer some of the numerous questions lately received.

Fig. 1.—AIR TRAP.

Fig. 2.—AIR TRAP.

Ice Houses may be made in any part of the country, and in fact, one which will keep ice well in Maine, will do so in Louisiana. The difference in the extreme summer temperature of the two States is really very little; and though ice will not keep so long at the South as at the North, yet the same principles apply to its successful keeping in both places. The essentials are two; 1st, a sufficient bulk of ice closely packed; 2d, non-conducting walls, bed and cover. These are very simply attained: as for instance, when a large mass of several tons of ice is piled upon a bed of rails covered over with two feet of straw, and then covered and packed about with straw enough to effectually shield it from the rains. In fact, it would be hard to invent a more perfect way of keeping ice than this,—but it would be inconvenient. A room in the middle of a hay bay would be excellent, and might be very convenient.

Taking the 2d essential first, we must consider that the bottom of the ice house, in order to be a non-conductor of heat, must be so far as possible dry, for water is a rapid conductor, and moist air will thaw ice much faster than dry air, even though the latter be the warmer. The ice will thaw somewhat, at any rate, which necessitates good drainage, and this must be so made that air can neither blow in nor draw out

Fig. 3.—ICE HOUSE.

through the drain. To effect this an "air-trap" is introduced at the entrance, and this must be protected from straws, sawdust, and dirt which might stop it up. We give figures of two traps

which will last a very long time without the necessity of being cleaned out. The bottom of

Fig. 4.—ICE HOUSE PLAN.

d, Door; d, d, Double Door; d w, Double Window.

the ice house is grouted, (covered with broken stone pounded flat, and cemented,) sloping to one point, usually the centre, where a round or square well, about a foot deep, is made, and also cemented thoroughly. Up into this well or depression comes the mouth of the drain. In fig. 1, it is a 2-inch glazed drain-tile coming through about 6 inches. This is covered by an earthen pot, also glazed, and set up from the bottom on four bits of stone or brick. Straws and dirt will be caught outside of the pot or upon the bottom, and the water only will flow out, while no air can flow either way. The same end is gained by the contrivance shown in fig. 2, but not so

Fig. 5.

well. Here a pipe, bent somewhat S-shaped, shuts out the air, while a cap of copper-wire cloth prevents the straws getting in. The pipe or drain tile may enter a stone or tile underdrain. Sometimes people simply make a well or depression in the bottom of the cemented floor and connect it directly with the drain, covering the drain and partly filling the well with gravel, topped with clean sand. This does very well for a time, but is apt to be stopped up finally, and may make mischief.

The ice house itself of course must stand where perfect drainage is attainable. It may be above ground or underground, or half-under—it makes little difference. We prefer those above ground, except for looks. The under or half-under-ground ones may be more easily concealed or ornamented. The article referred to (page 290, 1864,) gives a good plan for an above ground house, which we will not repeat. The elevation, fig. 3, and plan, fig. 4, show how a

fruit house or cool room for any purpose, may form a part of an ice house, and maintain a low temperature without seriously decreasing the ice. The ice house has foot-thick walls on three sides; the cool room is also thick walled. There is also an entry, which being shut off from the front room and communicating directly with the ice house, may be very convenient if there is plenty of ice, to hang a mutton carcase or a side of beef in for a few days in summer, the door into the ice chamber being opened.

Figure 5 represents an ice house made underground and covered with a summer house, being entered by steps from above with double doors to open outward.

Fig. 6. ICE HOUSE CORNER.

The walls of the ice house, be they above or below ground, should be of light porous material, like shavings, spent tan-bark, sawdust, etc., and should be so made as not to become wet either by water from without, or from the ice. For an above ground house upon a cemented stone or brick foundation, a few inches high lay sills, 10 inches wide and 2 inches thick, in cement; set upon these, and nail to them the studs, two at each corner, and about 4 feet apart elsewhere. Fig. 6 shows how a corner is framed and nailed.

The studs are 2-inch plank 8 feet high and 10 inches wide. Upon them, flush with the outside edges, are spiked the plates, 3 x 6-inch pieces. Corner posts of 3 x 3-inch stuff are heavy enough. The inside is of 2-inch hemlock; the outside of matched inch stuff, horizontal, or if not matched, put on perpendicularly and battened. The filling is best put in and rammed down moderately as the sides go up. Use 6 x 2-inch rafters, and board them on both sides, putting on the top boarding, last and stuffing in shavings to prevent a circulation of air between. In the upper part of the roof there should be a small ventilator, which may be closed more or less according to judgment. The air above the ice becomes somewhat moist, and if there is no ventilation it will become charged with moisture, and conduct the heat from the roof and thaw the ice. The door must give access to the top of the house, and should be double and close. In underground ice houses, the outer walls are brick or stone, cemented, or cement upon the earth sides, and furred out, filled, etc., as above

stated. The ice house floor should be of 2-inch plank laid level upon loose rails or scantlings. A thick level layer of straw is laid upon the floor. Then the house is ready for the ice, which should be laid in in solid blocks of uniform size, breaking joints like bricks in a good wall. Between the ice mass and the sides all around pack sawdust, or better the chaff from a fan mill, and in absence of these straw. Finally cover the ice with straw or chaff 2 feet thick.

Saving Seed Corn.—Fall Plowing.

Mr. J. Weldon, of Winnebago Co., Ill., communicates through the *American Agriculturist* the following advice for his western brethren, which it will not hurt our eastern readers to consider: "In several of even Northern counties, the seed corn last spring proved unusually defective; and it is my experience that little re-

liance can be put at any time in seed selected from the cribs, in this country. Allow me therefore to give your western subscribers a sure method of saving seed corn, so that every grain will grow.—As early as all the kernels are partially glazed, make choice of those ears which have the most rows—not less than 16—(usually the more rows, the less is the proportion of cob), entirely filled out at the small ends not shriveled up at all at the tips. If two such ears are on the same stalk, all the better. Leave on enough husks to tie four ears together, to hang them over poles, in some dry place—the upper part of a room, where a fire is kept. I have found a large smoke-house well adapted to such a purpose. The corn should be completely dried, cob and all, before any frost can reach it. Thus secured, cured and kept dry, it will readily germinate after many years. It is very desirable to have as much of the ground plowed in the fall for the next year's corn crop, as can be done well. This is the surest method to destroy the weeds, and to get the ground in the best condition to plant at the right time. It is very desirable to have the ground plowed while it is yet warm enough to cause fowl seed to sprout and grow; so that the weeds may be cut down by frosts before they yield ripe seed, hence early fall plowing is best for corn at the West. Land having a clayey subsoil, really ought not to be plowed less than ten inches deep, for should the ensuing July and August not have abundant showers the plants might suffer; but with such showers, a few inches less may do very well. I believe that one efficient hand, with a first-rate team, and furnished with the right implements, can very successfully cultivate 70 or even 80 of corn, if plowed early in autumn, and that he may have all the necessary cultivation finished by the middle of July—and so well that the crop will be out of the reach of a killing frost by the middle of September, and yield *full twice* the average of the six Northern counties of this State. If the land has been managed so slovenly that a very great quantity of fowl seed is mixed with the soil, it may take two or even three years to eradicate the weeds, so that one hand with one team could perform all the labor. He might need assistance in thinning out the plants in June."

Observations on Burying Bees.

BY BIDWELL BROS., ST. PAUL, MINNESOTA.

In a prosperous colony during a yield of honey, the Queen or mother bee continues laying to supply the place of bees lost from accident, or continued labor causing death. When the yield of honey fails, which often happens in summer, and always in autumn, the Queen ceases laying, and a gradual and certain reduction of numbers and stores takes place. In this way we are confident that more than one half the relative value of all stocks is lost in the ordinary methods of wintering bees. After a yield of honey, if the weather continues warm, many bees are lost during each successive day, in fruitless attempts to collect honey, requiring also an expenditure of stores for the exertion. From this cause alone, bees at the South are reduced to a mere handful during their mild winters. This can be obviated in a measure by darkening, not closing, the entrance to the hive. Another waste occurs by disturbing the bees in any way, allowing the wind to jar or to cause a draft of air through the hive, making them uneasy; this most frequently happens in windy situations—at times, in all places. The opposite extreme, a

want of ventilation, is equally bad, giving the bees much labor to replace with pure air the impure air accumulating in the hive. In moderate weather each rise and fall of the thermometer outside, is followed by a similar change of temperature within the hive, the bees expanding their bulk in warm terms of weather, and contracting in cold ones, keeping in a circle to best maintain their heat. Having to do this between several combs, some are left between outside ones, which become chilled and perish. In our climate, where the bees are compelled to remain in their hives several months during the winter, as they have no opportunity to carry out their dead, these accumulate on the bottom.

Placing thermometers in several hives, and outside; we ascertained that when the thermometer outside fell below freezing, and during all the time it remained so, the bees maintained a temperature within, of one degree above freezing, though the weather in the open air indicated a temperature as low as 37 degrees below zero, or 63 degrees below that of the bees. Giving three of the stocks a hard rapping, the temperature arose within to 84, 88, and 89 degrees above zero, or an average of 124 degrees above that outside.

In the union of the oxygen of the air with the carbon and hydrogen of the honey eaten, heat, carbonic acid and water are produced, a chemical phenomenon similar to common combustion. Unless the ventilation is very good, the watery vapor is condensed in cold weather to water and ice in the upper part of the hive. The carbonic acid, which is fatal to the bees, if not removed by ventilation, causes death. Hence the need of ventilating the cellars in which bees are kept. In warm terms of weather the ice or frost melts, and running down wets the bees. Should the weather change back to cold immediately, it would cause them to freeze, or closing the entrance with ice they would smother.

In some of these ways the numbers of the bees are diminished, and they seek to replace the loss by raising brood, which is also attended by many losses. For maturing the young bees, honey, which supports respiration, is consumed, and also pollen, which is necessary to support the growth of the body, and this is attended by a high degree of heat. The honey which is fed to the young bees with the bee bread, must contain a large proportion of water (more than is contained in sealed honey), and if the bees can not obtain water to dilute the honey with, the brood will perish. In unfavorable weather it should be given to them in a sponge or similar absorbent, placed within their reach. The proper consistency of honey fed to brood is about that of honey just gathered, which is half water. By observing when bees collect water, one can be sure they are raising brood and consuming honey. If bees remain quiet and are strong in numbers, only honey is needed to carry on respiration. This causes comparatively little waste, but should exertion become necessary, and new bees be required to replenish the hive, pollen is needed, which consists of nutriment and residuum. The latter, if not expelled, accumulates in the bodies of the bees, causing uneasiness and disease.

In burying properly under ground, the principle losses attending bees kept in other ways, are saved by an even temperature, (which we have found to remain at about 50 degrees), ample ventilation, complete dryness, and total darkness; these constitute all the essentials to success. After burying, the bees gradually become quiet, usually requiring two days, then an

even stillness prevails, which is not interrupted throughout the time they remain, unless heavy jarring occurs on the ground immediately adjoining. The time bees should be buried is when they cease collecting honey, even though it happens in warm weather; then the numbers, which are always large, can be preserved until a yield occurs again. In burying 7 lots of bees last winter, numbering from 1 to 40 colonies—in all 224 stocks—we found burying bees in trenches to require only half the material and labor that placing them in pits did, as described in the September number, last year. We ascertained it required but one pound per month to winter a strong colony, numbering from 40 to 50 thousand bees. Where the winters are not too severe, as the next best plan to burying, we would advise letting them remain on the summer stands, removing the honey board and placing in its stead a straw mat, like that described in the February number of the *Agriculturist* for 1863, page 49; place over it the honey board, and stand boards, evergreen boughs, or brush with the leaves on around the hives to keep off the warm sun and cold wind, removing occasionally in pleasant weather. This is far better than the usual practice of destroying the bees in autumn, or allowing them to waste away in winter, and might we think add millions of dollars annually as profit to bee-keeping.

What sort of Animal is the most Profitable for the Producer and Consumer?

This is, undoubtedly, that animal which has the least offal and fat, and yields the largest amount of the best pieces of meat for the table, in proportion to the weight of its carcass. Suppose the value of the dressed animal 17½ cents per pound—the present average price of good beef—the tender-loin alone might then be worth 70 cents per pound; the Porter House steak 40 cents; the fore-rib roasting-piece, 35 cents; sirloin steak, 30 cents; and the Rump (for corned beef), 25 cents. Of the other parts we need not speak, the above-mentioned being sufficient to illustrate our point.

The West Highland cattle, of Scotland, were formerly superior to all other breeds in the crops, from which part of the carcass the Porter House steak and the Tender Loin are cut; and, possessing in addition to this, a general evenness of form, made up of lean, tender, juicy meat, they command from a penny to twopence (two to four cents) more per pound in the London market, than most other breeds. The Devon comes nearest to them in a good carcass, next the Hereford and Short-horn, then other breeds.

Latterly, considerable attention has been paid by breeders of these last three famous species of cattle, to make them equal the West Highlanders in the crops and fore ribs, and great improvement has consequently been made in these desirable points; but with all their care, it will be a long time before Herefords and Short-horns generally equal them here. Devons being originally better in the crops; the best bred are now nearly equal to the Highlanders in this point.

It is because the South Down sheep so eminently excels all others in the same points, in which the Highland cattle are superior, that its carcass commands a higher price than any other. We do not take the little Welsh mountain sheep into consideration, because it is a *fancy* animal, whose superior mutton is made from the peculiar rich fine-scented grass it feeds on, affecting the taste of the meat in something the same way, as does their autumnal food the

flesh of our celebrated Canvass Back Ducks. It is a mistaken notion on the part of some to suppose that when we have lessened the offal of our domestic animals, and added a large proportion of fat, that we have done *all* that is necessary to perfect the carcass for the table. Great attention, as we have shown above, must be paid to increasing the proportion of the choicest parts of the animal. Suppose the whole carcass was equal to tenderloin; then it would be worth four times its present value in the market; or if equal to the fore rib, then double the present value. Fat is a dear product, and the less we have of it in the carcass, and the more we get of lean, tender, juicy meat, the better and more profitable it will be for producer and consumer. Fat is unhealthy food, particularly in warm weather, even in form of pork. The reason why the English and American people, who know their value, so much prefer the Berkshire breed of swine to all others for family pork, is, that they give a much greater proportion of lean meat to the carcass, especially in the hams and shoulders.

Rustic Gates for Hedges.

The formal gates of iron or of planed carpenter's work, that we often see in hedges, seem

Fig. 1.

out of keeping with the rural expression of the wall of living green upon each side of them. Gates of rustic-work, of pleasing designs, and well made, are appropriate in such places. Mr. J. V. Finbois, of Worcester, Mass., has given us designs for small and large gates, which are so simple that almost any one can construct them.

Fig. 2.

These, like most other rustic-work, should be made of red cedar poles, prepared by trimming off the twigs and branches, and leaving the bark as entire as possible. The ends are to be cut smooth and slightly rounded or pointed, to shed rain. "Figure 1, is a gate large enough to allow of the passage of carts; it is made of poles of from three to five inches in diameter. The two long pieces should be mortised into the uprights,

Fig. 3.

and the cross pieces may be bolted on, the heads and nuts of the bolts being counter-sunk. Figures 2 and 3, are small gates, made in the same

way. When neatly constructed, they are both pretty and durable. Figure 4, is a double gate with a roof. This is a rather novel form of gate, but is quite easily and cheaply built. The ends

Fig. 4.

are two posts placed about two feet apart; upon these a light roof with very wide projecting eaves is built, and supported by the cross braces which are bolted into the uprights. Between the uprights on each side is placed a shorter post, upon which the gates swing. The roof may be covered either with thatch or with cedar poles placed close together. If thatched with straw, wheat or rye will answer the best. A light pole must be placed a little above the eaves on each side, and held in place by three or four stones to keep the thatch smooth. In a hedge where there are a few tall trees, this roof has a very pleasing effect, and would add much to the appearance of a country place, besides preserving the gate from injury by the action of the weather."

The Seventeen-Year Locust.

(*Cicada septendecim*).

In the middle of June, as we drove into the grounds of a friend in Western Pennsylvania; we were quite surprised to hear, as we supposed, the sound of a threshing machine, and asked what they were threshing. "It is the locusts in the orchard," was the reply; "it is our locust year." We went to the orchard and found the trees filled with the insects, whose combined notes made a most remarkable din. It being the first time we ever happened to see

Fig. 1.

locusts in plenty, we watched their operations with much interest, and brought away specimens for illustration. Though called a "locust," the insect does not belong to the true locusts, but is a *Cicada*, or Harvest-fly, one species of which is common every year, though it does not appear in great numbers. The insect lays its eggs in little excavations made in the twigs of forest and fruit trees. The cavity is made obliquely, by means of a piercer, and from 15 to 20 eggs are deposited in it; then another cavity is made, and so on, until the insect has deposited between four and five hundred eggs. The appearance of the nests is shown in fig. 1. The twigs

thus perforated break off and fall to the ground, where in a few weeks the insect is hatched, or they may be hatched upon the tree and fall to the ground. The young insect is provided with very strong fore-legs, with which it burrows its way into the earth, where it lives for the remarkably long period of seventeen years in the grub state, living upon roots, not very far below the surface. The grubs slowly increase in size, and as the termination of their lengthy probation approaches, they gradually work towards day-light, making long and smooth cylindrical burrows that finally terminate at the surface. They issue at night in such numbers that the ground is completely honey-combed by their perforations. When they leave the earth they are still grubs, or rather pupae, and they immediately proceed to cast off the soiled suit they have so long worn in their subterranean life; it is no little effort for them to get rid of their old clothes. They

climb upon bushes and the trunks of trees, or any other convenient place for making their toilet, and fasten themselves by means of their claws. After some struggling the jacket opens at the back, and the insect pulls itself out of its garment, which is left standing entire, save the

Fig. 2.

rent through which its wearer escaped, (fig. 2). After the insect has stretched and dried itself, it goes to join its companions. Fig. 3 gives the perfect locust of the natural size. It resembles our common Harvest-fly in shape, but is more slender, its wings and body are marked with orange, and it has prominent red eyes. Near the tips of the wings there is a dusky line shaped much like the letter W, which has been considered by the superstitious to indicate war. The insects probably do much damage in the grub state to the roots of plants, and in their perfect condition the injury they cause to forest and fruit trees in perforating their twigs in the

Fig. 3.

manner already described, is considerable. They appear at only long intervals, and then in such astonishing numbers that any effort to destroy them would seem of no avail.

LIME VS. PHOSPHATE.—"T. W.," of Lancaster Co., Pa., asks: "Which is the cheapest fertilizer, Lime at 24 cts. per bushel, or Raw bone phosphate, at \$60 per ton?" With the same propriety we might ask him, "Which is the most economical beef at 20 cts. per pound, or cotton sheetings, at 30 cts. per yard?"—The two fertilizers named are entirely different in their action and uses in the soil. If they would both produce a similar increase in the crops, then the lime applied this fall and the superphosphate or bone-dust, applied upon spring crops, would probably give much better results. There are soils much benefited by lime, on which, after a while, it ceases to produce the same good effects. On such soils phosphoric acid is probably needed.

Wilson's Early Blackberry.

Whoever was instrumental in introducing the New Rochelle Blackberry, did a good thing, as it served to turn attention to a hitherto neglected fruit. Since then, other seedlings of merit have shown that the capabilities of the blackberry were not all exhausted in the New Rochelle. In October, 1864, we figured and described the Kittatinny, which is in every respect superior to the New Rochelle, and we now give a figure of Wilson's Early Blackberry, a variety possessing qualities that entitle it to especial notice. This variety was discovered in Burlington Co., N. J., by Isaac Wilson, who removed it to his garden about the year 1854, and there cultivated it for some years. It ultimately fell into the hands of some of the enterprising fruit growers of that section, who having tested and made known its merits, find that they have difficulty in propagating it fast enough to supply the demand for plants. While the Wilson is a sweet, productive and excellent berry, and ripe when it is black, its great value consists in its earliness, and the evenness with which it ripens. These are important qualities to the market grower, to whom a few days in the time of ripening is a matter of great pecuniary interest. The Wilson's Early yields the bulk of its crop before the Kittatinny and New Rochelle are ready for market. The picking of this variety is all over within three weeks, while the other sorts last much longer. While the Wilson can not supersede the other varieties we have named, it forms a most excellent companion to them, and by its greater earliness, prolongs the season of blackberries in a manner very important to the fruit grower.

The engraving is from a specimen from Mr. John S. Collins, Moorestown, Burlington Co., N. J., and shows the size, productiveness, and peculiarities of the leaf. We have seen the plantation of this variety of Mr. Wm. Parry, of the same Co., and were much pleased with the

vigor and productiveness of quite young plants. It is quite hardy near New York City, and we hope it will prove so farther north, as it is a valuable addition to our list of blackberries.

The engraving shows a peculiarity of the leaves that is quite characteristic of this variety. The leaves of the blackberry are usually three-

WILSON'S EARLY BLACKBERRY.

parted, but in this the divisions are often confluent, or run together, and sometimes one of the lateral divisions is entirely wanting, and the other joined to the central one, so that the outline of the leaf is like that of a mitten, the lateral division forming the thumb. When the plant is kept low, as it should be, by stopping the growth of the canes at four or five feet, this variety throws out a great number of fruit spurs, which are generally erect. It is a great mistake to allow any blackberry to make canes from six to ten feet high. Blackberries are easily multiplied by cuttings of the root, and one good plant will, with proper treatment, make a large number. This is done in the spring, and we shall give seasonable directions for doing it.

House Plants.

In spite of the many practical difficulties in the way of complete success, those who really love in-door gardening will contrive to have some growing things around them. Beginners in this work desire nothing so much as good ad-

vice; and we now propose to offer a little. First, then, in regard to air. So long as we warmed our houses by fire-places or open wood-stoves, and did not make our rooms air-tight, it was comparatively easy to raise house plants; but with air-tight coal-stoves and furnaces, and with hot, unventilated rooms, it is very difficult. Some measures must be taken to counteract this excessive dryness of the air. One method is to keep a pan of water in the hot-air chamber of the furnace; another to keep such a vessel on the stove in the apartment devoted to plants. And these pans of water should be so placed that they will evaporate several quarts per day. In addition to this, some persons adopt the following plan: Let the table for plants be as wide as the window-sill. Around the edge of this table fasten cleats about three inches wide, making a sort of sink or basin. Cover the whole of the wood-work with two coats of paint. Put into this basin

two inches sand, and cover the sand with one inch of fresh green moss. Set the pots on the top of this moss, slightly bedded in it. Any one can see that this will serve to diffuse moisture through the atmosphere, for the moss and sand will be saturated as often as the plants are watered. This is only one method for securing a healthy state of the air; let others be tried, which are practicable, for this is a very important matter. Of course, the room should be ventilated as often as possible, without injury to the plants from frost.

Secondly, as to soil. Different plants require different kinds of soil, for their highest health and vigor, but for the majority, the following answers an excellent purpose: A compost made of sand, leaf-mold, old manure, and earth from

an old pasture, in equal parts, well mixed.

Then, a few words as to watering, temperature, etc. It is a good rule to give water only when the ground is dry, and then to give it thoroughly, so that it will run through the ball of earth. No universal rule can be given, however. The African Lily, for example, needs water to saturation, while the Cactus family need but little. Watch the foliage, and never allow it to flag. Examine the soil, and never allow it to become dry. Experience will teach one when to water, by noting the sound of the pot when rapped with the knuckles, or by its weight when lifting it. Of course, the leaves should be sprinkled as well as the soil.

There is ordinarily more danger to our plants from heat than cold. As a general rule, 60° to 70° by day, and 45° to 50° by night, is high enough. The exceptions to this must be learned by experience.

About Lilies, Native and Foreign.

Plants that are readily obtainable by every one, are perfectly hardy, and are not particular about soil, commend themselves to popular favor. Most of the lilies possess these qualities, and we find them everywhere among the common plants. They are among the few flowers mentioned in the Bible, and one of them is the chosen emblem of purity. Every old garden has its clump of White, Tiger, and Martagon lilies—one or all of them; and though old and neglected varieties, they are not on that account to be despised. Indeed, for purity of whiteness and delicacy of fragrance, the old White lily may hold up its head among the more showy and costly newcomers. We have three native species common at the North, which, though seldom seen in our gardens, are highly prized in those of Europe. All of these, when introduced into the favorable soil of the garden, bloom much more finely than they do in their wild state, and they are moreover so common and readily obtained that even the poorest can have them. The Wild Orange-red Lily, *Lilium Philadelphicum*, is found in dry fields, etc. It produces only a few upright flowers, which are orange, with blackish spots. The Wild Yellow Lily, *L. Canadense*, grows in moister places than the foregoing. It has more flowers, which are nodding, and of various shades of yellow and orange, with brown spots. But the finest of our native lilies is the Turk's-Cap, or Superb, *L. superbum*. This will in cultivation often at-

tain a height of 6 or 8 feet, and produce a gorgeous pyramid of thirty or forty flowers, which have reflexed orange or scarlet petals, with dark purple spots. Any of our native sorts may be marked when in flower, and taken up when the foliage commences to wither. They bloom in July and August, and are all valuable, either by themselves, or in making up a collection. We have often mentioned the varieties of *Lilium speciosum*—or Japan Lily. This species, usually called by florists *L. lancifolium*, presents several varieties, all beautiful. The new and splendid Golden-handed Lily, *L. auratum*, was figured in

A. S. Fuller. This year a set of Japanese varieties, with such names as Iden Soto, Iska Wojarna and other Japanese names applied to them, have been introduced. We have flowered the most of these novelties, and can find no other quality than their earliness to recommend them. They are well enough in their way, but lack positive character. Lilies may be planted in autumn or in spring. They will do something in poor soil, but much better in one that has a plenty of old manure forked in to a good depth. We have said these lilies are hardy, and so they are about New York City, but even here, like other herbaceous plants, they flower all the better if they are covered with littery manure during the winter. Lily bulbs should never be long out of the ground, as they can not, like Tulips and Hyacinths, lose their proper roots without injury, although they will remain for some weeks in good condition, if packed in moss.

Bulbs—Plant Now for Spring Flowers.

Every one enjoys the spring flowers that come from the hardy bulbs, and yet we seldom see these in gardens, for the reason that they are forgotten in autumn—the proper season for planting them. As a reminder we will say, that the sooner, after the middle of October, the bulbs can be got into the ground, the better. If the bulbs are to be bought, purchase early, before the stock of the dealers becomes reduced. If the soil is not in good condition, it should be manured with old cow manure, and if disposed to be heavy, some sand may be worked in. The best success will be had if the old soil be dug out to the depth of twenty inches, and the space filled with fresh pasture loam and decayed cow manure.

THE LONG-FLOWERED LILY—*Lilium longiflorum*.

September, 1865, and though yet among our expensive bulbs, is one that we hope to see become as popular as the others. A rather old and neglected Japanese species is the Long-flowered Lily, *L. longiflorum*. This is seldom seen in gardens, probably for the reason that it was first introduced as a green-house plant. It is perfectly hardy, and throws up a strong stem, one or two feet high, which bears at its summit from one to three large and long flowers, of a pure whiteness and a delicious fragrance. In order to make this fine species better known, we give an engraving (of about half size,) from a specimen sent us by Mr. Isaac Buchanan, of Astoria. We have also had specimens of this beautiful lily from Messrs. Peter Henderson and

When the bed is prepared, let it settle, and then plant the bulbs. It is a good practice to put a little sand under each bulb. Hyacinths should be eight inches apart each way, and four inches deep. Tulips six or seven inches apart, and about three and a half deep. Crocuses may be nearer; three inches distant and two deep. Snow-drops, about the same as crocuses. Lilies are to be at least a foot apart each way, and five inches deep, and the same distance for the Crown Imperial. In making up the beds, it is well to leave them a few inches above the general level, as they will settle during the winter. Though the bulbs mentioned here are all perfectly hardy, yet they will come out all the stronger in spring, if covered when cold weather

sets in, by a layer of littersy manure, or leaves, which last may be kept down by sprinkling a little soil over them. Bulbs may be potted now and kept in a cool place until frosts come, when they may be placed in the cellar, from which they are to be taken during the winter at intervals, a few at a time, to a warm room to flower.

Insects and Plant Fertilization.

FIFTH ARTICLE.

Are all flowers then, it may be asked, aided by insects in the essential business of forming seeds? By no means. In many cases, where cross-fertilization equally takes place, the transport of pollen is left to the winds. Such flowers produce no honey, nor anything attractive to insects, and such flowers, we may add, have no showy corolla. So we may conclude that corollas, or bright colors in any part of the blossom, and also fragrance, are given to plants in order that they may attract insects, and be aided by them; an aid which many are absolutely dependent on. Not that all plants destitute of corollas get no help from insects. Willows, for instance, which bear stamens and pistils on different trees, as every one knows, are thronged by bees when in blossom, and the pollen is carried from the male to the female catkins. Pines, Spruces, and the like, on the contrary, are left to the winds to fertilize. And here it is worth while to notice what a great preponderance of male flowers these produce, and what a vast amount of pollen—many millions of grains for every female flower or seed—for, with only the winds to carry it, this seemingly wasteful superabundance of pollen is really a needful provision to secure fertility; while in Willows, where bees are invited to carry it from flower to flower, the proportion of pollen to the seeds is by no means excessive. Grasses and grains also depend upon the wind, and have accordingly a vast excess of pollen. Their flowers are most commonly hermaphrodite; but when the pollen is about to be shed, the anthers on their long and delicate filaments, and the feathery branching stigmas, are both hung out to the breeze together, so that there is sure to be a copious crossing.

Fig. 1.*

We now understand what the good of crossing is, and it may be asked, is crossing provided for in all flowers? Are there any hermaphrodite flowers in which self-fertilization is regular or certain? Yes: there is one class of such cases. Most of the earlier flowers in our Wild Balsam, Jewel-Weed, or Touch-me-not, fertilize in the early flower-bud; and so do most of the later flowers of Wood-sorrel, and of our common Violets. These flower-buds never open, have no showy corolla to attract insects, and no pollen but their own can reach the stigmas. These and the few stamens are shut up close together. Nature here being as careful to secure close-fertilization as she ordinarily is to prevent it.—Two things about this are worth

Fig. 2.

noticing. First, since fertilization is made sure by shutting up the anthers in close contact with the stigma, there need be no superfluity of pollen; and it is a remarkable fact that these anthers really contain only a dozen or two of grains of pollen, but these are large and unusually efficient, and almost every one of them does its work. Nature so prodigal where she has only winds and chance to rely on, but less so when insects are carriers, is parsimonious enough when her arrangements are such that no pollen is likely to be lost. Secondly, all plants which produce flowers of this kind (of which many are known), have ordinary blossoms also, with showy corollas, open to the visits of insects and actually cross-fertilized by their aid; so that the advantage of a cross is secured for each generation in a part of the flowers, while certain fruitfulness by close breeding is economically secured in the rest. We may fairly suppose that the latter could not go on for many generations unless it were alternated with the former. For if it could, what would be the use of the former sorts, which are always less prolific than the latter? No plant is known in which at least an occasional cross-breeding is not provided for.

At first view, however, we should say that we have just such a case in all the Fumitory family. Here there is only one kind of blossom, and that seemingly contrived on purpose for self-fertilization. The Showy *Dicentra*, commonly called *Dielytra*, of late years a great ornament of our gardens in spring, is the most conspicuous example. The red, heart-shaped corolla is seen, unopened, in fig. 1. The tips of the two outer and larger petals soon roll backwards, as in fig. 2. But the inner and smaller pair of petals remain stuck together at the tips, and may be likened to a pair of little spoons in contact, face to face; the cavity so formed completely shuts in the six anthers, closely surrounding the 2-lobed stigma. The anthers open early, and on their inner face, and the pollen is abundantly shed upon the enclosed stigma. Here, we should say, close-fertilization is a sure thing, and crossing is out of the question. But consider, first, that there is nectar in the sac at the bottom of the large petals; also that bees, especially humble-bees, visit these flowers; in reaching the nectar the bee brings his head down to the opening at the upper part of the flower on each side. When thus sucking out the nectar from one side of the flower, his head pushes the cap formed of the inner petals off to the other side, i.e., into the position represented in fig. 3, and brushes against the now exposed anthers and stigma. Some of the pollen which thus smears the head of the bee, carried to the next flower, is most likely to be in part deposited upon its stigma. So that here, after all, we have a beautiful arrangement for cross-fertilization! In both the *Dicentra* and in the smaller one-sided but otherwise similar blossom of *Corydalis*, we have seen the bees at work, carrying the pollen rapidly from flower to flower, and from plant to plant. And the crowning and very curious fact has recently been ascertained by experiment, that if insects be excluded, even these flowers set little or no seed. Yet the stigmas get completely covered with pollen from

Fig. 3.

their own stamens! So it must be that the pollen is powerless, or nearly so, upon the stigma of the same flower, but is efficient upon the stigma of neighboring flowers; and that breeding in-and-in, which seemed unavoidable from the structure of the blossom, is here prevented only by this differentiation of the pollen and stigma. The proof that this is really so, as shown by some other flowers, will be given in another article. A. G.

Preservation of Vegetables in Winter.

BY PETER HENDERSON, SOUTH BERGEN, N. J.

The following timely article is a chapter from Mr. Henderson's forthcoming work on Gardening, alluded to in the "Basket."

"Our manner of preserving vegetable roots in winter is, I think, peculiar to this district, and is very simple and safe.—After taking up such crops as beets, carrots, horse-radish, parsnips, turnips, potatoes, etc., in fall, they are put in temporary oblong heaps, on the surface of the ground on which they have been growing, and covered up with 5 or 6 inches of soil, which will keep off such slight frosts as are likely to occur until time can be spared to put them in permanent winter quarters, this is done in this section usually during the first part of December, in the following manner: A piece of ground is chosen as dry as possible; if not naturally dry, provision must be made to carry off the water, lower than the bottom of the pit. The pit is dug out from three to four feet deep, about six feet wide, and of the length required; the roots are then packed in in sections of about two feet wide across the pit, and only to the height of the ground level. Between the sections, a space of half a foot is left, which is filled up with the soil level to the top; this leaves the pit filled up two feet wide in roots, and half a foot of soil, and so on until the whole is finished. The advantage of this plan is, that it is merely a series of small pits, holding from three to five barrels of roots, which can be taken out for market without exposing the next section, as it is closed off by the six inches of soil between. Also that we find that roots of all kinds keep safer when in small bulk, than when large numbers are thrown into one pit together. In covering, the top is rounded so as to throw off the water, with a layer of from 18 inches to 2 feet of soil. This way of preserving roots, with perhaps the exception of potatoes, is much preferable to keeping them in a cellar or root house, as they not only keep fresher, retaining more of their natural flavor and color, but far fewer of them are lost by decay than when exposed to the air and varying temperature of a cellar. Unmatured heads of cauliflower or broccoli, however, are best matured in a light cellar or cold frame, by being planted in close together; in this way good heads may be had to January. Cabbages are preserved very simply; they are left out as late as they can be pulled up by the roots, in this section about the end of November, they are then pulled up and turned upside down—the roots up, the heads packed close together, in beds six feet wide, with six feet alleys between, care being taken to have the ground levelled where the cabbages are placed, so that they pack nicely. They are left in this way for two or three weeks, or as long as the ground can be dug between the alleys, the soil from which is thrown in on the beds of cabbage, so that when finished they have a covering of four or six inches of soil. This is not enough to cover the root however, which is left partly ex-

* Figs. 1 and 3.—Flowers of *Dicentra spectabilis*; 1, unopened; 2, open; 3, with the united inner petals pushed off to one side.

posed, but this is in no way injurious. Some prefer to cover them up at once by plowing a furrow, shoveling it out wide enough to receive the heads of the cabbages, then turning the soil in on the heads, and so continuing until beds of six or eight feet are thus formed. This plan is rather more expeditious than the former, but it has the disadvantage of compelling them to be covered up at once by soil, while the other plan delays it two or three weeks later, and it is of the utmost importance in preserving vegetables that the operation (particularly the final covering) be delayed as late in the season as frost will permit. Generally more is lost by beginning too soon than delaying too late.—Onions, we find, are best preserved in a barn or stable loft, in layers of from 8 to 10 inches deep, covered up with about a foot of hay or straw on the approach of severe frosts. The great point to be attained is a low temperature and a dry atmosphere; they will bear 20 degrees of frost without injury, provided they are not moved while frozen, but they will not stand a reduction of temperature much lower than this without injury.

Notes on Grapes and Grape Culture.

The date at which we write is too early to allow us to say what is the result this year with the newer varieties of grapes. We hoped to have met at the gathering of the American Pomological Association, at St. Louis, cultivators from every section of the country, and thus arrive at something like an "average verdict" upon the numerous grapes that are still on their probation. The unfortunate postponement of that meeting is a great disappointment to us, and will prove a serious detriment to the cause of horticulture in general, and to grape culture in particular. People are sufficiently waked up to the importance of planting vines, and the universal question is, "what shall I plant?" And we are no nearer a satisfactory answer than we were five years ago. The Hon. Horace Greeley, noticing during a recent trip in New England, the general failure of the large fruits, comes out with a strong appeal to the people to plant vines, and concludes it in the following characteristically practical way:

"I hope our Agricultural Societies and Farmers' Clubs will devise and adopt fit measures to stimulate the planting of the Vine; meantime, I, as a mere beginning, will pay a premium of \$200 to the first, and \$100 to the second township of not less than 100 houses, whose three principal officers shall certify to me that every dwelling in that township has not less than two well planted, thrifty Vines."

Doubtless many townships will take steps to obtain these premiums, and we shall have numerous applications for advice as to what to plant. Here is just the trouble and the point upon which people honestly differ. The only two varieties that we are able, with our present knowledge, to suggest for planting anywhere and everywhere with a fair prospect of fruit, are the Hartford Prolific and Concord. While we are well aware that neither of these can rank as first class grapes, they will, as a general thing, give fruit, and are more commonly free from disease—though not absolutely exempt—than most other sorts. We have many much better grapes than these, that in certain places are about all that can be desired, and we should be glad if we could recommend every one to plant them largely without previously testing them. The experience of one or two years in a few localities should not make or mar the reputation of

any variety. We recently saw the Creveling, a variety with a generally excellent reputation, almost killed with mildew, while along side, the Adirondac, a variety often badly mildewed, was freer from it than any other in a quite large collection. We ask one cultivator about his grapes, and he tells us that his Concorde are doing well, but his Iona's are badly mildewed; and another, in reply to the same query, says he has some mildew, but the Iona the least affected of any. In respect to the quality of the fruit of the leading varieties now before the public, we are well enough satisfied, but with regard to their hardness and freedom from rot and mildew, we are in as much uncertainty as ever. Now, will our grape growing readers help us to do what the Pomological Association ought to have done: give some grape statistics? We would like brief reports from all parts of the country, giving the behavior of the different varieties, age of vine, time of ripening, freedom from mildew, rot, sun scald, and hardness of vine. The soil and exposure of the vineyard should also be stated. If a sufficient number of these reports are received, they will be tabulated, and will probably show results both interesting and useful.

Small Fruits—New Raspberries.

It may appear to some that we devote an undue space to the culture of small fruits; but such have little conception of the great importance of this interest. Those who grow their broad fields of grain, no doubt look upon the growing of berries as small business, but a visit to any of the small fruit regions would convince them that "man does not live by bread alone," but uses a great deal of fruit with it, and that often times, these potters with small fruits, realize more ready money from a few acres than does the proprietor of an extensive farm.

Many an occupant of a place of a few acres near our country towns can pay a good part of his rent by attention to the culture of small fruits. This is one reason why we desire to keep the readers of the *Agriculturist* informed of all the new varieties that appear worthy of trial.

The great trouble with the raspberry has been want of hardness, and cultivators are now endeavoring to produce varieties that shall combine good quality with productiveness and hardness. We gave in August an account of the Philadelphia Raspberry, and now give brief descriptions of two others, which are likely to attract some attention. The descriptions are given from Fuller's Small Fruit Culturist, in advance of the appearance of that work.

THORNLESS BLACK-CAP.—Canes strong, very erect, and more branching than other varieties of this class, reddish purple, smooth and thornless. Leaves medium sized, occasionally with a very small prickle on the petiole. Fruit large, shaped like the common Black-cap, black, sweet, and rich; ripens a week earlier than the Doolittle.—An accidental seedling of the common Black-cap, which originated in the gardens of Mrs. Davison, Erie Co., N. Y., and sent out by Joseph Clinton, Angola, N. Y. It is exceedingly productive, and would be a valuable addition to our list of varieties, even if it had no other merit than that of being thornless.

CLARK.—Canes strong, erect; spines stout, numerous at the base of the canes, but scattered above, white, with the tips slightly colored. Leaves large, coarsely and unevenly serrate, wavy when young, but becoming flat and smooth with age, deep shining green above and silvery white on the under surface. Fruit large,

regularly obtuse conical, separating freely from the receptacle, moderately firm; grains medium in size, of a light crimson color; flavor very sweet and rich.—This variety—a very productive and hardy one, for one of its class—originated with E. E. Clark, of New Haven, Conn.; it promises to be one of the very best for family use, and also an excellent market berry, where the distance is not very great.

Heeling-in Trees.

The nursery man heels-in his trees or "lays them in by the heels" as soon as they are dug, provided there is to be any considerable interval between the taking up and the packing. It is something which may be practiced to advantage by the purchaser of trees whenever they are received from the nursery, and cannot be set immediately they arrive. Indeed, if trees are needed for planting next spring, it is much better to purchase them this autumn, and carefully heel them in for the winter. There are several good reasons for purchasing trees in the fall. The work at the nursery is much less hurried, the stock of varieties has not become reduced, the risks of transportation are much less, and in spring the trees will be on hand just when they are needed. The operation, to be successful, needs only a little care. A trench is to be opened, in a well drained place, wide enough to admit the roots, and deep enough to set the tree lower than it stood before. The trees are placed in an inclined position, to prevent the tops from being too much exposed to the winds, and they are set in close together, the roots being spread and carefully covered as the work progresses, allowing no vacant spaces. The earth is then banked up over the roots to the depth of a foot, trodden hard, and smoothed off to shed rain. Tender varieties of trees may have their tops covered with evergreen boughs.

The Tritomas.

These showy autumnal plants, now coming into blossom, deserve repeated and unstinted commendation. Their long, lance-shaped leaves look attractive during the early summer, and hardly need the addition of flowers. But when August and September come, the early variety (*Tritoma glaucescens*) sends up its blooming stalks, from two to four feet long, and eight or ten from a single root, crowned with spikes of orange-crimson blossoms which are truly gorgeous. In September and October, the later sorts (*T. scrotina*) follow, keeping up a constant and brilliant succession of blooms. A figure was given in November, 1864, of *T. Uvaria*, from which most of the garden varieties have been obtained.

It is truly remarkable, how independent and almost regardless of frost these plants are. Cold weather, which blackens the dahlia and kills down a multitude of other flowers, only seems to give these a new start. In England they keep on blooming up to Christmas. And in our country, medium sized plants may be taken up in August and potted, when, if watered and shaded a few days, they will go on growing, and will flower in the house till into December. This we know from experience.

Some persons winter their plants in the cellar, like cannas and dahlias. But this is unnecessary trouble. Bend down the stalks on the setting in of winter, lay over them a few inches of leaves or other garden refuse, then cover the whole with a roofing of sods, laid up

like a mound, so as to shed rain, more or less. In the spring remove this by degrees, and the plants will come out in first-rate condition.

Hedges and Hedge Plants.—2d. Article.

THE SWEET VIBURNUM.

In the article last month, it was stated that we had made little progress with hedging in this country, until native plants were taken for the purpose. There are doubtless many shrubs that are capable of forming good hedges, which have not yet been tested. The subject of the present article is one we have long thought would make a good hedge plant, but we did not know that it had been tried, until we received the subjoined communication from a valued correspondent, who is a great lover and close observer of trees and shrubs. The Sweet Viburnum, *Viburnum Lentago*, is quite common all over the country, and often forms a small tree, fifteen or twenty feet high, covered in May and June with clusters of white flowers, like those shown in the engraving. The flowers are succeeded by a small, one-seeded, berry-like fruit, blue-black in color, and ripe in autumn. The shrub belongs to the same genus as the common Snow-ball, but has all its flowers perfect, while in the Snow-ball, all or part are sterile, and very much larger. As an ornamental shrub it is worthy of more attention than has yet been bestowed upon it.

"Whoever travels in Westchester County in the last half of May, notices the Dog-woods in full bloom, and not less their companions in whiteness and beauty, the 'Nanny-berries.' It is known as the Sweet Viburnum, and in other localities as the Sheep-berry, probably from the fact that it flourishes in sheep pastures in spite of all the shortening-in it gets from those close nibblers. The goat is supposed to give it its name 'Nanny-berry,' and it is one of the best certificates of its extreme hardiness and vitality, that in highways and pastures it survives all the croppings of the goat, which makes a clean sweep of briars and most other shrubs. It was its low bushy head, formed under such treatment perhaps, that first suggested its use as a hedge plant. It is certainly one of the best of all deciduous shrubs for that purpose, and nothing but its commonness and cheapness can prevent it from having a rapid run and wide spread popularity for hedges.

A good deciduous hedge plant is still a desideratum. The Hawthorn, which is the glory of English hedges, and so prominent a feature in their landscapes, does not do well in our more fervid summers. We have never seen a good one this side of the Atlantic. The Osage Orange has many admirable qualities, but is not entirely hardy in all parts of the North. The Privet and Buckthorn, among the best, are very slow growers, and tax the patience of the planter.

Nothing that we are acquainted with meets all the requisites of a good hedge plant so com-

pletely as this neglected bush. It is a beautiful thing, cultivated simply as a flowering shrub, standing solitary beside the walk or carriage drive, or in masses in the midst of the lawn. Unlike the Dog-wood, its flowers will bear the closest examination, and a shallow dish filled with these flowers and leaves, is one of the most attractive ornaments of the center table in the month that boasts so much of floral beauty. Then it is a very hardy plant, thriving under

SWEET VIBURNUM.

neglect, and bearing any reasonable amount of shearing. In the hands of the gardener it is as plastic as the Box or the Yew, and may be moulded into any desirable shape. Planted in good soil and properly trained, it makes a thick hedge, impervious to the light, and strong enough to turn cattle.—It is easily multiplied from the seed, old pastures and woodlands abounding in young plants that have been sown by birds and cattle. In the neighborhoods where the shrub is already established, plants suitable for hedges are readily procured from the pastures. Those growing in the open ground, and that have been subjected to the severe cropping of the sheep and goats, are to be preferred.

In the grounds of R. L. Franklin, of Riverdale, may be seen a hedge of this plant only five years out. It is as perfect a specimen of live fence as can be found around any of our suburban residences, and that is saying much. As an example of the capabilities of the Sheep-berry for a hedge plant we regard that hedge as a great success."

We have no doubt that the plant will be valuable in the Northern sections of the country, though Mr. Mechan, who gives great attention to hedge-plants, informs us that near Philadelphia it has a somewhat rusty appearance in mid-summer.

Make Cuttings in Autumn.

A number of our hard-wooded plants are most easily propagated from cuttings. Among those most commonly multiplied in this manner from mature wood, are the currant, gooseberry, quince, grape, rose, etc., and it is probable that many of our ornamental shrubs, not usually propagated in this way, will succeed if properly treated. Any one who has ever watched the progress

made by a cutting will have found, that before any roots appear, there is a sort of growth going on. After the cutting has been for a greater or less time in the soil, there appears at the cut surface, and often at other points above it, an irregular whitish growth, which, if it occurred in the human subject, we should call "proud flesh," and that finally roots are pushed from this growth, which in gardener's language is called a "callus." When a twig is cut from the parent plant and placed in favorable soil, it puts forth an effort to live and form a new plant. It is without roots, through which to take up nourishment, and although it may apparently be vigorous for a while, and push out a new growth of stem and leaves, these are only produced at the expense of the material *already stored up* in the cutting, and after a brief season it dies. It is only when the cutting makes a *root* that it lives, and the first step towards making a root is the formation of the callus above mentioned; and this, like the leaf growth first alluded to, is formed at the expense of material on hand in the tissues of the twig or cutting. If this material be expended in leaf growth, as a general thing, no roots will be formed, hence it is the object of the propagator to induce the formation of a cal-

lus and roots rather than of stems and leaves. When artificial heat is used, the operator has the matter quite under his control, as he has only to keep the soil some degrees warmer than the air above it. In out of door propagation, in which our readers are most interested, these conditions are best attained by setting the cuttings in autumn, as then the soil is warmer than the atmosphere, and the callus (and even roots in some cases) forms before severe weather sets in. Cultivators well know that if a cutting be once callused, it is pretty sure to grow, and it often happens, if cuttings be made in fall and be kept in moist sand or sandy soil, out of the reach of severe cold, that the functions of vegetation will go on, and a callus be slowly formed, which, when the cutting is set out in the spring, quite surely emits roots. Quince cuttings done up into bundles, with their lower ends dipped for one third their length in thin mud, may be set in the cellar and occasionally watered. These will callus finely during the winter, and be ready to set in spring. Other cuttings would doubtless succeed with the same treatment. In setting cuttings of any kind, the soil should be firmly pressed about their lower ends, and attention to this will often determine success or failure. Currant, gooseberry, quince, and the

easier growing grapes, may have the cuttings made and put out as soon as the leaves have fallen. Where grape cuttings are to be used for in-door propagation, it is better to make them before the vitality of the wood has been impaired by severe cold weather. Cuttings of roses may be made as soon as the wood is well ripened. The leaves are removed, and the cuttings set in a cold frame, where they can be protected by covering from very severe frosts. Of course there are many plants that require all the skill and appliances of the experienced propagator, but those we have mentioned, and many others, may be propagated in the open ground with success by any one who will bear in mind the principles above indicated.

THE HOUSEHOLD.

Men's Shirts—A Woman's "Say."

[The "All about Men's Shirts," published in the August *Agriculturist*, page 293, has been the source of no little amusement. A great many write that "it's just my experience." The only one who attempts a solution of the difficulty, writes that "she thinks as a rule, ladies do not measure with enough mechanical accuracy. They are accustomed to loose garments with many yards and many folds, where an inch more or less is not noticed, while half an inch makes a great difference on a neck band that is designed to fit close to the neck, and yet not to come in so close proximity to the wind-pipe as to impede free breathing. I have seen a lady cut half a dozen shirts by one pattern, and assert's that they were all *just alike*. Yet I showed her by a careful measurement that there was a variation of $\frac{1}{2}$ to $\frac{3}{4}$ inch in the length of the neck binding. Again, a difference is made in gathering; and the amount of starching varies the ease of setting. Too much starch and wrinkled edges or folds will make a close fitting shirt neck very uncomfortable, which would feel easy if lightly starched and smoothly ironed. Still again, if the shirt is tight and draws behind the shoulders, it may pull back the neck binding, and make one very uncomfortable, especially when perspiring a little, so as to cause the shirt to stick and draw more than usual. I have found relief from former trouble, after getting one shirt to fit: 1st, by copying it with special care in cutting to have the pieces of exactly the same size, looking after the stretching of the fabric when laid down for cutting, etc.; 2d, by cutting the back and shoulders so that they cannot draw upon the neck; 3d, care not to over-wrinkle or contract the binding in gathering it on; 4th, care to have the neck band but lightly starched and uniformly ironed smooth on the inside...."]

Another urges us to publish anonymously her side of the subject, which we will do, though under protest, for the whole force of it seems to us to lie in the last sentence. Our observation is that those people are the happiest and get along best, who never say or feel "I won't yield." The best way is to harbor not so much as a thought about man's rights or woman's rights. These thoughts are always the beginnings of sorrow. The man and wife become one, and if they *feel* this, they will have no disputes about mine and thine, but consider each the others pleasures and miseries as *ours*. Well, here is the letter:

"I cannot claim to have had the supervision of a man's wardrobe quite 12 years, but would not the experience of a woman for 11 $\frac{1}{2}$ years be of a little value? I think your extract was very properly taken from 'Hours at Home,' for I should certainly think a woman with such an experience, would have found it *very necessary* to devote quite a number of her hours to her home.—I think the fitting of that shirt was the fault neither of the garment, nor of the maker, but simply of the wearer himself. There is surely no inherent wickedness either in cotton or woolen cloth.

In Adam's fall We sinned all;

but most certainly sin does not (in *this* manner) entail upon the *manufactures* of our hands. When in the garden our first parents sewed fig leaves together and made themselves garments, it is no where recorded that *Adam's* did not fit him. I think, therefore, that although originally woman was equally guilty with man, yet during the lapse of ages, man has gradually gained the ascendancy in wickedness, and the excess of the evil in his nature manifests itself specially in animadversions upon his luckless shirts.—How rarely you hear of a very great or good man spending his time moaning over the fit of such a garment. I really think Washington, Lincoln, Napoleon, etc., had a few other matters that demanded and received a small share of their attention. But seriously, I have had no trouble. To be sure every one can not expect to possess such a husband as I have. I have made and altered a great many shirts, but not more than I have other garments. *My* husband never invites me to ride, in order that he may incidentally grumble about his shirts; and I insist upon it, the trouble is in the men and not in the garment. Of course it requires skill in cutting and making, patience in altering when necessary; but none the less does it require in the wearer the manly quality of being satisfied with a really good fit. Does man, imperfect man, alone, expect perfection? Women do not. I do not say they do not wish it. (I certainly should think the one that had the trouble with *that* shirt would.) Simply they do not expect it. I am willing to cut, fit, make, unmake, and remake garments both for myself and husband, but when a reasonable amount of time and attention have been given them, if they will not fit nicely, we wear them as they are; neither of us grumble. *My* husband is unselfish; he thinks it equally important that his wife's bonnet and dress should fit tolerably, as well as his own shirts fit to a *T*; and I think my husband's pants, coats and vests should require equal attention with his shirts. *My* husband (I speak not boastfully) has known no hand but mine to make his clothes since first I claimed his name, to say nothing of my own garments. Now where should I find the time for all this, if my whole life had been devoted to fitting and re-fitting shirts. It is simply a morbid feeling, and a true wife's duty not to yield to its demand."

Husk Mattresses—Cheap, Comfortable, and Healthful.

Our rural friends are very hospitable, when we visit them they treat us during the day with the greatest kindness, but they are often cruel to us at night, and most always consign us to a feather bed, in the smothering depressions of which we pass a sleepless night. That a feather bed is a fit thing to sleep upon, is an idea rapidly disappearing, we are happy to say; yet in many communities feathers still prevail, and they are looked upon as silk dresses are, in some measure an index of the wealth, or competence of the owner. It is quite time that all this was changed, and comfort and health consulted, rather than show. We say comfort,—for no one after having slept for a few weeks on a hard bed, would willingly return to feathers. Curled hair makes the very best mattress, but is expensive; the next best thing is corn husks, a cheap material, and accessible to all. The inner husks, or shucks, as they are called in some places, allowed to curl up a little, are often used without any preparation. A softer bed is made by slitting the husks in strips, half an inch or so in width; a fork may be used to facilitate stripping. The best-husk-bed we ever saw was made from the husks of green corn, shredded by drawing through a flax hatchel. Husk-beds should be opened about once in six months, the husks shaken out from the fine particles and dust, be sprinkled, and allowed to lay in the sun for a while. Treated in this way the husks will be almost as good as new. We give this timely hint, in order that at husking time, those who would enjoy the luxury of a husk bed may take measures to secure the necessary material.

Original Contributions to the American Agriculturist.

Hints on Cooking, etc.

Chess Pie.—For two pies of common size, take 4 eggs, 2 cups sugar, 1 cup cream, $\frac{3}{8}$ cup butter, 1 tablespoonful flour, and flavor with nutmeg. Cover the baking plates with crust, pour in the mixture, and grate nutmeg over it. There is no upper crust. When a pretty brown, try with a spoon as for custard. This is the best pie we ever ate.—*Mrs. Samuel P. May, Grimes County, Texas.*

Apple Pudding.—Beat 2 eggs well with 2 tablespoonfuls of sugar; add butter the size of a walnut, or 2 tablespoonfuls of cream, and 1 pint buttermilk. Add flour sufficient to make it a little thicker than for griddle cakes. Take one small teaspoonful saleratus, dissolve in a little warm water, and put in with about 4 large apples sliced (sour apples); stir it together well, turn it into a pudding pail (or some pail with a cover), and set in a kettle of boiling water, covering the kettle; boil hard 2 hours; serve warm with sweetened cream, or milk, or sour sauce.—"*Novice,*" *Portage Co., O.*

A Cheap Tea Cake.—Take 1 cup sour cream, 2 cups flour, 1 cup sugar, 2 eggs, 1 even teaspoonful soda, flavor with vanilla. Beat the whole well together, and bake in a quick oven.—*Mrs. M. Ingalls, Muscatine, Iowa.*

Delicate Cake.—Take 1 cup flour, 1 cup white sugar, $\frac{1}{2}$ cup butter (stirred to a cream with the sugar before using), whites of 3 or 4 eggs stirred in last. Flavor with vanilla, rose water, or lemon.—*Mrs. M. Ingalls.*

Cream Cakes.—Take 2 cups flour, 1 cup butter, $\frac{1}{2}$ pint water; boil water and butter together, and stir in the flour a little at a time while boiling. When cold add 5 eggs beaten, and stir in $\frac{1}{4}$ teaspoonful soda. Make into cakes $\frac{1}{2}$ inch thick and 2 or 3 inches in diameter, and bake in an oven ready hot, not disturbing them until of a light brown. For inside or cream, beat together 2 eggs, 1 cup white sugar and $\frac{1}{2}$ cup flour, and stir in 1 pint of boiling milk, flavoring with lemon. Split the cake partly open with a knife, and put the cream inside.—*Name of writer unknown.*

"Tomato Wine."—To "Old Subscriber," Newark. We seldom notice any letters not accompanied by the real names of the writers. You mistake; the *Agriculturist* (vol. 16, p. 236) did not say of the tomato wine or cordial made by the following recipe, "that it would puzzle the best judges to tell the difference between it and the best madeira," as you quote, but simply said, "to one skilled, even in grape vines, it is *difficult* to distinguish its origin." The directions are: "Select and mash *well ripened* fruit; press out the juice; add 1 pint water and 1 lb. sugar to each quart of the juice, and set away in a partially filled vessel to ferment similarly to grape wine. After fermenting sufficiently, put in tight kegs and keep in a cool dry cellar until spring, when it may be carefully drawn off and bottled, adding a small piece of ginger root to each bottle. When opened for use, a brisk effervescence takes place." [The "piece of ginger," if large enough, may make it a ginger wine, or ginger alcohol.—*Ed.*]

Making Pickles.—*General Hint.*—From an examination of a considerable number of the recipes most highly commended, and those found most valuable in our own experience, it appears that almost all kinds of pickles keep far longer and are better, if the first pickle be poured off after a week or two, and a new hot pickle be substituted. The first liquor extracts the disagreeable and easily fermenting and molding properties of the fruit or vegetables to be preserved.

Sweet Pickles.—*Very Good.*—The following directions, furnished to the *American Agriculturist* by Miss S. C. S., have been tested by us for several years, and are well approved: For SWEET APPLES, PEARS OR QUINCES.—For $\frac{1}{2}$ peck of fruit, pared and cored, make a syrup of 1 pint of vinegar and 2 lbs. of white sugar, and cook the fruit in it

until tender. Remove the fruit from the syrup to a jar, and pour over it a *new* syrup made by boiling 1 pint vinegar with 2½ lbs. sugar, with a little bag of spices in it, containing say ½ ounce each of cloves and cinnamon, and a ¼ ounce mace if liked; the spice bag to go in with the fruit also. The first syrup may be used for cooking other fruit. The pickles made as above keep almost any length of time, if simply covered. They are economical, are only moderately tart, and are much relished by most persons. . . PEACHES pickled are especially fine. They may be pared, or for general common use be pickled with the skins on, but must be separately wiped or rubbed with a cloth. Place the fruit in a stone jar, and pour on it a syrup made by boiling for each 12 lbs. of fruit, 4 lbs. of white sugar in 1 pint of vinegar, and cooking it. Place the jar in a kettle of cold water over the fire, and heat until the fruit in the jar is cooked tender. Spice with an ounce or so of cloves, put in a bag, and placed among the fruit. Some prefer sticking the cloves separately in the peaches. After standing 3 or 4 days, pour off and scald the syrup and return it. They will then keep well through the winter without further trouble.

Pickled Green Tomatoes.—The following method we have used several seasons, and the pickles have often been commended by visitors, and the recipe solicited. Cut the tomatoes in thin slices and scald them in weak salted water. Lay them in a jar, sprinkling each layer with a little sugar and a trifle of ground mustard and cloves. Scald sufficient vinegar to cover them, and pour it over while hot. After 8 or 10 days drain off the vinegar, and reject it. Scald a fresh supply and pour it over them hot. If horse-radish is available, a little of this grated or chopped fine added in the new vinegar is an improvement. The pickles thus made are tender, and keep a year at least with no mold. If left in the first vinegar, they soon spoil.

Tripe—A Good Food—Preparation.
—Tripe is a wholesome, nutritious food, and would be more generally used but for an unwarrantable prejudice, and the supposed trouble of preparing it. It is obtained from the larger stomachs of all ruminating animals, but usually from beef cattle. Two subscribers to the *Agriculturist*, furnish simple directions as follows: H. B. Cartwright (residence not given) says: "Scald the stomach sufficiently, to loosen the inside coating, in water about the same temperature as for scalding hogs. Hang upon a hook, and with a knife scrape off the inside coating, which will be easily removed if rightly scalded. Then cut in five or six pieces, boil for an hour, and scrape again until perfectly clean. After this boil until tender, when it is ready to use in any way." . . . Sarah Young, Washington County, O., writes: "Take the stomach or paunch while still warm after killing, and wash thoroughly in three or four waters to remove all disagreeable odor and taste. Cut in convenient pieces to handle, and taking a piece at a time on a fork, scald it in hot water, lay it on a board and scrape off the inner coating, which is easily done if scalded just enough."—It is then to be well washed and cooked as may be desired. Boiling will make it tender. It may then be pickled in vinegar, or kept in salt and water, changed daily. It is good cooked like souse, or broiled like steak, buttered, and peppered well. It is also good dipped in batter and fried.

To our Household Correspondents.
—We have quite a batch of recipes on hand, some waiting room, some on trial, some for their proper or best season, etc., and some are duplications of things already published. — We solicit continued contributions to this department—on other topics than mere cooking recipes. Let us have hints about clothing, furniture, etc.

Give the Particulars.— "Miranda" writes: "I desire to ask contributors to the Household Department to be a little more explicit. For example, one says, 'use flour or meal enough to make of proper consistence'—now that proper consistence is just what I want to know."—[The hint is worth noting. We have ever aimed at getting in all the particulars possible so as in every

case to make the matter so plain that the merest novice can follow it.—Some old housekeepers however, say that the *Agriculturist* simplifies too much—the Editors seem to take it for granted that ladies don't know how to mix the ingredients of a cake without having it all explained. We give the particulars for those who don't know—those who do can pass by such explanations.—Ed.]

Hints to Butter Makers.—(Derived from experience.)—When cream is to be kept a few days or a week in warm weather, a teacupful of salt to a gallon of cream will help to keep it from spoiling. Put the salt into the first gathering of cream, or into the clean cream pot.—Another item quite as important, is, to stir the cream frequently and thoroughly—once a day at least, twice or thrice is better. . . . An ounce of salt to a pound of butter, after the buttermilk is out, is the rule of many good dairywomen who make butter for the Boston market. This is the minimum, I think. Some put 2 ounces to the pound. If to be packed it requires more salt than if put in rolls for immediate use.—S. C. W., of West Rutland, Mass.

To keep Burnished Steel from Rusting.—The simplest, easiest and most rational way we have ever employed, is the following. Take a box (tin is best) large enough to contain all the articles and not half fill it. Then take some quick lime, break the lumps up and sprinkle them with water, so that they will fall to pieces and yet become not nearly slaked. Put this half-slaked lime into the box and bury the steel articles in it. They will keep bright and clean, and need only dusting when taken out. Steel or iron will not rust unless water or dampness comes in contact with them. The unslaked lime has such an affinity for water that no particle of moisture can exist in the box, so long as the thirst of the lime is not entirely slaked. So the steel remains bright. If the box is well closed, the lime will be good for six months, and perhaps longer.

BOYS & GIRLS' COLUMNS.

New Weights and Measures.

Congress has commenced talking about making some changes in the weights and measures used in this country, and by the time the present boys and girls very probably grow to be men and women, some new system will be generally adopted. It usually takes many years to introduce any great change, especially in things in common use; our weights and measures certainly need some improvement. It seems probable that the French system may be introduced to this country, and perhaps this or something like it, will come into use all over the world—it would be a great convenience to business men to have but one scale of measures in dealing with all other countries. As it is now, a merchant doing an extended business needs to study the arithmetic of almost every country, to know how to buy and sell goods, as almost every nation has its own system of denominations. The French system has some very great advantages. In it, all the denominations of every weight and measure increase by tens, just as in our United States money, ten of a lower denomination makes one of the next higher, and also as in writing numbers, each place to the left is tenfold greater. Suppose for example, that ten pints made one quart, ten quarts one peck, and so on with all other denominations of measure. Then writing the number of pints, say 7285, would at once give the number of quarts, pecks, and bushels, that is, 7 bushels, 2 pecks, 8 quarts, and 5 pints, without any trouble of dividing by 2, 8 and 4 to reduce it to bushels. In the same way inches, or ounces, written out, would show the miles or pounds in the amount. Then in multiplying by dollars and cents to find the cost of articles, all trouble of reduction would be done away with, and only the right place for the decimal point would have to be looked after; this would save many mistakes, and make our arithmetic much simpler. It usually takes boys and girls many months to master the mysteries of Reduction, Ascending and Descending; under the new system, much of this time and hard study might be saved. The children would have cause for thankfulness, and their teachers no less so.

In the French system, the starting point or unit from which all other denominations are derived, is the *metre*, equal to 39.37079 inches, or about 3¼ feet. This was obtained in the following manner. First, surveyors measured a line North and South (part of a meridian), long enough to enable them to determine the length of a whole

meridian, that is a line extending around the earth, passing through the North and the South Pole. Then one ten-millionth of one-fourth, or a quadrant, of the meridian was taken for the metre. It was a grand idea to make the circumference of the earth serve as a standard for measure. It is said, however, that later measurements prove the French surveyors to have made a very slight error, yet the standard thus obtained has been in use in France since the year 1840. Ten metres make a decametre; ten decametres, a hectometre, etc. One-tenth of a metre is called a decimetre; one-tenth of a decimetre, a centimetre, etc. The other denominations are found in most arithmetics, and need not be repeated here. Square measure is derived by squaring the decimetre. Solid measure is founded on the cubic metre. Liquid measure has one *litre* for its unit, equal to a cubic decimetre. The weight of one cubic centimetre of distilled water was taken as a unit, called a gramme, and thus all necessary weights and measures were formed. We hope to see the day when the absurdities of Wine measure, Beer measure, Dry measure, Cloth measure, Avoirdupois weight, Troy weight, etc., shall be out of fashion.

Very Fine Writing.

Among the Assyrians, the common mode of keeping records of national and historical events, was by stamping the words upon bricks, tiles, or cylinders of clay baked after the impression was produced. Mr. Layard, the celebrated explorer, in digging among the ruins of ancient Nineveh, found many specimens of these records, most of which were written in such small characters, that their forms could only be made out with the use of a microscope. A rude magnifying glass, made of rock crystal, was found, which had probably been used for such a purpose. At the present day, instruments are used for producing microscopic writing, exceeding anything the ancients could execute, and almost surpassing belief. By an apparatus called a pentagraph, the Lord's Prayer has been written in a space looking to the eye like a minute dot, and covering only the 365,000th part of an inch! Under a good microscope the letters are beautifully clear and legible. It has been calculated that in this way the whole Bible might be written in less than the twenty-second part of a square inch. In using the machine, the operator writes with a pencil attached to the end of a long lever, and the marks thus made are reduced almost infinitesimally by a series of levers properly arranged, and engraved on a glass plate, which is made to move over a diamond point. By means of photography, reducing the size of letters with suitable lenses, equally astonishing writing has been produced. We do not know of any specially useful application made of such writing, but it might serve a good purpose in preserving secret despatches in time of war, which would escape notice if the messenger were captured.

THE PET KITTEN. — FROM A PAINTING BY CARL MURL.—Engraved for the American Agriculturist.

Which is happiest, the child or the kitten? The one that loves most, would be the proper answer. Now Master ———, you that tied a rattle-box to the kitten's tail a few days ago, to have fun in seeing her fright, this picture is for you to study and learn a lesson from. If you could hear the kitten purr it would sound very like "I love my master;" that certainly must give more pleasure than to hear the poor thing mew piteously when abused and frightened. The child who keeps a pet and cares well for it, is making the best feelings grow in his own heart, is cultivating a kind disposition, which will be a blessing to its owner and to others through life. It is a truth which should be printed in letters of gold, and learned by heart, that he who tries most to make others happy, secures most happiness himself.

Another "Owl Story."

A correspondent writes from Tioga Co., Pa.: "Early in July, little Mary closed the doors of her chicken and duck coops at night, as usual, leaving the old drake to stand on guard. The next morning at day-break; the old drake waked me by flapping his wings against the house at the head of my bed. I hastened to the door, and found him backing up to the door whipping and drawing a large

bird. I struck the bird over the head and he let go his hold on the drake, who fled around the corner, but soon came back, and seeing me holding up the enemy by the wings, he cheered me heartily. It proved to be a large Eagle-Owl, his wings measuring near five feet from tip to tip. The old drake received a severe wound in the breast from the owl's claws, but is now able to steal into the garden and steal cabbages, which he thinks he has a perfect right to, since he 'caught the owl,' as he and little Mary say. In truth the owl caught him, but caught more than he bargained for."

A Rich Man.

Governor Marcy, of New York, used to relate an anecdote illustrating that riches do not depend upon the amount a man possesses, but upon his condition of mind; some are poor with a hundred thousand dollars, others rich with less than one-fiftieth of that amount. A rough backwoodsman called upon the Governor one morning, and inquired if he was "Bill Marcy that used to live in Southport."—"Yes," said Mr. Marcy, who was quite curious to know who his visitor might be. "I told 'em so, but they wouldn't believe it—but you don't know me, do you?"—"Your face is familiar, but I can't call you by

name."—"My name is Jack Smith, and we used to go to school together thirty years ago, in the little school-house in Southport. Well, times have changed, and you have got rich since then, I suppose." The Governor shook his head, but the lumberman broke in, "Oh, yes, you are, no use denying it, for you've been in office a long time, and have got lots of money, and I'm glad of it."—"I suppose," said the Governor, "fortune has smiled upon you since you left Southport."—"Oh, yes, I can't complain, I must say I've got along right smart. You see shortly after you left Southport, we moved into Vermont, and I reckon we cleared up more land than any other family in the whole State."—"And so you have made a good thing of it. How much do you consider yourself worth?"—"Well," replied the satisfied man, straightening himself up, "I don't exactly know how much I'm worth, but I think if all my debts were paid, I should be worth *three hundred dollars*, clear cash." He was the richer man of the two, although the Governor could no doubt have counted his thousands.

Question for Shoemakers.—A boy correspondent says, "If the first thing a shoemaker uses to make a boot is the *last*, what will make the boot last?"

WHEELER & WILSON ROTARY HOOK

LOCK STITCH

SEWING MACHINES. 625 BROADWAY.

"WOMAN'S GREATEST BOON.—We would advise a man to forego a Thresher and thresh wheat with a flail, rather than to see the wife wear her health, vigor and life away in the everlasting 'stitch, stitch, stitch,' when a Sewing Machine can be obtained. The WHEELER & WILSON is an invaluable aid to every household. We have had several different kinds on trial, and after a six year's service, the WHEELER & WILSON has taken the precedence as the best, where all kinds of sewing are to be done in a family."

37 Park Row, New York.

PRINCE & Co.'s NEW ILLUSTRATED CATALOGUE.—We find on our table a copy of an elegantly printed pamphlet of some fifty-six pages, containing full descriptions of the various musical instruments manufactured by Geo. A. Prince & Co., Buffalo, N. Y. We had no idea that such an immense business could be so quietly carried on. The labor, skill and ingenuity employed in building up this mammoth establishment, almost defies competition. Nearly forty different styles of instruments are made—from the Magnificent Church Organ, down to the sweet little Teachers' Melodeon, all of which are of admirably finish, and great volume and sweetness of tone. The Automatic Organ, a splendid Parlor instrument, The School Organ and numerous other styles, particularly attracted our attention. To those interested we say, send at once for a copy of this Illustrated work which Prince & Co. very liberally send free of postage to all applicants.

AN EXPLANATION.

The additional size and enormous number necessary to supply the demand for our "Manual," has thrown the Printer behind in issuing it. It is expected here to-day (Sept. 4).

J. H. FOSTER, JR.—Dear Sir: Please send "Manual." The vines received of you last fall, were the finest we ever saw.

P. S.—We have thousands of wrappers now directed, and as soon as received the Manual can be mailed immediately. See large advertisement of

KNOX FRUIT FARM & NURSERIES.

GRAPES.

Our Vines are grown in the open air, from bearing wood, taken from our extensive Vineyards.

We are satisfied that our mode of producing Vines, is the very best that can be adopted; and we offer our present stock, which is the largest we have ever grown, confident of giving entire satisfaction to the purchaser.

It is Most Advantageous to Plant Vines of the best Quality.—See first and second pages of Catalogue.

Parties interested would do well to visit our grounds and examine both our Vines in fruit, and those we offer for sale.

Our Stock includes

Concord, Hartford Prolific, Creveling, Delaware, Diana, Elsinburg, Herbemont, Allen's Hybrid, Anna, Maxatawny, Rodgers' Hybrids, Iona, Israella, Adirondac, Ives,

RENTZ, MARTHA, BLACK HAWK,

Eva, and all other desirable kinds.

STRAWBERRIES.

Another season has confirmed our opinion, that the most reliable of all our Strawberries, is the

JUCUNDA---OUR No. 700.

For descriptions and illustrations of this Noble Berry, and all other leading kinds—see Catalogue.

CURRENTS.

The demand for this valuable fruit is greatly increasing every year. We have taken special pains to make the best possible collection, and our stock is, perhaps, much the largest in the country.

We offer very superior plants of

Versaillese.—The best of all.

Fertile de Angers.—Very similar to the above.

Cherry.—Excellent for jelly.

Victoria.—Very late and good.

White Grape.—Superior for Wine.

La Hatine.—Vigorous grower and very good

Black Naples.—Good for Jams and Jellies,

We can furnish any other desirable kinds.

Also,

Raspberries, Blackberries, Gooseberries, &c., &c.

Our Catalogue contains much valuable information on Culture of the above, and other Small Fruits, and will be sent to all applicants enclosing 10 cents.

J. KNOX,

Box 155, Pittsburgh, Pa.

IONA! IONA! IONA!

Adirondac! Adirondac!

Israella! Israella!

We offer for sale a very large and well-grown stock of the above

New Varieties of Grape Vines,

grown from single eyes, in borders, having strong fibrous roots and well ripened wood, which can not fail to give satisfaction to those who may favor us with their orders. Prices moderate.

Also the older varieties, a very fine stock of Concord, Diana, Hartford Prolific, Creveling, Delaware, Catawba, Isabella, Allen's Hybrid, etc., etc.

Large Stock of Standard Pears.

Mostly four years old, strong, handsome, thrifty trees, many of them extra size.

Also Dwarf Pears, Dwarf Cherry, Standard Cherry, Plums, Apricots, a large supply.

Strawberry Plants.

Agriculturist, Russell's, Great Prolific, Triomphe de Gand, Wilson's Albany.

Ornaumental.

New American Weeping Willow, Weeping Mountain Ash, Rosemary Leaved Willow, Evergreens of Norway Spruce, Balsam Fir, Austrian Pine, 3 to 4 feet, cheap. Seedlings of Apple, Cherry, and Plum. Send 2 cent stamp for Catalogue. W. & J. SMITH, Geneva, N. Y.

PARSONS & CO.,
offer for the Fall Trade, 600,000
GRAPE VINES

of all the best varieties, at reduced prices.

The accumulated experience of several years in their improved mode of culture, has resulted in the production, this season, of a class of plants superior to any they have before offered. The firm and well matured wood, and the large and thoroughly ripened roots of the plants grown this year, cannot fail to ensure success to those who plant them.

Being grown without bottom heat, from well-ripened wood, and in good, deep soil, not injured by extra manuring, they are the less liable to many diseases which freely attack vines grown by the forcing process.

In classifying their vines, they make no extras. Their No. 1 plants are the largest and best of their stock, and the average quality is not allowed to be diminished by selecting the largest for retailing as extras. Among the varieties are:

- Iona, No. 1, \$75 per 100; \$900 per 1000.
- do. 2, \$50 per 100; \$400 per 1000.
- Delaware, 2 years old, transplanted, very strong, \$35 per 100; \$275 per 1000.
- Delaware, 1 year, No. 1, \$25 per 100; \$200 per 1000.
- do. 1 year, No. 2, \$20 per 100; \$150 per 1000.
- do. 1 year, No. 3, \$12 per 100; \$100 per 1000.
- Concord, 1 year, \$12.00 per 100; \$100 per 1000.
- Ives Seedling, 1 year, \$25 per 100; \$200 per 1000.

- Hartford Prolific, \$20 per 100; \$200 per 1000.
- Diana, \$25 per 100; \$200 per 1000.
- Israella, 1 year, No. 1, \$100 per 100; \$800 per 1000.
- do. 2, \$75 per 100; \$600 per 1000.
- Norton's Virginia, \$10 per 100; \$300 per 1000.
- Adirondac, \$40 per 100; \$300 per 1000.
- Creveling, \$30 per 100; \$200 per 1000.
- Rogers Hybrid, \$40 per 100.

Where 10,000 are taken, a discount from these prices will be made.

The IVES SEEDLING can be safely recommended as a reliable and certain variety, grows rapidly, and after some years' testing, has been found free from mildew and rot.

For prices of other kinds, they refer to the Descriptive Catalogue of Vines.

They also offer REMONTANT and other ROSES on their own roots, and unusually thrifty, at

\$20.00 per 100; \$150 per 1000.

Also a large assortment of the best

TREES AND SHRUBS.

Address

PARSONS & CO., FLUSHING, N. Y.

Our aim is to Please and Satisfy our Patrons.

FRUIT TREES! FRUIT TREES!

Geneva, Ontario Co., N. Y.

GRAPE VINES AND WOOD.

Miss J. L. WARING

Offers for fall and spring sales, at wholesale and retail, her Stock of Vines, grown in Pots with great care. They are principally of the best new varieties—Iona, Israella, Adirondac, and Rogers' Hybrids; also, Delaware, Concord, Diana, Rebecca, Allen's Hybrid, Hartford Prolific, &c., &c. The Stock is now open for the inspection of buyers. For Price List or further information, address Miss J. L. WARING, Amenla, N. Y. (Harlem R. R.)

WANTED

A large quantity of GRAPE WOOD and GRAPE VINES, principally of Concord. Also Iona, Delaware, Diana, Creveling, etc., etc. Persons having the same to dispose of, please state variety, price and quantity. Address GRAPE, Box 5023, P. O., New York City.

IONA AND ISRAELLA

VINES.

TWENTY-FOUR PAGE PAMPHLET, GARDEN LIST, VINEYARD LIST, AND CLUB-PROPOSITIONS sent for a two-cent stamp.

VINEYARD LIST sent separately on application.

The VINEYARD LIST will be of interest to all who desire to plant largely, or to buy for planting in Vineyards. Prices will be found to be very low, and plants strong and hardy.

The GARDEN LIST and CLUB-PROPOSITIONS offer vines of remarkable quality at very low rates.

I also offer some fine plants, with excellent wood for propagation, grown in houses or in open air, as may be preferred. The grades of these, with description and number of buds, and length of ripe wood, will be found in VINEYARD LIST, with full statement of the performance of the IONA and ISRAELLA Vines the past winter, and during the present season.

A New Edition of the DESCRIPTIVE CATALOGUE may be expected in October, with important additions.

C. W. CRANT, Iona,

(near Peekakill,) Westchester Co., N. Y.

IONA GRAPE VINES.

The great demand for these vines has induced their propagation from green and feeble wood, which is likely to injure the reputation of this noble grape.

The subscriber was so fortunate last autumn as to secure a selection of wood from the Vineyard of Charles M. Beach, Esq., which is probably the best in New England, of some extent. I now offer a few thousand vines from single eyes of bearing wood at prices low as other good propagators. Also, Israella, Delaware, Diana and other leading varieties, from wood obtained from same source. A few nice two-years' vines of above kinds, and a small number of bearing vines with two strong canes, or two arms and spurs.  O. J. TILSON, Highland, Ulster Co., N. Y.

FIRST MORTGAGE BONDS

OF THE

CENTRAL PACIFIC RAILROAD COMPANY

OF CALIFORNIA.

Interest at the rate of Six per Cent. per Annum,
payable Semi-Annually on the first days
of January and July.

Principal and Interest payable in U. S. Gold Coin
in the City of New-York.

Amount of Issue, \$7,336,000,

In Coupon Bonds of \$1000 each.

The Bonds have Thirty Years to run, and are secured by a First Mortgage, constituting an absolute prior lien on that portion of the Road, Equipments, Franchises, and Entire Property of the Central Pacific Railroad Company, located in the State of California, and extending from Sacramento City to the California State Line, forming a part of the GREAT PACIFIC RAILROAD ROUTE, adopted and aided by the UNITED STATES GOVERNMENT.

The amount of these First Mortgage Bonds to be issued per mile is limited by law to the amount of United States Bonds allowed and issued to aid the construction of the Road, and the Mortgage by which they are secured is declared by Act of Congress to constitute a lien prior and superior to that of the United States Government.

The aid received from the Government (in amount equal to this First Mortgage) is economically and judiciously applied to the construction and equipment of the Road, together with nearly \$7,000,000, received from Stock Subscriptions

and other sources. The First Mortgage, therefore, amounts to but about 35 per cent. of the actual cost and value of the property which it covers.

The Road is now completed, equipped, and running from Sacramento City to Alta, a distance of 73 miles, and the earnings for the three months ending August 1st, were:

May, 1866.....	\$65,115.83
June, 1866.....	67,429.78
July, 1866.....	85,000.00

IN GOLD.

The earnings are steadily increasing, and are estimated at over \$100,000 in Gold for the month of August—the official report for that month not having been received at this date.

The construction of the Road is going vigorously forward—24 miles additional being nearly ready for the cars—and it will probably be in full operation to the California State Line—156 miles from Sacramento City—during the summer of 1867, when its earnings must be very large, as the entire trade of Nevada, and a large proportion of that of Utah, Idaho, and Montana, must pass over its line. It has been shown by reliable statistics that in 1863, over \$13,000,000 in Gold were paid for freighting goods from California to Nevada alone.

This part of the Great Pacific Railroad Route is destined to be one of the most profitable lines of railroad in the world, and its First Mortgage Bonds are among the best secured and most desirable investments ever offered.

Over \$1,000,000 have already been expended in grading beyond the point to which the road is now running, and the iron is bought and paid for sufficient to lay the track the entire distance to the State Line.

The road has been completed and equipped thus far without the sale of a single dollar of its First Mortgage Bonds, and they are now offered to the public for the first time, after the earnings of the road have reached the sum of \$100,000 per month in Gold, only about 25 per cent. of which is required for operating expenses.

The Bonds are offered at 95 per cent. and accrued interest from July 1st, in Currency. Orders may be forwarded to us direct, or through the principal Banks and Bankers in all parts of the country.

Remittances may be made in drafts on New-York, or in Legal Tender Notes, National Bank Notes, or other funds current in this city, and the Bonds will be forwarded to any address, by Express, free of charge. Inquiries for further particulars, by mail or otherwise, will receive punctual attention.

FISK & HATCH, Bankers,
No. 5 Nassau-st., N. Y.

N. B.—All kinds of Government Securities received at the full market price in exchange for the above Bonds.

BY
CUMMINGS & MILLER.
Carpenters, Builders, and Stone Cutters;

Your attention is invited to a NEW and PRACTICAL WORK ON ARCHITECTURE, giving in detail on a working drawing scale, the exterior and interior of various classes of buildings—with 382 designs and 714 illustrations, containing street fronts, suburban houses, cottages, cut stone work, &c., &c. It is 11 by 14 inches in size, containing only practical work, designs and illustrations that separately would cost hundreds of dollars. Price \$10.

Collections containing a fine assortment of all the leading varieties of the above will also be mailed post-paid, as follows: Collection No. 1, \$30; No. 2, \$10; No. 3, \$5.00; No. 4, \$3.00. For the contents of each collection and further particulars, see Catalogue.

Address **B. K. BLISS, Springfield, Mass.**

Lilium Auratum.

New Golden Striped Lily from Japan.

Thus described by Dr. Lindley, in the London Gardeners' Chronicle. "If ever a flower merited the name of glorious, it is this, which stands far above all other Lilies, whether we regard its size, its sweetness, or its exquisite arrangement of color. From this delicious flower there arises the perfume of Orange blossoms sufficient to fill a large room, but so delicate as to respect the weakest nerves." It is quite hardy and deserves a place in every collection. Flowering Bulbs mailed to any address upon receipt of \$5.00.

Address **B. K. BLISS, Springfield, Mass.**

Splendid Dutch Flowering Bulbs.

WASHBURN & CO.,

Seed Merchants, Horticultural Hall,

Also, For Sale in quantity, Fruit and Ornamental Trees of every desirable variety, Evergreens, Grape Vines, Shrubs, Roses, &c., &c. **KING & MURRAY, Nurserymen,** Flushing, L. I.

Early Sebec Potatoes!

This choice new variety, originating in Maine, the great potato State, has given great satisfaction this season. It is not only early, but yields abundant crops, and is of *first-rate* quality. I can supply them in September and October (there is risk from frost in spring) at \$2.00 per bushel, or \$5 per barrel.

Mr. THOMAS HURGON, of Youngstown, O., writes: "The ground is completely filled with them. I have Early Goodrich and Harrison, Gleason and Cuzco, with some sixteen or seventeen other kinds, but I think your's (the Sebec's) will beat them all in yield."—And let the public note in addition to the above, that their *QUALITY* is excellent. **JAMES J. H. GREGORY, Marblehead, Mass.**

Goodrich Seedling Potatoes.

Early Goodrich, \$1.25 per peck; \$3.50 per bushel; \$3 per dbl. Harrison - - - 1.50 - - - 5.00 - - - 12
Gleason, Heffron, Culico, \$1 per peck; \$3 per bus.; \$7 per dbl. Early Sebec and Early Prince, peck, \$1; bushel, \$3; barrel, \$5. Jackson White, Prince Albert and Garnet Chili, barrel, \$3. Packages, Cartage and Circulars, free. A liberal discount to the Trade, and on large orders. **C. W. GLEASON, Holden, Mass.**

Potato Onion Sets (or Seed).

I warrant my Potato Onion Sets (or Seed) to be pure, containing no shallots or any other variety of Onion. Potato Onions mature earlier than any other sort. I will sell at the rate of \$4 per bushel; or, \$10 per barrel, express charges paid as far as Boston.
Potato Onions should be ordered in the fall, as they require to be set out so early in the spring, as they can not then be sent for without danger of freezing. **JAMES J. H. GREGORY, Marblehead, Mass.**

EARLY GOODRICH AND GLEASON POTATOES, delivered on Cars at \$2.50 per bushel, \$6 per dbl., packages free. **LEMEUL R. WELLS, New Britain, Conn.**

EARLY GOODRICH, HARRISON, GLEASON, CALICO and CUZCO Potatoes by Mail. Four lbs of either post-paid for \$1. **P. SUTTON, Luzerne, Luzerne Co., Pa.**

EARLY GOODRICH POTATOES!—Grown by the subscriber and warranted true. Ready after Sept. 1st. Price per bushel, \$1; per dbl., \$3. Packages free. **J. W. RICHARDSON, Medway, Mass.**

AMMONIATED PACIFIC GUANO.

The attention of Farmers and Agriculturists is called to this article, as superior to anything else offered in the market. Equal to Peruvian Guano, and costing much less.

We offer this fertilizer in lots to suit all purchasers. A liberal discount made to the Trade.

Pamphlets with copies of Analysis by Dr. Liebig, of Baltimore, and Dr. Jackson, Massachusetts State Assayer, and testimonials from Agriculturists, showing its value, and directions for use, can be obtained from

J. O. BAKER & CO., SELLING AGENTS, 131 Pearl-st., New-York.

BONE TA-FEU !!

Has been tested by thousands of farmers and found superior to any other manure for Fall and Winter grain, and for a top-dressing on lawns and meadows.

It is manufactured for and used as a substitute for Peruvian guano, and judged by many to be fully equal to it. It is sold at the low price of \$40 per Ton.

Manufactured only by the **LODI MANUFACTURING COMPANY,** 66 Courtlandt-st., New-York, to whom all orders must be addressed.

Mr. M. A. Bradford, of Rye, Westchester Co., N. Y., says of "Bone Ta-Feu," that it is the very best compound I have ever used, combining those principles which promote rapid growth and also permanent benefit to the land. I used it on gravelly soil, which had always been very unproductive, although well manured, the result was so marked as to attract the attention of all who witnessed it. An abundant crop of rye was produced, measuring from 6 1/2 to 1 1/2 feet, followed by a heavy growth of timothy and clover. I have also used it in the garden, and in every case it has given perfect satisfaction.

BONE

For Sale by the Manufacturers. Pure Bone Dust and Fresh Bone Superphosphate of Lime. Address

A. LISTER & BROTHER,
Ceres Mills, Newark, N. J.

ILLINOIS.

Valuable Farm for sale, situated 2 1/4 miles South of Greenville, Bond Co., 48 miles East of St. Louis. It consists of 58 1/2 acres of land on the edge of the timber, is in a high state of cultivation, and all under fence and Oaage Orange, excepting 80 acres of timber—there are 120 acres of Meadow, 100 acres Blue Grass pasture; 20 acres of Orchard in heavy bearing, the balance in Corn, &c. Large and well finished dwelling house, 40 feet square, with brick cellar, and a 10 foot Verandah on 3 sides, the house contains 10 rooms and good closets. A very good cottage of 4 rooms for a man or tenant, 3 never failing wells and plenty of stock water. One large Barn for hay and grain; 1 Stable for 10 or 12 horses; a divided cattle shed, 60x55 feet, and several other sheds; large Coach House and Work Shop, also Sheep Sheds; a good Garden, Peach Orchard and Cherry Trees. The Stock on the Farm is also for sale—some 40 Horses, mares and colts, bred from imported stock; 500 Sheep, and some 30 head of Horned Cattle, of good breed. The above will be sold on reasonable terms, or exchanged for good desirable property in Western N. Y., or near the City of New York. For further particulars, address **Box 51, Geneva, N. Y.,** or Mr. H. HAMMOND, on the premises. The Village of Greenville, contains a large and well conducted Female College, and other unusual advantages. Three R. R. Depots within 15 miles, and the prospect of the Atlantic and Mississippi R. R. passing within a short distance.

GOOD HOMES IN NORTH MISSOURI.

PARMEIS, MECHANICS and MANUFACTURERS of the North and East should come to Missouri, because you can now do better for yourselves, families, society generally, and for posterity, than you can by staying where you are. By coming you can get better farms and homes, do more business and make more money, easier and quicker than to remain where competition is strong and sharp, and profits small. As others have done you can do, for the chances now are as good as ever, and in many respects better.

Missouri is rich in Agricultural resources. Provisions are abundant, Coal, Iron, Lead, Copper, Wood, Cotton, Hemp, Flax, and other raw materials to be wrought are at hand in a healthy climate giving vigor to labor, and in a central location with cheap and direct access to all the markets. These facts make Missouri a producing and manufacturing region; and when the surplus artisan population of old and less favored districts are wise enough to come here in sufficient numbers, then there will be an adequate supply of labor for the wants and facilities of this State, and make it a consuming country also. Thus the great department of human industry can and surely will combine to give the full prosperity this noble State generously invites and so richly deserves.

The **HANNIBAL and ST. JOSEPH RAILROAD** offers for sale at low prices on two or ten years credit nearly 500,000 acres of best prairie, timber and coal lands in Northern Missouri, which is the best Agricultural part of the State.

Documents giving full particulars are sent in packages gratis to all who wish to distribute them, to induce others to join in forming a neighborhood or colony.

A Sectional Map showing exact location of land is sold at 20 cents. Address **GEO. S. HARRIS,** Land Commissioner, Hannibal, Missouri.

New Jersey Lands for Sale,

in Tracts to suit purchasers.
21,000 Acres of Superior Soil in One Body, on Camden and Atlantic Railroad, in best location in South Jersey. Lands shown free of expense.

Apply to **E. WRIGHT,** Elwood, Atlantic Co., N. J.

Also many thousand acres of Cranberry lands. Circulars or other information cheerfully forwarded.

From the Report of **WM. L. ALLISON,** of the Working Farmer.—"At Elwood, a thriving settlement 37 miles from Philadelphia, the land is heavier and richer than those at Hammonton, and there is no drifting sand to annoy the cultivator."

Great Chance for a Bargain.

For Sale or Exchange for farm or city property, 30 acres land, good horse and out-buildings; plenty of fruit and shrubbery; good store, with excellent trade; Sanford & Mallory Flax Brake; excellent arrangement for oil mill; on proposed Railroad from Indianapolis to Vincennes; near a thriving town, in one of the healthiest locations in the State. For further particulars, address **J. F. ALLISON,** Point Commerce, Greene Co., Ind.

TO SELL

CAMPAIGNS

OF THE

ARMY of the POTOMAC,

By **WILLIAM SWINTON,**

One large Octavo Volume, Splendidly Illustrated.

This is everywhere admitted to be the finest book on the war. It is history and criticism combined, and the narrative is of absorbing interest.

Major General Hancock says "I consider it the most valuable addition to the military criticism of the Rebellion which has yet appeared in print."

Major General Franklin says "It tells the story as it is believed to-day by the honest actors in the scenes it narrates."

Major General Conch says "It is plain to see you have produced a truthful narrative—a new era in American military writing."

All the leading Generals speak of it in the same way. It is having an immense sale everywhere—every reading man needs it. Send for circulars giving full particulars, terms, &c., to
RICHARDSON & CO., Publishers,
540 Broadway, New York.

Also, ITALIAN QUEENS, of Parsons' or Langstroth's late importations. Orders for tested Queens filled in strict rotation. For particulars address
F. J. LEWIS, East Poutney, Rutland Co., Vt.

THE YANKEE BLADE.
This Neat Invention is a most Convenient WORK TABLE and WRITING-DESK COMPANION.

Recommended by Orange Judd, N. Y. Tribune, Mme. Demorest, N. Y. Independent, and hundreds more.

- IT COMBINES**
- 1st.—A Patent Sewing Ripper which takes out a seam faster than a Sewing Machine can make it. For this purpose alone, it is worth many times its cost in every family. It will rip Machine or hand-sewing equally well.
 - 2d.—Gathers Scratcher; just the thing for it.
 - 3d.—Paper Cutter and Folder, always handy.
 - 4th.—Eraser for removing blots, errors, etc.
 - 5th.—Letter Opener for men of Business.
 - 6th.—Nail Cleaner and Trimmer for everybody. Price only 35 cents; three for \$1, or \$3 per dozen. Ask your Storekeeper for it, or send price and receive it by mail.

MONEY TO BE MADE.
To introduce it more rapidly, I will give a Town Agency, except where there are over 10,000 inhabitants, to first person buying three dozen of the Yankee Blade. They sell very readily, the Ladies especially, like them much, and there is no risk in making a trial with the first three dozen.
Address
W. A. FITCH,
151 Nassau-street, New-York.

QUINBY'S BEE-KEEPING.

By M. QUINBY, Practical Bee-keeper. Fully Illustrated. Entirely new. The result of 35 years' of successful experience—with directions for all contingencies that can ordinarily occur; treating of Breeding, Movable-Comb and other Hives, Pasturage, Robbing, Feeding, Swarming, Queens, Diseases, Anger, Enemies, Wax, Transferring, Sagacity, Wintering, Care of Honey, Italian Bees, Purchasing, etc. Bee-keepers will find this new work of Mr. Quinby's fully up to the times in all practical matter. Price \$1.50.

Gratifying Opinions of the Press.

From the Christian Intelligencer.

"Quinby's Work is the very best. It has long been regarded as of the highest authority in the matters concerning which it treats."

From Moore's Rural New Yorker.

"This is a newly written and illustrated edition of Mr. Q.'s former work. That has proved of value to thousands of Bee-keepers, and this, with its riper experience and added knowledge, can not fail of giving better satisfaction. Thirty-five years experience!—What beginner in bee-keeping will not bring this to his aid? We notice the author has no Patent Hive to introduce, and expresses his opinions freely on the merits and demerits of the various hives seeking popular favor."

From the Vermont Farmer.

"The book is written in familiar style, with the endeavor to be practical rather than scientific, thereby making it a guide to the tyro in Apian knowledge, as well as a standard work of reference for the more experienced bee-keepers."

From the N. Y. Christian Advocate.

"All beekeepers should have this manual, and others may read it as a book of wonders."

SENT POST-PAID ON RECEIPT OF PRICE.

ORANGE JUDD & CO.,
41 Park Row, New York.

Downing's Landscape Gardening and Rural Architecture. Price, \$6.50.

Commercial Matters—Market Prices.

The following condensed, comprehensive tables, carefully prepared specially for the American Agriculturist, show at a glance the transactions for a month, ending Sept. 17, 1866, and the exports of Breadstuffs from this port thus far, since January 1, together with the annual exports of Breadstuffs for a series of years, ending Sep. 1:

1. TRANSACTIONS AT THE NEW-YORK MARKETS. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats.

Table showing receipts for 30 days this month and 24 days last month.

2. Comparison with same period at this time last year. RECEIPTS. Flour, Wheat, Corn, Rye, Barley, Oats.

Table comparing receipts for 30 days 1866 and 1865.

3. Exports from New-York, January 1 to Sept. 15: Flour, Wheat, Corn, Rye, Oats.

Table showing exports from New-York from Jan 1 to Sept 15.

4. Exports of Breadstuffs from the United States to Great Britain and Ireland, each of 20 years, ending Sep. 1:

Table showing exports of breadstuffs to Great Britain and Ireland for 20 years.

5. Exports from the United States to the Continent of Europe for 12 years, each ending Sept. 1:

Table showing exports from the US to Europe for 12 years.

6. Exports from the United States to all ports, year ending Sept. 1: Flour, Wheat, Corn, Rye, Oats, Bus.

Table showing exports from the US to all ports for the year ending Sept 1.

7. Exports from Canada to Great Britain and Ireland via St. Lawrence, year ending Sept. 1:

Table showing exports from Canada to GB and Ireland via St. Lawrence.

We give above, in accordance with our custom, a series of very interesting tables, illustrative of the movements in Breadstuffs, not only for the past month, but for a series of years. These tables have been prepared from official and other authentic records, and may be regarded as thoroughly reliable.

They leave us very little room for our usual notice of the month's business. The receipts of Breadstuffs have fallen short of the requirements of buyers since our last, and there has been a general rise in prices; the market closes less buoyantly. The export demand has been fair. There has been a great scarcity of prime wheat, which has been much needed by local millers. Provisions have been in fair demand, but have been depressed and unsettled in price. Butter and cheese have been in very liberal supply. Cotton has been more active, closing firmly and buoyantly. The receipts at this port, year ending Sept. 1, were: 668,575 bales; amount taken by spinners, same time, 379,720 bales; exports, same time, 495,309 bales; stock here Sept. 1, 1866, 68,408 bales. The total receipts at all the chief shipping ports, year ending Sept. 1, were 2,188,278 bales; and the exports therefrom, same time,

1,431,600 bales. Wool has been in rather more demand at about previous quotations. Hay has been less plenty, and has been in good demand at buoyant prices. Hops, seeds, and tobacco have been quiet at irregular figures.

CURRENT WHOLESALE PRICES.

Table listing current wholesale prices for various commodities like gold, flour, wheat, etc.

New York Live Stock Markets.

The supply during the past five weeks has been very good for a season of medium demand, as here shown:

Table showing live stock market data including week ending, beefs, cows, calves, sheep, swine.

It will be seen that the average receipts of Cattle, Sheep and Hogs, have advanced materially. Beef Cattle have fluctuated, but close at about last month's prices, or at rates equivalent to 17 1/2 c. @ 18 1/2 c. per lb. dressed weight for a few extras; 17 c. @ 17 1/2 c. for really good cattle; 16 1/2 c. @ 15 1/2 c. for common; 15 c. @ 13 c. @ 12 c. @ no sale for inferior to worst.

Milk Cows are in very little demand at any price. Excellent pasturage, produced by frequent rains since August 1st, have supplied milk enough without more cows. Prices range \$45 @ \$60 for poor and common, calf included; \$70 @ \$80 for good; \$90 @ \$100 and upwards for extras. Veal Calves are in fair request at 12 c. @ 13 c. per lb. live weight for the best; 11 c. @ 9 c. for fair to very poor.

Sheep and Lambs, after being lower and higher, close at last month's figures, viz: 7 c. @ 7 1/2 c. per lb. live weight for best; 6 1/2 c. @ 5 1/2 c. for good to poorest; Lambs 9 1/2 c. @ 7 1/2 c. for extra good to poorest. Live Hogs are in better supply and prices down to 10 1/2 c. @ 11 1/2 c. for different grades.

W. C. CHAMBERLAIN'S PYLE'S SALERATUS AND CREAM TARTAR.

Are the best in market. All first-class Grocers keep them.

The Celebrated New Grape, DIANA HAMBURGH.

The subscriber will send out his share of the stock of this noble grape Nov. 1st. Price \$5 per plant; \$60 per doz. Also extra sized plants of Iona, Adirondack, Delaware, Concord, &c. Address JOHN CHARLTON, Rochester, N. Y.

Pure Iowa Timothy Seed, For sale by W. C. CHAMBERLAIN, Agricultural Warehouse and Seed Store, Dubuque, Iowa.

GRAPE VINES FALL 1866.

Delaware, Iona, Israella, and other leading varieties of vines of good quality, for sale in quantities at low rates. Send for Circular. J. W. HELMER, Lockport, N. Y.

MERINO RAM "GOLDEN FLEECE."—BRED AND OWNED BY E. S. STOWELL, CORNWALL, VT.—*Drawn and engraved for the American Agriculturist.*

We selected this ram as best representing his breed of any at the New England and Vermont Fair at Brattleboro, and our artist produced, in our view, an admirable portrait. Golden Fleece is 4 years old, and was this year winner of the sweepstakes prize as the best merino ram of any age on the ground, and of the 1st prize in his own class, (Rams 3 years old and over.) His fleece, this year, (unwashed of course) weighed 26½ lbs.; that of 1865 weighed 26¼ lbs.; it

would be interesting to give the weight of cleansed wool, but we cannot. The excellence of the animal may be judged by the fact that the flock of which he is the leader, and to a considerable extent the sire, bore off 6 first and 3 second prizes, besides the 2 sweepstakes prizes at the above named fair. He exhibits remarkably the compactness, solidity and depth of carcass, with the desirable shortness of legs, which are well woolled down, the full dewlap with the

abundant wrinkles and folds of the Vermonters, together with the astonishing oiliness of fleece. Such animals are held at wonderfully high prices,—\$5,000 to \$15,000. The latter price has, we learn, been refused for Golden Fleece. This breed, the American Merino, originated from the careful breeding, for many years, of Spanish Merino sheep by Stephen Atwood, of Conn., and subsequently by Edwin Hammond, of Vermont, and is now widely disseminated.

Contents for November, 1866.

NEW-YORK, NOVEMBER, 1866.

There is a northern army marching southward with power. The winds are its scouts, and Jack Frost is on the picket line. Its skirmishers are in the forests of Maine; they fill the Adirondacs, and skirt the chain of great lakes. Some daring companies have pushed far in advance of their reserves into the prairies and the valleys of the West. Behind them comes the grand army in its march to the sea, leaving no green thing behind it, save the cedars and pines with which it seems to fraternize. But we have weapons and resources, which will enable us to sustain the siege. Then, too, we have one great ally, but for whose partial withdrawal, to attend to business farther South, we should not experience the present attack. This ally is the Sun, who fights for us by day, but leaves us to take care of ourselves by night. Our resources are wood and coal, and peat, good shelter and the abundant corn. The first nippings of the frost should have set us to finishing up farm work, and making ready for winter. When we cast our eyes over the hints for November given in previous years, we feel the need of ten times the space we have to make suggestions upon every important subject, but with so little space as we have we must be somewhat general in our hints. First, however, a word about *Permanent Improvements*.—Multitudes of farmers and their families are satisfied with their present homes, but many others want to move. They are looking West or South, and are ready to take a good offer and clear out. The result of this is, that they do not half take care of the farms they are on, and if they sell at all, they will not get half the price they might. We say then, wherever you are, make the surroundings as attractive as possible. Make permanent improvements, good buildings, good fences, walls, etc., lay underdrains, reclaim swamps, and in short, work as if you were going to live in one place all your life, and your children after you. So you will have the comfort, as you go along, of seeing every thing improving, and such investments are safe and usually pay a good interest, if not annually, they certainly increase the value of the farm. But do not let any work upon the farm nor the material welfare of yourself and family lead to the neglect of the moral and intellectual.

The Common School should have the solicitous care and attention of every citizen, no matter what his profession, or how light his family responsibilities. Statistics bear us out in saying that the poorest schools and the least attention to education exist among the most purely agricultural districts; and it is also true that in more populous sections farmers, as a class, are not the ones to forward efforts for better and more thorough schools. The great safe-guard of our liberties is universal intelligence. A good public school is a security to any community against petty thieving, stack burning, orchard robbing, and a thousand other annoyances from bad boys and bad men, which can hardly be over-estimated. The contamination of one's children by ignorance, which is almost always vicious and the cause of poverty, should be provided against by securing the very best school houses and the best teachers for all the children of the community. This is every man's and every woman's business, and a duty for which an account must be rendered as much as for the heartless neglect of the hungry and naked. It is not necessary at this season to direct attention to

The Poor, for we have them always with us. It is much pleasanter of a winter night to think of those who have been and are warmed and fed by our unostentatious charities, than of those to whom it may have been said, "depart in peace, be ye warmed and filled (by somebody else)." This month occurs the usual season of Thanksgiving, which, formerly observed by only a few of the older States, has now become a National festival.—May this be among the many causes for thankfulness of our readers and of ourselves, that as God has prospered us, God's poor have shared his bounty by our hands.

To those of our readers who read the October Hints we have little to say under the heads of *Buildings, Cellars and Ice Houses*, that will not seem repetitious. In short, put all in perfect order for cold weather, so far as repairing, cleaning, white-washing and painting go. There is one important subject which might well have been dwelt upon last month, namely

Cisterns.—Old ones should be cleaned out if they get low during Indian Summer weather, when we often have little rain for some weeks, and they should be protected from the action of frost. Clean caves troughs, pipes and conductors of leaves and rubbish, and make every thing ready for winter. New cisterns may be set at this time, and where running water cannot be secured either at the house or stock-yard, capacious cisterns certainly should be. It is very easy to make a cistern in any soil in which a pit may be cut down with perpendicular sides. All that is necessary is to lay on a good even coating of cement directly upon the sides and bottom of the pit, which may be about 8 or 10 feet in diameter. Lay a flatish boulder on the bottom in the middle to stand upon, and near it make a depression into which all sediment may be made to flow, to be pumped or dipped out. Such a cistern may be covered with plank and 2 feet of soil, or by a dome or jug-shaped top, all below the surface and below frost. To construct this, make a frame of boards going from a center-post to the sides, and form the top with a smooth surface of hemispherical form by filling in with pieces of wood, and finishing off with clay or soil sprinkled and smoothed off. On this lay a coat of cement mortar, and a grouting of stones 6 inches thick. A half-barrel tub should be set in the dome in the middle, or a little to one side, for a "man-hole." Water enough falls upon ordinary farm buildings for all the stock that they can cover. After all, cisterns are a poor substitute for running water brought to the barn in pipes.

Horses.—In November we expect to get all our stock into the barns, and should take good care of them. There are no animals, however, that with plenty to eat will bear the cold so well as horses—full-grown horses. "Weathering" stunts colts shockingly. We have no doubt of the truth of the statement, that farmers in Vermont frequently winter their horses in the open meadows with barely a shed to run under, giving them a little hay or straw only during ice storms, when they cannot paw down through a foot or two of snow and get at the grass and clover aftermath, which was left for them. They are said to grow fat upon such treatment. Nothing is worse for horses than too much blanketing and tender care. Keep them clean—they can't be too well groomed—but let them have fresh air and cold air, plenty of it, but not in draughts through windows, floor cracks, etc. When they are sweaty, rub them and blanket them until dry, and for an hour or two after they are cool. After grooming, a linen cover may be put on to keep the coat down.

Colts ought to be accustomed to being handled very young, and may be kept in stalls or loose boxes. Never use the whip, but try the efficacy of a little sugar instead. (It will pay even at 16c. per pound.) Any young horse is much easier coaxed than whipped, and punishment is rarely necessary.

Bees should be pushed forward in fattening as fast as possible. Be careful not to over-feed, but judiciously increase and vary the feed so as to secure always good appetite and digestion. Water regularly; keep salt always before them; feed ground or cooked grain; never let them worry for a meal, but be ready as soon as the time comes; also never prepare their food before them, making them wait half an hour, restless and thrashing about, but prepare for the next meal while they are eating. See that cattle are fed uniformly the same amount of grain, roots, oil cake, etc., daily, or increase with regularity. Variety and occasional changes of feed are well, and most economical.

Cows.—As the quantity of milk decreases, its richness in butter may be made to increase by proper feeding, and it is worth while to take advantage of

the very high price which butter brings. We heartily wish farmers could realize the retail prices asked in the cities and large towns for their products—butter 65 cents per pound—think of it; get it if you can—though 35 cents will pay. Examine hay for evidence of ergotized seed (grown three or four times its natural size—the effect of a disease). This probably is the cause of abortion in cows, which has been so disastrous in many sections of late years. Any cow that is ailing in the least, should be removed from others. If one of a herd elinks her calf, three or four may follow suit, and probably will. Filthy stables provoke abortion.

Young Stock of all kinds should be kept vigorously growing all winter. Warm dry yards, sheds or stables, some grain or roots, and plenty of fresh water and salt, with regular care, will ensure thrift and much better sized animals than if the winter treatment checks their growth, as is usually the case. Their manure will be worth something, too.

Sheep.—If sheep are in poor condition now, they must be gradually brought up; feed oats in the sheaf, a few daily, and some roots and good hay. When grass fails, hemlock boughs once or twice a week are good. Let all have the range of dry yards or fields, and warm sheds well ventilated. The period of gestation in ewes is about 5 months, (152 days,) and a flock in good order is rarely served in less than 3 to 5 weeks. If sheep put up to fat at this season, sell in February, March, or April for enough to pay their present value, and for all the grain fed to them, there is a profit. Their manure will be full pay in many places.

Hogs.—Watch the pork market, and if there is a certainty of taking advantage of high prices before the general killing takes place, do so, otherwise complete the fattening. If nowhere else, there is at least a large gain in the manure heap. Refer to articles on hog killing in the January number (p. 12). In killing all squealing and fighting is stopped by shooting a wooden plug into the head between the eyes, easily done, and a most humane practice; use very little powder. Feed only cooked or soaked food; ground if possible.

Poultry.—See article on fattening fowls. It is equally applicable to other poultry. For ducks for your own table, feed meal scalded and mixed with celery leaves chopped fine, for 2 or 3 weeks before killing. It gives them the flavor of canvas-backs. In warm, light houses, spring pullets lay all winter.

Manure.—The value of the manure of animals stands in direct relationship to the value of the food they eat. Poultry have the richest food; men next, hogs next, fattening cattle, horses, sheep, cows and growing stock follow in about this order. The feed of well fed bees is usually richer than that of horses, and so is that of fattening sheep sometimes, but this varies. Here, however, is a true measure of the value of the droppings, and of the care that should be taken of each kind. The farmer's business is to make manure just as much as it is to make money, and he should do it first by saving. Hen-dung is easily saved by making the birds roost over a floor sprinkled with earth, which is swept up and freshly earthed every week. Calculate to have $\frac{1}{3}$ manure and $\frac{2}{3}$ earth. Save the next on the list on precisely the same principle—that is, mingling it with $\frac{2}{3}$ its bulk of dry fine soil, but do it every day or two.—See the box, etc., figured on page 319.—Hog manure is saved and preserved by mixing it with earthy or vegetable matters, anything that will decay, but especially articles soft, porous and bulky, as weeds, sods, bogs, peat, etc. The droppings of horses are very profitably added either to the manure of the sty, or mixed with that of neat stock, especially to that of young cattle and cows, which is thus brought up to a higher standard. Manure of all other kinds is kept and improved by admixture of straw, leaves, etc., and especially by being laid up in heaps over beds of rails, so that the liquor which leaches from it naturally, or after being pumped on, may be returned and pumped over it again. Where this can not be done, it should be mixed with sods, dry peat, or muck, or even simple soil, and laid up a

compost heap as fast as it accumulates. The manure harvest is from November to May.

Plowing.—By all means do as much plowing this fall as possible. Use a plow that will lay a furrow as flat as a floor. Plow in manure deep for corn, potatoes and root crops, but not for small grains. Leave no manure on the surface, except fine composts that may be harrowed in. Land is well prepared in this way for seeding in spring to clover or grass without an accompanying grain crop.

Grain Fields.—Prevent water standing anywhere on winter grain or young grass, by

Surface Drains.—Make surface water courses to conduct off water from spots where it may wash and do damage, by cutting channels or by banking on dirt or gravel. Continue

Under-draining also, as long as the ground is not frozen hard. Laborers are easier got in November than at most other times. The ditches must be well filled, and the earth pounded down, or the water will wash them out in the spring.

Wood.—See article on splitting. It is a good time now to gather the "down stuff" in the wood lot, which is useful for light quick fires.

Orchard and Nursery.

When we advocate autumn planting, we do not mean to advise planting in winter. In general, the present month is too late to plant, and it is much better to heel-in the trees, received thus late, than to set them. Trees properly planted will not need stakes, but if it must be done to save a weak or injured one, a single stake with a twisted straw rope, as described in April, 1863, will be best. See page 399 for protecting young trees during winter.

Cider Making still continues. Good, sound, and clean apples, absolute cleanliness of the casks and every thing used in the process, are essential to the production of the best article. If what the Germans call apple wine (Apfel-Wein) be desired, follow directions for grape juice in Sept., page 325.

Cellars.—Close up only when there is danger of freezing. Fruit should be kept at a uniform low temperature—as low as it can be without injury. The changes that go on in ripening fruit, generate heat, and this should be borne in mind. They also cause the liberation of injurious gases, and when fruit is stored in cellars under dwellings, ventilation should be provided. An opening into the flue of a chimney is as good as any other.

Cions may be cut at any time after vegetation has ceased. Select this year's shoots with short joints, tie in bundles, label carefully, and keep cool and from drying. Damp sand or earth will do, but sawdust is better, as it will not injure the grafter's knife.

Labels.—Trees from the nursery often have the labels closely wired to a limb; these should be loosened, or what is better, taken off altogether, and have the small copper wire replaced by one of lead or by a leather strap. Have every tree labelled for convenient reference, and so recorded as to leave no possibility of losing the name.

Manure can be put upon the orchard at any time after the ground is frozen. Manure the whole surface, and do not make a mound around the trunk.

Stocks must be taken up before the ground freezes. Those intended for root-grafting are to be assorted, tied in bundles and packed in the cellar in sawdust. Take up all apple and pear stocks, and preserve those too small to graft, to set again next year.

Seedlings generally have a hard time of it the first winter. Leaves and the boughs of cedar and other evergreens make a good protection.

Cuttings, if the ground is open, may be set. See article on cuttings in October, page 364.

Kitchen Garden.

Whenever the ground is open, something may be done to help along next spring's work. See last month for suggestions about manures. Clear up all rubbish, lay drains, and do all preparatory work whenever the weather will allow.

Pits for Vegetables, made as directed in October,

page 362, will need a gradual covering; or, if the roots have been put in heaps, pits may yet be made.

Cabbages.—Plants in cold frames are to be fully exposed every mild day. Take in the late crop, as directed last month. Cattle relish the loose leaves.

Celery should never be put in too soon, it will stand light frosts, but should not be thoroughly frozen. See last month's directions for wintering.

Horse-radish.—Dig and cover in pits, as directed for other roots. Save small roots to set next year.

Hot-beds.—If not already done, procure a lot of good soil and put under cover, or cover with boards.

Parsnips and Salsify may be dug whenever the ground is open, but it is best to have a supply for use in cold weather preserved in sand in the cellar.

Rhubarb.—Whenever the ground is open, new beds may be made, by dividing the old roots, taking care to keep an eye or bud with each, and setting deeply in richly manured soil.

Spinach.—Cover with straw or leaves.

Fruit Garden.

The general directions of last month may be followed wherever they will apply. In locations where the climate will admit of it, planting of dwarf trees, blackberries, currants, etc., may continue. Manure as directed under orchard.

Figs Trees are to be laid down and covered with earth, or if there is danger from much water, take up with a large ball of earth and put in the cellar.

Grape Vines.—Prune as soon as the leaves are off—this is when to prune. How to prune will depend upon the vine and the person's knowledge of its manner of growth. We can only give general directions. Look at your vine now that it is divested of leaves. All that is seen of the wood of the present year's growth, has borne and done its duty. The buds upon the canes, that now look so insignificant, are next spring to throw out vigorous shoots and bear fruit. If all the buds are left, there will be many weak shoots and little fruit. If this year's shoots are cut back to two or three buds, these remaining buds will push out vigorous shoots and produce much better fruit than if the vine had been allowed to run wild. Have this in mind whenever the vine is pruned—the buds, and not the wood now on the vine, are to produce the fruit. Prune understandingly. We have given full directions with engravings in previous numbers.

Grapes may be preserved a long time, if put in boxes and kept at an even low temperature. The Catawba and Diana are the best keepers. Grapes with a tender skin, that breaks at the least pressure, are not good for keeping.

Pears.—The winter sorts are to be kept as heretofore recommended for winter apples. Keep them cool until the time of their ripening, and then bring them into a warm room.

Raspberries.—Tender kinds are to be bent down and covered with earth. If the old canes have not been cut out, do it at the time of laying down.

Strawberries.—There is no need of covering until the ground is crusted. The object of covering is, to avoid alternate freezing and thawing. Too much covering, provided it smothers the plants, is worse than none at all.

Flower Garden and Lawn.

All work here will be governed by the character of the season. In fine weather, grading, making new walks, new borders, etc., may be carried on. It is well to compare the views, after the leaves have fallen, with those of midsummer, and observe where pleasing views may be opened by removing the trees, and note the unpleasant objects that may be shut out by judicious planting. Clean up all rubbish. Cover tender plants and put everything needing it into winter quarters by the end of the month.

Bulbs.—Take up Gladiolus, Tuberoses, Tiger-flowers, etc., before hard frosts. Dry them off and then put in paper in a dry place, where mice will not reach them. If the ground is open, put out spring flowering bulbs, Hyacinths, Tulips, etc.

Chrysanthemums remain as the last ornaments of the garden. Mark fine ones for propagating next year. Cut away the stems when done flowering.

Dahlias.—If the roots have not already been lifted, take them up on a fine warm day, putting the label with each—or note the color, if the name be not known—dry during the day in the sun, and set them in any cellar that will keep potatoes.

Frames and Pits.—Give the plants full air on mild days. Those set on the bottoms of the pits should have a layer of coal ashes under them. See that pits are mice proof—and poison any that intrude.

Lawns may have a dressing of good compost, which can be put on any time during the winter.

Leaves.—Collect all possible. We have mentioned on page 402 several uses for them. Another is, that they make excellent bedding for cows and other cattle, and by spring are rich manure.

Roses are to be protected as directed in September. If climbers can be taken down and covered with earth, they will flower all the fier.

Viburnums north of New York are not safe unless laid down and covered with earth.

Protect all herbaceous perennials, hardy or otherwise, with coarse manure, or a covering of leaves.

Green and Hot-Houses.

The plants being all in the house, the principal thing to look after is the temperature. In warm days, no fire will be needed, and again a sudden change will require care to keep the temperature from getting too low. In green houses the mercury may range from 35° to 45°, while in hot-houses 60° and 75° should be the minimum and maximum. Ventilate whenever external temperature allows, and water according to the requirements of the plants.

Bulbs, if not already potted, are to be put in for winter blooming. Keep in a dark and rather cool place until they have formed abundant roots.

Camellias should be kept cool, unless early flowers are wanted. Syringe freely; look out for insects.

Propagation of quick growing things may continue. *Salvias*, *Cupheas*, etc., will soon make strong flowering plants.

Greens.—Where bouquets are in demand, lay in a stock of *Lycopodiums*, Ink-berry and other greens.

Annuals.—Where there are not many flowering plants, a good show may be made with annuals. They may be sown now. *Mignonette* is always wanted for its perfume. *Rhodanthes*, *Nenophilas*, and *Lobelias* make fine house plants. Sweet *Alyssum* and *Candy-tufts* may be used if there is room.

Cold Grapery.—Remove the decaying berries from any clusters that may remain upon any vines in the house. In damp weather, close the house and keep it as dry inside as possible.

Apiary in November.—When a proper selection of stocks for keeping over has been made, there will be no tendency to rob. There is little to be done, unless important things have been neglected. The first cold weather makes bees very stupid—more so than that which follows, and if stocks have not been thoroughly examined, take advantage of the first freezing weather to do so. It is the part of humanity to take up small weak stocks now, rather than leave them to starve and freeze to death. Unfilled boxes may be stored for next season's use, and any dry combs should be saved for another year. Protect the hives from mice, by contracting the entrances. Hives containing stocks may be painted at this season without serious injury to the bees, and new hives or empty ones ought to be painted now, to get thoroughly dry before next season. Honey taken up this month will probably be very thick, and require gentle warming in order to strain it nicely.

Previous Numbers to New Subscribers.—We have on hand all the previous numbers of this journal back to January, 1856, and print more as needed, from our electrotype and stereotype plates. Price of single numbers, 15 cents; of annual volumes, \$1.75 per year, postage included, or \$2.50 if sent bound. But any new subscriber received this autumn, who gets free the two or three numbers, can have the back numbers of this year to complete his volume, at the rate of 10 cents each.

AMERICAN AGRICULTURIST.

ORANGE JEDD & Co., Publishers, 41 Park Row, N. Y. City.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies; Four to nine copies, \$1.25 each; Ten to nineteen copies, \$1.20 each; Twenty copies and upwards, \$1 each. Papers are addressed to each name.

Suggestive Questions To Everybody.

Preliminary Statements.—What the *Agriculturist* is, and has been so far this year, its readers know—how many beautiful and instructive large and small engravings (which alone cost about \$5,000!), how many articles on various topics, how many hints and suggestions, etc. Many would have the paper different—would omit this and insert that; but we have constantly acted up to our best judgment, taking into account the general interests of all concerned, and we think no one would willingly part with all he has read and be without the thoughts that have been suggested by what has been read.—Now, with constantly increasing experience, and facilities, we are able to promise even a far superior paper for next year. We expect to expend about \$10,000 in getting engravings that will be beautiful to look upon, that will cultivate taste, and be an ornament in the homes of our readers, and that will also furnish many practical hints in the various departments of Rural Industry. We expect to expend \$12,000 to \$15,000 more, in procuring and preparing a great amount and variety of useful and reliable information for the Farm, the Orchard, the Domestic Animals, the Garden, and the Household, including the Young People, and the Little Ones. We mean to have the best that unceasing industry, and any amount of money, can possibly secure. The result of this expense and effort—including the ten thousand dollars' worth of engravings, and the twelve to fifteen thousand dollars paid out for information, etc., including much information obtained by the \$1,350 offered for Prize articles on Prairie and Western Farming, on Cotton Culture, on Timber and Fencing for Prairies, and for Housekeeping Essays—can all be enjoyed by any person for the small amount of \$1.50 for the whole year, and less to clubs. The immense circulation divides all the expense among so many that we have to charge only a few cents to each subscriber above the cost of printing paper. Now then for

THE QUESTIONS.

QUESTION FIRST.—Is there one Post Office in all the United States or British America, where there are not 13 families or single persons, who would each find it a paying investment to expend \$1.50 for the *Agriculturist* for 1867, with all the advantages above set forth? (Any one subscribing this month gets the December paper also, without extra charge.)—Well, any person who will call on these 13 families, and talk about the paper and get their subscriptions and forward them, may call upon us for Five Dollars' worth of Garden or Flower Seeds, or any three back volumes of the *Agriculturist* in numbers, and the articles will be sent post paid. Two subscribers less will secure Morton's best No. 5 Gold Pen, a capital article, with pencil in Coin silver extension case. One subscriber more (14) will bring the No. 6, or large pen. We have written thousands of pages of letters and manuscripts with one of these pens and it is still in first-rate order. (See Premium list in another column, and full description given on pages 349 to 352, in October paper.)

N. B.—There are very few places where more than the cost of 13 subscriptions has not been lost by Hum-

bugs, which would have been saved had the *Agriculturist's* exposures been read there in season.

QUESTION SECOND.—Is there one Post-Office in the United States or British America, where there are not 15, 16, 17, 18 or 19 families, or persons, who would not be well repaid in the above advantages, for \$1.50 invested in the *Agriculturist* for a whole year (or 13 months now)? (It is less than 3 cents a week, or half a cent a day.)—Well, to any person who will shaply talk this matter over and collect 15 such subscribers, we will present Six Dollars' worth of beautiful Japan Lily Bulbs, or four back Volumes, or a splendid Book (Downing's). For 16 names three bound Volumes. For 17 names, one dozen beautiful best Silver-plated Teaspoons. For 18 names, the best Clothes-Wringer made; or a beautiful case of Mathematical Instruments; or four bound Volumes; or a large \$10 Architect Book; or a \$10 Library. One name more (only 19 in all) will bring 100 best Concord Grape Vines; or a \$12 Barometer; or Worcester's Great Dictionary; or 6 back Volumes unbound; or the Aquarius. The last column in the Table tells how many names at the lowest club price (\$1 a year,) will get any of the articles referred to.

QUESTION THIRD.—With the exception of a very few of the newest settlements, is there a Post-Office in the United States or British America, within the bounds of which there are not 20 to 30 families or single persons, who would not be well repaid, in the above advantages, for \$1.50 used in securing the *Agriculturist* for a year (or 13 months now)?—Well, just run the eye down the Premium Table, and examine the *stipendium* (?) different good articles that are offered free to anybody who will simply take the matter in hand, and collect and forward the subscriptions of these 20 to 30 persons who ought to have the paper, and would be glad to have it, if some one would tell them all about it.—Try it, and receive a present of Iona Grape Vines, or the best Washing Machine, or a splendid Pitcher, or the very best Table Spoons or Forks, or 7 to 10 back Volumes, or 5 to 8 bound Volumes, or a \$15 Library, etc., etc. Remember that every thing offered is the very best of its kind—nothing second-hand, but every thing is new and warranted first-rate.

QUESTION FOURTH.—Are there not at your Post-Office, or in your Town, or within your reach at different Post Offices, at least 30 to 60 families or single persons who would be well repaid for \$1.50 invested in the *Agriculturist* for 1867 (and an extra number to those subscribing this month)? Can you not, in evenings, on rainy days, on election days, etc., call upon these persons, tell them about the paper, and what they will get, and obtain from 30 to 60 names, with little or no expense to you?—Well, look in the Table of Premiums, and see the fifteen valuable articles offered, for 31 to 60 subscribers:—the Sewing Machines, the Silver Ware, the Watch, Gun, Plow, Chest of Tools, Libraries, etc. Why! these premiums will pay somebody for getting up such clubs of subscribers in every settled town on the Continent. Read the Description of the articles given last month.

QUESTION FIFTH.—If in every settled town in the country, some enterprising person would hunt up half of the people who would be pleased and benefited by receiving the *Agriculturist* for a year, and who would take it, if it were properly and earnestly brought to their attention, would not there be found from 60 to 500 such people?—Well, please look at the table, and see the great number of good things offered for the larger clubs!

QUESTION SIXTH.—The paper is good; the people are to be found who want it; somebody can get the splendid premiums for finding them. May it not as well be you, as any one else?

MORE THAN 8000 Persons have obtained good premiums, in past years, and hundreds have already secured them this year. There is plenty of room for others to do the same thing. We are ready to send one or more premiums to each of the 25,000 Post-Offices in the United States and British America, if called for. Will you get one of them? It is easy to do so. Try it.

Table of Premiums and Terms, For Volume 26.

Table with 4 columns: No., Names of Premium Articles, Price of Premiums, and Number of Subscribers required. Lists items like Garden Seeds, Sewing Machines, and various tools with their respective prices and subscriber counts.

Every article offered is new and of the very best manufacture. No charge is made for packing or boxing any of the articles in this Premium List. The forty-three Premiums, Nos. 1, 2, 6, and from 29 to 32, and from 40 to 75 inclusive, will each be delivered FREE of all charges, by mail or express, to the Post-Office or express office nearest recipient, to any place in the United States or Territories, excepting those reached only by the Overland Mail.—The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance that may be specified.

By Wholesale purchases, by advertising arrangements, etc., we can pay much more in premiums than in cash. Every article is given at the regular price which it would cost any purchaser.

Each article offered is for a definite number of subscribers; every one thus knows just what is required. A premium is not dependent upon favoritism, or upon what some unknown person elsewhere is doing.

Over Eight Thousand Persons have hitherto received our premiums with great satisfaction; we have not heard of one in a thousand who has not been highly pleased.—It is a good work. The tens of thousands of persons persuaded by our canvassers to take and read the paper, have been benefited by so doing.

Many Clergymen are receiving the Cyclopaedia, Sewing Machines, Melodeons, etc., as premiums. Some make up the subscription lists themselves, with the freely rendered aid of their congregations. Others receive the articles from their Parishioners who unite their efforts and make up a premium club for the paper.

We take so much pains to procure only good articles in all cases, that any one securing anything from our premium list, saves the risk usually run of getting poor or indifferent goods, when buying of unknown or irresponsible parties. Every thing we send out as a premium is guaranteed to be the best of its kind and price.

Our premiums are standard articles, and enough can be obtained to supply all calls for premiums for six months. Every canvasser can take abundant time, but

As fast as subscriptions are obtained, send them along, that the subscribers may begin to receive the paper; and when all the names that can be obtained are forwarded, select the premium, and it will be promptly furnished. To save mistakes and keeping accounts, send with each list of names, the exact subscription money (in Post Office money orders, drafts or checks on N. Y. City; or, if these can not be had, registered money letters.)

Every name designed for a premium list must be so marked when sent in.

NOW is the best time to begin to raise a club, as every new subscriber for 1867, received in November, gets the December number of this year free, as noted elsewhere.

Old and new subscribers count in premium lists, but a part should be new names, for it is to obtain such that the premiums are in part offered. Papers to Premium clubs need not all go to one Post Office. Of course the extra copy, usually offered to clubs of ten or twenty, will not be furnished when a premium is called for.

Specimen Numbers of the Agriculturist, Cards, and Showbills, as may be needed, will be supplied to Canvassers. These should be used carefully and economically, as each extra copy of the paper with postage (2c.), which must be pre-paid, costs about 12 cents.

For Full Description of the several premiums see October Agriculturist, pages 349 to 352, or peruse a Descriptive List, which will be furnished free. We have room here for only the following:

No. 14—Clothes-Wringing Machine.

A very useful, time-saving, strength-saving, clothes-saving implement, that should be in every family. The wringing of clothes by hand, is hard upon the hands, arms and chest, and the twisting stretches and breaks the fibres with lever power. With the Wringing Machine, the garments are passed between two elastic rollers which press the water out better than hand wringing, and with no wrenching of the fibres. It is done as fast as the left hand can pick up the garments, while the right hand turns the crank. It is so easily done that a child of 10 or 12 years can quickly wring out a tub-full of clothes, dropping them from the machine set upon the side of the wash-tub directly into a clothes basket, ready to hang out. We offer the family size, "Universal Wringer," provided with Cogs which make the rollers turn together, and which we consider essential to prevent injury to the fabrics, loosening of the rubber, etc. We used a single one of these Wringers, one of the first make, several years without any repairs, and with the greatest satisfaction.—It weighs only 15 lbs., and can be readily carried by hand, or sent by express, or freight, to any part of the country, ready to be set upon any form of tub, and used at once. We have given over a thousand of these as premiums, with almost universal satisfaction. At least a thousand families may get one this year as a premium.

Nos. 40 to 49—Volumes of the American Agriculturist (Unbound).

These amount to a large and valuable library on all matters pertaining to the Farm, Garden, and Household, and contain more varied information on these subjects than can be obtained in books costing three times the money. We have stereotype plates from the Sixteenth to the Twenty-fourth Volume complete, and will have Vol. 25, soon after Dec. 1st. From these plates we print as needed. The price of the volumes is \$1.50 each, at the office, or \$1.75 if sent by mail, as they must be post-paid. They are put up in clean numbers, with the Index to each volume.

They are profusely illustrated, the Engravings used in them having alone cost about Twenty Thousand Dollars! Those obtaining premiums for from one to nine volumes, can select any volumes desired, from XVI to XXV, inclusive. For ordinary use, the sets of numbers unbound will answer quite well.—Many hundreds of these volumes are taken every year as premiums.

Nos. 50 to 59—Bound Volumes of Agriculturist.

These are the same as Nos. 40 to 49 above, but are neatly bound in uniform style, and cost extra for binding and postage. All are sent post-paid.

Nos. 63 to 74—GOOD LIBRARIES.

In these premiums, we offer a choice of Books, for the Farm, Garden, and Household. The person entitled to any one of the premiums 63 to 74, may select any books desired from the list below, to the amount of the premiums, and the books will be forwarded, paid through to the nearest Post Office, or Express office, as we may find it most convenient to send them. We need not enlarge upon these premiums: every one knows the value of good books. Twenty-five or Fifty dollars' worth of books on subjects pertaining to the farm will give the boys new ideas, set them to thinking and observing, and thus enable them to make their heads help their hands. Any good book will, in the end, be of far more value to a youth, than to have an extra acre of land, on coming to maturity. The thinking, reasoning, observing man, will certainly make more off from 49 acres, than he would off from 50 acres without the mental ability which reading will give him.—Our premiums will enable many a family to secure a larger or smaller Library. This is a good opportunity for the farmers of a neighborhood to unite their efforts and get up an Agricultural Library for general use.

No. 75—General Book Premium.

Any one not desiring the specific Book Premiums, 63 to 74, on sending any number of names above 25, may select Books from the list below, to the amount of 10 cents for each subscriber sent at \$1; or to the amount of 30 cents for each name sent at the (ten) club price of \$1.20 each; or to the amount of 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid by us.

BOOKS FOR FARMERS and OTHERS.

[For sale at the Office of the Agriculturist, or they will be forwarded by mail, post-paid, on receipt of price. All these are included in Our Premiums 63 to 75 above.]

Table listing various books for sale with their prices. Includes titles like 'Allen's Rural Architecture', 'American Farm Book', 'American Diseases of Domestic Animals', etc.

Containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Mark All Subscriptions sent in, as *New or Old*.

For Market Report, See Page 415.

Please Send on the Renewals of Subscriptions.—It will greatly assist us in the great work of re-entering and arranging names on the new Mail Books for 1887, if those who find it convenient will begin, at an early day, to send in their renewals of subscriptions. Can not every present subscriber get at least three others to join him, and make up a club of four at \$5? The new subscribers have the extra inducement of the December number *free*, if the names are sent this month, as noted elsewhere.

British America Subscribers-Postage.—Subscribers in the Canadas, New Brunswick, Nova Scotia, etc., will save half the postage by sending 12 cents a year to have it paid in advance here. Most do so, but some omit it.

Our Advertising Column — To Readers and Advertisers — Explanation, etc.—As this Journal goes to several thousand new readers each week, and among these are some who offer advertisements, we give a few explanations: While it is impossible to guarantee all the advertisements, we try to come as near it as practicable. Our aim is to advertise nothing we would not have read by a brother or most esteemed friend. Patent medicines and all other secret things are rejected. Also all advertisements deceptive in form and substance. Parties offering advertisements, who are unknown to the editors personally or by general good repute, are expected to furnish evidence that they have both the *INTENTION* and *ABILITY* to do what they promise to do in their advertisements. We want none to advertise in these columns to whom we would not ourselves send orders, or cash in advance, if we happened to want what they advertise and at the price they ask.—By living up to these rules, we make the advertising columns exceedingly valuable both to our readers and to the advertisers.—Our readers will find the advertisements worth looking all through, to learn what is for sale, and by whom.—We repeat a former request, that those who order from our advertisers or write to them for circulars, catalogues, etc., will state *where* they saw the advertisements. It is useful and gratifying to business men to know through what channel they reach the largest class of enterprising persons.

Correspondents Please Observe:—Use any initials or signature desired, but send your full name and address with the article. We frequently wish to communicate with a writer, and are unable to do so for want of the name. We never publish a name when some other signature is chosen.—Always name State and County. There are several Washington's, Monroe's, etc., and an answer often depends upon our knowing the climate, etc.—Do not date from "Spring Grove"—"The Dell"—or any other name by which your own place is known to yourself and immediate friends. We cannot be supposed to know it, a thousand miles away.—Do not ask too many questions at one time, especially on different subjects.—Do not write about farm, garden and household matters all on one sheet. A mixed letter often goes to the department indicated by the first query, and there stops.—We answer questions on their merits, and first, such as will interest the greatest number of readers.

Big Cabbages.—As usual at this season, Mr. R. Criswell, "the Long Island Cabbage Farmer," ornaments our table with some of his fine, hard Flat Dutch cabbages. They weigh 22 to 22½ pounds (trimmed.) He shipped over one hundred thousand last season to Southern ports.

To Post-Masters, and Subscribers — Mailing Papers.—EXPLANATIONS WHY PAPERS GO TO SOME BEFORE OTHERS.—AS fast as subscriptions or renewals are received, they are numbered and recorded in the Entry Books daily. (In busy seasons when 1,000 to 5,000 names come in a day, an entry Book for each day in the week is used.) The Posting Clerks sort out the names from the Day Books and arrange them in the Mail Books for the different States and Territories, putting all

those at the same Post-Office together, and indexing the Post-Offices alphabetically. (To find any person's name we must know his State and Post-Office.)—Our mail clerks begin a month in advance to write wrappers for all names then posted from the Daily Entry Books. These are first sent off, all those to the same Post-Office in one or more parcels, at the same hour. This is called the "regular mail." Afterwards all names arriving within a month are written from the Entry Books and mailed in the order of reception. Sometimes half a dozen different parcels go to the same P. O., but a week or more after the regular mail is sent to old subscribers. These new names are then posted into the Mail Books, and the next month they go in the "regular mail." It will thus be understood why new names and renewals get their first copies later, and not with the first regular mail. This system is necessary to ensure entire accuracy.

Plants Named.—F. Berlene. Some Begonia, probably *B. fuchsoides*, but it lacks flowers. Samuel Johas, Mo. *Verbena Aubletia* (early). Partridge Pea, *Cassia Chamærista* (yellow), and *Sabbatia angularis* (rose) M. R. Allen, Me. A variety of the common Evening Primrose, *Oenothera biennis*, and Water Plantain, *Alisma Plantago* Mrs. A. D. Gray, Pa. Spotted Dead-nettle, *Lanatum maculatum*, an old garden plant. P. H. Adams, Texas. *Erythraea Brychidii*, one of the Centaureas. D. N. Begun, O. *Euphorbia marginata*, often grown in gardens. Mrs. E. A. Robinson, R. I. A green-house species of Milk-weed, *Asclepias Curassavica*, sometimes grown as a bedding plant. P. F. Ferris, No. 1. *Gerardia quercifolia*, No. 2. Great Purple Orchis, *Platanthera peramona* J. B. Metz, Pa. The common Live-for-ever, *Sedum Telephium*. It has great tenacity of life, and must be grubbed up completely. Mrs. J. Prescott, N. J. Joseph's Coat, *Amaranthus tricolor*, a very old "foliage plant." J. Fitzgerald, Pa. *Gerardia pedicularis*.—A lot of rubbish and incomplete specimens remain undetermined.—In regard to naming plants, we are very glad to help those who cannot get at the name in any other way, and who will send us good specimens—never more than three at a time, and then properly marked.—We don't propose to spend time in guessing at single leaves and ends of growing shoots. Nor can we fill our space with giving botanical names of garden plants. The person who, without name or date, enclosed us some dozen or more garden and green-house things, with the common names, and asking for the botanical names, should have some good book on the subject.

"Donation Parties" are much in vogue, and often very pleasant affairs. Our business letters describe several such parties a little out of the usual line. In these cases, the members of a congregation, headed by two or three individuals, have quietly raised a premium club of subscribers, and secured a set of the Cyclopedia for their Pastor, or a Sewing Machine or Melodeon for his family. Premiums 15 to 20, 25, 31, 39, etc., in this year's list, will afford pleasant additions. The matter is easily accomplished, and a double object is attained; the paper is scattered and read more widely, while the useful premiums are secured without expenses. Where this has not been done or thought of by the people, the pastors themselves have secured the much valued Cyclopedia, etc., by a little effort in making up a club.

About Insects.—They eat our potatoes, and bore our trees, destroy our crops, sting our fruit—yea, even sting us and bite us, and suck our blood; they bless us too in a thousand ways. The study of insects and their habits is most useful and interesting, and every body is interested to read about them. We can recommend without qualification the *Practical Entomologist*, published at Philadelphia, and refer our readers to the Publishers' advertisement. It is *practical* and not so "scientific" as not to be entirely "popular," and easily understood by every body.

"Diamond Cut Diamond."—Some time ago we inserted full paid advertisements of the Herald and World, for the "reasons" stated last month, (page 345.) and two or three cried out "stop my *Agriculturist*." For the same "reasons" we inserted a large advertisement of the Tribune in September, and then came "a stop my paper," and complaints from others because we did not have in the same paper advertisements of the Herald and World, which chanced just then to be pulling together politically. (We did not have their advertisements, for the very good reasons that they did not happen to bring them in and pay for them.) As the friends of the World complained of us that time, we will call the World on the stand as a witness in our defense, and quote from an editorial in that paper (the World) of Sept. 29: ".... We can do the public morals a service without being suspected of a sinister motive. That

service is to enjoin upon every republican to buy the Tribune and read that, and to refuse to buy the Herald at any price.... The Tribune holds its principles in sincerity, and advocates them because it really believes the country will be the better for adopting them. The Herald advocates them because it thinks their advocacy will pay; because it thinks they are likely to succeed...."—N. B.: This is not a "political item." We just want to show our protesting friends that we have pretty high authority for admitting an advertisement of the Tribune, as some seem to think we need to ask permission for advertising anything of any kind.

The Lake Shore Grape and Wine-growers' Convention was held at Cleveland, O., on the 10th, 11th, and 12th, of last month. The attendance was large, the discussions animated, and the display of fruit and wines very fine. The interest of the meeting was enhanced by the presence of veteran pomologists, Hon. Marshall P. Wilder, Prof. J. P. Kirtland, Dr. Wauder, George Graham, etc. We gathered many notes at the meeting, and shall hereafter allude to some of the prominent features.

Our Young Folks, published by Messrs. Ticknor & Fields, Boston, has, from its commencement taken the first rank as a magazine for Boys and Girls. The instructive yet lively articles it contains monthly, attract the attention of many "children of a larger growth," as well as always delighting the juveniles. The plans for the coming year promise increased excellence, and we commend it to all who would furnish their children with good matter which they will read.

Hay and Cotton Presses.—These have been very greatly multiplied of late years, and increased in power so that many of the most bulky substances sent to market, Hay, Cotton, Straw, Rags, etc., are now pressed into small bulk and can be as easily handled, or loaded on cars or vessels as flour or similar merchandise. We saw recently a press called the Champlon, advertised elsewhere in this paper, which exhibits an astonishing combination of mechanical powers. A screw operates upon the periferies of two wheels, which move a "toggle-joint" lever, which does the pressing, with great power and rapidly.

N. Y. Time Tables.—Benedict Brothers, 171 Broadway, issue monthly a very convenient Guide, giving the full time tables, etc., of all the numerous Railroad Trains, and the Steamboats centering in this city, including a condensed map of the city and its streets up to 59th street, and of parts of Brooklyn and Williamsburg. Price 20 cents.

"A Sow (writes 'X.'). owned by John Ambler, of Cambridge, O., recently produced a litter of 23 pigs!"

Bommer's Method for Making Manure.—Some 20 years ago letters patent were issued to Geo. Bommer, for a method of making manure of great value out of the common rubbish and litter of the farm, at a small expense for a few articles, or their equivalents, which indeed are usually at hand. This patent, now expired, was somewhat extensively sold at \$10, for a farm right, we believe. The account of the process was given minutely in an 8vo. pamphlet of 90 pages. These pamphlets we now offer on our *Book-list*. The information is just as valuable as if the patent right were still in force, and the process we know by experience and observation is a most excellent one to increase both the quantity and value of the manure.

Shell Marl as a Fertilizer.—A Caution.—The investigations which the peat swamps have undergone of late, have developed the fact that many of them are underlaid with shell marl. This is chiefly carbonate of lime, and is a valuable manure where it can be had in large quantities. The value may be \$1 to \$3 per cart load. The quality of marls varies greatly, and the quantity applied, in like manner. Thus 12 to 20 tons of some kinds and on some soils—and 60 to 100 tons being applied in other cases. The idea of making shell marl an article of commerce like the phosphatic guano, or even the green-sand marl, to say nothing of more valuable manures, is simply absurd!

The Evening Post appears again in a new dress, new type, and printed on better paper. Though in its 66th year, it has all the freshness and vigor of any of its more youthful competitors. Mr. Bryant's writings have always been its principal charm, and it is gratifying to know that his pen is still active as ever. See Advert.

Manure and Corn.—We have already many interesting responses to our questions (page 278,) about the prices of the two articles, but would be glad of more. As our readers return their names and subscriptions for 1867, they will not put in a slip for the *Editors*, saying:—"I can buy common barnyard manure for \$— per cord, (or per cubic yard,) and corn is worth here — cents per bushel."

Tall Corn.—Isaac Beardorf, of Jay Co., Ind., writes: "I raised the past season a stalk of corn 16 feet high, with 2 good ears, the upper one being 21 feet above the ground. There were plenty of stalks nearly as high. Who can beat it?"

Ashes.—L. T. Fribert, of Dodge Co., Wis., writes: "I have a city garden, keep no domestic animals from which to get manure, burn a great deal of wood in my house, and have plenty of ashes. I learn from the *American Agriculturist*, that ashes are a valuable manure, that I may use them on my compost heap to mix with muck, etc., (but unfortunately I have, like the most of the city folks, no compost heap,) that I can scarcely give my garden ground too much leached ashes, and that unleached ashes are much more valuable as a fertilizer than leached ones. But the question is—'What shall I do with my unleached ashes—having no compost heap?'"—Answer: After spading or plowing the garden, scatter them over the surface evenly and rake or harrow them in. Scatter them around the fruit trees, grape vines, etc., on the surface; they need not be spaded or forked in, for they will naturally work down. Give the grass a dressing, sowing them by hand, or very evenly with a shovel, raking the grass over to break the lumps afterwards. If you have any left, make a leach tub and leach enough ley to make soft soap for the year. Don't mix ashes with animal manure.

Coal Ashes.—"D. St. G. F.," Bedford Co., Pa., asks: "Will coal ashes be of any benefit to clay soil? The soil here is a very heavy clay, and we use no fuel but coal. I thought the ashes would have the effect of loosening the soil without injuring it."—This is just the effect they have, and just such soils as yours are most benefited. They ought to be screened and the clean ashes applied—the clinkers and stones will do no good.

Pigs Born with Teeth.—W. H. Rodney, of Sussex Co., Del., wrote sometime since, in answer to a question in the *Agriculturist*, that "some litters of pigs in this section in the fore-part of this year all died off, and continued to do so until it was discovered that when they were born they had long sharp teeth, which prevented their sucking. They cut their tongues very badly and soon died. But the teeth being broken off even with the gums with a pair of nippers, they could then suck, and in all cases I have heard of, the pigs did well. The teeth are not very solid and are easily broken. This trouble about pigs has not been known long in this section, but it has become very common now for persons to notice young pigs when they are first born, and if they have teeth, to break them out, or they will soon die.

Death in the Chicken Yard.—T. Forth, of Preble Co., Ohio, has very bad luck with his chickens. They are well, grow pale about the head, their flesh blue, and they die after a few hours' or a day's sickness. It seems to us they are poisoned. Where rats are poisoned, they run out into the yards and vomit; the chickens eat this and die.

Hops in Michigan.—A correspondent informs us of the very great increase of hop culture in some sections of Michigan. This year the crop is light, but prices high. The louse is beginning to be troublesome, and should be met next spring with the best remedies yet suggested. We hope our readers who have tried any remedies, will report their success or failure.

Constitution for a Farmer's Club.—The undersigned hereby associate themselves as the Farmer's Club of ——. Their objects in so doing are to promote their own welfare and intelligence, as farmers and citizens, and their enjoyment socially, with their families. The members are those who regard themselves as such and who have attended meetings within 3 months. The officers shall be a President chosen at each regular meeting, a Treasurer and Secretary, chosen annually, whose duties shall be those usual to such officers, and who shall constitute the executive committee. The club shall be governed by established Parliamentary usages, enforced as strictly or otherwise, as the chairman may deem expedient. The regular meetings shall be held on the 2d Thursday evening of each month. The executive committee shall have power to call meetings, lay taxes, and have charge of all the property of the club. No taxes exceeding 25 cts. per month shall be laid and collected. This constitution may be amended only with

the consent of two-thirds of the members present at a meeting, and two-thirds of all the members.

Fruit Preserving Houses.—Several Correspondents. We believe that the universal testimony is in favor of these. The house is a large refrigerator, with ice at the top to keep the temperature low, and within the house is placed a quantity of chloride of calcium to absorb the moisture. The fruit is thus kept cool and dry, and the house being tight, the fruit is soon enveloped in an atmosphere of carbonic acid from its own exhalations. These are the general features, and are a combination of well known and long used expedients. We have said but little about this, as we assume that holders of patents will do their own advertising. This one holds his "rights" at a price so outrageously high that, while we admit the utility of the thing, we regret that the estimate put upon its value is so great, as to keep it out of the hands of all but capitalists.

Salve for Chapped Hands, etc.—"The following is a well tested, excellent remedy for chapped hands, and sores of this nature. Put together equal weights of fresh, unsalted butter, mutton tallow, beeswax, and stoned raisins; simmer until the raisins are done to a crisp, but not burned. Strain and pour into cups to cool. Rub the hands thoroughly with it, and though they will smart at first, they will soon feel comfortably and heal quickly."—*Cayuga County Girl.*

Wringing Machine Rollers—Repairing.—Answers to several inquiries. The rubber rollers very seldom give way in well made machines, especially if there are cogs to relieve the strain upon the under roller. They can be easily repaired, however, by merely sending the defective shaft to the manufactory, or to any leading agency of the respective companies. The cost is about \$3 to \$4 per pair (less for one) at the factory, to which add freight or expressage.

Grease for Cow-hide Boots.—Heat well together, in any iron vessel, 1 pint linseed oil, 2 ounces tallow, 1 ounce beeswax, and 3 tablespoonfuls of lampblack. Apply with a brush. I have used this 15 years with entire satisfaction.—*A. M. Knapp, Poultney, Vt.*

The Last Ant, abili, excessit, evasit, erupit—atque sine controversia vicinus.*"—R., of Watertown, N. Y., sends an amusing account, too long to print, of sundry contests with ants, closing with the above quotation. The gist of it is, that a little kerosene oil poured or injected into or about their habitations, invariably causes them to quit for parts unknown, instantaneously. This applies to all kinds of ants, black, red, wood gnawers, etc. He thinks with little trouble in applying this, our country may soon be as free of ants as Ireland is of toads.

Taking Care of Brooms.—Have a screw with an eye or ring on its end; this can be screwed into the end of the handle of each successive new broom. It is handier to hang up by than a string, though the latter answers if always used. It is bad for a broom to leave it standing upon the brush. If not hung up, always set it away with the stick end down.—*O. K.*

Butter-making Hints—Wheel Grease—Fruit Stains.—Mix all the cream thoroughly together 10 or 15 hours before churning, so that it will be of equal sourness and all "come" at the same time.... To extract wheel grease, rub on the yolk of an egg, let it dry, and wash out in clean water, without soap. Repeat two or three times if necessary.... To extract fruit stains, dip the fabric in boiling water before wetting with suds.—*Extracts from a pleasant Springfield, O., letter—no name.*

More Home-made Ink Recipes.—(Sent with good specimens.) Put 2 ounces each of gum arabic, extract of logwood, powdered nutgalls, and coppers, in a stone jug with a quart of hot water; set the jug in a kettle of water upon the stove, for 12 hours. Shake it up occasionally, and it will be fit for use in about a month. Frost does not injure it. I have used this for 18 years.—*Thomas Bragden, Omro, Wis.*... Dissolve in 1 gallon of rain water, 10½ ounces powdered nutgalls, 3½ ounces gum arabic, and 3 ounces coppers. Shake frequently, and in 2 or 3 weeks it will become good. Keep closely corked. It will endure for centuries.—*M. K., Foxboro, Mass.*

The Secret of Washing Easy.—"U. S. Y.," writes, that a servant refused to leave for another place, simply because she would not go where there was not a wringing machine. [This is one of the "machines" which even the servants like generally, as much opposed as they are to machines of all kinds.] "U. S. Y." thinks the secret of the success of the wringer, and the great argument in favor of washing machines, is the fact that

with them boiling water can be used without burning the hands, and this removes filth and oily materials left in garments by the skin—far better than merely warm water.—There is undoubtedly much in this. Another secret is the soaking of the garments over night. Water with a little soap in it, is a great dissolver, but it needs time to act. Half the labor is saved by soaking the garments several hours before the washing begins.

Lard and Resin, for Preserving Metals from Rust, for Boots, for Chapped Hands, for Sore Teats, etc.—We have often commended a mixture of lard and resin, ("rosin," "rosun,") as excellent for preserving all metal surfaces from rust. It may be applied and rubbed off nearly clean, and yet enough be left to shut out the oxygen of the air. It therefore answers for delicate instruments, and for steel household implements not in constant use, as well as for plows and other large implements, since it is very cheap.—A subscriber in Birmingham, Erie Co., Ohio, says he finds 1 part resin to 3 parts fresh lard the best proportion. It needs merely to be warmed and stirred together, and can then be kept any length of time. He finds it excellent for greasing boots to keep out water, for chapped hands, old sores, etc., for sore teats on cows, for scab or scurvy on hogs, etc.

Keeping and Settling Coffee.—The following appears valuable: "For 1 lb. coffee, take one egg and beat it well. When the coffee is nicely browned and cool enough not to rook the egg, pour the egg over it, stirring it until every kernel is coated with a varnish, and let it stand a few minutes in a warm place until it dries. This will prevent the escape of all aroma, is not affected by moisture, and the egg helps settle the coffee when it is ground and steeped."—*Farmer's Daughter, Hastings, Mich.*

Hotch Potch.—Chop very fine, 3 parts green tomatoes, and 1 part onions, with more or less of garden pepper pods and salt; let it stand 12 hours, then put in ajar and cover with vinegar. Excellent with meat in winter.—*Mrs. Sam'l P. May, Plantersville, Texas.*

Tomato Crout.—Pick the last green tomatoes before frost, and chop very fine with any desired quantity of green peppers, allspice, cloves, and cinnamon. Pack in jars and set in a cool place until it sours, when it may be cooked like cabbage crout, or eaten raw.—*"A Friend to the Agriculturist," Prairie City, Mo.*

To Hull Corn.—Boil in weak ley until the hulls begin to come off; next rinse well two or three times, in plenty of water; then add clear water and boil until done through.—*Marion Chaffin, North Star, Mich.*

Soda Crackers.—Rub well together, 14 cups flour, 1 cup lard, 4 teaspoonfuls cream of tartar, and 2 teaspoonfuls of soda. Add 3 cups of water, and work the dough very thoroughly. Roll, cut, and bake quickly.—*Mary Mendenhall, Roseville, Penn.*

Chatanqua County Corn Bread.—The following is very good for general use, and I think would have taken the prize at your Corn Bread Exhibition: Take 4 quarts corn meal, 1 quart flour, 1 cup molasses, 1 teaspoonful soda, 1 tablespoonful salt, 1 pint milk emptyings; mix quickly with milk or water, and bake slowly 4 hours. It is improved by remaining in the oven over night.—*W. H. S. Grant, Poland, N. Y.*

About Unbolted Flour.—I admit that unbolted flour will make the most healthful bread, but bran and flour separated will keep sweet longer than if mixed. We have tried the following with satisfaction. Bolt and keep separate as usual. For bread, mix the pure flour and let it rise two-thirds of the necessary time; then wet the bran, mix it with the dough, and let it all rise the rest of the time; then bake. You thus obtain very good, sweet, sound bread.—*M. Nieder, Ozaukee Co., Wis.*

Wood's Parlor Gymnasium.—Mr. John Wood, who has long maintained the excellent Gymnasium, cor. of 5th Avenue and 25th street, supplies a valuable little apparatus for developing the muscles and promoting the healthful activity of the organs of the body. It is readily and quickly put up and taken down in any room in the house, and is faithfully used by sedentary persons, and all who do not have sufficient physical labor to give the best vigor, it will prove of great value. We have one in our home study, and when engaged long in writing, we spring up occasionally and use the handles, cords, pulleys, and elastics a few minutes, with decided advantage, regaining a flow of blood in the veins, and an increased elasticity of spirits. By using one, two, or three of the elastic cords, it is adapted to children, females, or strong men. It packs in a box 4x6x8 inches. Price \$10.

"Introduction of the Verbena."

In August we gave an account of the introduction of the verbena, now so common in our gardens. Several have written from the "far West," claiming that "the verbena" grows wild there, and seem to think that South America gets credit for a plant that belongs to their region. We well know that several verbenas grow wild in different parts of this country, and that one of those of the West and Southwest is tolerably showy, and has been cultivated. This is *Verbena Aubletia*, which has been recently sent out as *Verbena montana*. It is a rather weedy plant, but is hardy and keeps long in bloom. The article alluded to referred solely to the bedding plant, so common as to have monopolized the generic name Verbena.

Strawberries in Iowa.

"T." in referring to our note in last month's basket, says: "Allow me to modify your advice somewhat. Plant in spring on the highest and driest spot you can select. If not perfectly dry, dig a small trench around the bed in autumn, throwing the dirt outside, and if you don't want some big prairies in it, don't try to protect with anything in winter, not even the slightest mulch. I will say, even to the *Agriculturist*, if there is a better berry for the Northwest than Albany Seedling, take it altogether, I have yet to see it."

Cutting Strawberry Runners.

"W." Ishester, Ill., asks, if there is any implement for cutting strawberry runners. We believe that one or two contrivances for this purpose have been invented, but we never knew them to be used. Our large growers nip the runners by hand, or if too old, they cut them with a knife.

The Agriculturist Strawberry.

We did not intend to say anything more about this fruit at present, but here are two opinions that we like to put side by side. In the words of the showman, who was asked which was the tiger and which the hyena, "You's paid your money and you takes your choice."—From *Hovey's Magazine* for July, 1866. "*Agriculturist Strawberry*. * * * It is simply a good sized, rough looking, and fair-flavored berry—all and even quite as much as was expected of it, and probably of no real value, compared with *La Constante* and *Hovey's Seedling*. The vines have not wintered well generally, and it is exceedingly variable according to cultivation."

In the *Horticulturist* for August, 1866, Mr. J. M. Merrick, Jr., Walpole, Mass., (Walpole being 18 miles away from Boston.) writes: "*Agriculturist*. In size and vigor of plant, size of berry, and general excellence, this famous kind stands at the head of the list and surpasses all the other kinds—some thirty-two in number—which I now have on trial. * * * In brief, I may say that in my opinion, the best berry, taking all things into account, is the *Agriculturist*."

Fine Asters.

Only those who recollect the China Aster of twenty-five years ago can appreciate the improvement that has been made in this flower both in form and color. They are annuals, and every one can raise them. A splendid show of these flowers was made at our office by Cuno Kretschmar Bros. & Co., of Brooklyn, N. Y., and a very fine bouquet of them was received from P. Hannah, of Newburgh, N. Y.

Grape Queries.

"Yankee," Fairfield, Iowa. Draining is "essential," unless there is a very open subsoil that gives a natural drainage. If you cannot get tiles, make stone or rubble drains, or use boards. None of our American grapes have yet been profitably converted into raisins.

The Giant Wax Bean.

Under the above name we have received a sample of beans from Mr. Henry A. Dier, Seedsman, Philadelphia. The pods are 6 to 9 inches long, thick and fleshy, of a pale yellow color, and a waxy appearance. The seeds are red. The peculiarity about this variety is, that its pods, even when full grown, are perfectly tender, and may be used as snap beans. We have tried them both separately and in succotash, and consider them really delicious. The variety is a pole or running bean, its origin is unknown; but wherever it came from we welcome it as a valuable addition in our list of varieties.

Propagating Plants.

"A. M.," Macon City, Mo., asks: "Whether a small room with the south all glass will not be a good substitute for a hot-bed in starting plants, making the bed so as to receive the light and heat of the sun through the glass, and when cold, heat the room with a stove."—This is one of similar queries that come from those who think that any glass structure will do for a propagating house. A room like the one described would probably answer as a greenhouse for wintering some plants, but it would be a very poor place for starting plants from seeds or cuttings. Structures for propagating need to have the soil some

degrees warmer than the air (bottom heat), and to have the glass as near the bells as possible.

Burying Hollyhocks.—Helen A. Burrough, Floyd Co., Iowa, failing to winter hollyhocks by covering, keeping in the cellar, etc., at last tried burying them a foot deep in the soil of the garden. They kept well and grew finely when set out in the spring.

Fine Gladiolus Flowers.—We thought we had seen the Gladiolus as fine as it could be, but some specimens from Mr. Geo. Such, South Amboy, N. J., convinced us that there was a "touch beyond." Mr. S. is an enthusiastic cultivator, and imports all the new and rare European varieties of Gladiolus.

Country Roads—Cross-ways for Water.

"Birmingham," of Chester Co., Pa., sends us a few hints worth practicing upon. The cuts show sections and birdseye views of country roads: a is the horse track in the middle of the road; b, b, the wheel tracks; c, d, the gutters; e, e, the wash-ways off from or across the road. If it is desired to turn the wash off on both sides, very slight depressions (e, e, fig. 1) commencing in the wheel track on each side, and widening and deepening to the gutters, with a slope towards the bottom of the hill, are all that is necessary and will not cause a jolt to a wagon that will break any thing or be uncomfortable. If the wash is designed to cross the road, let it do so in a long diagonal (e, e, fig. 2). It does not take a very high cross-way to turn water where it has a free course, but if it is dammed up and turned at right angles, it will take of course a high bank or cross-way to turn it. It is not always practicable to keep the middle of the road the highest, but it can be easily accomplished in many more cases than it is done.

Fig. 1.

Fig. 2.

Unruly Salsify.

"Carolus," Danville, Ky., complains that his Salsify, the seed of which came from a reliable dealer, instead of making a biennial root, ran to seed the first year and was worthless. Moreover, the plants from this seed did the same thing. It is not unusual to see a number of plants in a field of biennial plants, such as carrots, parsnips, etc., flower the first year, but we never knew a whole crop to do so. We can only account for this occurrence by supposing that the growth of the Salsify was checked by a drouth, and the plant as effectually put to rest as it would be by cold, and when a "growing time" came again, the plant started to flower just as it would in spring.

How to Mend a Mill Stone.

We have already cautioned against the practice of filling the cavities of mill stones with lead. Spencer Haines, of Burlington Co., N. J., writes that he uses melted sulphur with sand poured into the cavities while the mixture is hot, and finds it to answer every purpose, and to last.

Internal Revenue.

Every one pays taxes in one way or another now-a-days, and is interested in knowing what the law requires. There have been several publications of the revenue laws, but the best we have seen is one compiled by Horace Dresser, published by D. Appleton & Co. It contains the original law of 1864, with all the subsequent amendments conveniently arranged for reference with marginal notes, and a complete analytical index. Price 50 cents.

Good-looking Husbands.

should be careful where they get their photographs taken. A lady writes us, that while on a visit from home, a female friend showed her, very confidentially, a picture of the said friend's promised husband. Judge of her surprise to find the photograph a very accurate likeness of her own husband, whom she supposed to be entirely unknown to her friend. Her first thoughts were of unfaithfulness, and all that, but the matter was finally explained thus:

The husband in question, when in the city, had his photographs taken in quantity for his friends, but rejected half a dozen or so which he thought not correct. The lady friend above referred to, seeing an advertisement of a "fortune teller" to "send any one a likeness of her future husband for 50 cents," had invested that sum with the swindling sorceress, and received the picture in return. The fortune teller supplied her customers with rejected miscellaneous photographs, gathered at a cheap rate at the photographic establishments, selecting of course the best looking ones, so as to please the fancy of her dupes. Ergo, good-looking husbands (and wives too) should be careful where they get their likenesses taken, and carry away all the copies made; otherwise they may find jealousy and trouble created by the fortune tellers.

Annealing Nails.

As a very easy and effectual method of annealing nails, a subscriber recommends heating them red hot and plunging in cold water. Better to heat and then cool slowly in ashes or sand.

Brine on Sour-Crout.

Q. R. Comstock asks why the brine on sour crout rises and falls, and states that sometimes the brine is several inches above the crout, and vice versa. We do not suppose that the brine changes at all, but that the apparent rise and fall is due to the crout, which, being in a state of fermentation, gives off gas, the bubbles of which being entangled in the crout, make the mass light enough to rise. The activity of the fermentation is affected by warmth.

Toes of Shoes.

Wm. H. Maxwell, Johnston, O., writes: "A line in the *Agriculturist* says: 'Copper tips protect the toes of children's shoes.' I know a better way. Make them what is called 'Scotch bottoms,' that is, a sole projecting one eighth of an inch, or about that, beyond the usual rule and always sewed. That makes a bottom on which to walk, an elastic easy sole, and protects the toes."

Something Entirely Unwarranted.

The following is cut from a report of the proceedings of the American Institute Farmer's Club for Sept. 4th: "*Names for Grasses.*—A. M. Burns, Manhattan, Wiley County, Texas, wants to send a variety of grasses for names. We commend him and others desiring such information to send specimens to Prof. Thurber, No. 41 Park Row, New York; or J. Stanton Gould, Hudson, New Jersey, and always be careful to enclose \$5." We can only say that no one connected with this office was ever known to make any charge for information, and we have no doubt that Mr. Gould will feel quite as much surprised at the implication as does the gentleman whose name is associated with his. We believe the reporter of the proceedings meant kindly—but when we are advertised to do jobs, we prefer to be consulted. Send on your grass, and pay your postage, but keep your \$5.

Surface Indications of Water

are often difficult to detect, and frequently wanting altogether, even where water is close at hand. Sufficient perseverance will generally be rewarded, and so the willow, peach, or hazel-wand indications, if followed, will usually come to water sooner or later. Water obtained by digging wells is of two kinds; that which flows into the wells from the adjacent ground in which it is held as in a sponge or a basin, being supplied from the surface, and hence called "surface water;" and that which flows in under-ground channels at indefinite depths. If a well is sunk near, or cuts one of these channels or subterranean brooks, the supply of water is usually more permanent than surface water. Surface indications are uncertain, unless the inclination of the strata of rocks, or of gravel, clay, sand, etc., is obvious, and the water flows out on side-hills where these strata crop out, or unless the spongy or dishing character of the soil is obvious or proven. We would rely on no general indications of water, but would dig our wells where we wanted them to stand, unless so doing would be in opposition to geological indications, or to facts established by other attempts to find water in the immediate neighborhood. Certainly we would never follow the Water Wizard and his witch, in many cases fallacious.

Let us see Your Figures.

—A Winnebago Co., Ill., correspondent asks this simple question, viz.: "Which is the most economical way to fatten 20 steers—1st, to feed them corn on the ear (the usual way); 2d, to take the corn to mill and give one eighth (they take one sixth), for grinding; or, 3d, to buy a mill, for \$75 and grind your own corn?"

Paint—Coal Tar.

"Is coal tar good paint for the outside of a small house?" asks S. L. E.—Yes, if you like a black house, which no sane man can. We know of no cheaper and better paint than good boiled linseed oil, with best white-lead or zinc-white, tinted of an agreeable stone-color or earth-color.

Poetry not Desired.—Occasionally a contributor sends us poetical contributions. Some of these are of sufficient merit to publish, had we room for such articles. As it is, we are obliged to decline them, and as this is a general rule, no one will feel slighted.

Lost Parentage, or "Credit."—Though sometimes gratifying to one's vanity, it is often vexatious to see his literary offspring wandering around the world in a state of orphanage—or even worse, as the legitimate offspring of others in whose company they are found. Owing to the unpardonable habit certain editors have, of appropriating others' brains, with scissors and paste, we every month see hundreds of items and longer articles, of course our best, printed and re-printed, either with no credit, or with an entirely wrong credit. One paper is more quoted than almost any other, because, though providing very readable columns, it adopts as its own, the gems of our periodical literature.—The *Agriculturist*, because almost entirely original, suffers quite as much as any other journal, in respect to the plagiarism complained of. Take a single example out of thousands, as an illustration: The *Central Christian Advocate*, of June 23, contains a beautiful piece entitled "A Free Concert," or the Singing of Birds, and places before it, "From the *Religious Telescope*." The fact is, that article was written for the *Agriculturist*, June 1857, (Vol. XVI, p. 226). Where the *Telescope* got it, or what paper first deprived it of its parentage, we do not know.

Root Cutters.—Roots are cut up for stock in many ways. We have used with satisfaction a sharp spade, cutting perpendicularly, or slid back and forth against one end of a strong box. The other end of the box is taken out, and this end raised up a few feet. Another good way is to mash the roots with a heavy mallet. Root cutters are sold at various prices—\$22 to \$65. Allen's (\$65), made according to an English pattern, cutting them either in slices or narrow strips—is strong and good.

"Cattle Food."—We have refused advertisements from many parties offering various prepared "foods" for cattle, horses, etc. Some of these are, undoubtedly, useful to animals in a weak or low condition, as tonics. After being made acquainted with its composition we have now admitted an advertisement of one of them which is highly commended by parties of our acquaintance who have used it, and the composition of which is not objectionable. The only exception we would take to it is, the recommendation to feed it to animals *after* they are brought into good condition. Men stick to tonics from habit; we would not let animals do so.

"Prepared Photograph Paper," which requires no instruments, but is all ready to take excellent pictures, is advertised in Western city papers. Is it not a humbug? Thus writes Nellie Smith, Walworth Co., Wis., and we answer, Yes, and No. Yes, in so far as it conveys the impression that pictures can be taken upon it. No, when it is considered as a amusing and rather expensive toy. The paper is of two kinds, one has a picture already taken upon it, but invisible; the other is impregnated with a chemical solution. When this last paper is wetted and laid upon the first, the picture *already there* is brought out.

Answers to Queries.—The *Agriculturist* has a serious fault in not affording its editors 100 pages per number to answer all the questions proposed to them. Many letters receive personal answers where such are not requested; others are answered in the "Basket" whose writers desired personal responses; for many others, answers are written, put in type, and crowded along from one month to another, until they finally get a place, or until it is too late for them to appear at all, and so our readers think their letters are over-looked. We answer all that we can and as soon as we can. Still, many are crowded over every month, and we see no help for it. Send in the queries if you can be patient, and we will continue to do the best we can.

Even-Blast Fan Mill.—"A. R." If you make a fan on Mr. Leach's plan, you of course infringe his patent. The honest way is to communicate with him.

"Charles Reade" — "Prurient Prudes."—What singular notions some foreigners have of the American people and their tastes. A marked case of this misconception has just occurred. Charles Reade, a writer of some note, who dates from "No. 5 Albert Terrace, Hyde Park, London," has been supplying a story to an American Journal. A paper or two took occasion to criticise the story rather sharply on the score of morality, etc.—Whereupon Mr. Reade sends over a letter, headed "Prurient Prudes," which he expects, almost demands, that "all editors of American journals

who have any justice, fair play, or common humanity to spare," will print. After seeing Mr. Reade's bombastic, ill-natured, self-conceited letter, in which he shows out his real nature, we have no desire to ever read another book of his, and we advise every American to give a severe go by to any thing written by Charles Reade of Hyde Park. The *Evening Post* well calls his letter, "a bucket of dirty water." No man who could write and sign such a letter is fitted to furnish proper or acceptable mental diet for enlightened Americans.

"How it Works."—A gentleman in sending \$20 for twenty copies of the *Agriculturist* to be distributed in his neighborhood, writes "... Aside from the good I may do to others by this expenditure, I expect to receive it back, ten, if not a 'hundredfold.' Twenty of my neighbors reading the paper for a year will be led, insensibly, to brush up their farms, and improve the general look of things; they will plant more shade and fruit trees from simply having their attention called to the subject; they will talk about and put in practice improved modes of cultivation—in short, the result will eventually be to so change the tone and look of things in the neighborhood, that my whole farm will sell for at least \$5 or \$10 an acre more than it would otherwise. That's the way it works...."—No doubt of it. No family can read the *Agriculturist* regularly without insensibly acquiring an improved taste, from its engravings alone, while its hints and suggestions have set tens of thousands of people to thinking, inquiring, comparing views, and making improvements, no matter whether they have followed out its direct teachings or not. The results have been far more valuable than the small cost. Then, in the present year, this journal has saved to honest people millions of dollars by its exposure of humbugs alone.—We hope every reader will see that some one is making up a premium club at his Post-Office. The premiums are too good not to have at least one of them go to every town, and the wide circulation of the *Agriculturist* is of too much importance to be omitted. Those who will be least likely to take it without being urged to do so, are just the ones who need it most.

Sundry Humbugs.—We report a gratifying decrease in the letters respecting attempts at swindling. Instead of the bushel or two that came when we commenced a new and vigorous onslaught and exposure, we have this month but 56 such letters, and these refer to only 19 swindlers, mainly parties already shown up by us. We intend to follow up and expose these swindlers until their operations shall entirely cease to be remunerative, if they are not wholly made so now. The wide circulation of the *Agriculturist*, amounting to an average of half a dozen regular copies to every Post-Office in the United States and British America, makes it a formidable stumbling block in the way of those whose deceptive schemes are exposed in its columns. Numerous threats and attempts at prosecution will only stimulate its efforts. No one doing a legitimate business, in a legitimate way, need fear injury. If in exposing more than a hundred and fifty operators, as we have done this year, we should by any chance do the remotest injustice to a single person, (which we do not believe has been done,) our columns are always gladly opened for correction. We only aim to guard our readers and the community against the wily schemes of those who, by plausible circulars, advertisements, etc., deceive the trusting and ignorant. The honest people are least suspicious of wrong in others, and are therefore the most likely to be imposed upon. The country, from Maine to Oregon, has been privately canvassed, and the names and address of almost every person is recorded in some of the numerous swindling establishments. These play into each other's hands, by exchanging lists of names, and thus it happens that the same person receives "private" and "confidential" circulars from many concerns. Our readers will please promptly send us every *new* circular that comes to hand. Never mind the 20 or 25 days, or other limited time allowed to secure some wonderful prize for a very small investment. If anybody wants one of the \$60 watches offered for \$5 (after paying \$5 for the ticket), we can supply one, which we purchased at one of the most plausible and close mouthed ticket operators, for the sake of investigation. It cost us an \$X, but after trying it two months, and calling in the aid of a good watch-maker, the beautiful thing don't "go" except as we carry it.... *Harris Brothers* were duly exposed last month. Many generous persons, wishing to aid the soldiers in every possible way, have unwittingly sent their \$5 each to them, and received and forwarded the "subscription certificates" to us, which have of course been promptly returned. We have not learned whether or not the "Rural American" accepts the bribe of "an immense increase in circulation," and winks at the operations of *Harris Brothers*. Nothing is said about it in that paper. Has any one obtained that, or any other journal, for one of *Harris Brothers*' "certificates." It was a gross imposi-

tion upon us for them to attempt to make us even appear to countenance their "Lottery," for their scheme at best is no better than any other lottery, while they attempt to take advantage of people's kind feelings towards disabled soldiers. We are glad to learn that in sundry places where the scheme "took" at first, the people decided to wait until the October *Agriculturist* came to hand.... *J. D. Miller* still carries on his "Depository of Merchants' Manufacturers' swindle," but of course not among the readers of the *Agriculturist*. The latest letter of his sending out which we have received, he dated Sept. 29th.Nine parcels of tickets before us, of recent issue, show that *Mackey & Co.* still operate under the old name. See September *Agriculturist*, page 311, for exposure of this concern and others.... *W. T. Orton*, for Wood, Ellis & Co., dating at Progress, N. J., continues his swindling schemes, making offers calculated to lead green "agents" to help him sell bogus tickets.... *Lottery* dealers have been rather quiet since the "Massachusetts Decision" about U. S. Licenses, but we find before us the circulars of *Murray, Eddy & Co.*, Box 4304, N. Y. City, which will of course be taken from them. See about Lotteries page 172, March *Agriculturist*.... *Dr. Ogden* should go into partnership with the (Rev.) *Edward Wilson*. See page 211, June *Agriculturist*. They both operate in the same way, if not the same party, and are to be avoided. *Edgar Tremain*, also "L. C. W.," also *Mrs. M. Merritt* are all of the same class. Don't touch their "benevolent" medicines.... "The Great American Paint Company," so called, charges a dollar to tell you to make a mixture mainly of lime with some sugar and salt in it, and adding whiting or other coloring materials. A Big company that! We paid a dollar for the prescription, which being of no value we have temporarily mislaid, or we would print it here.None but very foolish people will spend their money for the "Magic Wand," "Perfume of Love," and a lot of things sold with them.... *Madam Hentzelman*, a professed "soldier's widow," is smart enough to take care of herself (*himself*?). She (he?) has tried to get even editors to help her sell the people without charge.... The Nassau Street Gift Associations are all frauds.... Notes on several other humbugs must go over to next month, for want of room.

Look Out for the Meteors.—Scientific men predict a large meteoric shower about Nov. 13—perhaps on the 12th or 14th, and probably a considerable number on each of the three evenings. The show will be free to all who are wide awake—especially those who are out on those evenings making up their premium clubs of subscribers for the *Agriculturist*. December number free to all new subscribers received in November.

Addresses at Fairs—A Novelty.—At the Queens County Show this year a plan was adopted, which we think may often be pursued with profit, especially when it is impossible to secure the presence of some distinguished public man who will, by his reputation, draw a large crowd of paying visitors, that would not otherwise come out. Instead of one address, there was half a dozen short talks, by as many practical men from different localities, each one of whom discussed his favorite subject or mode of practice. In this way variety is secured, and more of general interest learned, than if one man does all the talking.

"Useful Everywhere."—"Western Farmer" writes: "I was glad to notice your remarks in October number about the general utility of the *Agriculturist*. We have a local agricultural paper that has harped much upon our 'sustaining our own home journal' which would be all very well if it said less about it, and did not say so much *against* all others. Why, it has 23 subscribers at our P. O., every one of whom was first lead to read anything about his business by the sorghum seed and other premiums given by the *Agriculturist*, and this is largely the case in the West.—Last year I tried to raise a premium club for you here, urging people that they would find it pay to take both that and their home paper. They said 'no, we want no distant papers—they are not adapted to our culture.' I loaned my *Agriculturist* to one of them regularly, and asked him to compare that with the 'home paper.' To-day he joined the club I send you, saying 'that three-fourths of all in the home paper was copied from the *Agriculturist* directly or indirectly, and the latter paper contained many other things he wanted to see.'—I have found dozens of hints in the *Agriculturist* that have each been useful beyond the cost of the paper. You have some matters, like manures, adapted to particular localities, but how could the paper be of general value everywhere, if it did not refer to these things peculiar to limited areas, for there are such peculiarities in all parts of the country. This attention both to topics of general interest, and to local matters as well, is in my opinion what gives the great general value to the *Agriculturist*...."

Maternal Instinct.—Mr. A. C. Coleman, of Preble Co., Ohio, sends us the following curious and interesting statement: "A short time ago the children of Mr. Hapner brought from the barn four little forsaken chicks, and put them in a box for protection. A pullet not yet half grown entered the box, and remained brooding over them, until it was removed to the hen-house and the chicks covered up for the night. The next day the pullet again claimed her little charge, and since then has remained with them constantly, scratching the ground, feeding them and clucking in a most pompous manner, although the clucking, like the pullet, is on a small scale. The pullet in fact is so small, that it can scarcely cover its four little chickens when brooding them."—Instances of the adoption of the young of other animals, by males as well as females, and often not of the same species, are not very rare. We know no similar case to the one reported, but pullets that have never laid, and young cocks even, may be made to sit, hatch and take care of chickens.

A Mammoth Squash, weighing 130 lbs., is on exhibition at our office, contributed by Mr. Jas. Beveridge, of Flushing, L. I. Like most big things, the seed was reported to have come from California. Mr. B. thinks its size due to a special fertilizer used.

Permanent Fair Grounds. The Queens County Fair was a great success this year, as it could not fail of being when such men as Samuel Taber, President, and John Harold, the long time Secretary, determined to make it so. After years of talk and discussion, a majority vote was secured in favor of a "permanent location," which did not agree with the wishes of some parts of the County, and the feasibility of which is still an open question in the minds of a large number of the leading agriculturists throughout the county. The town of Hempstead gave a perpetual lease, for exhibition purposes, of 40 acres of land, near the Mineola Station, on the L. I. Railroad. It was well enclosed and suitable buildings erected in a brief time, including a fine central structure in the form of a Greek cross, covering 8000 square feet. The arrangement of the grounds and the buildings are a model well worthy of being consulted by all who contemplate permanent locations. We have visited some State Fairs which scarcely exceeded that of Queens County this year, and so long as John Harold and his present coadjutors manage the Society, the experiment of a permanent location will be successful there. Whether under ordinary circumstances and management, the good grounds and buildings always ready for use, counterbalance the advantages of competition among different towns, and of working up an interest, often in remote localities where it is most needed, may still be discussed pro and con.

The Fairs—Cattle Shows—Fruit Shows.—We are obliged to refrain from noticing in our crowded columns, except in a general way, the various exhibitions of this season, many of which we had the pleasure of attending. The interest and attendance upon some held during the last week in September, were unfavorably affected by a north-east storm, but prevailing good weather ensured large attendance. The Pennsylvania State Fair, at Easton, was famous for the wonderfully fine show of hogs made—the Chester Co. breed greatly predominating. We think a few such shows will indicate their claim to being a distinct breed. The Illinois Fair was a success, especially in the classes of neat cattle, draught horses, and implements. The Missouri State Fair is reported as very creditable in all departments, and a great pecuniary success. The Canada West exhibition, so far as we can learn, exceeded as a cattle show any held in the States. We have numerous reports of successful county and town fairs also, and congratulate the managers on their successful efforts—but cannot record particulars.

Calves—Rearing without Milk.—A subscriber asks for the experience of our readers in regard to raising calves without milk? We know it may be done, but without great and constant care many calves will droop and die. The practical questions really are: How may calves taken from the cow at birth be best raised? How soon may all milk be safely withheld? What is the best substitute for milk? What course of feeding or medicine, or treatment (which includes both,) is best to check the scours or their opposite in young calves brought up by the pail?—Our columns are open to valuable hints and experience.

Reynold's Stove Hook (or "Dexter," as he calls it) is an ingenious arrangement of two pieces of iron like a pair of shears, combining a stove-cover lifter, kettle lifting hook, pie-tin lifter, a small hammer head, and sundry other uses about a cook stove—on the whole a convenient addition to the kitchen furniture.

The Moon.—"A great many about here," says a Rootstown subscriber (State not given.) "stick to the notion that shingles should be put on, garden 'truck' planted, pork killed, sheep sheared, etc., etc., just at such a time of the moon. What do you think?"—We think: Do your work when you are ready, with the ground prepared, and the weather favorable, and let the moon take care of her affairs; she won't trouble you. Let those wait and watch the moon who have nothing else to do.

Tobacco.—We are often inquired of by Farmers and others, as to some method of preparing for use the tobacco which they raise. The sailors' way is simple and good. After the curing and drying process is complete, select the inner and best outer leaves of the tobacco; sprinkle with pretty sweet molasses and water, and lay them together, until they become uniformly damp. Then twist them into a roll, say 12 or 15 inches long, and 3 inches through. Bind them together tightly with twine. The twine should be wound on the tobacco in 2 or 3 layers, like thread on a spool, and drawn as tightly as its strength will allow. After remaining for 2 or 3 weeks it will be fit to use, although the longer it is kept the better it becomes, if not allowed to mould, which may be prevented by wiping occasionally with a rag wet in molasses, or liquorice and water. This will be found better for smoking and chewing than the ordinary tobacco to be had in country stores.

Curious Growth of a Radish.—A radish from the garden of Mr. Halsey Minton, near Dover, N. J., presents such a curious form that we have had an engraving made of it. It is not unusual to see the long radish split up into several prongs and twist about in a curious manner; but this appears to be a round radish, bent on repeating itself in the manner shown in the illustration. A frierd, who ought to be ashamed of it, suggests that it ought to be called a "fourhorse radish," certainly it has one characteristic in common with a tandem team. What circumstances induce these freaks of nature, no one knows. Sometimes the influence would seem to affect the seed before germination, and at others afterward. The investigation of them would be difficult, but not less interesting—often instructive.

Irrigation.—"W. W. O.," Suffolk Co., N. Y., writes: "I can turn the water of a brook upon my ground by laying a pipe 1½ miles, with a fall of about ten feet. My plan is, to lead it through the center of my land, and place a faucet every ten rods, to which I can attach a hose and use the water as I wish. The grand question is, will it pay? If so, what kind of pipe do I want, of what size, and what will it cost?"—*Answer.*—There is much land in many parts of the country, where it would pay well to irrigate thus. We can hardly decide in a particular case without a full examination. The best pipe would be galvanized iron, about 2 inches in diameter (cost 75c. per foot). Thin sheet iron pipe lined with cement and laid in and covered with the same, would do also, at less cost, though not so durable.

Pennyroyal Ground.—"B. B.," Washington Co., Pa., asks how to reclaim land that is "ad-dicted" to Dewberry vines and Pennyroyal. The soil appears rich, but it is a hard matter to get grass started.—Try plowing this fall, harrowing in 100 to 150 bushels of lime, planting corn next spring, manuring in the hill with a shovelful of good compost or yard manure, and hoe well, by horse and by hand. If a good dressing of manure is spread and plowed in for the corn, with flat culture, the briars may possibly be so far destroyed that grass can be sown among the corn in August, and by rolling the ground flat in October, when the crop is off, a good sward may be obtained within the year.

Farcy in Horses.—"J. W. H.," Franklin Co., Mo., and others. Farcy and Glanders are the same disease exhibiting itself in different forms. It is incurable, and very dangerous. The only safe way is to kill the sufferers, and take great care that the disease is not communicated to men. In the early stages the disease is not conspicuously evident, and unscrupulous persons often sell glandered horses. This ought to be a State Prison offense. The symptoms and treatment are minutely described in our last volume, page 309, (October, 1865).

A Good Team marks a farmer as a general rule; horses or oxen, it is all the same.—"Progress" says: "If you see a farmer with a poor team, you may be sure there is a screw loose somewhere."

13 Months in a Year!

All new subscribers to the *Agriculturist* for 1867, whose names are received during November, will receive **free of charge** the December number, which will be a very valuable one. This will give **13 months** for a year's price. The offer applies to all new subscribers, singly, in clubs, in premium lists, etc. Extra time allowed for the arrival of names from the Pacific Coast and other distant points, if started soon after this notice is received. All new names must be marked **new**, in order to receive the extra number.

1867.

The American Agriculturist Annuals.

We propose soon to issue two Annuals for the year 1867, the one *Agricultural*, the other *Horticultural*. They will each contain about 120 or more pages, 12 mo., and will be in a sense, a continuation of the *Rural Annual*, published by us, and formerly by Mr. Harris of the Geesee Farmer. The names "Rural Annual," "Rural Register," "Annual Register," etc., are so constantly confounded that we reluctantly drop the old name. These Annuals will, we hope, be worthy of and will doubtless gain a very large circulation. A limited space will be allowed for first class advertisements in either or both, which must be sent in before December 1st.

The *American Agricultural Annual* will contain a brief review of the past year—notice of important events, inventions, publications, etc., affecting the agricultural interests of the country, importations of stock, introduction of new crops, etc.; contributed articles of an interesting and practical character, fully illustrated; practical hints in regard to work, and machinery, besides convenient tables, and a full almanac.

The *American Horticultural Annual* is the first of what we hope to make a permanent series. As it is late in the season, we cannot hope to make it entirely what it is ultimately intended to be—a record of the years progress in horticulture, giving positive land marks, describing what has been done in the past year, and indicating what should be done in the coming one, though the first number will be valuable to all. It will contain contributions from well known horticulturists, and embody much useful, practical information. No annual of the kind has before been published in this country.

The \$1,250 Prizes: Prairie and Western Farming—Cotton Culture—Timber and Fencing for Prairies.

As announced in October *Agriculturist*, page 344, we offer the following Prizes: For the Best Treatise or Essay on *Prairie and Western Farming*, \$350; For the Second do., \$100; For the Third do., \$50.... For the Best Treatise or Essay on *Cotton Culture*, \$400; For the Second do., \$100.... For the Best Treatise or Essay on *Timber and Fencing for Prairies*, \$150; For Second do., \$75; For Third do., \$25.—The manuscript on *Cotton Culture* to be ready Jan. 1st; on *Timber and Fencing* Feb. 1st, and on *Prairie Farming* March 1st. For full particulars, see October *Agriculturist* and printed slip furnished at this Office to those proposing to write.

\$100 Housekeeping Prize.

For the Best Essay on Housekeeping, to make 20 to 25 columns in the *Agriculturist*, the Publishers will pay a prize of \$100 cash. Something after the manner of "Walks and Talks on the Farm" may perhaps come the nearest to what is wanted, though we do not limit the offer to any particular form or style. What we want, is, to get an article to be continued through the year 1867, of 1½ to 2½ columns in a paper, which shall be interesting and instructive to Housekeepers—one which shall bring in the work and cares of daily life. That Essay will be the most valuable which shall in the least space convey the greatest number of practical hints and suggestions in a readable, easy style. The Essays to be received on or before Dec. 1st, or at least enough of each to exhibit its general style and ability. The first chapter is desired for the January number. After the selection is made, the writer will have opportunity to amend and improve the chapters subsequent to the first, as the time is limited for their first presentation.

The Woodchuck.—(*Arctomys monax*).

We present our readers this month engravings of two more of our familiar native quadrupeds. The Woodchuck has a very wide geographical range North and South, and westward probably as far as the Mississippi. The marmot of Europe, and the prairie dog of the western plains, are animals of the same genus (*Arctomys*), and of similar habits. The woodchuck is 16 to 18 inches long, with a solid robust body, broad head, short, rounded ears, bright prominent black eyes, numerous whiskers, and short legs with long claws. The fur is short and woolly, and sprinkled full of coarse hairs. It varies much in color, being gray, inclining to reddish and brown, ashy-gray upon the nose and throat, usually grayest upon the shoulders, and reddish-brown on the legs and pate. Woodchucks live in pairs in burrows, which are generally made in light sandy or alluvial land, the animals preferring the neighborhood of cultivated fields and fruit-orchards, where the damage a single family will do in one summer, is considerable. When undisturbed, the fields, even of a small farm, will often become in a few years filled with the burrows and tenanted by hundreds of woodchucks. They excavate chambers below the reach of frost, and store up clover heads, apples, and other food not liable to decay, for the winter's use. They are rather difficult to catch, for, being chiefly nocturnal, it is quite inconvenient to watch the traps. Steel traps are generally used, and set in the entrances to their holes and covered with earth, or baited with sweet apples. If caught

by the head or body, they are secure; but if caught by one leg, they will gnaw it off, and lookout for traps thereafter. We doubt not there are thousands of three-legged woodchucks alive and well about the country. The burrows are so long and deep, usually being in a bank, that it is hard to dig them out, and there are always, in our experience, two entrances. The young are peculiar

sage-looking little fellows, and well represented in the engraving. Taken young, they are easily domesticated, and become very tame, affectionate, and exhibit considerable intelligence.

The flesh of the Woodchuck, though coarse, is palatable, and if taken in the autumn, fat and juicy. The fur has little value, as it lacks beauty, but makes very comfortable mittens, tippets, etc.

WOODCHUCK—(*Arctomys monax*.)

The Musquash.—(*Fiber zibethicus*.)

The Musquash, or Muskrat as it is often called, is another peculiarly American animal, which is so well known as scarcely to require description. It is also very widely distributed over the United States, frequenting alike land bordering upon salt and fresh water, choosing swamps

of the musquash is "compressed vertically," that is, it is flat, the edges being above and below. The beaver, which the musquash greatly resembles in its habits, and which is naturally close akin to it, has a broad horizontally flat tail. Like the beaver, the musquash builds dome-like houses in the swamps, and plasters them well with mud on the inside, so that they turn

the rain, while outside they look simply like a heap of sticks and reeds. The fur is valuable, and is chiefly exported. The skins, which, a few years since sold for 18 to 25 cents each, now bring \$1. They are taken for the fur in fall and in early spring. Freshets in the streams, or extraordinarily high tides, drive these animals from their holes, and then they are easily shot, clubbed, or speared. They eat the roots of aquatic plants, Calamus, Pond Lilies,

etc., and are very fond of fresh-water shell-fish, especially of the *Unio*. So far as their food goes, they do the farmers little damage; but wherever embankments are made to shut out the tides, or canals are dug to convey streams to mills or for irrigation, or dams are erected, there the muskrats do great damage by burrowing through the embankments just below the sur-

face of the water, and causing leaks. We gave on page 253, (July), descriptions of traps for taking muskrats, which are said to be very effective, but most persons rely upon the fowling piece, and a war of extermination in times of high water. In the winter time they are rarely seen upon land, except close about their breathing holes in the ice; but their food and the entrance to their burrows and houses being both below water, they get along very well, except in times of severe

MUSQUASH—(*Fiber zibethicus*.)

with dry sandy banks, or earth embankments, in which it burrows. It is 10 to 12 inches long, with a thick set body and arching back; head short, but rat-like, and the gnawing or front teeth very large, long, and powerful. The hind feet are very long, and a short web is found only between the two longest toes, yet the animals are rapid and strong swimmers. The tail

cold and little snow, when the entrances to their holes freeze up, and in times of flood, as already mentioned.—The name Muskrat is obviously derived from the strong odor of musk, which comes from glands near the tail. Musquash is said to be the Indian name, and is preferable, for the animal is not a rat in any proper sense, but, so to speak, a beaver on a small scale.

Skunks Destroy Honey Bees.

Mr. M. S. Snow, Forestville, Chautauqua Co., N. Y., reports to the *American Agriculturist* an original observation in regard to the fact stated in the heading of this article. He writes:

"It is a well-known fact that Skunks dig out the nests of the Bumble bee, taking the bees, but leaving the honey undisturbed. There is hardly a farmer, or farmer's son, but has met with their work while going about the pastures and meadows. But it will surprise people to know that they will attack bees in their hives and eat them readily, as though they were harmless as flies. This occurs when the hives are near the ground, or within their reach. They carry on the work dextrously. If no bees are outside, and the pickets are withdrawn, they will actually stick their noses into the hives and snuff, to bring them to a sense of their duty; and when they come out, they take them right and left. At other times they scratch upon the hive to accomplish the desired effect. Those who keep hives near the earth, and find the alighting boards considerably soiled, and the grass or earth scratched over, may be sure that skunks have been at the bees. This is a matter of my own original observation."

A Talk on Sheep Breeding.

Mutton and wool being the products of the Domestic Sheep, the one, or the other, or both equally, are the especial aim of the sheep keeper. Improvements in the carcasses of sheep of particular breeds have been attempted, and resulted in distinguished success. Efforts to cause flocks of sheep to yield finer wool and heavier fleeces, have also been eminently happy in their results. It seems as if sheep breeders had, at least until lately, regarded good mutton with a well shaped carcass as incompatible, or undesirable, in the fine-wool producing breeds. That mutton is a less than secondary consideration with fine-wool growers is natural enough, for while mutton sheep live but a few years ordinarily, and are best kept in rather small flocks and conveniently near to market, fine-wool sheep are allowed to live, and are fattened and killed, often, only when their teeth give out. They may be kept too in large flocks at a great distance from market, their product of wool being easily packed and safely transported. Hence hardiness, and vigor of constitution, are of much more importance than fitness of the carcass for the table. No small portion of the mutton raiser's profits arises from the wool, hence to him the latter is of more importance than is mutton to the wool raiser. The kinds of wool too, which are yielded by the mutton breeds of sheep, meet an active and constant demand in the market.

The attention of farmers has within a few years past been called especially to improvements in the Spanish Merino sheep. The sheep are larger, yield heavier fleeces (and more wool), and being thoroughly acclimated, are probably harder than when first introduced. Spanish sheep were taken not only to America, but into France and Saxony, and from Saxony into this country, Silesia and Russia, and in each of these countries were subject to peculiar treatment in accordance with the views of the sheep breeders in whose hands they were; hence we have several quite distinct breeds of Merino sheep, all departing more or less from the original type of the best Spanish flocks, which varied also among themselves.

In all the great advances that have been made

in the breeding of cattle, sheep, or other animals, it has been the object of breeders to direct the vital strength of the animal to the development of the most valuable portions, and to do away with the useless or less valuable portions,—to "breed in" good points, and to "breed out" bad ones. In the short-horn cattle, for instance, big heads and horns, coarse fleshy tails and legs, and skinny necks, are bred out; and fine bony heads, thin tails, small bones, sinewy legs and thin necks, free from dewlaps, are bred in. A similar course was followed by Bakewell, in improving the long-wool sheep.

It becomes fine-wool sheep breeders to inquire candidly whether the system hitherto practiced by them is founded upon as correct principles. We have been painfully impressed with the fact that many breeders of American Merinos, at least in their conversation about their sheep, and in indicating their good points, talk more about the color and abundance of the yolk, and the number and position of the wrinkles, than about the quantity, strength, and fineness of their wool, their well-shaped bodies and hardy constitutions.

There is a tendency in the Merinos to wrinkle—that is for the skins to be very loose and lie in folds or wrinkles over the body. Now as no more wool grows on a wrinkle sheep than on a smooth one, and as wrinkles make a fleece harder to shear, and as the wool is not so uniform and good on the wrinkles and between them as upon smooth parts of the body, we say wrinkles are useless, a nuisance, a deformity, and should be bred out if possible. Yet some of these breeders seem to pride themselves in wrinkles, and show them off as if they were one of the greatest merits their sheep possessed.

Moreover there is also a natural tendency in all sheep, and especially in fine-wool sheep, to secrete an oily soap in the wool, which is called grease or yolk. This prevents the felting of the wool, and its getting dry and breaking; it prevents also the moth attacking the fleece, and may have other uses, but a maximum good effect is attained with a comparatively small portion of yolk. It seems to us that the greatest quantity really needed, cannot be more than twice the weight of the wool. Yet many will wring locks of fleece, and exhibit with great glee the drops of oil which exude from them, and actually claim it as a great merit. The production of 10, 15, or 20 pounds of this greasy soap, (which is not uncommon), containing as it does about 33 per cent of potash, is a serious tax upon the vital powers of the sheep; it is moreover useless, a tax upon the land, and an unnecessary weight to transport to market. Hence we condemn excessively greasy fleeces. The weight of the fleece is no criterion of the actual weight of wool it contains. Manufacturers know this, and avoid the purchase of this greasy wool, or pay for it only very safe prices.

The mutton sheep of the improved breeds are hornless, both ewes and rams. The rams of fine wool breeds all carry heavy horns as a general rule. These are ornamental, it is true, and a wrinkled head with its ponderous circumvolved and gnarly horns, is very picturesque upon a flock leader; but horns are useless, a great tax upon the vital powers to produce, dangerous weapons besides. Why not then breed out the horns? It may be easily done. Years ago an American sheep fancier ably advocated smooth, no-horned Merinos, and actually bred them. And we must record our hope and anticipation that before long we shall have a breed of hardy, good-bodied, short-legged, smooth, fine-

wool sheep, peculiarly American in common-sense fitness for their uses.

We were very much gratified to observe that the judges at the late New York State Fair at Saratoga awarded a first prize to a Vermont Merino ram nearly hornless—having a single horn not bigger than one's finger. A Vermont breeder of fame, not less than Mr. Hammond's, shook his head and said: "That never could have happened in Addison County."—We hope it may some day.

Mr. Hammond and the other sheep breeders of Vermont, who have made such improvements upon the original Spanish sheep, have certainly gained a much better form for their sheep. They are less leggy, their bodies are more compact and deeper, they are heavier fleeced, and there is more wool in the fleece. The wool besides grows all over the sheep, covering the legs and the bare spots which used to be on the bellies, and, though not so fine, it is of greater length. We give a fine portrait of one of these sheep, winner of one of the first prizes at the New England and Vermont Fair, on our first page. It exhibits well the striking peculiarities of the breed. It is claimed by the breeders, who appear to set a high value on wrinkles and grease, that these are marks of vigor of constitution and ability to transmit their good qualities to the progeny. This we are not inclined to dispute, but would like to have the proof.

Chicken Ailments.

GAPES.—Our discussion of this subject in former numbers has been tolerably full, but especially bearing upon a cure—which is effected by removing by a feather-tip the worms in the windpipes of the chickens, which are the cause. The prevention of the ailment is thus treated of in a communication to the *American Agriculturist* by N. B. Worthington, Esq., Editor of the *American Farmer*, of Baltimore, which journal, though suspended during the war, is now a welcome monthly visitor.

"I have a word to say to the 'wide, wide world' of Chickendom, and ask your permission to say it through the *Agriculturist*. Here, in Maryland, I have insisted over and again, that chickens *must not have* 'Gapes,' and our well bred chickens will no more gape in your presence, than the well bred boys and girls will yawn before folks. Elsewhere, I find that chickens are gaping still, and scarcely an agricultural Journal, but a remedy is asked or given. A favorite one is to throttle the poor innocent, and, with a feather or hair, twist a bunch of worms out of its throat. This may cure, when it does not kill, but it reminds me too much of an attempt I made in my young days to unchoke an ox, that had an apple in his throat. My bungling attempts killed him. I let the next one alone, and he managed the apple himself. The chickens may not be so successful, but having tried this and many other remedies, I would, if my chickens had gapes, which they have not, diligently *let them alone*. So much for remedies.

"For preventives, the New England Farmer says: 'This disease is caused by colds and sore throat, which the chickens get by wandering in the wet grass,' and the preventive is to keep them dry. A Bucks Co. correspondent of the *Germantown Telegraph*, replies: 'How is it that they never get that complaint when fed on wheat screenings, and allowed to run when and where they please?' This writer adds: 'Years ago, we fed exclusively on Indian meal, and invariably had the 'gapes' to contend with.'

Avoid Indian meal, is his preventive. I cite these as specimens of how Doctors differ on this point; and let me say in passing to this last, that I feed with Indian meal always, and almost exclusively, and never have "gapes."

Now, to pass to the point: Did any one of your readers ever see a chicken with "gapes" on an absolutely new settlement—a place just built upon? We saw once a whole brood have it on such place, which, at ten days old, was brought from an old place infested with the disease. Every one of the brood took it, after coming to their new home, or rather, brought it with them undeveloped. Not one took it that was hatched after the removal. I was impressed with the fact, because, with great love for poultry as a boy, I had 'seen my fondest hopes decay' at the old place, without remedy.

"Taking the hint, I have never allowed my chickens to remain for many successive years on the same 'run.' I plow up thoroughly the old yards, and spade the floors of houses; or, what is better, remove the yards to any ground on which poultry has not been confined before. It is *their own accumulated filth*, not that of other animals, which poisons them.

"Of course, chickens must not be kept on ground retentive of moisture, nor required to drink filthy water; nor allowed, when quite young, to run through wet grass; but with ordinarily decent management, I believe 'clean ground,' an absolute preventive of gapes."

Fattening Fowls.

Many hundreds of thousands of fowls to be killed and eaten this autumn, are now running about growing fast and picking up seeds and such insects as have survived the frosts. These are very good to eat, taken just as they are, if properly cooked; but the majority of purchasers think fat fowls much better than lean; therefore, as soon as chickens have nearly or quite their full growth, the best policy is to fatten them, for not only will the weight be much increased, but if properly marketed, they will bring much higher prices. We very rarely see thoroughly fattened poultry in our markets; certainly it is not because people will not buy them, for there are people in our large cities who will buy high priced things simply because high prices are the only indication they have of superiority. Fat poultry keeps, and bears carriage and exposure to air, much better than lean, which alone adds several cents per lb. to its value.

Some breeds of fowls are naturally disinclined to wander and take much exercise—these will fatten tolerably if allowed their liberty; but most will only get into a condition of good flesh, however much they be fed. Yet if these birds are confined in close quarters, so that they will have very little space to move about in, and are fed well, and have water, gravel, and some green food regularly, they will take on flesh and fat with astonishing rapidity. Fowls are profitably confined in fattening cages, set up a foot or two above the ground or floor, so that they shall have fresh air. Mr. Saunders, in his work on poultry, (see our book list,) advises the use of a cage for 24 fowls, 2 feet high, 3 feet long, 23 inches wide, standing 2 feet from the ground. The entire coop is made of bars 1½ inches wide, round or flat. The bars on the bottom should be 1½ inches apart, the rest 3 inches apart. Several in the front and sides should be movable for convenience in catching the fowls. There should be one or two plain board partitions to separate

quarrelsome fowls, or make the coops smaller for a proportionally smaller number of fowls. There should be a board in front, or in front and rear both, with triangular feeding troughs. When the troughs are emptied, they may be removed, rinsed and filled with water, or pans of water may be placed on the feeding boards, on which also gravel should be frequently scattered.

The chickens are fed three times a day, at day light, at noon, and at dark. The feed is scalded meal of semi-fluid consistence, Indian meal being mingled with meal of other grains, or other soft food being occasionally substituted. Barley and buckwheat are excellent. The trough should be scalded out once every day, and the food given be always freshly mixed. Any quarrelsome bird, and any drooping one, should be removed at once, and others substituted, so as to keep the coop full. If there are not enough birds to fill the coop, a partition should be inserted between the bars to contract the space. Such coops may best stand in open sheds, where they will have fresh air. Those who try them once will continue their use.

FATTENING COOP FOR 24 FOWLS.

"Cramming" has been written down and talked about in this country, as if it were one of the most horrid and cruel things that could be done to poor dumb things. The truth is, the birds are highly pleased with the operation. They are not hurt in any way, and like their food so, as well as in the natural way. A fowl is held in the lap, and rolls of meal, mixed stiff with milk and a little suet, are taken by the crammer in one hand, and dipped in milk and dropped down the throat, while with the other hand the mouth is held open. The little finger is used to help the cram well down into the throat, and the bird swallows it with satisfaction. Sometimes it is well to stroke the throat gently to assist the swallowing. The crop should be empty before one begins to cram, it should be well filled, and in 3 hours it should be all digested. A little Cayenne pepper aids digestion, and is good to give now and then. Crammed fowls fatten much more rapidly, and may be made much fatter than those which pick up their food; and if the process is successful, as it usually is when the fowls are kept quiet and clean, gently handled and supplied with gravel and fresh water regularly, no evidence of disease can be discovered. If, however, it be long continued, and they do not fat fast, nor digest all of one meal before the next is given them, and the water is stale, and they quarrel, etc., before they become very fat, they will be likely to show by white combs and droopy looks that they are diseased. Such fowls must be given their liberty, for they will not be fit for the table, and should never be sent to market unless in perfect health.

Imperfections of Forced Queens.

BY BIDWELL BROS., ST. PAUL, MINN.

The system adopted by American bee-keepers, during the last several years, in attempting to Italianize their apiaries in compelling the bees to replace their queens removed, by rearing them from worker eggs or larvæ, is one of oft repeated disappointment and numerous failures. The only apparent exception to it is after, by long experience, one learns the evils to be avoided. A deficiency of honey and pollen as food, or a want of bees to furnish, and warm weather to help prepare it, produces a dwarfed or imperfect growth, which even an abundance thereafter can not wholly replace. The essential conditions necessary to natural queens which attend natural swarming are, an excess of mature bees, maturing brood to take their place, an abundant yield of honey and pollen with fair and warm weather. By repeatedly placing a swarm under these circumstances, we have swarmed them out 6 times in 64 days, obtaining 48 natural queens. In forcing queens, one or more, or all the previously mentioned conditions are wanting, which materially affect the forced queens, leaving you one or more queens poorer than the one you take away. A worker larva 6 days old, which is not until then transformed into chrysalis, can not be converted into a queen after that, because only 5 days are allowed a queen larva before transformation and sealing, nor can a worker larva 5 days old be altered to a queen, as some time is required to effect the change; hence, the longer time would produce the more perfect change, as in the natural queen they are started from the egg. We have repeatedly tried the different days of development of the worker larvæ for forced queens, and found those started nearest the egg the largest and best, those taken in the later part of the fifth day seldom hatching, those on the sixth never maturing. In their desire to replace their queen they strive to do it in the shortest possible time, and the worker being but an imperfect queen, which is dwarfed by cold, or imperfect food and reared in a small cell, one or more in an advanced stage is taken; they enlarge the cells and alter the food, and one or more of the youngest larvæ are taken, until as many queens are started as their time and resources admit of, covering all likely failures. Now the queen from the most advanced worker larva hatches first, and having been fed and dwarfed for a worker longest, is the poorest, and only one being needed it is allowed to kill the rest, which are the best. For natural queens the cell is built first, and the egg, or larva, not being in the way, the base of the cell is made broader and larger, while the base of the forced queen's cell is unavoidably contracted.

There is still another difficulty that must also be avoided. In their selection of eggs or larvæ (on account of the size of the cells, as both are fed alike and are similar in appearance), they choose occasionally drone eggs or larvæ instead of the worker eggs, and failure thereby occurs. A natural queen ordinarily hatches in clear and warm weather, and in two or three days flies out to meet the drones, and in two or three days more commences laying, but if retarded two or three weeks she gradually loses her desire to meet the drones. Each day's delay then, to say the least, reduces her prolificness, and as she only flies out when the temperature is near summer heat, many days often elapse (even clear ones) at the time of year when forced queens are ordinarily reared—early or late in cool weather.

The Manufacture of Drain Tiles.

In our last number (page 356) Mr. J. W. Penfield, of Willoughby, Ohio, described the sheds, kiln, etc., of his tile works. We reluctantly divided the article, and so in what follows must refer our readers to it for a fuller understanding of the subject. The clay pit is a semi-circular dishing place within the horse track, with plank sides. From this, the clay, of such quality as is described in the article referred to, is shoveled into the tile machine. Here it is worked by horse-power and moulded into the shape of tiles, the clay being forced out horizontally through dies at the bottom of the machine. The clay tubes are received upon drying boards, as they are pressed through the dies, cut into suitable length for the tiles, allowing for shrinkage in drying and burning, and placed at once upon the drying racks. These for convenience of

switch is provided at each end of the shed to transfer empty cars. Fig. 5 shows a switch; timbers 6x6 inches square, and 8 feet long make the rails of the switch track, and 2x4

on the top, nor at the sides of the kiln, as there is more liability for them to crack or be poorly burned. After the 8th course is set, four or five courses can be laid horizontally over the tops, close together, all over the kiln. Then put on two courses of bricks flatwise, and so as to break joints over them, and the setting is completed. After the door is bricked up, the kiln is ready to fire. A moderate fire for the first six hours should be made, by using large sticks of wood, and placing them entirely outside the flues, building the fire at the end next the flue. In this way the wood will burn slower than if the fire were made at the other end. A little heat and smoke is all that is necessary at first to start the tile sweating, and prepare them to

Fig. 1.—DRYING SHEDS.

Fig. 2.—DRYING RACK.

moving are cars upon a rail-track, described by Mr. P. as follows:

"The Drying Racks or Cars, should be 12 or 14 feet long, and the length of three tiles wide ($14 \times 3 = 42$ inches), divided into three spaces for holding the drying boards. The bed pieces for car are made of 4x4 hard wood scantling; axles 3x3 of the same stuff. Wheels may be made of a log hard to split, 1 foot in diameter, turned with a flange, 2 3/4 inch holes being made for the axles. After the axles are spiked on the bed pieces, then spike on 4 2x4 scantlings, as long as the car is wide, flatwise on the top, and it is ready for the first course of shelves. The shelves are inch boards, 5 inches wide. Planks 2 inches thick, 5, 6, 7 and 8 inches wide are set edgewise, and nailed fast, to support the rest of the shelves. A car when finished is 6 feet high, and will hold 1,000 2-inch tiles. Tracks for the cars to run on are made of 4x4 hard wood scantling, and firmly spiked to ties bedded in the ground. Fig. 4 shows the best way to splice the rails. In making tiles, a car is run to the machine, and when filled, is drawn by a horse or pushed by two men under the drying shed on its way to the kiln. A

scantling set edgewise partly "halved" with the underside of the rails hold the rails, and form bearings for the gudgeons of the switch wheels. These cars are a great saving of labor in moving and handling tile, and will soon save their expense. Tiles dry quicker and straighter, and less than one-half the expense for lumber, will dry more tiles in this way than when packed close in a wide shed, on stationary shelves. The liability to breakage is materially lessened, as much of the handling is avoided, the tiles remaining on the cars till dry, and frequently not handled, till taken from the drying boards, to go into the kiln. The drying boards vary in width to suit different sizes of tiles. In the engraving some are shown filled with tiles, and in place in the car, others are piled up in the middle division. When thoroughly air-dried, the tiles are removed from the cars to the kiln.

receive more heat, which may be made by pushing the brands partly into the flue. At the expiration of six hours more, the wood may be

put the whole length into the flues and the doors closed, with a good draft under them. The flue doors should be hung on an iron frame, fastened in the arches, when the flues are building. They are used to regulate the draft at all times during the burning. After the doors are closed, there is but little danger of too much firing, if the fires are allowed to burn evenly, and are kept at the ends of the flues. As soon as the corners and heads of the kiln get red hot, a full blast of fire may be kept up until the flues come to a white heat the whole length. By this time the heads of the kiln will be burned, and the heat tending to the center. Care in firing should now be used, as the flues and lower course of tiles are easily melt-

Fig. 3.—BED PIECE OR DOUBLE TRUCK.

Setting and Burning Tiles.—Tiles are set on end one course above another, putting small ones in the large ones—1 1/2-inch go inside 3-inch, 2-inch go in the 4-inch, 3-inch in the 5-inch, and

Fig. 4.—SPLICE FOR RAILS.

the 4-inch in the 6-inch. Larger tiles than 3 inch should not be set on the bottom course, nor

ed. Sufficient time must be given after a fire is built to let it burn down, and the flues allowed to darken before building another. If there appears any trouble in getting the heat to run to the center, the draft at both ends can be increased by leaving the doors partly open, which will drive the heat to the center, and with a few good fires the whole length of the flues, the middle of the kiln will begin to settle. In case the fire should leave the heads before they settle or are properly burned, the middle

should be allowed to settle, and then the flues closed tight at one end, and the doors left open at the other end, and all the firing done there until the opposite head settles; 6 hours will generally accomplish this, and then the fire can be changed to the other end, and the same plan adopted till the kiln is finished. If a kiln works as it should, it will burn evenly, commencing at the corners and spreading each way until the whole is heated. After the middle gets thoroughly hot, six hours will finish it. Three days and two nights, if the tiles are properly dry when set, will burn a kiln well. A kiln should be provided with a roof that can be taken off, or shoved away from the top of the kiln when hot, or while burning, in fine weather. In case of rain during the first 24 hours, the kiln should be covered; after it is hot all over, the rain will do no harm. In case of high winds blowing in one direction, a wind-brake can be put up on the wall of the kiln, on the windward side, which will prevent its affecting the top of the kiln. Some burners practice covering with clay as fast as the tile get to a certain heat (or when nicely red). This practice would help in windy weather, and is well enough at other times.

It is impossible to be successful in burning without a GOOD KILN, good wood, and dry tiles. A little experience, with a good rig, will enable any one with ordinary skill to burn successfully. The great art is to tell when they are burned enough. This is determined by their settling. Good clay is sure to shrink when well burned. One-half inch to the foot is, perhaps, the average shrinkage, which would make four inches in a kiln of eight corners. Some places will settle more, and some less, according to the heat. When the last fires are built, the doors should be left closed, and the draft shut off, that the cold air may not crack the arches or tiles. There is liability to get some soft tiles in every kiln, with the best management, and these, if not cracked, should be burned over."

A Long-used Stall Fastening for Cattle.

The comfort of his cows should receive the attention of the dairyman, nearly as much as provision for their maintenance. The distressed beasts which poach up the mud and manure in the cold wet barnyards, and stand back up against the north-easters

of a whole winter, are only more miserable than those who have their heads locked in between two upright stanchions in narrow-as-possible stalls. Neither know much of the comforts of the life of a well kept dairy cow. Geo. Hatton, of Warren Co., Ohio, sends us a description and drawing of a neck-yoke for tying cows in stalls, which we were familiar with many years ago, and which really looks like the portrait of an old friend. The yoke consists of a bow and a cross piece. The bow is of hickory or ash, with one end shaped as shown at 1, by cutting a notch on each side. This is the end marked 2 in the cut. The other end of the bow has a knob or ball left upon it. The cross piece (3) connects the ends of the bow, and is made of hardwood 3/4 to 1 inch thick, 3 inches wide, and

about as long as a cow's neck is thick. There are 3 holes bored in this piece of wood; 2 are inch holes, (4, 4); the other is a 1/2 inch hole (5), a little distance from one of the inch holes, and between the two holes a slot is cut, so that the end (2) of the bow being passed through the inch hole on the right, and also through the big hole on the left, will spring through the slot and into the hole (5) where it will hold. The yoke hangs on the cow's neck in the position as shown, and by it she is chained or tied. A cow can turn her head and neck in it very easily. It is hardly possible for her to split or break it, and it is perfectly secure, and forms a cheap and very convenient fastening for cows and young stock.

Fig. 1.

Splitting Wood by Horse Power.

A tread horse-power, with circular saw attached, affords a means of reducing fire wood to suitable lengths for stoves, and as stoves are constructed now-a-days, it is desirable to have it in very short lengths, sometimes requiring even 7 cuts in 4-foot wood. The relief afforded by the horse-power to back and arms is so great, that we take the splitting as mere pastime, and cheerfully "peg away" at the blocks. This labor too may be easily and quickly done by Dobbin, and we figure a simple machine for the purpose. It is a frame of two uprights of pine or chestnut, about 12 inches square, and 6 feet high, framed substantially as shown, and set and braced in 4-inch sills about 6 feet long. The knife is a blade about 12 inches long, 3/4 to 1 inch in thickness, and brought to a rather obtusely wedge shaped, steel faced edge, and is set in a 4 x 8 hard wood stick, and secured by strong bolts with large and strong washers to strengthen the wood, lest a twist of the block might split it.

Fig. 2.

Fig. 3.

One end of this "ax helve," if we may so call it, is set by a strong bolt in a mortise in one of the uprights, and the opposite end passes through the opposite upright in a long mortise, to give it freedom to move up and down. The ax, or

splitting blade, is set near to the fixed end, the position varying somewhat with the motion to be given to the other end. The frame sustains upon the tops of the uprights a rod running in metal bearings, which has a belt-pulley on one end, and a fly-wheel on the other. A pitman connects the fly-wheel with the end of the ax bar, and gives it an up and down motion. The speed may be determined by the size of the pulley, and ought to be about 120 strokes a minute. The motion of the blade is 2 inches or more. The height at which the ax is set above the strong hard wood bottom piece, must be sufficient to take under the largest sized blocks that will be used. The best way to split the wood up is to hold it by a strap passed around the block, and to cleave it by parallel splits across in one direction, and then by others, at right angles, if for firewood, (fig. 2,) but obliquely if for kindlings, (fig. 3). One such machine will split pitch pine for kindlings for a whole village, and supplying kindling wood might be made a source of considerable profit. In many of our larger cities such kindling wood is sold in great quantities, and to a very great extent has taken the place of charcoal. The pieces are about 5 inches long, and when put in little close bundles, 8 inches in diameter, intended to be just enough to kindle a fire in a common coal stove, sell for 3 to 4 cents per bundle in New York and Brooklyn.

Spelt, or Spelt-Wheat.—(Triticum Spelta.)

We have had several inquiries in regard to

this grain. The Swiss and German readers of the *Agriculturist* remember it, and want to get seed and cultivate it here. There are both winter and summer, bearded and bald varieties, and were Spelt as much cultivated as is wheat, it would probably sport into as many different kinds. Spelt is remarkable for having adherent chaff or husks, like barley, which it very much resembles in its marketable condition, though in growing it looks like wheat. We give drawings of two kinds. Fig. 1 is a Winter Spelt, and fig. 2 a Summer variety. It does not require quite so strong a soil as wheat, and bears an open winter better, and some varieties are especially valued for the stout rigid straw. It is cultivated in North-

Fig. 1.

Fig. 2.

ern Italy and Switzerland, and is valued for the fine white flour and starch made from it, due to its containing more starch than other kinds of wheat. Spelt weighs 36 to 40 lbs. to the bushel. It has been cultivated in the United States, and has done well. Seed may be got through some seed importer.

Walks and Talks on the Farm.—No. 35.

I sent my Amber wheat to the city yesterday. I had made up my mind weeks ago to sell when I could get \$2.50. I could have got it before I threshed. But the price fell to \$2.25 before it was ready, and I held on. Yesterday I was offered \$2.55. This was what they were paying for the general run of amber wheat, but I thought mine better than the average, and asked twenty-one shillings. The miller said he did not wish to pay more to one than he paid to others, just justifying those farmers who say it does not pay to clean their wheat and try to furnish a good article. I have always contended that the better you could make it, the better price it would bring. Such certainly ought to be the case, and I believe it will be found so as a general rule. Well I was finally offered \$2.61, and took it for the one load. The miller, after he had bought, said it was the best wheat he had seen this year, and showed it to several other millers. He took the whole crop at \$2.62½. I presume it will be higher—but this is high enough—for those who have to buy. But is there not a pleasure in raising a good crop and getting a good price for it?

I lost considerable from not having barn room for all my barley. That which was stacked out of doors was weather-stained, and will not bring as much by 10 cents a bushel, as that put in the barn—though fully as good a sample in other respects. My loss this year from stacking would pay the interest on a good sized barn.

It annoys me to see farmers sacrificing their barley, simply for want of correct information. Large quantities have been sold in this section at 85c. to 90c. per bushel, and a dollar is about the outside figure for choice four-rowed. Farmers seem to have been seized with a desire to sell at once, and have rushed in the crop and taken just what they could get, from the idea that as the yield was large, prices must be low. But they forget that hitherto a great portion of our barley has been brought from Canada, and that, large as the crop is with us, it is not large enough to supply the demand, and that the deficiency must be obtained from Canada. The price at which Canada barley can be bought, therefore, will determine the price in this market. At the time when farmers were selling here for 90c. to \$1.00, barley in Toronto was worth 60c. in gold—say 90c. in our money. The duty is 15c. more, also in gold, say 22c., and the expenses of buying, commission, freight, etc., are about 20c. more, so that a Rochester malster can not get barley from Canada for less than \$1.32 per bushel. Had our papers given this information, they would have saved to the farmers of Western New York over a million dollars. As it is, we have lost all the benefit of the duty on barley. I called the attention of one of our largest brewers to these facts. "Well," said he, "I am buying all I can handle at 85c. to \$1.00, and of course shall not pay more as long as I can get it for less. But," he added, "I shall pay \$1.25 if that is the market price." He admitted that they could afford to pay it, and the only reason barley has sold so low is, that farm-

ers were afraid to hold it, under a mistaken apprehension that the market was overstocked.

Potatoes are rotting badly—especially the Mercers. I am told that a farmer in this neighborhood offered to sell five acres for five dollars, and that, after examining the crop, the offer was refused. The Squire says his Mercers are more than half rotted. On the low land my Flukes are considerably affected, but on dry upland they are excellent. They are about the best variety I have yet raised—little inferior in quality to the old Mexicans, and not unlike them in shape and smoothness of skin, while they yield far better. It seems essential, however, to change the seed frequently. On good land, I believe, as many Flukes could be raised per acre as of Peach-blows. But it would be necessary to plant much thicker in the rows, and the rows closer together. I would have the rows only two feet four inches apart, and the sets ten inches in the rows. Manure high and cultivate thoroughly, and on good warm soil a great yield might be expected. Many people object to manure, but if it is thoroughly rotted, I do not believe it promotes disease. The trouble with Peach-blows is, that they require a long season to attain their best yield. They will usually keep growing until frost comes. But this year the tops of mine withered on the second week in September, just at the time when the tubers ought to have been making their greatest growth. The result is, that there are a great many small, immature potatoes. The yield, as it is, will be large, but if the season had been favorable for continued growth until the middle of October, I think we should have had three hundred bushels or more per acre. The Flukes, which mature three weeks earlier than the Peach-blows, had attained their full growth, and suffer little from this early withering up. The cause of this early withering of the Peach-blows I do not know. We had a severe frost on the 22d of September, but the tops of the potatoes were withered a week or ten days earlier, and before we had any frost. It does not seem to be the disease—at all events there are as yet no symptoms of rot on the tubers. But perhaps there will be in a few days.

The Squire paid me a visit this morning, and we walked over the whole farm. He says my young clover, where we put the superphosphate and other artificial manures on the wheat, is the best he ever saw. At harvest it looked thin on the ground and quite poor. But after the wheat was cut, it improved rapidly. It is now as thick as it can stand, and is nearly a foot high. I am saving it for the sheep I intend to buy for fattening this winter. As a general rule it does not pay to feed young clover too close in autumn, especially with sheep, as they sometimes eat out the crown. But I think where there is a good heavy growth, they will not injure the plant.

When we came to the corn lot, he had a good chance for "a dig." The cultivators were still in the field where they were last used. "Well, now," said he, "if that was on my farm I should not be surprised, but I thought you were going to set us a better example." I was fairly caught. I told him we intended to have gone through the field once more. "Yes, but that is two months ago, and I should think a model farmer would have found or made an opportunity to have got them home before this."

They shall not be there another day—or possibly they will be there all winter. I will send a wagon for them purposely. I might have done so before, but thought we might have a

chance to bring them home without sending a team on purpose for them. But I am satisfied that the better plan in such cases, when a tool or implement is done with for the season, is to put it up at once, even if you have to send a man half a mile to get it. But my precept is better than my practice. I try to get things put up, but it seems almost impossible.

But the Squire thought my corn was a capital crop. It was injured by the severe frost three nights ago (Sept. 22), and there will be plenty of nubbins for the pigs. It is very unsatisfactory food for fattening hogs, but if well steamed, cob and all, and mixed with sound corn meal, or barley meal, it will give a pretty good account of itself. To feed it alone raw is a great waste. Last year I kept my soft corn in a crib, made of rails and covered with boards, for several months, feeding it out in small quantities through the winter. In frosty weather it would shell and grind nearly as well as the sound corn—and that which was left on the cobs was not lost, as the cows and pigs cleaned it all up. But this year, if I mistake not, there will be a good deal of corn that will be altogether too immature to keep in this way. Still, there can be little doubt that such corn will ripen to a considerable extent in the crib, from the sap in the cob. Of course the crib must be a narrow one, or the corn, if very soft, will be liable to mold. In very cold weather, however, there is not much danger of its spoiling. I see the *Agriculturist* for last month, in its "Hints about Work," recommends spreading the soft corn to dry on a loft. This is a good "hint," and will be worth more to me this fall, as some of the old correspondents of the *Genesee Farmer* used to say, "than the subscription price of the paper for a year." It is a simple matter, but farming is made up of just such simple things, and I confess I had not thought of spreading out corn to dry. It is no great "discovery," (excuse me Col.) but it is just such little "reminders" that make these "Hints about Work" so useful.

We are making a cellar under the old barn. The soil is very dry, and I spread a few cart loads of it on the top of the manure on the wettest parts of the barn yard. I was astonished at the effect. It absorbed the moisture and made a drier surface for the cattle far sooner and better than a good layer of straw. Of course we want some straw as well, but it is evident to me that a few cart loads of dry sand, or what is far better, dry muck, would save a good deal of straw in littering yards and stalls.

Sand, too, when mixed with manure, has the effect of increasing fermentation. Prof. Way's experiments proved this to be the case to an extent far greater than any one had previously thought possible. In our cold climate, where it is difficult to get manure ready for spring crops, a little sand scattered occasionally on the manure yard would increase fermentation and prove beneficial.

I have two cows, mother and daughter, that both leak out a good deal of their milk. Is there any cure for it? I am now milking them three times a day, and this prevents it, but it is some trouble to go to the field just to milk these two cows. But we get nearly or quite as much milk from them at noon as we formerly did at night. But we do not get near as much at night as we do at noon. Why is this?

A lady met me in the city yesterday and told me she had just seen the Deacon, and that he said I "was going to make farming pay."

Good for the Deacon! I believe he sincerely wishes me success—and that, I fear, is more than I can say for all my neighbors. They are all very nice people too. If I was sick, or in trouble, they would give me their aid and sympathy. If I want to borrow, they lend freely—and that is a pretty severe test of neighborly feeling, especially when you are not very prompt in returning the articles. I have had many evidences of their kindness. But they don't think I shall succeed as a farmer—and possibly they don't want me to. Why? Will it hurt them? If I was a speculator and should buy their barley at a dollar, and sell it again in two or three months for a dollar and a half, what I made they would lose. But if I should succeed in renovating my farm and should double my crops, would they be any the poorer?

The great objection to my farming is, that I "spend too much money for hired help." But I cannot get along with less. And I find the best farmers expend the most money for labor. "I have always kept a great many men," said John Johnston, "but I was always with them and kept them at work." That is the point. If the labor is well directed, and is judiciously employed—if the farmer plans his work so that there shall be no loss of time, he can better afford to hire extra help, than to let teams lie idle.

We cannot farm now as when the country was new. If we attempt it, as many do, poor crops and run down farms will be the result. We must expend more labor and more capital. We must cultivate our land better, feed higher, make richer manure, and see that it does not run to waste. I am fattening over fifty hogs. "It would pay you," said a good old-fashioned farmer in the neighborhood, "to let a man devote his whole time to feeding them." No doubt about that; but you say I keep too many men already. My horse barn is separate from the other buildings. The litter is thrown out into a loose heap, and if suffered to remain so, soon heats, and becomes fire fanged. I draw it with a one-horse cart into the barn yard, and the pigs work it over and make it into the richest kind of manure. But this takes labor. I clean out the pigpens every day, and give fresh litter. But this, too, takes labor. One of my neighbors says, I wash my pigs with warm water and castile soap. This is one of his jokes. But I *do* try to have the pigs and the pens washed occasionally, by throwing water on to them with an aquarius. The pigs evidently enjoy it, and thrive better; but this, too, takes labor. I am drawing the potato tops into the barn yard for the stock to tread into manure. It will pay twice over, but it takes time. The diseased potatoes I steam up for the hogs, and mix some corn and barley meal with them while hot, mashing up the potatoes. It makes splendid food, and is the best way to use potatoes partially decayed. But the sorting out the decayed ones, washing them and steaming and mashing with meal, involves considerable work. It would be much easier to have a pen of rails on the ground, to throw all ears of corn into the mud, and let the pigs do their own shelling, grinding, and cooking. I know more than one of my critics that adopt this "system," and of course, they do not hire much extra help.

To farm properly, we need capital and labor. The latter we are now getting at fair rates, as compared with the price of living. And the thousands of stalwart emigrants that arrive every month need work, and farmers, at present prices of produce, can afford to employ them. I have a Prussian working for me that came over a month or two ago. He cannot speak

English, but when you show him what to do, he will do it faithfully and well. He is a right, good man, and I should not object to see all our shipping engaged in bringing such men by thousands to our shores. We have land enough and work enough. But we need more capital and a lower rate of interest. And surely those men are to be honored who, having large capital, (I could wish I was one of them,) go on to a farm and employ it in developing the resources of the soil. There are hundreds of such men, and the number is rapidly increasing. Their influence and example must tend to the improvement of our general system of agriculture.

The City Poor.

No country resident can, without a personal examination, have any adequate conception of the poverty and low condition of multitudes in New York City—a center to which tend the poor and degraded from almost every part of the globe. The first week after coming here to reside, we called at the Ladies' "Five Point Mission," in the "Old Brewery," and on going into a school room where were some hundreds of children, gathered from the streets, and washed, and combed, and dressed in the clothing contributed, almost the first object we saw was one of these children clad in garments formerly worn by our own recently deceased child. The garments had been added to a parcel made up for this Mission. Our emotions can be imagined. Since then, we have often visited that famous locality to witness the success of the enterprise, though for a dozen years past, our residence in the country has made these visits less frequent than formerly. Last week our leading artist brought to us, without previous notice, the engraving on page 398, which he had, for a long time past, worked upon at odd spells, grouping together some of the scenes he had witnessed, in various visits to the locality in which he had become interested. These are mainly from the Five Points House of Industry, though their counterpart are to be found in the Five Points Mission, occupying the site of the "Old Brewery," a picture of which, as it was, is seen at the left. Our readers will be interested in the picture, and a brief account of the locality.

The "Five Points" is a small open space or square, a short distance Northeast of the City Hall, so named because the streets so meet here as to leave five points or blocks of buildings around the open space. This place was once a swamp or pond, where Fulton made some of his first experiments in applying steam to propel boats. It was subsequently filled in and drained, streets were made through it, and it became the residence of the poorest people, addicted to most revolting forms of vice. Little children learned to be thieves and drunkards; they went about half naked even in winter, and lived by stealing and begging chiefly. Murders were often committed there, and respectable persons seldom, even in daylight, went there unless accompanied by policemen. On the south side of the little square stood an old stone building, formerly used as a brewery, which, 25 years ago, was occupied by about 200 families of the lowest and poorest class, some above ground, and some below, crowded into small rooms, but few of which admitted the full daylight. Rag pickers, beggars, street women, etc., hired lodgings at sixpence or so per night, and thus about a thousand human beings of both sexes were nightly packed in upon the floors, like so many

swine, and as thickly as they could lie down.

In 1850 the Ladies' Home Missionary Society of the Methodist Church, determined to try to do something for this terrible locality, though it seemed like hearing the lion in his den. They began in the building opposite, but soon bought the entire "Old Brewery" building and grounds. They were incorporated as a Society, by Act of Legislature, in 1856, and have continued in active and very successful operation to the present time. The Old Brewery was demolished, and on its site was erected a large, commodious, brick structure (not shown in the engraving), containing several school rooms, chapel, bath, and washing rooms, offices, etc., and a large number of domicils or suites of rooms, which are furnished rent free, to poor, worthy families, and to others whom they attempt to reform and elevate. We have to-day seen, in different parts of the building, hundreds of poor, almost homeless, and parentless children, gathered in from the surrounding streets, alleys, and tenements, all neatly washed and clothed, and under the tuition of faithful, self-sacrificing teachers. During last year, over 1,200 such children were brought under its influence, the usual number connected with the Mission at one time, being about 400. The children are clothed, receive food, and instruction, etc. Many of the first ladies of the city meet weekly at the Mission, to prepare new garments, and assort and adapt the hundreds of parcels contributed from other places. Over 4,000 garments were used in 1865, besides boots and shoes, and about 40,000 meals or rations, were given out. As fast as children are prepared for it, those who can be obtained from their parents, if they have them, are provided with permanent homes in the country.—We have not space to describe the work at length. Every visitor to the city should plan to drop into the Old Brewery Mission, say between 9 and 10 o'clock A. M., or between 1½ and 3 o'clock P. M., and see for themselves the hundreds of interesting human beings gathered there. Let others send 25 cents to the Superintendent, Rev. J. N. Shaffer, (Five Points Mission, 61 Park-st., New York City,) and receive for a year the monthly journal called the "Voice from the Old Brewery"—well worth its small cost.

We have spoken particularly of the "Old Brewery Five Points Mission," as it is the original enterprise, and has continued on uniformly, and somewhat quietly in its large and efficient work. Other enterprises have grown out of it, each of which is doing a valuable work—particularly the Five Points House of Industry, under the charge of Mr. S. B. Halliday, and the Howard Mission, under Mr. Van Meter, who was previously employed as the Agent of the Old Brewery Mission for five years.

IN THE PICTURE, No. 1 is a group of the bright, ragged, saucy, dirty children as they come in from the streets and alleys. No. 3 is a view in the school room where the children are seen clean, combed, and clothed. No. 2 is a Hospital where the sick ones are, some in bed, others able to be about, and read or play quietly. No. 7 is one of the great sleeping rooms for boys. No. 8 is the nursery. No. 9 the great play room on the ground floor—the same room which is seen in No. 5, the middle picture, ornamented with greens, and with long tables set in it. This represents the children gathered for a Thanksgiving or a Christmas dinner; the blessing is being asked. The table is bountifully spread with the many good things sent in by the kind friends of the school.

Suffer little Children, and forbid them not, to come unto me, for of such is the Kingdom of Heaven

SCENES AT THE FIVE POINTS MISSION HOUSE.—(See page 397.)

The Bayberry or Wax-Myrtle.

(*Myrica cerifera*.)

Near the coast of the sea, and of our great lakes, is found growing in almost every variety of soil and situation, a low and rather irregular shrub, known as the Bayberry. It is quite dwarf and stunted in all its parts, when it grows in the sandy soil of the shore, but when it is found along the borders of marshes, it is much more luxuriant. The usual size of the leaves, and the general aspect of one of the smaller branches, are shown in the engraving. The leaves are entire, or with a few notches near the apex, of a fine shining dark green, and thickly sprinkled over with minute resinous dots. When slightly rubbed, the leaves give off a pleasant balsamic fragrance. The staminate and pistillate flowers are borne on

different plants, both kinds are produced in small cone like scaly aments or catkins, and not at all showy. The fertile flower clusters produce several small one-seeded berries, or more properly nuts, which are at first green, but at maturity they are covered by a whitish granular powder, which is wax. This shrub extends from Nova Scotia to the Gulf of Mexico, and in some localities is turned to considerable profit. Its fine green leaves, which do not readily wither, are extensively used in making up the bouquets sold in our city streets, and are one of the most available greens for this purpose. The great value of the plant, however, is in the wax with which the berries are encrusted. The berries are boiled in water and the wax melts, rises upon the surface, and may be dipped off or allowed to harden there as the water cools.

Where the shrub abounds, the wax, or "Bayberry tallow," as it is frequently called, is collected in considerable quantities for domestic use and for sale. The wax is greenish white, has a slight odor, and is more brittle, and has a more greasy feel than beeswax, and it melts at a lower temperature than that does. It is used for making candles, either alone or mixed with tallow. When mixed with tallow it gives greater firmness, and the candles in burning diffuse a pleasanter odor. The wax is used in some preparations for leather, and it is the material employed for stiffening the ends of circular lamp wicks. Another species, *Myrica Gale*, the Sweet Gale, found in wet places, has less fragrant foliage, and its fruit does not furnish wax.

OUR NATIVE ASTERS.—In this month of October the road-sides and fence-corners are gay with the bright yellow of the Golden-rods and

the blue and purple of the Asters. Many of our wild Asters are prized in Europe as garden plants, but they are so common that we seldom find them in cultivation in our gardens. While as single flowers they are a little coarse, the effect of a mass of them is fine. They are

animals, no matter whether they have two or four legs. If one has trees in grounds usually approached by a curved path, they stand a poor chance when snow is on the ground. There are certain heathens who will strike a bee line with their sleighs and sleds from the gate to the house, and if there are any young trees in the way, so much the worse for the trees. We once suffered very severely in this way, and when remonstrance was made, all the satisfaction we got was the information that there were no roads when snow covered the ground. — We know of no way of dealing efficiently with these two-legged brutes, but there are some small four-legged ones that need looking after, and whose depredations can be warded off. Mice are often troublesome in a young orchard. If clean culture has not been followed, it is not too late to remove all dead weeds and other rubbish that can

harbor mice. The little fellows like to work under cover, and the remains of weeds and grass afford them convenient shelter. They have a grand time under newly fallen snow, and it is well to head them off by tramping the snow firmly around the trees. Among the various preventives of the attacks of rabbits, none are perhaps more easily applied, or more efficacious than that proposed by Doct. Warder, at one of our pomological meetings. The rabbit is rather fastidious as to its food, and has a great dislike to animal matters. Indeed it was long ago recommended to shoot a rabbit, split it open, and rub the tree with its body, as a warning to its fellows. Doct. Warder's plan is to spatter the tree with blood. Blood is readily obtained wherever slaughtering is done, and with a vessel of this and a swab made of corn husks tied to a stick, one can bespatter a young orchard in a short time. Doct. W. states that a single application suffices for a whole winter.

The Stock and the Graft.

It has been a generally received opinion among the best observers, both at home and abroad, that the stock exercised no other influence upon the graft that is inserted in it, than to dwarf it. Prof. Caspary has published in The Bulletin, of the Amsterdam Botanical Congress, an article in which he attempts to show that some hybrids have been produced by grafting. That is, that the flowers and fruit upon a graft sometimes show a cross between those proper to the graft and to the stock. From the instances—mainly of ornamental trees and

BAYBERRY OR WAX-MYRTLE.

readily transplanted, and in the rich soil of the garden they are even finer than when they grow wild. We have not space to enumerate the best species; any that seem attractive in their wild state, will give satisfaction in the garden.

Young Trees in Winter.

Many persons seem to think that when they have set out fruit trees, they have done their part, and if the trees do not flourish, the blame is laid to the nurseryman, or they conclude that their land is not suited to fruit. Besides neglect, trees have active enemies, both biped and quadruped. A good fence, with gates securely fastened, is a great protection against the larger

roses—cited by Prof. C., we do not think he has made out a very strong argument. Still, a proposition coming from so high an authority deserves respectful attention, and we allude to it as a topic likely to cause some discussion among horticulturists. Who knows but the case of our puzzling sweet and sour apple may serve help support Professor Caspary's view?

Insects and Plant Fertilization.

SIXTH ARTICLE.

In our foregoing illustrations, insects are seen to carry the pollen of one flower to another exactly like it; or else to bear the pollen from a male flower to a female flower, belonging perhaps to a separate plant or tree, as in willows. In the present article we will call attention to a still different case, viz., that of *dimorphous* flowers. That is, where they are of two sorts, but both hermaphrodite. Instances of this kind are common enough; but, as we have room only for a single illustration, we will take for our example a pretty little spring flower which every body knows, or ought to know, the little *Houstonia*. Almost every wet pasture or meadow, or grassy bog, is decked in spring by these tiny flowers. They are all alike as to the corolla, and all hermaphrodite, having good stamens and a good pistil. But on inspection it may be seen that, while all the blossoms of one clump are as in fig. 1, and show only the tips of the four anthers in the eye or throat, the style being short and included (see fig. 1a), all those of some other clumps will be as in fig. 2 (seen dissected in fig. 2a), the four anthers out of sight low down in the tube of the flower, but the tip of the style with its two stigmas emerging into view. There are, on the whole, about as many of one kind as of the other; and the seeds from the pod of either will produce plants of both sorts. Both sorts mature seeds freely. No. 1, the short-styled sort, may fertilize itself, as the pollen may drop from the bursting anthers upon the stigma underneath. The long-styled flower (No. 2), however, is not likely to be fertilized without help. Both are in fact fertilized by aid of insects, and the one sort is habitually fertilized by the other sort. How this is done, and how perfect the arrangement for doing it is, will be seen at a glance now that the thing is understood. If any small flying insect, with a proboscis about long enough to reach the bottom of the flower, should visit No. 1, it will probably smear its face with some of the pollen of the anthers it comes in contact

Fig. 1.—Flower of *Houstonia* or *Oldenlandia cœrulea*: 1a, enlarged view of the same with the ovary or seed-vessel, cut half away, and the corolla split down and laid open, showing the 4 stamens (anthers) attached high up, while the style is short.

Fig. 2.—Another flower of *Houstonia*, and 2a, a similar dissection of it; the style long and projecting, but the 4 anthers attached low down.

with; and in passing to other blossoms of that sort, it can do little more than to transfer some of the pollen from one anther to another; though it is quite likely that some grains of pollen, sticking to the proboscis, may be carried down to the stigma of the same or of the next flower. If the insect visits a succession of long-styled flowers, No. 2, it will rub its face repeatedly upon the projecting stigmas, with a mere chance that a grain of pollen, extracted by the proboscis from one of the included anthers, may be dropped by the way upon the stigma of the next flower. But suppose the insect passes from the short-styled flower, No. 1, to the long-styled, No. 2. Why, then the pollen which smears its face at No. 1, will be brushed off upon the stigmas of No. 2. And if the insect then proceeds from No. 2 to a fresh No. 1, any pollen adhering to the proboscis from the anthers of the former, would be neatly transferred, most probably, to the corresponding stigmas of the short style of the latter; and so on.

Here not only are individual flowers cross-fertilized, but the two sorts of flowers cross-fertilize; and that is what the whole arrangement is evidently for. The flowers of the *Mitchella* or Partridge-berry of our woods, which are produced about midsummer, are on the same plan. So are those of Primroses; and it was in the Primrose that this *dimorphism* was first detected, many years ago; but the meaning of it was completely unknown until Mr. Darwin made it out four or five years ago. This capital investigator also showed that, not only are these flowers, of either sort, nearly barren when insects are excluded,—which might be expected, inasmuch as little or no pollen would reach the stigmas unaided,—but even that the pollen of either sort produced much less effect upon the stigmas of that sort than it did upon the stigmas of the other kind. Indeed, he found that in some such plants, the pollen which perfectly fertilized the other sort, would not act upon its own sort of stigma at all. This is so in the Red-flowered Flax, grown in our gardens for ornament, and to some extent in a wild blue-flowered Flax; while the blossoms of the common field Flax are not dimorphous at all. All this clearly proves that in dimorphous flowers we have merely another way in which nature secures cross-fertilization; and all the dimorphous flowers we know of are fertilized by insect-agency.

In following up this subject, Mr. Darwin lately discovered that the blossoms of the Spiked Loose-strife (*Lythrum Salicaria*) are *trimorphous* or of three sorts; and we may close this article with a very brief account of this curious case. From seeds of the same pod come three forms, in about equal numbers, viz.:

1.—The *long-styled* form; which has 6 short stamens enclosed in the calyx, 6 mid-length stamens, protruding out of the calyx, and a style which is still longer (fig. 3).

2.—The *mid-length styled* form, with 6 long and 6 short stamens. The stigma and the anthers of the long stamens of this and the last have changed places. (fig. 4)

3.—The *short-styled* form, which has 6 mid-length and 6 long stamens. The stigma in this answers, in position, to the anthers of the short stamens of the two preceding forms, its mid-length anthers to the stigma of one of the preceding, and those of the long stamens to the stigma of the other. All the flowers of any one plant are alike. The three sorts of anthers have distinguishably different pollen; and each sort of pollen proves to be more effective upon some other stigma than that of the same sort of flower.

Here, in the hermaphrodite flowers of one and the same species, are three sets of males (and in function even five sets of males), and three

Figs. 3, 4, 5.—The three forms of Spiked Loose-strife (*Lythrum Salicaria*), one side of the calyx cut away, and the petals taken off; 3, the long-styled and mid-length and short-stamened; 4, with mid-length style and long and short stamens; 5, with short style and mid-length and long stamens. The dotted lines and arrows show the routes by which pollen is effectively carried to stigmas by bees, etc.

sets of females, about as distinct in action as if they belonged to so many distinct species. For Mr. Darwin has shown that only the longest stamens will fully fertilize the longest pistil, the middle stamens the middle pistil, and the shortest stamens the shortest pistil. Artificially we can make a dozen distinct crosses; but only those above mentioned, which experiment proves to be the most prolific, are very likely to be made in nature. And these are made thus: The flowers are visited by bees and the like. They invariably alight on the upper side of the flower, and insert their proboscides along the upper and inner margin of the calyx, where some room is conveniently left for the purpose, giving access to the bottom of the flower. When the bee reaches with his proboscis the bottom of the flower, where the honey is found, the long stamens of figs. 4 and 5 rub against his abdomen, and sprinkle it with their pollen. Flying to the long-styled form (fig. 3), its stigma rubs against the same place and takes some of the pollen. The middle-length stamens (figs. 3 and 5) dust with their pollen the under side of the bee's thorax, between the front pair of legs; the stigma of the mid-length pistil (fig. 4) hits the same spot. The anthers of the short stamens (figs. 3 and 4) are hit by the chin and the proboscis of the bees, the front of the head only being inserted into the throat of the calyx; and this sort of pollen only will be carried to the stigma of the short pistil (fig. 5), which rubs in its turn upon the bee's pollen-powdered chin.

What advantage has this triple arrangement for crossing over the more common dimorphous plan? Perhaps there is some economy in it or greater certainty of effective crossing. If, say only two plants grew near each other, there is only an equal chance that they may be of different forms, and so both fertile. But when there are three sorts, each capable of fertilizing the other two, the chances are two to one in favor of any two contiguous plants being of different sorts and so both productive. A. G.

Interesting Jaunt Among the Grapes.

"The Catawbas have not failed to give a crop in ten years, we have no rot, no mildew, and no trouble with insects nor birds," is a summary of our talk with an old grape grower. The reader will ask where such a favored spot can be, and we will endeavor to tell him, and as much about it as our space will allow. In Steuben Co., N. Y., is Crooked Lake, at one end of which is Penn Yan, and at the other, some 20 miles distant, is Hammondsport. Penn Yan is on the N. Y. Central R. R., and connects with Hammondsport, by steamer, which place is also reached by stage from Bath, a station eight miles distant on a branch of the Erie R. R. The general region is known as Pleasant Valley, and the grape district lies mainly in the towns of Urbana and Pulteney. The lake is deep, pure, and seldom freezes; it is enclosed by hills which, upon the west side, rise in terraces, mostly with very steep sides, while the slope of the land upon the eastern shore is more gentle. The proper grape region is upon the western shore of the lake, and extends some twelve miles from Hammondsport. The hills are about four hundred feet high, and at frequent intervals are cut through by deep ravines running down to the lake. The soil is a disintegrated shale, more than gravelly, as it is full of stones, which are often so numerous as to cover the surface. This peculiar soil is of an indefinite depth, and is of a character that insures a perfect natural drainage. One could hardly imagine a more unfavorable place to set a vine, than the best Catawba lands, at first sight appear to be. The following are the natural advantages of the Pleasant Valley region: a large body of water that secures a uniformity of temperature, and prolongs the ripening season; a favorable exposure to the sun, with shelter from violent winds; a deep and strong soil, with a perfect natural drainage. The vineyards are from five to ten acres in extent, though much larger tracts are cultivated by associations and companies. Some 3000 acres are set in vineyards, held by over two hundred proprietors. The best lands sell at \$300 to \$400 an acre, while others not so favorably located, or so well adapted to the growth of the Catawba, are to be had at less prices. The Catawba and Isabella are the principal varieties in cultivation. Delaware and Diana are cultivated to some extent, while the Concord, considering its popularity elsewhere, is not as yet largely planted. The distance of planting varies somewhat; but eight feet by six is the usual way of setting the Catawba, while it is thought best to give the Isabella a little more distance in the rows. One feature of the cultivation here is deep setting; surface roots are removed from the cuttings, and their future growth is not encouraged. No manure is used. The first year the vines have their own way. The second year they are trained to stakes or a trellis is put up. The trellis now employed is of oak posts, with horizontal wires at about 18 in. apart. The pruning is a modification of the renewal system, two canes being allowed to fruit, while two are being grown for next year's bearing. Summer pinching of the laterals, or "kites"—as they are called here—is closely followed. The fruiting canes are attached to the lower wire, and the fruit is thus brought near the ground, where it ripens better and develops the qualities necessary in a wine grape more perfectly than it does if the canes are higher. The grapes for market are cut by means of scissors of the style shown in the engraving. The fruit is laid carefully in open

crates, which are placed in the fruit house for two or three weeks, to cure. It is then packed, a work usually done by ladies, who carefully select the best bunches and place them in the boxes. The usual size of boxes is 9 inches long, 6 inches wide, and 4 inches high. The packing

SCISSORS.

is done as described on page 323 (Sept.). The small bunches are sold for wine making. There are three wine companies with abundant capital, who have extensive wine cellars and large vineyards. We can not say more about the wine business in the present article, except that the market prices for table grapes are so much higher than the wine makers can afford to pay for fruit to crush, that the wine business has not yet attained its full development. The average yield of a vineyard in full bearing is about 9,000 lbs. to the acre. The crop for the whole region is estimated at between 400 to 500 tons. The best market grapes net the raiser about 15 cts. per lb. The wine cellars are offering 10 cts. for Catawbas. We can not close this imperfect sketch of a remarkable region without recommending those who are interested in vine culture, to go and see for themselves how much the reality exceeds any description, however elaborate it may be. The scenery is beautiful, and one can look upon vine clad hills without visiting the Rhine. The enterprise has had a healthy and gradual growth from a very humble beginning. There is an air of prosperity, for every one is well to do. Fruit culture seems to have had its refining influence upon the people. Though there are so many in the same pursuit, they seem to have no jealousies, they are hospitable, and have no secrets about their cultivation. We wish this enterprise continued success, and may blight and mildew ever be strangers to the fitly named "Pleasant Valley."

New Fruits—The Bronx Pear.

The Western New York Fruit Grower's Association, at their summer meeting, expressed in a resolution their belief that no new fruit should be put before the public, without it first has the endorsement of some Pomological Society. In the main, we agree with this, but what are we of Eastern New York to do who have no Pomological Associations to go to? True, we have a "Farmer's Club," so-called, whose opinion we had much rather not have, as it is given altogether too freely upon all subjects within the range of human knowledge.—We shall soon have an opinion on medicine from them, as they have appointed a committee to report on some chap's *bitters*! There are several new pears that we intended to submit to the American Pomological Society, but that body was put asleep for a year by fear of cholera, and we are obliged to be a Pomological body all by ourselves.

THE BRONX PEAR.—This fruit was first brought to our notice some years ago by the Rev. Wm. Clift, Comptroller of Woodlawn Cemetery, who, at our request, has drawn up the following account of its origin:

"This new pear was raised by James P. Swain, Esq., of Bronxville, about the year 1850, the last year that the horticultural exhibition of the American Institute was held in Castle Garden. The parentage has not been definitely ascertained. A large quantity of seeds taken from pears exhibited at the Institute that year, were planted. Among them were the Beurre d'Arenberg, Beurre Diel, Beurre Ranz, Colmar, Catillac, Glout Moreceau, Passe Colmar, Napoleon, Easter Beurre, Duchesse d'Angouleme, Vicar of Winkfield, and some others. About eleven thousand seedlings were raised upon a gravelly soil, fully exposed to the sun and wind, that their hardiness might be duly tested. All the blighted and delicate plants were immediately destroyed, and the result of the last thinning left only five hardy seedlings, and these were subsequently reduced by accident to three.

The first of these proved to be an early bearer, giving fruit in its ninth year, and was named by

BRONX PEAR.

Mr. Swain the Bronx, from the river of its birth place. The original tree is an upright grower, inclined to assume a pyramidal shape without the use of the knife. The limbs droop somewhat with age and full bearing. The wood is of a reddish brown color, and has never shown the least disposition to blight. The foliage is a bright glossy green, and is retained until the close of the season. It is a regular and abundant bearer, setting fruit three or four inches apart, and retaining it until ready for picking. It has borne regularly abundant crops for 7 years.

The fruit has not yet been exhibited at the horticultural fairs, but has been submitted to some of our best pomologists, who have given it their unqualified praise. It has not yet passed out of the hands of the proprietor, but has been considerably multiplied. We consider it a valuable addition to our already large class of September pears."

Fruit medium, obovate pyriform. Skin, dull greenish yellow, thickly sprinkled with russet dots, which frequently run together and form patches of russet, especially near the stem and calyx, where the skin is often completely russeted. Stem about 1½ inches long, moderately stout and enlarged at its insertion, which is usually in a well marked uneven cavity, though in some specimens, where the form approaches to turbinate, the cavity is wanting. Calyx open, with short segments, set in a slight and obscurely furrowed basin. Flesh, yellow-

ish white, slightly coarse grained, very juicy and melting—sweet and rich, and when well ripened, with a delicate perfume. Season, from first to middle of September. The engraving is from an average specimen. With proper thinning, the fruit would doubtless be much larger.

Tea Roses—Marechal Niel.

Most of us can recollect when a Tea-rose was a great rarity; now they are among the most common of roses.

They are deservedly popular, for they are such free bloomers, and the beauty of their flowers, and the delicacy of their fragrance commend them to all. It is true they are tender and require to be protected from the severity of our winters—but those who really love roses will not mind this. Some of the more hardy Tea-roses, such as Safrano, may be laid down and covered with earth, in the manner described by Mr. Henderson, in September last, and it is probable that in favorable situations, all but the very delicate ones may be wintered in this way. Those too tender to be risked out under a covering of earth, may be potted and put

in a cool green-house or cellar. Among the new Tea-roses none has received more universal approbation among European cultivators than the Marechal Niel. It is a seedling of M. Pradel, of Montauban, France, and was flowered this summer for the first time in this country. We saw a fine lot of it in the grounds of Mr. Peter Henderson, and took a specimen from which the engraving is made. We can only show the form of the bud and partly open flower, while the fine yellow color must be left to the imagination. The expanded flowers are large and full—but like those of other trees—less beautiful than when they are only partly opened. The foliage is good, the habit of the plant vigorous, and it is a very free bloomer. In France, it is regarded as one of the hardiest of its class, but with us it will require the experience of this winter to prove it in this respect.

Hedges and Hedge Plants.—(3rd Article.)

THE OSAGE ORANGE AND BARBERRY.

It is not necessary to advocate the Osage Orange as a hedge plant. It has probably been more extensively planted than all others, and wherever the winters are not too severe, it is one of our most valuable fence plants. In the present article we merely wish to say a word

about the young plants and seeds, to give a general answer to numerous letters of inquiry. There was a large quantity of seed sown last spring and many will lose their plants from not knowing that the first winter is usually very severe upon them—especially in ground liable to be thrown by the frost. The proper way is to take up all the seedlings when frost has checked the growth. The bed is usually mowed over, to remove the immature tops, and the plants are either plowed out, or if the quantity

best to spread it and let it ripen under cover, and after the seed is fully developed it may be allowed to freeze. The fruit is mashed in spring and the seeds are separated by washing.

THE BARBERRY is now attracting considerable attention as a hedge plant, and since the publication of an article in last June, page 213, we have inquiries about the seed. The Barberry is very abundant in New England, especially in Massachusetts and Rhode Island. The fruit is usually to be found in the markets of those

States. The seed may be separated by putting the berries in water and then allowing them to stand until softened, when they may be rubbed between the hands, and the pulp be washed away from the heavier seeds.

Scattered Treasures.

In the natural way of things the leaves decay where they fall, and thus return to the earth more of organic matter than the tree takes from it. In cultivation we do not allow things to go on in their natural way, but wish some portions of earth to be unnaturally fertile, and we accumulate manures. Besides, in our civilization we have certain ideas of neatness

MARECHAL NIEL.

is small, dug by the spade. The plants are then assorted, all of the same size put together and tied in bundles of 100. To preserve them during the winter, they may be placed in the cellar and covered with sand, sandy earth, or sawdust fresh from the mill. Anything that will keep them from drying and not be too wet, will answer. The plants may also be heeled-in out of doors, if a properly drained place be selected. Thus treated, the plants winter safely, and the assorting, which is always necessary to secure evenness in the hedge, is done more at leisure than it can be in spring. With regard to seed, in Texas and Arkansas, where the tree grows naturally, the fruit, when ripe, is thrown into heaps to rot, and the seeds are washed from the pulp. This does well enough where the season is long enough to mature the fruit on the tree. At the North there are many old hedges and trees also, that bear fruit, which, though it attains its full size, does not ripen upon the tree. With this fruit a different course must be followed. The seed must have an opportunity to perfect itself within the fruit. The fruit is in size and shape like an orange, and in structure much like an enormous round mulberry. Each seed is surrounded by fleshy envelopes, which, though the seed may be quite immature when the fruit is gathered, serve to nourish and perfect it. With the northern fruit it is therefore

with which fallen leaves conflict, and we gather them up because they have a slovenly look that offends us. Every leaf should be saved, and if not allowed to decay and enrich the ground where it falls, it should be made to do good service elsewhere. In our country towns and villages, so generally planted with shade trees, the crop of leaves is blown about and usually goes to waste. The careful gardener will be on the look out for these "scattered treasures," and gather them all for preservation. Gathering the autumn leaves is excellent work for children, and men and women need not be ashamed of it, for it is merely accepting one of the gifts of a bountiful Providence. Leaves are nature's own winter mulch for the wild flowers of the woods, and we can have nothing better for our beds and borders. For bulbs and all herbaceous plants, strawberries, and all things requiring a winter covering, the otherwise wasted leaves will be found most useful. Then when we come to make hot-beds in early spring, they serve to mix with manure in the proportion of one-fourth to one-half, and make a better heating material than manure alone. And after having served this purpose, their vitality is not exhausted. The old heating material, mixed manure and leaves, thoroughly rotted, makes a manure that every gardener knows the value of. Save the leaves then, there is money in them.

THE HOUSEHOLD.

(For other Household Items, see "Basket" pages.)

About Alkalies and Acids.

These two words occur so frequently in every day life, that a few explanations of them will be acceptable to the unscientific reader.—**ALKALIES.**—Potash and Soda are familiar examples of *alkalies*. When pure, they have a strong caustic or burning taste. They dissolve readily in water, and also unite with oil or grease. Water and oil will not unite together, but put some alkali with them and this will take hold of each and bring them together, as in making soap. The strongest and most common alkalies are Potash, Soda, and Ammonia or Hartshorn. Ammonia is a powerful alkali, but as we usually see it, it is dissolved in a large amount of water. There are other alkalies, and many alkaloids, that is, vegetable substances that have alkaline properties, such as quinia, morphia, strychnia, etc. Then there are alkaline earths, as they are called. Lime is one of these, which, when newly burned, is very caustic. Magnesia is another. Lime and magnesia, and especially lime, are useful in many cases as alkalies. As an alkali is often wanted, sometimes in haste, to neutralize an acid, as explained below, the unscientific reader will remember the five most common alkaline substances, by the initials PSALM, standing for *Potash, Soda, Ammonia, Lime, Magnesia*.

ACIDS.—The word *acid*, means *sour*, and most of the common acids are very sour to the taste. Acetic acid, or vinegar, when pure, is intensely sour, and would destroy the flesh, but good strong vinegar contains only 5 or 6 parts of acid dissolved in 100 parts of water. Sulphuric acid, commonly called "oil of vitriol," is one of the strong acids. A drop of this in a pint of water will make it taste sour. Nitric acid, called aqua-fortis, is another of the strong acids. So is hydro-chloric acid, commonly called muriatic acid, or spirit of salt. Then we have citric acid, the sour of lemon juice; malic acid, the sour of apple juice; tartaric acid, the sour in grapes and some other fruits; lactic acid, the sour formed in milk, etc., as common examples. We generally say when anything becomes sour, that it is acidified. Almost all the acids, when strong, are injurious to the flesh, and poisonous if swallowed, but when greatly diluted with water, they are frequently tonic or strengthening. Some fruits are for this reason often useful, and generally healthful, if well mashed or masticated so as to be easily digested. Vinegar is much used with some kinds of food to aid in their digestion, but too much of it injures and weakens the stomach, and it is not advisable for constant use.—*Carbonic acid* is very abundant, but we never see it alone, because when not combined with something else, it always takes a gas or air-like form. It is produced wherever any vegetable substances, as coal, wood, oil, etc., are burned. It is this acid that bubbles up in soda water, and gives it a sourish taste. It is carbonic acid that fills the little interstices or air-holes that make bread, cake, batter, etc., light. It unites with potash to form saleratus, with lime to make limestone, chalk, or marble.

The *acids and alkalies* unite together, and usually destroy each other's acid properties, forming what are termed "salts." Thus strong sulphuric acid (oil of vitriol), unites with the powerfully caustic soda, and forms the mild compound known as Glauber salts (sulphate of soda). So also when this powerful oil of vitriol which eats into the flesh, and even chars wood, is united with the intensely caustic fresh lime, the two neutralize each other's properties, and form the mild, tasteless sulphate of lime, (gypsum or Plaster,) which we sow on land, and use in making casts, cornices and ornaments on plastered walls, etc. Aqua-fortis (nitric acid), as powerful as it is to destroy the flesh, and to dissolve metals, when united with caustic lime, makes a compound as mild as plaster, and when united with potash, makes saltpetre. Soda put in acid or soured batter neutralizes the acid formed.

One practical lesson to be learned from the above, is, that when trouble results from the accidental or over use of either an acid or alkali, it is to be counteracted by applying the other. For example, if an acid is accidentally swallowed, follow it as quickly as possible with some alkali,—as a weak solution of potash or soda, or lime water. A strong solution of soap swallowed freely, is the best common remedy. The effects of potash, soda, lime, strong soap, etc., upon the hands, are neutralized by a weak wash of any acid, as acetic acid (vinegar). Acid spilled upon the garments should be quickly neutralized with potash, soda, ammonia, or lime water.

About Soap—Soap Frauds, etc.

It has been estimated that, in the United States and England, the annual consumption of soap, for domestic purposes alone, amounts to an average of 8½ lbs. of hard soap for each inhabitant, equal to 41½ lbs. to each family of five persons, and about 250,000,000 pounds for our entire country—worth fully \$3,000,000. Large quantities are also used for manufacturing purposes, as in woolen manufactories, etc. All soaps are essentially alike in their composition and action. Their principal use is to remove oily matters, which are dissolved by *alkalies*. (See notes on alkalies above.) The alkalies in a pure state are too strong for the hands, and they usually injure fabrics. They are therefore made less caustic by first combining them with some oil or grease in the form of soap. Potash united with any kind of oil or grease, makes a watery compound called "soft soap." Soda with oil or grease, forms "hard soap." If we put soda, or salt which contains the metallic element of soda, into soft soap, the soda unites with the oily material, making hard soap of it, while the potash is expelled and remains dissolved in the liquid. Ordinary good soft soap, contains in each 100 lbs., about 43 lbs. of oily matters, 9 lbs. of potash, and 48 lbs. of water. Good white hard soap, about 60 lbs. of oily matters, 7 lbs. of soda, and 33 lbs. of water. Castile soap, 75 lbs. oily matters, 10 lbs. soda, and 15 lbs. water. Other hard soaps vary from 50 to 80 lbs. of oily matters, 4½ to 10½ lbs. soda, and 8 to 45 lbs. water in each 100 pounds.

Common Domestic Soft Soap is made in two ways: Where wood is the chief fuel, the ashes supply a large amount of potash. This is obtained by leaching, that is, running water slowly through the ashes. The lye thus obtained is boiled down to any degree of strength, and oil or soap grease added at any stage of the boiling. It will boil away faster without the grease, but is in the end stronger if the grease be added at first, as less carbonic acid is absorbed from the air. For the same reason, fresh run lye, or that kept closely covered, is stronger than that much exposed to the air. So also, it is desirable to keep the lye, in its passage from the ashes, as little spread out or exposed to the air, as possible. It may not be generally known that fresh slaked lime, mixed with the ashes, a quart or two to the bushel, and especially with the ashes in the bottom of the leach, is highly beneficial. The lime withdraws the carbonic acid from the potash, and leaves a stronger lye. Lye is much improved in strength, by stirring a quart or two of fresh slaked lime into a barrelful, letting it settle, and pour off the clean lye when ready to add the grease for soap making. The amount of boiling is not essential, except to reduce the soap to a convenient consistence or thickness.—The other process, where ashes are not made at home, is to purchase potash, dissolve it in water, about a pailful to a pound, more or less, and boil it with 2 or 3 lbs. of grease—the proportions depend wholly upon the strength of the alkali, and the quality of the grease, of which sufficient is to be used to leave it weak enough not to corrode or injure the hands. If left too strongly alkaline, it will injure the fabric.—This brings us to

Bad Soaps in the Market.—There is great need of caution on the part of housekeepers, in this respect. As a rule, the "labor-saving

soaps," all those recommended as quick washers, etc., are dangerous. They are made by incorporating into them an undue amount of alkali, which, while it does promote the quick cleansing of garments, does so *at the expense of the fabric*. The washer-woman, and even the housekeeper herself, is pleased with the ease with which the dirt is cleaned out, and she will not only purchase the same soap again, but recommend it to her friends and neighbors, and even give a written certificate of its excellent properties. It is true that every time it is used, it is eating away the strength of the fine fabrics, but this is not so rapid as to be noticed from week to week. The garments wear out early, but that is charged to the manufacturer who "makes such poor material in these days." *We have no doubt that millions of dollars worth of garments are destroyed every year by these much puffed, quick washing soaps, now so extensively used!* The best recipe we could give for reducing the present high price of cotton and other goods, would be to abolish from the country everything in the form of a patented, quick-washing, labor-saving soap. If anybody wishes to persist in using something that will "wash quick," let her dissolve the common bar soap, and add a few ounces of cheap washing soda. This will get all the effect of the best labor-saving soap at a far less cost. But nothing of the kind should be used.—Never buy a soap which, on drying, leaves on the surface of the bar a white coating of soda, or other alkali. Pale bar soap, that dries smooth, is the best. That which is of a light brown, from the admixture of resin, is equally good with the white, for cotton and linen cloth, but for woolen or worsted, nothing but pale soap should be used, as the brown, resin soap is injurious. *Dark brown soap, which contains much resin, should be rejected. Soap which shrinks ½ or ⅓ in drying, is not profitable. Some manufacturers incorporate a great deal of water, which adds to the weight and bulk, but is a clear loss to the buyer.*—The above remarks apply to a dozen recipes now before us, contributed by subscribers, which give directions for making excellent quick washing soaps, costing only 2 to 4 cents the pound or gallon. Those who use them, should take into account the loss of fibre they are invariably enduring. The same remarks apply also to the thousand-and-one washing fluids, for which recipes have been sold so extensively.

Another Fraud is found in the white soft soaps sold at the grocery stores in cities and villages. They are made of a little grease and soda (instead of potash). As the soda naturally makes a hard soap, much water, together with starch flour, silicate of potash, borax, etc., are mingled to give it the jelly like consistence. All this stuff is to be avoided. We have seen it sold of so poor a character that a barrelful of it was really less valuable than 3 or 4 lbs. of bar soap. We have heard of its being made and sold at 75 cents a barrel, at a round profit to the maker. Yet the poor and ignorant buy this in immense quantities, because it is sold at a low price by the gallon, though at an exorbitant price compared with its real worth.

There are many other interesting and useful items about common soaps, toilet soaps, fancy soaps, shaving soaps, etc., which we must defer a month or two, or until we have space for them.

For the American Agriculturist.

"Above Half Right."

"Above half right, above half right," exclaimed Mr. Marvin, at the close of a long reverie, as he sat by the kitchen stove.

"What is above half right?" asked his trim little wife, who was just entering to call him to tea. "Oh, no matter, Fanny, but I am glad if tea is ready—the chill has gone, *outside*, and that will set me all right within."

"But I insist upon knowing to what that oracular conclusion referred," said Fanny, playfully intercepting her husband's way to the dining room.

Now with the bright face of his wife, and the pleasant prospect of supper before him, Mr. Mar-

vin would rather have been excused from telling his previous cogitations; but Fanny "insisted."

"Pour me a cup, then, and if you are willing to risk a spoiled supper, you shall know."

"What is the mystery?" said Fanny, as she passed the fragrant cup of tea to her husband.

"No mystery at all. I was only drawing a comparison, as I sat by the kitchen fire, between Tom Hughes' home, manner of living, in fact house-keeping arrangements generally, and our own."

"And *who* is 'above half right?'" asked Fanny quickly—"surely not Tom and Clara—everything at loose ends—perfect carelessness, not to call it slackness, stamped on everything, out of doors and in. Such a yard and garden! Sweet flowers, to be sure, but overrun with weeds—walks neglected—borders broken, or altogether lost; and *inside*, oh! dear, I could never describe it!"

"I know! I know! But comfort is what I was looking at, Fanny, *comfort!*" And Mr. Marvin laughed in spite of himself, at Fanny's blank look.

"More confusion than comfort, I should say!"

"Well, it's all as one feels about it. Too much precision is apt to be chilling;" and visions of linen-cased chairs and ottomans, gauze-covered pictures, and darkened windows in his own perfectly kept parlors, would rise up in contrast with the pleasant freedom of his friends' less pretentious and more commonly used rooms.

"Oh, you got wet to-night, and because I didn't rush, as Clara would have done, and hurry you into the parlor, wet boots, dripping coat, umbrella and all, to ruin the carpet and marble hearth, you sat and had all these fancies over the kitchen fire."

"Fanny!" and Mr. Marvin's voice assumed a harsher tone than usual, "you *would* know my thoughts—a man isn't responsible to his wife for having them, I take it; so don't be offended if I revealed them at your own request. I believe I love neatness and order as well as any man, but I do not love to be cramped and hampered at every turn, afraid to step here, or sit there. A little more use and a little less ceremony, a little more wear and tear, and a little less formality, wouldn't it seem more homelike, Fanny?"

"This 'letting down' of things I never could bear," was the quick reply. "Now tell me, candidly, Edward, would you be willing I should let Alice and Arthur bring their blocks and dominoes into the parlor, to build forts and railroads with, on the carpet, or let Susie have her dolls and tea-set there; or thump over the piano-keys with her merciless, fat fingers for the sake of a perfect jargon of noise, instead of keeping them in the nursery, and allowing them only to come in the parlor when properly dressed and at suitable times?"

"Candidly, yes; I would really like it! Dear little things, let them be happy in *every* room and any room, and not have a parlor seem to them, as Sunday used to seem to me. I should not give them an inkstand, uncoiled, to play with, nor allow rude games, nor have them make the piano a 'stamping ground;' but anything short of this, which could afford pleasure, let them enjoy."

"And what a beautiful noise there would be when the door-bell should ring—bustling about putting back chairs from Arthur's train of ears, and stopping to shake him into quiet because he cried that his train was ruined, picking up this, and straightening out that, until you meet your friend with a face flushed to fever heat, and a hearty wish that parlors might never be nurseries."

Edward laughed; and Fanny, unappeased, went on "And would you have the blinds open all day, and the sunshine in, spoiling everything?"

"Rather brightening and sweetening everything."

"And the covers off the furniture, and all worn and threadbare in a month! Only yesterday Clara was darning a place in her sofa, where copper toes and high heels no doubt often came down with sufficient force to please the greatest advocate of freedom and unrestrained use! And then you would like such a garden as Tom's! Faded pea-vines, clinging to the dead brush, and Dahlias blooming from out the tangled mass. Roses and Spearmint, Asters and Asparagus growing in lover-like proximity—while the walks are gracefully arched with

strong weeds, lacing themselves across the way in a very free and easy manner!"

Mr. Marvin laughed again in spite of himself, as he thought of his own carefully kept yard and garden, where one weed would be plucked up as an intruder, where not a dock or dandelion, or presuming plantain had for years dared to lift their heads, and where every walk was as precisely straight (since Fanny had been the mistress, at least) as the line that divided the glossy tresses of his wife's hair. On the whole, he had grown very fond of order; but there were times when his soul felt trammled, and in his rebellion he felt disposed to knock around, overset, and break up stiffness out doors and in, with a vengeance!

"No! Fanny, I would never have broken borders and weed arches, nor sofas turned into a playground; but I would have less fear of a little use, and more open, sunny, genial freedom. I would rather bequeath to my great-grand-children worn furniture, threadbare carpets, and tarnished silver, than portraits wrinkled into railroad-maps, from care-lines made by the constant strain to keep these things fresh, whole, and bright. There are always extremes in everything. I would have only a pleasant mean. If I had but one room below and one above, with a four feet wide yard in front, I would not, like poor Sam Wilt, have melon rinds and refuse apples, broken glass and bits of earthenware, occupying half the space, and broken chairs and useless traps filling every inch within. No, I would show that a little room could be made comfortable, and at all hazards homelike."

"Well, you are 'above half right,'" said the willful little Fanny, "and you'll see if I don't prove it!"

And sure enough Mr. Marvin found, in less than a week, a sun-lighted parlor, with unceasing furniture; and actually heard from its cheerful recesses the merry voices of children who are ever the first to appreciate the blessedness of a true home. Fanny had "a mind of her own," but she was proud to yield gracefully when convinced that her husband was "above half right."

Original Contributions to the American Agriculturist.

Hints on Cooking, etc.

Moravian Recipes.—[Rev. E. E. Reinkle, Pastor of the Moravian Church at Olney, Ill., writes a very pleasant letter to the *Agriculturist* and its work, which it would be gratifying to print, had we room for one in a thousand of such agreeable epistles. Wishing to make a return for good received, and contribute what he can to the general good, he sends a variety of well tried recipes, in use mainly if not only in Moravian communities. We shall print them as we have room from time to time. First we select the following four:]

Excellent Stock Yeast (which will keep six months, if hung up in a bag in the air): In $\frac{1}{2}$ pint water, boil for 5 minutes a handful, (about a gill,) of good hops. Strain this still boiling hot over a pint of flour into which there has just been grated a raw potato the size of an egg. After standing until just lukewarm, stir into it a teacupful of good yeast or of dissolved leaven kept over from the last baking, or of "rivels" dissolved by soaking in cold water. Allow it to rise twice, stirring it down each time. This will require 2 to 3 hours. Now take flour, or better, equal parts of corn meal and flour, and with the hands rub in enough to work the whole mixture into quite dry fragments. (These are known in old fashioned cookery as "rivels.") Spread these bits, or rivels, thinly on cloths laid on trays or boards, and leave them to dry—occasionally turning them over with the hands. These dry much sooner than yeast cakes, and are less apt to sour. In baking bread, use a small teacupful of the rivels to each 4 quarts of flour.

To make Yeast at First (without stock of any kind to start with). Take 1 tablespoonful of molasses—thin, raw New Orleans molasses is best—1 tablespoonful of flour, and 1 tablespoonful of water. Mix and allow it to stand a day or more in a warm place, near but not on the stove, until it ferments. Then use this with the hop water flour, and potato dissolved, as above, for "Stock Yeast," and go on and make up the rivels with flour and meal as there described. You will thereafter have some yeast, or rivels, to start with. This recipe will be invaluable where no yeast of any kind can be had to begin with.

Good Home-made Bread—(Note all the particulars). Take 4 quarts of good flour. Scald

one teacupful of it with boiling water, and then mix with it a teacupful of the "rivels," or stock yeast, above described, and previously dissolved in cold water. When cool add a pint more of the flour and a little lukewarm water to make a batter or "sponge." When this is well leavened (in about 2 hours), add the rest of the flour, and 2 heaping tablespoonfuls of salt, and lukewarm water enough to form the dough. Knead thoroughly, 10 to 15 minutes, according to the strength applied, and allow it to stand about 2 hours, or until "light." Make into 4 loaves, merely rounding without kneading the dough. Put the loaves into tin pans, or straw baskets, and let them rise again about 1 hour to recover any shrinking in handling; then bake in a moderately heated oven so as not to scorch the top.—To test a hot oven, throw in a little flour, and if too hot it will scorch the flour to a crisp immediately. The teacupful of scalded flour, put at first with the rivels or yeast, makes the crust both soft and tenacious. . . . **To Keep Bread** well where there is no cellar, wrap it in a clean towel as soon as cooled, and put it in a tin box, or in a large covered tin pan; or, better still in the top of a refrigerator if you have one. . . . **For Bread in Winter**, proceed as above, but instead of rivels, use a teacupful of sponge from the last baking, kept covered during the interval; and in scalding the first teacupful of flour, use water in which a pinch of hops (with 3 fingers) has first been boiled. This will make the leaven very active.

Fine "Christmas Cakes."—[Good for "Thanksgiving," and all other times.] Will keep for months in winter, and for weeks in summer if put in a tightly covered tin pan as soon as cold: Take 1 quart molasses (good, thick, dark syrup, New Orleans molasses will not answer at all), 1 lb brown sugar, $\frac{1}{2}$ lb. lard, $\frac{1}{2}$ lb. butter, and dissolve all together on a stove, stirring well.—We always add exactly 2 grated nutmegs, 1 oz. ground cloves, 1 ounce ground cinnamon (thin bark), and $\frac{1}{2}$ ounce mace, stirring all well together. Some add a little ginger, allspice, or orange peel, or use less of the other spices named. Stir in well, flour until the dough is stiff. Now let it stand over night at least. Keeping 4 or 5 days if not convenient to bake all at once, will not injure, but rather improve it. Roll about $\frac{1}{4}$ inch thick, and cut out into any shapes desired, with a tumbler, cake jugger, or fancy tin moulds. Grease the baking tins well.

Snow in Fritters—Why?—Make a rather thick batter of flour, milk, and a little salt. Add for each pint of milk used, a teacupful of newly fallen snow, and at once drop the batter into fat previously made hot. Eat with sugar, flavored with lemon juice. (These directions have come so often, and from so many different sources, that there seems to be something in them, though one would suppose the pure snow could be no better than an equivalent of water. Probably the air carried in by the porous snow and distributed all through the cold batter by stirring, is retained sufficiently to produce lightness, as the hot fat instantly crusts over the outside. This looks plausible, and the recipe can be easily tried when the snow comes. Success will depend upon having the fat ready hot, and cooking before millions of little air bubbles can unite and escape.)

Thanksgiving Pudding.—Take $2\frac{1}{2}$ quarts of milk, 4 crackers, 4 eggs, $\frac{1}{2}$ lb. butter, 4 table-spoonfuls of sugar, $1\frac{1}{2}$ teacupfuls of raisins, and spice to the taste. Bake $1\frac{1}{2}$ hours with a moderate fire.—Mrs. E. H. Randall, Worcester, Mass.

Molasses Cake—Soft Ginger Cake.—**Molasses Cake:** $\frac{1}{2}$ cup cream, $\frac{1}{2}$ cup sour milk, 1 cup molasses, 1 teaspoon saleratus, 1 tablespoon ginger, or other flavoring, a little salt and flour to make the whole rather soft. It is light and good.—**Soft Ginger Cake:** 1 cup sweet milk, 1 cup molasses, 1 tablespoon butter or melted lard, 1 teaspoon salt, 1 teaspoon soda, 2 teaspoonfuls cream of tartar, flavor with ginger or any other spice.—Mrs. M. Ingalls, Muscatine, Iowa.

The Cheap Cake Frosting, to be made with corn starch thickened with pulverized sugar, which came recommended by a subscriber, and is published in some other journals, we have tried and it did not work well. It would not thicken up enough.

Drop Cakes.—1 cup sour cream, 1 cup butter, 2 cups sugar, 4 beaten eggs, $\frac{1}{2}$ teaspoonful soda, spice to taste, and flour enough to make it stiff enough to drop from the spoon.—Mrs. Samuel P. May.

Bread Griddle Cakes.—(Good way to use stale bread:). Crumb the bread and add sour milk enough to soften it, and let it stand over night. Then mash fine with a spoon, add a beaten egg and a teaspoonful of soda for each quart, with flour enough to make the batter considerable thicker than for common griddle cakes.—As fast as baked, put on a plate over a basin of hot water, covering them closely with a large bowl or other dish. This keeps them warm and moist.—Miranda.

BOYS & GIRLS' COLUMNS.

Premiums for Boys and Girls.

We remind our young readers that the extensive list of Premiums, fully described last month, and noticed elsewhere in this number, contains many things within the easy reach of boys and girls of all ages.

The Game of Checkers or Draughts.

POSITION NO. 9.—Black to play and win. Black.

White.

GAME NO. 3.—SUTER OPENING. (*)

(Position 8, page 366, October Agriculturist.)

Table showing Suter Opening moves for Black and White pieces, including file and rank coordinates.

(*) Suter, Scotch—signifying Shoemaker. Is so called from its being the favorite opening of an old Paisley player of that craft.

A Debt not Easily Paid.

If we possessed nothing more than what had been gained by our own efforts, we should be poor indeed. Taking no account of the good things with which God has filled the earth for the use of man—the sunshine, clouds, fruitful fields, teeming waters, healthful air, and all the innumerable expressions of His bounty in nature—every man, woman, and child, are debtors to the skill and industry of our fellows.

why almost half the world had some thing to do toward making that coat; and thus it is with nearly all the things we possess. Now no one man can ever really pay for all he has received.

Dog Stories.

A friend in Brooklyn relates that the family dog, Jip by name, being a great favorite, was generally invited to be present at lunch time, and was well remembered with occasional tit-bits.

Another occasion a spy entered the army unsuspected, as he spoke the French language perfectly; but Monstace no sooner scented him than he seized him by the leg, barking fiercely.

Impracticable Inventions.

It is related of Brunell, the great English engineer and inventor, that he was much annoyed by unpractical and ignorant men, who solicited his attention to projects often of the most absurd kind.

comfort and no little danger, besides being injured by the unhealthfulness of their hard occupation. The proposed plan was extremely simple: a broom was to be worked from above as well as below, and thus every nook was to be easily swept out.

Answers to Problems and Puzzles.

The following are answers to the Puzzles, etc., in the October number, page 367. Comical Picture.—Two donkeys, besides the seven donkey-like faces, may be found in the picture, by turning it upside down, and side-wise.

The following have sent in correct answers: F. W. Kleinschmidt, Robinswood, Fidelia R. Lord, Daniel Frohman, T. J. Bowerman, Charlie Frohman.

New Puzzles to be Answered.

No. 233. Illustrated Word.—Needed to read the puzzle. No. 234. Mathematical Problem.—What length of wire 1-10th of an inch in diameter, can be made from a solid foot of copper?

No. 235. Mathematical Problem.—Two men agreed to build the part of the gable end of a brick house between the rafters. The house was 18 feet wide, and from the ridge pole to the center of the end plate, was 20 feet.

No. 236. Illustrated Word.—Endeavor to do it plain. No. 237. Grammatical Puzzle.—To which nouns do the pronouns in the following sentence refer.

No. 238. Illustrated Rebus.—A very obvious truth.

[COPYRIGHT SECURED.]

A STRANGER IN THE FAMILY.—FROM A PAINTING BY WM. BEARD.—Engraved for the American Agriculturist.

This lively little guinea pig, in his wanderings, has made his way into a private family circle, where his reception is somewhat doubtful. The different kittens are prepared to entertain him, each according to its own disposition. One lifts a spiteful paw for a scratch at his nose; another sees a chance for a game of romps with the new comer, and is ready for the first spring; while another is rather shy of the stranger, and waits to see how he will conduct himself. One little fellow thinks more of his dinner than of any thing else, and makes good use of his opportunities while the rest are busy otherwise. The old cat seems willing that her young should make a new acquaintance, but she keeps a watchful eye on the stranger, ready to pounce upon him, should he prove dangerous or troublesome. It is a charming family scene, full of life, and shows the real genius of the artist, Mr. Wm. Beard, of New York, whose animal paintings tell their own story without any description.

"Lift a Little."

This is the singular title of a little book published by the Boston Tract Society, which we have just been reading, and which every boy and girl in the land would find interesting and profitable. It tells of a number of girls who formed a society called the "Burden Bearers." They were each pledged to try and do something to help those around them, to lighten their burdens, and their excellent motto was "Lift a little." Once a week they met and related their successes. One little girl had risen an hour earlier in the morning and taken care of a fretful baby, so that her mother could get a little rest after being disturbed by the crying child during the night; another had tried to keep from making unnecessary noises with hands and feet, which she had a habit of doing, and thus disturbing the household; a third had endeavored to keep a playmate from whispering in school time and annoying her teacher, and thus in many ways they "lifted a little" of the care and weariness from their friends and neighbors. Such an excellent sugges-

tion should have the widest possible circulation, and we therefore recommend the plan to the *half million* or more young readers of the *Agriculturist*. The boys as well as girls can easily find many ways to "lift a little." Many of those gray hairs and lengthening wrinkles which you may see changing the features of father and mother, are marks made by little cares and troubles, many of which might be prevented by thoughtful children. Few persons are called upon to perform a great deed, but it will be just as noble to abound in "little acts of kindness." Begin to-day to do your part and try to "lift a little."

Plenty of Oysters.

From the immense quantities of oysters consumed every year, one might fear that the supply of these delicious shell fish would finally become exhausted. There is little prospect of this, however, as will appear from the following fact. At an exhibition recently given at the London University College, a portion of oyster spawn, (eggs), was exhibited under a magnifying glass, which by calculation showed that a single oyster would produce 1,200,000 young. Should these all come to maturity they would fill 1,200 barrels. If nothing hindered this rapid propagation, the ocean must in a few years be too small to contain the oysters alone. But there are myriads of other hungry inhabitants of the sea which feed upon the oyster spawn; other larger creatures eat them, and so by multiplying and eating, and being eaten in turn, there is food enough for all, man included, and the proper balance of inhabitants in ocean and on land is kept up.

About Snakes.

A young correspondent sends to the *Agriculturist* Office the skin of a snake's egg (they have no shells), with an account of finding a whole nest full, 36 in all, while plowing by the road side. That snakes are produced from eggs may be new to some of our young readers. Our correspondent writes that when the eggs were broken,

there crawled from each a lively little snake, about ten inches long, and nearly as large around as a common lead pencil. Although entire strangers in the world, they seemed to know very well how to take care of themselves, as they would raise their heads and dart out their tongues in a very threatening manner when molested. They were of the common striped variety, and we hope they were left to go on their way and do good. "A snake do good!" many are ready to exclaim. "Ugh! I always kill them when I find them."—Well, that is because you have never become acquainted with them and learned their habits. They live mostly on worms and insects, occasionally taking in a frog that comes in their way, and never injure any person. Surely that ought at least to entitle them to live. The rattlesnake, adder, and other poisonous reptiles are, of course, outcasts, to be destroyed at sight; but the common small snakes found on most farms in this country earn their right to live there. Even the dreaded black snake would rather run than fight, and need not be feared. We would not advise to make pets of them, but would not have children suffer by being foolishly afraid of such harmless creatures.

The Floating Grindstone.

The following is said to have occurred among some simple fishermen on the English coast. A party were gathered together on a rocky promontory just toward dark, to see a wonder, a *floating grindstone*. As such things were quite valuable in those days, a boat was soon manned and away they went, the mover of the expedition being in the bow of the boat. As they approached the grindstone, this man planted his foot on the edge of the boat ready for a spring. Presently he cried out "All my own, and none for nobody," and sprang off upon the grindstone. Lo! to his great surprise he sank under water, and presently came popping up again, with his head within the charmed circle, to be greeted with roars of laughter. He had leaped into a sheet of sea foam, which had gathered within a large hoop.

(Business Notices \$2.00 per Agate Line of Space.)

WHEELER & WILSON ROTARY HOOK

SEWING MACHINES.

625 BROADWAY.

"WOMAN'S GREATEST BOON.—We would advise a man to forego a Thresher and thresh wheat with a flail, rather than to see the wife wear her health, vigor and life away in the everlasting 'stitch, stitch, stitch,' when a Sewing Machine can be obtained. The WHEELER & WILSON is an invaluable aid in every household. We have had several different kinds on trial, and after a six year's service, the WHEELER & WILSON has taken the precedence as the best, where all kinds of sewing are to be done in a family." [American Agriculturist, Jan. 1865.]

THE GREAT FAMILY SEWING MACHINE.

HIGHEST PREMIUM Elastic Stitch SEWING MACHINE. 495 Broadway, New York.

TAKE YOUR CHOICE!

We have already given nearly THREE HUNDRED SEWING MACHINES as premiums for getting subscribers to the NEW YORK OBSERVER. Sixteen new subscribers will secure a \$35 SEWING MACHINE, either Wheeler & Wilson, or Grover & Baker, if sent before January next. ON AND AFTER THE FIRST OF JANUARY, 1867, WE SHALL REQUIRE EIGHTEEN NEW SUBSCRIBERS. The machines give great satisfaction. Send for circulars and sample copies; they will be sent FREE. Terms, \$3.50 a year, in advance. SIDNEY E. MORSE, JR. & CO., 37 Park Row, New York.

GET THE BEST.—The extraordinary success of Prince & Co., Buffalo, N. Y., in the manufacture and sale of their superb Melodeons, Automatic Organs, etc., has indeed a host of imitators all over the land. A comparison of a Prince & Co.'s instrument alongside of any of these imitations, will convince the most skeptical of the vast superiority of the Buffalo article. In addition to this superiority, Prince & Co. have several valuable improvements which they own exclusively, and which cannot be obtained in any Organ or Melodeon, not of their manufacture. Of these, the "Basso Tenuto," or sub-bass,—"The Divided Swell,"—"the Graduated Swell,"—and the "Automatic Swell," stand prominent. This establishment of Prince & Co. has been in operation over 20 years, and has a world-wide reputation. Send for their new Catalogue, which is sent free of postage.

AGENTS WANTED FOR THE NEW UNION U. S. MAP.

A COPPER-PLATE County, Railroad and Battle-field Map, showing everything from the Atlantic to the Pacific; 36 by 56 inches; and for the Rebellion Battle Book.

A profusely illustrated, 700 page royal octavo, One Volume History of the Civil War, with 253 distinct battle descriptions. The best book for agents extant. And also for Hundreds of New Maps, Charts, Engravings, and Photographs in Great Variety. Address H. H. LLOYD & CO., Publishers, 21 John Street, New York.

Our Young Folks

This Monthly, begun in January 1856, has already won the reputation of being "the best Juvenile Magazine published in any land or language." Prominent Educators, distinguished Clergymen of all denominations, and the Press generally, have commended it in the highest terms. Its contents are always thoroughly interesting and healthy, at once variously attractive and useful.

Among its contributors are the most eminent American writers, and it is profusely illustrated from designs by the best American artists. Full-page illustrations are now given in every number. An ample department of Evening Entertainment and Correspondence makes OUR YOUNG FOLKS a HOUSEHOLD DELIGHT.

TERMS: \$2.00 a year in advance; Three Copies, \$5.00; Five Copies, \$8.00; Ten Copies, \$15.00; Twenty Copies, \$30.00, and a copy GRATIS to the person procuring the club.

Every Saturday

This popular Weekly reproduces promptly for American readers the best and most readable portions of European periodicals. These embrace Serial Tales, Short Stories, Essays—Biographical and Descriptive,—Poems, Sketches of Travel and Adventure, Literary Intelligence, and popular papers on Science. Translations from the admirable French periodicals are a prominent feature.

Among the authors represented in EVERY SATURDAY are many of the wisest and wittiest writers of Europe. EVERY SATURDAY contains weekly 40 double-column large octavo pages.

TERMS. Single Number, 10 cents; Yearly Subscription, \$5.00 in advance; \$4.00 a year to subscribers for any other periodical published by TICKNOR & FIELDS. MONTHLY PARTS, 50 cents a number. Yearly subscription, same as for Weekly Part.

TICKNOR & FIELDS, Publishers, Boston.

The Best Children's Paper in America.

Fighting against Wrong, and for the Good, the True, and the Beautiful.

A First-Class Monthly Paper, of 16 Pages, for BOYS and GIRLS. \$1.00 a Year in Advance.

Specimen Copy sent for Ten Cents. Address, ALFRED L. SEWELL, Publisher, Chicago, Ill.

Forney's Philadelphia Daily Press says of it: "THE LITTLE CORPORAL is destined to become the great children's paper of America."

THE LITTLE CORPORAL is the most interesting and instructive monthly in the Union. Louisville Democrat.

THE LITTLE CORPORAL is universally admitted to be the best juvenile paper now in existence.—Dubuque Daily Times. It is the cleverest thing of its kind yet realized in America.—(Boxbury Class.) Journal.

After a careful examination, we can cheerfully say of THE LITTLE CORPORAL, that it deserves all the praise that has been lavished upon it by the press everywhere.—Philadelphia Episcopal Recorder.

The Little Corporal for one year will do your children more good than a Quarter's Schooling.

The very Best Illustrated Magazine FOR BOYS AND GIRLS.

Containing Splendid Stories, Original and Spicy Dialogues, Excellent Music, Rebuses, &c., &c., and edited by the well-known and brilliant writer,

who writes a continued story expressly for THE STUDENT AND SCHOOLMATE, published the first of every month at \$1.50 a year. Single Number, 15 cents. Now is the time to subscribe, as a new volume, (the eighth), begins with the January Number for 1867, and one dollar and fifty cents sent to the Publisher without delay will secure the Nov. and Dec. Numbers of the present year gratis.

Mason & Hamlin CABINET ORGANS

ADAPTED TO SECULAR AND SACRED MUSIC;
 FOR DRAWING-ROOMS, CHURCHES, SUN-
 DAY AND DAY-SCHOOLS, LODGES, &c.,

Writing to a considerable extent the capacity of the Piano-Forte with that of the Pipe-Organ, and costing much less than either.

They occupy little space; are elegant as furniture; not liable to get out of order, and are securely boxed, so that they can be sent anywhere by ordinary freight routes, all ready for use.

FORTY STYLES, PLAIN OR ELEGANT CASES; ONE TO TWELVE STOPS; PRICES, \$110, \$130, \$140, \$150, \$160, \$170, \$200, \$225, \$250, \$300, \$435, \$500, \$550, \$600, AND UPWARDS.

THEIR SUCCESS HAS BEEN ENTIRELY BEYOND PRECEDENT.

and proves how greatly such an instrument was needed. Again and again the manufacturers have been compelled to double their manufacturing facilities, until they have been increased six-fold. From the most eminent of the musical profession, the most distinguished pianists, organists, composers, and musical directors, the MASON & HAMLIN CABINET ORGANS have received an amount and degree of commendation never before bestowed upon any similar musical instrument. More than two hundred and fifty of the most eminent musicians in the country have given written testimonials to the value of the improvements contained in them, and that they excel all other instruments of this class.

FIFTY-TWO GOLD OR SILVER MEDALS, or other highest Premiums, have been awarded to MASON & HAMLIN for the important improvements effected by them, and for the SUPERIORITY OF THEIR INSTRUMENTS TO ALL OTHERS.

Constantly exhibiting their instruments in competition with others, they have been awarded the highest premium in every instance, but three or four.

They are adapted to a wider range of music than the piano, being better fitted for all sacred music and for much secular music, while their quickness of action is such that the most lively, rapid music, can be played on them. Then their cost is greatly less, as well as their liability to get out of order.

The MASON & HAMLIN CABINET ORGANS must not be confounded with other reed instruments, from which they vary essentially, their superiority being largely derived from PATENTED IMPROVEMENTS, which can not be employed by other makers.

Mason & Hamlin Portable Organs.

In order to meet the demand for low-priced instruments, MASON & HAMLIN have commenced the manufacture of a new series of Organs, the design of which is to furnish really good instruments in the most economical form, and at the lowest prices possible. They are smaller in size, and more compact than the Cabinet Organs, and hence will be known as the MASON & HAMLIN PORTABLE ORGANS. The cases, which are all of walnut, are very plainly, though neatly and tastefully finished; and in various details, such as ivory keys, pedal coverings, music desks, hinges, &c., &c., not affecting the practical usefulness or durability of the instruments, less expensive materials and workmanship are employed than in the Cabinet Organs. This economy of manufacture is not, however, allowed to extend to the working parts of the instruments, which are all made with that scrupulous care and thoroughness for which the Mason & Hamlin Cabinet Organs are celebrated.

Each one is furnished with the Automatic Bellows Swell, two Blow Pedals, Combination Valves, and such other of the patented improvements of Mason & Hamlin as are applicable to them.

Prices of M. & H. Portable Organs: FOUR OCTAVE, SINGLE REED, \$75; DOUBLE REED, \$100; FIVE OCTAVE, SINGLE REED, \$90; DOUBLE REED, \$125.

Circulars, with full particulars respecting all the styles of Mason & Hamlin CABINET ORGANS, also PORTABLE ORGANS, sent free to any address.

IONA AND ISRAELLA GRAPE VINES.

The Two Best in Cultivation for every purpose, both very Early, and Israella the Earliest of All.

My Stock of the IONA and ISRAELLA Vines, both grown in open air, and under Glass, is very extensive, comprising plants specially adapted for the Garden, and also for the Vineyard.

The IONA is the only native grape of good size for the table that is equal to the best foreign kinds.

In hardness, constancy of production, and perfect ripening of fruit it is unequalled by ANY of our most hardy natives.

It is the only unexceptionable grape for the family. DEL-AWARE IS EXCELLENT. IONA is equal in all respects and MUCH BETTER in several very important points.

The Iona is the best Grape for Wine.

The IONA is the only Grape which pays the cost of best vines by its cutting the first year.

It is the ONLY NATIVE GRAPE whose fruit is eagerly sought for at ONE DOLLAR per pound.

The following letters are instructive:

Dr. C. W. GRANT:

DEAR SIR: Although you have always in your publications urged those planting vines to plant only the best and of the best varieties, all in the best manner, I cannot forbear expressing gratitude to you for your letters of direction contained in your Manual.

Where I have followed these my success has been complete. My Delawares yielded well, and I sold the crop for 50 cents per pound. The Iona vines, two years planted, produced a bountiful crop, and the fruit sold readily at \$1 per pound. I could have sold any quantity of such grapes.

Your extra vines truly gave an extra performance. The cuttings taken from them paid the cost of vines the first season. The second paid a handsome income; and this season they are of much greater value by the increased quantity.

Hartford, Conn., Sept. 26, 1866. C. M. BEACH.

NYACK, N. Y. Sept. 28, 1866.

Dr. GRANT:

DEAR SIR: I take pleasure in informing you of the condition of my vines and my success the present season. My old vineyard is of Isabella and not satisfactorily profitable. My new vineyard was planted mostly with Concord, Iona, and Delaware in May, 1861. All have done well, but the result

with the Iona has been most gratifying.

The Ionas have grown as rapidly as the Concord, and produced an abundant crop of the best fruit I have ever tasted. Many of the bunches were each as large as your engraving, which I had before considered a misrepresentation. One bunch I laid down over the engraving covered every part of it. My Concord averaged between five and six pounds per vine, and the fruit brought 18 cents; my Delaware, five pounds per vine at 25 cents; your justly favorite Iona from five to six pounds per vine, which I sold at \$1 per pound.

Yours truly, J. V. ONDERDONK.

The Terms for Club-Agents and Dealers are extremely favorable, and the quality of the plants and other inducements are worthy of particular attention this season.

To any one willing to act as Agent in forming Clubs, or to such as are expecting to plant largely, I will send on receipt of \$10, *sample Vines of Iona*, to that amount, at hundred rates, of first, second, or third class, as may be desired. Vines will be sent securely by mail, post-paid. All can thus learn if *Iona* is best, where the Iona and Israella originated, is not the best and cheapest place to obtain good vines. Large discount from hundred rates on large orders.

Manual of the Vine (comprising Illustrated and Descriptive Catalogues), a thorough and comprehensive treatise, in which every operation is clearly represented by engravings, 150 in number—sent for fifty cents.

Twenty-four page Pamphlet, containing a full account of the Iona and Israella, with their distinctive characteristics "The Present and Future of American Grape-Culture," and other important matters, with engraving of Iona and Israella Vines in bearing, sent for two-cent stamp.

C. W. GRANT, Iona,

(near Peekskill), Westchester Co., N. Y.

Iona Grape Wood.

A few thousand choice buds of Iona, also very choice lots of Delaware and Concord, by the large quantity, for sale by the subscriber. Address

BLOOMINGTON NURSERY.

15th year; 8 large Green-houses; 275 acres Fruit, Ornamental and Nursery Stock, a very complete assortment, including

- 500,000 Apple, of which 100,000 1 year, 1000, \$50.
- 150,000 Pear, of which 50,000 1 year, Stand, 1000, \$120.
- 500,000 Grape, largely Concord layers, Catawba, Clinton, Delaware, Hartford, Ives, Iona, Rogers, &c.
- 500,000 Apple Stocks, 1 and 2 year, \$10 and \$15.
- 500,000 Apple Root Grafts in winter, 10,000, \$100.
- 150,000 Stocks, Quince, Pear, Plum, Mahaleb, &c.
- 10,000 Rhubarb.
- 100,000 Strawberry, 40 sorts.

- 1,000,000 Osage Orange, 1000 1st class, \$3; 200,000, \$150.
- 500,000 Evergreens, mostly medium and small.
- 150,000 Ornamental Trees, large and small.
- 2,000 Althea, superb double, named, 100, 2 feet, \$12.
- 10,000 Deutzia, Eouomyous, Honeysuckle, Lilac, Snowball, Spiraea, Syringea, Tamarac, Wigelia, all fine, medium size, 100, \$6 to \$12.

- 20,000 Roses, all classes, old and new sorts.
- 20,000 Hardy Bulbs for fall planting, Tulips, Hyacinths, Green-house Plants, &c.

Catalogues.—Wholesale and Retail sent for 1 red stamp each. F. K. McGENIX,

BLOOMINGTON NURSERY, McLean Co., Ill.

IONA GRAPE VINES.

The great demand for these vines has induced their propagation from green and feeble wood, which is likely to injure the reputation of this noble grape.

The subscriber was so fortunate last autumn as to secure a selection of wood from the Vineyard of Charles M. Beach, Esq., which is probably the best in New England, of same extent. I now offer a few thousand vines from single eyes of bearing wood at prices low as other good propagators. Also, Israella, Delaware, Diana and other leading varieties, from wood obtained from same source. A few nice two-year vines of above kinds, and a small number of bearing vines with two strong canes, or two arms and spurs. I can offer a limited quantity of choice wood from the same vineyard the present season.

Address CHARLES S. MASON, West Hartford, Conn.

TO THE FRIENDS OF THE POOR.

The Five Points House of Industry, need clothing and clothing material of all descriptions; articles of food, vegetables, &c. Shoes, though much worn, are very servicable, as they can be repaired in the House. Bedding for the sick and out-door poor, is often a great want. MORE THAN FOUR HUNDRED THOUSAND MEALS WERE GIVEN TO THE POOR LAST YEAR, AT THIS INSTITUTION, and some hundred different poor children were taught and clothed.

Packages may be directed to

very useful to the manufacturers of PAPER from this material.

THE CHAMPION PRESS, for pressing and compressing ANY and EVERY material, FARMERS, PLANTERS, MANUFACTURERS, WAREHOUSEMEN and all persons desiring to economize space want

"THE CHAMPION PRESS," Cotton and Wool can be pressed so compactly that either will sink in water.

LIKE A STONE. Worked by HAND, HORSE, WATER OR STEAM POWER. With 3-HORSE POWER, the PRESSURE is 25 TONS to the SQUARE INCH.

The pressure required is easily regulated. It acts promptly is simple in its construction, does not get out of order, and requires less power to accomplish the same results, than any other Press in the World.

From these facts it is named and claimed as the CHAMPION PRESS OF THE WORLD, from the advantages it possesses over all other presses. READ THE RECOMMENDATIONS which are from the HIGHEST AUTHORITY, given for the value of the invention, and for the advancement of SCIENCE IN MACHINERY.

OFFICE OF THE NOVELTY IRON WORKS, } NEW YORK, Sept. 22, 1866.

A. BALDWIN, Esq.—Dear Sir: Having examined the model of your COTTON PRESS, I am favorably impressed with the design as combining great power with the most simple combination of parts, so that there is the least chance for delay caused by break-downs. Also the mode of applying the power to produce the graduated effect by means of the worm wheel and screw, is a combination of great simplicity and fine mechanical arrangement to produce the result, with the least expenditure of power. Hoping you will have success with it, I remain, yours truly, ISAAC V. HOLMES, Constructing Engineer and Superintendent.

PROGRESS MACHINE WORKS, N. Y., Sept. 22, 1866.

A. BALDWIN, Esq.—Dear Sir: We agree entirely with the opinion expressed by the gentleman of the "Novelty Iron Works" as regards the simplicity, strength and power of your Cotton Press. Respectfully yours, A. & F. BROWN & Co., Proprietors.

WEST POINT FOUNDRY, COLD SPRING, } Putnam County, N. Y., Sept. 19, 1866.

We have seen Mr. Baldwin's New Patent Press. We consider it one of the best arranged machines for the purpose, and have little doubt that it will take a leading position in machinery for pressing Cotton and other materials. Respectfully yours, J. RUMPF, Constructing Engineer, PETER B. LAWSON, Manager.

EAGLE STEAM ENGINE WORKS, N. Y., Sept. 27, 1866.

Mr. BALDWIN: I have examined your Press, and believe it to be the best I have ever seen, and that it will be generally used by the public when it is seen. It is what has long been wanted, a simple, powerful, and durable Press. WILLIAM MCKENZIE, Proprietor.

DRY DOCK IRON WORKS, N. Y., Sept. 27, 1866.

A. BALDWIN, Esq.—Dear Sir: I have examined your Champion Press, and have no hesitation in saying that it is of great power, combined with a simplicity of construction unequalled by any machine of its class. The power is without limitation, being capable of exerting by the arrangement of its parts to any extent that may be required. Respectfully, MRS COYELL, Proprietor.

GLOBE IRON WORKS, N. Y., Sept. 27, 1866.

A. BALDWIN, Esq.—Dear Sir: We have seen your Press in operation, and find it to be a machine of great strength and power, as well as simple in its combinations. We consider it a valuable machine, and will not fail to give satisfaction to all who may use it. Very respectfully, M. M. WHITE & CO., Proprietors.

PHENIX IRON WORKS, N. Y., Sept. 23, 1866.

A. BALDWIN, Esq.—Dear Sir: We have examined your Press in operation, and we must say that we consider it the best of the kind that we have seen, and have no doubt that it will become a useful and profitable machine for any one requiring its use, and also to your benefit. Respectfully, MURPHY, McCURDY & WARREN, Constructing Engineers and Manufacturers of Land and Marine Engines and Boilers.

The scientific and the public are respectfully invited to call AND EXAMINE.

H. T. HELMBOLD, President Champion Press Company, No. 591 Broadway, New York. To whom all orders should be addressed.

AND THE

UNIVERSAL CLOTHES WRINGER.

THE UNIVERSAL CLOTHES WRINGER, with Cog-wheels, has taken the First Premium in the State Fair of every Northern State; also the First Premium at the last two fairs of the American Institute, AND HAS JUST BEEN AWARDED THE FIRST PREMIUM BY THE UNANIMOUS VOTE OF THE COMMITTEE OF THE GREAT NEW-ENGLAND FAIR OF 1866, AFTER THE MOST SCRUTINIZING TRIAL OF THE VARIOUS MACHINES OF NUMEROUS COMPETITORS.

The Wringer, without injury to the most delicate garments, wrings clothes almost dry and never gets tired.

ORANGE JUDD says: "It is a clothes-saver, a time-saver and a strength-saver. We think the machine more than pays for itself every year in the saving of garments. We think the Wringer should be fitted with cogs."

OLON ROBINSON says: "My family would as soon give up the cooking-stove as this Clothes Wringer. It cannot be too highly recommended."

The Rev. Dr. BELLOW says: "I heartily commend it to economists of time, money and contentment."

From the Rev. THEO. L. CUYLER.

Life is too short and human strength is too precious for our woman kind to be kept at the old process of clothes-washing and wringing. In the laundry of my house there is perpetual thanksgiving on Mondays for the invention of your excellent Wringer. I wish human hearts could be cleansed as easily.

Exclusive right of sale given to the first responsible applicant from each town. Illustrated Circulars, giving Wholesale and Retail terms, sent free.

On receipt of the price from places where no one is selling, we will send one Washer and one Wringer, either or both, free of freight charges. Family size Washer, \$14; No. 1 1/2 Wringer, \$10; No. 2 Wringer, \$8.50.

R. C. BROWNING, General Agent, No. 33 Cortlandt-street, New York, (opposite Merchants' Hotel.)

\$300,000,000

is our Annual loss by Insect Pests!

We cannot ignore these minute little beings, but their ravages can be decreased. Subscribe to the

PRACTICAL ENTOMOLOGIST,

a monthly journal—the only one of its kind published—and it will tell you all about your Insect Enemies, and how to deal with them. It is recommended by all the best Agricultural and Horticultural journals, and by Dr. Warden, Sanford Howard, Solon Robinson, F. K. Plafly, C. Y. Riley, Charles Downing, J. J. Thomas, Dr. I. P. Trimble, J. Knox, Prof. Glover, and many other prominent Agriculturists and Horticulturists.

Price only Fifty cents a year, payable in advance. Send a 2-cent stamp for specimen copy and prospectus.

Address PRACTICAL ENTOMOLOGIST, Philadelphia, Pa. 3

Borage for Bees.

Those wishing to try Borage as a honey producing plant, can procure 1 paper of seed for 25 cents, or 1 lb. for \$2, sent post-paid. One lb. will plant an acre. Plant like Corn, giving clean culture. Address S. & W. S. ALLEN, BIDWELL BROTHERS, St. Paul, Minn.

DEWEY'S COLORED FRUIT PLATES.

1,000 Specimens.

Premium Fowls for Sale.

75 varieties of pure breeds, and Fancy Fowls and Pigeons that have taken the first premiums at the New England, Vermont State, and New York State Fairs. Send stamp for circular of prices, or 25 cents for Pictorial Descriptive Catalogue. Elgin Spring House, Vergennes, Vermont.

POULTRY FOR SALE.—Pure White-Faced Black Spanish, and English Grey Dorkings. All of best quality. Address J. L. BOARDMAN, Flushing, N. Y.

DOTY'S WASHING MACHINE has again been awarded the FIRST PREMIUM AT THE GREAT NEW-ENGLAND FAIR OF 1866.

Doty's Washing Machine took the FIRST PREMIUM at the last Fair of the American Institute—also at the GREAT NEW-ENGLAND FAIR OF 1866—and at the recent State Fairs of New Hampshire, Michigan, Wisconsin, Iowa, &c. These are the cheapest and best machines for washing and wringing clothes. The Washer, using boiling hot suds, saves three-fourths the labor and time; takes out all dirty, no sore hands; no fetid air; no injury to the clothes.

OLON ROBINSON says: "I assure you 'our machine,' after a year's use, is thought more of to-day than ever, and would not be parted with under any consideration."

Mr. ORANGE JUDD, Editor of the American Agriculturist, says: "Our 'better-half' says this is taken to most kindly by the 'help,' and that she cannot persuade them to use any other while this is at hand."

Prof. YOUNG, M. D., says: "Our family is not small, but a smart girl, 11 years old, did the washing last week in about four hours, and that, too, more as a frolic than a task."

BISHOP SCOTT, of the M. E. Church, Odessa, Del., says: "I took hold which, of course, I should not have done if we had no machine, and in 2 1/2 hours we put through eleven dozen pieces, many of which were sheets, and they were well done, too. We like our machine much; could not be persuaded to do without it."

WHAT THE PRESS SAYS OF IT.

It is worth \$1 per week in any family.—[N. Y. Tribune. Growing in favor the more it is used.—[Fairfax Farmer, Chicago.

It really merits all the good that can be said of it.—[Rural New Yorker.

Easily worked, and does its work well.—[Ohio Farmer. After a fair trial we give it the preference over all others.—[Iowa Homestead.

Ha, Ha, Ha! Ha, Ha, Ha! Here are Your Games.

THE LONG EVENINGS ARE COMING.—THE HOLIDAYS ARE COMING.—PARTIES ARE COMING—AND YOU WILL WANT SOME OF THESE.

K. K. K. Komikal Konversation Kards.—A Kapital combination of kurlously kontrived konversational komikalities, komposed, kompounded and kompressed by KEZIAH KENT, K. K., a kute and komikal karaktar of Kambodge Kollege. In a handsome box, 50 cents.

GRAPE VINES AT TEN CENTS EACH.

PARSONS & CO.,

offer Concord and Delaware at \$100 per 1000, and other

GRAPE VINES

of all the best varieties, at reduced prices.

The accumulated experience of several years in their improved mode of culture, has resulted in the production, this season, of a class of plants superior to any they have before offered. The firm and well matured wood, and the large and thoroughly ripened roots of the plants grown this year, cannot fail to ensure success to those who plant them.

Being grown without bottom heat, from well-ripened wood, and in good, deep soil, not injured by extra manuring, they are the less liable to many diseases which freely attack vines grown by the forcing process.

In classifying their vines, they make no extras. Their No. 1 plants are the largest and best of their stock, and the average quality is not allowed to be diminished by selecting the largest for retailing as extras. Among the varieties are:

- Concord**, 1 year, \$12.00 per 100; \$100 per 1000.
- Delaware**, 1 year, No. 3, \$12 per 100; \$100 per 1000.
- do. 1 year, No. 2, \$30 per 100; \$150 per 1000.
- do. 1 year, No. 1, \$25 per 100; \$200 per 1000.
- Delaware**, 2 years old, } \$35 per 100; \$275 per 1000.
- transplanted, very strong, }
- Iona, No. 1**, \$15 per 100; \$600 per 1000.
- do. 2, \$50 per 100; \$400 per 1000.
- Ives Seedling**, 1 year, \$25 per 100; \$200 per 1000.

- Hartford Prolific**, \$30 per 100; \$200 per 1000.
- Diana**, \$25 per 100; \$200 per 1000.
- Isabella**, 1 year, No. 1, \$100 per 100; \$800 per 1000.
- do. 2, \$75 per 100; \$600 per 1000.
- Norton's Virginia**, \$40 per 100; \$300 per 1000.
- Adirondac**, \$40 per 100; \$300 per 1000.
- Crevelling**, \$30 per 100; \$200 per 1000.
- Rogers Hybrid**, \$30 per 100.

Where 10,000 are taken, a discount from these prices will be made.

The **IVES SEEDLING** can be safely recommended as a reliable and certain variety, grows rapidly, and after some years' testing, has been found free from mildew and rot.

For prices of other kinds, they refer to the Descriptive Catalogue of Vines.

They also offer **REMOYANT** and other **ROSES** on their own roots, and unusually thrifty, at

\$20.00 per 100; \$150 per 1000.

Also a large assortment of the best

TREES AND SHRUBS.

Address

WOOD & MANN STEAM ENGINE CO'S CELEBRATED

Portable Steam Engines,

FROM 1 TO 35 HORSE POWER.

ALSO PORTABLE SAW MILLS.

We have the oldest, largest and most complete works in the United States, devoted exclusively to the manufacture of Portable Engines and Saw Mills, which, for simplicity, compactness, power and economy of fuel, are conceded by experts, to be superior to any ever offered to the public.

The great amount of boiler room, fire surface and cylinder area, which we give to the rated horse power, make our Engines the most powerful and cheapest in use; and they are adapted to every purpose where power is required.

All sizes constantly on hand, or furnished on short notice.

Descriptive circulars with price list, sent on application.

WOOD & MANN STEAM ENGINE CO., Utica, N. Y.

Branch Office, 96 Maiden Lane, New York City.

FLAX.

MALLORY & SANFORD'S IMPROVED FLAX AND HEMP BRAKES,

As now made, are the strongest and best ever used. They occupy about 5 feet square, weigh about 1,000 lbs., require one man and a boy, and one to two horse power to work them; breaks from 2,000 to 3,000 lbs. Flax straw in 10 hours, taking out 65 to 75 per cent. of the woody matter. This machine will save 120 lbs. to the ton more than any other machine in the world. It will break tangled straw as well as straight. We have also an entirely new TOW SHAKER AND PICKER, works perfectly and does its work quicker and better than any other machine, and prepares the stock for rope. Also a NEW TOW COMBER, which cleans and straightens the tow, free from shive, rapidly making it fine and straight. Send for circular or see machines in operation at 88 William-st., New York. Address: JOHN W. QUINCY, Treasurer, No. 98 William-st., New York.

INGERSOLL'S IMPROVED HORSE AND HAND POWER

HAY AND COTTON PRESSES.

These machines have been tested in the most thorough manner throughout this and foreign countries to the number of over 3000.

THE HORSE POWER is worked by either wheel or capstan, and in many respects possesses unequalled advantages. We invite those wanting such machines to write for a catalogue containing full information with cuts, prices, &c., or call and examine personally. Orders promptly attended to, by addressing: INGERSOLL & DOUGHERTY, Greenpoint, Kings Co., L.I.

A. N. WOOD & CO.

Premium Farm Grist Mill—grinds rapidly, and is simple, durable, and cheap. Send for Descriptive Circular. Address WM. L. BOYER & BRO., Philadelphia, Pa.

GOOD HOMES IN NORTH MISSOURI.
FARMERS, MECHANICS and MANUFACTURERS of the North and East should come to Missouri, because you can now do better for yourselves, families, society generally, and for posterity, than you can by staying where you are. By coming you can get better farms and homes, do more business and make more money, easier and quicker than to remain where competition is strong and sharp, and profits small. As others have done you can do, for the chances now are as good as ever, and in many respects better.

Missouri is rich in Agricultural resources, provisions are abundant, Coal, Iron, Lead, Copper, Wool, Cotton, Hemp, Flax, and other raw materials to be wrought are at hand in a healthy climate giving vigor to labor, and in a central location with cheap and direct access to all the markets. These facts make Missouri a producing and manufacturing region; and when the surplus artisan population of old and less favored districts are wise enough to come here in sufficient numbers, then there will be an adequate supply of labor for the wants and facilities of this State, and make it a consuming country also. Thus the great department of human industry can and surely will combine to give the full prosperity this noble State generously invites and so richly deserves.

The HANNIBAL AND ST. JOSEPH RAILROAD offers for sale at low prices on two or ten years credit nearly 500,000 acres of best prairie, timber and coal lands in Northern Missouri, which is the best Agricultural part of the State. Documents giving full particulars are sent in packages gratis to all who wish to distribute them, to induce others to join in forming a neighborhood or colony.

A Sectional Map showing exact location of land is sold at 50 cents. Address GEO. S. HARRIS, Land Commissioner, Hannibal, Missouri.

LOOK HERE, READER.—Do you want to change your place of residence? do you want to buy a New Jersey Farm already improved? if so, I will sell the following Farms:

- 1 Farm 35 acres, \$1,000.
- 1 Farm 120 acres, \$65 per acre.
- 1 Farm 55 acres, \$50 per acre.
- 1 Farm 75 acres, \$3,500.
- 1 Farm 70 acres, \$100 per acre.
- 1 Farm 50 acres, at \$20 per acre.
- 1 Farm 50 acres, at \$1,000.
- 19 Acres improved, \$40 per acre.
- 12 Acres improved, \$35 per acre.
- 1 Handsome residence and 13 acres, at \$6,000.
- 100 Acres good land, price \$20 per acre.

Various lots of land, from 5 acres up to 1,000 acres. Those wanting Houses and Lots, or any description of land, will address with full particulars, stating size wanted, or information of any kind will be given.
J. H. COFFIN & CO., Franklinville, N. J.

RICHARDSON & CO., Publishers,
540 BROADWAY, NEW YORK.

SCHOOL TEACHERS WANTED.—The subscriber wishes to employ one male teacher in each town in the United States, to canvass for the "Illustrated History of the Bible," by John Kitto, B. D., F. S. A., edited by Alvan Bond, D. D., of Norwich, Conn.

This is the best selling book I have ever published. Agents make from \$100 to \$200 per month, and say "they never knew a book to sell so well." Apply immediately in person or by letter to the publisher.

HENRY BILL, Norwich, Conn.

Short-Hand Without a Master,

by which the nature of taking down Lectures, Sermons, Trials, Speeches, &c., may be acquired in a few hours. FIFTY-SECOND EDITION, with a Supplement. Price 25 cents. Sent post-paid, on receipt of price, by O. A. ROORBACH, 123 Nassau-street, New York.

NEW BOOKS.

Saunders' Domestic Poultry.

By S. M. SAUNDERS.

New Edition Revised and Enlarged.

This Book contains Articles on the Preferable Breeds of Farm-Yard Poultry, Their History and Leading Characteristics, with Complete Instructions for Breeding and Fattening, and Preparing for Exhibition at Poultry Shows, etc., etc., derived from the Author's Experience and Observation.

The work is compact, full of valuable hints and information, and beautifully illustrated.

An appendix contains an account of Poultry breeding on a large scale, as practiced in the neighborhood of Paris, and is a very important addition to the work.

Price, paper 40 cts., cloth 75 cts.

ORANGE JUDD & CO., 41 Park Row.

Money in the Swamps.

PEAT! PEAT! PEAT!

FUEL - MANURE.

WHERE TO FIND IT.

HOW TO MAKE AND USE IT.

ITS VALUE.

A NEW WORK ON PEAT, THOROUGH AND PRACTICAL;

By PROF. SAMUEL W. JOHNSON, of Yale College.

It gives a full history of PEAT, MUCK, etc., telling what they are, where found, and how to estimate their value

It describes the various methods of using Peat for manure, as an absorbent, as an ameliorator of the soil, etc., and it is especially explicit in regard to the

USE OF PEAT AS FUEL,

describing minutely the various processes employed in preparing it to burn, from the simplest to the most complicated; such as are in use in this country, and Europe. It is illustrated with many Engravings of machines, etc.

The work is invaluable to those having Peat or Muck swamps, or wishing to invest in Peat Companies.

ORANGE JUDD & CO.,

41 PARK ROW, NEW-YORK

Quinby's Bee Keeping.

By M. QUINBY, Practical Bee-keeper. Fully Illustrated. Entirely new. The result of 35 years' of successful experience—with directions for all contingencies that can ordinarily occur; treating of Breeding, Movable-Comb and other Hives, Pasturage, Robbing, Feeding, Swarming, Queens, Diseases, Anger, Enemies, Wax, Transferring, Sagacity, Wintering, Care of Honey, Italian Bees, Purchasing, etc. Bee-keepers will find this new work of Mr. Quinby's fully up to the times in all practical matter.

Sent Post-paid. Price \$1.50.

Gratifying Opinions of the Press.

From the Christian Intelligencer.

"Quinby's Work is the very best. It has long been regarded as of the highest authority in the matters concerning which it treats."

From Moore's Rural New Yorker.

"This is a newly written and illustrated edition of Mr. Q.'s former work. That has proved of value to thousands of Bee-keepers, and this, with its ripe experience and added knowledge, can not fail of giving better satisfaction. Thirty-five years experience!—What beginner in bee-keeping will not bring this to his aid? We notice the author has no Patent Hive to introduce, and expresses his opinions freely on the merits and demerits of the various hives seeking popular favor."

From the Vermont Farmer.

"The book is written in familiar style, with the endeavor to be practical rather than scientific, thereby making it a guide to the tyro in Apian knowledge, as well as a standard work of reference for the more experienced bee-keepers."

From the N. Y. Christian Advocate.

"All bee-keepers should have this manual, and others may read it as a book of wonders."

SENT POST-PAID. PRICE \$1.50.

ORANGE JUDD & CO., 41 Park Row.

New Book of Flowers.

By JOSEPH BRECK, Practical Horticulturist.

Beautifully Illustrated.

This work, while preserving scientific accuracy, is written in a familiar style, and with the enthusiasm of a life-long lover of flowers. Its teachings are eminently practical, and cover all branches of out of door gardening. Bulbs, Annuals, Perennials, Herbaceous Plants and Shrubs, have their methods of cultivation and propagation fully given, with popular descriptions of the most desirable garden varieties. Just the book for the novice or amateur in gardening.

SENT POST-PAID. PRICE, \$1.75.

ORANGE JUDD & CO., 41 Park Row.

HURRAH! BOYS AND GIRLS, HURRAH!

Demarest's Young America!
Ever success to thee!
Mentor and guide to the steps of youth.
Oh! thou wilt lead to the fount of truth—
Hence the star of the true.
Eagerly, long, impatiently
Sought we thy treasures bright;
Teeming with beauty they come at last,
Shining like gems of light.

Young America! glorious name;
O'er thee sparkles a crown of fame;
Unsmiled and pure its jewels glow.
None but the good its worth can know;
Go, little volume, and tell them so.

DEMAREST'S YOUNG AMERICA!
Each boy and girl will read and prize it
Monitor to every teacher,
O'raile to every parent.
Rich its pages with instruction,
Every branch of useful knowledge,
See how brilliant are its features;
True philosophy it teaches,
Such a monthly never was equaled.

YOUNG AMERICA! children's museum,
Onward in their mental culture,
Up the hill of science leading;
Novel, pure, and full of interest,
Grand the truths each page discloses.

IS NOW READY.

A new, very entertaining, instructive, artistic and splendidly illustrated monthly Magazine for boys and girls, to include pleasing illustrations of Philosophy, the Arts and Sciences, moral and interesting Stories, Music, Poems, and other entertaining literature, presenting a museum of the good, the useful, and the beautiful, for very Young America,

AMERICA! with beauty glowing,
Many pictures drawn exquisite,
Each a gem of truth portraying;
Rich in poems, stories, music,
Introducing all that's pleasing,
Come and prove this comely volume,
All its merits half unfolded.

America! thou sunny clime!

My inmost soul with rapture thrills;
E'en now I hear thy welcome lay
Resounding sweetly far away
In triumph o'er thy templed hills.
Contentment, union, liberty
Are twined, forever twined with thee.

without frivolities or exaggerations, and a well-spring of instruction and pleasure for the household.

Single copies, 15 cents; yearly \$1.50; additional copies, \$1.00, or Five copies for \$5.

A large and beautiful colored engraving presented FREE with the first number, also to each single subscriber at \$1.50, a good microscope or a pack of Magic Photographs, as a premium.

The rise in gold has been very marked since our last, influencing all commercial values, favorably for sellers. Breadstuffs have been in active demand, partly on speculative account, and prices have rapidly improved. Receipts have been moderate. Crop accounts from the interior have been discouraging. Toward the close, holders of flour, wheat, and barley seemed more eager to realize, and the market became depressed. Corn, rye and oats, however, continued in lively request at advancing rates. There has been comparatively little doing for export, as shippers have not been prepared to pay ask-

ing figures.... Cotton has been quite briskly sought after, by spinners and speculators, and prices have advanced materially, closing buoyantly, under favorable telegraphic news from Liverpool. According to the official annual exhibit of the cotton trade of the United States, for the year ending Sept. 1, 1866, the total receipts at all the shipping ports of the United States, were 2,151,013 bales, against 3,656,086 bales in 1860-'61; total exports, 1,554,664 bales, against 3,127,565 bales in 1860-'61; total taken for home consumption, etc., 667,292 bales, against 843,740 bales in 1860-'61. The total receipts at all the shipping ports from May 1, 1865, to Sept. 1, 1866, were 2,571,043 bales.... Provisions have been less freely dealt in, especially by speculative buyers, and the tendency of prices has been downward.... Wool has been in very moderate demand at declining rates, influenced by the liberal receipts and accumulating supplies of domestic.... Tobacco has been in fair request at steady figures.... Hay, hops and clover seed have been decidedly more active and buoyant in price.... One year old broom corn has been in moderate supply and limited demand at 6c. @ 10c. per lb. for fair to good. The new crop has not yet begun to arrive freely.

New York Live Stock Markets.

The supply during the past five weeks has been very good for the season, as is shown in the following table: WEEK ENDING, Bees, Cows, Calves, Sheep, Swine. Oct. 16, 6824 98 1,234 25,176 19,958 Oct. 9, 6315 99 1,301 27,211 15,127 Oct. 2, 6448 72 1,033 25,411 14,496 Sept. 25, 8,034 112 1,629 23,710 10,719 Sept. 18, 6,315 112 1,456 26,082 12,031 Total per Month, 33,966 511 7,925 127,573 71,691 Average per Week, 6,793 103 1,587 25,514 14,326 do. do. last Month, 6,237 92 1,299 23,300 11,968 do. do. prev's Month, 5,300 111 1,116 18,018 7,240 do. do. do. 1865, 5,255 118 1,500 16,021 11,023 do. do. do. 1864, 3,361 115 1,241 15,315 12,676 do. do. do. 1863, 5,150 129 891 9,911 21,070

The weekly receipts of all kinds of animals have advanced considerably upon the previous month. As shown above, the weekly increase in cattle is 566 head. The average weekly receipts, 6,793, compare with 5,257 the weekly average for all of 1865, or an increase of 1,536, equivalent to 256 for each day, Sundays excepted....

Beef Cattle, under the very large receipts noted above, have gradually declined in price, with not very good present indications for a recovery. The sales at the last regular market were at rates equivalent to 15c. @ 17c. per lb. dressed weight, for some of the best cattle, perhaps 17c. @ 18c. for a dozen of the extras; 16c. @ 17c. for the general run of really good cattle; 15c. @ 16c. for common or medium grades; 14c. @ 15c. for inferior and poor; 12c. @ 11c. for some of the worst....

Milk Cows.—The demand has been slightly better the present week, but the cow trade has generally been quite dull. Poor cows are hard to sell at \$50 @ \$55, common to fair, \$60 @ \$70; good, \$75 @ \$85, extras, \$90 @ \$95, and upwards for a few fancy animals....

Veal Calves of very good quality have improved a little in value, and have sold at 13c. @ 14c. per lb. live weight; fair qualities, 11 1/2c. @ 12 1/2c.; inferior to poorest, 11c. @ 9c....

Sheep and Lambs have been in unprecedented supply, averaging over 25,000 head per week, and prices have fallen off materially, the very best sheep hardly receiving 7 1/2c. per lb. live weight; most good sheep, 6c. @ 6 1/2c.; common to very poor, 5 1/2c. @ 5c. Lambs, 6 1/2c. @ 8c. for poor to best....

The American Institute Show of

fruits, flowers and vegetables, at their rooms in the Cooper Institute, New York City, was an attractive and instructive display. The grapes competing for the third time for the Greeley prize of \$100 formed a prominent feature. The show made by Mr. H. Z. Ellis, of Vineland, N. J., of pears, apples and quinces of great excellence, as well as other products, corn, egg-plants, etc., astonished those of us incredulous as to the great fertility of the Vineland district.—Mr. Horace Greeley showed monster squashes, and Solon Robinson made an exhibition of fruits "as they grew."—some fair, and large, and some curiously distorted and deformed by insect stings, and cracks, worm-eaten ones, etc. This was to show the fruit consumers of the city what the fruit raisers have to contend against, and why fair handsome fruit is really worth so much. The "Walter" grape shown by Ferris & Caywood, of Poughkeepsie, is a seedling of promise, said to be a cross of Delaware and Diana, and it looks so. Mr. W. S. Carpenter covered much space with the fruits of his orchard and farm, and Reising & Hexamer made an especially fine show of potatoes. The impression is prevalent that no award can fairly be made of the Greeley prize for the best grape, all things considered, and that the matter will drop here, though the committee should certainly report in full,

(Business Notices \$2.00 per Agate Line of Space.)

STARTING OF THE GREAT AMERICAN TEA COMPANY.

The Proprietors became fully convinced, several years ago, that the consumers of Tea and Coffee were paying too many and too large profits on these articles of every day consumption, and therefore organized THE GREAT AMERICAN TEA COMPANY, to do away, as far as possible, with these enormous drains upon the Consumers, and to supply them with these necessaries at the smallest possible price.

To give our readers an idea of the profits which have been made in the Tea trade, we will start with the American houses, leaving out of the account entirely the profits of the Chinese factors.

1st.—The American House in China or Japan makes large profits on their sales or shipments—and some of the richest retired merchants in this country have made their immense fortunes through their houses in China.

2d.—The Banker makes large profits upon the foreign exchange used in the purchase of Teas.

3d.—The Importer makes a profit of 30 to 50 per cent. in many cases.

4th.—On its arrival here it is sold by the cargo, and the Purchaser sells it to the Speculator in invoices of 1,000 to 2,000 packages, at an average profit of about 10 per cent.

5th.—The Speculator sells it to the Wholesale Tea Dealer in lines at a profit of 10 to 15 per cent.

6th.—The Wholesale Tea Dealer sells it to the Wholesale Grocer in lots to suit his trade, at a profit of about 10 per cent.

7th.—The Wholesale Grocer sells it to the Retail Dealer at a profit of 15 to 25 per cent.

8th.—The Retailer sells it to the consumer for *all the profit he can get*.

When you have added to these *eight* profits as many brokerages, cartages, storages, cooperages, and waste, and add the original cost of the tea, it will be perceived what the consumer has to pay. And now we propose to show why we can sell so very much lower than other dealers.

We propose to do away with all these various profits and brokerages, cartages, storages, cooperages, and waste, with the exception of a small commission paid for purchasing to our correspondents in China and Japan, one cartage, and a small profit to ourselves—which, on our large sales, will amply pay us.

Parties getting their Teas from us may confidently rely upon getting them pure and fresh, as they come direct from the Custom House Stores to our warehouses.

The Company have selected the following kinds from their Stock, which they recommend to meet the wants of Clubs. They are sold at Cargo Prices, the same as the Company sell them in New York, as the List of prices will show.

All goods sold are warranted to give satisfaction.

PRICE LIST:

YOUNG HYSON, 80c., 90c., \$1, \$1.10, best \$1.25 per pound.

GREEN TEAS, 80c., 90c., \$1, \$1.10, best \$1.25 per pound.

MIXED, 70c., 80c., 90c., best \$1 per pound.

JAPAN, \$1, \$1.10, best \$1.25 per pound.

COLONG, 70c., 80c., 90c., best \$1 per pound.

IMPERIAL, best \$1.25 per pound.

ENGLISH BREAKFAST, 80c., 90c., \$1, \$1.10, best \$1.25 per pound.

GUNPOWDER, \$1.25, best \$1.50 per pound.

[For Clubs see former editions of this paper, or send for the GREAT AMERICAN TEA CO.'S ADVOCATE.]

P. S.—All towns, villages, or manufactories, where a large number of men are engaged, by CLUBBING together, can reduce the cost of their Teas and Coffees about one-third by sending directly to the

GREAT AMERICAN TEA COMPANY,
31 and 33 VESEY STREET, corner of Church.
Post Office Box, 5,643 New-York City.

BRICKS.

The NATIONAL BRICK MACHINE is a clay tempering machine, and with only

TWO HORSES MAKES
30,000 GOOD BRICKS PER DAY.

If the machine does not do this, it will be TAKEN BACK AND THE MONEY REFUNDED. For Lights and Machines Address ABRAM REQUA, General Agent, 141 Broadway, N. Y.

Herald of Health on Trial.

We will send the Herald of Health 3 months for half price, that all may see how valuable it is. MILLER, WOOD & CO., 15 Light-street, New York City.

AGENTS WANTED, AWEDWOOD'S GOVERNMENT and LAWS of the UNITED STATES.

A Comprehensive View of the Rise, Progress and Present Organization of the State and National Governments.

It contains the minimum of law which every citizen should possess to enable him to discharge, with intelligence and fidelity, his duties to the State and to the Nation, and to conduct his private affairs with perfect safety to himself and justice to others.

IT IS STRICTLY A SUBSCRIPTION BOOK.—Reliable, active men and women, who wish to do good and make money, can do both by canvassing for this book. Some of our Agents are making over \$100 per week. A circular, giving Title-page, Table of Contents, Testimonials, and Specimen pages, with Agency documents, will be sent on application. Territory assigned, and liberal inducements offered. J. W. SCHERMELHORN & CO., Publishers, 439 Broome-st., N. Y.

"YOUNG ETHAN."—OWNED BY HOLABIRD & SATERLEE, SHELBURN, VT.—*Drawn from Life for the American Agriculturist.*

This noble horse was the winner of the first prize in his class at the New England and Vermont Show, at Brattleboro, this fall. He is one of Ethan Allen's best sons, and takes after the old horse in many points, exceeding him much in size. His dam was a Hambletonian and Morgan mare; he is of a dark bay color, 15 $\frac{1}{2}$ hands high, and eight years old. It is rare to find a better combination of blood for a horse of all work. His grand-sire Black-hawk (the sire of Ethan Allen), undoubtedly owed many of his best qualities, as well as his color, to his dam, a black, half-bred English mare, while he re-

tained in a high degree the excellencies of the Morgans. (His sire was Sherman, son of Justin Morgan.) In the Hambletonians there flows the blood of some of the best thorough-bred horses that we have ever had in this country. The stock has long been justly famous, and many notable trotters have sprung from it. Ethan Allen is the "honestest," squarest trotter we ever saw go, and one of the very fastest. So it is not to be wondered at, that the fine stallion above pictured, standing, as he does, nearly 16 hands high, and superior to his sire in weight and muscle, while his action on

the road is exceedingly similar, should have made some very fast time. We have no record at hand giving his best performances. At the time of the exhibition, though not in trim for trotting, he went his mile in 2.43". He weighs 1120 pounds. We have been sorry to see the Morgans losing size, as was true of most of them, but if they are working up to this standard, without falling off in style, bottom, and other useful qualities, we can not desire anything better as a class of horses for the road. Such stallions, crossed upon large mares of good constitution, produce our most showy carriage horses.

AMERICAN AGRICULTURIST.

NEW-YORK, DECEMBER, 1866.

Plowing, stump pulling, wall-laying, field-clearing of stones and roots, underdraining, etc., must cease when the thermometer drops down towards zero. Still these are the appropriate labors of those favored sections where the plow may run in every month of the year, and where white clover and annual grasses afford abundant pasturage, though often cropped, from November to May.

This season is one of comparative rest to both the farmer and his stock. It is a time for him to read, to plan for the next year, to lay in a store of ideas, like as he collects choice seeds for his next spring's planting. We have often said that winter is the seed time of practical ideas, which bear their fruit in the season of labor. It is especially a time for farmers to compare notes. A. B. went to the fair, perhaps to the State fair; he brought away the hand-bills, cards, catalogues and posters of fifty different dealers, and he will never weary of talking over what he saw, and you may copy off the addresses and write to the parties for catalogues of stock, implements, fruit trees, or any thing you like. Almost all send such things free, or something free, though many charge a small fee for their very extensive and expensively illustrated catalogues, which are almost always very instructive. An immense stock of information may be thus gathered, and readily turned to account.

The Farmer's Club is the place for discussing improved stock, implements, new crops, better seed, and all such things, and were the readers of the *American Agriculturist* aware of what the benefits of such an organization might be to them, and what pleasure as well as profit they would realize, there would be a good club maintained in every country school district, or village at least.

The Retrospect.—We have climbed the hill, and before this month is past we may look over upon the sunlit prospects of the coming year; but now if we face about in the clear wintery air of these December days, we may well take a survey of the road we have travelled, of the mistakes we have made, and the points won—the failures and the gains. The year has had its anxieties, (more than usual). It has been a prosperous one on the whole; abundant harvests, ready markets, and high prices, have rewarded the toils of the husbandman. To a limited extent only has disease prevailed among flocks or herds. Other nations have suffered from war, from murrains, and from the failure of their harvests, while we are spared this distress, and our products are in great demand.

Our commerce increases, and even our internal disquiet does not prevent the most marked recognition of our prosperity and greatness as a nation. So ends the year. What the future has in store is known only to Him who has guided us thus far in prosperity and in adversity, and whom in thankfulness we trust to lead still in ways of prosperity and usefulness, and that our ill-deserts may not be remembered against us.

Hints about Work.

As we have hinted above, the farmer's most important winter work may be in cultivating his own mind, and not his alone, but those of his children and dependents. In this free and independent country, it is often hard to tell which is the servant, he who gives the labor of his free hands for money, or he who gives his money for labor. They sometimes change places, and very often the hired man becomes the more intelligent, cultivated, and wealthy of the two. Many a man has voted for a former day laborer as his representative in the Legislature, or in Congress. This comes only by good use of the golden hours of winter evenings.

Books.—The world is full of good ones. The less one knows, the better is he satisfied with what he knows. Those books upon subjects bearing upon a man's own calling, are a never failing source of

interest and profit; and in connection with books, *Periodicals* both professional and those of general interest, are very important as educators. These things should be made available in each neighborhood, by means of a well selected

Circulating Library, established in a central location, in the school-house, a store, or in a private family, and open at regular hours. Even at present prices of literature of all kinds, a small sum only is required to establish and maintain such a library, if it be selected by a good agent.

Schools.—Review hints in previous numbers on this most important subject.

Accounts.—To begin the new year aright when it comes, the old year must be finished rightly. Farmers are very apt to run into careless habits about their accounts—not so much in money transactions as in their store bills, especially where the farm products are seldom sold for money, but are exchanged for family groceries. Go over all accounts, and get ready to commence with a clean balance sheet January 1st, 1867. A plain account book has prevented many a law suit, for it is the very best witness a man can take into court, provided it has been regularly and accurately kept.

Protections against Frost.—Protect cellars by banking up outside the walls with sods and dirt, or what is better, tan bark. Conduct off water dripping or flowing from leaves, and pack straw or leaves against such windows and doors as are not constantly in use. Pumps or hydrants may be protected by setting headless barrels around them and filling them with tan-bark, or manure, or manure. Protect underground cisterns, if necessary, by covering them with more earth. If water pipes freeze, clear the ice out by pouring hot water upon the ice through an India rubber tube. Exposed pipes may be protected very well by winding them with hay rope, and smearing this with clay.

Fodder.—It makes little difference how abundant fodder is; its waste is criminal. Those who throw out hay, straw, or stalks, to be trampled upon, and trod into the ground by cattle and sheep, do a very foolish thing, for if properly used as bedding even, it would be worth a good deal for manure. Racks ought to be provided for the yards and sheds, as well as for the stalls, and so constructed that all the cattle refuse may be worked over, as indicated.

Live Stock of all Kinds require the farmer's especial care and daily personal attention. The cold weather is apt to induce carelessness on the part of the hands, and animals are not all well watered or equally foddered, or systematically carded or elcauded, unless the master's presence secures faithful work. Feed and water regularly and well, and keep salt before horses, cattle and sheep. We like the Liverpool rock salt best. This comes in solid, hard masses, weighing several pounds, and lumps may be laid in the mangers or in salt troughs in the yard. Give all kinds of cattle a daily airing of two or three hours. Young cattle and sheep may have much more liberty. No class of stock should be allowed to run down in flesh—it is so hard to bring them up again, and keep the young stock growing.

Colts and Steers.—When we get a snow of a foot or more deep, it is a capital time to break steers and colts. For hints on horse-breaking see p. 432.

Horses.—See hints in last number. Look out for having them well shod and caulked as soon as icy weather comes. The best application for bruises and sprains is usually cold water and thorough rubbing. If very painful, put on rum and a little tincture of arnica, but not on raw spots. Cuts, or bruises, when the skin is broken, are best treated with grease and pine tar, melted together to a soft salve. See "Horse Hospital" in our Basket.

Working Oxen, if used, should be well shod and caulked, at any rate in front, otherwise one runs a great risk of having them get falls and sprains.

Cows.—Keep their stables clean, sprinkle gypsum to prevent the odor of ammonia. Give abundant ventilation, but not cold drafts. Make them exercise daily when it is not very icy. If kept in a

yard, see that the shed is dry, well roofed, and if possible board up the front in part, and put up feed racks. Put balls or boards on the horns of the "bullies" and of quarrelsome ones. It is said that corn mibbins fed to cows on the ground is a preventive of abortion. If there be any virtue in it, it probably lies in the cows' picking up some earth with the corn. It is well to give occasionally a handful of wood ashes, and if a cow's breath is not quite sweet, give pulverized charcoal and a table-spoonful of nitre (saltpeper) in her food.

Hogs.—Towards the last part of the fattening season, hogs gain slowly. As a general rule, feeding hogs is said to pay as long as they gain daily half of one per cent. That is, when a 200 pound hog gains a pound. Even that depends altogether on the price of corn and pork, and changes in the market may make it pay to feed hogs some weeks even, though they gain nothing at all. Slaughter hogs for family use in the coldest weather before Christmas. A friend of experience who advocates shooting hogs, fears that the recommendation of a correspondent to shoot a wooden plug into the forehead, would not be effective, unless with a pretty good charge of powder. He prefers shooting with a ball through the temples. A little experience will settle the question, and enable every one to avoid all music on slaughtering day.

Poultry.—After the hogs are killed, the poultry will receive unsalted scraps and will not fit for cows, and it will promote a tendency to commence laying, if they have warm quarters. Those who breed for prizes will take care to provide warm sunny rooms, and keep them warm even by artificial heat, so as to get out a clutch or two of chicks of each breed they fancy, as early as the first week in February if possible. It will pay to take great care of fowls for eggs only, when they sell for four or five cents a piece, as they do now at retail in New York City markets.

Manure.—See hints in former numbers. We do not approve of hauling out manure in the winter, and spreading it, or leaving it in heaps on the land. It may be moved to distant fields when the shedding is good, and there laid in large compact heaps trodden down, and if possible covered with dirt.

Wood Cutting, Getting out Fence Stuff, etc., will occupy the attention of many farmers, and at the South, fence making is the order of the day as soon as plowing is finished. The time is now to provide dry fire-wood for a year hence, and posts and rails for next spring's setting, and use in fence-mending.

The Ice Harvest comes rarely in December, but it is well to be ready. If the ice-house is empty, have it cleared out, the straw dried, and renewed if too much broken; take out the sawdust altogether. The first ice is usually the purest and most free from bubbles, and it is great good luck to get one's ice all stored before the "January thaw."

Orchard and Nursery.

In December there is little to add to the notes for November. Whenever the weather will allow the work there indicated to be done, do it. In mild seasons, or in Southern localities, ground for the orchard may be plowed and subsoiled. If nothing can be done to facilitate spring operations, see that no harm comes to trees already planted.

Fences and Gates must be looked after, and put in a condition to keep domestic animals out of young orchards. They will either browse or bark the trees, and do more damage in a few hours than will be regained in all of next year's growth.

Rabbits and Mice, among wild animals, often do serious damage. The best way to keep off rabbits is, to sprinkle blood upon the trees. Leave no rubbish near young trees to harbor mice, and trample snow down so hard that they can not work under it.

Cions may be cut whenever the wood is not frozen. Saw-dust or damp moss are better packing than sand, for the reason that they come out free from grit. The object should be to preserve the natural moisture, and not keep them any damper or dryer than they would be if left upon the tree.

Manure often benefits an old orchard wonderfully. It may be carted out while the ground is frozen.

Fruit in the fruit room will need looking at occasionally. Keep the fruit room and fruit cellar at a low and uniform temperature. Send choice specimens to market just before the holidays. In the

Nursery the heading back and shaping of young trees is carried on in mild weather, and when the weather is inclement, the hands are occupied indoors in root grafting. In grafting, too much care cannot be exercised, and it is well to work at only one variety at a time to avoid all possibility of mixing kinds. See that surface drains are opened to carry water away from young trees, and that no water stands around stocks that have been heeled-in.

Fruit Garden.

Where an open month allows, ground may be manured, plowed or spaded for spring planting.

Trees in the garden will need the same precautions against animals, as noted under Orchard. If light snows accumulate in the heads of trees, shake it out before it becomes icy.

Manure may be spread around trees and shrubs.

Pruning of small wood on trees may be done, and currant and other bushes trimmed in a mild time, as may any neglected

Grape Vines; and if the wood is wanted for propagation, cut it into suitable lengths, tie it in bundles and bury it, upper end down, in a dry place, and cover the spot with leaves or litter. Cuttings treated thus will often callus nicely and be ready to make roots when set out in spring. If

Strawberry Beds have not yet been covered, do it before the ground is frozen and thawed many times. Straw, leaves, or corn stalks, will answer. Do not cover the crowns too much; the roots rather than the tops need protection from freezing and thawing.

Kitchen Garden.

The amount of out of door work will depend upon the weather. If the ground is not frozen hard, it will benefit stiff soils to throw them up in ridges, that they may receive the ameliorating influences of the frost. Clean up all rubbish; lay drains if the season permits, and do everything that will save a day's work in spring.

Roots, Celery, etc., stored in pits or trenches, as heretofore advised, will need gradual covering as the cold increases. Recollect that such things suffer more from covering too soon and heating than they do from freezing. Do not put on the final covering until winter has fairly set in.

Cellars, where roots are stored, should for the same reason be kept open as long as can safely be done without freezing the contents.

Cold Frames, in which cabbages, cauliflowers and lettuce are wintered, should be daily aired whenever the thermometer is above freezing. The great point is, to keep the plants hardy, and this is done by preserving a low and uniform temperature. Cauliflowers are more tender than the others, and in very severe weather the glass should be covered with mats or shutters. Poison or trap every mouse.

Hot-beds will be wanted in February and March. Have the sashes and frames in readiness now that there is leisure. Paint, re-glaze, and have all in working order. Accumulate a supply of

Manure for hot-beds; the best is that from horse stables, long and short together. Manure for plowing and spading in should be looked out for, and all available materials, whether from the house, privies, stables, piggeries, or hen-houses, should be saved. Look around in the neighborhood for any mineral, animal or vegetable material, going to waste, that may be profitably secured as a fertilizer.

Seeds should be overhauled, and those of doubtful vitality rejected. If uncertain as to the value of a lot, plant a few in a saucer or other dish of earth; keep moist in a warm place. Order seeds early.

Tools should be looked over and repaired as needed. Paint all parts that need it, and supply deficiencies by purchase.

Flower Garden and Lawn.

Plan in winter that which is to be executed in spring. If the weather serves, something can be done towards laying out walks, and in making other improvements. It

Tender Shrubs or other plants are without winter protection, give it before severe freezing comes on.

Climbers, such as Wistarias, climbing roses, etc., will in very cold localities do much better if laid down and covered with a little earth.

Lawns will appreciate a good dressing of composted manure, which may be applied any time in winter. Do not let

Evergreens nor close shrubs be broken by accumulated snow. Shake it out before it becomes ice.

Rustic Baskets, vases, seats, etc., may be made indoors. Branches of Cedar, Laurel, Wild Grape, and many other things may be used for the purpose.

Green and Hot-Houses.

In green-houses, which are only to preserve things for the winter, all will go well if the thermometer does not go below 40°, but if flowers are wanted, it must be about 60°. That of the hot-house must be governed by the character of the collections. Ventilation must be properly attended to. Bring forward pots of

Bulbs, a few at a time, so as to have a succession of bloom, and when the flowers are past their prime, cut away the stalk and allow the leaves to grow to perfect the bulb.

Camellias need to be kept cool, and the atmosphere moist by free use of the syringe.

Cacti need but very little water, except the Epiphyllums that are now blooming.

Pelargoniums should be put where they have plenty of light.

Insects will require attention. Tobacco smoke quickly does for the green fly, and a moist atmosphere is destructive to the red spider.

Cold Grapery.

Do not let the house get too warm, but open the ventilators on warm days and close them at nights, and on cloudy and cold days. The vines should be laid down and covered. They may be bound up with straw, or a board put up in front of them on edge, supported by stakes, and the vine covered with forest leaves. It has been recommended to paint over the vines with a mixture of whale oil soap $\frac{1}{4}$ lb., sulphur 4 lbs., tobacco $\frac{1}{4}$ lb., and powdered nux vomica 1 oz. These are to have a gallon of boiling water poured over them and stirred well together. When cold, apply to the vines with a brush to destroy the larve and eggs of insects. In laying down the vines, be careful not to make too short a bend.

The Apiary for December.—Those having bees will doubtless find in this month the most leisure to repair old or make new hives and honey boxes. In view of which, if the number of swarms admit, it would be advisable to build a small house, say 10 x 12 feet, placing it near to the apiary, in which to make, repair, and paint hives, as well as for storing them, straining and storing honey. It is a convenient place into which to remove a colony for any operation that may be desirable or necessary. Bees being more easily handled if removed from their accustomed stand, the other hives being less disturbed, will less annoy you. A house can be easily and cheaply made, requiring but a door in one end and a window in the other, a work bench on one side, space for hives opposite, and for boxes overhead, a barrel, containing a basket set in one corner, into which to throw broken honey combs for straining, a shelf under the bench with paints and brushes, 2 planes, 1 square, a hammer, a saw and nails above. Thus furnished, all is ready for work at any and all times. If your time or skill will not enable you to make good hives, the better you get them made, the less repairs

they will need thereafter. A good hive should last a life-time. If one intends to increase his bees, he should not forget to provide sufficient hives. In deciding this, let him consider if flowers are plenty yielding pollen during the season; if not, can they be supplied. If honey is his object (which also includes an abundance of honey producing flowers), large boxes, without top or bottom, holding frames, called "supers," as well as boxes, will be necessary, though supers without boxes are often preferable. Non swarming hives have been patented to obtain large yields of surplus honey, (still the bees do frequently and repeatedly swarm); their greatest fault is, that you lose the reproductive force of the hive. By using supers, into which you lift frames from below, replacing them with empty ones, you avoid swarming and increase the working force.

AMERICAN HORTICULTURAL ANNUAL for 1867.

An Important Work.

This Annual is rapidly progressing, and will be ready before the opening of the New Year. Its plan will be different from any heretofore published in this country, and it will aim to be a

Record of Horticultural Progress, for the year 1866, free from matters not legitimately belonging to Horticulture.

The Material is all New,

and not a reproduction of old articles that have served their turn elsewhere. The volume will be

Liberal Illustrations,

with engravings made especially for the purpose. That a Year Book of Horticulture is needed, is shown by the readiness with which

Distinguished Horticulturists

have contributed to its pages. Among other contributions from experienced cultivators, there will be

The Apples of 1866, by Doct. John A. Warder, President of the Ohio State Pomological Society, Author of American Pomology, etc. New Ohio Apples; New Indiana Varieties; Southern Varieties fruited at the North, etc. *Illustrated.*

New and Noteworthy Pears, by P. Barry, author of the Fruit Garden, etc., giving descriptions of new varieties as well as of the less known ones that have been fully tested. *Illustrated.*

New Bedding and other Plants of 1866, by Peter Henderson, Florist, etc. An account of the new varieties of bedding and other flowering plants, and their success and failure during the past year. *Illustrated.*

The Rarer Evergreens that have Proved Valuable, by Thomas Meehan, Editor of the Gardener's Monthly and author of the American Hand-book of Ornamental Trees.

New Vegetables of 1866, by Fearing Burr, Jr., author of American Field and Garden Vegetables; giving the author's experience with newer culinary vegetables.

Small Fruits in 1866, by Andrew S. Fuller, nurseryman, author of the Grape Culturist, Forest Tree Culturist, etc. A valuable summary of all the small fruits, excepting grapes.

Home Decorations, by A. Bridgeman, Florist. How to treat Ivy; Hanging Baskets, Rustic Stands, etc. *Illustrated.*

New Roses of 1866, by John Saul, Florist, of Washington, D. C., and well known authority on Roses.

The Cultivation of Horse-radish, by Peter Henderson, author of Gardening for Profit. Concise directions for growing this profitable crop. *Illustrated.*

Grapes in 1866. From notes by Geo. W. Campbell, Delaware, Ohio, and other Grape Growers.

Propagating Grapes in the Open Air, by William Patrick, Terre Haute, Ind., giving a method by which the Delaware and other difficult varieties may be grown—without artificial heat.

Useful Seed Tables, by James Fleming, Seedsman, New York, giving the amount of seed to the acre, to a given length of drill, etc.

Other communications by well known authorities, besides a great amount of Editorial matter, including a

Calendar for each month in the year, articles on Wine Grapes, Table Ornaments, Hedges, Farm Nurseries, Tree Labels, New Potatoes, List of Engravings of New Fruits and Flowers published in 1866. List of Works on Horticulture for 1866. A Dictionary of Horticultural Terms, and a host of other matters of interest, both to the professional and amateur gardener.—Price

Containing a great variety of Items, including many good Hints and Suggestions which we throw into smaller type and condensed form, for want of space elsewhere.

Mark All Subscriptions sent in as New, or Old.

For Market Report, See Page 451.

—The report of the Live Stock Markets show unprecedented large receipts of cattle, sheep, and hogs, with a consequent heavy decline in prices, though the selling rates are still far above former times. Now, 15@16c, per lb. dressed weight for good cattle is considered very low; it is not many years since 8@9c. was considered very high. Other farm products are even above the war prices.

Sundry Business Items, important this month, will be found on the *inserted* extra sheet, pages 425 and 426.—The Title page, and Index to the volume are on a *loose* extra sheet, which should be preserved, as noted on page 425. These extra sheets each cost the price of quite a farm, on our enormous edition, at the present exorbitant prices of printing paper; but with the generous patronage extended by our readers and advertisers, we can afford to make these additions instead of curtailing the reading matter in the least.

Ink Recipe—Correction.—Instead of the directions on page 346 (Oct. No.) read, as corrected, Mr. Bull: In one gallon rain water put 2 ounces of *extract* of logwood, and $\frac{1}{2}$ ounce of bi-chromate of potassa. Heat, and when dissolved, strain, and add $\frac{1}{2}$ ounce of aqua ammonia. The articles are kept by most druggists.

The American Agricultural Annual will contain a brief review of the past year—notice of important events, inventions, publications, etc., affecting the agricultural interests of the country, importations of stock, introduction of new crops, etc.; contributed articles of an interesting and practical character, fully illustrated; practical hints in regard to work, and machinery, besides convenient tables, and a full almanac. The publication of this will be a few days later than that of the *Horticultural Annual*. We can promise articles from distinguished contributors, varied and practical in character, and a store of valuable facts for reference.

Gardening for Profit, by Peter Henderson. We hoped to be able to announce in this issue that this book was ready, but the crowd of work in the engraving room has delayed the illustrations. The work is otherwise nearly ready, and we shall doubtless be able to fill the numerous orders by or shortly before the new year.

Steaming Fodder.—Coarse fodder may be made to go a great way, with a little art. Cattle and horses refuse cornstalks, not because they are not good feed, but because they are hard to chew, and they choose not to chew them. Cut up by a good stalk cutter that either cuts them in half-inch pieces, or slices them very diagonally, and soaked 24 hours, wet with hot water, meal and the hardest salt being added, will almost all be eaten. Still, *steaming* is better, for it does not necessitate keeping 24 hours' stock of prepared feed on hand all the time. The most convenient steaming apparatus is probably a hoghead hung in trunnions, the steam being passed to the bottom through a rubber hose from a boiler. With such an arrangement all kinds of fodder, straw, stalks, hay, roots, etc., may be cooked for cattle or swine, and the greatest possible economy in fodder attained.

Smart-weed for Fodder.—A writer in the Nov. Gardener's Monthly has an article on the use of Smart-weed as fodder for horses. As Smart-weed is a very acrid plant, and will cause severe inflammations when applied to the skin, it struck us as rather strange horse food; but on reading the article, we find the botanical name put down as *Polygonum Persicaria*, which is not Smart-weed at all, but is Lady's-thumb, which a horse might be ungallant enough to eat. Smart-weed is *Polygonum Hydropiper*. It is not often we catch our friend Meehan out in his botany, and this is really only a misapplication of common names, which are quite apt to get mixed. We only picked him up for the sake of let-

ting him down very gently, and congratulating him upon making so useful and excellent an horticultural journal. Its title indicates its real character as *Gardener's Monthly*.

The Common Milking Goat.—"T. M." Alleghany Co., Pa., wishes information about the Common Goat. "How much milk will one give? Are they not good milk stock for those living near railroads?" *Ans.*: The quantity of milk varies greatly. There is a Maltese breed said to give 1 gallon per day; 1 quart per day is, however, not unusual, and considered a good quantity. The goat is a very intelligent animal, and in little danger of harm from locomotives, boys, or dogs. The milk is held in Eastern countries to be better than cow's milk for those affected by miasmatic diseases (chills and fever, etc.), probably a mere notion. Goats are great nuisances, getting very familiar, and pushing themselves where they are not wanted, besides they will bark any fruit and shade tree they can get at.

Cows for a Small Dairy.—"G. W. A.," Morgantown, West Va., asks "What breed of cows is best for a small butter dairy?" Were we to stock a yard with dairy cows, they should be selected without reference to breed from some good dairy region: if the object were butter especially, we would buy besides one or two good Alderney cows and an Alderney bull.

Sheep for a Small Flock.—Our questioner, "G. W. A.," asks about sheep. We presume his wish is to raise mutton for his own table, so without hesitation we recommend the South Down as the preferable breed. If, however, he wishes to raise mutton to sell, the Cotswolds, Leicesters, or some other large long wool sheep might be more profitable; depending on the market.

Musquash Skins.—Dealers inform us that prices paid last year, when there was an unusual foreign demand, form no criterion to judge of the prices this year, which will probably rule as low as 30 to 35 cents for prime skins, and perhaps less.—So the fashions vary.

The Sabbath School Question Books, entitled "*Lessons for Every Sunday in the Year,*" are being rapidly adopted by schools of all Christian denominations throughout the country. They seem to exactly meet the wants of teachers, judging from the fact that over half a million copies have already been called for. They are supplied at about cost, viz., \$12 per hundred, or \$1.50 per dozen. If by mail, 4c. per copy extra, or 3c. each if in parcels of ten or more copies. Four sample copies (Nos. 1, 2, 3 and 4.) will be sent post paid for 65 cents. Superintendents and Teachers are invited to examine these books.

Long Subscription Letters are not necessary or desirable. Here is a convenient short form.

WASHINGTON, JOHNSON CO., IOWA, Dec. 1, 1866.
Messrs. Orange Judd & Co., New York City:
Enclosed are Five Dollars for the American Agriculturist for four subscribers, to begin January 1st, 1867, viz.
John Doe, Washington, Johnson Co., Iowa.
Richard Roe, do, do, do.
Peter Smith, Webster, do, do, do.
S. J. Karl, Freeport, Sioux Co., Wis. (German).
Yours, respectfully,
JOHN DOE.

Seal tightly, and address plainly to Orange Judd & Co., 41 Park Row, New York City.—Let all matters referring to the reading columns only, such as information given, notes, queries, etc., (which are always welcomed,) be on a separate piece of paper, marked "for Editors," each piece containing the date, name and residence of the writer.

Iona and Israella Grapes.—W. B. Waldo. Both these varieties grow from cuttings in the open ground, but the wood is as yet too valuable to use in this way.

Trade Sale of Grape Vines.—The experiment of a regular Trade Sale of Grape Vines, at auction, commenced by Parsons & Co., last year, is to be continued this season, as will be seen by their advertisement. There are many advantages in this method of supplying the wants of dealers, which should lead them to encourage the permanence of this arrangement.

The Buckeye Mower.—This implement was selected and placed in our Premium list last year, and again this year, before we had the least inkling of the probable decision at the great Auburn trial. We are, of course, highly gratified, on finding the propriety of our selection confirmed by the result of that trial, which was far more thorough and exhaustive than anything of the kind previously undertaken in this country. The award was announced in the October *Agriculturist*, page 346. Farmers will, of course, work all the harder now to secure this premium. Several obtained it last year, and many more can do so this year.—By the way, our atten-

tion has been called to what was, to say the least, very far from an honest, straightforward business transaction. An editorial notice appeared in the N. Y. Daily Times, referring to the award of the gold medal to the Buckeye for sundry enumerated excellencies as a mower. This notice had an extensive circulation in other journals, with the name of W. A. Wood's machine substituted for that of the Buckeye, and the notice changed to read "for the best combined mower and reaper," followed by an enumeration of the excellencies of the Buckeye, printed as if belonging to the Wood, viz., "Perfection of work in all kinds of grass, and on every variety of surface, lightness of draft, ease of management, perfection of mechanical construction, simplicity, strength, and durability." The committee, on the contrary, gave to the Wood machine the preference over its chief competitor, the Eagle, for ease of draft, and smallness of side draft. They gave the Eagle machine the preference for quality of work and facility of management, as compared with the Wood machine, and placed them on the same level as regards simplicity of construction and durability. The Buckeye will, of course, not be injured in the end by this improper borrowing of its plumes. The actual decision of the Auburn committee will not be obscured by any specious efforts of interested parties. We are favorably disposed toward the Wood machine for its real excellence, but it is our duty to refer to the attempt to use the press to give a wrong coloring to the facts, as we understand them.

Crib-Biting.—An "Ex-Officer," who has studied this disease in the army, before he entered it, and since he returned from service, makes some suggestions which, considering the very indefinite views usually held by veterinarians about it, are worthy consideration. We regret he has no experience in regard to a cure. "I have read the *Agriculturist* for years past, and have found that authors call this disease an affection of the stomach, or locate it in other places, still more remote from the seat of the complaint. I have taken pains for the last six or seven years, both in the army and while out of it, to look into every horse's mouth that gave the well known intimation of being afflicted with what is generally termed 'cribbing,' or 'wind-sucking,' and I have in no instance failed to find that the gums grow down between the upper teeth—some within a quarter of an inch of the ends of the teeth, others not so far, but all that characteristic without exception. From this I conclude it is a crowding of the teeth and gums, instead of any intestinal diseases. The pain and irritation caused by the pressure, makes the horse press his teeth upon the first horizontal piece of anything he comes in contact with, to obtain relief. The pain he is in, no doubt causes him to grunt, and the eructation of wind from the stomach is but the effect of having the head and neck in the position he takes. For a cure, I would suggest that keeping the teeth from crowding each other, or the gums, or both, will at once cure the malady."

White Wire for Clothes Lines.—

"White Wire" is simply galvanized iron wire, that is, iron wire coated with zinc, which prevents its rusting. Most telegraph wire is thus prepared. Several correspondents have written that they use this telegraph wire obtained from the telegraph companies, and find it to answer a very good purpose, while it is permanently durable. The "Washburn & Moen Wire Works" make this galvanized iron wire with extra smooth surface for clothes lines. It is wholesaled by the Agent in this city (E. A. Moen, 42 Cliff street) by the ton, at 13 or 14 cents per lb., and in half mile coils (about 170 lbs.) at 15c. per lb. The No. 8 or No. 9 size is that used for clothes lines. No. 8 weighs about 7 lbs. to the 100 feet, which at 15c. per lb. would cost one cent per foot, exclusive of freight. A few neighbors could readily combine and get a ½ mile coil, the smallest quantity sold by the agent, and divide it. Allowing \$2.60 for freight on 2,640 feet, would make the cost only \$1.10 per 100 feet. We presume hardware dealers would get it and retail it at about 2c. per foot if requested to do so. Anybody has a right to buy, or sell, or use this wire.

To the Wives of Generals, Judges, Senators, etc.—

We have been shocked recently by seeing the names of the wives of some of our most esteemed Generals, U. S. Senators, etc., boldly published as patrons and endorsers of various "Gift" and other enterprises, ostensibly got up in aid of charitable or benevolent objects. A close examination shows that in most cases the operators use these names only indirectly, though in such a manner as to deceive the public into a belief that these ladies are really at the head of the schemes, or at least largely interested. But in some of our humbug investigations, noted elsewhere, we have seen letters, undoubtedly genuine, from some of the ladies referred to, in which they do give their direct countenance and encouragement to Gift Enterprises, presentation festivals, charitable fairs, etc., which are in

reality neither more nor less than "covert Lotteries." These are of a worse character, if possible, than the old fashioned "regular" lotteries, where a man is boldly told the risk he runs, the chances in his favor, what he is to pay, and what to hope for. In these, on the contrary, his kind feelings and sympathies are worked upon, to filch money from him, ostensibly for good objects, when the chief part of it really goes into the pockets of the shrewd managers. We earnestly entreat these ladies not to lower the good reputation of their husbands, whose names we have delighted to honor, by connecting them in any way with these enterprises, and not to allow themselves to be made the instruments of extracting money from people who would not think of giving it but for the endorsement of distinguished and esteemed names. Give liberally to our country's defenders and their families, but do it directly—not \$1 to them, and \$4 for poor plated ware, and to the pockets of artful operators.

Manure Making by System.—Last month (p. 386,) we noticed the fact that Bommer's Patent Method for making manure was open to the public, and that we had a stock of the pamphlets describing the process for sale.—(See Book List.) We have received so many letters that we add: The description is in both English and German, illustrated sufficiently to give a clear idea of the process by which all kinds of herbaceous vegetable growth, muck or peat, in short all the litter and refuse of the farm may, with the addition of a certain quantity of animal manure, solid and liquid, on simple substitutes easily obtained, be converted into a rich manure.

Paintings, Engravings, etc.—To several inquirers in regard to objects of art, we will say that the largest and best retail stock in the city of these things, including beautiful carved work in wood, artists materials, etc., is probably at Knødler's (late Goupil & Co.), 772 Broadway, cor. 9th st. There is a fine picture gallery connected with the establishment, to which admittance is usually free, that is well worthy of a visit.

Large Flocks of Chickens.—

"A. C. H." Washington, Iowa.—We have never known of more than a few hundred fowls being kept in one yard in this country, and these large flocks did not do well more than a year or two. It is our opinion that, with ordinary care, when 25 or 35 hens and 2 or 3 cocks are wintered in one well furnished yard, and are allowed to hatch 300 to 350 chickens before the middle of June, that these may all be well cared for upon one acre of ground, and the chickens, say 250 to 300 of them, fattened for market. But even then we would plow this acre, a quarter at a time, once or twice during the summer, and the next year take a new piece of ground, and raise a crop on the first. With this practice we think a man might keep as many separate yards of fowls as he can devote land and labor to, allowing about 3 acres to each yard, and having conveniences to isolate diseased birds, if it is desirable to give them a chance for life. On some such plan great numbers of healthy poultry may probably be raised on the same farm.

Experience with Sick Chickens.—

Mrs. E. A. F. A., of Vincennes, Ind., writes in sympathy with Mrs. J. R. T., thinking the disease he describes on page 347 (October) is identical with one by which her poultry has suffered. She says she dissected many that died, and found in every instance the liver badly diseased. "We tried every remedy we could hear of without avail; as a last resort we shut them up in a light airy coop, and lost no more until we again let them run at large, when they again sickened, and we again confined them as before. This fall, after several weeks, we again let them out, when five took sick and died. Since then we keep them shut up, and they are in perfect health, and when we occasionally kill them for the table, we find their livers very different from the gangrenous things of those that sickened and died when allowed their liberty."

Barberry Seeds.—

T. Roselough, Douglas Co., Kansas. It is not necessary to sprout these. The seeds may be sown as soon as ripe, or they may be kept mixed with sand, in a cool place, until spring.

Plants Named.—

J. McNicol, Co. Bruce, C. W. The grass is probably *Elymus striatus*, a species of Lyme Grass, or Wild Rye.... H. F. Hyde, West Woodstock, Conn. Not a Cactus at all, but one of the very best Sedums, *Sedum Sieboldii*; a most valuable recently introduced herbaceous plant, as it is a late bloomer.... Doctor Lœffler, N. Y. The vine is *Boussingaultia basseloides*, commonly known as Madeira Vine, a useful climber with very fragrant flowers. The leaf is that of the common Pitcher-plant, or Side-saddle flower, *Sarcocolla purpurea*.... Wm. Warder, Pine Meadow, Conn. The Fringed Gentian, *Gentiana crinita*, and one of the most beautiful of our wild flowers.... R. Parnell, Queens

Co., N. Y. Apparently *Solidago latifolia*. Solidagos and Asters are not always certainly determined from fragments.... H. Stidolph, Jefferson Co., Mo. The Spider-wort, of which flowers but no leaves are sent, is probably *Tradescantia pilosa*.... N. B. B., Troy, N. Y. Apparently *Coronilla varia*, but pods too young to tell certainly.... Mrs. M. Beck, Litchfield Co., Conn. The annual is *Centrostegia macrosiphon*; the other is some *Zephyranthes*, but too much broken.... L. W., Johnson's Creek. No. 1 is like the leaf of *Artemisia vulgaris*, or Mug-wort. No. 2, the young growth of Red Cedar—or some such.... J. K. Leaning, Otsego Co. Some *Euphorbia*, which needs seeds for determination.... A. L. Child, Glendale, Nebraska. No. 1, an Aster, related to *multiflorus*, no telling without leaves. No. 2, another Aster, ditto. No. 3, ditto. No. 4, *Gentiana Saponaria*, Soapwort Gentian.—With the exception of a few specimens put aside for more careful examination than we can now give, we have named all the plants on hand that could be named, and the rest have gone into the rubbish basket, and we thus close up our botanical matters for the year. Now a word to the good friends who send us specimens. We do not keep a guessing shop, we cannot afford to soak out crumpled specimens. Such help as we can give in determining plants, is given cheerfully, but you must do your part, and give decent specimens. When the lower leaves of a plant differ from the upper ones, send one of them. We like conundrums, but don't care for them in the shape of plants, and hereafter shall not guess at the little snips that are sent. Very few have any idea of how much time may be wasted in trying to make out what would be plain enough, did the collector take a little pains to give us a leaf with the flowers.

Planting Chestnuts.—

S. Seymour, Rockford, Ill.—The nuts are difficult to keep and do best if planted in autumn. Plant in seed beds of light soil, not deeper than the thickness of the nut; then cover the bed with several inches of leaves, upon which a little earth may be sprinkled to keep them from blowing away. This closely imitates the natural sowing in the forest. Of course the leaves are to be removed in spring.

Marble-head Mammoth Cabbage.

—Mr. J. J. H. Gregory, of Marblehead, introduced this variety some years ago. He sent us one of the kind he buries for the winter to be used for seed raising next spring. The man of the Independent will please notice that this was a Cabbage and not a Cabbage Stump. We are glad Mr. G. sent only one, or there would not have been much room for anything else in the office. This head, divested of its outer leaves, measures 24 inches in diameter; weighs over 30 lbs.; is very solid, and is crisp, and sweet in the raw state; certainly a fine specimen.

Sundry Humbugs.—

Subscribers are continually writing to inquire about parties that have already been shown up in these articles. We cannot afford room for reprinting. Please look through the past numbers. Over 200 swindlers have been directly or indirectly exposed during the present volume.... After the continued hard knocks administered to the swindling fraternity, in every paper for a year past, we are half disposed to take a "breathing spell" for a month. We would very gladly drop the subject entirely, as it is always a disagreeable one; but somebody should do it, and until the press of the country generally shall help to open the eyes of the people, and cease to aid swindlers by advertising for them, we shall not shrink from the labor, at whatever cost of time, expense, and pleasure. If need be, a half column, or more, will be devoted to this subject in the numbers of the next volume, and our readers will, therefore, please aid in the important work, by keeping us promptly advised of all new circulars and other schemes that come to their knowledge. The reports for a month past, embraced in a peck or so of letters before us, we will not take up in detail, but give a few general hints covering most of them: 1st, Here are nine different gift enterprises, generally of a very plausible character, and well calculated to deceive the unwary, and even some intelligent people. The most dangerous of these are those got up *professionally* to aid wounded and disabled soldiers, or their wives, widows, or orphans. Concerts, tickets, gifts, greenbacks, houses, farms, pianos, watches, sewing machines, jewelry, etc., etc., are offered to subscribers in large amounts as bonuses, to be distributed by lot to subscribers to these charitable funds, of which, ostensibly, a large, but really a very small proportion, is *promised* to such funds. The daily, weekly, and illustrated papers, set up these schemes in large displayed type, and attractive form. The names of generals, and of men in high places, and their wives—generally obtained under false pretences, are used without any permission—or displayed in a way to make them appear patrons of these enterprises. We have looked into the machinery and operations, and mark our words, *all of these soldiers', soldier orphans' and widows' charitable festivals, concerts, etc., in which presents are*

promised by lot to subscribers, are frauds upon the community. There are at least a dozen on a large scale, throughout the country, and many smaller local affairs for monuments, etc. We speak not of legitimate fairs and festivals, but of all those where gifts, presents, etc., are offered for distribution. There are, universally, private parties who really manage them, and into whose pockets the main profits eventually go. This playing upon people's good intentions and kind feelings towards our soldiers and their families, is the meanest kind of *stealing*. These enterprises are *bona fide* lotteries, except in name, and the most disreputable of all lotteries—wolves in sheep's clothing. 2d, There are a score or so of purely gift enterprises, where, for a small sum returned for the tickets sent you, often professedly, but not really, at your request, you are offered a chance to draw, or have drawn, a prize varying from \$5 to \$100, or more. We have examined more than a hundred of these, and we here say that there is not one of all these ticket schemes, and gift enterprises that is not a fraud. Not one in a hundred of those who have sent their money for the tickets have ever heard from it, unless to hear the stalling falsehood, that it was "lost by mail." Some showy prizes, not really valuable, have been sparingly distributed as a bait to others, but the second crop invariably gets cheated, usually the first one too. 3d, We have closed up so many advertised medicines, and doctors for all sorts of diseases, that we are prepared to brand the whole tribe of advertising doctors as pernicious quacks. Not half of them can be found at the places they pretend to occupy. They get letters at these places at hours when you cannot catch them. 4th, "Agencies"—There are a large number of persons in this city, and elsewhere, offering by private circulars "agencies," some for one thing, some for another, and some for a variety of things, household apparatus, etc. A few of these are genuine; many are swindles, and some are about "half-and-half." It takes much investigation to get at the reliability and value of these concerns, and we advise extreme caution, especially when any money is required to try them. Our silence in regard to several recently inquired about, implies that they are bogus, or near to it, or of doubtful character. 5th, Eschew all "Art Associations." The "Michigan Art Association," with its only office in N. Y. City, is a fair specimen of many of them swindles. So is the pretended Masonic affair, at Medina, N. Y. Almost all are unmitigated humbugs. One or two, like the Crosby Art Association, may do what they promise, but how they differ from any other lottery is more than we can explain, except in accomplishing the same object in a meaner way; they add the "sympathy dodge." Beware of "One price watch companies," and of all watches by tickets; of "Howard" and all other benevolent medicine associations; of "American Jewelry Association;" of Ann Arbor \$2 tickets; of Jas. Pendergast & Co.; of "H. Camp, M. D., who insults respectable young ladies, by sending them circulars offering disgusting medicines," of all cheap sewing machine offers, etc., etc. P. S.—A villainous scheme just comes to light—a pretended Franklin Benefit Association in Chicago, claiming Gen. Wm. B. Logan as President.—It is impossible he could officer such a scheme. One Joo. L. Andrews of Ohio, writes to ladies offering for \$50 to tie them tickets through worth \$500?—A deep-dyed villain!

Mareschal Niel Rose.—An "Old Florist" objects to the engraving of this rose given in the November *Agriculturist*, which he says does not do justice to this splendid variety. With him the flowers were as large as those of any good rose, and the color—which cannot be given in an engraving—is as yellow as saffron, improving as the flower opens. Our engraving was from the only accessible material, a partly opened flower. It is not strictly a Tea Rose, but a Noisette, and is a runner, after the style of the Lamarque, and like that, adapted to planting out in the open ground of the green-house; treated in this way, it attains its greatest perfection.

Grape Vines Growing in Autumn. T. Bost, Hemepin Co., Minn., writes, that the leaves of his small vines were killed by frost in September, and that subsequent warm weather has started the buds for next year, and asks if this will hurt the vines. It will be apt to injure them, and the young vines will require care. It is probably only the upper buds that have started, and that good buds still remain near the ground. Prune back severely, and start a new cane from a bud near the base.

Irrigation—Windmills.—W. Hawkins and several neighbors, of Sayville, (State not given) are interested in the subject of irrigation. There are two plans, one to "pipe" the water 1½ mile, the other for each to dig a well and get a windmill and tank on the upper part of his land. The former plan would be very expensive for one man to do, but might do for several combining to lay a large pipe. The windmill plan is feasible, and yet another may be better. A well on high

ground will often furnish a supply of water which may be delivered by a syphon (a simple pipe extending from near the bottom of the well to a lower level on the slope of the hill,) at a tank or reservoir. Windmills for simple pumping are advertised at about \$150.

Page's Pump and Sprinkler.—We saw this new contrivance for throwing water at the Cleveland Grape Show, and it impressed us as being very simple and efficient. Some apparatus for throwing a jet of water is very handy in various ways, and if this one is found to work as well in the hands of every one as it did in those of the exhibitor, it will take the place of more expensive machines.

White Willow.—E. F. Dunne, writes from Humboldt Co., Nevada, saying: "Away out here, 'Where the wild sage-stems of the desert die, In the cold white marshes of alkali,"

we live, farm and read the *Agriculturist*, and have a better home than the writer of the quoted lines imagined. We raise, first crop on the sod, 1,500 pounds of barley to the acre, and sell it, in bulk, for 8c. per pound *com.* We are much exercised though on the subject of hedge-fences. Won't you tell us about that White Willow that Levi Smith writes to you of in September number, 1866. Where we can get it and how to manage it. Won't you put an item in the 'basket' for us?"—*Ans.* It is not hard to get the White Willow; almost any good nurseryman would send you the right thing, and once obtained, you could multiply it indefinitely in a few years. A few cuttings might be sent by Post. Your California nurserymen probably have it. But whether it will grow "in the cold white marshes of alkali," that is another question, which indeed you do not ask. Remember it bears several names, white, gray, powder, etc., besides the Latin, *Salix alba*.

English Market Measures.—In reading over the reports of the Covent Garden Market, one is puzzled at terms not in use in this country. We have been at a little trouble to look them up, and perhaps the result may interest others besides ourselves. *Pottle* is a long tapering basket made of shavings, and holding a pint and a half. *Punnets* are shallow baskets, varying in size for different articles; radish punnets are 8 inches across and 1 inch deep; those for mushrooms are 7 inches by 1; white salad punnets are 5 inches by 2 inches deep. A *Sieve* is a basket 15 inches in diameter and 8 inches deep, and holds 7 imperial gallons. The *half-sieve* holds 3½ gallons, and is 12½ inches across by 6 inches deep. The *Bushel sieve* is 17½ inches in diameter at top, 17 at bottom, 11½ deep; the *Bushel Basket* is at top 14½ inches, at bottom 10 inches, 17 inches deep.

Shades of Color in Outside Painting of Houses.—J. W. White, of Millin Co., Pa., asks:—"In painting a wooden house should the cornice, window-facings, etc., be of a lighter or darker shade than the body of the house? Also, should the panels of doors, window shutters, etc., be darker or lighter than the panel frames?" The colors appropriate to wooden houses are light ones of some agreeable neutral tint, avoiding all positive colors, and all dark colors. The cornices, base and corner strips, pilasters, door and window casings, etc., should be of a slightly darker shade than the body of the house. So likewise should the panel frames be a little darker than the panels.

The Illustrated Annual Register of Rural Affairs for 1867. By J. J. Thomas. Albany: Luther Tucker & Son.—Another volume is added to this series, and, like its predecessors, is a useful compendium of agricultural and horticultural matters. It is sufficient praise to say of this volume that it is as good as the previous ones, and is well worth the modest sum it costs—\$30 cents. We would gladly stop here, but one of its contributors has been guilty of an act that we cannot, and ought not to allow to pass unnoticed. Upon page 84 is "A Chapter on Various Practical Subjects." [Written for the Annual Register, by S. Edwards Todd.] This article contains nine illustrations; eight of these are re-drawn from the *Agriculturist* for 1865; and the remaining one is taken bodily and literally from a work of which we hold the copy-right—American Weeds and Useful Plants—without the slightest acknowledgment. The figures from the *Agriculturist* are re-drawn, slightly modified in one way or another, so as to avoid the copy-right. (Our original articles are paid for well, and every number of the paper is copy-righted in full, and not to be copied without credit.) The author of this article was, unsatisfactorily to us, for a short time employed to aid upon the *Agriculturist*, and he may possibly think that he has a right to illustrations drawn for some articles of which he made the rough notes. Other people think differently. We are quite sure that neither our good friend, the editor of the Register, nor its publishers, had any suspicion of the trick of which they have been made the victims. They paid for the article as new, and will feel chagrined to find

they have instead a re-hash of old matter that has already appeared in a widely-circulated paper, illustrated by figures that will appear old and familiar to a large proportion of those who may purchase the Register. The publishers have our sympathy, as they will that of all honest men.

Trouble with a Steep Path.—"A Subscriber" in Tennessee, who lives on a mountain side, finds that every hard rain turns his path into a gully, and wishes to know what he can put upon it, as stones wash out and planks warp. Perhaps a little engineering would turn the bulk of the water in another direction. In such a place we should try gas-tar and gravel, or sand. As much tar as will stick the sand together, will soon harden and make a durable and pleasant walk. If, as appears likely, the path is below the general surface, then the cement should be laid upon the sides of the depression, as well as to prevent the water from working under. Another plan would be to pave the foot way, and make very capacious gutters on each side of the pavement, and plaster them over with a mortar of water lime. The latter plan is followed in some portions of Central Park.

Hardiness of the Quince.—D. P., 3,000 feet up on the Catskills, wishes to know the probable success of Quinces in that locality. As he raises apples and pears, we doubt not that Quinces would succeed. Do not plant in low wet ground, give good and well enriched soil, and take care of them as if they were pet pears.

The Study of Geography, as usually taught, involves a great waste of time. The pupil struggles through a long list of names which his burdened memory refuses to retain, and many of which would be mere rubbish if retained, so far as any practical use is concerned. A new primary work by Miss Hall, published by Samuel F. Nichols, Boston, is a step in the right direction. By means of interesting reading lessons, accompanied with common-sense maps and illustrations, it leads the child to acquire information, and a relish for the subject at the same time. Teachers and parents will do well to examine the work.

"The Methodist" has made an important arrangement with Rev. Henry Ward Beecher, and other eminent clergymen, for a weekly sermon to be published in its columns.—See advertisement.

A New Map of N. Y. City and 1,200 square miles of the adjacent region, just published by the reliable firm of Messrs. H. H. Lloyd & Co., N. Y., gives a very complete view of the region, locating all rail-road stations with their distances from New York, the country roads, small streams, etc., more minutely and accurately than we have seen in any similar publication. It is a valuable work of reference.—Price \$5.00.

Documents Acknowledged.—The following catalogues of general nursery stock have been received: "The Evergreens," Saml. Edwards, La Moille, Ill.; Central Nurseries, Edward F. Evans & Co., York, Pa.; Thomas Wright, Rochester, N. Y.; Georgetown (Conn.) Nursery, Geo. Perry & Son; Eric (Pa.) Commercial Nurseries, I. A. Plattmann; Westbury Nurseries, Isaac Hicks & Sons, North Hempstead, L. I., N. Y.; Greenvale Nurseries, W. D. Strowyer & Co., Oswego, N. Y.; John Murphy, Dansville, N. Y.; South Bend (Indiana) Nursery and Fruit Farm, A. M. Purdy; Reading (Mass.) Nursery, J. W. Manning. "The three best Market Berries," Wm. Parry, Cinnaminson, N. J. Catalogues of Grapes from A. M. Burns, Manhattan, Kansas; J. M. McCullough & Son, Cincinnati, O.; H. B. Lum, Sandusky, O.; Holton & Zundell, Haverstraw, N. Y.; A. J. Hatfield, Niles, Mich. Catalogues of Bulbs, Seeds and Strawberries, Vilmorin, Andrieux & Co., Paris, France. Catalogue of Farm Stock, Dogs, Fowls, etc., S. & W. S. Allen, Vergennes, Vt. Catalogue of Edge Tools, Collins & Co., Hartford, 112 Water St., New York. Catalogue of German Periodical Literature (*Zeitschriften-Liste*), 1866, E. Steiger, New-York.

The Festival of Song.—This is a gift book, published by F. J. Huntington & Co., New York. It consists of choice extracts from ancient and modern poets, compiled by Frederick Saunders, Librarian of the Astor Library, and prefaced by a brief account of the authors. The work is splendidly printed and bound, illustrated with original drawings by leading artists of the National Academy of Design—some of which are really charming.

The "Golden Leaves Series."—These are neat volumes, containing selections from the best productions of the older British, modern English, dramatic and American Poets. The selections by J. W. S. Hows, seem to be made with taste and good judgment.

Heaves in Cows and Horses.—Lyman Pike, of Iroquois Co., Ill., writes: "In the *American Agriculturist* of October (page 317) I notice a case of a 'cow with the heaves.' I have never seen nor even heard of such a case before, but as I have been 16 years a practising physician, I think I can prescribe for the case. Horses having the heaves, on coming to the Prairies, soon get rid of the affection, and observation has proved that the cure is effected by rosin-weed (*Silphium terebinthaceum*). Of late the same article has been successfully used in the treatment of asthma in the human subject. May it not prove equally beneficial in the treatment of heaves in cows."—[There are several *Silphiums* all called rosin-weed, and possessing similar characters, and most probably they have like medicinal properties.—Ed.]

Bearing Calves without Milk.—In answer to our inquiry of last month, "E. S.," of Bedford, Mich., writes: "Calves should have the mother's milk until three days old, yet they can be safely reared on the following gruel: Take one tablespoonful of wheat flour, and a teaspoonful of salt; mix with cold water to a paste; stir the paste gradually into three pints of boiling water, let it boil a moment, and remove from the fire. As the calf increases in growth, increase its food, which must be given *blood-warm three times a day*. When a week old, give a lock of hay or fresh grass. When a calf, three weeks old, let it have a gruel of sifted corn meal—one teaspoonful of meal to three quarts water; boil thoroughly, and never omit the salt. A handful of young mullen leaves boiled in sweet milk will cure the scours. 'Their opposite' is relieved by half tencup of melted lard—poured down the throat—repeated if needful."

Pears at Hammondsport, N. Y.—On another occasion we have mentioned the remarkable immunity from grape diseases enjoyed by the region around Hammondsport. The locality seems to be equally favorable to the growth of other fruits. We saw in the grounds of J. W. Davis, Esq., President of the Urbana Vine Co., several trees of the Virgalieu, loaded with fruit without a spotted or cracked specimen to be seen. That the pears were as good as they looked, we know from some specimens forwarded to us by Mr. Davis.

Buere Clairgean Pears.—If a handsomer plate of pears can be shown than one of Buere Clairgean, that has graced our table for a week past, we should like to see it. The specimens were from Ellwanger & Barry, the well-known Nurserymen, of Rochester, N. Y.; they were so brilliant in color that many supposed them to be artificial. For quality, this variety cannot rank in the very first class, though we do not mean to say that it is bad, or even indifferent; it has a fine flesh, is sweet, but is rather lacking in spirit. Still its good size, great beauty, and the abundance with which it bears, combine to make it one of our most popular varieties.

The Tilden Tomato.—In the October "Basket," we stated that our own experience with this variety, as well as that of our neighbors, was to the effect that we had the wrong sort, or that the variety had been over estimated. Specimens from Mr. Tilden, Davenport, Iowa, Mr. Henry A. Dreer, Jr., Philadelphia, and reports from many correspondents, convince us that the Tilden tomato, as they grow it, is really a good thing—as good as need be—regular in shape, solid, few seeded, and of excellent flavor. We have either had the wrong sort, or the soil was not suited to this variety. The weight of the testimony received is decidedly in its favor.

Fine Cranberries.—"Are those Lady Apples?" asked a stranger on seeing a dish of cranberries on our table. We do not wonder at the mistake, for they were the finest cranberries we ever saw. They came from Mr. Orin C. Cook, South Milford, Mass.

Chestnuts and Horsechestnuts.—"Enquirer." Whoever told you that the large Spanish Chestnut was produced by grafting the common Chestnut on the Horse-chestnut, simply told that which was not true. The Horse-chestnut is in no wise related to the common Chestnut, any more than the Pineapple is to an Apple, or a Prickly-pear to a Pear, and there is not the slightest chance of the one growing if grafted on the other.

The Madras Radish.—*Raphanus cundatus*.—We scarcely open an English horticultural journal but what we find the merits of this thing discussed, and have several times seen it figured. It is a radish, the root of which is worthless, but is grown for the pods, which are 12 to 15 inches long, according to the soil. While some say that the pods are palatable when cooked like asparagus, others consider the thing worthless. We grew it some six years ago, found the pods a great deal

longer, but no better than any other radish pods, and discarded it as of no use. As the plant is making some stir in England, and may be again imported, we give our experience with it.

The Philadelphia Horticultural Society.—Mr. Henry A. Dreer, Jr., Treasurer, has sent us a photograph of the new Horticultural Hall now being erected in Philadelphia, with a description of the building, which will be of a size ample for the purposes of the Society, and of a style that will make it an ornament to the city. We look upon this picture with mingled pleasure and mortification. It is gratifying to know that Philadelphia has a Horticultural Society so thoroughly alive and prosperous as to need a spacious and elegant edifice, and we wish them the continued success. Our mortification is, that we can point out no temple in New York devoted to Flora and Pomona. In the very center of one of the largest gardening communities of the Continent, we have no Society to encourage the amateur, and no place to which the originator of a new thing can go for an endorsement. All other arts and sciences have a home, but Horticulture is shut out of New York as strictly as if it were a pestilence.

Insects and Plant Fertilization.—The concluding article of this series appears in the present issue, and in behalf of those who have read them with interest and profit, we thank their author for them. The facts that have been presented in these papers, have an interest to all who grow plants, while to the merely curious in natural phenomena, they open a new field of observations, which we doubt not many will improve. It is proper to add that these are from the pen of Dr. Asa Gray, of Harvard University.

Practical and Scientific Fruit Culture.—By Charles R. Baker. Boston: Lee & Shepard. In August last we gave a notice of this work, and should not recur to it now but for a conspicuous advertisement, in which the publishers see fit to make the following statement: "The publishers have the pleasure to announce a new edition of this elegant and popular work, which, according to the expressed judgment of candid and unbiassed critics in England and America, evinces the most extensive research, observation, and experience, and which has also excited the fears of rivals."—This statement is followed by several quotations, mostly from political papers. The above implies that those who have criticised this work adversely, were neither "candid nor unbiassed," and reflects upon every one of our horticultural cotemporaries, who are supposed to be at least as qualified to judge of a pomological work, as the literary editor of a daily paper, and not one of whom but is ready to welcome any work that shows merit or promise. There never was a work upon horticulture so severely and justly criticised as this has been in this country; it may be true that it has been praised in England, for so much of it is quoted from English authors, that it must have to the English critic a very familiar look. As long as the publishers see fit to advocate this book on what merits it may have, we have nothing to say, but when they seek to prop it up by unfair innuendoes, we suggest that they are taking a course that will not be likely to accomplish what they seek.—If any of our readers desire to see how a large work can be made by "extensive research" among the writings of others, let him invest \$4 in Baker's Practical and Scientific Fruit Culture.

Snails or Slugs in Cellars.—One who has waged an unsuccessful war upon snails (slugs) in his cellar for many months, asks if some one who has been similarly annoyed and has succeeded in getting rid of the pests, will give through the *Agriculturist* the means employed.—The slugs or soft snails vary in size from an inch long to the size of a man's finger, and leave their slimy tracks everywhere on walls, vegetables, utensils, etc., and when cleaned out, soon re-appear. We should think a free use of slaked lime would cure the evil, but trust to hear from the experienced.

Langstroth's Bee-Hive—Patent Extended—Important to Bee-Keepers.—Mr. Langstroth has devoted a good part of his life to the study of bees—and the bee-keepers of this country owe much to him. His invention consisted in having moveable frames to which the combs are attached by the bees so placed in the box hive as to have the tops of the frames, in whole or in part, separated from each other, with a narrow open chamber above the frames, and narrow spaces also on each side—so narrow that there is not room for the bees to build combs in these spaces, which will practically interfere with the removal of the frames. This gives ability to remove the frames and combs at pleasure. Mr. Langstroth patented his invention in 1852; it was re-issued in 1863; and just before its expiration (a few weeks

since), it was confirmed, and extended for 7 years. This extension inures to Mr. Langstroth's benefit, and not to those who have received rights or privileges from him, except so far as he chooses to renew their privileges.

The invention of this moveable comb hive has wrought a complete revolution in bee-keeping, the progress of which has been greatly accelerated by its aiding so much the introduction and dissemination of the Italian bee. Within a few years past a great many (not less than 30) moveable frame hives have been made, which, unless licensed by Mr. L., are infringements upon his patent. It has been currently stated, and believed by many, that Mr. L.'s patent was worthless, from having been anticipated in Europe, or in this country. On account of these statements boldly made, and endorsed by some prominent journals, Mr. L. applied for a confirmation of his patent and reissue in 1863, and as he found the Patent Office library very deficient in works on bee-culture, he brought his extensive collection of works, chiefly European, bearing on this subject, with him, for the assistance of the examiners. We learn that his claims to originality were thoroughly established. As he has realized comparatively little from his invention, he applied recently for an extension of his patent. In this he was vehemently opposed, and much evidence was taken. The Chief Examiner in his report to the Commissioner of Patents stated that the testimony of those opposing Mr. Langstroth was so contradicted by their own letters and published works, as to be "unworthy of consideration." The decision of the Examiner was appealed from, and a hearing was had before the Commissioner in person, who confirmed it, granting the extension. Mr. Langstroth's claims are therefore fully established, and all who wish to use moveable comb frames on his principle, will have to apply to him for the right to do so. This he proposes to grant on very reasonable terms.

Medicines for Plants.—We don't believe in them. One has a patent for peach-curl, another keeps out borers by putting some compound in the crotch of a tree. The efficiency of these preparations is certified to by people who doubtless think they are doing the public a service, but they are not known out of their own neighborhood as horticulturists. We wish no advertisements for plant medicines for this journal.

The Forest Tree Cultivator.—By Andrew S. Fuller. New York: Geo. E. & F. W. Woodward. In whatever comes from Mr. Fuller's pen, we look for a certain amount of practical value, and while in this respect we are not disappointed in the present treatise, we cannot help regretting that he did not make it a more exhaustive one. The work is mainly devoted to the cultivation of our native trees, and will be found a useful guide to the tree planter. Price by mail \$1.50.

Woodward's Rural Art.—This is the first volume of what is intended to be an annual of Architecture, Landscape Gardening and Rural Art. It is a neatly prepared volume, containing 58 designs of dwellings of various styles, out-buildings, plans for laying out small places, etc. Published by Geo. E. & F. W. Woodward, We send it by mail for 75c. in paper, or \$1 in cloth.

Bulbs: A treatise on Hardy and Tender Bulbs and Tubers, by Edward Sprague Rand, Jr. Boston: J. E. Tilton & Co. A volume of about 300 pages, that includes the common as well as the rarer plants usually called bulbs. As far as we have been able to peruse it, the directions for culture are plain and practical, and we doubt not it will meet a want long felt by amateurs. The book is produced in very handsome style. Price \$3.00. We shall keep it on sale, and to send by mail.

Artificial Honey—The Best.—We have from time to time published various specifications for making sweet preparations that resemble honey; and some of which answer very fairly as substitutes for that article. Indeed, some people prefer the manufactured to the natural. Every now and then some chap gets hold of a recipe, and fixing up a glowing circular, persuades sundry trusting people to pay him from 25c. to \$5.00 for his "secret," or "patent," or "copy-right."—To find him out we paid one of these fellows \$2 for a "right" to our own previously published recipe.—Here is a recipe which we guarantee to make an article equal to or superior to any of the dollar or five dollar recipes offered. Put 10 lbs. of white sugar in 2 quarts of water, and gradually heat it, stirring it occasionally until brought to the boiling point. Then remove from the fire, and add 1 lb. of real honey. When half cooled, add $\frac{1}{2}$ lb. more of honey, and when only blood warm, add another $\frac{1}{2}$ lb. of honey. When nearly cold, add 10 drops of good essence of peppermint. This makes 16 lbs. in all of a very pleasant sweetening. Its flavor can be varied to the liking by adding less or more peppermint essence.

Make the Frost Aid You.—Few are aware of the beneficial effects upon all kinds of soil, and especially upon heavy land, of a thorough freezing and thawing. Eight cubic feet of water in freezing, swells to nine feet at least. Soils filled with water expand in the same way. The water dispersed all through the pores when freezing, cracks and pulverizes the soil, and fits it for plants, and releases much plant food. This freezing also kills many insects, insect eggs, and weed seeds. It is wise, then, to plow fields and spade the gardens into ridges and furrows in Autumn, so as to let the frost down as deeply as possible. This can be done at any time before the ground becomes solid. If so wet that it packs, the freezing will lighten it up again. The operation pays well. If ground be left in ridges with deep dead furrows or ditches, it will drain and dry off, and become warm a week or two earlier in spring, which is an important gain for the cultivator at that season.

Coal Tar as Paint for Houses.—"J. T." writes from Madison, Ind., "to the question: 'Is coal tar good paint for the outside of a small house?'—You answer, 'yes, if you like a black house.' I would answer, yes for either a small or large house. A good paint that will outlast any oil paint, on either wood or brick, and not be black either, can be made with coal tar."—In whatever way "J. T." modifies the color, we presume he cannot avoid having it very dark, and this we decidedly object to for dwelling houses at least, which should be of a light cheerful color, if of wood, or of a natural stone color, if of brick or concrete.

What a Young Man Did.—We were pleased, on more than one account, by a recent call from a young man in Putnam County, a farmer boy student, we believe. Seeing our premium offers he started out, and in about four days work, all within a week, he obtained 157 subscribers to the *Agriculturist* at \$1.50 a year. His call was to bring in the names and order his premiums, viz.: the 16 volumes of Appleton's *Cyclopedia* and the Tool Chest, which were promptly furnished. He is thus well equipped for *mind* work and *hand* work. (The *Cyclopedia*, \$80, and the Tool Chest, \$14.50, or \$124.50 for four days work, is pretty good pay—it would pay well for forty days work.) Why may not you, reader, and hundreds, yes, thousands of others do the same thing. There are in our country more than ten thousand different Towns, which each contain more than 157 persons who would afterwards be grateful to any one who should persuade them to subscribe for this journal for 1867.

Butter Costs More than Flour.—After some inquiry, we estimate that in a family of ten persons, including two or three children between three and eight years old, a barrel of flour lasts 36 days. This is nearly the general average, of a barrel of flour a year for each full grown person. The same family (of ten) consumes an average of 1½ lbs. of butter per day, or 2 ounces each, including that used in cooking. The average retail price here, for good articles, has been for some time past, about \$16 per bbl. for flour, and 50c. per lb. for butter. (Both are higher now.) At these figures, it takes \$22.50 worth of butter to use up \$16 worth of flour—or an excess of \$6.50, equivalent to full 40 per cent. If we reduce the butter to 1 lb. per day, or 13-6ths ounces each, its cost will still be nearly 20 per cent. greater than the flour. This proportion will hold good throughout most of the country, as the relative prices of flour and butter are about the same as here.

Why the Best Flour is Cheapest.—Two dollars extra on the price of a barrel of flour, will secure a much superior quality. Any one who will devote a little observation to the subject, will notice that with poor bread, people eat from ¼ to ½ more butter than they do with that which is of superior or extra quality. If we reckon ¼ more, it will be seen by the calculations of the preceding item, that \$2 saved in the price of flour involves \$5.62 more expense for butter, or for other condiments to make the poorer bread palatable.

Beware of Advertised Recipes for Ink, Paint, Vinegar, Honey, etc.—We notice a good many of these advertised in newspapers and by private circulars, at from \$1 to \$5 each, with promises of wonderful profits to the purchasers. One editor offers as a premium for new subscribers, an ink recipe by which "you can make hundreds of dollars worth of splendid ink, in a few minutes, for less than half a dime per gallon!" All of these advertised recipes have been published in the *Agriculturist* this year, with no patent or copyright to prohibit their general use. We have also published the vinegar and honey recipes. So don't give \$1, \$2, \$3 or \$5 to somebody who sets up a claim for their exclusive use. The Recipe of the "Great American Paint

Company" which we have referred to. (Aug. p. 278, and Nov., p. 389), has turned up. It amounts to fresh slaked lime with about 1-6th its weight of salt, and 1-6th its weight of sugar, mixing it with milk, and adding ¼ of its weight of Spanish whiting for white paint. For other colors, use, instead of the Spanish white, some yellow ochre for straw color, chrome yellow for lemon, indigo for lead or slate, chrome green for green, etc. The amount of these, and the mode of mixing, are not stated. For implements, use linseed oil instead of milk. (What say practical painters to mixing fresh slaked lime with linseed oil?) This is what we got for \$1 paid to the so-called "Great American Paint Company," by way of investigation.—The "Company" don't claim any "patent," but only say "copy-right applied for."—[Mem: Club subscribers will please credit us \$1 for this information, which is all they will get from the said "Company" for the same money. So we end the year square; you paid in \$1 and we return it here—throwing in the year's papers.]

Preparation for Leather.—The "Shoe and Leather Reporter" translates from the *Gerber Courier*, the following recipe for a preparation which is said to be excellent for boots, harness leather, and belting, giving pliability, softness, and consequent durability: Melt 7 ounces of lard, add 1 ounce rosin, and stir well together when both are melted. In another vessel dissolve 3½ ounces of good hard soap in a quart (or 2½ pounds) of clean rain water. When dissolved and heated to the boiling point, add the prepared lard and rosin, boil gently a few minutes, and it is ready for application. The preparation is easily and cheaply made, and will doubtless render the leather pliable, even if it does not turn water, of which we are in doubt.

What we Saw.—On one of the coldest mornings of November, when the sterner sex were glad to wear gloves, thick overcoats well buttoned up, and not a few had winter caps on, well down on their ears, we saw a well dressed lady belonging to a well to do family, get out of the cars with a gentleman, and walk off through the cold wind, *bonheaded!* (There was something flat lying on the crown of her head, but it was so small we could not tell what it was.) A friend at our elbow said she was a *fashionable* lady.—We guess so.—[Mem. (from our note book): Hadn't we better open our advertising columns to the latest patent medicine, *consumption curing genuises!* Where's (Rev.) Edward Wilson, and the other such like humbugs?—The "catarrh" humbug medicine dealers may increase their stock, too, for the present fashion will largely increase this disease, and those who catch it, because they will conform to fashion at any cost or risk, are foolish enough to patronize such pretenders.]

Fastening Pencil Marks.—It is often desirable to prepare pencil notes or marks so that they will not rub off readily. A thin solution of gum arabic in water, or shellac in alcohol, applied with a soft brush, will do it effectually. But this is not always convenient, as when one is traveling, or at a library, as at the Astor Library where no ink is allowed in the reading room. Rev. I. L. Langstroth, the Bee man, writes us that a little saliva applied with the tongue or otherwise, over pencil notes, drawings, etc., will cause the lead to adhere so firmly that it will not come off without friction enough to injure the paper surface. He has used it for over 16 years with decided satisfaction, and thinks that, though a simple thing, it is very useful to know, and he has met with no one else who understood it. We have often used it for 25 years, but it did not occur to us that it was not known by everybody until reminded of it by Mr. L.

Ink—Vinegar—Humbugs.—Mr. Chas. C. Kulp, of Montgomery Co., Pa., sends the copy-righted, printed recipes, which some chap in Biddeford, Maine, is selling at a high price, claiming that they came from Brazil, that he has refused \$5,000 for the "right" to make them in New York alone, etc., etc. Mr. Kulp sends us recipes for the same things copied from his old scrap-book where they have been at least ten years, and they are almost identical with those which this Maine fellow has dug up, and is now selling to agents and others. We may add here, that many of the advertisements for "agents" at "\$100 a month," "employment at \$150 per month," etc., are from parties who have got some old recipe, quite likely taken from the *Agriculturist*, and giving it a new name, they persuade agents to undertake its sale as something of great value. A fellow recently advertised for agents, sent applicants a long circular to persuade them to buy a honey recipe, and rights to make it at \$5 each, and to all green enough to send him the \$5, he returned a sugar-honey, or artificial honey recipe, which we published many years ago with a caution as to its value. He probably got it from our columns.—Here

are Mr. Kulp's old recipes; purchasers of the Maine operators "right" will see that they are almost identical with those which have cost them \$2 to \$5.—VINEGAR: 40 gallons water, 1 gallon molasses, and 4 lbs. acetic acid, mix and let it ferment until it is strong vinegar.—INK: (a) 1 gallon hot water, 2 ounces extract logwood, ½ ounce bi-chromate of potash. Stir together and let it stand to settle, and strain. (b) Dissolve ½ lb. extract logwood in 5 gallons hot water, and add ½ ounce bi-chromate of potash; stir for a short time. Five gallons cost 25 cents. These recipes copied from a very old scrap-book, are as good (if good at all) as the \$5,000 recipe of the Maine man.

How they Cook Grouse in the Rocky Mountains.—An old prospector in the Rocky Mountains, writes us: "Perhaps you would like to know how we live out here. We are govrmands—Venison, bear meat, Grouse and trout, are our every day food. How do we cook? I'll tell you, and you'll say you have never eaten a Grouse if you take the trouble to try it. First, shoot your bird, and as soon as you pick him up, bleed him by an insertion of your penknife into his jugular. Being in camp for the night, dig a hole in the sand about 1 foot deep, and build a fire in it. When it is thoroughly heated leave it about ¼ full of coals, which cover well with ashes or very dry sand. Make a paste of mud or clay, in which encase your bird, leaving the feathers on, to the thickness of ¼ of an inch or so, and lay him in the hole, covering with ashes and coals, and filling up with dirt. After ¼ of an hour, dig him out, and give him a rap on the ground, when the casing will fall off, taking with it feathers and skin, and leaving you the Grouse cooked in his own juices. Eat with 'hard-tack,' and tell Delmonico you have dined elsewhere. Perhaps I'll tell you how to cook a trout some day."

Cooking Salsify, or Vegetable Oyster.—We hope many of our readers have a liberal supply of this vegetable, or will have another year. It is grown as easily, and just like carrots or parsnips, and if rightly cooked affords a very agreeable dish, especially in spring. It is all the better for standing in the ground, as it grows all winter, although we usually take up late in autumn a quantity for winter's use, and pack it in boxes of moist sand in a cool cellar. We clean the roots well, cut in short pieces, boil tender, drain, salt it, add a little salt codfish picked very fine, and butter, thicken with a little flour and milk, and pour it over toast.—C. W. C., Howells, Orange Co., N. Y., writes: Wash and scrape the roots, cut in thin slices, boil in a little water until soft; pour off the water and mash the roots fine. Season with salt, pepper, butter, and a little cream.

Hop Culture.—Preston Miller, Dauphin Co., Pa. It is not practicable for us to reprint articles on special culture. In March, 1865, we published a prize essay, and have since issued a pamphlet (see Book-list) that contains about all that is known on the subject.

Our Rocky Mountain Friend on Trout.—"I promised to tell you how to cook a trout. You think you've caught trout in the streams that run among our dear old Green Mountains, or down the slopes of our Berkshire hills, but you must come out here to see the real fish. Every one you hook, from 15 to 22 inches long, and as gamey as the shiest that hid himself under the old stump by the Alders, near home, years ago. There! you've landed him. Stick your knife in the back of his neck, and slash his gills the first thing. (Always bleed your fish as soon as you land him, it makes his flesh hard.) When you are ready for your supper, make a small incision at the throat, and draw the entrails. Then fill him up with a wedge of fat pork or bacon. Wrap him in several thicknesses of paper, well wet, (oak leaves will do), and lay him in the hot ashes, covering him well with ashes and coals. Leave him for from 20 minutes to ½ an hour, when you may unearth him, and eat with whatever accompaniments you may have. The first thing you'll do next morning, will be to go fishing.—There are other ways to cook him, but when you've eaten this fellow you won't care to know them."

Who Eats Sparrows?—These little birds are found, by the Maltese and Italian, to be most epicurean. They are best in the fruit season. Find a tree in which they roost, and by burning a little sulphur under it you may bag any quantity. Pluck and clean them. Lard them, or better still, pin across the breast a very thin slice of pork. Wrap them in young grape leaves, and put in the oven. When cooked, serve up in the center of a dish of boiled rice. Cover well with a rich tomato sauce. The grape leaf will furnish an agreeable accompaniment. Other small birds are deliciously cooked in the same manner, and it may be particularly recommended for the "Reed birds" of the Delaware and Potomac, and "Rice birds" of the South.

The Ohio Pomological Society will hold its annual meeting at Zanesville, O., on the 4th, 5th, and 6th of the present month, (Dec.) The fruit growers of the Muskingum Valley propose to show those who come, some fine collections. There will be various reports, discussions, and a good time generally; besides a "visitation of orchards," which may be a very good thing to have for ought we know. We advise those of our eastern fruit growers who have never been to a western "fruit fight," to go and see the vim that these Buckeyes and Hoosiers put into their meetings, and when they come home not to forget to bring a little of the heaven with them.

An Abridged Manual of Grape Culture and Annual Catalogue, by J. H. Foster, Jr., Pomona's Home Nurseries, West Newton, Pa.—Formerly, a nurseryman's catalogue was simply an enumeration of the stock on hand, but within a few years they have taken the form of a manual or hand-book. The one of which we have given the title, contains quite full and well considered directions for the cultivation of grapes and other small fruits. It modestly enough does not pretend to exhaust the subject, but refers those who wish to know more, to larger treatises.

Fruit Growing for Stock Feeding.—George Neff, Monroe Co., Ohio.—If apples are abundant, and you have not help sufficient to gather them for market, or to make them into cider, it will of course pay to feed them to hogs, especially if they are sweet ones. Good, rich, early winter or late fall apples of high-toned yet subacid flavor, make the best cider, though a large admixture of sweet apples is no disadvantage, as it adds strength. So much for the general policy of raising apples to feed hogs—the least profitable way of disposing of them, provided you can do anything else with them. Perhaps some of our readers will give Mr. Neff, through the *Agriculturist*, their notions of the best way to feed apples to horses, cattle, sheep, or hogs, cooked or uncooked, with corn meal or other grain.

Osage Orange.—"Subscriber."—This will, no doubt, succeed in southern Pennsylvania. Seed is sown in spring. We cannot specify any particular seedman. All the principal dealers have it.

Good Books Pay.—Take any good book you please, for illustration. Let it be the "American Farm Book," for example. This contains a large amount of information, the best the intelligent author could collect, at the time it was written, by many months of careful thought and work. It discusses soils, their kinds, peculiarities, treatment, the various crops, describing each with engravings showing the plants themselves, the kinds of soil and manures best adapted to them, harvesting, etc. There are 323 pages of these thoughts and hints. Any one can, for \$1.50, have this book delivered to him at his own Post Office. Now we say, unhesitatingly, that there is not a cultivator on the face of the earth, no matter how experienced or skillful, or how ignorant, if he can read at all, who could take this book, and read it through, without getting hints, and having trains of thought started, that would, in the end, bring many times \$1.50 profit on the same amount of hard work. Take Herber's Hints to Horsekeepers," costing \$1.75. No man owning a single horse can read that book, without getting hints that will make the use of that horse worth \$5 to \$50 more to him in the long run. The same reasoning applies to almost every book in our whole list (p. 426.) The truth is, one man's success beyond another's depends largely upon his *intellect*, his better understanding of his business, his better planning of his work, etc., and everything a man reads about his business, is disciplining and strengthening his mind, and furnishing material for thought. The more he reads and thinks, the better will he practice, and the better will he make his work pay. The above is a money view of the subject. There is a higher one. The more a man understands of the objects of his toil, the soil, its nature, the crops, their varieties, peculiarities, etc., the more he has to think about while at work, the happier he is, and the more elevated in the intellectual scale he feels himself. The influence upon the minds of his family, of his sons, and his daughters too, of having books to read that give character and dignity to their occupation, and awaken interest in it, is of great importance. So, we say, let cultivators and mechanics get and read all the books they can treating about their business. One acre less of land, put in good books, will make the rest of the farm pay much more profit.

Good Papers also Pay.—The above reasoning in regard to books, applies still more forcibly to good periodicals, that come to us fresh from month to month, and bring information up to the latest dates.

Mark All Subscriptions sent in, as New or Old.

TO-DAY

YOUR SUBSCRIPTION EXPIRES—unless it be one of the many thousands which have already been paid up for next year. (The reader will know how that is.) If it is yet to be renewed for 1867, it can usually be done as well

TO-DAY

as at any other time.—More than 100,000 subscriptions are still to be renewed, and reentered on our books. We want our old experienced clerks to do this as far as possible. It will be a *very great convenience* to us to receive renewals and new subscriptions the first of December.

We can then arrange the names properly on the entry and mail books, write the wrappers, and send off the January number in due season. If, therefore, it be at all practicable, please send in your renewal, and any new names ready,

TO-DAY.

We trust it is needless to urge any reader to subscribe again. The present Volume speaks for itself. Its 452 ample pages, its multitude of Engravings, large and beautiful, its great amount of carefully prepared reading matter, its constant efforts to guard the interests of its readers, are more persuasive than anything the Publishers can say here. For the *Next Volume*, we can confidently promise even more. Increased experience and enlarged means and facilities will secure this. Every thing that untiring industry, and expense can do, will be done to make the first volume of the new Quarter of a Century one of extraordinary value to every reader. Among other plans, we shall for volume 26 expend over

\$20,000

in procuring reliable, instructive, practical reading matter, and valuable engravings alone; *in addition* to the usual heavy cost of paper, printing, mailing, office, clerk-hire, etc., etc. The *best* information and illustrative engravings must and shall be obtained. Now, then, *every* subscriber will himself receive the full benefit of all this outlay of labor, thought, care, and money, for the whole of 1867,

FOR ONLY \$1.50.

Or, for \$1.25 if in Clubs of Four to Nine;
Or, for \$1.20 if in Clubs of Ten to Nineteen;
Or, for \$1 in Clubs of Twenty and upwards.

THE AGRICULTURIST is thus supplied to subscribers at just about the present cost of its printing paper and mailing. (The number of subscribers is so great that good advertisers willingly pay all the other expenses and profits.) Will it not be a favor to your friends and neighbors who do not know the fact, to explain to them where they can obtain so much for so little money? If so, please give them the information, and thus confer a favor both upon them and us. We want every body to have this journal who will be benefited by it.—As it will so greatly aid our work in this, our busy season, we again ask as a special favor, to have the renewals of subscriptions and new names, whenever convenient, sent in

TO-DAY

CLUBS Can at Any Time be Increased, by remitting for each addition the price paid by the original members, if the subscriptions all date at the same starting point. Or, the rates may be *decreased*. Thus, for example, any one sending 10 subscribers for \$12, may afterward add 10 names more for \$8, that is, 20 subscribers for \$20, and so of other club terms. Members of the same club may receive the paper at different Post-Offices. In Premium clubs are included all names sent by one person at different times, and from different places, if for the same volume of the paper, and if each list of names is marked "for premium," when sent in.

Receipts for Subscriptions Not Given.—It would be an immense work to send receipts for a hundred thousand subscribers. The paper is only sent so long as subscribed for, and its receipt is an acknowledgment that it is paid for. Those subscribing at the Office desk, will receive receipts when desired. Any one sending a subscription by mail, if particularly desiring it, can have a receipt returned, by enclosing a ready directed post-paid envelope, to forward the receipt in. A three-cent letter stamp is required on such envelopes.

A Gift Often Repeated.—Many this month send some token of regard to a son, brother, relative, friend, or neighbor. Will not the 26th Volume of the *Agriculturist* often be a most acceptable Gift? While appreciated at first, each successive number, as it comes through the year, will remind the recipient of the giver, and we are sure the volume will contain many things that will be pleasing as well as useful. In such cases of gifts, when desired, we will enclose in the first number forwarded, a subscription Receipt, noting on it the name of the one who paid it, as well as the name of recipient.

Bound Volumes—Covers for Binding.—As soon as this number is mailed, we shall bind up a supply of copies of this volume (25th), ready for those desiring them. They are bound in neat black cloth covers, with gilt title, complete index, etc., all in our regular uniform style. Price per volume \$2, or \$2.50 if to be sent by mail. Any of the previous nine volumes (6 to 24) furnished at the same rate. The volumes are supplied *unbound* for \$1.50, and 24 cents extra it to be sent by mail. Any single numbers, from No. 120 to No. 239 (Vols. 16 to 25, inclusive) supplied at 15 cents each. We print clean, new numbers, as needed, from our electrotype plates of these volumes.—Volumes sent to the office are bound in our regular style for 75 cents each, and missing numbers supplied at 12 cents each.—We have the regular form of Binding Covers or "jackets," for the above volumes, into which any book-binder can easily insert the numbers, and bind them at small cost. Price of covers 50 cents each; or 60 cents if sent by mail. See p. 426.

What is your P. O. Address?—It is strange indeed, that so many people omit their P. O. and State. We have received hundreds of letters, of which the following are examples: T. J. J., writing, wanting an early answer. His letter indicates "Mercer" inside, but is Post-marked Henderson. No State or date. Somebody sends us \$50, with names of subscribers to correspond, but there is no signature, and nothing to tell us from which of 20,000 Post Offices it came. We will keep it until somebody sends us for not sending on the papers. One man sent us a subscription letter and has complained three times, the last time bitterly, because we did not even respond; but not one of the four letters gives us any clue to his State. Will be please tell us both his State and Post Office, definitely. Here are envelopes directed to us, each containing money, but not a scrap of paper or writing. They are Post-marked: Pittsburg, Bath, Marlboro, etc. These are samples of sturdy letters now in waiting.—AGENTS: If changes are to be made, we *must* know where the paper previously went, before we can transfer the address.

Clubs of Subscribers need not all be at one Post Office.—The reduction in price to clubs of four or more names, is partly made to encourage the getting up of large lists, and partly because it costs much less to mail a large number in one package. But we do not object to names added from other Post Offices, as such names usually soon become centers of other clubs. Names for Premium lists may also be gathered at any number of Post Offices, if all are sent by the same person.

Save the Index Sheet.—To save cutting out the threads, we print the Index and Title page of this volume on a second extra sheet, and put it in *loose*. Though more liable to be lost, it is in this form all ready to place in front of the January number, in stitching or binding the numbers of the volume. Some simple methods of doing this are explained and illustrated on page 439.

AMERICAN AGRICULTURIST.

ORANGE JUDD & Co., Publishers, 41 Park Row, N. Y. City.

ANNUAL SUBSCRIPTION TERMS (always in advance): \$1.50 each for less than four copies; Four to nine copies, \$1.25 each; Ten to nineteen copies, \$1.20 each; Twenty copies and upwards, \$1 each. Papers are addressed to each name.

Now for the Premiums In Earnest.

Canvassers for our excellent Premiums have been busy, but thus far mainly out on the "skirmish line," picking up new subscribers, of which about 25,000 have already been gathered, entitling the canvassers to nearly \$5,000 worth of desirable articles. Now begins the heavy campaign, as over 100,000 subscriptions expire with this number. The renewals of any of these when gathered by canvassers will count in their premium lists along with the new names already sent in, and those hereafter furnished. A little thorough energetic work now will gather names enough in almost every town to secure one or more of the valuable articles named in the table in next column. (For description of these articles, see October Agriculturist, or send for a printed Premium Descriptive List, which will be sent free to all applicants.)

Anybody can get a premium. Even if half a dozen start a club in the same place, there are usually people enough to furnish a premium club to each. Many small country towns and villages have 50 to 250 subscribers.

Most of those who have sent in premium lists thus far, have written in enthusiastic terms. Many have earned from \$10 to \$25 a day, in just such articles as they desired. See "what a young man did," on page 424.

Read Again the "Six Suggestive Questions" which were printed on page 384 of the November Agriculturist.

Note the bordered column, on page 425. Please let us have the names as fast as gathered. There will be a rush of work, at best, towards the end of the month. Send along the names now, and take any desired time to increase the list for a large premium, or more than one.

You can hardly Promise too much for our next volume. It shall be worth many times its cost to every subscriber, whether living in Country, Village and City.

The Paper is Good; the people are to be found who want it; somebody can get splendid premiums for finding them: may it not as well be you, as any one else?

Over 8000 Persons have obtained good premiums in past years, and many hundreds have already secured them this year. There is plenty of room for others to do the same thing. We are ready to send one or more premiums to each of the 25,000 Post-Offices in the United States and British America, if called for. Will you get one of them? It is easy to do so. Try it.

By Wholesale purchases, by advertising arrangements, etc., we can pay much more in premiums than in cash. Every article is given at the regular cash price.

Each article offered is for a definite number of subscribers; every one thus knows just what is required. A premium is not dependent upon favoritism, or upon what some unknown person elsewhere is doing.

About Nine Thousand Persons have so far received our premiums with great satisfaction; we have not heard of one in a thousand who has not been highly pleased.—It is a good work. The tens of thousands of persons persuaded by our canvassers to take and read the paper, have been benefited by so doing.

Many Clergymen are receiving the Cyclopedia, Sewing Machines, Melodeons, etc., as premiums. Some make up the subscription lists themselves, with the freely rendered aid of their congregations. Others receive the articles from their Parishioners who unite their efforts and make up a premium club of subscribers for the paper.

Table of Premiums and Terms, For Volume 26—(1867).

Open to all—No Competition.

Table with columns: No., Names of Premium Articles, Price of Premium, Number of Subscribers required at \$1.50, and Price at \$1. Includes items like Garden Seeds for a Family, Flower Seeds for a Family, and various sewing machines.

Every article offered is new and of the very best manufacture. No charge is made for packing or boxing any of the articles in this Premium List. The forty-three Premiums, Nos. 1, 2, 6, and from 29 to 32, and from 40 to 75 inclusive, will each be delivered FREE of all charges, by mail or express, to the Post-Office or express office nearest recipient, to any place in the United States or Territories, excepting those reached only by the Overland Mail.—The other articles cost the recipient only the freight after leaving the manufactory of each, by any conveyance that may be specified.

We take so much pains to procure only good articles in all cases, that any one securing anything from our premium list, saves the risk usually run of getting poor or indifferent goods, when buying of unknown or irresponsible parties. Every thing we send out as a premium is guaranteed to be the best of its kind and price.

Our premiums are standard articles, and enough can be obtained to supply all calls for premiums for six months. Every canvasser can take abundant time, but

As fast as subscriptions are obtained, send them along, that the subscribers may begin to receive the paper; and when all the names that can be obtained are forwarded, select the premium, and it will be promptly furnished. To save mistakes and keeping accounts, send with each list of names, the exact subscription money (in Post Office money orders, drafts or checks on N. Y. City; or, if these can not be had, register money letters.)

Every name designed for a premium list must be so marked when sent in. (We can not count others.)

Old and new subscribers count in premium lists, but a part should be new names, for it is to obtain such that the premiums are in part offered. Papers to Premium clubs need not all go to one Post Office. Of course the extra copy, usually offered to clubs of ten or twenty, will not be furnished when a premium is called for.

Specimen Numbers of the Agriculturist, Cards, and Showbills, as may be needed, will be supplied to Canvassers. These should be used carefully and economi-

cally, as each extra copy of the paper with postage (2c.), which must be pre-paid, costs about 12 cents.

For Full Description of the several premiums see October Agriculturist, pages 349 to 352, or apply for a Descriptive List, which will be furnished free. We have room here for only the following:

No. 63 to 74—Good Libraries.—These can be selected by the recipients, from any of the books in the list below. The books will be delivered free of cost, by mail or express.

No. 75—General Book Premium.—Any one not desiring the specific Book premiums, Nos. 63 to 74, on sending any number of names above 25, may select Books from the list below, to the amount of 10 cents for each subscriber sent at \$1: or to the amount of 30 cents for each name sent at the (ten) club price of \$1.20 each: or to the amount of 60 cents for each name at \$1.50. This offer is only for clubs of 25 or more. The books will be sent by mail or express, prepaid by us.

No. 76 (New)—Sewing Machine.—Owing to a chance failure to meet the Proprietors, we were not able to include the Finkle & Lyon Machine in our previous premium list of valuable Sewing Machines (Nos. 7 to 12). We are happy to announce now that this too is open for selection (See table). We know it to be a good machine, from the long experience of a sister, and of several neighbors, and we have recently been trying it in our own family with much satisfaction. All we said in October (page 360) applies equally to this machine. It will be noted that we offer the \$60 machine. For further particulars, or descriptive circulars, send to Finkle & Lyon Sewing Machine Company, 587 Broadway, N. Y. City; or 89 Washington St., Chicago.

BOOKS FOR FARMERS and OTHERS.

[For sale at the Office of the Agriculturist, or they will be forwarded by mail, post-paid, on receipt of price. All these are included in Our Premiums, Nos. 63 to 75 above.]

Table listing various books for sale, including 'Allen's Rural Architecture', 'American Farm Book', 'American Diseases of Domestic Animals', etc., with prices.

The White-haired Porcupine.

Erethizon dorsatus.

Among the great family of *rodents*, which includes rats and mice, rabbits, squirrels, marmots, etc., there is no group of genera more interesting than the porcupines. We have two which are quite common in this country, the White-haired Porcupine, which inhabits the Northern United States and Canada, and the Yellow-haired Porcupine which is found in the region of the upper Missouri, and in the Pacific States. The former is probably familiar to most of our readers. It is an animal about 2 to 2½ feet long to the tail which is 7 to 10 inches in length. It weighs 20 to 30 pounds. The head is short and flat, and the spines are partly concealed in its coarse hair. It has soft fur next the skin, of a brown color,

and mingled with coarse hairs with white ends, giving it a greyish look, which is lightened by the spines. These are white, with dark, barbed points, 2 to 3 inches or more long, erectile, and easily shed and renewed. The animal may be able to loosen them somewhat, at will, but the idea that it can shoot, or throw them even a short distance, is absurd. It is extremely sluggish in its motions, and when attacked neither attempts to escape nor shows fight, but with a succession of quick sideways motions, makes it dangerous for any animal to touch it. The erected spines, barbed at the end, will stick into the mouth or other part of the body, and hold there, working in deeper and deeper, so that dogs, wolves and lynxes, are sometimes killed by the irritation and inflammation consequent. The animal climbs readily, and feeds upon fruit, twigs, leaves, and the tender inner bark of trees. When numerous they are said to do great damage to the elm and basswood trees, girdling and barking the limbs or trunks so that the trees die. The creature is held in no favor, being in all respects a nuisance, and to none more so than to the owners of fine hunting dogs, which it often spoils. The Indians hunt them, using them as food, and employing the spines, which they usually color brilliantly and cut in small pieces for use, as beads, to ornament

leggings, mocassins, canoes, baskets, trinkets, etc.

This animal is frequently called *Hedgehog* in America, especially by people of New England origin, and that the incorrectness of the appellation may be the better seen, we give a picture of the Hedgehog of Europe (*Erethacus Europæus*). This little animal is common through-

of the body; the belly is covered with whitish fur. The Hedgehog is easily domesticated, and does good service in cellars, kitchens, out-houses, and gardens, eating cockroaches, beetles, etc., etc., driving away mice, and ridding the garden of snails and grubs. Its habits are nocturnal, and it hibernates during the winter, sleeping in a nest of hay and leaves in some hollow log or heap of stones.

Hints on Improving the Land.

Money properly used is the source of many of the comforts of life; hence the great end of farming is to make money. It is not to embellish the land, to build fine houses, barns and fences; to raise fancy stock, or in any other way to make a show in the world. It is to make money, to acquire property, with the ultimate view of taking the comfort of it. The grand question is, how can a farm be

rendered the most profitable? And the answer is, first and last, by improving the soil so as to make it most permanently productive. The great defect of American farms, at least this side of the Alleghanies, is their impoverished condition. They have been cropped and re-cropped, their products sold, and but little returned to the land to keep up its fertility. Any body can see that the net products of a farm which yields 50 bushels of corn to the acre, are much greater than one which gives 40. For, if 30 bushels will pay the expenses of tillage, there is a profit on the former of twenty bushels, and on the other of only 10. Supposing this to hold good on all the crops of the farm, is not one acre of this first farm worth two of the second? In whatever way we can increase the income of the land above the expenses, we gain so much more profit, and this decides the value of the farm. If land which gives a clear gain per acre of \$7, is worth \$100 to the acre, then that which gives \$14 gain

is worth full two hundred dollars per acre. It costs nearly as much to till land which yields only a profit of \$3.50, as that which yields \$14. Why not, then, apply the extra manure, and the extra brain-work, and get the \$14? The first man barely gets a living; the second grows rich. The best agriculturists here and in England, have found out this true prin-

Fig. 1.—WHITE-HAIRED OR CANADA PORCUPINE.

out Great Britain, and the Continent of Europe. It is very different from our Porcupine in every respect, except that it is a quadruped armed with spines. It is an insect-eater, closely allied to the moles and shrews, though it is said to eat some kinds of fruit, and it is well known as a destroyer of mice, snakes, and toads, worms, snails, etc., devouring birds' eggs also, and small birds. It is only about 8 or 10 inches long, and has a slender snout, fringed at the

Fig. 2.—EUROPEAN HEDGE-HOG.

end. When attacked or alarmed, it rolls itself into a ball, presenting only its spiny back to its foes. The muscle by which it does this underlies the skin where ever the spines are, and the motion erects the spines and holds them firm. The spines are about an inch long, of a dark brown color, tipped with white, and arranged in clusters, covering the upper surface and sides

ciple, and it is the key to their success. They make it a settled, invariable rule, to enrich the land, in proportion as they crop it, and to invest their surplus money in the soil if they can be sure of a fair interest for it.

And this brings us to the old question, how to enrich the soil? Few farmers have the means to bring up their lands at once. When the land-holder and his land are both poor, the farmer is in a pretty tight place. There is so little to begin with. The great reliance must be on the barn-yard, pig-pen, poultry-house, privy and green crops, and the muck bed.

By some means, let him contrive to raise more grass and fodder crops; this will enable him to keep more stock, and this, of course, brings the increased manure. By buying a few extra tons of manure to start with, this will give the first increase in the grass, and so the ascent will surely follow. Grain and root crops will then come in for a share of the land, and produce a share of the profits. The importance of draining, of deep plowing, etc., we need not now dwell upon. No good farmer will neglect them. It must also be understood, at the outset, that the work of renovating an old worn-out farm is the work of years, and must be prosecuted with patience.

Walks and Talks on the Farm.—No. 36.

I made a great mistake in not cutting up my corn immediately after the frost. It was hardly glazed, but the frost was so severe that there was no probability of its ripening any better for being left standing. I cut up about three acres and intended to have finished the field. But the beans wanted pulling, the clover seed had to be cut, the potatoes on the low land were rotting, and what few apples we had needed picking. And extra hands were more difficult to get than I ever knew. Labor was at a premium. Everybody wanted men and bid high to get them; and it seems as though the scarcer men are, and the more you pay them, the less they do. I have been paying \$1.50 a day for men, \$1.00 for women, and 50 cents a day for boys, and at this season they do not average more than nine hours a day.

No, we cannot afford to pay such wages; but what can we do? It is better to pay them than to let the crops rot in the ground. And then, everything is high that the men have to buy, and judged by this standard, wages, after all, are not much, if any higher, than before the war. I should not complain if they *would only work*. Our National debt and high taxes must be paid out of the industry of the nation. We shall all be obliged to work harder; but few will do it until compelled by absolute necessity.

Well, I stopped cutting the corn in order to pull the beans. These I was fortunate in securing in capital order. We have had glorious weather. Nothing could be finer. But one night we had a sharp frost, and a few potatoes that were exposed in the hill were nipped a little. The next day all my Dutch hands, men and women, stayed at home to dig their own potatoes. For more than a week none of them came to work. Then one of my own men who is engaged by the year was taken sick, and I could do little but worry and fret. The result was that my corn was not finished cutting until about the first of November. In the meantime, we had a high wind, and the corn stalks being very dry it stripped off the leaves, blew down the stalks—making it tedious work to pick up

and cut up the corn,—and destroyed the best part of the fodder. I shall know better next time. I should have cut up the corn at once, and stuck to it until it was done, no matter how pressing other matters were.

I am now paying six cents a bushel for husking, and may have to pay more, but I am tired of bidding high in order to secure men. It is of no use. I saw at the State Fair a husking machine that did the work admirably, and I hope by another season it will be generally introduced. If there ever was a time when "labor-saving machines" were needed, it is now.

My potatoes are all dug. My Flukes on the low land were more or less decayed, but the yield was good. The Peach Blows on the low land were sound, but the yield was very light. The hot, cold weather in August checked their growth, just at the time when dry, warm weather was most needed. The Flukes, being two weeks earlier, suffered far less. On the dry upland, the Peach Blows were excellent in quality, but there were more small potatoes than there should have been. As it was, however, the yield was very fair. I did not measure the whole, but I measured off seventy yards of one row and found it gave 4½ bushels, full measure. And as the rows are 3 feet 4 inches apart, this is at the rate of 294 bushels per acre.

The crop, in this section, as a general rule, turns out much more than was anticipated from the growth of the vines in summer. Mercers have rotted badly, and the Peach Blows are not as large as usual, though sound. Farmers expect good prices for potatoes in the spring. They argue that as New York has hitherto received large supplies from Nova Scotia, and as there is now a duty on them, we ought to get the benefit of it. Everything else is high, and the consumption of potatoes this winter, while they are cheap, will be greater than usual, and create an active demand in the spring.

I am trying to buy some sheep to fatten this winter, but they are higher here than in New-York. Grain is advancing, and John Johnston says he has always found most profit in fattening sheep when grain was highest. The reason of this, of course is, that farmers hesitate to feed grain when they can sell it at a high price. Few sheep are fatted, and consequently in the spring they command high prices. The profit of fattening sheep in winter is not due so much to the increase in the weight of the sheep, as to the improvement in the quality of the mutton, and to the increase in the price per lb. Last winter there was no money made in fattening sheep. The price in the fall was as high as in the spring, and the sheep did not pay for the food consumed. He was fortunate who obtained reasonable pay for the food, and got the manure for his trouble.

One of my neighbors has sold his farm for \$100 an acre. On asking him how he came to sell, he replied, "I am going West, and intend to buy a small farm that I can work alone. *I am tired of paying hired help two thirds of all I can raise.*"

I told him I should be quite contented to do so, provided I could raise enough. Thirty-three per cent. profit would do very well. A friend of mine who lives in the city and rents out a farm on shares, says he should be perfectly satisfied if the man would only steal one-quarter more than his share; but he *steals the whole!* Shall we ever be able in this country to carry

on farming in the same way that other business is conducted. I do not mean amateur farming, but real, practical farming, with an experienced man to direct and furnish the capital, and others to do the labor? It must be confessed that there are few instances of success in this direction, and many of failure and disgust. The general opinion among practical farmers is, that such a system cannot profitably be carried out. And the majority of them think that a farmer who pays two-thirds of all he receives from his crops for hired help and expenses, will soon get tired of agriculture. A man who undertakes the business and who has the necessary personal qualifications, with sufficient capital, can usually carry on a manufacturing establishment with profit. Why cannot farming be carried on in the same way. If it cannot, it must be owing to the difficulty of getting intelligent labor, or of making it, from the nature of farming, efficient. If this is really the case, we must have small farms, and much of the work must be done by the farmer himself and his family. It would seem difficult to have a high order of farming on this principle, or to use machinery to advantage.

What proportion of the money obtained for the produce of a farm is expended in labor? The late John Delafield, kept accurate accounts of his receipts and expenses on his farm of 350 acres, near Seneca—273 acres under cultivation, and 77 acres woodland, for five years, from 1847 to 1851. The income from all sources in 1847, was \$3,044.05, and the amount paid for labor, \$804.62, or about 26½ per cent. In 1848, it was 31 per cent., and 1849, 29 per cent. In 1850 (the receipts being \$3,338.88), it was only 21 per cent. The average cost of the labor was about 40 cents per day.

At the present time, labor is about 2½ times as high, and produce, on the whole, is also about 2½ times as high as at that time. If our crops were as good now as then, this would do very well. Instead of receiving \$3,000 from the farm, the sales would amount to \$7,500, while the labor, instead of costing \$800, would cost \$2,000. The profits in the one case would be \$2,200, and in the other, \$5,500—or 2½ times as large. "Other expenses" would probably be about 2½ times as large now as then. If it took *all* the balance then and now, there is no difference. If anything was saved, there ought to be 2½ times as much saved now. The present high prices do not help a poor farmer at all—it is only the good farmer, who receives more than he spends, that derives any benefit.

The prices obtained in those days read oddly enough at the present time. Thus one item of the receipts is: "6 pigs.....\$3.00."

The same pigs, say six weeks old, would now bring \$15. I know of a litter that were sold at two months old for \$5 each, and I sold some myself at \$4.00. It is not many years ago since such pigs could have been bought in the fall at from 50c. to \$1.00. Milch cows have advanced almost as much. At an auction sale near here a few days since, the cows brought over \$100 each, and one ran up to \$125. Before the war, \$30 to \$40 would have been a good price for such cows in the fall. The advance on beef cattle is not as great as on milch cows. Sheep, mutton, wool, buckwheat and potatoes are now comparatively low. Sixteen years ago I sold good cider for \$1.00 a barrel. It now is \$10.

There is one cause of high prices of farm produce, which is seldom alluded to—the increase in population. It is said that, from the

partial returns of the census of 1865, taken by the States, the indications are that we have now a population of *forty-five millions!*

In 1860 the total population of the country was not quite 31½ millions, and in 1850 23 millions. From 1850 to 1860, a period of profound peace and prosperity, the increase in our agricultural products barely kept pace with the increase in population. And taking the country together—North and South—it is very doubtful if our aggregate production is any greater than in 1860, and yet we have forty-five millions of mouths to fill instead of thirty-one or two millions. In 1860 the Southern States produced nearly as much wheat, in proportion to population, as the Middle States, and *three times as much corn*. It is reasonable to suppose that their productions have fallen off greatly during the war. In 1860, the New England and Middle States did not raise enough produce for home consumption, and the deficiency was made up from the West. At the present time, the New England, Middle and Southern States must all more or less look to the West to make up their deficiencies. If we *have* a population of forty-five millions, and if it keeps on increasing at this rate, the farmers of the United States must bestir themselves, or we shall come nearer to a *famine* than was ever dreamed possible in a country where land is so abundant.

The fact is, farmers, until within a few years, have not received prices high enough to induce them to adopt an improved system of farming. They have been obliged to rely to a considerable extent on the native fertility of the soil, and could hardly afford to spend much labor or money in applying manures. But this state of things is rapidly passing away. Prices are now high enough to warrant high farming, and he is a fortunate man who has a farm in a high state of cultivation, capable at once of producing good crops. A poor crop takes nearly as much labor to raise and gather it, as a good one, and the profits are all eaten up by the high wages, while the good crops leave a handsome balance. Look at the situation from what point we may, one fact is prominent—the *necessity and the advantage of improved farming*.

We need more capital—or rather, perhaps, we need faith enough in good agriculture to use what we have, in improving our farms. Had the millions of dollars which have been sunk in oil wells, been invested in underdraining and other improvements, how much better it would have been for the country! Those who complain so loudly of high prices of farm produce, should know that the absorption of capital for speculation is one cause of the present scarcity of the necessaries of life. The farmer needs capital to carry on his business as much as the merchant. But as things now are, it is rare that he gets any accommodation from the Banks. The necessity of capital among farmers is seen in the fact that at auction sales, where nine months on a years' credit is given, prices go far higher than at cash sales. There are few farmers who have anything like the amount of capital that they could use to advantage. We invest our money in buying the land and have not enough left to farm it properly. One reason of the high position occupied by English and Scotch farmers is, that their means are not locked up in the land. This is owned by the large landlords, while the farmer has all his capital free for active employment. Had he money enough to own the land and farm it too, he would probably feel that he was rich enough "to live without work," and the farm would

soon run down. Of course I do not advocate this system of renting farms. It is far better to own them, but it involves the necessity of obtaining more capital for active use. A merchant worth ten thousand dollars would probably borrow, directly or indirectly, twenty thousand in addition to carry on his business. He gives notes at four or six months to those who sell him goods, and takes notes from those to whom he sells, *and gets them discounted at the bank*. And in this way an enterprising merchant sometimes borrows three or four times as much money as his original capital. This is all very well. The business of the country could not be carried on without credit. But how is it with farming? A farmer worth \$10,000, which he is not risking in business, seldom uses his credit at all. He is "good," but the banks will not accommodate him, *because he requires the money for nine months or a year*, and the banks can make more money on shorter paper. This is the real difficulty in the case. The farmer can seldom turn his money to advantage in a shorter time, and he is not safe in giving three months' paper, which must either be renewed when it comes due, or he must sacrifice something to meet it. There is probably no remedy for this state of things, except in a superabundance of capital seeking investment at a low rate of interest, conjoined at the same time with a better knowledge on the part of bank managers with the business and wants of farmers, and confidence enough on the part of farmers themselves to employ money in a better system of agriculture.

"But farmers are producers, and should not be under the necessity of borrowing money to carry on their business, like those engaged in buying and selling." This is true, in one sense. But farmers are traders as well as producers. If I raise a litter of pigs, and at weaning time sell them for \$2.00 a piece, or if I raise a crop of corn and sell it for \$1.00 a bushel, I am so far a producer. I have produced these articles and sold them and got the money. But if instead of selling them, I feed out the corn to the pigs, and keep them six months, and then sell them, I am in one sense a trader or a manufacturer. The pigs and the corn are the raw material out of which I manufacture pork and manure. It is for this that I am warranted, on the ordinary principles of business, to borrow money from the bank. If I sell the pigs and the corn to a distiller instead of fattening them on the farm, *he* borrows money from the bank, and no questions are asked. Look at the thousands of half-fat cattle that are sold in our large markets every week. Would it not pay the farmer to get them in "ripe" condition before he parts with them? Frequently he has the food to do it, but either lacks confidence to feed it out, or else is pressed for money, and not being able to borrow, must sacrifice his cattle—to his own loss and the loss of the community. He loses half the benefit of all his feeding, for in fattening cattle the last month gives the profit.

Rats are a great nuisance. My pig-pens and buildings are overrun with them. I often wish for a pair or two of ferrets and a couple of good terrier dogs. We could have some glorious sport. When I was a boy, in England, I used to keep ferrets, and can well remember many days when I was too sick to go to school; but cannot re-call a day when I was not well enough to go "a ferreting!" We used to stack nearly all our grain, and as it was never threshed until the winter, and frequently not before the next

summer, the stacks that were on the ground were a favorite haunt for rats. I have seen old stacks that were completely riddled with rat holes—sides, top, and bottom. Such a stack afforded real sport for us youngsters. Armed with a good stick, we stood one on each side of the stack. The ferrets, having been fasted over night, were turned into the holes. They would creep along there slowly at first, but as soon as a rat was scented they were more active, and when the game was fairly started Master Rat, or Madam, must make good pace to save their skin. With a rush he leaps from the stack, when a terrier makes short work of him. When the sport is lively, half a dozen or more are on the ground at once, and dogs and boys have all they can do to attend to them. We did not muzzle the ferrets when hunting rats—only when hunting rabbits. It is seldom that an old rat allows himself to be caught. Sometimes the ferrets catch a young one and may lie in the stack. But rats are not a favorite food of ferrets. They seldom eat anything except the blood and the head and neck, and there is little risk of losing a ferret when hunting rats.

The smaller the ferret the better, as she can follow the rats more easily and rapidly through the holes. The large male ferrets are seldom as good rat catchers—or more properly, *rat frighteners*—as the small female ferret. We used to buy them for about a dollar a piece, sometimes for half a dollar. If kept perfectly clean and in a warm but well ventilated pen or box, and fed regularly with a little new milk and scraps of fresh meat, birds, heads of chickens, blood, etc.; there is no difficulty in raising them. The only disease that troubled them was the foot-rot, from neglect to keep their pens clean and dry.

Why cannot we keep ferrets in this country? The only difficulty I can think of is our severe winters. But it would seem that this could be overcome by keeping them in a barn cellar and furnishing them with plenty of dry bedding, in which they can burrow and form a nest.

Perhaps, as the *Agriculturist* suggested a month or two ago, there are American varieties of the ferret that could be domesticated, and which would stand our climate better than the imported ferrets. The subject is worthy of attention. Rats are getting to be such a nuisance that something must be done to destroy them.

I see ferrets are advertised in the *Agriculturist* last month at \$20 a pair! When I was a boy I frequently raised seven, and in one case nine at a litter, and used to feel rich when I could sell the young ones for \$1.50 per pair. They breed twice a year; and some of our young farmers' sons, especially in the milder sections, would find a pleasure and profit in keeping them.

Stone Walls—Raised or Sunken Foundations.

Judge McVean, of Wheatland, whose name was printed McLean in the Sept. No. (page 318), sends us the following letter describing his method of raising the mounds upon which his walls stand. The objections of our correspondents are mainly, if not altogether, set aside by knowing accurately how the work is done.

* * * "I assume that the essential thing is to secure a dry foundation by elevation; or to protect it by depression below the action of frost. The latter has been practiced here to some extent, but space at present limits me to treat of the first mode only. The first person here who adopted this plan was David McVean, about 30

years ago. We made a radical mistake at first in building our mounds so narrow that they gave way at the sides and failed to support the wall. A finished wall on this plan requires some 3 feet to stand on, a moderate slope of $2\frac{1}{2}$ feet on each side to the ditch, with an elevation of at least 1 foot above the general level, under the wall, being a mound of 8 feet in width. The ditches (which with the slope should be well seeded while the ground is pliable) will each be some 3 feet wide, thus with the mound breaking the surface 14 feet wide. This looks formidable, but can not be helped. One can not judiciously plow nearer than $2\frac{1}{2}$ feet to any wall or fence. The ditches are invaluable to drain the wall, and frequently the adjoining land, and to carry off the spring snow banks, while the grazing is not lost. To make the mound, turn two heavy furrows 8 feet apart inward toward the line of the wall, leave them undisturbed, within this space you have 6 feet, into which throw the subsequent furrows one at a time, with forks and shovels. It is surprising how quickly and cheaply four men will raise a mound. I build on it when freshly made, throwing 2 inches of earth against the bottom stones, and seed down. More earth than this prevents drainage, and makes a trough to hold water.

On such mound we build a wall from 30 inches to 3 feet wide at bottom, according to the size of the stones, and 12 to 14 inches at the top, with a height of $3\frac{1}{2}$ feet besides the caps, which superadded make the height 4 feet or more. It has been my practice of late, when the ground is clear, to build such mounds for rail fences, believing that it will pay for this purpose only, as with the increased protection of the ditches, rails enough may be saved to pay its whole cost; besides, it is ready for a wall at any future time. The mound should be of such slope, and the ditches of such width and depth, that one can drive upon it with a stoneboat, which in case of heavy loads may be facilitated by throwing 2 or 3 rails into the ditch. The elevation of the mound and the depression of the ditches amount to at least 18 inches. When an animal approaches it with evil intention, his hinder feet being in the ditch, his body is out of balance. I have never known a horse to break it over with his neck and chest. An educated sheep will jump any stone wall, and for division walls we sometimes put in light posts 7 feet apart, and nail on one board above the wall; this requires less stone. It is not my purpose to depreciate or object to any other mode, but only to offer some suggestions in regard to this, and I am glad to see that the subject is being canvassed in the *Agriculturist*. Some ten years past, Hon. A. B. Dickinson, of Steuben Co., in a series of most valuable articles recommended, among other things, a system substantially like this. It would be interesting to know what his views are now."—Will Mr. D. please respond.

Extension Ladders, Fruit Ladders, etc.

Mr. Hosea Barnes, of Kenosha Co., Wis., furnishes the readers of the *American Agriculturist* with the following description of an excellent ladder of his invention: "In a recent number of your paper, I notice illustrations of ladders. Having invented, made, and used one which appears to me to be better adapted to farmers' use than any I have seen illustrated in that or previous numbers, I send you two hurried sketches, which will serve to make my description intelligible. The ladder is made in three lengths. The middle one is just wide

enough to fit nicely between the sides of the lower one, to which it is attached by means of slots 4 inches in length, the centres of which are $14\frac{1}{2}$ inches from the lower end of the middle ladder, and through these the upper rung of the lower length passes. Slots, $2\frac{1}{2}$ inches in length,

Fig. 1.—JOINTED LADDER.

are cut in the bottom of the middle length, which, when the ladder is in an upright position, shut or slide down upon the next rung to the upper one of the bottom length. When the middle joint is fully drawn out, it will move back and forth as on a hinge; when shut together, the two lengths are as stiff and strong as if each side of the ladder were a single piece.

"The upper joint is fastened to the middle joint in a precisely similar manner. The projection at A, fig. 1, should be 4 inches in length, so that the joints can only be folded in one direction. This will make the ladder safer to use;

Fig. 2.

for, otherwise, should the joints be even drawn apart with a person on the ladder, it still remains stiff, unless it be turned over. The lower ends of the side pieces of the upper two joints should then be made as represented by the enlarged end on the left hand side of fig. 1. A good length for the bottom and middle joints is 8 feet each, of the upper 7 feet; this will give a

total length of about 18 feet, when shut together and used as shown in fig. 1. In case a ladder of 12 or 14 feet is wanted, and a greater length becomes inconvenient, draw out and let the upper length swing down; it is then out of your way. This is a very desirable feature for building and painting, also in stacking hay and grain out of doors, as is done in this section of country. When folded, as in fig. 2, it becomes a first-rate fruit ladder, allowing two persons at the same time to ascend on opposite sides. The upper length, having notches in the sides near the end, which shut over the lower rung of the bottom length, acts as a brace, making the fruit ladder firm and safe. The rungs are 1 foot apart."

Cattle Plagues.—Rinderpest. Texas Murrain, etc.

We have had little to say of late in regard to the direful malady which has visited the herds of the farmers of Great Britain during the past year, because it has been rapidly decreasing in activity, and distinguished veterinarians and others have been most studiously investigating its nature, causes, and treatment. An immense amount of matter has been printed upon the subject—nine-tenths, or more, of which has been the crudest speculation, and the most empirical "bosh." The whole country, so to speak, has run mad after one remedy or another; and the natural anxiety of cattle owners (who saw their herds or those of their neighbors, swept off by this mysterious contagion) to get something, or do something to stay the plague, was seized upon by unprincipled men to make money in one way or another. That kine pox was a cure was once the cry, and so cattle were vaccinated. Then some one said that small pox was a better protection, so the poor beasts were inoculated with small pox. Then it was claimed that cattle, inoculated with the rinderpest itself, would have it lightly and escape, and so there were plenty of people found to try this. There was scarcely any end to the medicines recommended as cures or as preventives. All the schools of medical practice, regular homeopathic, hydropathic, depletive, stimulating, etc., etc., all had their say and their followers; but all this

POLE AX.

was of no avail. Sensible people from the first followed the practice of the thorough veterinarians of the continent, and regarding the pole-ax as the efficient remedy, used it faithfully, and so great districts were saved. In an interesting review of this subject, which has lately appeared in the English papers, Prof. Simonds powerfully enforces this fact, viz.: in those districts, as for instance in Cheshire, where timid councils prevailed, and where cures were attempted, the most terrible devastation occurred and was perpetuated. In the above named county upwards of 72,000 cattle are reckoned among the victims of the disease, of which less than 8000 recovered, and a debt of \$1,500,000 is saddled upon the county. In other counties, where there was no temporizing, but every infected animal, sick or well, was killed and buried

at once, and the most stringent quarantine or isolation enforced, and all the movements of cattle by rail or on foot stopped, almost entire exemption has followed.—This disease may never reach America; but the lesson should be understood and heeded. There are other diseases not so bad, but perhaps bad enough to make it worth while to pursue the same remedy. One of these is the *Texas Murrain*, which has of late spread itself through parts of Missouri, Kansas, and we believe somewhat in Tennessee and Kentucky. The State Governments should act promptly, if the Legislatures are not in session, and by the most stringent measures put an end to a plague which may sweep off 30 to 50 per cent. of the herds of their respective States. The Missourians have, in many cases, very properly made laws for themselves and their own neighborhoods, and ordered back those herds, enforcing these orders with their rifles. So the cattle have gone round through Kansas or Kentucky. We get Texas cattle now and then in our Eastern markets. Who knows but we may get the murrain upon our farms, with the Western store cattle we buy for feeding? We commend the question seriously to all farmers.

To enforce our opinion of what is the only safe way of dealing with such diseases among cattle, we give a picture at the head of this article, of what is proved to be the *certain cure for the Rinderpest*, if dexterously applied—an implement which has become of historical interest from the role it has played in England the past year. If danger attends treatment—kill.

Portable Sheep Rack.

In our last volume, p. 369, (December), we gave a description of the sheep rack invented and used by Mr. N. B. Pearsall, of Otsego Co.,

Fig. 1.—SHEEP RACK.

N. Y. Mr. P. made this *patent and free* to the public through the *American Agriculturist*, not in consideration of the exclusive right to make and use granted to him and his assigns for 17 years by the Government. The inventor suggested its use as a double rack, and on looking over the advertisements in some of our English exchanges, we find figured a rack set on low trucks, and roofed,

Fig. 2.—CROSS SECTION.

which for some purposes might be very convenient. From the same we take a hint in regard to wire hay racks. We therefore combine these with Mr. Pearsall's double rack, and trust the suggestions may prove of value to sheep raisers. The cuts make clear the construction. The outer racks have 6-inch spaces, and 6-inch pales. The troughs are for grain or roots, and will catch all the hay seed. The inner racks,

Fig. 3.—INNER RACK.

(made of wire or slats), keep the hay out of the troughs, and may be lifted out, or made to lean

Fig. 2.—WIRE RACK.

back out of the way if desired. The roof may be lifted off at any time by one man with ease.

Fig. 1.
Cow Stables.

The well being of cows, and the ability to get the greatest amount of milk, depends in no small measure on the comfort of their quarters; but the comfort of the dam is vastly more important to ensure fine offspring. Some months since we took some measurements in the cow stables of a noted breeder of Shorthorns, and give the following outlines, figures 1 and 2, partly from memory. The cows stand in two rows facing the outside of the building. The entire floor is of brick in one stable (fig. 1), and of stone in the other (fig. 2), laid in cement upon the ground. The cows stand in double stalls, 8½ feet wide in fig. 1—6½ feet wide in fig. 2, each tied near the dividing

partitions. The feeding troughs are of the width of the stalls, 2 feet wide and 15 inches deep, made of 2-inch plank. In front of the stalls is a passage 3 feet wide for feeding, and at the rear a gutter laid in brick and cement, 14 inches wide in fig. 1, 12 inches wide in fig. 2. The floors of the stalls being made slightly slanting to the rear, to allow the liquids to flow off. The difference in the appearance of these stables is much greater than appears from the sections, the one represented in fig. 2 being

Fig. 2.

much more cheaply constructed throughout, and intended for milch cows. The feeding troughs

in this stable are not fixed in the position shown, but capable of being moved to the rear to accommodate the length of different cows, and should be so placed that the droppings will all fall into the gutter. In fig. 1 the troughs are stationary. The floor between the gutters in each stable is wide enough for a cart way, and ventilation is abundantly provided for. The floors are daily strewed with gypsum, the manure all being removed to a shed at a distance from the stables. Cows in such spacious quarters are vastly less liable to disease, their calves are healthy, and their milk is incomparably better

than that of those represented in fig. 3. This is a sketch of the cows in one of the best milk stables we know of near New York. The cows stand on the ground, are confined by stanchions, fed from half-barrel tubs, or have their hay or green fodder thrown to them on the floor. The space allowed each cow is about 3 feet. These stables are cleaned out daily, and the cows have an hour or two to run in a large yard. Nevertheless there is more or less of fever and disease prevalent, as indicated by the lack of sprightliness in their looks, here and there a gaunt animal with staring coat and hot breath, and the stump tails which several have. These are the two extremes of stable treatment. The best is

Fig. 3.

none too good for a choice herd; the second cheaper, and good enough for milch cows, for the milk consumer, and the profit of the owner.

A Great Invention in Bee-Culture.—How to Empty Combs.

The Bee papers of Europe and this country are filled with accounts of a discovery of a German Apiarian, of a method of emptying combs of honey without injuring them. The process is exceedingly simple and consists only in slicing off the caps of the cells, and then causing the combs to revolve on the periphery of a wheel or cylinder, which empties one side of honey—then the other side is turned and emptied. Liquids upon bodies which are whirled or revolved tend to fly off by what is called centrifugal force. In this case the revolution is so graduated that only the honey flies off, and dead bees, bee-bread, etc., remain behind, so that not only is the comb saved, but the honey is purer and better than that strained. The temperature requisite to success, is about 80° Fahrenheit, which is gained in a warm room, or on a summer day.

The value of this invention may be the better appreciated, when it is known that it requires the consumption by the bees, of 15 to 20 pounds of honey (estimates vary), to make 1 pound of wax, consequently, that the comb requires for its construction the use of just about as much honey as it will contain when filled. It may be found that in the economy of bee life, it is essential for the bees to make or excrete a certain amount of wax in order to remain in good

health—but this is hardly probable, for it has long been the practice of bee-keepers to save empty or partly filled combs with scrupulous care, and give them to the bees. And no bad results have ever been noticed.

Cotton Culture—Costs and Risks.

BY H. HINKLEY, M. D., EUTAW, GREENE CO., ALABAMA.

"Timothy Bunker, Esq.," (p. 316, Sept.) has gone into big figures in his estimate for a cotton place, and his figures may be considerably reduced. His estimate of yield takes for granted a crop is certain. But cotton is one of the most precarious crops grown, and has numerous enemies. A man in Sumter, ten miles from here, who planted 600 acres cotton, will make one bale to 50 acres; cause of failure, rust and worms. His loss will be over \$20,000. This is but one case in many this year. I planted 300 acres, expecting to make 100 bales cotton. Rain, rust, boll worm, and caterpillar, will cut the yield off so I shall be glad to get 20 bales. Others are better or worse, as the case may be. Tim Bunker puts down 60 hands for a 500 acre place. Forty hands are plenty, and 30 is all I want. I cultivate this year 300 acres corn, and 300 cotton, with 18 hands; will make 6 or 8 bushels corn, and had it not been for causes above mentioned, would have made 100 bales cotton. I have 16 mules, run eight double plows, part time, and part time six. I worked corn and cotton with Sulkey cultivators. Wages \$10 per month, and doctor's bills. Rations 3½ lbs. bacon and one peck meal per week. Three thousand bushels corn do the plantation one year. Mr. Bunker only enumerates wages for 10 months; it takes the whole 12 on a cotton place, and sometimes 13 could be used up. There is no rest or intermission in work for cotton.

Land is scarce that yields one bale to the acre; the majority of cotton land yields only half a bale—much land one bale to three acres; a bale is 500 lbs. Land can be rented at less than \$10 per acre—for all except the very best. Five hundred acres land worked in cotton, could be stocked and worked for \$15,000 per annum for first year, by any white man with brains, very easily, after first year; cost of stock and implements to be deducted, and seed also.—Half a bale to the acre would yield 250 bales of 500 lbs., at 30c. per lb., worth.....\$37,500.00

Deduct \$30 per bale for rope, bagging, hauling, wharfage, insurance, tax, commission, etc., etc.....\$7,500.00
Leaves.....\$30,000.00
Less expenses of plantation..... 15,000.00

Leaving a profit of \$15,000 for first year, provided nothing happened to injure the crop, etc. White men who improve their own land, work improved machinery, and work better than negroes, may do better even.

There is no need of rushing at the thing so largely. Why not be satisfied with one or two hundred acres? The cotton fever is likely to kill some, some never recover, and some are not injured by it. This year it will kill a good many. A New York General has thrown up a large plantation in disgust, and gone back to New York; others are weathering the storm.

The Slaughter of Animals for Food.

There are certain facts concerning the killing of the animals which form so large a portion of our food, that should be known by every meat buyer, if not meat eater, because they effect the condition of the meat, its healthfulness and keep-

ing qualities. Our own attention has been particularly directed to the subject by the opening of an immense slaughter-house near the City of New York, by capitalists and butchers of Chicago. The new *Abattoir* is in fact a regular Chicago slaughter-house for all kinds of animals, on a larger scale than anything existing there.

The old fashioned way of killing beeves, was to knock them in the head with a pole-ax, then cut their throats, and while bleeding commence skinning and slinging them up by the hind legs. Our butchers were slow to learn of the Jews, who practice throwing and slinging the animal and then cutting its throat, and in this way securing the most perfect possible bleeding, and following the Mosaic command, "the blood thereof, which is the life thereof, shalt thou not eat." Our butchers are now following a very similar practice, modifying it by hitting the beasts a merciful rap now and then on the head to destroy consciousness. In this way the beef bleeds better, as all the blood of the hind quarters at least tends to the throat.

There is a serious objection to knocking beeves in the head. The shock to the nervous system is such as to cause tremor and great rigidity in the muscles, although it is the part of humanity to put the poor beasts as soon as possible in a condition of unconsciousness. But this is a serious hinderance to free bleeding. European butchers have long practiced what is termed "pricking down," and this has also been to some extent done, or rather tried in this country. It consists in driving a narrow knife blade by an instantaneous motion in between the head and the first vertebra, piercing the spinal marrow. This destroys all sense, and paralyzes all the muscles of the body, leaving them soft and flexible. When an animal is in this condition, it must be slung up by the hind legs and bled at once, when the blood will flow quite as freely, as if the animal were conscious. This method therefore combines the excellence of the Hebrew way, and the humanity of the old knocking down process.

When an animal is killed during, or soon after a fright or great heat and exhaustion, it rarely bleeds well, but the meat is left bloody and feverish, it soon spoils, and is besides unhealthy. Whether the paroxysm of fear, which occurs when the animal is suddenly in full consciousness slung up by one or both hind legs, and which lasts until it dies, has any bad effect on the meat, physicians must determine. The superiority of the pricking down process is so evident, that we think it ought always to be followed.—It was not practised at the new *Abattoir*—though the killing there was done very expeditiously and the beef looked exceedingly well.

Horse-breaking and Horse-sense.

A horse's sense is good common sense. Many a man does not know half so much about some things as a horse, and there is a great difference in horses. The horse is not naturally suspicious, but he is timid when young. He learns very soon what his weapons are—teeth and heels—and in what his security lies—flight. His boldness and "the glory of his nostrils" come when "he rejoiceth in his strength." With his age comes the knowledge of his powers, and if he has never been mastered—never made to yield to any will but his own—if he is to be made useful, the struggle must come sooner or later, and man's-will or horse-will must triumph. We think it is best to begin quite young with colts to controll them. So advise to halter a colt

while it runs with the mare, and to do it after feeding it carrots and sugar, until it thinks it will get only caressing from mankind, and has no fear of any man. The colt submits easily, because it is the easiest and pleasantest thing he can do, provided he is not frightened, and would as lief be led as to run loose if the curtailment of his freedom is made up by sweets or carrots. The sense of smell in horses is very acute, and if they are suspicious of anything, they always approach it cautiously and smell of it. They should be indulged in this, and harness, saddle, etc., should all be investigated by the nose as well as by the eye, before a more intimate acquaintance is forced upon the horse. A horsering of 40 to 50 feet diameter is one of the greatest aids a horse trainer can have. In this a horse too restive and spirited to take a lesson may be tired out, so as to be very docile, and a tired horse is much more susceptible to both favors and instruction, than one full of *vim*, and fire and play. There are a few very simple common sense rules which, if followed, will commend themselves to the horse as well as to the trainer, viz.:

1st.—Always *feel* kindly toward a horse, no matter what he does to you, and consequently never show "temper." Remember the horse knows instinctively how you feel.

2d.—Never go near a horse if you are afraid of him, the horse will know it and take advantage of it, before you acknowledge it yourself.

3d.—Never undertake anything with a horse that you do not *know* you can carry out.

4th.—"Make haste *slowly*," teaching the animal what you want of him, as a child learns its A-B-C-s, one letter at a time, being sure that he knows each simple thing before you attempt to teach another; and repeat lessons often.

5th.—Reward each effort to do as you wish, whether he means it or does it accidentally.

6th.—Be sure that it is your will and not his that conquers every time.

Following these rules, you may make a horse do almost any thing, if he has not been spoiled before you get him.

Good Farming at the West.

[Another Western boy, of Lasalle Co., Ill., who selects the rather trite *nom de plume* of "Sucker," takes an evening in harvest time to tell the readers of the *Agriculturist* how a New England farmer has adhered to New England notions about manure, etc., and the success which has followed. There is no reason why Western farmers should not maintain the pristine excellence of their wonderfully fertile soil, and may even improve it for certain crops.—Eds.]

"My father is a native Yankee, but I suppose by this time considers himself a full-blooded "Sucker." But his having been in Illinois thirty-five years, can not get him out of the notion of good farming and high manuring.

"We consider that ordinary barnyard manure, without composting, or anything of the kind, will pay on an average one dollar per ton on the first crop, to say nothing of the benefit to crops afterwards. We have cultivated our farm for twenty-eight years, and it is as good as new land. While (whatever "Western Boys" may tell you) in this section, newly broken prairie always rents much better than old, and produces larger and earlier crops, except the old land has been manured.

"We expect to haul from 500 to 1000 loads of what our neighbors consider their valueless

manure upon our farm this fall and winter—one man and team hauling and spreading from six to eight tons per day. The best way we can see to Timothy, is to sow on well plowed potato ground in the fall or early spring. The yield of hay is much larger than after any other crop we have yet tried. If the clover is allowed to stand more than three years, a good dressing of manure will greatly increase the crop. Before that time, however, manure will make the grass so heavy as to be apt to fall down before it is fully in blossom. To raise the best potatoes with the greatest yield, we first raise a crop of small grain on well manured land; after harvest, plow the ground shallow, but deep enough to turn under all the stubble; then plow very deep in the spring, and plant in rows two and a half feet apart each way. Corn will respond for manure applied to it in any shape. The farmers in this section used to rake and turn their corn stalks on the ground, where they intended to plant corn again, the corn being almost always husked in the field and the stalks left standing. But of late years they have been using rollers with knives, to cut the stalks in short pieces so that they can be plowed under, out of the way of their corn plows. They say they get a great deal better crops for it. Now, if this kind of manure pays, why not any other. In raising corn, we plow the well manured ground deep and plant as soon after as possible. Then, when the corn is nearly up, if the land is not too wet, we take a two-horse cultivator, (or one-horse plow), and set the shovels to throw the dirt up to the corn, and plow it out by the marks, covering the corn deeply. Then follow the plow, immediately with a good heavy roller, lengthwise of the ridges, rolling the ground down nearly flat again. The corn will be up in a day or two, and thus get two or three weeks start of the weeds. The corn is then large enough to run a cultivator crosswise of the ridges, close enough to the corn to cover up all the fine weeds in the hill. And this advantage, if well followed, obviates the necessity of hoeing. But if something of the kind is not done to give the corn a start of the weeds, hoeing is necessary. The same rule holds for potatoes, sorghum, etc."

A Hint on Improving an Old Place.

Once or twice a year we make a visit to a friend who came into possession of an old farm, and who has already made great progress in improving and beautifying it. Like many places of this kind, it was enclosed in a solid, but not very sightly stone wall. The matter of a boundary fence was considered by him in all points of view, and he finally fixed upon and carried out successfully the following: The old wall was allowed to remain, and close to it, upon the outside, a hedge of Norway spruce was planted. The trees, from a nursery close at hand, were set a year ago, in August. All weeds have been kept closely mowed, the grass has taken a foot-hold, and the result is, that from the roadway proper, there is a belt of grass to the hedge, and this has, although set in August, lost scarcely a tree, and has become so dense as to already nearly conceal the wall from view. The whole presents an aspect of finish and elegance, in marked contrast with the slovenly appearance of the opposite side of the road. The spruce hedge is protected from injury by cattle and other causes, by means of a few lengths of galvanized wire stretched to temporary posts. Another year will probably show the complete success of this treatment of a boundary wall.

Colored Foliage Plants Last Summer.

To meet the demand for plants with foliage other than green, some very fine things have been introduced, and among them, others more odd than elegant. The old annual, *Perilla Nankinensis*, is one of the best known of these. Its blackish purple foliage is not so common in our gardens as formerly, it having been superseded by others. The best of these plants with colored leaves, to our notion, is *Coleus Verschaffeltii*,—we wish it had a more comely name. When grown in the green-house, its leaves are green with purple markings, but when planted out with the sun fall upon it, they are all purple, and with a tinge of bronze. Nothing can be richer. *Coleus atropurpureus*, has a sprawling habit; leaves of a dark liver color, and not worth growing. There are some other varieties of *Coleus*, but none of them equal to the first named. A great deal was predicted of the *Iresine Herbstii* or *Achyranthes Verschaffeltii*, which we figured in February last. We hardly open an English horticultural journal but we find a discussion upon its merits. We consider it quite inferior to the *Coleus*, as its color is too dull for any brilliant effect.

Some of the *Amaranthus* are very fine. *Amaranthus melancholicus*, var. *ruber*, is a brilliant annual, but *A. paniculatus*, var. *sanguineus*, is much finer, and is one of the showiest of all the colored leaved plants, both these *Amaranthus* are annuals, as is the tri-colored variety of *A. melancholicus*, an old plant known as "Joseph's Coat," but very showy when well grown.

About Covering Things from Frost.

In some things it is well to recollect the old proverb, "Make haste slowly." Many persons, as soon as the first frosts have hinted that winter is coming, hasten to put everything into winter quarters. Apples are hurried into warm cellars, half hardy plants are shut up in close frames, or those that remain out of doors are smothered with a covering of straw or manure, and various other examples of "killing with kindness" are to be seen. Living plants, that are to be covered, need to be quite at rest, and they should first have all the cold they can bear without injury. Much of our covering is not so much to protect from cold as from the sudden changes of freezing and thawing, and such plants may be left until the ground is crusted. Cabbages, celery, and such things, need to have the covering put on gradually, and thus avoid heating. Indeed, some prefer to allow their cabbages to freeze first and then cover them with straw and earth to keep them frozen all winter. Winter fruit should never go into the cellar until there is danger of its freezing, and then the cellar should be kept open as long as the state of the weather will safely permit. Water often does more harm than frost, and all crops left in or on the ground, or stored in pits, should have provision for draining off the water. Where half hardy plants are put into pits or cellars, or cabbages, cauliflowers, etc., are wintered in cold frames, give air every mild day. The transition from the open air to confinement, should be gradual. In removing pot plants to the dwelling, this should be borne in mind; it will be found much better to place the plants in a room without a fire until really cold weather, than to remove them at once to a heated sitting room. When plants of any kind have been frozen, the thawing should be very gradual. A tolerably hardy plant will be injured if

brought into a warm room to thaw, while a tender one may often be saved if set in a dark cool place to thaw out gradually. When plants are put in a cold pit, green-house or cellar for winter protection merely, it is desirable to keep them perfectly dormant. Such plants should have no more water than is actually necessary to keep them from injury by drying. The functions of vegetation now go on very sluggishly, and but little water is needed. If the earth in the pots is nearly dry, it may be frozen through without much injury to the plants.

Holidays and Evergreens.

[SEE NEXT PAGE.]

Christmas without its evergreens, would lose half its holiday charms. The custom of decorating churches and private dwellings is a pleasant one, and, in cities at least, well nigh universal. Most children know, and those of us who are no longer children recollect, the pleasures of anticipation, as well as the realized enjoyment of which the Christmas tree is the center. We might say much of the genial influences of the Christmas tree—for no other tree bears fruit so fragrant with the best affections of our natures—but we set out to write upon its business aspects. Unsentimental as it may seem, all this holiday decoration results in putting money into some one's pocket. We never fail to make several visits to the markets in the week that precedes Christmas. The sight is one which would astonish a stranger. Not only do the woods and swamps of New Jersey repeat the wonder of "Burman's Wood" coming to "Dunsinaue," but our nurserymen send in their over-grown evergreen stock by the load, and turn all the streets near the markets into green avenues, where the city odors are for the time replaced by the balsamic scent of the fir and cedar. The traffic in these green commodities is very large, but so irregular and divided up that it is difficult to get any statistics. The articles bring good prices, for in holiday times the purse is as open as the heart, and the vendors know it, and profit by their knowledge. Our artist has given a sketch from the evergreen market, and surrounded it by leaves of some of the principal kinds used for decoration. Spruces and Firs, are always in demand for Christmas trees, and bring better prices than they would as living trees for planting. Holly, especially with berries, Laurel, Inkberry and Hemlock, are all sold in great quantities. The smaller evergreens are made up into wreaths or "roping," as the dealers call it, of various lengths; there are usually of one of two or three species of Clubmoss and sell at about five cents a yard. Another class of decorations is made with a frame work of lath or twigs, and covered with some kind of green. These are formed into crosses, stars, and other devices. Some of the wreaths, etc., are prettily decorated with bright berries, while others, to meet a cruder taste, are made gaudy with flowers cut from brightly colored paper. The huge piles gathered around the markets are soon scattered; every express wagon takes a share, men and women ride in omnibuses and cars with their hands filled with them, and the poor woman who takes home her own market basket, bears a bit of holly or other green with it. These evergreens now cease to be articles of traffic, as soon as they are taken to the house of rich or poor they become consecrated by entering the sanctuary of home, and contribute to the enjoyment of that holiday that celebrates the announcement: "Peace on earth; good will toward man."

[COPYRIGHT SECURED.]

EVERGREENS IN THE HOLIDAYS. — (See preceding page.)

DOUBLE GERANIUM.

Bedding Geraniums—A Double One.

The common name, Geranium, has become so well established in the popular mind, that were we to say *Pelargonium*—the proper botanical name—a large class of our readers would be at a loss to know what plant was intended. Pelargoniums differ from the true Geraniums in the structure of their flowers, and the two are separated by botanists—but for our purpose we will follow the majority and call them Geraniums. Not many years ago Geraniums were grown exclusively as pot plants. Now they are among the most valuable of our bedding plants, and each spring our propagating establishments turn them out by thousands. From the old Scarlet Geranium, with its plain green leaves, and the Horse-shoe Geranium with a dark semi-circular mark upon its foliage, we have a great variety of seedlings and sports. Some of these have the leaves green and white—others yellow and green, and then a series with the foliage striped with reddish brown, white, and yellow—as gay as a leaf need be. But alas! these beautiful sports, about which English cultivators write so enthusiastically, can not endure our hot suns, and we are obliged to give up the most of them for bedding uses. Some, however, do tolerably well, and perhaps the most satisfactory are: the Mountain of Snow, green and white, and Cloth of Gold, green and yellow. A circular or oval bed cut in a lawn, planted in the center with some of the free flowering scarlet varieties, and bordered with these variegated ones, makes a very brilliant show.

Altogether the finest scarlet Geranium we have ever seen is an American seedling, called General Grant; we believe it originated in Ohio.

The flower is of good size and color, the truss so enormous in size as to hide the foliage and make the bed one sheet of flowers. We saw a bed of this remarkable variety in the grounds of Ellwanger & Barry, and doubt if a finer thing in the way of geraniums was ever seen. Quite a novelty among geraniums was brought out this year by Mr. Henderson, in which the flowers are perfectly double. This is called by the rather absurd name of *ranunculiflora*. We say absurd, as we object to the use of Latinized names for florists' flowers. A double geranium is such a novelty that we have had an engraving made of it. When we saw the plants they were too small to judge how effective they would be in the mass. Certainly this will prove valuable to the bouquet makers, on account of its brilliancy of color and double character. Geraniums are favorite window plants, and when they have plenty of room and light, bloom freely. Generally we see them badly shaped and drawn up into long-legged, forlorn looking subjects. No plant is more tractable than the geranium, and by pinching and pruning it may be brought into any desired shape.

HALF HARDY PLANTS.—It is well known that certain plants will pass the winter safely, if they have only a slight protection; but most cultivators do not seem to be aware that this

protection is given as much against heat as it is against cold. Like the man who was reported as having died, not of his disease, but in getting well, many of our plants can stand freezing better than they can thawing, and if protection to so-called tender things is not given until mid-winter, it often answers perfectly. A barrel, put over a shrub, shields it from sudden changes. A good light and dry cellar is a great help, in absence of a green-house. Tender roses, Lantanas, Oleanders and many other things that are very useful, when put in a cellar and just kept from freezing, will "worry along" nicely and they will generally come out all right in spring.

The Diseases of Trees.

It is with not a little surprise that we look upon the number of letters inquiring about diseased trees, that have accumulated upon our hands. It is the opprobrium of scientific horticulture that so little has been done to investigate the subject of plant diseases. We have read about all that has been written on the subject, have talked with the most experienced pomologists East and West, and find that there is really little positive information extant. All admit the existence of certain maladies, and attempts have been made to enumerate them. A recent work on horticulture gives us Latin names for these tree troubles; though it may gratify the inquiring mind to know that freezing is *congelatio*, and that decay is *caries*—we are unable to see that it adds much to our knowledge. Among the causes assigned for the unhealthy condition of our trees, some are sensible and others absurd. It is a very common

thing for the would be scientific, to attribute phenomena they cannot explain to electricity—and this agent has been the refuge of several of those who have written upon the diseases of plants. We have one letter before us from a photographer—who, taking a photographic view of the subject, is quite sure that the pear blight is due to the effect of the sudden light of flashes of lightning in a dark night—though he fails to tell us why this affects one tree, and leaves another of the same variety, next to it, untouched. In discussing this subject, we must recollect that all fruit trees are, in a measure, unhealthy; that the larger or finer our apples and pears, the more they have departed from the natural condition. This being the case, we ought not to look for perfect health in every cultivated variety. As to our ability to cure diseased trees by any medication, we doubt if it will ever be attained. To many who write us with the view that we can prescribe something to cure their trees, we must confess our inability to do so. If good feeding will not help them, together with drainage, we fear that the case is hopeless. Want of vigor or health is often due to a lack of alkaline matter in the soil, and benefit is often experienced from a free use of lime or ashes—but this is fertilization and not medication. Some of the most serious troubles, such as bark bursting and cracking, are due to changes of temperature beyond our control. The selection of varieties that mature their wood early, and the use of low headed trees, rather than those with long and naked stems, are the best preventives against these troubles. As to the leaf blight, that as yet remains a mystery. Until its real nature is understood, we must act empirically, and cut severely whenever it appears, even if it takes the tree down to the ground. Our pomological societies have, as a general thing, given too much attention to the quality of fruit, to the neglect of the character of the tree. Of late years there has been an improvement in this respect. We have good fruits enough, now let us go in for healthy trees.

Grafting Nut-bearing Trees.

This subject seems to be one that is exciting considerable interest, and we have asked for the experience of cultivators without receiving any satisfactory replies. We find in a French journal an article by M. Peretti, who claims to have had satisfactory success with ordinary cleft and crown grafting. He prepares his trees beforehand by cutting them back so as to induce them to throw out numerous young shoots, and when these shoots are a year old, he saws them off about 18 inches from the trunk and inserts a cion in Spring in the usual way, by cleft or crown grafting.—We shall be very glad to hear of the success of this or any other method of grafting the walnut and chestnut, as there are many trees that produce fruit of so fine quality that it is desirable to propagate it.

Cut-leaved and other Odd Plants.

We are never satisfied with the ordinary way of things. If we have a new plant with a red flower, we are not content unless it "breaks" into all the shades that red flowers are capable of, and if it will only sport into stripes and blotches, our happiness, as far as this flower is concerned, is complete. Trees, in branching, have their limbs form some respectable angle with the trunk, but let one get an unnatural twist and it is forthwith propagated as a "Weeper,"

and our grounds are filled with miserable, distorted, unsightly abortions, called weeping va-

know how to grow decently, being catalogued as a weeping variety. Then we have plants with variegated foliage—sold often at enormous prices. Some of these with distinct and well defined markings, are well enough to make up a variety, but the most of them are poor, sickly things, that fortunately soon die out. Another class of variations from the usual condition is found in the cut-leaved plants. In these the blade of the leaf has its margins more or less deeply indented—sometimes quite down to the midrib. Now we do not object to the striving after novelties, for it is to this spirit, that satiated with its present achievements, strives to attain to something beyond, that we are indebted for our great progress in horticulture. But we do dislike the indiscriminate praise of a thing simply because it is new or odd. In matters of horticulture, taste should be considered, and if we are to have monsters, let them be lovely ones, and possess real beauty of color and form. There are many of these abnormal forms of vegetation that we

Fig. 1.—SKELETON-LEAVED HORSE-CHESTNUT.

rieties of trees, that in their normal state are beautiful. There are some graceful weeping va-

really like, and many others, that, like animal monsters, ought never to be propagated.

Fig. 2.—CUT-LEAVED SUMACH.

rieties, however, that are really fine, "we only protest against every miserable thing that don't

Some of the most pleasing of these freaks are found among the cut-leaved plants, in which we often get a remarkable effect from the finely divided condition of their foliage. Cut-leaved birches, beeches, maples, etc., are not rare, and are to be had at our principal nurseries. We have seen in the grounds of a friend a new thing in the way of cut-leaved trees—the "skeleton-leaved" Horse-chestnut. One would suppose that the leaf of the Horse-chestnut was cut up enough naturally; but in this the leaflets themselves are sub-divided, giving the leaf a most singular appearance, which we have represented in fig. 1. We recently saw in the grounds of Mr. D. D. Buchanan, of Elizabeth, N. J., a cut-leaved variety of the common Sumach. This was discovered many years ago in Westchester Co., Penn., and we first saw it in the grounds of our venerable friend—the late Doct. Darlington. Every one knows the common Sumach, *Rhus glabra*, so frequent in sterile soils. In this variety, the long pinnate leaves are sub-divided in such a way that the whole plant presents a delicate fern-like appearance. We have only room to illustrate a single leaf, and this does not convey an adequate idea of the beauty of the whole shrub. The green of the leaf is very dark, and the stem is of a rich purple color, that contrasts finely with that of the leaves. This variety in autumn takes on the same gorgeous scarlet and crimson colors as does the usual form, which is a plant that, by its intensity of color, adds much to the brilliancy of our autumn scenery.

THE SURPRISE APPLE.—This is an old variety, though one that is seldom seen. It has no great value as an eatable fruit, but is worth growing in large collections as a curiosity. It is a small, rather pretty apple, with a clean yellow skin, and when cut, the flesh is found to be red throughout. From the appearance of the exterior no one would expect to find it red within, and when cut it is truly a surprise.

Insects and Plant Fertilization.

SEVENTH ARTICLE.

One more arrangement for natural cross-fertilization remains, which we will notice very briefly. We take as an illustration the Plantain. The common Plantain of door-yards would probably be the best example, the flowers being less crowded than in the Ribwort Plantain (*Plantago lanceolata*), which we have actually adopted. All the blossoms are perfect and alike, and have four stamens with very slender filaments, and one pistil with a slender style, the upper part of which is hairy and acts as stigma. But when a spike of Plantain comes into flower—which it does from below upward—we may see, as in fig. 1, only the long stigmas

Fig. 1.—A spike of the Ribwort Plantain (*Plantago lanceolata*), just coming into blossom, the stigmas only protruding from the lower flowers. Fig. 2—Another spike, a little later; the stamens of the lower flowers now hung out.

protruding, as if it were a female plant only. Later, and after the stigma of these lowest flowers have begun to wither, the stamens will appear, the anthers hanging out on the long, delicate filaments. And so, as the flowering proceeds up the spike, day after day, the stigma will be protruded quite in advance of the stamens, the corolla just opening at the tip to let it pass through, while the anthers, as yet on short filaments, are snugly enconced within. After a day or two, the four-lobed mouth of the corolla

will open, the filaments will suddenly and greatly lengthen, and the anthers, which are now discharging

their pollen, will be hung out in the wind—for the Plantain-flowers produce no honey, and are neglected by insects. The accompanying figures exhibit the whole case: and the explanation, now that we understand it, is simple enough. We have already seen in dimorphous flowers, also hermaphrodite, the stamens and pistils reciprocally long in one flower and short in another, otherwise similar; so that the pollen is more or less prevented from reaching the stigma of the same flower (and sometimes even unable to act upon it if it did), but is in the way of being carried by insects to the stigma of the other sort, upon which it promptly takes effect. In Plantain the same end is reached by a different way. Close-fertilization is absolutely prevented by the stigma being thrust out of the still closed blossom, long before the anthers that surrounded it are able to shed a grain of pollen. But this same stigma is exposed to the pollen of other flowers, belonging either to a lower part of the same spike, or to some neighboring plant. By the time the stamens of any flower appear, the accompanying stigma will probably have been

acted on by other pollen, and will be too far gone and withering to take any of that same flower. So cross-fertilization is here made as sure as if the flowers were separated into male and female—and with great economy of material.

This arrangement in Plantain and some other flowers was pointed out by Sprengel, about half a century ago; and he gave it the name of *dichogamy*. He saw that it meant cross-fertilization. But as neither Sprengel or any one else

Fig. 3.—Section lengthwise of a spike of the same, enlarged; several of the flowers with the stigma projecting, but the anthers still enclosed; the two lower left-hand flowers with their stigmas withering, and their stamens hung out.

in those days discovered any particular advantage in this crossing, the subject attracted no attention, until the sense of it was recently brought out by Mr. Darwin.

Dichogamy occurs in many Grasses, which are also fertilized by the wind. But it is not rare in flowers which are visited by insects; where the arrangement is as effectual as dimorphism in securing crossing. It is very common in the Umbelliferous family; and is very neatly exhibited in *Amorpha* or *False Indigo*, a peculiar genus of the Leguminous family. Here the sim-

Fig. 4.—A piece of the same spike, more magnified, with one of the earlier and one of the later flowers remaining, the rest removed. The stigma of the lower flower, with the stamens out, is withering; that of the upper, with the anthers still enclosed, is ready to receive pollen.

gle petal is wrapped around both the stamens and the style of the opening flower; but the stigma projects a day or two before the anthers are disengaged; and a bee, passing as it does up the spike, carries off pollen from the lower and earlier flowers, deposits some of it upon the stigmas of higher flowers, and the remainder upon those of the next spike or plant visited.

With these illustrations, which may serve as

a guide, we commend the whole subject to the observation of the curious, confident that many interesting facts remain to reward careful observation, when the proper season returns. A. G.

Notes on Grapes and Grape Culture.

The notes prepared for last month were crowded out, and now a press of other matter compels us to be very brief.

Catawba.—Some specimens at Cleveland showed what this grand old variety can do where circumstances are all favorable. It succeeds perfectly in a few localities, and where it does, there is nothing better.

Iona.—We hope to have more full accounts of the behaviour of this, in widely separated localities, than have yet been supplied. We saw about 50 vines in the vineyard of Mr. Onderdonk, at Nyack, N.Y., which for health and fruitfulness were all that could be desired. In some places it has mildewed. It has been somewhat largely planted at Hammondsport, but the vines, though vigorous, are not yet old enough to fruit. We have no doubt that in Pleasant Valley the Iona will attain its highest development.

Lydia.—This is a very handsome white grape, good sized berries, the clusters are not large, though we only saw the first fruiting of a vine. Probably too late for general culture, as it seems to ripen about with the Catawba.

Mottled.—This is, we believe, a Kelly's Island seedling. A good sized berry, of a Catawba color, mottled with a lighter shade, which gives the fruit a not altogether healthy look. Judging from the first fruiting of young vines, this seems to be a promising variety, and will probably be valuable as a wine grape.

Walter.—A seedling by Ferris & Caywood, Poughkeepsie, N. Y., claimed to be a cross between the Delaware and Diana, a claim which the fruit seems to sustain. That this is a fruit of marked excellence is shown by the award of the first prize, "quality to rule," at the Cleveland exhibition. This award created some discussion, the committee being three for the Walter and two against. Mr. Mottier expressed his dissent from the award. This grape has a remarkably fine flavor, is very sweet, but is rather tougher than some others. It is claimed that the vine is perfectly hardy and a rampant grower. The leaf is certainly very robust. We shall know more about this variety another year. To save answering questions we may state that this variety is not yet in the market.

Rodgers' Hybrids.—Though these grapes have the endorsement of those whose opinion carries weight with it, we have nothing to modify in our notes given last year. We hope some good ones may be found among the many numbers, but we have yet to see one that is not too "foxy" for a table grape.

The meeting at Cleveland very properly passed a resolution requesting that the best of the varieties might be selected and named.

Norton's Virginia.—Something after the style of the Clinton, but with larger berry and bunch. The vine is difficult to propagate, and in Missouri it has not this year sustained its former reputation. The fruit is only fit for wine, the quality of which is alluded to in another article.

Ives' Seedling.—There is a history to this

grape for which we have not now space. It has been known for some twenty years as a healthy vine, a good grower, and an abundant bearer. Bunches somewhat after the style of the Isabella, but longer. Fruit very sweet and decidedly foxy. An indifferent table grape, but one that promises to become of the first importance to the wine grower. The vine propagates easily, and the young plants, of which we have seen some thousands, show a remarkable vigor.

Allen's Hybrid.—The reports of this grape the present year are generally favorable. One cultivator tells us that his returns received for those sent to market were sixty cents per lb. at wholesale.

Seedlings.—We hear but little of the new seedlings of the past two years. New "hybrids" and other seedlings that attracted some attention, do not seem to have fruited this year. Less than the usual number of "new grapes" have been sent us, and some that we have had, have been so poor that our advice has been, to root up the vine at once, and put something tolerable in its place. We have had to pay the express charges on several parcels of grapes that no one, with a civilized nose, could tolerate in the same room with him. If persons will send these wild foxy things, they should at least put them here without cost to us. Every now

and then a foreign grape turns up, the fruit of which, in a favorable spot, will mature. Mr. Geo. Van Nest, of Pluckamin, N. J., sent us a cluster of a grape of this kind, which was well ripened, and so like a Golden Chasselas, as not to be readily distinguished from it. Our friend "Horticola," of Hoboken, N. J., has raised a seedling from a Crimean grape, that in his grounds is remarkably healthy, and which bears most excellent fruit. We hope that it may do well elsewhere. It is not impossible that we may yet get a seedling of the European vine that shall be perfectly hardy in our climate. The so-called Allen's Hybrid is tolerably hardy—and this is by most good judges considered as purely a foreigner. We are as yet very skeptical on the subject of hybrids; *i. e.*, crosses between the European and any of our grapes. We know that crosses of varieties have been made, and while we do not by any means say that a hy-

brid is impossible, we can say that we have yet to see a grape that unmistakably gives evidences of being a hybrid.

The Mountain Ashes.

Among the ornamental trees useful for the brilliancy of their fruits in autumn, the different species and varieties of the Mountain Ash hold the first rank. Aside from their showy ripe fruit, the trees are pleasing in shape, have good

best authorities keep them as distinct species. The European Mountain Ash, (*Pyrus aucuparia*), has larger fruit than ours, and the divisions of its leaves are shorter, blunter, and of a paler color. We have in the Middle States a variety of the American tree as distinct from the usual form as that is from the European; it is known as the Small-fruited Mountain Ash; it forms a shrub not over 10 feet high, with fruit not larger than pepper-corns, and sometimes in cultivation.

In the city of Rochester we have noticed that

what is known as the Oak-leaved Mountain Ash, is a favorite ornamental tree. It has a very erect habit of growth, forms a compact head, has a robust and dark-green foliage, and produces an abundance of brilliant scarlet berries. We give an engraving showing the shape of the leaf, from specimens obtained at the nurseries of Frost & Co., Rochester. We judge that this is what has been called *Pyrus pinnatifida*, and is considered by some as a garden hybrid. Mr. Barry informed us that they imported it from Scotland, many years ago, under the name of *P. quercifolia*, but that now the name seems to be dropped from the foreign catalogues. Whatever may be its proper botanical relations, Oak-leaved Mountain Ash is a sufficiently distinctive name for one of the most beautiful of our ornamen-

OAK-LEAVED MOUNTAIN ASH.

tal trees, and one that we hope to see more widely known and cultivated than it now is. Mountain Ashes are raised from seed, and particular varieties are continued by grafting. The seeds remain in the ground over one year before they germinate, and it is necessary to keep them in a rotting heap for a year. The berries are mixed with light soil and spread in a layer, 10 or 12 inches in thickness; this is covered with some 3 inches of sand, and allowed to remain until the next spring, when they are sown in beds. The plants appear the following spring.

The American Mountain Ash, (*Pyrus Americana*), is quite common in the mountainous districts at the North. It grows 15 or 20 feet high, and is much more robust in cultivation than in its wild state. Both this and the European Mountain Ash, or Rowan-tree, are common in cultivation, and the two are so much alike that some botanists have regarded the American as a mere variety of the European tree; but the

tal trees, and one that we hope to see more widely known and cultivated than it now is.

The Greeley Grape Prize.

In the autumn of 1864, the Hon. Horace Greeley offered a prize of \$100 for the variety of grape best suited to general culture, the award to be made by a committee of the American Institute. At the fruit exhibition of the Institute

that autumn, the prize was awarded to Doct. C. W. Grant, for the Iona. As but few kinds were offered in competition, on account of the short notice, Doct. Grant relinquished his claim to the prize and the matter was again thrown open. A new committee was appointed, which met in the fall of 1865, but adjourned for a year without making any award. In September last, another exhibition was held, at which there was another competition for the prize, and on October 27th, we find in an obscure corner of the Tribune an announcement of the award. The committee, after stating the grounds of their determination, give the prize to the Concord. Let us hope that we have seen the last attempt at selecting one variety, of any kind of fruit, as the best for everybody, everywhere. It was well intended, but has produced more dissatisfaction than can be offset by any good that will result.

THE HOUSEHOLD.

For other Household Items, see "Basket" pages.

TO HOUSEKEEPERS.—The high appreciation of this department of the paper, expressed by so many of our fair readers, leads us to lay out plans for increasing its value materially during the course of the next volume. The \$100 prize offered last month (p. 390), and other expenditures, the procuring of additional editorial aid in this department, and the devotion of more time to it, are among our plans for the future. We solicit abundant communications, and any number of questions about practical topics. We desire something beyond mere recipes, though, when good, a limited number of these are valuable. There are a multitude of interesting topics—those which occupy so much of the housekeeper's thoughts, and are the source of so many anxieties—that may be appropriately talked over in these columns, such as clothing, furniture, variety of food, care and health of children, etiquette, arrangement of the table, economical variety of food, etc., etc. If every housekeeper who, in visiting, or in her own experience, gets a new idea about the best mode of doing this or that, would note it down in simple plain words and send it to us, the probability is that the idea would be new and valuable to ten thousand others.—We are apt to think that what we now know well, is understood by everybody else. But multitudes of others are now just where we all were in knowledge only a few years ago.

Home-Binding of Papers, Pamphlets, etc.

In response to an inquiry in June, we have numerous plans for home-binding of copies and volumes of the *Agriculturist*, from which we select the following—applicable to all kinds of smaller papers, pamphlets, etc.:

(A)—By N. H. Coleman, Lamotte, Iowa: *First*.—Open two consecutive numbers, as January and February, in the middle, and place them back to

Fig. 1.

back, that is, outside against outside (fig. 1). Run a needle with a strong thread in at *a*, up on the other side to *b*, bring it through to you, put in again at *a*, bring it through at *c*, and up to *a*, and tie the two ends in a fast knot. Close the papers, and bring them round to their proper position, one upon the other. They may then be cut and read as desired.

—*Second*.—When the numbers of a volume are all thus stitched in pairs, lay them together in order (as in fig. 2), and with a straight awl punch 6

holes as near the edge as you can and be sure to catch inside the running thread previously sewed in. Put the needle in at the upper *a*, bringing it back at *b*, in at *a*, back at *c*, and tie at *a*, as above. Repeat the same at the lower three letters. This is all quickly done, and will leave the whole a strong book, with a back entirely elastic. The thread first sewed into the pairs will be caught by the through threads, and hold the whole firmly. Let the thread be strong and doubled.

Fig. 2.

—It is better still, to put strips of paste-board along the edges and sew through them in the final binding. Or full sized paste-board covers may be fastened on in the same way. A leather back may be added, and colored or fancy paper be pasted upon the paste-board, and over its edges. [Single numbers may be sewed as described for two, though this leaves the thread exposed at the backs. We print this year's index and title page separately, so that they can be readily placed in front of the volume in binding.—Ed.]

(B)—By Mrs. C. H. M. Newell, Wilbraham, Mass.: Cut two pieces of stiff card or box-board, a little larger than the paper to be bound. Cover the edges and the outside with any fancy colored paper; make four holes about 1/2 inch from one edge of each, and fasten into each hole firmly a common eyelet. Take four short pieces of red tape, tie a knot in the end of each, and put the other ends through the front cover. As each new paper comes to hand, makes holes in it, then take off the back cover, put the paper in and the strings through, and tie them in two pairs. The knots will hold the other ends. This method has served my purpose very well. [By having the horizontal threads described in A, the papers can be punched much nearer the backs so that they will open more freely, and the whole will be stronger. Then, this cover, B, will be neat and convenient for adding successive numbers.—Ed.]

Fig. 3.

(C)—By J. Fleming, Craigleth, C. W.: Provide two pieces of strong tape, 1/2 to 3/4 inch wide and about 3 1/2 inches long; draw it through paste, stripping the surface clean, and dry in the form of fig. 3. Place the papers evenly together, press them well awhile, and then place them on the tapes as in fig. 4. Mark down each side of the tapes as a guide; then sew the papers upon the tapes, letting the strong sewing thread pass along on the inside of each paper and over the outside of the tape just as books are sewn on to cords, which may easily be seen by dampening and taking apart an old book. Round the back a little, and coat with thick glue. For covers, cut two pieces of stout paste or cardboard, 1/8 inch larger on all sides than the trimmed papers. Glue the projecting tapes to the inside of the covers in book form, and glue over each tape end a bit of canvass to hold it firmly to the cover. Glue a piece of coarse canvass over the back of the book. When all is dry, the whole may be covered with paper, cloth, or leather, according to fancy.

Fig. 4.

(D)—By E. H., Geneva, Ohio: I cut two pieces of paste-board large enough to cover the paper, and

pass twine through them thus (fig. 5), leaving ample space between for a volume. The numbers as received are stitched in in book-binder's style. [The thread is run along the inside of each paper, but put through the back and around each cross string at the back, as above described. Ed.] —At the end of the year the ends of the cord are drawn down and tied firmly, making a strong volume. This is not very elegant, but it is substantial and cheap, [and is far better than to have the numbers scattered around in loose leaves.—Ed.]

Fig. 5.

(E)—By Amos L. Griffith, Jasper, Tenn.: Make a cover of two pieces of paste-board or bonnet board, and a piece of calf or sheep skin long enough and wide enough to cover the back and lap about 1/4 inch upon each side cover. Stitch it on firmly, as in fig. 6, using strong, well waxed thread. If desired, hide the stitches by pasting on a piece of cloth or paper [which may extend over the whole cover.—Ed.] Put in the papers, and run a strong waxed

Fig. 6.

twine or shoemaker's "wax-end" through the whole, four times. I have used this method on books and papers for 15 or 20 years, and the first one made, though in constant use, is as good as new. The binding did not cost ten cents. [In all these methods, the papers should first be sewn with a strong thread running along the inside, and through and through the back. The cross threads through the back will come inside of this to hold the papers fast.—Ed.]

(F)—We keep on hand at the office regular *Agriculturist* covers for binding, or "jackets," as the book-binders call them, which have gilt backs and are all ready for any book-binder to insert the volumes, at a cost of 25 to 50 cents. These can be used during the year as portfolios to hold the papers, and then be bound up at the end of the year. We have them for 1866 and 1867, and for each of the past nine years. They are furnished for any year desired at 50 cents each, (60 cents if sent by mail.)

Don't Buy the Bitters.

Before us is a Religious Journal having a "Bitters" advertised flamingly in a whole column, and the editor endorses and commends it, because the manufacturer asserts that it contains no alcohol. Yet, from a bottle of that same "Bitters" bought of one of its agents, we readily extracted 14 per cent. of pure alcohol, without a close analysis. Common whiskey, by a similar incomplete analysis, yielded only 29 per cent. of pure alcohol. A bottle of material sold under the name of "Temperance Bitters," yielded 11 per cent. of alcohol, by the same treatment. A few years ago we gathered bottles of every kind of bitters we could find advertised and sold, and they every one yielded alcohol, the lowest 9 per cent., and the highest 24 1/2 per cent. The truth is, all these various "Bitters" so extensively advertised (to the amount of more than a million dollars a year!) are cheap whiskey or gin, diluted with water and adulterated with a little bitter extract, some of them having a small quantity of Rhubarb and other drugs added. The bitter principle extracted from Gentian root, Peruvian bark, etc., is sometimes useful in cases of weak digestion, or a debilitated state of the system, if properly taken under medical advice, and only used temporarily. But the general use of these adver-

tised bitters is doing an immense, an incalculable injury, not only by being wrongfully taken and begetting a necessity for regular stimulants, but they are creating and extending an appetite for other alcoholic liquors, which promises to make us a nation of drunkards. A person buys a bottle, takes a little, is stimulated by the alcohol and what of bitters they contain, and temporarily "feels better." He continues the use, increases the dose when the reaction occurs, and usually falls into drinking habits.

A gentleman recently informed us that he counted 127 bottles in his attic which had been emptied of one kind of bitters by his now invalid wife, and other members of the family, during four years past. For awhile they seemed to help her, but latterly she had experienced unpleasant effects from the large doses required to keep her up, and she was now depending upon Bourbon Whiskey.—The stimulating effect of the alcoholic bitters when first used, led her to dismiss her physician. She is now looking forward to the grave near at hand; her physician, called back too late, gives no hope of life. "Do," said our friend, "Do expose these worse than humbug bitters. My children, accustomed to the daily use of some of 'mother's bitters', are now always sick, if not given some frequent stimulants." That friend is a wealthy merchant of this city, and the bitters were first introduced into his household by a glaring advertisement in his favorite religious journal.

We assert positively that all the "Bitters" advertised contain a considerable percentage of alcohol; they would not "keep" without it. Their constant use is always detrimental and dangerous; their use at all is of doubtful utility; they are cheaply made and sold at an enormous profit; and no one should countenance their sale, or assist their manufacturers in humbugging the ignorant, by ever purchasing a single bottle. If a temporary tonic is needed, and it should only be temporary, get a reliable physician to prescribe it, and the extent of its use. His bill, and that of the druggist, will be far cheaper and more effective, and infinitely safer than the trial of anything of secret composition, put up in bottles, and sold by specious advertisements.

Selecting Wall Paper and Carpets.

The Hall is generally a mere passage-way to something better beyond, and therefore it should not be so embellished as to attract special notice. Paper with figures of light pillars or pilasters, looks well, as does that which is marked off in courses representing marble or stone, or grained to represent oak or other woods.—The Parlor is for a different purpose, and should receive a different treatment. It is the flower of the house, the place for superior dress, courtly manners, the expression of the finer sentiments, and its adornments should be delicate and ethereal. The covering of the walls should not be obtrusive and glaring in color and forms. An over-dressed wall looks as unseemly as an over-dressed man or woman. A parlor wall should be a pleasant surface and background for objects, and not be a conspicuous object in itself. It should seem airy and light, shutting us in loosely, giving a sense of freedom and breathing space. Moreover, this wall is designed partly for the support of paintings and engravings, and these appear to much disadvantage on a surface broken up by scrolls and bosses, and huge bouquets.—The Living-Room should have a cheerful toned paper, less delicate than the parlor, but by no means gaudy and glaring. The Dining-Room should be plain, but rich. The Bed-Rooms, of course, must be neat and simple, the prevailing colors by no means dark. The Library should be of some sober, neutral tint, yet warm and cheery.

The Carpeting of these several rooms should correspond in style to the papering. A few years ago, the designers of carpet figures ran mad with huge designs, and glaring, ill-assorted colors. In crossing a floor, one had to tramp over scrolls, cornucopias, and bouquets, several feet long. But latterly, a change has come for the better. Even now, there are vivid colors and monstrous figures

enough, but we advise our friends to pass these by, and leave them to the upholsterers when hired to embellish flash hotel parlors, and steamboat saloons. Our homes must be embellished with something more subdued and chaste, and therefore more permanently pleasing.

Original Contributions to the American Agriculturist.

Hints on Housework, Cooking, etc.

Information Wanted.—Our Household Drawer contains numerous queries, which will be answered as we find room, and time for investigation, but hints from our readers on any of these topics will always be in order, and thankfully received. Housekeepers can greatly aid each other by talking together through these columns—asking questions, and giving answers. Fancy and other Soaps are much inquired about, that is, how to make them. We have more notes to add to the long article on Soaps, on page 403, November No., waiting room.—Boot and Shoe blackings, can some one give us condensed notes all about these, the kinds, the good, and the bad, with the best mode of detecting the injurious articles sold? If no one does this better, we will try it soon.—One asks how to remove from cloth, stains made by "Davis' Pain Killer." Easily answered if some one will tell us what it is made of. We use no secret or patent medicines.

"Cheap Farmers' Pudding."—In a 2 quart pudding dish or tin basin, put 3 pints of sour apples sliced: cut 3 or 4 ounces of fat salt pork very thin and fry well, and pour the whole over the apples; salt a little, pepper and spice to the taste; mix a batter with sour milk and a little cream, thickened with flour, pour it over the apples and steam an hour; to be eaten with sugar or sauce.—"A Farmer's Wife."

Tapioca Pudding.—3 tablespoonfuls of tapioca soaked over night, 1 quart of milk, the yolks of 3 eggs; boil all together in a farina kettle, or in a tin pail set into a kettle of cold water and boiled; add sugar to your taste. When thoroughly cooked, take the whites of the 3 eggs and beat to a stiff froth, and pour over the whole while hot.—Mrs. L. P. C., New Haven, Mo.

Cracker Mince Pie.—For three pies, take 3 crackers rolled very fine, $\frac{1}{2}$ cup of vinegar, 1 cup of sugar, 1 cup of molasses [or an equivalent of sugar]; sprinkle in all kinds of spice desired; bake in crust the same as an apple pie.—Mrs. L. P. C.

Steamed Apple Pudding.—Make a dough as for biscuit, of 1 pint flour, 1 teaspoonful cream of tartar, $\frac{1}{2}$ teaspoonful saleratus; mix with milk if convenient, or if with water, add a little shortening. Divide into three portions. Then take a pint of apples quartered, and put a layer at the bottom of a pudding boiler, cover them with crust, and put a layer of apples and crust alternately, taking care to have the crust on the top. Steam two hours.—It is very good.—Mrs. L. L. Decker, Manchester, Mass.

Puff Pudding.—3 eggs well beaten, 9 tablespoonfuls of flour, 1 pint of sweet milk; bake in cups in a quick oven; serve with sauce.—Mrs. L. P. C.

Cottage Pudding.—Take 1 quart flour, 2 cups sugar, 6 tablespoonfuls melted butter, 2 cups sweet milk, 2 beaten eggs, 2 teaspoonfuls cream tartar, 1 $\frac{1}{2}$ teaspoonfuls soda. Mix well and bake or steam in a mold or large tin basin, [which should be only part full, as it rises up nearly double.—Ed.] Serve with beaten butter and sugar, or wine sauce. What is left from dinner is good for tea cake.—Mrs. H. W. G., Oregon, Illinois.

Wine Sauce.—Stir to a cream, $\frac{1}{2}$ teacupful each of butter and sugar, with the white of an egg. Add $\frac{1}{2}$ cup water, with a very little flour, and boil all together with a cup of wine, or less, according to its kind and strength.—Mrs. H. W. G., Oregon, Illinois.

Bread without Yeast.—(Of Wheat or Rye flour.) 1 quart sour milk, 2 tablespoonfuls lard, 1 teaspoonful each of cream of tartar and soda sifted and well worked into the dry flour. Also use flour enough to mold up well. Let it rise 1 hour in pans in a warm place, and bake in a quick oven.—H. D., Fairhaven, Conn.... [As the lightness is produced by the soda with the combined acid of the cream of tartar and sour milk, which act quickly, we should say the bread would be lighter to bake as soon as mixed; if left awhile, some of the freed gas would escape.—Ed.]

Feather Cake.—(Simple and good): 1 cup white sugar, 1 teaspoonful of butter, 1 egg, 2 even cups sifted flour, $\frac{1}{2}$ cup of milk, 1 teaspoonful cream of tartar, and $\frac{1}{2}$ teaspoon saleratus or soda. Flavor with essence of lemon.—Mrs. B. V. Foster, South Danvers, Mass.

Pilaff.—This is the great dish of the Orientals, and is so truly delicious and so cheaply and easily made, that it is a wonder it has not become, ere this, a common dish in other countries. It is prepared in the following manner: Boil sufficient rice (according to the number of mouths to feed) in a large quantity of water. It should be put in cold water with a little salt, and not stirred while cooking. When thoroughly done, strain off the water through a colander or sieve, and each kernel will be separate and solid. Then season with salt, pepper, butter, and a little tomato sauce; cut up (not very fine) roasted or boiled mutton, or veal, and mix with the rice in proportion of about $\frac{2}{3}$ to $\frac{1}{3}$ meat. Let them simmer together a few minutes, and serve hot with the meat gravy. The water that the rice has been boiled in makes the very best starch for fine work. P.

Another Oriental Dish.—The Vegetable Marrow, or any other summer Squash cooked in the following manner, is very delicious, and will make a dish for an epicure. Split the squash lengthwise and remove the seeds. Then stuff with finely minced roast veal, or mutton, and tie together firmly. Boil until the squash is nearly done, then take out of the pot, and opening it, put in a piece of butter and whatever seasoning you may prefer, and closing it up again, place it in the oven for a few minutes, until it finishes cooking. When entirely done, serve it up, and you will be satisfied with your effort. The smaller kinds of squash are the best. P.

To Fry Fish.—The ordinary manner of frying fish in a shallow pan with only a small quantity of grease, may be much improved upon by imitating the Greeks, from whom we may also learn many other useful lessons in the culinary art. Take a large quantity of lard in a deep kettle, and let it boil as for frying doughnuts. While boiling, drop in the fish, having previously rolled them in flour or meal. In a few minutes they will be of a rich, uniform brown, when they may be taken out and served while hot. They will be found infinitely more delicate in flavor, as well as more inviting in appearance than when cooked in the old way. This is recommended by the long experience of the writer, and it will be endorsed by all who try it. P.

[The philosophy of frying is well illustrated by the Greek process detailed by our traveled correspondent. We may add that success in frying always depends primarily on having plenty of hot fat. If there is but little fat, the article cools it down to that degree that is readily absorbed by the food. This fact, that cool grease is absorbed before it has time to cook the article fried, while plenty of very hot grease cooks it quickly, and is not absorbed at all, should be impressed upon all cooks.—Ed.]

Sour Curd Cheese or "Smeerkase"—Cements, Paints, etc.—After milk curdles naturally, it is skimmed of its cream, the pan set over hot water on the stove and left until it is scalded but not boiled, which would spoil it. As soon as the curd separates freely when stirred, strain it through a cloth laid on a perforated vessel, or basket. When it ceases to drip, it is ready for use. This is "Smeerkase," to be salted and eaten in any way preferred.... Smeerkase when mashed with a spoon, thinned with sweet cream, salted, spiced with kummel (caraway), then spread upon steaming hot "Irish cups," or other equally good potatoes, boiled with the skin on, forms my favorite dish for supper, and is good enough for a king.—[The curd of cheese which is the caseine, is a nutritious food, similar to lean meat in its muscle-strengthening effects.—Ed.]... **LIME AND CURD CEMENT.**—Air-slaked lime in fine powder, thoroughly mixed with smeerkase without water, forms a strong cement or putty, for broken crockery, etc. Lime enough is added to thicken it to a proper consistence. Lime with white of eggs also makes a strong cement, but dries too soon for convenient use.... **LIME AND CURD PAINT.**—Quick lime slaked in water to a milky condition and poured into a hole in the ground, soon thickens. This, as wanted, is mixed with an equal amount of Smeerkase and used for paint, and for water-proof glue. A very good way to preserve lime for use in small quantities as needed, is to run it into the ground as above, and cover it with sand or anything else that will keep out frost.—H. Goepfer, Warren Co., Ohio.

Men's Shirts.—Mrs. B. V. F., of South Danvers, Mass., writes, that 8 years ago her husband obtained a good fitting shirt, and she ripped it enough to cut an exact linen pattern. This pattern has been always used since, and with complete success, even to the making of flannel under shirts, which fit better than any that are usually sold. "The pattern is a yoke with a point down between the shoulder blades, the back being sloped back so as to meet, and gathered slightly. This leaves it smooth on the neck and shoulders, and loose where the movement of the arms would be affected by any tightness."—[As hinted in October, the main trouble lies in not cutting out these garments with sufficient accuracy.]

BOYS & GIRLS' COLUMNS.

The Boys and Girls are Getting Many Premiums this Year.

During September, October, and November, we have received a great many more premium clubs than in any former year, and the young people are sharing in them. These are very acceptable, for aside from their pecuniary value to us, we like to see these business habits cultivated by the young. For many years to come our boys, and girls too, will be writing with the excellent gold Pens they are now receiving from our Office as premiums. Some will be constantly gathering information from their Cyclopedias and Great Dictionaries obtained in the same way. Others will always be "up to time," because they carry our premium Watches. Others will be busy making something new and useful with their chests of Tools. Many gardens will be planted next spring with our premium vegetable and flower seeds. Quite a number of aged people will be happy over the presents received from our premium list through the exertion of one or more of the little folks. A good deal has already been done in this way, mainly in getting new subscribers. The work can now begin in earnest, as there are more than a hundred thousand subscriptions to be renewed, which, with the multitude of new subscribers that can be found, will afford a large field for getting up premium lists of subscribers. Let every boy and girl go to work and try it this year. Some may get only two or three subscribers, perhaps, yet that will give them experience, and next year they will be much more successful. But let every one go to work determined to succeed this year. You have all the month of December, and if needed January and February too, to make up a premium club. Look over the list on another page.

A Boy Cuts a Cord of Wood.

"That's not much, I've cut dozens of cords," responds one of our fifteen-year old lads. But "H.," of Riply County, Ind., who was an officer in the war we believe, informs us that his boy of only eleven years old wanted to earn the Agriculturist himself last year, and he volunteered to cut a cord of wood to get it, and he did it! (Give us his name Maj. H., and give him a shake of our hand by proxy.) We like the spirit manifested. Boys who like to do something useful for themselves and others are the ones who will succeed when they are men. All such incidents are to us pleasant episodes, bright spots, in the laborious routine of our business life.

How Rain Falls.

Where does the rain come from? You answer, "From the clouds." But where do the clouds come from? You may think the wind blows them over you. But if it blows clouds over you from somewhere else, it also blows them from over you to other places. The fact is, the water of the clouds is just as much over you on a clear day as on a cloudy or rainy day. On a fair day when no clouds are seen, the water is divided up into such small particles, that it does not obstruct the sun's light, and so you see no clouds or water. A change of temperature in the atmosphere, as when a warmer and colder current of Air meet, causes the small particles of water to unite in pairs, and the pairs unite, and these quadruple drops unite, and so on until hundreds or thousands of the small invisible particles unite in one, and even then that one may be many hundred times smaller than a pin's head. A mass of these combined drops which are still small enough to float in the air, reflects, refracts, or bends out of their course so many of the sun's rays that they stop and often darken its light. It is thus that clouds gather in a clear sky. When enough drops unite to make one too heavy to float in the air, it begins to fall. It meets and unites with many others in falling, and often so many unite that great rain drops are formed by the time they get to the ground. Each large drop is made up of thousands, perhaps millions of the small drops that float in the unseen air in a clear sky.

Great Amount of Rain.—Problems.

Did you ever think how much water there is in the air, floating unseen? It always amounts to nearly 3 gallons above each foot of the earth's surface, and often much more. As new vapor is always rising, the amount of rain that falls during a year is very large. At one place as many as 300 inches deep falls in 12 months—or enough if it all fell at once to cover the land with water 25 feet deep. In this latitude 35 to 45 inches deep fall annually. If this fell altogether, it would cover the earth deep enough to drown all the little boys and girls under 12 years old. If we covered our garden or fields with empty barrels, they would all be more than filled with falling rain in less than a year. ... A pint of water weighs just a pound. A gallon contains 231 cubic or solid inch-

es. A barrel holds 31½ gallons. If we call the annual fall of rain 40 inches, (1) How many barrels of water falls on a house, 25 by 40 feet?—(2) How many pounds of water fall on it?—(3) How many barrels of water falls on your roof?—(4) How many pounds falls on your roof?—(5) How many barrels, and how many pounds of water falls on a garden 25 by 100 feet?—(6) How many barrels, and how many pounds fall on a ten-acre lot. (There are 43,560 square feet in an acre.)—(7) How many tons of water fall upon the surface of the earth in a year, if the average depth that falls be 40 inches?

The Game of Checkers or Draughts.

POSITION NO. 10.—Black to play and win. Black.

White.

GAME NO. 10.—FIVE OPENING. (*)

Table with 4 columns: Black, White, Black, White. It lists various opening moves for a draughts game, such as 1-11 to 15, 2-9 to 14, etc., and indicates which player wins or draws.

(*) It has been so named since Mr. James Wylie, the present Champion of Great Britain, played it against Mr. Andrew Anderson, at their great match for the championship in Edinburgh, Feb., 1817. (a) 26 to 23, draws. (b) 19 to 16, draws. (c) 18 to 23, draws. (d) 26 to 23, draws. (e) 11 to 16, draws. (f) 24 to 20, Black wins. (g) 15 to 19, draws. (h) 31 to 27, Black wins. (i) 18 to 22, draws. (j) Position No. 9. (November Agriculturist, page 405.)

Something About Meteors.

Almost any clear night those who watch may see what are called "shooting stars" darting across the sky. Sometimes these are very large; occasionally they explode with a loud report, and in some instances leave long trains of light behind them. Many of our young readers may have seen the remarkable meteor which was observed by the writer on the night of July 20th, 1860, and which was witnessed by thousands of persons throughout New York, and the Eastern States. It appeared first in the form of a large ball of fire, of a bluish color, like the ball from a Roman candle, but soon separated into two large and several smaller ones, accompanied by a brilliant path of light. One was seen in England in 1818, at 2 o'clock P. M., which shone as brightly as the sun, and descended vertically. Another passed over England in 1719, which eclipsed the light of the moon and stars, and burst with a tremendous report. Others of various magnitudes are recorded as having been seen in various parts of the world. Probably the most brilliant display ever known, was that of the night of November 12th, 1833, which was visible all over the United States, Mexico, and the West Indies. The heavens appeared filled with showers of stars, many of the first magnitude, darting along with almost inconceivable speed, and seriously alarming thousands, who thought that the Day of Judgment had surely come. As noticed in the Agriculturist last month, some astronomers are confidently expecting a similar phenomenon this year, as it is said to occur once in about thirty three years. At the date of this writing (Nov. 3rd), of course we can not know whether it will take place, but we shall be on the lookout for it. No man can tell with certainty what is the nature of these fiery visitors. It seems quite certain that they are composed of solid matter in a state of combustion, as many unconsumed fragments have fallen to the earth and been picked up, some of them very large, weighing many tons, others no larger than a bullet. The most probable theory respecting them is that a zone or belt of dark bodies of matter is revolving about the sun, and that its path is occasionally crossed by the Earth

in its revolution; that they are moving with such immense velocity as to take fire by friction, when they come in contact with our atmosphere, and that the attraction of the Earth causes them to leave their own orbits, and fall upon our planet, if they be not consumed before reaching it. One philosopher suggests that similar bodies swarm throughout the celestial spaces; that myriads of them are attracted by the sun, and that the force expended by them in their fall upon that body causes the heat which is developed from it.

Answers to Problems and Puzzles.

The following are answers to the Puzzles, etc., in the November number, page 405. No. 233.—Illustrated Word.—Ability....No. 234. 220,015,27 inches of wire....No. 235. Mathematical Problem.—5,85+feet....No. 236. Illustrated Word.—Eoundate....No. 237. Grammatical Puzzle.—The first him stands for bishop; his stands for patron; he stands for bishop; the last him stands for clerk.No. 238. Illustrated Rebus.—Line upon line, precept upon precept, benign injunctions, striking example and wise advice, are not infrequently overlooked; but experience enforces a lesson on all.

The following have sent correct answers to problems, up to Nov. 1st: Etoma Waterman, R. W. Fair, R. Ellis, Henry J. Meixell, Warren J. Buckalew.

New Puzzles to be Answered.

No. 239. Mathematical Problem, to be solved arithmetically. The crew of a ship consisted of Sailors and Soldiers. There were 22 sailors to every 3 guns and 10 over. The whole number of men was 5 times the number of sailors and guns together. After an engagement in which one-fifth were slain, there lacked 5 to be 13 men to every 2 guns. How may guns, sailors and soldiers at first?

No. 241. Mathematical Problem.—A man has a triangular piece of ground whose sides measure respectively, 500, 300, and 200 feet each. How can he divide it equally among his four sons, giving each a plot of the same form?

No. 242. Geographical Problem.—Suppose a person to start from New York on Monday noon, and travel westward at the same rate the earth revolves eastward, thus passing around the globe in 24 hours. It would of course be noon the whole length of his journey; at what point in his journey would he find the inhabitants calling it Tuesday noon, supposing the whole of his route to be inhabited?

No. 243. Conundrum, from the "London Fun." Why is opium like a truthful father?

No. 244. Illustrated Rebus.—Worth remembering.

Our Young Soldiers.

When the late strife first commenced in this country, most of our soldiers were yet to be trained. They were working upon their farms, and in shops and stores. At the call of their country they took the field, and soon as fine an army as ever appeared, was ready to defend the right. Should another war break out during the lifetime of the present generation, there will be thousands ready trained in the manual of the soldier. The veterans who have returned to their homes, have kindled the martial spirit among youth, and as in the picture here given, even young children are taught to "shoulder arms," and play soldier. Boys so trained will scarcely grow up cowards. The memory of what their fathers did will ever inspire them, and we may feel sure that they will suffer no disgrace to befall American arms, if the times should demand their use. To engage in a fight for the love of strife, for the mere sake of fighting, is brutal, but to be ready to stand up for the right, on the battlefield if necessary is manly. We would have every American youth inspired by the true soldier's spirit, determined neither to do wrong, nor to suffer wrong to be done to our country. Besides this manly spirit which we expect to see developed by our recent history, the boys may receive great benefit by the physical training necessary to make a good soldier. Heads up, shoulders thrown back, form erect, step firm and elastic; these are indispensable to the good soldier, and valuable for every man. With a nation of boys with bodies and minds such as soldiers should have, there will be little danger of war; the nation will be far too strong to be attacked by any foe.

Grudging Forgiveness.

It is related that two men, former friends, became angry, and for a long time would not speak to each other. Finally one of them attended a Camp Meeting and professed conversion. One day not long after, he met his former enemy, and at once a severe struggle took place in his mind. He felt it his duty to speak to his enemy, and to be reconciled to him; but still the old grudge rankled. At last he determined to make an effort towards duty; he advanced, and, extending his hand, exclaimed, "How d'ye do Kemp? I am humble enough to shake hands with a dog." It was not surprising that the man so addressed should turn on his heel saying, "I'm not dog enough to shake hands with you!" In this case was well shown the fallacy of the expression often heard, "I can forgive, but I can't forget!"—which really means "I want the credit of having forgiven, and the privilege of still indulging ill-feeling."

The Gypsies.

Within a few years past this singular people have appeared in considerable numbers in different parts of the United States. They have been well known all over Europe for hundreds of years. They are called Zingari in Italy, Gitanos in Spain, Zigeuner (wandering rogues), in Germany. The Gypsies, wherever found, are much alike. In features they resemble some of the Asiatic races, having very dark skins, sharp black eyes, black hair, high cheek bones, the lower jaw slightly projecting, narrow mouth, and fine white teeth. They call

themselves Roma, also Sinte, and Pharaons; some of them believe their ancestors came from Egypt; others think the country near the river Indus was their ancient home; the latter idea is the more probable. The Gypsies, wherever found, have much the same manner of life. They have no fixed homes, but wander about from place to place, encamping where night overtakes them, usually carrying tents, or in some cases making for themselves temporary huts from branches of trees, and collecting leaves for their beds. They profess to make a living by mending tin ware, umbrellas, and other small articles, and by fortune telling. This latter occupation has given them great profit in ignorant communities. By keeping their sharp eyes and ears open, they usually manage to make themselves acquainted with the history of the persons in their neighborhood, and by making shrewd use of this knowledge, they are sometimes able

from time to time enacted against them in Europe, yet in spite of these it is said they number nearly a million souls there. As many parts of this country, especially the thinly settled localities offer many attractions to the Gypsies, we may expect to see their number increasing here; but increasing intelligence among the people will ultimately drive them to honest ways of living.

A Comical Misapprehension.

The following amusing incident is condensed from a long account of it given in a Southern paper: A countryman who was very deaf, driving a pair of mules before a wagon, was met by a negro with an ax on his shoulder, who asked him for some tobacco, which was promptly given. The negro thanked the donor, and looking steadily at him, repeated several times, "thank you, thank you." The white man, not understanding him, thought he was asking for money, and became very much frightened, and declared he had no money. The negro perceiving he was deaf, now shouted, "I didn't ax you for money;" but the man in his fright only heard the word "money." The shouting started the mules, who turned to the opposite side of the road, and the negro, fearing they would overturn the wagon, seized the lines to bring them back. The white man now felt sure that robbery was intended, leaped from his wagon, and started at full speed for the woods, with the negro following him and shouting to him to stop. Finding he was being overtaken, the white man suddenly stopped, and as the negro approached, sprang upon him and endeavored to take his ax. This alarmed the negro, who feared he might be killed, and a desperate struggle ensued. Finally the ax was thrown far away, and each combatant springing to his feet started and ran from the other. The white man soon gained a neighboring house where he told a fearful story of the attack made upon him, and not long after the negro made his appearance and related his version of the story. It was finally decided that he should be kept in custody, and the whole matter referred to the Freedman's Bureau the following day. Accordingly the negro was confined, and the white man stood guard over him. The next morning the sentinel was found lying fast asleep by the

[COPYRIGHT SECURED.]
UNDRESS PARADE. — FROM A PAINTING BY JAMES BEARD.

to tell many things surprising to those who consult them. We need not assure our young readers, that their pretended revelations of the future are only random guesses, and their fortune telling an imposition upon the credulity of those who seek their aid. But a larger part of their income is derived by petty thieving, robbing hen-roosts, clothes-lines, and taking many small articles which in country places are often left exposed. They are greatly attached to their way of living and to their kindred. Instances are recorded of persons marrying some of the beautiful girls that occasionally have appeared among them; but the habits of a wandering life proved too strong, and after a few years of unhappiness in civilized life, they have returned to their outcast kindred. A few of these people are found in settled occupations. Occasionally one is seen in New York as a street dealer in crockery, tin ware, etc., and others are said to have become farmers; but these are rare exceptions, and are despised by their vagrant kindred. Severe laws have been

door of the room where the prisoner had been placed, and the negro was not found at all, having apparently concluded it best to take his chances without a trial.

The Motions of a Watch.

A gentleman has made a calculation of the revolutions which the wheels in an American watch make in a day and a year. The result is interesting. For example: the main wheel makes 4 revolutions in 24 hours, or 1,440 in a year; the second, or centre wheel, 24 revolutions in 24 hours, or 8,760 in a year; the third wheel, 192 in 24 hours, or 59,080 in a year; the fourth wheel, (which carries the second hand) 1,440 in 24 hours, or 525,600 in a year; the fifth (or scape-wheel), 12,960 in 24 hours, or 4,728,400 revolutions in a year; while the beats or vibrations made in 24 hours are 385,800, or 141,812,000 in a year. Have you read the fable of the clock pendulum, that, frightened by the work of a year, forgot its present duty?

(Business Notices \$2.00 per Agate Line of Space.)

LOCK-STITCH SEWING MACHINES.

Highest Premium, Fair of American Institute, 1863. CELEBRATED REVERSIBLE FEED MOVEMENT. UNIFORM SELF-ADJUSTING TENSION. FOUR SEPARATE DISTINCT STITCHES. WILL GATHER AND SEW A RUFFLE AT ONCE. OFFICES OF THE COMPANY, 305 Broadway, N. Y., and 97 Cheapside, London, England.

WHEELER & WILSON ROTARY HOOK

SEWING MACHINES. 625 BROADWAY.

"WOMAN'S GREATEST BOON.—We would advise a man to forego a Thresher and thresh wheat with a flail, rather than to see the wife wear her health, vigor and life away in the everlasting "stitch, stitch, stitch," when a sewing Machine can be obtained. The WHEELER & WILSON is an invaluable aid in every household. We have had several different kinds on trial, and after a six year's service, the WHEELER & WILSON has taken the precedence as the best, where all kinds of sewing are to be done in a family." (American Agriculturist, Jan. 1865.)

THE GREAT FAMILY SEWING MACHINE.

GRAPE VINES at AUCTION.

PARSONS & CO.,

At **FLUSHING**, near **NEW YORK**,

Will hold their

SECOND ANNUAL TRADE SALE,

On **Wednesday, December 12, 1888 A. M.**

There will then be offered **300,000** Vines of fine quality, including **50,000** Delawares, 2-years old.

In order to invite the attendance of Dealers, and their confidence in the absolute character of the sale, the Vines will be started at half the Catalogue price, and the sale will be absolute above that point.

The plants are all grown from single eyes, of well ripened wood. They will be the best of their respective classes, and will include

- | | |
|-----------------------|-----------------------------|
| Delaware, | Concord, |
| Iona, | Israella, |
| Ives Seedling, | Hartford Prolific, |
| Adirondac, | Norton's Virginia, |
| Diana, | Ailen's Hybrid, |
| Rebecca, | and other varieties. |

Circulars giving particulars, will be sent to all applicants. By packing in double boxes at small comparative expense, the Vines can be sent to any distance safely with the thermometer at zero.

IONA AND ISRAELLA

GRAPE VINES.

The Two Best in Cultivation for Every purpose. Both very Early, and Israella the Earliest of all.

The **IONA** is the only native grape of good size for the table that is equal to the best foreign kinds.

In hardness, constancy of production, and perfect ripening of fruit it is unequalled by ANY of our most hardy natives.

It is the only unexceptionable grape for the family. **DEL-AWARE IS EXCELLENT.** **IONA** is equal in all respects and **MUCH BETTER** in several very important points.

The Iona is the best Grape for Wine.

The **IONA** is the only Grape which pays the cost of best vines by its cutting the first year.

It is the **ONLY NATIVE GRAPE** whose fruit is eagerly sought for at **ONE DOLLAR** per pound.

It is the only grape, native or foreign, whose fruit is pronounced by the best judges equal to Muscat of Alexandria, and preferable to all other foreign kinds grown in glass houses.

My 21 page pamphlet, containing description of best varieties—"Present and Future of Grape Culture," etc., also Price Lists for Garden and Vineyard Planting, and Method of Obtaining Samples, will be sent for 2-cent stamp. Address

C. W. CRANT, Iona,
 (near Peekskill), Westchester Co., N. Y.

NOTE.—It is easy for any Club, Agent or other person interested in purchasing good vines, to ascertain by sample, if Iona Island, where these vines originated, is not the best and cheapest place to obtain good varieties of Iona and Israella.

Pamphlets with copies of Analysis by Dr. Liebig, of Baltimore, and Dr. Jackson, Massachusetts State Assayer, and testimonials from Agriculturists, showing its value, and directions for use, can be obtained from

J. O. BAKER & CO., SELLING AGENTS, 131 Pearl-st., New-York.

GOOD HOMES IN NORTH MISSOURI. FARMERS, MECHANICS and MANUFACTURERS of the North and East should come to Missouri, because you can now do better for yourselves, families, society generally, and for posterity, than you can by staying where you are. By coming you can get better farms and homes, do more business and make more money, easier and quicker than to remain where competition is strong and sharp, and profits small. As others have done you can do, for the chances now are as good as ever, and in many respects better.

Missouri is rich in Agricultural resources, provisions are abundant, Coal, Iron, Lead, Copper, Wool, Cotton, Hemp, Flax, and other raw materials to be wrought are at hand in a healthy climate giving vigor to labor, and in a central location with cheap and direct access to all the markets. These facts make Missouri a producing and manufacturing region; and when the surplus artisan population of old and less favored districts are wise enough to come here in sufficient numbers, then there will be an adequate supply of labor for the wants and facilities of this State, and make it a consuming country also. Thus the great department of human industry can and surely will combine to give the full prosperity this noble State generously invites and so richly deserves.

The HANNIBAL AND ST. JOSEPH RAILROAD offers for sale at low prices on two or ten years credit, nearly 500,000 acres of best prairie, timber and coal lands in Northern Missouri, which is the best Agricultural part of the State.

Documents giving full particulars are sent in packages gratis to all who wish to distribute them, to induce others to join in forming a neighborhood or colony.

A Sectional Map showing exact location of land is sold at 30 cents. Address: GEO. S. HARRIS, Land Commissioner, Hannibal, Missouri.

FARM SALE.—A WELL IMPROVED FARM OF 160 Acres, in Lee Co., Iowa, eight miles from Mississippi River, and near two Railroads. Address: J. C. FRENCH, Eddyville, Iowa.

The Best Opportunity to Secure a Home.

Mild and healthy climate; soil suitable for all crops—the BEST FRUIT SOIL IN THE UNION—best for markets. One thousand acres already planted with choice fruit—from \$200 to \$300 cleared from one acre in Small Fruits. Lots of all sizes for sale in the famous HAMMONTON FRUIT SETTLEMENT, 20 miles from Philadelphia, near the New York Railroad. A large population already located and prospering; hundreds are settling, good society, perfectly healthy, all advantages. A large tract is now divided into farms to suit the actual settler. Price for 25 acres and upwards, from \$20 to \$30 per acre, smaller lots for sale. Terms liberal, Title perfect. For full information address

BYRNES & JONES, Hammonton, N. J.

All letters answered.

New Jersey Lands for Sale,

in Tracts to suit purchasers. 21,000 Acres of Superior Soil in One Body, on Camden and Atlantic Railroad, in best location in South Jersey. Lands shown free of expense.

Apply to E. WRIGHT, Elwood, Atlantic Co., N. J. Also many thousand acres of Cranberry lands. Circulars or other information cheerfully forwarded.

From the Report of Wm. L. ALBION, of the Working Farmer.—"At Elwood, a thriving settlement 37 miles from Philadelphia, the land is heavier and richer than those at Hammonton, and there is no drifting sand to annoy the cultivator."

SUPERIOR FARM LAND.—20,000

Acres, Franklin Tract, at Newfield, Gloucester County, New Jersey, on the Railroad running from Philadelphia to Cape May, 30 miles South of Philadelphia—adjoining the Vineland Tract, and 2 miles North of the Vineland Station—for sale at low prices and on easy terms, in lots to suit purchasers. Circulars, with reports of Solomon Robison, Hon. William Parry, and others, with full information, sent to applicants, free. Address JOHN H. COFFIN & CO., Newfield, Gloucester Co., N. J. Improved Farms also for Sale.

MALLORY & SANFORD'S

IMPROVED

FLAX AND HEMP BRAKES,

As now made, are the strongest and best ever used. They occupy about 5 feet square, weigh about 1,000 lbs., require one man and a boy, and one to two horse power to work them; breaks from 2,000 to 3,000 lbs. Flax straw in 10 hours, taking out 65 to 75 per cent. of the woody matter. This machine will save 120 lbs. to the ton more than any other machine in the world. It will break tangled straw as well as straight. We have also an entirely new TOW SHAKER AND PICKER, works perfectly and does its work quicker and better than any other machine, and prepares the stock for flax. Also a new row comb, which cleans and straightens the row, free from shive, rapidly making it fine and straight. Send for circular of these machines in operation at 98 William-st., New York. Address: JOHN W. QUINCY, Treasurer, No. 98 William-st., New York.

National Field Trials.

Two great National Field Trials of Mowers and Reapers have been held in New York State. The first at Syracuse, in 1857, and the second at Auburn, in July, 1856. The FIRST PREMIUM GRAND GOLD MEDAL, was at each of these trials borne away by the "BUCKEYE MOWER." This justly merited distinction is endorsed by State, County and Town Agricultural Societies, and by a large majority of the farming community in all sections of the country.

Circulars with official Report of Auburn Trial of Mowers can be obtained on application to

ADRIANCE, PLATT & CO., Manufacturers & Proprietors, 105 Greenwich-street, New York.

Only One Dollar

For

WOOD & MANN STEAM ENGINE CO'S CELEBRATED Portable Steam Engines,

FROM 4 TO 35 HORSE POWER. ALSO PORTABLE SAW MILLS.

We have the oldest, largest and most complete works in the United States, devoted exclusively to the manufacture of Portable Engines and Saw Mills, which, for simplicity, compactness, power and economy of fuel, are conceded by experts, to be superior to any ever offered to the public.

The great amount of boiler room, fire surface and cylinder area, which we give to the rated horse power, make our Engines the most powerful and cheapest in use; and they are adapted to every purpose where power is required.

All sizes constantly on hand, or furnished on short notice.

Descriptive circulars with price list, sent on application.

WOOD & MANN STEAM ENGINE CO., Utica, N. Y.

Branch Office, 96 Maiden Lane, New York City.

We warrant our Engines to be what we represent them, and to give unqualified satisfaction in all respects.

A. N. WOOD & CO.

Caution to those using Moveable Comb Frames.

My Patent on Moveable Comb Frames, granted October 5, 1852, and re-issued May 26, 1863, having been extended for seven years from October 5, 1865; I hereby notify all parties that their rights to make, use or sell any new hives of the Langstroth patent ceased on October 4th; and that while they have the right to use hives already made, they must procure authority to make new hives from those owning the extended patent. The most liberal terms will be granted to all such parties. I hereby notify all parties using other patented Moveable Comb Hives, that such hives use the essential and patented features of my invention, and cannot be legally used or sold without a license from the owners of my extended patent.

L. L. LANGSTROTH, Oxford, Butler Co., Ohio.

Wood Sawing Machine.

Call or send for Illustrated Circular.

WM. B. BRADBURY, WARE ROOMS, 47 BROOMFIELD, NEW YORK.

PARLOR ORGANS. CARHART & NEEDHAM,

97, 99, and 101 East Twenty-third St., N. Y. (ESTABLISHED 1846).

Are the oldest manufacturers of Improved Reed Instruments in the United States, and are the inventors and patentees of the essential improvements made in this class of instruments up to the present date.

During this long period they have manufactured a vast number of instruments of all styles, and when they have been exhibited in competition with the instruments of other makers, they have invariably taken the highest premium.

At the last FAIR OF THE AMERICAN INSTITUTE, these instruments were considered by the judges above competition, and, giving the ordinary prize to another firm, they created a NEW CLASS PREMIUM and presented to CARHART & NEEDHAM

A "SPECIAL" GOLD MEDAL, a new and hitherto unawarded testimonial of excellence. Send for Illustrated Circular.

Engraved for the Farmers' and Stock Breeders' Advertiser, from Photograph.

Chester White Boar, Grant, 18 months old, weight, 800 lbs. | Chester White Sow, Beauty, 15 months old, weight, 750 lbs.

Bred and Owned by N. P. BOYER, Gum Tree, Chester Co., Pa.

PREMIUM CHESTER WHITE PIGS.

Progeny of Hogs that have taken State and United States Premiums, sent in pairs, not akin, to all parts of the U. S., Canada, Cuba, and South America.

Our Pigs have always taken the highest premium wherever exhibited. They have all the good qualities desirable in a Hog; they are quiet, kept easily, have a good square form, deep and wide chest, plenty of play for the Lungs, very heavy hams and shoulders, broad in the back, short head and legs, and without exception always white; they readily fatten while young, or at any age, and will grow to weigh from 500 to 800 lbs., at 11 or 16 months old. They will make more pork in a given length of time, with a given quantity of food, than any other breed of Hogs. We have had them to weigh 1,280 lbs. at 21 months old.

We always have a large stock of Hogs on hand, of all ages, from 1 to 18 months old, and can fill orders at almost any time.

We insure the safe arrival of the Pigs.

They are carefully boxed, with feed and trough; the Express or Railroad agents feed and water them.

For Circulars and Prices, Address

N. P. BOYER & CO.,
Gum Tree, Chester Co., Pa.

We give the following Testimonials, received from parties who have ordered "Chester White Pigs" from us: H. O. Brown, a well known manufacturer, of Castleton, Rutland Co., Vermont, says: "The boar pig you sent me, is the handsomest I ever saw. He took the First Premium at our Agricultural Fair. People came for miles to see him, he has over fifty Sows engaged at \$2.50 each. I don't believe there is another as good a hog in the New England States. I sold one of the pigs from the Sow I got of you, five weeks and two days old, for \$50, to a gentleman in New York."

Dorsey Scott, of Lamolite, Bureau Co., Ills., writes: "The Sow I got of you measures 18 inches across the shoulders (not fat). I was offered \$120 for her, she had 10 pigs, sold all at \$10 to \$12 apiece, four weeks old. Everybody says they are the best pigs that have ever been raised in this part of the State."

L. L. Smith, of Brooklyn, Poweshieck Co., Iowa, writes: "The pigs I got of you last spring, took the First Premium at the Scott Co. Fair. The Boar I got of you some two years ago, weighs 1,400 lbs., and is still growing. I bred one Chester White that weighed 1,250 lbs., at 22 months old."

Cashmere! Cashmere!

I have just received direct from the district of Angora, in Asia Minor, a new importation of Angora (Shawl) Goats, (known in this country as Cashmere,) which I offer for sale at moderate prices.

Also for sale a few young Holstein, or Dutch Bulls, and "Texel" or "Mouton Flaudin" Rams.

WINTHROP W. CHENERY, Highland Stock Farm, Belmont, Middlesex County, Mass.

PREMIUM STOCK FOR SALE.

CHESTER COUNTY WHITE PIGS, Short-horn Cattle, Leicester Sheep, Saddle and Carriage Horses, Pigeons, Spanish Merino Sheep, in different varieties of Pure Breeds and Fancy Poultry, English Coach and Scotch Shepherd Dogs. FOR FOWLS. Prepared and Sold by WM. A. MACRAE, Chemist, North Shore, Staten Island, N. Y. And may be had of all the leading Druggists. Price 50 cents per box, or by mail, 60 cents.

Lewis Maxwell, of Atlanta, Logan Co., Ills., writes: "The pair of pigs you sent me are hard to beat, the Boar has had 60 Sows, and will weigh 400 lbs."

John Murphy, of Buckeye, Garrard Co., Ky., writes: "The pigs you sent me are the best pair I ever saw, and Hog-raising has been my business for twenty years."

"The pigs arrived safe, and meet my fullest expectations," writes F. A. Bliss, Rehoboth, Mass.

F. E. T. & J. H. Hazen, of Hollowayville, Bureau Co., Ills., writes: "We have now had our pigs six weeks, and they have doubled their size in every way, length, breadth, and height. They are the finest pigs, and the most rapid growers we ever saw. They are perfect beauties. There can be no better feeders, everything they eat, appears to be immediately converted into muscle and fat."

D. B. Waterman, of Aurora, Kane Co., Ills., writes: "I have just returned from our State Fair at Chicago, where I saw all the different herds of Chesters, from Illinois, Iowa, and Michigan, and know I am justified in pronouncing unqualifiedly, the pigs you sent me, much superior in every point of view, to any I saw at the above Fair. My pigs are now 4½ and 5 months old. The Boar will weigh 250, and the Sow 200 lbs."

John C. Palmer, of Helena, Arkansas, writes: "My pigs gained 33 pounds apiece in 31 days, from 5 to 9 weeks old. I don't think any other breed can beat this."

Sent Free, three Months for Nothing.

100,000 Copies of this National Work

CAN BE

SOLD IN ONE YEAR.

Every Household should possess a copy of the Domestic

LIFE OF WASHINGTON

DURING THE REVOLUTION.

SOLD EXCLUSIVELY BY SUBSCRIPTION.

At the low price of \$5.00.

Containing Twenty-five splendid Steel-plate Portraits of the Noted Benefactors of the Revolutionary Period, engraved from original Possessions by W. D. Easton, Copley, Gainsborough, Stuart, Traumbull, Malbone, and other contemporary painters. The work is entitled

The Republican Court,

OR,

AMERICAN SOCIETY in the DAYS of WASHINGTON.

BY RUFUS W. GRISWOLD.

In one volume, Royal 8vo, containing 481 pages.

The design of the "Republican Court" is to give an interesting and faithful view of the "Private and Social Life of this Country, in the Days of Washington." Referring as briefly as possible to political affairs, it introduces the great characters of that illustrious age in their personal connections—in the parlor, ball-room, the theatre—in anecdotes, descriptions, and details of every-day experience. It embraces particular narratives of President Washington's celebrated Tour through the Eastern States, with all its festivities, parades, &c., and of the subsequent Tour through the Southern States, with the imposing and enthusiastic reception in Charleston, Augusta, &c.

Agents wanted throughout the country. Liberal terms and exclusive territory given. Bound prospectuses, with ruled paper for subscribers' names, and showing sample of binding, supplied to agents for \$1.50.

Apply at once to

D. APPLETON & CO.,

443 and 445 Broadway, New York.

THE METHODIST

Is an eight-page Weekly Newspaper, now in its seventh year of highly successful publication. It is Religious and Literary; Independent, Fraternal, Loyal and Progressive.

As a Family Paper it is unsurpassed. It commands some of the best Literary ability of the

Methodist Episcopal Church,

and of other Christian Denominations, and is largely patronized by all classes of Christians, as a Family paper.

It is Edited, as heretofore, by

REV. GEORGE R. CROOKS, D.D.

Assisted by the following able Editorial Contributors:

REV. ABEL STEVENS, LL.D.

REV. JOHN McCLINTOCK, D.D. LL.D.

REV. B. H. NADAL, D.D.

REV. H. B. RIDGAWAY, and

PROF. A. J. SCHEM.

It has a valuable Correspondence, both Domestic and Foreign; a fresh Story every week for the Children; a Financial, Commercial, Mercantile, and Agricultural Department; a valuable Religious and Secular News Summary, brought up to the hour of going to press.

TERMS: \$2.50 per year, payable in advance.

Twenty cents must be added by Subscribers in the British Provinces, to pre-pay postage.

Reasons for Subscribing Now.

Those subscribing for 1867, will receive, free of charge, all numbers published this year, after their subscriptions are received. Those subscribing during November, will get all of December free.

Liberal Premiums are allowed to those forming Clubs of subscribers.

Specimen Numbers sent free, on application.—Address

THE METHODIST,

114 Nassau-street, New York.

Agents wanted in every School, and at every Post-Office in the United States. Address

J. W. DAUGHLADAY, Publisher, 129 1/2 Chestnut-street, Philadelphia, Pa.

A NEW NOVEL,

By SOLON ROBINSON,

THE VETERAN AGRICULTURAL EDITOR

OF

THE NEW YORK TRIBUNE.

A novel by Solon Robinson, long and well-known as the Agricultural Editor of THE TRIBUNE, will be commenced in THE WEEKLY TRIBUNE of December 5th. It is called

NEWONTOC:

A STORY OF WESTERN LIFE, INDIAN AND DOMESTIC

Though Mr. Robinson's first novel, we do not doubt that it will newly prove the worth of the pen that in so many chapters of successful writing for the farm and the fireside, and in behalf of the friendless poor of a crowded city (witness the "Hot Corn Sketches"), has been entertaining and instructive.

A true Indian novel is among the varieties of latter-day fiction, and the pioneer life of the West, abounding, as it does, in rude but rich material for the work of the novelist, has found, of late, but few faithful delineators. It is not too much to say that few Americans have been so near to the American people in their homestead life and characters as settlers and pioneers, as the author of Newontoc; few have traveled so far and observed so closely amid the varieties of the farmer's and pioneer's life, East and West; and no writer for the daily press has had a keener relish for, and livelier sympathy with, the fresh and free out-door life which enters into the element of his novel. Mr. Robinson's writings have always been marked by a quaint and direct force; pictures, simple, but graphic, of things as they really are; practical and minute knowledge of the useful and the beautiful as they are brought together into every-day consciousness—these are some of the features of a style of word painting with which the readers of THE TRIBUNE have been long familiar.

The new novel, which will be begun the first week in December, will continue during the Spring.

In addition to this, THE WEEKLY TRIBUNE will contain, as usual, features of entertainment, instruction, and variety, surpassing those of any other journal published to benefit the home life of the people, and justify the ever-increasing support which has made it the most widely circulated paper in America.

The New York Weekly Tribune

is printed on a large double-medium sheet, making eight pages of six broad columns each. It contains all the important Editorials published in THE DAILY TRIBUNE, except those of merely local interest; also Literary and Scientific Intelligence; Reviews of the most interesting and important New Books; the Letters from our large corps of correspondents; the latest news received by Telegraph from Washington and all other parts of the country; a Summary of all important intelligence in this city and elsewhere; a Synopsis of the Proceedings of Congress and State Legislature when in session; the Foreign News received by every steamer; Exclusive Reports of the Proceedings of the Farmers' Club of the American Institute; Talks about Fruit, and other Horticultural and Agricultural information essential to country residents; Stock Financial, Cattle, Dry Goods and General Market Reports; making it, both for variety and completeness, altogether the most valuable, interesting and instructive WEEKLY NEWSPAPER published in the world.

The Full Reports of the American Institute Farmers' Club, and the various Agricultural Reports, in each number, are richly worth a year's subscription.

TERMS:

Table with 2 columns: Subscription type and price. Mail subscribers, single copy, 1 year—32 numbers... \$2.00; Mail subscribers, Clubs of five... 9.00; Ten copies, addressed to names of subscribers... 17.50; Twenty copies, addressed to names of subscribers... 34.00; Ten copies, to one address... 16.00; Twenty copies, to one address... 30.00

An extra copy will be sent for each club of ten, cost to be paid in advance.

Drafts on New York, or Post Office orders, payable to the order of THE TRIBUNE, being safer, are preferable to any other mode of remittance. Address

THE TRIBUNE, New York.

CURRENT WHOLESALE PRICES.

Table listing current wholesale prices for various commodities such as Flour, Wheat, Corn, Rye, Barley, Oats, and other agricultural products.

ing prices, but suddenly breaking down about the beginning of November, and since fluctuating widely. Toward the close the demand was becoming brisk again, and prices were quoted steadier.

New York Live Stock Markets.

Table showing weekly receipts of beef cattle and cows, and prices for various types of livestock.

The weekly receipts of beef cattle and cows have been nearly the same as the previous month; veal calves 367 per week less; sheep nearly 4,000 per week more; live hogs nearly 7,000 per week more.

A Horse Hospital.

Every one who keeps only two horses should be able to separate them if one is sick, and it is hardly the fair thing to turn the well one into the yard. If possible, have a box 10 feet square, 8x10 will do.

(Business Notices \$2.00 per Agate Line of Space.)

THE GREAT AMERICAN TEA COMPANY ALWAYS A WHOLESALE ESTABLISHMENT.

We have many enquiries (10 to 20 letters a day) asking what discount we make to the trade from our prices as published in the PRICE LIST. These are our lowest wholesale prices. We consider ourselves only a Wholesale Corporation, and we have but one price.

The way in which we came to break packages at all, was that during the high prices of Teas we furnished parties with packages as small as five pounds. Our fame spread far and wide; and parties with small means thought it very hard to be compelled to pay, elsewhere, about a dollar per pound more than we were selling the same goods for, simply because they could not afford to buy five pounds of us at one time. Therefore, in order to lighten these burdens, we consented to supply their wants in quantities as small as one pound at the wholesale prices.

Parties of small means wishing for goods to sell, can have their orders put up in small packages to suit their trade, but we cannot make any reduction in price, as our profits for the last six years have not averaged more than two cents per pound.

To give our readers an idea of the profits which have been made in the Tea trade, we will start with the American houses, leaving out of the account entirely the profits of the Chinese factors.

1st.—The American House in China or Japan makes large profits on their sales or shipments—and some of the richest retired merchants in this country have made their immense fortunes through their houses in China.

2d.—The Banker makes large profits upon the foreign exchange used in the purchase of Teas.

3d.—The Importer makes a profit of 30 to 50 per cent. in many cases.

4th.—On its arrival here it is sold by the cargo, and the Purchaser sells it to the Speculator in invoices of 1,000 to 2,000 packages, at an average profit of about 10 per cent.

5th.—The Speculator sells it to the Wholesale Tea Dealer in lines at a profit of 10 to 15 per cent.

6th.—The Wholesale Tea Dealer sells it to the Wholesale Grocer in lots to suit his trade, at a profit of about 10 per cent.

7th.—The Wholesale Grocer sells it to the Retail Dealer at a profit of 15 to 25 per cent.

8th.—The Retailer sells it to the consumer for all the profit he can get.

When you have added to these eight profits as many brokerages, cartages, storages, cooperages, and waste, and add the original cost of the tea, it will be perceived what the consumer has to pay. And now we propose to show why we can sell so very much lower than small dealers.

We propose to do away with all these various profits and brokerages, cartages, storages, cooperages, and waste, with the exception of a small commission paid for purchasing to our correspondents in China and Japan, one cartage, and a small profit to ourselves—which, on our large sales, will amply pay us.

Parties getting their Teas from us may confidently rely upon getting them pure and fresh, as they come direct from the Custom House Stores to our warehouses.

The Company have selected the following kinds from their Stock, which they recommend to meet the wants of Clubs. They are sold at Cargo Prices, the same as the Company sell them in New York, as the List of prices will show.

All goods sold are warranted to give satisfaction.

PRICE LIST:

- YOUNG HYSON (Green), 80c., 90c., \$1, \$1.10, best \$1.25 per pound. GREEN TEAS, 80c., 90c., \$1, \$1.10, best \$1.25 per pound.

- MIXED, 70c., 80c., 90c., best \$1 per pound. JAPAN, \$1, \$1.10, best \$1.25 per pound. OOLONG (Black), 70c., 80c., 90c., best \$1 per pound. IMPERIAL (Green), best \$1.25 per pound. ENGLISH BREAKFAST (Black), 80c., 90c., \$1, \$1.10, best \$1.20 per pound. GUNPOWDER (Gunpowder), \$1.25, best \$1.50 per lb.

ATLANTA, Ga., Oct. 30, 1866. To THE GREAT AMERICAN TEA COMPANY, 31 and 33 Vesey Street, New York.

FIFTH ORDER FROM THIS CLUB. Table listing various tea and gunpowder items with prices.

This is the Fifth Order; so you see it suits pretty well. Yours, etc. E. K. LONG.

P. S.—All towns, villages, or manufactories, where a large number of men are engaged, by clustering together, can reduce the cost of their Teas and Coffees about one-third by sending directly to the

GREAT AMERICAN TEA COMPANY, 31 and 33 VESSEY-STREET, corner of Church. Post-Office Box, 5,643 New-York City.

We call special notice to the fact that our Vesey Street Store is at No. 31 and 33 Vesey Street, corner of Church Street—large double store.

Parties looking for our store will please bear in mind that ours is a large double Store, Nos. 31 and 33 Vesey Street, corner of Church-street. This is an important fact to be remembered, as there are many other Tea Stores in Vesey St.

Herald of Health on Trial.

We will send the Herald of Health 3 months for 25 cents, that all may see how valuable it is, or for the year, \$2.00. MILLER, WOOD & CO., 15 Laight-street, New York City.

Will be mailed postage paid, on receipt of the retail price. F. J. HUNTINGTON & CO., PUBLISHERS AND BOOKSELLERS, 459 Broome-st., New York.

The Scientific American

To Be Enlarged for 1867.

This widely circulated and popular Journal of the Industrial Arts and Sciences, enters its 23d year on the 1st of January next, and the Publishers propose to signalize the occasion by enlarging it to the size of some of the most costly Scientific Journals of Great Britain, without, however, increasing the subscription price. It is almost superfluous to speak of the great value of this popular and useful journal, to all classes; and especially to Mechanics, Manufacturers, Inventors, Engineers, Chemists, Agriculturists, and all who love to read of the wondrous progress which now marks every department of Mechanical Engineering, and the Industrial Arts and Sciences generally. The Editorial Department is very ably conducted, and many of the best scientific writers in this country and Europe, are contributors to its pages. Many of the articles have the charm of romance about them, and inspire the mind with noble ideas. The wonder is that so good a journal in every sense, has not a half million readers in this thriving land. Its circulation, however, is very large in all parts of the world.

The Engravings of NEW INVENTIONS, TOOLS, IMPLEMENTS for the FARM, WORKSHOP and HOUSEHOLD, are very numerous and splendidly executed by the best artists in the world. This feature of the paper is very striking and has won the praise of the united press of this country and Europe.

Another feature peculiar to the SCIENTIFIC AMERICAN, is the Official publication of every patent granted by the Government PATENT OFFICE. Each number contains a weekly issue of Patent Claims, together with copious notices of New Inventions, together with Reviews of Foreign Inventions and Discoveries in every department of Science. Whoever reads the SCIENTIFIC AMERICAN is not only amused, and is not bothered with any of the ordinary

The American and European Patent Office, in connection with the SCIENTIFIC AMERICAN, furnish a large number of mechanical novelties, which are sent to the employment of a large corps of Scientific Experts, who prepare drawings and specifications for patents. No man is so doubt the most complete of his work.

Now is the time to subscribe to the SCIENTIFIC AMERICAN, so as to receive the new volume. The number for the year makes a most splendidly illustrated volume of 32 pages, 10 cents per annum, \$1.50 for six months, \$1 for four months, 50 cents and upwards, \$2.50 each. Canadian subscribers, \$2 per annum, always in advance. Specimen numbers free, also a Pamphlet of advice to Inventors. Address

MUNN & CO., No. 37 Park Row, New York.
