PRINCIPAL CONTENTS.

ENCYCLOPÆDIA BRITANNICA.

KAOLIN

KAOLIN, a name applied to the pure white clay which forms an important ingredient in the manufacture of porcelain, and which is, therefore, known also as *china clay.* Large quantities are raised in Cornwall, whence it is frequently termed *Cornish clay.* The name *kaolin* is said to be derived from a hill near King-tih-chin, in China, named Kao-ling or "lofty ridge." The clay from this locality was first sent to Europe, under the name of kaolin, by the Père d' Entrecolles, a Jesuit missionary who resided at King-tih-chin in the early part of the last century. A similar white clay was soon afterwards found at Aue, near Schneeberg in Saxony, and was used by Böttcher in the manufacture of porcelain, thus laying the foundation of the factory at Meissen for producing the famous Dresden china. In England kaolin was first detected in Cornwall by William Cookworthy of Plymouth about 1755, a discovery which resulted in the manufacture of hard paste china at Plymouth and Bristol. In Cookworthy's writings the clay is called "caulin." Kaolin is found in Nebraska, and in several of the eastern States of the American Union.

Certain clays, when examined under the microscope, are seen to contain crystalline pearly scales of a mineral which Messrs Johnson and Blake have described as *kaolinite* (*American Journal of Science*, ser. ii. vol. xliii., 1867, p. 351). They regard this crystalline substance as a distinct mineral species, a hydrated silicate of aluminium, forming the basis of pure kaolin. Its composition appears to agree with Forchhammer's formula for true kaolin, viz., $Al_2O_3.2SiO_2 + 2H_2O$. Mr J. H. Collins regards the crystalline scales which are associated with the Cornish kaolin, not as kaolinite, but as a white lithia-mica or lepidolite.

Kaolin is almost invariably a product of the alteration of felspar, and is therefore always found in association with felspathic rocks, usually granite. The china-clay rocks of Cornwall and Devon are simply granites in which the orthoclase-felspar has become decomposed or kaolinized. Such rocks are termed by Mr Collins *carclazite*, after the Carclaze mine, near St Austell, where typical varieties occur. The production of kaolin from felspar is rather difficult to explain, inasmuch as the alteration is sometimes observed under conditions which appear to preclude the operation of atmospheric agencies. It is not simply the effect of water charged with carbonic acid, whereby the felspar might be decomposed and its alkaline silicate removed as a soluble carbonate, while the silicate of aluminium remained behind, in a hydrated condition, as kaolin or china clay. Many chemists have been inclined to attribute the decomposition to the effect of water or watery vapour at a high temperature, charged with hydrofluoric and boric acids. It is certain that minerals containing fluorine and boron—such as fluor spar, lepidolite, and schorl—are common associates of kaolin.

The localities from which kaolin is obtained in Britain are all situated in Cornwall and Devon; in the former county the workings are principally in the neighbourhood of St Austell, St Stephen's, and Breague, while in Devon they are situated at Lee Moor and Meavy, on the south of Dartmoor. In working the clay the "overburden" or superficial deposit is first removed, in order to reach the clay-bearing rock. The rock is broken up by the pick, and water is introduced to wash out the clay. A quantity of sand is left behind, and requires to be constantly removed. The water containing the clay in suspension is either pumped to the surface up a shaft, or, if the working be upon a hill-side, is run out at an adit level. This clay-water is led into channels called "drags," where the sand and coarser flakes of mica are deposited. From the drags the liquid passes into another set of channels called "micas," in which further deposition of suspended matter occurs. Thus purified, the clay-water is conducted into a series of pits and tanks, where the finely-divided particles of clay slowly subside. In the tanks it is allowed to settle until it acquires a thick creamy consistency, when it is transferred to the drying house or "dry." Formerly the clay was dried naturally by exposure to sun and air, but it is now always artificially dried by means of heated flues, and the preparation of the clay is thus greatly facilitated.

China clay is not only used in the manufacture of pottery, but is also extensively employed by the paper-maker and by the calico-bleacher. It is likewise used to a small extent in the manufacture of alum, artificial ultramarine, and some other chemical products. In 1880 the quantity of china clay raised in Cornwall amounted to 278,572 tons, and in Devon to 25,370 tons.

See J. H. Collins, in *Journal of the Society of Arts*, May 5, 1876, and *Treatise on China Clay*, by D. Cock, 1880.

KAPURTHÁLA, or Kopurthella, a native state in the Punjab, India, lying between 31° 9′ and 31° 39′ 30″ N. lat., and between 73° 3′ 15″ and 75° 38′ 30″ E. long. Area, 800 square miles; estimated population, 250,000. The Kapurthála family at one time held possessions on both sides of the Sutlej, and also in the Bari Doáb. The cis-Sutlej estates and scattered possessions in the Bari Doáb were escheated owing to the hostility of the chief in the first Sikh war, but the latter possessions were afterwards restored to the family in recognition of the loyalty of Rájá Randhír Sinh during the mutiny of 1857, when he led a contingent to Oudh which did good service. He also received a grant of estates in Oudh, 850 square miles in extent, and with an estimated population of 220,000. In these tracts, however, he exercises no sovereign powers, occupying the status only of a large landholder. His total revenue is estimated at £170,000, subject to a charge of £13,000 payable to the British Government in commutation of military service.

KARÁCHI. See Kurrachee.

KARA-HISSAR is the name of several towns in Asiatic Turkey. (1) Afium Kara Hissar has been already noticed, vol. i. p. 244. (2) Eski Kara Hissar, lies 10 miles to the north of Afium. It is identified with the ancient Synnada, which in the time of Pliny was the chief town of a considerable district. The quarries of Docimia, which furnished the famous Synnadic or Docimitic marble, are about 2½ miles distant, and in the town numerous traces have been found of ancient sculpture in various stages of execution (see Hamilton's *Asia Minor*, i. 461, ii. 177; and Texier, *Asie Mineure*). (3) The eastern Kara-Hissar, usually distinguished by the prefix Shabin (*i.e.*, "alum"), is situated in the vilayet of Siwas, about 70 miles east of Niksar, on a northern tributary of the Lycus. It is the seat of a mutasarrif or vice-governor, and on a hill to the east there is an old castle which must at one time have been of military importance. The population is estimated at 11,000, mainly Mohammedans, though Armenians also form an important element. The district is rich in mineral products—silver, lead, copper, and iron; but only the alum mines, yielding from 120 to 250 tons per annum, are worked. The remains of the citadel, the ruins of a Byzantine church, traces of Roman brickwork, ancient coins, and a few Greek and Latin inscriptions, all go to show that Kara-Hissar has passed through many vicissitudes. The old town was evidently built not at the foot but up the steep slope of the hill, tier above tier. In 1473 Kara-Hissar made voluntary submission to Sultan Mohammed II. A full description, with a plan of the town and neighbourhood, is given by Barth in Petermann's *Mittheilungen, Ergänzungsheft*, 1860. See also Taylor's "Journal," &c., in *Journ. Roy. Geogr. Soc.*, 1868.

KARAITES, or Caraites, a Jewish sect of the Middle Ages, claiming to be distinguished by adherence to Scripture as contrasted with oral tradition, whence the name (from קרא, as if "readers," *scripturarii*; sometimes also בְּנֵי מִקְרָא). They have frequently been identified with the Sadducees or with the Samaritans, with neither of whom have they any historical connexion or much spiritual affinity. The schism arose at Baghdad about the middle of the 8th century, when the hereditary claims of Anan, a learned Talmudist, to the office of Resh Galutha were set aside by the Gaonim or heads of rabbinical schools at Sura and Pumbeditha because he was believed to undervalue the authority of the Talmud. An appeal by Anan to the caliph proved unsuccessful, and he appears even to have been imprisoned for some time; but ultimately he was permitted to migrate along with his followers to Palestine, where they erected in Jerusalem a synagogue which continued to be maintained until the time of the crusades. From this centre the sect diffused itself thinly over Syria, spread into Egypt, and ultimately reached south-eastern Europe. Anan, who is said to have died in 765 A.D., was the author of a commentary on the Pentateuch and other works in Talmudic Hebrew and Arabic,—all of which unfortunately are lost; for our knowledge of the distinctive principles maintained by him we are thus left entirely dependent on the hostile indications of opponents. In general we know that he showed great bitterness against the Talmud and its upholders (the "Rabbanites") for their falsification of the written law by arbitrary additions and subtractions, but there is nothing to indicate that he himself had the insight or the fervour by which he could have become the pioneer of any really great reformation in religion or morals. The questions in dispute appear to have turned entirely on points of very minute detail. Several of them related to the regulation of the calendar, the new moon, for example, being fixed by the Karaites by direct observation, not by astronomical calculation, and the intercalary year also being determined empirically; others related to paschal and pentecostal ritual, such as the precise hour for killing the lamb or for burning its remains. The differences which affected social life most deeply were those relating to Sabbath observance and the forbidden degrees of marriage, the Karaites not recognizing any distinction between relationships of consanguinity and those of affinity, while in their zeal to avoid all risk of infringement of the sacredness of the day of rest they prohibited the burning of any light at all in their houses from sunset to sunset. Little information as to the Karaites can be derived from their liturgies, which are comparatively modern; though differing from those used by the Rabbinical Jews, they are not characterized by any marked divergence in principle. The controversies as to the rule of faith which so deeply divided the Christian church in the 16th century gave to this obscure sect an illusory and passing importance, the Catholics frequently hurling the epithet Karæi, in token of contempt, at the Protestants, who in their turn willingly accepted it as sufficiently descriptive of their attitude towards Scripture. The Karaites never have been numerous; the present community in Jerusalem numbers only about ten families. They occur in Constantinople and elsewhere in Turkey, but are chiefly met with in southern Russia, and especially in the Crimea, where in 1874 they numbered some 6000, chiefly in Eupatoria, Theodosia, and Sebastopol. In the Crimea their historical capital and chief synagogue was formerly the "Jews' Castle" (Tshufut-Kale), near Bakhchisarai. The place is now deserted; its cemetery was the seat of Firkowitsch's notorious forgeries (inscriptions of 1st century), by which he sought to establish a fabulous antiquity for his sect. According to Strack (*A. Firkowitsch u. seine Entdeckungen*, 1876) the oldest tombstones do not go back beyond the 14th century. The modern Karaites are generally well spoken of for their honesty, perseverance, and simple habits of life; but their enslavement to tradition is quite as complete as that of any Talmudist could possibly be.

Among the older authorities may be mentioned Morinus, *Exercit. Bibl.*, lib. ii. ex. 7, 1669; and Triglandius, *Diatribe de Secta Karæorum*, 1703. See Grätz, *Gesch. der Juden*, especially in vol. v., 1860; and Fürst, *Gesch. des Karäerthums*, 1865.

KARAKORUM, or Karakoram, a name applied to a city, a mountain range, and a mountain pass in Central Asia. For the range and pass see Kuen-lun. The ancient city or rather camping-ground of Karakorum (the Caracaron of Marco Polo), was situated near the upper course of the Orkhon, a tributary of the Selenga. Founded, according to Chinese authority, by Buku, khan of the

Uigurs, in the 8th century, it was at the time of Jenghiz the chief seat of Togrul Wang, Marco Polo's Prester John, and under Jenghiz's successor Okkôdai it became what it continued to be till 1256, the capital of the Mongolian power. It was visited by Carpini (1246) and Rubruquis (1253). Some ruins of earthworks are still to be traced.

See Rémusat, *Rech. sur la ville de Karakorum*; Yule, *Marco Polo*; *Geographical Magazine*, 1874.

KARAMZIN, Nikolai Mikhailovich (1765–1826), Russian historian, critic, novelist, and poet, was born at the village of Mikhailovka, in the government of Orenburg, and not at Simbirsk as many of his English and German biographers incorrectly state, on the 1st of December (old style) 1765. His father, an officer in the Russian army, of Tartar extraction, was anxious that his son should follow his own profession. The idea was not, however, persevered in, and the future author was sent to Moscow to study under Professor Schaden, whence he afterwards removed to St Petersburg, where he made the acquaintance of Dmitrieff, a Russian poet of some merit, and occupied himself with translating essays by foreign writers into his native language. After residing some time at St Petersburg, he went to Simbirsk, where he lived in retirement till induced by a friend to revisit Moscow. There, finding himself in the midst of the society of learned men, he again betook himself to literary work. In 1789 he resolved to travel, and visited Germany, France, Switzerland, and England. On his return he published his *Letters of a Russian Traveller*, which met with great success. They are elegantly written, and show the feeling of a poet for the scenery of the countries through which he passed, but to many readers of the present day they will appear insipidly sentimental. These letters were first printed in the *Moscow Journal*, but were afterwards collected and issued in 6 vols. (1797–1801). In the same periodical Karamzin also published translations of some of the tales of Marmontel, whose sickly elegance was then in fashion, and some of his own original stories, among which may be mentioned *Poor Liza* and *Natalia the Boyar's Daughter*. To judge by the cheap editions which are continually appearing, these tales still find readers in Russia. The best of them is *Marfa the Posadnitza of Novgorod*, but all are more or less disfigured by the sentimentalism already referred to. In 1794 and 1795 Karamsin abandoned his literary journal, and published a miscellany in two volumes, entitled *Aglaia*, in which appeared, among other things, "The Island of Bornholm" and "Ilia Mourometz," a story based upon the adventures of the well-known hero of many a Russian legend. In 1797–99 he issued another miscellany or poetical almanac, *The Aonides*, in conjunction with Derzhávin and Dmitrieff. In 1798 he compiled the *Pantheon*, a collection of pieces from the works of the most celebrated authors ancient and modern, translated into Russian. Many of his lighter productions were subsequently printed by him in a volume entitled *My Trifles*. In 1802 and 1803 Karamzin edited the journal *The European Messenger*. It was not till after the publication of this work that he realized where his strength lay, and commenced his *History of the Russian Empire*. In order to accomplish the task, he secluded himself for some years; and, on the cause of his retirement becoming known to the emperor Alexander, Karamzin was invited to Tver, where he read to the emperor the first eight volumes of his history. In 1816 he removed to St Petersburg, where he spent the happiest days of his life, enjoying the favour of Alexander, and submitting to him the sheets of his great work, which the emperor read over with him in the gardens of the palace of Tzarskoë Selo. He did not, however, live to carry his work further than the eleventh volume, terminating it at the accession of Michael Romanoff in 1613. In 1825 the health of Karamzin began to decline, and the emperor Nicholas, who had succeeded to the throne in that year, and continued the favours which his brother had bestowed on the historian, ordered a frigate to be got ready, that he might visit a warmer climate to recruit his failing powers. It was, however, too late; on the 22d of May (old style) 1826, Karamzin died in the Taurida palace. A monument was erected to his memory at Simbirsk in the year 1845.

As an historian Karamsin has deservedly a very high reputation. Till the appearance of his work little had been done in this direction in Russia. The preceding attempt of Tatistcheff was merely a rough sketch, inelegant in style, and without the true spirit of criticism. Karamzin was most industrious in accumulating materials, and the notes to his volumes are mines of curious information. The style of his history is elegant and flowing, modelled rather upon the easy sentences of the French prose writers than the long periodical paragraphs of the old Slavonic school. Perhaps Karamzin may justly be censured for the false gloss and romantic air thrown over the early Russian annals, concealing the coarseness and cruelty of the native manners; in this respect he reminds us of Sir Walter Scott, whose writings were at this time creating a great sensation throughout Europe, and probably had their influence upon our author. Karamzin appears openly as the panegyrist of the autocracy; indeed, his work has been styled the "Epic of Despotism." He does not hesitate to avow his admiration of Ivan the Terrible, and considers him and his grandfather Ivan III. as the builders up of Russian greatness, a glory which in his earlier writings, perhaps at that time more under the influence of Western ideas, he had assigned to Peter the Great. In the battle-pieces (*e.g.*, the description of the field of Koulikovo, the taking of Kazan, &c.) we find considerable powers of description; and the characters of many of the chief personages in the Russian annals are drawn in firm and bold lines. The study of ethnology and historical criticism has advanced so much since the days of Karamzin that some of his work has necessarily become obsolete, but it will always be read with pleasure and advantage. No translation into English of this *opus magnum* has appeared, although even modern Greek boasts its version. Of the French translation by MM. Saint Thomas and Jauffret Karamzin himself had a mean opinion; he declared that the average number of mistakes in each of the many volumes was two hundred. As a critic Karamzin was of great service to his country; in fact he may be regarded as the founder of the review and essay (in the Western style) among the Russians. He had read extensively, and modelled himself upon Addison and others of our best writers. As a novelist and writer of tales he imitated the sentimental school then in vogue throughout Europe. As a poet he occupies a subordinate place, but his productions are above mediocrity. Many of his lyrics are graceful and melodious, and the sentiments expressed are those of a benevolent and healthy-minded man. The little poem entitled *The Grave* deserves special mention.

KARASU-BAZAR, a town of Russia, in the government of Taurida, near the rivers Tunas and Karasu, in 45° 3′ N. lat. and 34° 26′ E. long., 27 miles from Simpheropol on the road to Theodosia. The site is low, but it is surrounded by hills, one of which, the Ak-Kaya or White Rock, not only affords protection from the north wind, but so reflects the sunshine upon the town that it enjoys a much milder climate than the surrounding region. The dirty streets full of petty traders, the gloomy bazaar with its multitude of small shops, the market squares, the blind alleys, the little gates in the dead court-yard walls, all give the place the stamp of a Tartar or Turkish town, and remind the visitor that here was after 1763 the seat of the Crimean khans. In 1861 there were twenty-four mosques, but several have fallen into decay; in one of them is the tomb of Yakubaga-Rudzvitch, the founder of the well-known Crimean family. Of the numerous caravanserais, the Tash-Khan is the most notable —a strong half-fortified building erected in 1656. Placed on the high road between Simpheropol and Kertch, and in the midst of a country rich in corn-land, vineyards, and gardens, Karasu-Bazar used to be a chief seat of commercial activity in the Crimea; but it is gradually declining in importance. The population consists of Armenians, Greeks, Jews, Tartars, and (in smaller numbers) Russians. The bulk of the trade is in the hands of the Armenians, and they are also the owners of the great proportion of the buildings in the town. About 2000 of the Jews are what are known as Krimtchaks, or sometimes as Constantinopolitan Jews. From the ordinary "rabbinical Jews" of Russia they differ by wearing the Tartar costume and by the use of the Tartar tongue, instead of the German jargon. They are engaged in making leather, Tartar knives, Tartar embroidery, and similar articles. The population of Karasu-Bazar is given by the St Petersburg *Calendar* for 1874 as 14,397. Round about the town lie cemeteries of unusual extent.

By Thunman and others Karasu-Bazar has been identified with the Greek town of Mauron-Kastron, but Professor Bruhn thinks that, as there has never apparently been any fortress at Karasu-Bazar, the site of the "Black Castle" is more probably at Mangup-Kale. The caves of Akkaya, however, give evidence of early occupation of the spot. When in 1736 Khan Feta Ghirei was driven by the Russians from Bakhchisarai he settled at Karasu-Bazar, but next year the town was captured, plundered, and burned by General Douglas. In 1784 it was the temporary seat of the Russian administration of the Crimea.

KARATCHEFF, a town of Russia, in the government of Orel, near the river Snezheti, 59 miles north-west from Orel on the railway to Smolensk. The population is given in the St Petersburg Calendar for 1874 at 10,023. A yearly fair is held in the adjoining village of Berezhka, and a good trade is carried on in agricultural produce, as well as in the oil, wax candles ropes. &c., furnished by the local industry.

Karatcheff is mentioned as early as 1146. In the 17th century it was one of the frontier or "watch" towns of Russia towards the Crimea, and sent out its scouts as far as Kursk. About half the inhabitants perished of the plague in 1654. Only since 1778 has the town been at the head of a district in Orel; it formerly belonged to the governments of Kieff (1708) and Bielgorod (1732).

KARATEGIN, a country of Central Asia, now subject to Bokhara, consisting of a highland district between the Hissar and the Darwaz chains. It is bounded on the N. by the Russian province of Ferghana (Khokand), on the E. by Kashgar, on the S. by independent Darwaz, and on the W. by Hissar and other Bokharian provinces. The plateau is traversed by the Surkhab or Kyzyl Su, a right-hand tributary of the Oxus, which rises in the Alai mountains, and for the first 132 miles of its course "runs through gorges of extreme wildness." Below the hamlet of Khantia-hota (according to Abramof), the valley widens considerably, and at Sar-i-pul, the only point where it is crossed by a bridge, the river has a depth of 7 feet. With the neighbouring lands Karategin has no communication except during summer, that is, from May to September. The winter climate is extremely severe even in the more populous districts; the snow begins to fall in October, and it is May before it disappears. During the warmer months, however, the mountain sides are richly clothed with the foliage of maple, mountain ash, apple, pear, and walnut trees; the orchards furnish, not only apples and pears, but peaches, cherries, mulberries, and apricots; and the farmers grow so much corn that the surplus is a regular article of export to the neighbouring states. Every householder has a portion of the soil which he can call his own; but if he leave it fallow for more than three years in succession, he runs the risk of having it confiscated by the Government. Some proprietors possess as much as from 300 to 500 acres, and keep from ten to twelve yoke of work oxen and from six to twelve labourers. The necessity of storing fodder to last for five months tends to keep low the number of domestic cattle. Both cattle and horses are of a small and hardy breed. The wild animals—bears, wolves, foxes, jackals, lynxes, martens, otters, &c.—are of no small economic importance; but the hunters and trappers are obliged to sell their pelts to the Government at half the market price. Rough woollen cloth and mohair are woven by the natives during their long winter; and they make excellent fire-arms and other weapons. Trade is still carried on by barter, there being neither coinage nor fixed market-place in the country. Foreign wares—iron, cotton, silk, combs, mirrors, soap, &c.—are introduced by merchants from Kashgar and Hissar, who receive in exchange mainly cattle, hides, and skins. Gold, however, is found in various places, more particularly at Sarym Saly (according to Abramof); and there are salt-pits in the mountains near Langar-sha. The chief town, Harm or Gharm, is a place of some eight hundred houses (Arandarenko says three hundred and forty) situated on a hill on the right bank of the Surkhab. With the exception of about five thousand tents of nomadizing Kirghiz, the inhabitants of Karategin are understood to be Galtchas—by some identified with, by others distinguished from the Tadjiks. They speak a Persian dialect and profess the Mohammedan faith. Schuyler, who met with some of them at Khokand, describes the Karateginese as swarthy, thickset, good-natured fellows, who, gathered in a circle, would after prayers and supper tell tale after tale and legend after legend till they dropped off to sleep. It is calculated that the settled population of Karategin may amount to about 382,000 souls, the number of households being 36,672, distributed among four hundred settlements.

Karategin has hardly been touched by European exploration (the first expedition was that of Oshanin in 1878); and of its history almost nothing is known. The native princes or shahs, who claimed to be descended from Alexander the Great, were till 1868 practically independent, and kept up a considerable degree of state. Their allegiance was indeed claimed in an ineffective way by Khokand, but eventually Bokhara took advantage of intestine feuds to secure their real submission. Some geographers (Kiepert, for example) have been disposed to recognize in Karategin the Parætaceni of Alexander's historians, and Colonel Yule has conjecturally identified it with the Holumo (Garma ?) of Hwen Tsang.

See Abramof in *Journ. Roy. Geogr. Soc.*, 1871; Arandarenko's paper in the *Russische Revue*, epitomized in *Das Ausland*, 1878; and letters from Oshanin in *Globus*, 1878. See also Colonel Yule's essay prefixed to Wood's *Journey to the Source of the River Oxus*, 1872.

KARAULI, or Kerowly, a native state in Rájputana, India, lying between 26° 3′ and 26° 49′ N. lat., and between 76° 35′ and 77° 26′ E. long. It is entirely surrounded by neighbouring states, and has an area of about 1260 miles, and an estimated population of 140,000. Almost the entire territory is composed of hills and broken ground, but there are no lofty peaks, the highest having an elevation of less than 1400 feet above sea-level. The Chambal river flows along the south-east boundary of the state. Iron ore and building stone comprise the mineral resources of Karauli. The prevailing agricultural products are *bájra* and *joár*, which form the staple food of the people. The only manufactures consist of a little weaving, dyeing, wood-turning, and stone-cutting. The principal imports are piece goods, salt, sugar, cotton, buffaloes, and bullocks; the exports rice and goats. The Bráhmans form the most numerous class of the population. The Minas, who come next, make up the bulk of the cultivating class. The Rájputs, although numerically few, constitute the most important section. These belong almost entirely to the Jadu clan; they make good soldiers, but are indifferent agriculturists. The feudal aristocracy of the state consists entirely of Jadu *thakúrs* connected with the ruling house. They pay a tribute in lieu of constant military service, but in case of emergency or on occasions of state display they are bound to attend on the chief with their retainers. The mahárájá is the head of the clan, which claims descent from Krishna.

Karauli, or Kerowly, the capital of the above state, is situated in 26° 30′ N. lat. and 77° 4′ E. long. The town, which is fortified, is surrounded by a wall of sandstone, and is also protected on the north and east by deep winding ravines. The streets are narrow and irregular, and almost impassable for wheeled conveyances; there are, however, many costly houses and handsome temples, the sole building material being sandstone. The population is estimated at 28,000.

KARCZAG, or KARDSZAG, a corporate town of Hungary, and formerly the capital of the district of Great Cumania (now included in the county of Jász-Nagy-Kun-Szolnok), lies about 88 miles east-south-east of Budapest, with which city it is connected by railway, in 47° 19′ N. lat., 20° 56′ E. long. Karczag is a large straggling town, and contains Roman Catholic, Greek Orthodox, and Protestant churches, royal and magisterial courts of law, and tax and post offices. The soil of the surrounding country is exceedingly humid and fertile, and enormous quantities of melons, fruit, grapes, wheat, maize, rape-seed, and mangcorn are grown. In the more marshy places water-fowl and tortoises are caught in large numbers. Population in 1880, 15,962, almost exclusively Magyars.

KÁRIKAL, a French town and settlement in India, situated on the south-east coast, within the limits of Tanjore district, 10° 55′ 10″ N. lat., 79° 52′ E. long., with an area of 52 square miles, and a population of 92,516. The site was purchased by the French from the Tanjore rájá in 1738. It was captured by the English in 1760, restored in 1765, again taken in 1768, and finally restored in 1816. It formed the base of Lally's operations against Tanjore. The town is neatly built on one of the mouths of the Kaveri (Cauvery), and carries on a brisk trade with Ceylon, Europe, and the French colonies, exporting rice, and importing chiefly European articles and timber. A chef de l'administration, subordinate to the government at Pondicherri, is in charge of the settlement.

KARMATHIANS. See ARABIA, vol. ii. p. 259, and MOHAMMEDANISM.

KARNAK. See ARCHITECTURE, vol. ii. p. 390, and EGYPT, vol. vii. p. 777.

KARNÁL, a district in the lieutenant-governorship of the Punjab, India, lying between 29° 9′ and 30° 11′ N. lat., and between 76° 13′ and 77° 15′ 30″ E. long., bounded on the N. by Umballa (Ambala) and the Patiála state, W. by Patiála and Jínd states and by Rohták district, S. by Delhi district, and E. by the Jumna river. The area is 2351 square miles. Karnál forms a portion of the low dividing ridge which separates the watersheds of the Indus and the Jumna. The district falls naturally into two divisions—the *bángar*, or upland plain, and the *khádar*, or low-lying land, which skirts the valley of the great river. The banks of the larger streams are fringed with magnificent forest trees, and groves of mangoes mark the neighbourhood of every temple or homestead. Irrigation is afforded by the western Jumna canal. As a whole, Karnál is better supplied with trees than most of the plain country of the Punjab. The Jumna itself here presents the usual characteristics of the upper part of its course. Sandbanks shift from one side to the other of the main channel, and from time to time the whole stream suddenly changes its bed, transferring half a dozen villages together from Muzaffarnagar to Karnál, or *vice versa*. The district is famous for its sport.

The population in 1868 amounted to 610,927 (330,763 males and 280,164 females)—Hindus, 356,305; Mohammedans, 151,723; and "others," 93,604. Játs numbered 74,840, representing the chief agricultural element; Bráhmans, 52,396, most of them engaged in tillage; Rájputs, 47,860, chiefly Mohammedans; Chamárs, the landless labouring class, 37,053; pastoral Gújars, 20,857, about one-third of them Mohammedans. Five towns have a population exceeding 5000, viz., Karnál, 27,022; Pánipat, 25,276; Káithal, 14,940; Sewán, 6206; and Kunjpurah, 5163. The area under cultivation is 645,120 acres, the uncultivated area 860,800 acres, of which 578,027 are cultivable. The principal spring crop is wheat; the autumn harvest consists of rice, cotton, and sugar-cane, besides millets and pulses for home consumption. The growth of the more lucrative crops is on the increase. Grain and raw materials are exported to Umballa, Hissár, and Delhi,—the return trade consisting of European piece goods, salt, and refined sugar. A considerable quantity of cotton is woven for local use. Sal-ammoniac is obtained from the clay of Káithal and Gúla *tahsíls* to the value of £3450 per annum. Karnál town has a few blanket factories, and ornamental glass-ware is made at Pánipat. The Grand Trunk Road connects Karnál with Delhi and Umballa. The district is administered by a deputy commissioner. In 1872–73 the revenue was £78,847, of which £67,048 was derived from the land; and education was afforded by 99 schools, with 2541 pupils.

No district of India can boast of a more ancient history than Karnál, as almost every town or stream is connected with the legends of the *Mahábhárata*. The city of Karnál itself is said to owe its foundation to Rájá Karna, the mythical champion of the Kauravas in the great war which forms the theme of the national epic. Pánipat, in the south of the district, is said to have been one of the pledges demanded from Duryodhana by Yudisthira as the price of peace in that famous conflict. In historical times the plains of Pánipat have three times proved the theatre of battles which decided the fate of Upper India. It was here that Ibráhím Lodí and his vast host were defeated in 1526 by the veteran army of Baber; in 1556 Akbar reasserted the claims of his family on the same battlefield against the Hindu general of the house of Sher Sháh, which had driven the heirs of Baber from the throne for a brief interval; and at Pánipat too, on the 7th of January 1761, the Marhattá confederation was defeated by Ahmed Sháh Duráni. During the troublous period which ensued, the Síkhs managed to introduce themselves, and in 1767 one of their chieftains, Desu Sinh, appropriated the fort of Káithal, which had been built during the reign of Akbar. His descendants, the Bháis of Káithal, were reckoned amongst the most important cis-Sutlej princes. Different portions of this district have lapsed from time to time into the hands of the British. The towns are not generally in a flourishing condition, but the district possesses considerable commerce and great agricultural resources.

KARNÁL, a municipal town, the headquarters of the above district, 29° 42′ 17″ N. lat., 77° 1′ 45″ E. long., with a population in 1868 of 27,022. The civil station stretches to the west of the town. The Government maintains a large stud farm. There is a brisk trade with Delhi and Umballa; country cloth is manufactured for local consumption, and blankets for export, the latter trade employing about one hundred looms.

KARNÚL, a district in Madras, India, bounded on the N. by the Tungabhadra and Kistna rivers and by Kistna district, S. by Cuddapah and Bellary, E. by Nellore and Kistna, and W. by Bellary, lies between 14° 54′ and 16° 14′ N. lat., and between 77° 46′ and 79° 15′ E. long., with an area of 7151 square miles.

Two long mountain ranges, the Nallamalais and the Yellamalais, extend in parallel lines, north and south, through the centre of the district. The principal heights of the Nallamalai range are Biranikonda (3149 feet), Gundlabráhmeswaram (3055 feet), and Durugapukonda (3086 feet). The Yellamalai is a low range, generally flat-topped with scarped sides; the highest point is about 2000 feet. Several low ridges run parallel to the Nallamalais, broken here and there by gorges, through which mountain streams take their course. Several of these gaps were dammed across under native rule, and tanks formed for purposes of cultivation. One of these is the magnificent Cumbum Tank, closed in by a dam across the Gundlakamma river. It covers an area of nearly 15 square miles. The principal rivers are the Tungabhadra and Kistna, which bound the district on the north. When in flood, the Tungabhadra averages 900 yards broad and 15 feet deep. In 1860 an anicut or weir was built across the river at Sunkesala, 18 miles above Karnúl town, and a canal dug for irrigation and navigation. The Kistna flows here chiefly through uninhabited jungles, sometimes in long smooth reaches, with intervening shingly rapids. The Bhavanási rises on the Nallamalais, and falls into the Kistna at Sungameswaram, a place of pilgrimage. Below their junction is a whirlpool which is regarded as holy by the native pilgrims. There are three recognized forest divisions in the district—the Nallamalai, the Vellikonda, and the Yellamalai. The first two are conserved by the forest department. The chief timber-trees are teak and *yepi.* In the northern parts, where the jungle is poor, there are extensive level grassy lands, which afford pasture to numerous herds of cattle. The jungle products consist of gall-nuts, honey, wax, tamarinds, stick-lac, and bamboo rice. Tigers are numerous in the Nallamalais, and commit great havoc among the herds of cattle pastured in the jungles. The other animals include cheetahs, wolves, hyænas, foxes, bears, spotted deer, wild goats, several varieties of antelopes, bison, porcupines, and pigs.

The population in 1871 numbered 914,432, of whom 819,453 were Hindus, 60,579 Mohammedans, and about 3844 Christians, chiefly Roman Catholics, whose principal station is at Polur. The Catholics originally belonged to the Kapu caste, and their conversion to Christianity has not made any material change in their manners and customs. They eat and drink with Hindus, and in several cases intermarry with them. The Protestant converts are almost entirely low-caste natives in rural tracts. The wild tribes or Chenchus live on the Nallamalais in small communities called *gudems.* Each *gudem* includes several tribes, and has a portion of the hills allotted to it by common consent. The Chenchus are unwilling to cultivate, but are sometimes employed by the villagers in the plains to watch their fields during the harvest, and some of them are employed as road watchmen. During the hill festival they collect fees from pilgrims. Some of them also enjoy free lands for guarding the jungles. The principal towns are Karnúl (population in 1871, 25,579), Nandial (9378), Cumbum (7137), Gúdur (5525), Meddikera (8586), Kodumúr (6064), and Paikali (5076).

The chief crops are rice, wheat, and other cereals, gram, cotton, tobacco, indigo, sugar-cane, betel, chillies, &c. The staple of the district is *cholam* (*Sorghum vulgare*). The total area under cultivation in 1877 was 2,089,689 acres, area uncultivated but capable of cultivation 1,017,389 acres, and uncultivable waste 1,396,602 acres. There is not much waste land in the plains, but there is a good deal in the Nallamalais, which was cultivated in ancient times, but is now overgrown with jungle. The main canal of the Madras Irrigation Company, intended for both irrigation and navigation, runs 142 miles within Karnúl; the extent actually irrigated in 1875–76 was 10,479 acres. Both Karnúl and the neighbouring district of Bellary suffer from droughts at periodic intervals; and, the mass of the population being small landowners, with no reserve capital, the failure of a single monsoon involves general distress; 1804, 1810, 1824, 1833, 1854, 1866, and 1876 were all years of drought and consequent scarcity. In the famine of 1876–77 nearly £600,000 was spent on relief works, yet the number of deaths recorded from 1st October 1876 to 30th June 1877 was 48,000, as compared with 19,974 in the corresponding period of the previous year. The chief manufacture in Karnúl is weaving. Iron is worked at the foot of the Nallamalais. Of late years this industry has greatly diminished, native iron being superseded for agricultural implements by imported iron. Diamond mines have been worked from early times in the quartzite beds of the Yellamalai hills, which are now rented out by Government for about £20 a year. Quarrying stones is an important industry. Indigo and sugar are also manufactured. Weekly markets are held in most of the towns and important villages. There is little or no export of grain. Salt is imported from the eastern coast, but earth salt is largely manufactured. Cotton, indigo, tobacco, and hides, with cotton carpets and cotton cloth, are the chief exports. European piece goods, areca-nut, cocoa-nut, and various dry condiments required for native households are the chief imports. The total net revenue of the district in 1870–71 was £196,468, the total civil expenditure £46,998; the land revenue was £135,929. Education is backward, only 4 per cent. of the population in 1871 being returned as able to read and write. In 1875 there were altogether 263 schools, with 5781 pupils. The climate is on the whole healthy The prevailing winds are west and north-east, and the mean temperature is about 85° Fahr. The total annual rainfall is about 35 inches. In the villages along the foot of the Nallamalais, a severe type of fever prevails, accompanied by enlargement of the spleen

KARNÚL, the headquarters of the above district, in 15° 49′ 58″ N. lat. and 78° 5′ 29″ E. long., had a population in 1871 of 25,579. It is a hot unpleasant town, built on rocky soil at the junction of the Hindri and Tungabhadra rivers. The old Hindu fort was levelled in 1865, with the exception of one of the gates, which was preserved as a specimen of ancient architecture, and in some measure restored. In the famine of 1877–78 Karnúl and the surrounding country suffered terribly, owing to their isolated position. The nearest railway station is Gooty, 80 miles distant; and it was only by extraordinary efforts that food was conveyed to the town. The population is half Hindu and half Moslem, this unusual proportion marking the long rule of the Pathán nawábs.

KARS, a fortified town of Armenia, formerly at the head of a sandjak in the Turkish vilayet of Erzerum, but since 1878 the centre of a territory attached to the Russian governor-generalship of the Caucasus. It is situated in 40° 36′ 52″ N. lat. and 43° 5′ 76″ E. long., 30 miles south-west of Alexandropol (Gumri) and 130 miles north-east of Erzeroum, on the eastern end of a spur of the Soghanli Dagh, the site of the town proper being cut off from the rest of the range by the Kars Tchai, a sub-tributary of the Araxes. There are three considerable suburbs—Orta Kapi to the south, Bairam Pasha to the east, and Timur Pasha on the western side of the river. To the south-eastward opens up a vast plain. Owing to the bareness of the dark basalt hills, and the sombre colour of the buildings, a touch of melancholy mingles with the picturesqueness of the view. At the north-west corner of the town, overhanging the river, rises the ancient citadel (the Itch Kaleh of the Turks), which in earlier times was a strong military post, but is now of almost no moment in a regular siege, being commanded completely by several of the surrounding eminences. The value of the position depends on the line of forts, and even this is greatly diminished by the fact that they are disposed in a circuit of about 10 miles round the town. Of chief importance are the works on the Kara Dagh heights to the north-east and the line on the heights above the left bank of the river. The population of Kars was at one time estimated at 40,000; but, according to Baron von Seidlitz, it had in 1878 only 8672 inhabitants (including 7330 Turks, 1191 Armenians, 138 Greeks).

Though during the 9th and 10th centuries the seat of an independent Armenian principality, Kars has nothing to boast of beyond its military fame. The citadel, it would appear, was built by Amurath III. during the war with Persia, in the close of the 16th century. It was strong enough to stand a siege by Nadir Shah in 1731, and in 1807 it successfully resisted the Russians. After a brave defence it surrendered on 23d June 1828 to the Russian general Paskievitch, 11,000 men becoming prisoners of war. During the Crimean war the Turkish garrison, guided and stimulated by General Williams (afterwards knighted as Sir W. Fenwick Williams of Kars) and other foreign officers, kept the Russians gallantly at bay during a protracted siege; but, after the garrison had been devastated by cholera, and food had utterly failed, nothing was left but to capitulate (November 1855). The fortress was again stormed by the Russians in the war of 1877–78

B. Norman, *Armenia and the Campaign of* 1877, 1878, Greene, *Russian Army and its Campaigns in Turkey*, 1879.

KARSHI, an important town of Central Asia, the centre of a begship dependent on Bokhara. It is situated about 85 miles south-south-west of Samarkand, in a vast plain at the junction of two of the main confluents of the Kashkadarya, a river which, though fed by numerous mountain streams, soon loses itself in the sands. It is a large and straggling place, with a circuit of 5 miles, and the population within the walls amounts to 25,000. There are three colleges, with accommodation for upwards of three hundred students. The Biki mosque is a fine building inlaid with blue and white tiles. All the ordinary houses are built of clay, but they are often two stories high. Along the river stretches a fine public promenade sheltered by clumps of poplars. Round the town lie gardens and fields watered from wells. Poppies and tobacco are both largely grown, the tobacco being deemed the best in Central Asia. There is also a considerable trade in grain; but the commercial prosperity of Karshi is mainly due to the fact that it is a meeting point for the roads from Samarkand, Bokhara, Hissar, Balkh, and Maimene, and serves as the mercantile centre for the surrounding steppes, the market where horses are obtained for the caravans, and where the Turkomans and Uzbegs dispose of the products of their camps (carpets, seats, &c.). The knives and weapons manufactured in Karshi are known as far as Persia and Arabia, and its coppersmiths turn out excellent work.

KARWAR, or CARWAR, the chief town and headquarters station of North Kánara district, Bombay, 50 miles south-east of Goa, 14° 50′ N. lat., 74° 14′ E. long. It was once an important place of commerce; the East India Company had a factory there in the year 1663. It is the only safe harbour all the year round between Bombay and Cochin. In the bay is a cluster of islets called the Oyster Rocks, on the largest of which is a lighthouse. There are two smaller islands in the bay, which afford good shelter to native craft and small vessels during the strong north-west winds that prevail from February to April. The average annual value of the imports at Kárwár port during the five years ending 1873–74 was £244,469, of the exports £310,884. Population in 1872, 13,263.

KASAN. See KAZAN.

KASANLIK, or KEZANLYK, a town of Roumelia, in the vilayet of Adrianople, is situated at the foot of the Balkans, about 5 miles south of the Shipka Pass, in a highly fertile plain watered by the Tundja and its numerous tributaries. Throughout the plain there are extensive fields of roses grown for the manufacture of attar of roses, which is exported largely to western Europe. Maize is also grown; and cattle and sheep are reared in considerable numbers. The town is surrounded by valuable woods of walnut trees. The Russo-Turkish war of 1877–78 has done serious injury to the prosperity of the whole region, and has told on the production of attar of roses, which formerly was estimated at about 200 gallons for the Kasanlik district. The population is variously estimated at from 10,000 to 12,000. Two-thirds of these are Bulgarians and Christians; the remainder are Turks.

KASCHAU (Hung., *Kassa*; Lat., *Cassovia*), an ancient royal free town, and capital of the cis-Tisian county of Abauj, Hungary, is pleasantly situated on the right bank of the Hernád, in a valley surrounded by sloping vineyards, about 130 miles north-east from Budapest, with which city, as also with Cracow, Lemberg, and other centres, it is connected by railway, 48° 42′ N. lat., 21° 17′ E. long. Kaschau is the see of a Roman Catholic bishop suffragan of Eger (Erlau), the headquarters of the general administration for the county, and has royal and magisterial courts of law, as well as boards of assay, finance, and postal direction, and the supervision of the tobacco manufacture. Kaschau is one of the best built towns in Hungary, and consists of the inner town, intersected by the Csermel, which forms an island and is crossed by several bridges, and three suburbs (upper, middle, and lower) approached by a broad glacis. The most remarkable edifice, considered the grandest masterpiece of architectural skill in Hungary, is the cathedral of St Elizabeth, situated in the great square, and built in a faultless Gothic style. Commenced about 1270 by Stephen V., the structure was continued 1324–82 by Queen Elizabeth, wife of Charles I., and her son Louis I., and finished about 1468, in the reign of Matthias I. (Corvinus). The interior was transformed in the 18th century to the Renaissance style, and restored in 1859–65. The church of St Michael and the Franciscan or Garrison church date from the 13th century. The royal law academy, founded in 1659, and sanctioned by golden bull of King Leopold I. in 1660, has an extensive library; there are also a museum, a Roman Catholic upper gymnasium and seminary for priests, and other schools and benevolent institutions. Kaschau is the centre of the trade for the surrounding counties in wine, gall-nuts, salt, and most descriptions of grain, and from its commercial importance forms a kind of provincial capital. About 3 miles north-west of the town are the baths of Bankó, with alkaline and ferruginous springs. The population of Kaschau in 1880 amounted to 26,422 (in 1870 it was 21,742), consisting of Magyars, Germans, Slovaks, and Ruthens. The majority are Roman Catholics.

Kaschau consisted originally of two villages, Upper and Lower Kassa, of which the latter was created a town and granted special privileges by Béla IV. (1235). Under Stephen V. (1270) the two separate portions were united, and raised to the rank of a royal free town. In 1290 it was surrounded with walls. The subsequent history presents a long record of revolts, sieges, and disastrous conflagrations. In 1430 the plague carried off a great number of the inhabitants. In 1458 the right of minting money according to the pattern and value of the Buda coinage was granted to the municipality by King Matthias I. The bishopric was established in 1804. In the revolutionary war of 1848–49 the Hungarians were twice defeated before the walls of Kaschau by the Austrians under General Schlick, and the town was held successively by the Austrians, Hungarians, and Russians.

KASHGAR, or KÁSHGHAR, an important city of eastern Turkestan, in 39° 24′ 26″ N. lat., 76° 6′ 47″ E. long., 4043 English feet above the sea-level. It consists of two towns, Kuhna Shahr or "old city," and Yangi Shahr or "new city," about 5 miles apart, and separated from one another by the Kizil Su, a tributary of the Tarim river, which receives and deposits in the distant lake Lob Nor the drainage of the vast semi-desert plain included between the Kuen-lun, Thian Shan, and Pamir mountains. Situated at the junction of routes from the valley of the Oxus, from Khokand and Samarkand, Almati, Aksu, and Khotan, the last two leading from China and India, Kashgar has been noted from very early times as a political and commercial centre. Like all other cities of Central Asia, it has changed hands repeatedly, but its greatest modern prominence is probably due to its having formed a few years ago the seat of government of the Amir Yakub Beg, surnamed the Atalik Ghazi, who established and for a brief period ruled with remarkable success a Mohammedan state comprising the chief cities of the Tarim basin from Turfan round along the skirt of the mountains to Khotan. During his rule both Russian and British missions visited Kashgar, and it is chiefly to this circumstance that we are indebted for a full and tolerably recent knowledge thereof. Kuhna Shahr is a small fortified city on high ground overlooking the river Tuman. Its walls are lofty and supported by buttress bastions with loopholed turrets at intervals; the fortifications, however, are but of hard clay, and are much out of repair. The city contains about 2500 houses. Beyond the bridge, a little way off, are the ruins of ancient Kashgar, which once covered a large extent of country on both sides of the Tuman, and the walls of which even now are 12 feet wide at the top and twice that in height. This city—Aski Shahr as it is now called—was destroyed in 1514 by Mirza Ababakar on the approach of Sultan Said Khan's invading army. About 2 miles to the north beyond the river is the shrine of Hazrat Afák, the saint king of the country, who died and was buried here in 1693. It is a handsome mausoleum faced with blue and white glazed tiles, standing under the shade of some magnificent silver poplars. About it Yakub Beg erected a commodious college, mosque, and monastery, the whole being surrounded by rich orchards, fruit gardens, and vineyards. The Yangi Shahr of Kashgar is, as its name implies, quite modern, having been built in 1838. It is of oblong shape running north and south, and is entered by a single gateway. The walls are lofty and massive, and topped by turrets, while on each side is a projecting bastion to protect the curtains by a flank fire. The whole is surrounded by a deep and wide ditch, which can be filled from the river, at the risk, however, of bringing down the whole structure, for the walls are of mud, and stand upon a porous sandy soil. In the time of the Chinese, before Yakub Beg's sway, Yangi Shahr held a garrison of six thousand men, and was the residence of the *amban* or governor. Yakub erected his *orda* or palace on the site of the amban's residence, and two hundred ladies of his harem occupied a commodious enclosure hard by. The mixture of the various types seen in the markets of Kashgar has struck more than one traveller. A square-faced flat-nosed Calmuck, with high cheek bones and a ruddy hairless countenance, stands next to an Afghan of gigantic proportions, with nut-brown complexion, handsome features, and glossy black beard, while one's eye rests next on the fair, full face and Dutch built frame of the Andijani, who is jostled in turn by the familiar black-skinned and oily-faced Hindustani Mussulman, the muddy-complexioned opium-smoking Chinaman, and the brown-skinned bewhiskered and gentle-looking Badakshi, with high full forehead, long arched finely carved nose and oval face of the true Aryan stamp. The population of Kashgar at the time of the visit of Sir Douglas Forsyth's mission in 1873 was about 112,000.

With the overthrow of the Chinese rule in 1865 the manufacturing industries of Kashgar declined, and in the case of some of the profitable arts altogether disappeared. Silk culture and carpet manufacture have flourished for ages at Khotan, and the products always find a ready sale at Kashgar. Other manufactures consist of a strong coarse cotton cloth called *kham* (which forms the dress of the common people, and for winter wear is padded with cotton and quilted), boots and shoes, saddlery, felts, furs and sheep skins made up into cloaks, and various articles of domestic use. A curious street sight in Kashgar is presented by the hawkers of meat pies, pastry, and sweetmeats, which they trundle about on hand-barrows just as their counterparts do in Europe; while the knife-grinder's cart, and the vegetable seller with his tray or basket on his head, recall exactly similar itinerant traders further west.

The earliest mention of Kashgar of which we have any authentic record is during the second period of ascendency of the Han dynasty, when the Chinese general Pan-Shan conquered and wrested from the hands of their masters the Hiungnu, Yutien (Khotan), Sulei (Kashgar), and a group of states in the Tarim basin almost up to the foot of the Thian Shan mountains. This happened in 76 B.C., about the time that the Chinese and Roman empires attained their furthest expansion of dominion westward and eastward respectively, and were separated only by the breadth of the Caspian. Kashgar lies in the country which Ptolemy calls Scythia beyond the Imaus; in this he has a *Kasia Regio*, possibly exhibiting the name whence Kashgar is formed. Next ensues a long epoch of obscurity. The Chinese lost their hold over the western provinces, and Ptolemy found no successor to continue his investigations into the countries of the far East. In 634 Tai-tsung re-established Chinese sway over eastern Turkestan and Sulei (Kashgar), and other places were converted into garrison towns. It was shortly after this that Hwen Tsang passed through Kashgar (which he calls Kie-sha) on his return journey from India to China. The Buddhist religion, then fast decaying in India, was working its way to a new growth in China, and contemporaneously the Nestorian Christians were establishing bishoprics at Herat, Merv, and Samarkand, whence they subsequently proceeded to Kashgar, and finally to China itself. In the 8th century came the Arab invasion from the west, and we find Kashgar and Turkestan lending assistance to the reigning queen of Bokhara, to enable her to repel the enemy. But although the Mohammedan religion from the very commencement sustained checks, it nevertheless made its weight felt upon the independent states of Turkestan to the north and east, and thus acquired a steadily growing influence, which, aided as it was through the channels of trade, facilitated the spread of the faith, and brought it into serious collision with the Chinese religion, a struggle which has endured down to our day, and can by no means be said to be unlikely to recur. It was not, however, till the close of the 10th century that Islam was established at Kashgar, when a prince of the hereditary family of Bughra Khan became a convert thereto, and enforced it upon his subjects at the point of the sword. After an interval, during which the Kara Khitai, a nomad race from the north-east under rulers called the Gur Khans, became suzerains of Kashgar, the growing power of Jenghiz Khan began to overspread the Kashgar borders. This great conqueror in the space of six years overran the entire country from Azerbijan on the west to the Indus on the east, and from the steppes of Kipchak on the north to Seistan on the south, laying waste and butchering with a ferocity which is said to have left its traces for centuries after. The invasion of Jenghiz Khan had given a decided check to the progress of the Mohammedan creed, but on his death, and during the rule of the Chaghatai Khans, who became converts to that faith, Islam began to reassert its ascendency. In 1389–90 Timur the Mughal undertook a campaign for the conquest of Moghulistan, and one of his armies ravaged Kashgar, Andijan, and the intervening country. Moghulistan was at this time under the governorship of Khudadad, a beneficent and popular ruler, who at a later date entertained the famous embassy sent from Shah Rukh to the emperor of China. Kashgar next passed through a troublous time, and in 1514, on the invasion of the Khan Sultan Said, was destroyed by Mirza Ababakar, who with the aid of ten thousand men built the new fort with massive defences higher up on the banks of the Tuman. The dynasty of the Chaghatai Khans collapsed in 1572 by the dismemberment of the country between rival representatives; and soon after two powerful Khojah factions, the White and Black Mountaineers (*Ak* and *Kara Taghluk*), arose, whose dissensions and warfares, with the intervention of the Calmucks of Zungaria, fill up the history till 1759, when a Chinese army from Ili invaded the country, and, after perpetrating wholesale massacres, finally consolidated their authority by settling therein Chinese emigrants, together with a Manchu garrison. The Chinese had thoughts of pushing their conquests towards western Turkestan and Samarkand, the chiefs of which sent to ask assistance of the Afghan king Ahmed Shah. This monarch despatched an embassy to Peking to demand the restitution of the Mohammedan states of Central Asia, but the embassy was not well received, and Ahmed Shah was too much engaged with the Sikhs to attempt to enforce his demands by arms. The Chinese continued to hold Kashgar, with sundry interruptions from Mohammedan revolts,—one of the most serious occurring in 1827, when the territory was invaded and the city taken by Jahanghir Khojah; Chang-lung, however, the Chinese general of Ili, recovered possession of Kashgar and the other revolted cities in 1828. A revolt in 1829 under Mohammed Ali Khan and Yusuf, brother of Jahanghir, was more successful, and resulted in the concession of several important trade privileges to the Mohammedans of the district of Alty Shahr (the "six cities"), as it was then named. Until 1846 the country enjoyed peace under the just and liberal rule of Zahir-ud-din, the Chinese governor, but in that year a fresh Khojah revolt under Kath Tora led to his making himself master of the city, with circumstances of unbridled licence and oppression. His reign was, however, brief, for at the end of seventy-five days, on the approach of the Chinese, he fled back to Khokand amid the jeers of the inhabitants. The last of the Khojah revolts (1857) was of about equal duration with the previous one, and took place under Wali-Khan, a degraded debauchee, and the murderer of the lamented traveller Adolf Schlagintweit. The great Tungani revolt, or insurrection of the Chinese Mohammedans, which broke out in 1862 in Kansuh, spread rapidly to Zungaria and through the line of towns in the Tarim basin. The Tungani troops in Yarkand rose, and (10th August 1863) massacred some seven thousand Chinese, while the inhabitants of Kashgar, rising in their turn against their masters, invoked the aid of Sadik Beg, a Kirghiz chief, who was reinforced by Buzurg Khan, the heir of Jahanghir, and Yakub Beg, his general, these being despatched at Sadik's request by the ruler of Khokand to raise what troops they could to aid his Mohammedan friends in Kashgar. Sadik Beg soon repented of having asked for a Khojah, and eventually marched against Kashgar, which by this time had succumbed to Buzurg Khan and Yakub Beg, but was defeated and driven back to Khokand. Buzurg Khan delivered himself up to indolence and debauchery, but Yakub Beg, with singular energy and perseverance, made himself master of Yangi Shahr, Yangi-Hissar, Yarkand, and other towns, and eventually became sole master of the country, Buzurg Khan proving himself totally unfitted for the post of ruler. Kashgar and the other cities of the Tarim basin remained under Yakub Beg's rule until 1877, when the Chinese regained possession of their ancient dominions after a campaign which, originally organized years before, and conducted in the most leisurely fashion, was characteristic of the measured tenacity and resolution with which this nation follow up a settled policy. Since the reoccupation of the country by the Chinese, trade has much declined, especially with India, this traffic being regarded as illegal by the Chinese authorities. Heavy exactions are made for military purposes, and considerable emigration has taken place to Ladak and India. (C. E. D. B.)

KÁSHÍ, the name given to the glazed and coloured ornamentation of Mohammedan buildings in parts of Persia and India, and to the art of making it. The work is of two kinds—on clay (bricks or tiles), and on cakes of lime mortar. For surfaces of one colour, domes, &c., both kinds are used, differing only in the shape of the tiles or mortar-cakes. Figured patterns are differently treated with the different materials. On clay tiles, the designs with their several colours are laid on by stencilling, and the tile then glazed. Designs in coloured mortar work have each separate piece of colour on a separate cake of hardened mortar, cut to the required shape; and these, glazed separately, are afterwards cemented together on the walls of the building, or first made up into complete panels, which are then set in their place on the walls. The designs are commonly foliage and flowers, or geometrical figures and interlacing arabesques, and inscriptions in Arabic and Persian characters, and are, many of them, very beautiful.

The colours chiefly used are blue, green, yellow, purple, brown, and white. A tile is first painted over with a very fine clay paste, to make a smooth surface on which to apply the colour; and similarly the little mortar cakes are first painted, on the side to be coloured, with a thin liquid glass. It is perhaps owing to defect in this part of the process, or to imperfect burning, that the tile figured work on some old buildings, particularly on the south side, has flaked off. The glazed work on mortar, and on tiles of one colour, is generally more permanent.

The best specimens of káshí work in India are at Tatta and Hyderabad in Sind, and at Multán and Lahore in the Punjab. There are also buildings thus ornamented, chiefly of the time of Akbar and Jahangír (16th and 17th centuries), at Delhi, Agra, Gwalior, and some other places, but the best and most numerous are in the western provinces above named, particularly at Lahore and at Tatta. The buildings at Lahore having the finest figured káshí work are the mosque of Wazír Khan, the gateways of certain old pleasure gardens, and the Gola Sarai. There is a tomb at the same place (the tomb of Abd' ur Razzák) built in the early part of the 16th century, which bears the name of the blue dome, its covering being of clay bricks coloured blue on the narrow exposed face. Another, built about fifty years later (the tomb of Shah Músa), is known as the green dome. It is covered with little mortar blocks, in shape half cylinders, coloured and glazed on the flat face, and with two deep nicks on the rounded back to give a hold on the plaster in which they are set. A celebrated tomb at Meshhed in northern Persia bears the same name, and likewise another at Kirman; the domes of these buildings, however, though called green, are in reality blue. At Tatta the káshí work is all on clay tiles; there is no inlaid work of coloured mortar. The finest of the buildings at Tatta, a mosque built by Shah Jahán, has lately had the defective parts of the figured tile-work restored.

The art is now carried on at Tatta, at Hala, a village 30 miles north of Hyderabad, and at a few other places.

KASHIN, a district town of Russia, in the government of Tver, 125 miles north-east of the government town, near the Kashinka, a subtributary of the Volga. A considerable trade is carried on in the despatch of grain to St Petersburg. The chief buildings are the cathedral and three monastic establishments. Kashin, first mentioned about 1238, was in the 14th century a separate principality which contended with Tver for pre-eminence in the region. There are still some remains of the defences erected in 1661. Population, according to St Petersburg Calendar for 1874, 7346.

KÂSHKÂR, also called CHITRÂL, from the residence of the prince, a high-lying Mohammedan state among the spurs of Hindu Kush, has been already spoken of under HINDU KUSH (vol. xi. p. 838). Since that was published, a work (*Tribes of the Hindoo Koosh*, Calcutta, 1880) has come from the pen of Major Biddulph, the only European known to have visited the state, and we here enter a very few corrections or new particulars from his work. The geographical position of Kâshkâr is likely to give it great interest in the future. A considerable part of Upper Kâshkâr belongs to Yassin, in the Gilgit basin (see GILGIT, vol. x. p. 597). Indeed the left bank of the Chitrâl river, down to within 20 miles of Chitrâl itself, belongs to Yassin. The chief place of this Upper Kâshkâr is Mastûj (vol. x. p. 596). The rulers of the two states are of the same blood, sprung from a Khorâsâni adventurer who immigrated hither about the first half of the 17th century, and are respectively descended from two brothers of his family, Shâh Katôr and Shâh Khûshwakt, who lived a century later. The two royal families are hence known as *Katôré* and *Khûshwakté* respectively; they generally act in concert, though neither is dependent on the other. We know not the origin of the former name, but most probably it is connected with an ancient tribal name in KÂFIRISTÂN (*q.v.*). The ruler of Chitrâl is known both as *Mihtar*, or "Prince," and by the pretentious title of *Bâdshâh*. He has five viziers, of whom the chief, or Dewân-begi, has charge of the king's slave-agency, an important part of the reigning system. Under this the rulers of Chitrâl have come to regard the sale of their subjects as a legitimate and ordinary supplement to their revenue. But of late the market has become circumscribed. The population of the kingdom is estimated at 200,000, not including the tributary tribe of Bashgali Kafirs, who occupy a nearly parallel valley on the west, confluent with that of Kâshkâr. The ethnology of Kâshkâr is very intricate. The largest, and probably aboriginal, population are called *Kho*. Their language, *Khowâr*, is closely allied to the dialects of the Kafir tribes. There are also tribes in a depressed position, immigrants from the other side of the watershed, and speaking the language of Munjân, a hill canton of the Oxus valley, calling themselves *Yidghâh*. In the lower part of the valley is a race, also with a peculiar language, called *Gabar* (mentioned by Sultan Baber), and some broken tribes of Siâhposh, &c. All these constitute the lower or *ryot* class, who alone pay regular revenue, cannot hold slaves, and are styled *fakîr mushkîn* ("poor beggars"). Above them are several privileged classes, descended from the founders of the reigning family, or from older ruling families also of foreign blood. We may add that Chitrâl is identical with the *Shang-mi* of Hwen Tsang (644 A.D.), see *J. R. As. Soc.*, new ser., vol. vi. p. 114. A somewhat later Chinese record gives, as an alternative name of Shang-mi, *Khiu-wei*, which evidently contains the *Kho* just mentioned. In this *Kho* also we have probably an element of *Choaspes*, the Greek name of the Chitrâl river. A singular point in Chitrâl history is the fact that it was invaded by a Chinese army about the middle of last century, probably in 1759–60, and continued to send occasional tribute to China at least to 1769, *i.e.*, twelve years after the battle of Plassy. This was brought to notice by the present writer in 1872 (*J. R. G. S.*, xlii. 477), when tracing the curious history of the name *Bolor*. And now Major Biddulph has found in the country itself the memory of the Chinese invasion, and thus entire corroboration of the identification of the Chinese *Poloeul* or Bolor with Kâshkâr. (H. Y.)

KASHMÍR, or CASHMERE, an elevated and enclosed valley in the Himalaya mountains, north of the Punjab. It is surrounded by lofty hills, with one opening on the west, by which flows out from the valley the river Jhelum. The enclosing hills on the north and east belong to the Bára Lácha chain, and on their outer side is the broad mountainous region which holds the valley of the upper Indus, and which, beyond the Indus, culminates in the great parallel range of Karakorum or Mustágh. On the west and south, the hill boundary, which joins the other half of the enclosure at the south-east end of the valley, is the Panjál or Panchál range, which on its outer side sends down its branches southward. through the Jamú territory, to the plains of the Punjab. The length of the Kashmír valley, including the inner slopes of its surrounding hills, is about 120 miles from north-west to south-east. Its greatest width is about 75 miles. The low and comparatively level floor of the basin is 84 miles long and 20 to 24 miles broad. Its lowest part is 5200 feet above the sea, and its mean height 6000 feet.

This valley is but a small portion, in area, of the dominions of the maharájá of Kashmír, which, in addition to the Jamú territory on the south (the previous possession of the present maharájá's father, Ghuláb Singh, before he acquired Kashmír), include Baltistán and Gilgit on the north, and Kishtwár and Ládák on the east. On the west Kashmír is separated from the valley of Khagán by a continuous range of high hills, and from the British district of Hazára by the river Jhelum.

Jamú, to which Kashmír was annexed in 1846, occupies the southern slopes of the Panjál range, with a strip of plain country at their foot, and extends about 220 miles from east to west, with a greatest direct breadth, north to south, of about 75 miles. All the rest of the maharájá's dominions is hill country.

The hills forming the northern half-circuit of the Kashmír valley, and running beyond, include many lofty mountain masses and peaks, the most conspicuous of which, a little outside the confines of Kashmír, is Nanga Parbat, a grand hill (35° 15′ N., 74° 35′ E.), rising 26,629 feet above the sea, with an extensive area of glacier on its eastern face. The great ridge which is thrown off to the south-west by Nanga Parbat rises, at a distance of 12 miles, to another summit 20,740 feet in height, from which run south-west and south-east the ridges which are the northern watershed boundary of Kashmír. The former range, after running 70 miles south-west, between the valleys of the Kishanganga and the Kunhár or Nain-súkh, turns southward, closely pressing the river Jhelum, after it has received the Kishanganga, with a break a few miles further south which admits the Kunhár. This range presents several prominent summits, the two highest 16,487 and 15,544 feet above the sea. The range which runs south-east from the junction peak above-mentioned divides the valley of the Kishanganga from that of the Astor and other tributaries of the Indus. The highest points on this range, where it skirts Kashmír, are 16,795, 16,930, and 17,202 feet above the sea. For a distance of more than 50 miles from Nanga Parbat there are no glaciers on this range; thence eastward they increase; one, near the Zójí-lá Pass, is only 10,850 feet above the sea. The mountains at the east end of the valley, running nearly north and south, drain inwards to the Jhelum, and on the other side to the Wardwán, a tributary of the Chenáb. The highest part of this eastern boundary is 14,700 feet. There are no glaciers. The highest point on the Panjál range, which forms the south and south-west boundary, is 15,523 feet above the sea.

The river Jhelum or Behat (Sanskrit *Vitasta*)—the Hydaspes of Greek historians and geographers—flows north-westward through the middle of the valley. After a slow and winding course it expands, about 25 miles below Srínagar, over a slight depression in the plain, and forms the Wúlar lake and marsh, which is of ill-defined extent, but may be called about 10 miles long and 6 broad. The hills which this lake touches at its north end give it a more defined margin on that side. Leaving the lake on the south-west side, near the town of Sópur, the river pursues its sluggish course south-westward, about 18 miles, to the gorge at Baramúla. From this point the stream is more rapid through the narrow valley which conducts it westward 75 miles to Muzaffarábád, where it turns sharply south, joined by the Kishanganga. At Islámábád, about 40 miles above Srínagar, the river is 5400 feet above sea-level, and at Srínagar 5235 feet. It has thus a fall of about 4 feet per mile in this part of its course. For the next 24 miles to the Wúlar lake, and thence to Baramúla, its fall is only about $2\frac{1}{4}$ feet in the mile. On the 80 miles of the river in the flat valley between Islámábád and Baramúla there is much boat traffic; but none below Baramúla till the river comes out into the plains.

On the north-east side of this low narrow plain of the Jhelum is a broad hilly tract between which and the higher boundary range runs the Kishanganga river. Near the east end of this interior hilly tract, and connected with the higher range, is one summit 17,839 feet. Around this peak and between the ridges which run from it are many small glaciers. These heights look down on one side into the beautiful valley of the Sind river, and on another into the valley of the Lidar, which join the Jhelum. Among the hills north of Srínagar rises one conspicuous mountain mass, 16,903 feet in height, from which on its north side descend tributaries of the Kishanganga, and on the south the Wangat river, which flows into the Sind. By these rivers and their numerous affluents the whole valley of Kashmír is watered abundantly.

Around the foot of many spurs of the hills which run down on the Kashmír plain are pieces of low table-land, which are called *karéwa*. These terraces vary in height at different parts of the valley from 100 to 300 feet above the alluvial plain. Those which are near each other are mostly about the same level, and separated by deep ravines.

The level plain in the middle of the Kashmír valley is fine clay and sand, with water-worn pebbles. The karéwas consist of horizontal beds of clay and sand, the lacustrine nature of which is shown by the shells which they contain. The hills surrounding the valley are chiefly gneiss and schists. In the Lidar valley are slate and sandstones of the Carboniferous period over green slate of a period corresponding to Silurian. The irregular ridges of the Panjál range are granite and gneiss, with schists and slates. Limestone is found in parts of the east and west ends of the valley, and in the hills upon the Mánas Bal lake. In various places are marks of glacial action, down to a height of about 500 feet above the level part of the basin. From the plain rise isolated hills of trap; among these are the Hari Parbat and the Takht-i-Sulimán at Srínagar, on the former of which stands the fort, and on the latter a conspicuous and well known ancient Hindu temple. No fossils have been found in Kashmír below the rocks of the Carboniferous period. The chief mineral resources of the maharaja's dominions are outside the Kashmír valley, specially in Ládák.

In the hills of the north boundary are two passes, the Burzil (13,500 feet) and the Kamri (13,200). By the former is the direct route between Srínagar and Iskardo. It is usually practicable only between 15th July and 15th September. The road from Srínagar to Lé in Ládák goes by the Zójí-lá Pass (11,300 feet), near the north-east corner of the valley. Only a short piece of the road, where snow accumulates, prevents this pass being used all the year. At the south-east end of the valley are three passes, the Murgil (11,600 feet), the Hoksar (13,315), and the Murbul (11,550), all leading over to the valleys of the Chenáb and the Rávi. South of Islámábád, on the direct route to Jamú and Siálkót, is the Banihál Pass (9200 feet). Further west on the Panjál range is the Pír Panjál or Panchál Pass (11,400 feet), with a second pass, the Rattan Pír (8200 feet), across a second ridge about 15 miles south-west of the other. Between the two passes is the beautifully situated fort of Báramgali and a well-known rest-house for travellers. This place is in the domain of Raja Móti Singh of Púnch, cousin and tributary of the maharaja of Kashmír. At Rájáori, south of these passes, the road divides: one line leads to Bhimbar and Gujrát, the other to Jamú and Siálkót by Aknúr. Next, south-west of Baramúla, is the Hajjí Pír Pass (8500 feet), by which crosses the road to Púnch. From Púnch one road leads down to the plains at the town of Jhelum, another eastward through the hills to the Rattan Pír Pass and Rájáori. Lastly there is the river pass of the Jhelum, which is the easy route from the valley westward, having two ways down to the plains, one by Muzaffarábád and the Hazára valley to Hassan Abdál, the other by the British hill station of Marri (Murree) to Ráwal Pindí.

The valley of Kashmír, sheltered from the south-west monsoon by the Panjál range, has not the periodical rains of India. Its rainfall is irregular, greatest in the spring months. Occasional heavy storms in the monsoon pass over the crests of the Panjál and give heavy rain on the elevated plateaus on the Kashmír side. And again clouds pass over the valley and are arrested by the higher hills on the north-east side, on which they pour themselves. Snow falls on the surrounding hills at intervals from October to March, and sometimes in great quantity. In the valley the first snow generally falls about the end of December, and never to any great amount. The highest monthly average of temperature from May to October, at Srínagar, is 89° in the shade at noon. There has been no regular winter register; but the temperature is never very low.

For all crops except rice, which is irrigated, the rain is ordinarily sufficient. Barley, sown in November, ripens in June; wheat in July. Rice, sown in May and June, ripens in October. Millet, maize, and buckwheat, also turnips, pease, and mustard, are grown in considerable quantity.

There is no natural forest in the level parts of the valley. Of the cultivated trees the finest is the plane (*chinár*), which grows to a large size, and is of great beauty. The principal other trees of the valley are the poplar, willow, cypress, walnut, apple, pear, quince, apricot, cherry, mulberry. Vines are grown extensively, commonly trained up poplar trees. There are many kinds of grape. On the hills around are deodar, *Pinus excelsa* and *Gerardiana*, *Picea Webbiana*, hazel, birch, viburnum, juniper, rose, &c. The herbaceous plants and flowers are very numerous. The umbelliferous plant called *prangos*, growing on the drier hills, is much valued as winter food for sheep. In spring the bright orange-coloured colchicum shows itself in great quantity; and in autumn are seen many acres of saffron with its beautiful light purple flowers, grown in large fields divided into small square beds. Saffron was among the articles of annual tribute to the Mughal emperors. The Dal lake at Srínagar is full of reeds and water plants, *Potamogeton*, *Nymphæa*, *Nelumbium*, &c. On this lake there are floating gardens: a shallow layer of soil on sheets of the great leaves of water lilies is made to grow quantities of vegetables. The curious *singhara*, or horned water nut (*Trapa bispinosa*), which grows in great quantity in all the lakes, is much used for food, prepared in various ways. Since 1874 hops have been grown experimentally for the Murree Brewery Company, with fair success, in five different parts of the valley.

Much has been said and written about the beauty of the vale of Kashmír. Spring encircles a fresh, green, smiling valley with a noble belt of glistening snow-capped ridges; autumn fills the eye with the wonderful richness of the many-coloured foliage. At all times flows on the quiet glassy river, showing back the groves and avenues upon its banks, the strange tall shadowy wooden houses, and the craggy hills. There is no place or season which has not something to show of real beauty. The rapturous praises of Mohammedan writers may be often extravagant; and it is with some of their materials, reproduced with more modern additions, that Moore has built up great part of his romance; still few will really think that here extravagance and fiction have left truth much too far behind.

Many Englishmen every year resort to Kashmír for shooting. The game is in consequence now only to be found within reduced areas of the more secluded little valleys and more difficult hill sides, and many sportsmen now cross over into Ládák. The animals chiefly sought in both countries are the *Ovis ammon*, *Ovis poli*, antelope, ibex, *már-khór* or wild goat, musk deer, Tibetan stag, brown and black bear, and leopard. In various parts of Kashmír are to be found the fox, lynx, weasel, marmot, and hare. The black and grey monkey (*langúr*) is common on the Panjál range. Kashmír has the snow pheasant, snow owl, wild goose, duck, and teal; and the eagle is also found.

The Kashmír valley has a large number of old buildings of the Hindu period, interesting from their style, which is peculiar to Kashmír, and from the traces which many of them bear of Greek art. Their ruinous condition is ascribed partly to Sikandar the idol-breaker, partly to earthquakes, which are frequent in Kashmír. The most ancient of these buildings (about 220 B.C.) is the temple of Shankar Acharya (or, as it was formerly called, of Jaiasht Iswar), on the hill at Srinagar, known as Takht-i-Sulimán, or Solomon's Throne,—a designation thought to be a Mohammedan adaptation of the name of Rájá Sandhaman, who repaired or rebuilt the temple. The other Hindu buildings mostly belong to the time from the 5th to the 10th century. The chief points which distinguish them from Hindu buildings in India are the trefoil-headed doorways and recesses, high pediments, high straight-lined pyramidal roofs, and fluted pillars.

The temple of the sun at Marttand or Matan has been one of the finest. It occupies a very striking position on a karéwa or natural terrace about 3 miles from Islámábád, and commands a splendid view of the valley of the Jhelum. Of the others the most worthy of notice are the remains of two of the four temples at Avantipúr, 15 miles south-east of Srínagar; the temple of Bhúmzo near Marttand, built in a cave; Páyach, on the karéwa of Naunagar near Avantipúr, a small temple, the whole superstructure built of six stones; Pandrétan, 3 miles south-east of Srínagar, standing with its floor below the water, in a tank; Bhániár (Bhawániár) and Kutrúi, a few miles west of Baramúla, both backed by fine wooded cliffs crowned with deodars. A mound, with masonry in and about it, at the village of Ushkara near Baramúla, is supposed to be the remains of a Buddhist tope (*stúpa*), the place taking its name from Hushka, one of the Tartar kings of Kashmír.

Srínagar, the capital (34° 4′ 6″ N., 74° 48′ 5″ E.), said to have been founded by Pravara Sén, in the beginning of the 6th century, is built on both banks of the Jhelum. It is a somewhat confused mass of houses, many of them built of wood, with balconies and carved lattice windows, and projecting upper stories propped on poles, and overhanging the narrow streets or the little canals which in some parts are the streets. The city has seven bridges across the river, built of beams laid on stone and timber piers. In the fort on the south side of the river is the palace. There are several small Hindu temples in the town. The two chief mosques are the Jámi' mosque and that of Shah Hamadán, the latter one of the most conspicuous buildings, with walls of stone and timber, low sloping wooden roof, and little wooden spire. On the shores of the Dal lake are the old pleasure-gardens of the Mughals.

The people of Kashmír are now mostly Mohammedan. Physically of fine form, a large proportion of the town-people are enfeebled by poverty and sedentary occupation in close rooms. A few years ago the shawl weavers of Srínagar were reckoned to be about 22 per cent. of the inhabitants. The proportion is now less, owing to the reduced demand for Kashmír shawls, both loom-made and hand-sewn. The maharájá has endeavoured to meet the depression of the shawl trade by extension of silk manufactures; silk is successfully worked, and well dyed. The chief demand for shawls has generally been from France, and French patterns have somewhat interfered with native art. At Islámábád also many hands are employed in shawl and blanket weaving. A kind of coarse chintz is also made there. Embroidery on fine woollen cloths is the employment of many Kashmírís, both in their own country and in their Indian settlements, Amritsar, Núrpúr, and Ludhiána. The manufacture of a variety of articles in papier mâché and ornamental painted wood-work employs a number of people in Srínagar. The silversmiths do a good deal of business in ornamental vases, goblets, flower-holders, &c., silver and silver gilt. Engraved and embossed copper work employs a smaller number of people; also the manufacture of ornamental vessels of tinned copper, and some other minor kinds of work. A very good kind of paper is made in Kashmír. A museum of Kashmír products and manufactures was established at Srínagar in 1875. The people of the country, with more healthful occupations and surroundings than those of the towns, especially Srínagar, are robust and of active habits. The Kashmírís, both men and women, wear commonly a kind of loose gown with sleeves, called *phêran* (Pers., *pairáhan*, "a robe"). In cold weather they are in the habit of carrying, under this loose dress, a small portable brazier with heated charcoal. The country people and boatmen use a more close-fitting costume. The mountaineers, like those of neighbouring hill countries, bandage the legs from the knee to the foot for protection in walking.

According to a report prepared by order of the maharájá in 1873, the population of the valley at that time was nearly 492,000. Of these about 64,000 were Hindus and the rest Moslems, about 4 per cent. of the latter being Shiites. The estimated population of Jamú was 861,000, of Púnch 77,500, of Ládák, Iskardo, and Gilgit, 104,500; total about 1,535,000:—Hindus, 507,000; Moslems, 919,000; Buddhists, 20,000; and "miscellaneous," 89,000. Of Srínagar the estimated population was about 132,000, of which number nearly 40,000 were Hindus. A great diminution, caused by deaths and emigration, has followed the famine of 1878. It was said that the towns of Islámábád and Sopúr lost nearly two-thirds of their inhabitants. The rice crop of 1879 was abundant, and the rains of the next year seasonable and plentiful. The shawl-weaving and carpet-making trades revived in 1880, and numbers of people who had left the country during the famine returned.

The language of Kashmír (which is spoken only in the valley itself, and in the few outlying settlements of Kashmírís in the neighbouring hills and in northern India) is of the Aryan family. It is allied to the Hindí, Sindí, and Punjábí, and also to the current Urdú of India (Hindústání). It uses a form of the Sanskrit character like the Nágarí of the Punjab. It may be said to possess no literature, though Kashmír has produced many literary men. The Urdú is now very generally understood in Kashmír, among the better educated people and more intelligent artisans.

The chief articles of export from Kashmír are shawls and other woollen fabrics, rice, saffron, fruits. The chief imports are shawl wool, English piece goods, Indian cloths, metals, precious stones, skins, felts, dye-stuffs, tea, *charas* (hemp juice), groceries, and salt. The imports into Kashmír from British India are much below those into Jamú, except tea (of which the Kashmírís are extremely fond), indigo, and earthenware. Kashmír imports annually a very large amount of rock salt from the Punjab. The gross annual value of the imports is about £210,000, and of the exports about £172,000. This latter amount is less than formerly, owing chiefly to the reduced demand for shawls. The import duties, which used to be very heavy, were modified in 1864; the duty on piece goods was limited to 8 per cent. and on other imports to 12½ per cent. In April 1870 a commercial treaty was entered into with the British Government for developing trade with eastern Turkestan, in which, among other things, the maharájá agreed to abolish all transit duties. Joint commissioners were appointed, on the part of the two Governments, to reside at Leh.

The gross annual revenue of Kashmír is believed to be about £550,000, and of the maharájá's whole territories a little over £800,000. The chief source of income is the land revenue. Of this there is now a cash settlement in place of the annual valuation of crops which was the practice till lately. The Government ordinarily takes one-half the gross produce. Grain is stored in public granaries, and sold at fixed rates to the army and the civil officials. Much grain is also purchased from the zamindárs, and stored by Hindu merchants in Srínagar.

The maharájá's military force numbers 25,600 infantry (including police), 1400 cavalry, and 1200 artillery, with 78 field guns and 80 other pieces.

At Srínagar and elsewhere the maharájá has established dispensaries, with native medical men educated in India; and he has built at his own cost a large hospital for the medical mission at Srínagar.

The current rupee of Kashmír, called *chilkí* ("glittering"), has varied in value at different times from one-half to five-eighths of the rupee of British India. The latest issued bears the latter value.

The admission of British visitors to Kashmír each season is limited. To military officers, up to a fixed number, permission is granted by the commander-in-chief or by the Government of India. Others do not require previous permission, but must intimate their intention of going to Kashmír, and obtain a copy of the rules. In like manner, more than eight centuries ago, as we learn from the Arabic historian Al Birúní, the passes used to be watched, and few outsiders admitted. Connected with this long-cherished exclusiveness has been the general badness of the roads. A really improved road has been made by the present maharájá from Kohala to Baramúla, the easiest and best entrance to the valley. The author just referred to mentions the covered litters, in which people in Kashmír used to be carried, raised on men's shoulders. The same conveyances are in use now. To the present day there are no wheeled conveyances in Kashmír. For English visitors four routes are authorized by the Government of India, one by the Pír Panjál Pass and three by Baramúla,—from Púnch, from Murree, and from Muzaffarábád.

In the government of his own territories the "maharájá of Jummoo and Kashmír" is independent. His relations with other states are subject to the supreme authority of the Government of India. The Government of India has no resident at either of the maharájá's capitals, but annually an "officer on special duty," as he is officially termed, is sent to Kashmír during the season from March to November. A native news-writer, employed by the British Government, remains in Kashmír. The annual tribute of the maharájá, presented in token of the supremacy of the British Government, in accordance with Act X. of the treaty of March 1846, is "one horse, twelve perfect shawl goats of approved breed (six male and six female), and three pairs of Kashmír shawls." The maharája receives in British territory a salute of nineteen guns.

History.—The metrical history of the kings of Kashmír, called *Rájá Tarangini*, was pronounced by Professor H. H. Wilson (1825) to be the only Sanskrit composition yet discovered to which the title of history can with any propriety be applied. It first became known to the Mohammedans when, on Akbar's invasion of Kashmír in 1588, a copy was presented to the emperor. A translation into Persian was made by his order, and a summary of its contents, from this Persian translation, is given by Abu'l Fazl in the *Á'ín-i-Akbarí*. The *Rájá Tarangini* is a series of four histories. The first of the series, by Pandit Kalhana, was written about the middle of the 12th century. His work, in six books, which bears the name afterwards given to the whole, makes use of earlier writings now lost. Commencing with traditional history of very early times, it comes down to the reign of Sangrama Déva, 1006; and two more books attributed to the same author bring the history to the reign of Singha Déva (called Jai Singh in Abu'l Fazl's summary) about 1156. The second work, called *Rájá Vali*, by Júna Rája, takes up the history in continuation of Kalhana's, and, entering the Mohammedan period, gives an account of the reigns down to that of Zain-ul-ábad-dín, 1412. Then follows the *Srí Jaina Rájá Tarangini*, by Pandit Sri Vára, to the accession of Fattah Shah, 1477. And the fourth work, called *Rájá Vali Pataka*, by Prajnia Bhatta, completes the history to the time of the incorporation of Kashmír in the dominions of the Mughal emperor, 1588.

In the earliest of the four histories it is stated that the valley of Kashmír was formerly a lake, and that it was drained by the great *rishi* or sage, Kasyapa, son of Márichi, son of Brahma, by cutting the gap in the hills at Baramúla (Varáha-múla). When Kashmír had been drained, he brought in the Brahmans to occupy it. This is still the local tradition, and in the existing physical condition of the country we may see some ground for the story which has taken this form. Bernier suggested that earthquakes may have rent the gorge at Baramúla. M. Troyer considers it to have been the work of man, taking advantage of facilities pointed out by nature. It is possible that the river, having at one time flowed with more even fall than at present, may have been choked by land slips at the Baramúla gorge. The Jhelum, stopped at Baramúla, would spread over the low wide valley with very slow and quiet rise, till, overtopping the barrier, the water would escape with a great descent to its old channel, having meantime raised the bed of the lake, by slow accumulation of deposit, to a nearly uniform high level. The name of Kasyapa, however, is by history and tradition connected with the draining of the lake, and the chief town or collection of dwellings in the valley was called Kasyapa-púr—a name which has been plausibly identified with the Κασπάπυρος of Hecatæus (Steph. Byz., *s.v.*) and Κασπάτυρος of Herodotus (iii. 102, iv. 44). Kashmír is the country meant also by Ptolemy's Κασπήρια. The ancient name Kasyapa-púr was applied to the kingdom of Kashmír when it comprehended great part of the Punjab and extended beyond the Indus. In the 7th century Kashmír is said by the Chinese traveller Hwen Tsang to have included Cabul and the Punjab, and the hill region of Gandhara, the country of the Gandaræ of classical geography. Then, under the Mughals, after the annexation of Kashmír to their empire in the end of the 16th century, the name of this newer possession was, for administrative purposes, extended over a much larger area in Afghanistan, to which again it became united; and at one time Ghazni, at another time Cabul, was made the capital of the province of Kashmír.

At an early date the Sanskrit name of the country became *Kásmír*. The earliest inhabitants, according to the *Rájá Tarangini*, were the people called Nága, a word which signifies "snake." The history shows the prevalence in early times of tree and serpent worship, of which some sculptured stones found in Kashmír still retain the memorials. The town of Islámábád is called also by its ancient name Anant-nág (eternal snake). The source of the Jhelum is at Vir-nág (the powerful snake), &c. The other races mentioned as inhabiting this country and the neighbouring hills are Gandhara, Khása, and Darada. The Khása people are supposed to have given the name Kásmír. In the *Mahábhárata* the Kasmíra and Darada are named together among the Kshattriya races of northern India. The question whether, in the immigration of the Aryans into India, Kashmír was taken on the way, or entered afterwards by that people after they had reached the Punjab from the north-west, appears to require an answer in favour of the latter view (see vol. ii. of Dr J. Muir's *Sanskrit Texts*). The Aryan races of Kashmír and surrounding hills, which have at the present time separate geographical distribution, are given by Mr Drew as *Kashmírí* (mostly Mohammedan), in the Kashmír basin and a few scattered places outside; *Dard* (mostly Mohammedan) in Gilgit and hills north of Kashmír; *Dogra* (Hindu) in Jamú; *Dogra* (Mohammedan, called *Chibáli*) in Púnch and hill country west of Kashmír; *Pahári* or mountaineers (Hindu) in Kishtwar, east of Kashmír, and hills about the valley of the Chenab.

In the time of Asóka, about 245 B.C., one of the Indian Buddhist missions was sent to Kashmír and Gandhara. After his death Brahmanism revived. Then in the time of the three Tartar princes, Hushka, Jushka, and Kanishka, who reigned in Kashmír immediately before, and in the beginning of, the Christian era, Buddhism was to a great extent restored. The kingdom of Kanishka (called also Kanerkes) included the Punjab and Cabul as well as Kashmír. Buddhism again declined, though for several centuries the two religions existed together in Kashmír, Hinduism predominating. Yet Kashmír, when Buddhism was gradually losing its hold, continued to send out its Buddhist teachers to other lands. In this Hindu-Buddhist period, and chiefly between the 5th and 10th centuries of our era, were erected the Hindu temples in Kashmír. In the 6th and 7th centuries Kashmír was visited by some of the Chinese Buddhist pilgrims to India. The country is called *Shie-mi* in the narrative of To Yeng and Sung Yan (578). One of the Chinese travellers of the next century was for a time an elephant-tamer to the king of Kashmír. Hwen Tsang spent two years (631–633) in Kashmír (*Kia-chi-mi-lo*). He entered by Baramúla and left by the Pir Panjál Pass. He describes the hill-girt valley, and the abundance of flowers and fruits, and he mentions the tradition about the lake. He found in Kashmír many Buddhists as well as Hindus. In the following century the kings of Kashmír appear to have paid homage and tribute to China, though this is not alluded to in the Kashmír history. Hindu kings continued to reign till about 1294, when Udiána Déva was put to death by his Mohammedan vizier, Amír Shah, who ascended the throne, taking the name of Shams-ud-dín. Two Hindus who reigned afterwards for a short time were the last kings of that race in Kashmír. The notices of Kashmír by Marco Polo belong to a time near the close of the Hindu rule, when the people were mostly Hindus and Buddhists.

Of the Mohammedan rulers mentioned in the second of the Sanskrit histories, one, who reigned about the close of the 14th century, has made his name prominent by his active opposition to the Hindu religion, and his destruction of the temples. This was Sikandar, known as *But-shikan*, or the "idol-breaker." It was in his time that India was invaded by Timúr, to whom Sikandar made submission and paid tribute. The country fell into the hands of the Mughals in 1588. In the time of Alamgír it fell to Ahmed Shah Abdáli, on his third invasion of India (1756); and from that time it remained in the hands of Afghans till it was wrested from them by Ranjít Singh, the Sikh monarch of the Punjab, in 1819. Eight Hindu and Sikh governors under Ranjít Singh and his successors were followed by two Mohammedans similarly appointed, the second of whom, Shékh Imám-ud-dín, was in charge when the battles of the Sutlej, 1845–46, brought about new relations between the British Government and the Sikhs, involving a change in the government of Kashmír.

Ghuláb Singh, a Dogra Rajpút, had from a humble position been raised to high office by Ranjít Singh, who conferred on him the small principality of Jamú. On the final defeat of the Sikhs at Sobráon (February 1846), Ghuláb Singh was called to take a leading part in arranging conditions of peace. The treaty of Lahore (March 9, 1846) sets forth that, the British Government having demanded, in addition to a certain assignment of territory, a payment of a crore and a half of rupees ($1\frac{1}{2}$ millions sterling), and the Sikh Government being unable to pay the whole, the maharájá (Dhalíp Singh) cedes, as equivalent for one crore, the hill country belonging to the Punjab between the Biás and the Indus, including Kashmír and Hazára. The governor-general, Sir Henry Hardinge, considered it expedient to make over Kashmír to the Jamú chief, securing his friendship while the British Government was administering the Punjab on behalf of the young maharájá. Ghuláb Singh was well prepared to make up the payment in defect of which Kashmír was ceded to the British; and so, in consideration of his services in restoring peace, his independent sovereignty of the country made over to him was recognized, and he was admitted to a separate treaty. Ghuláb Singh had already, after several extensions of territory east and west of Jamú, conquered Ládák (a Buddhist country, and till then subject to Lassa), and had then annexed Iskardo, which was under independent Mohammedan rulers. He had thus by degrees half encircled Kashmír, and by this last addition his possessions attained nearly their present form and extent. Ghuláb Singh died in 1857, and was succeeded by his son, Ranbír Singh.

KÁSIMBÁZÁR, or COSSIMBAZAR, a decayed town in Murshidábád district, Bengal, 24° 7′ 40″ N. lat., 88° 19′ E. long. Long before the days of Murshid Kulí Khán, who founded and gave his name to the city of Murshidábád, the trade of Bengal was centred at Kásimbázár. The different European nations who traded to India had factories there from very early times. An English commercial agent was appointed to Kásimbázár in 1658; and at the close of the century it had become the leading English commercial agency in Bengal. The decay of the town dates from the beginning of the present century, when its climate, which had previously been celebrated for its salubrity, underwent an unexplained change for the worse; and its ruin was completed in 1813 by a sudden change in the course of the Bhágirathi, on which it stood. The site is now a swamp, marked by a few ruins.

KASIMOFF, a town of Russia, in the Ryazan government, situated in 54° 56′ N. lat. and 41° 3′ E. long., 90 miles east-north-east of the government town, on the left bank of the Oka, a tributary of the Volga. It possesses a cathedral, and a mosque supposed to have been built by Kasim. Near the mosque stands a mausoleum built by Shah Ali in 1555. Lying on the direct road from Astrakhan to Moscow and Nizhni Novgorod, Kasimoff is a busy place, with numerous industrial establishments. Of special note are the Kasimoff bells, whose jingle may be heard on the post-horses throughout the country. The waiters in the best hotels of St Petersburg are mostly Kasimoff Tartars. Population, according to St Petersburg Calendar for 1874, 12,027.

Kasimoff existed in the 14th century under the name of the Meshtchersk Gorodets or Gorodok (from the Meshtcheryaks, a Turko-Finnish tribe). It was laid completely waste by the Mongolians in 1376, but shortly afterwards rebuilt on a new site. About 1452 the place was bestowed by Basil the Dark on the Tartar prince Kasim who had come to assist him in his wars, and thus became the seat of a Tartar principality or kingdom, which lasted till 1677. The last of the line of Kasim accepted Christian baptism, and received the name of Jacob. On his death the principality was incorporated with the empire; and Peter I. sent a number of the Tartar inhabitants to Voronezh.

KASSA. See KASCHAU.

KASTAMUNI, sometimes COSTAMBONE, the chief town of a Turkish vilayet of the same name in Asia Minor, is situated on the Gök Irmak, about 250 miles east of Constantinople. It is the seat of a commercial court, consisting of two Mohammedan and two Christian members. The mosques are said to number thirty-six, and there are four dervish monasteries. Situated as it is in the Angora goat district, Kastamuni has a large trade in goat's hair (about 980,000 ℔ annually), and carries on the manufacture of mohair cloth. Copper is obtained in the neighbourhood, and the copper wares of Kastamuni are well-known in Asia Minor. Coal was for a time worked close to the town, but, the people objecting, it is said, to the smoke, the governor closed the mines. The population is estimated at 40,000. Kastamuni is the Castamon frequently mentioned by the Byzantine historians.

KASTORIA, a town of European Turkey, in the vilayet of Monastir and sandjak of Prisrend, about 33 miles south of Monastir (Bitolia), on the western banks of a lake (6 miles long and 4 broad) which drains into the Indjeh, Karasu, or Bistritza. It is the seat of a caimmacam, and the inhabitants carry on a good trade. Of the twelve quarters of the town three are occupied by Turks, two by Jews, and the rest by Christians. Kastoria is the ancient Celetrum, captured by Sulpicius during the first Macedonian campaign, 200 B.C., and better known for the defence maintained by Bryennius against Alexis I. in 1084 (see Anna Comnena's *Alexias*). A Byzantine wall with round towers runs across the peninsula on which part of the town is built. Population, 8000.

KATER, HENRY (1777–1835), a distinguished physicist of remarkable experimental skill, was born at Bristol, April 16, 1777. At first he purposed studying law; but this he abandoned on his father's death in 1794, and entered the army, obtaining a commission in the 12th regiment of foot, then stationed in India, where he rendered valuable assistance in the great trigonometrical survey. Failing health, however, obliged him to return to England; and in 1808, being then a lieutenant, he entered on a distinguished student career in the senior department of the Royal Military College at Sandhurst. Shortly after he was promoted to the rank of captain. In 1814 he retired on half-pay, and devoted the remainder of his life to scientific research. He died at London, April 26, 1835.

His first important contribution to scientific knowledge was the comparison of the merits of the Cassegrainian and Gregorian telescopes, from which (*Philosophical Transactions*, 1813 and 1814) he deduced that the illuminating power of the former exceeded that of the latter in the proportion of 5 : 2. This inferiority of the Gregorian he explained as being probably due to the mutual interference of the rays as they crossed at the principal focus before reflexion at the second mirror. His most valuable work, however, was the determination of the length of the second's pendulum, first at London and subsequently at various stations throughout the country (*Phil. Trans.*, 1818, 1819). In these researches he skilfully took advantage of the well-known property of reciprocity between the centres of suspension and oscillation of an oscillating body, so as to determine experimentally the precise position of the centre of oscillation; the distance between these centres was then the length of the ideal simple pendulum having the same time of oscillation. As the inventor of the floating collimator, Captain Kater rendered a great service to practical astronomy (*Phil. Trans.*, 1825, 1828). He also published memoirs (*Phil. Trans.*, 1821, 1831) on British standards of length and mass; and in 1832 he published an account of his labours in verifying the Russian standards of length. For his services to Russia in this respect he received in 1814 the decoration of the order of St Anne; and the same year he was elected a fellow of the Royal Society. His attention was also turned to the subject of compass needles, his Bakerian lecture "On the Best Kind of Steel and Form for a Compass Needle" (*Phil. Trans.*, 1821) containing the results of many interesting and valuable experiments. The treatise on "Mechanics" in Lardner's *Cyclopædia* was partly written by him and partly by Dr Lardner; and his interest in more purely astronomical questions was evidenced by two communications to the Astronomical Society's *Memoirs* for 1831–33—the one on an observation of Saturn's outer ring, the other on a method of determining longitude by means of lunar eclipses.

KÁTHIÁWÁR, or KATTYWAR, also SURÁSHTRA, a peninsula forming a collection of native states in Guzerat, western India, lying between 20° 41′ and 23° 8′ N. lat., and 68° 56′ and 72° 20′ E. long. It is bounded on the N. by the Runn or Gulf of Cutch, on the E. by Ahmedábád district and the Gulf of Cambay, and on the S. and W. by the Arabian Sea; the extreme length is 220 miles, the greatest breadth about 165 miles, the area about 22,000 square miles, and the estimated population 2,500,000.

It is divided into one hundred and eighty-eight separate states, large and small, of which thirteen pay no tribute, ninety-six are tributary to the British Government, and seventy to the gáekwár as the representative of the Marhattás, while of these three classes of states one hundred and thirty-two pay a tax called *zortalabi* to the nawáb of Junágarh. The states are arranged in seven classes: the chiefs of the first and second classes exercise plenary jurisdiction, both civil and criminal; the judicial powers of the lesser chiefs are graded in a diminishing scale, the residuary jurisdiction being vested in four British officers, each superintending a group of states. The political agent controls the whole. As a rule, no appeal lies from the decision of a chief; but on presumption of maladministration his proceedings may be called for and reviewed. During the past twenty years the states have established civil and criminal courts and written codes. Justice is administered by the political officers on the non-regulation system over 2058 square miles, or about one-tenth of the whole area. Outlawry, political and predatory, has been suppressed, and life and property are as safe as in British districts. A village police has been established, and municipal funds are voted by the states. In 1878 there were 488 schools, with 28,171 scholars; while at the Rájkumar College, and three high schools many of the chiefs receive a liberal education during their minority. There is railway communication with Wadhwán, and an extension is in progress to Dhoráji and Bhaunagar, while a network of good roads extend from Rájkot, the headquarters of the agency, over the greater part of the province. Káthiáwár is divided for administrative purposes into four *prants* or districts,—Jhaláwár, Hállár, Soráth, and Gohelwár; but the old territorial *prants* are ten, viz., Jhaláwár in the north, containing about fifty states; Machhukántá; Hállár, with twenty-sixty states; Okhamandal, belonging to Baroda; Baradá or Jaitwár, also known as Porbandar; Soráth; Babriáwár; Káthiáwár; Und-Sarviya; and Gohelwár. The last-named comprises the Gogo district, belonging to the Ahmedábád collectorate; Bhaunagar, probably the foremost state in Káthiáwár; and many others.

Generally speaking, the surface of the country is undulating, with low ranges running in very irregular directions; with the exception of the Tánghá and Mándhav hills, in the west of Jhaláwár, and some unimportant hills in Hállár, the northern portion of the country is flat; but in the south, from near Gogo, the Gir range runs nearly parallel with the coast, and at a distance of about 20 miles from it, along the north of Babriáwár and Soráth, to the neighbourhood of Gírnár. Opposite this latter mountain is the solitary Osam hill, and then still farther west is the Baradá group, between Hállár and Baradá, running about 20 miles north and south from Gumti to Ránáwan. The Gírnár clump of mountains is an important granitic mass, the highest peak of which rises to 3500 feet. The principal river is the Bhádar, which rises in the Mándhav hills, and flowing south-west falls into the sea at Navi-Bandar, in Baradá; it is everywhere marked by highly cultivated lands adjoining its course of about 115 miles. Other rivers are the Aji, Machhu, and Satrúnji—the last remarkable for wild and romantic scenery. Four of the old races, the Jáitwas, Churásamas, Solunkis, and Wálás are now existing as proprietors of the soil who exercised sovereignty in the country prior to the immigration of the Jhalás, Járejas, Purmars, Kathis, Gohels, Játs, Mohammedans, and Marhattás, between whom the country is now chiefly portioned out.

The principal agricultural products consist of cotton, *bájrá*, and *joár*, and in some parts sugar-cane, turmeric, and indigo. Horse and sheep breeding is carried on to a great extent—these animals, together with food grains, raw cotton, and wool, forming the chief exports. The principal imports are cotton manufactures, metals, and sugar. Iron is found in many parts of Baradá and Hallár. Many iron-mines have, however, had to be abandoned of late years owing to the scarcity of fuel for smelting the ore. The principal towns are Jámnagar, Bhaunagar, Junágarh, Rájkot, Porbandar, and Mangrol. The last two, as also Veráwal, are thriving seaport towns. Káthiáwár has many notable antiquities, comprising rock inscriptions of Asoka, Buddhist caves, and fine Jain temples on the sacred hill of Gírnár, and at Pálitana.

KATÍF, or El Katif, a town of Arabia, in the maritime region which skirts the northern part of the Persian Gulf on the low muddy shore of the northmost of the secondary bays that break the outline of the Bay of Bahrein, in 26° 29′ N. lat. and 50° E. long. Town and district are sometimes considered as part of El Hasa, sometimes as an independent province. The town lies embosomed amid luxuriant palm groves and gardens, but, according to Palgrave, is "crowded, damp, and dirty." As the sea port of Nejd, it has a considerable trade. The principal building is the fortress or palace,—a strong and spacious structure, whose erection is popularly assigned to Abu Sa'íd el Jannáby el Karmaty, the founder of the Karmathians. Katif was the chief seat of the Karmathian power. About the middle of the 18th century we find it, along with El Hasa, in the hands of Ibn Muflik, whose influence was paramount throughout Nejd. In 1791 it was captured by Sa'úd, the leader of the Wahhábv revolution. In 1871 it was attacked, and according to their own account subjugated, by the Turks from Baghdad. The population of the town and district is given as from 90,000 to 100,000. Katif is not far from the probable site of the ancient Gerrha, which was inhabited by Chaldæan exiles from Babylon (Strabo, xvi. 766); in more modern times the population has been recruited from Persia.

See Captain G. F. Sadlier, in *Trans. Lit. Soc. Bombay*, 1823; Pelly, in *Journ. Roy. Geogr. Soc.*, 1865; Palgrave, *Central and Eastern Arabia*, 1873; Zehme, *Arabien und die Araber*, Halle. 1875.

KATSENA, Kassina, or Kashna, a town of Central Africa, situated about 170 miles to the east of Sokoto, the capital of the state to which it now pays tribute. The walls have a circuit of between 13 and 14 English miles, but at the time of Barth's visit only the north-western quarter was inhabited, and he estimated the population at not more than 7000 or 8000. In the 17th and 18th centuries it appears to have been the largest town in the whole region, and its inhabitants cannot have numbered less than 100,000. The date of its foundation must be comparatively modern, for at the time of Leo Africanus there was no place of any considerable size in the province which bore the name now applied to the town. In the beginning of the present century it fell into the hands of the Fellatah, but only after a protracted and heroic defence.

KATTOWITZ, chief town of a circle in the government district of Oppeln and province of Silesia, Prussia, is situated on the Rawa, in a busy mining and manufacturing region near the Polish border. There are large iron-works, foundries, and machine shops in the town, and near it zinc and anthracite mines. The growth of Kattowitz, like that of many villages in the same circle, has been very rapid, owing to the development of the mineral resources of the district. In 1815 it was a mere village, in 1865 it became a town, and in 1875 it had a population of 11,352.

KATWÁ, or Cutwa, a town in Bardwán district, Bengal, India, situated at the confluence of the Bhágirathi and Ajái rivers, 23° 38′ 55″ N. lat., 88° 10′ 40″ E. long. It is one of the principal seats of district trade, and the residence of many wealthy native merchants. Now a purely commercial town, it was formerly regarded as the key to Murshidábád. The old fort, of which scarcely a vestige now remains, is noted as the scene of the defeat of the Marhattás by Alí Vardí Khán. Population in 1872, 7963.

KAUFBEUREN, an ancient town in the government district of Swabia and Neuburg, Bavaria, is situated on the Wertach, about 55 miles south-west of Munich by rail. The chief industry is cotton spinning and weaving, and there is a tolerably active trade in cotton-stuffs and cheese. The population in 1875 was 5553.

Kaufbeuren is said to have been built in 842, and to have become a free imperial city by purchase in 1286 or 1288. In 1803 it passed to Bavaria. It was formerly a resort of pilgrims; and Roman coins have been found in the vicinity.

KAUFFMAN, or KAUFFMANN, ANGELICA (1740-1807). This once popular artist and Royal Academician was born at Coire in the Grisons, October 30, 1740 or 1741. Her baptismal name was Maria-Anne-Angelica-Catharine. Her father, John Joseph Kauffmann, was a poor man and mediocre painter, but apparently very successful in teaching his precocious daughter. She rapidly acquired several languages, read incessantly, and showed marked talents as a musician. Her greatest progress, however, was in painting; and in her twelfth year she had become a notability, with bishops and nobles for her sitters. In 1754 her father took her to Milan, where she diligently studied the great masters. Later visits to Italy of long duration appear to have succeeded this excursion, and in 1763 she visited Rome, returning to it again in 1764. From Rome she passed to Bologna and Venice, being everywhere fêted and caressed, as much for her talents as for her personal charms. Writing from Rome in August 1764 to his friend Franke, Winckelmann refers to her exceptional popularity. She was then painting his picture, a half length, of which she also made an etching. She spoke Italian as well as German, he says; and she also expressed herself with facility in French and English,—one result of the last-named accomplishment being that she painted all the English visitors to the Eternal City. "She may be styled beautiful," he adds, "and in singing may vie with our best virtuosi." While at Venice, she was induced by Lady Wentworth, the wife of the English ambassador, to accompany her to London, where she appeared in 1765. One of her first works was a portrait of Garrick, exhibited in the year of her arrival at "Mr Moreing's great room in Maiden Lane." The rank of Lady Wentworth opened society to her, and she was everywhere well received, the royal family especially showing her great favour.

Her firmest friend, however, was Reynolds. In his pocket-book her name as "Miss Angelica" or "Miss Angel" appears frequently, and in 1766 he painted her, a compliment which she returned by the Portrait of Sir Joshua Reynolds, ætat. 46, which was exhibited by Lord Morley at the "Old Masters" in 1876. Another instance of her intimacy with Reynolds is to be found in the variation of Guercino's "Et in Arcadia ego" produced by her at this date, a subject which Reynolds repeated a few years later in his portrait of Mrs Bouverie and Mrs Crewe. When, in 1768 or thereabouts, she was entrapped into a marriage with an adventurer who passed for a Swedish count, Reynolds befriended her, and it was doubtless owing to his good offices that her name is found among the signitaries to the famous petition to the king for the establishment of the Royal Academy. In its first catalogue of 1769 she appears with "R.A." after her name (an honour which she shared with another lady and compatriot, Mary Moser); and she contributed the Interview of Hector and Andromache, and three other classical compositions. From this time until 1782 she was an annual exhibitor, sending sometimes as many as seven pictures, generally classic or allegorical subjects. One of the most notable of her performances was the Leonardo expiring in the Arms of Francis the First, which belongs to the year 1778. In 1773 she was appointed by the Academy with others to decorate St Paul's, and it was she who, with Biaggio Rebecca, painted the Academy's old lecture room at Somerset House. It is probable that her popularity declined a little in consequence of her unfortunate marriage; but after her first husband's death (she had been long separated from him) she married Antonio Zucchi, a Venetian artist, then resident in England. This was in 1781. Shortly afterwards she retired to Rome, where she lived for twenty-five years with much of her old prestige. In 1782 she lost her father; and in 1795—the year in which she painted the picture of Lady Hamilton now at South Kensington—her husband. She continued at intervals to contribute to the Academy, her last exhibit being in 1797. After this she produced but little, and in November 1807 she died, being honoured by a splendid funeral under the direction of Canova. The entire Academy of St Luke, with numerous ecclesiastics and virtuosi, followed her to her tomb in St Andrea delle Frate, and, as at the burial of Raphael, two of her best pictures were carried in procession.

Popular as they were during her lifetime, the works of Angelica Kauffman have not retained their reputation. She had a certain gift of grace, and considerable skill in composition. But her drawing is weak and faulty; her figures lack variety and expression; and her men are masculine women. Her colouring, however, is fairly enough defined by Waagen's term "cheerful." Rooms decorated by her brush are still to be seen in various quarters. At Hampton Court is a portrait of the duchess of Brunswick; in the National Gallery an allegorical composition of Religion attended by the Virtues. There are other pictures by her at Paris, at Dresden, in the Hermitage at St Petersburg, and in the Pinakothek at Munich. The Munich example is a portrait of herself; there is a second in the Uffizi at Florence, and a third in the National Portrait Gallery, South Kensington. A few of her works in private collections have also been exhibited among the "Old Masters" at Burlington House. But she is perhaps best known by the numerous engravings from her designs by Schiavonetti, Bartolozzi, and others. Those by Bartolozzi especially still find considerable favour with collectors. Her life was written in 1810 by Giovanni de Rossi. It has also been used as the basis of a romance by Léon de Wailly, 1838; and it prompted the charming novelette contributed by Mrs Richmond Ritchie to the *Cornhill Magazine* in 1875 under the title of "Miss Angel." (A. D.)

KAULBACH, WILHELM VON (1805-74), an acknowledged leader in modern art, was born in Westphalia 15th October 1805. His parentage was humble, and his father, who was poor, combined painting with the goldsmith's trade, but means were found to place Wilhelm, a youth of seventeen, in the art academy of Düsseldorf, then reorganized, and becoming renowned under the directorship of Peter von Cornelius. Young Kaulbach at the outset had to fight a hard battle: his circumstances were necessitous; he contended against hardships, even hunger. But his courage never failed; and, uniting genius with industry, he was ere long found foremost among the young national party which resolved that the arts of Germany should see a great revival.

Munich is the city most closely identified with Kaulbach. The large and ambitious works by which Louis I. sought to transform the capital of Bavaria into a German Athens afforded to the young painter an appropriate sphere. Cornelius had for some years been commissioned to execute the enormous frescoes in the Glyptothek, and his custom was in the winters with the aid of Kaulbach and others to complete the cartoons at Düsseldorf, and then in the summers, accompanied by his best scholars, to carry out the designs in colour on the museum walls in Munich. But in 1824 Cornelius became director of the Bavarian academy. Kaulbach, not yet twenty, followed, took up his permanent residence in Munich, laboured hard on the public works, executed independent commissions, and rose to such distinction that in 1849, when Cornelius left for Berlin, he succeeded to the directorship of the academy, an office which he held for a quarter of a century, up to the day of his death. The training, experience, and opportunity of Kaulbach had been extraordinary; he became a prime mover in one of the most signal of art manifestations known in modern times; he matured, after the example of the masters of the Middle Ages, the practice of mural or monumental decoration; he once more conjoined painting with architecture, and displayed a creative fertility and readiness of resource scarcely found since the era of Raphael and Michelangelo.

Early in the series of his multitudinous works came the famous Narrenhaus, the appalling memories of a certain madhouse near Düsseldorf; the composition all the more deserves mention for points of contact with Hogarth. Somewhat to the same category belong the renowned illustrations to *Reineke Fuchs*. These, together with occasional figures or passages in complex pictorial dramas, show how dominant and irrepressible were the artist's sense of satire and enjoyment of fun; character in its breadth and sharpness is depicted with keenest relish, and at times the sardonic smile bursts into the loudest laugh regardless of the propriety and solemnity appropriate to high art. Thus occasionally the grotesque degenerates into the vulgar, the grand into the ridiculous, as in the satire on "the Pigtail Age" in a fresco outside the New Pinakothek. Yet the genius of Kaulbach was far too transcendent to be marred by these exceptional extravagances: such exaggerations came not of weakness but from excess of power; they are as the sturdy traits and lawless forces of the Teutonic and northern races whence the Westphalian painter had sprung. Kaulbach tried hard to become Grecian and Italian; but he never reached Phidias or Raphael; in short the blood of Dürer, Holbein, and Martin Schöngauer ran strong in his veins. The art products in Munich during the middle of this century were of a quantity to preclude first-rate quality, and Kaulbach contracted a fatal facility in covering wall and canvas by the acre. He painted in the Hofgarten, the Odeon, the Palace, and on the external walls of the New Pinakothek. His perspicuous and showy manner also gained him abundant occupation as a book-illustrator: in the pages of the poets his fancy revelled; he was glad to take inspiration from Wieland, Goethe, even Klopstock; among his engraved designs are the Shakespeare gallery, the Goethe gallery, and a folio edition of the Gospels. All these signal examples of what may be called "the Munich school," though by the many applauded to the skies, were yet subjected to censorious criticism. In a volume entitled *Social Life in Munich* it was with some show of reason urged that Kaulbach had been unfortunate alike in having found Cornelius for a master and King Louis for a patron, that he attempted "subjects far beyond him, believing that his admiration for them was the same as inspiration"; the lack of real imagination he supplied by "a compound of intellect and fancy"; he "thinks his feelings," and his creations are but "the triumph of intellect."

Nevertheless no one appreciating at their worth such master compositions as the Destruction of Jerusalem and the Battle of the Huns can deny to Kaulbach creative imagination. As a dramatic poet he tells the story, depicts character, seizes on action and situation, and thus as it were takes the spectator by storm. The manner may be occasionally noisy and ranting, but the effect after its kind is tremendous. Within the whole range of modern art no finer composition can be named than the Battle of the Huns, no bolder conception than the fierce fight in mid air between the spirits of the warriors slain in combat. The drawing, the foreshortening, the grouping and lines of composition, are almost as a matter of course masterly. The cartoon, which, as usual in modern German art, is superior to the ultimate picture, was executed in the artist's prime at the age of thirty. At this period, as here seen, the knowledge was little short of absolute; subtle is the sense of beauty; playful, delicate, firm, the touch; the whole treatment artistic.

Ten or more years were devoted to what the Germans term a "cyclus,"—that is, a series of pictures which, as successive chapters or essays, illustrate one theme, as Raphael in the Vatican gave pictorial exposition to universal knowledge under the distinctive titles of Theology, Philosophy, Jurisprudence, and Poetry. The fundamental idea whereon Kaulbach discoursed was civilization or the progress of the human race as displayed in the following historic epochs:—the Tower of Babel, the Age of Homer, the Destruction of Jerusalem, the Battle of the Huns, the Crusades, and the Reformation. These major tableaux, severally 30 feet long, and each comprising over one hundred figures above life-size, are surrounded by minor compositions making more than twenty in all. The idea is to congregate around the world's historic dramas the prime agents of civilization; thus here are assembled allegoric figures of Architecture and other arts, of Science and other kingdoms of knowledge, together with lawgivers from the time of Moses, not forgetting Frederick the Great. The chosen situation for this imposing didactic and theatric display is the Treppenhaus or grand staircase in the new museum, Berlin; the surface is a granulated, absorbent wall, specially prepared; the technical method is that known as "water-glass," or "liquid flint," the infusion of silica securing permanence. The same medium was adopted in the later wall-pictures in the Houses of Parliament, Westminster.

The painter's last period brings no new departure; his ultimate works stand conspicuous by exaggerations of early characteristics. The series of designs illustrative of Goethe, which had an immense success, were melodramatic and pandered to popular taste. The vast canvas, more than 30 feet long, the Sea Fight at Salamis, painted for the Maximilianeum, Munich, evinces wonted imagination and facility in composition; the handling also retains its largeness and vigour; but in this astounding scenic uproar moderation and the simplicity of nature are thrown to the winds, and the whole atmosphere is hot and feverish. The painter verily had within him a fire which burnt fiercely; and, when past the age of sixty he received visitors within his spacious studio, he looked the perfect impersonation of his art. On the walls, upon easels, even on the floor, were large cartoons, rolls of canvas, piles of drawings—fruits of a restless and inexhaustible intellect. Kaulbach in the midst moved to and fro impulsively and discoursed volubly on the creations he was about to call out of chaos. But his career was drawing to a close; seized by the cholera, he died in 1874, at the age of sixty-nine.

Kaulbach can scarcely be counted among religious painters; yet the range of his thought is most lofty. Whatever is noblest in humanity, whatever has raised the human race, freed or enlightened the mind, given dignity and beauty to life, or reared the body into godlike frame, falls within the province of his art. Nothing small or mean finds a place; the accidents and crudities of common nature are cast out; typical forms are selected and matured; and all is brought into harmony with beauty. Kaulbach's was indeed a beauty-loving art. He is not supreme as a colourist; he belongs in fact to a school that holds colour in subordination; but he laid, in common with the great masters, the sure foundation of his art in form and composition. Indeed, the science of composition has seldom if ever been so clearly understood or worked out with equal complexity and exactitude; the constituent lines, the relation of the parts to the whole, are brought into absolute agreement; in modern Germany painting and music have trodden parallel paths, and Kaulbach is musical in the melody and harmony of his compositions. His narrative too is lucid, and moves as a stately march or royal triumph; the sequence of the figures is unbroken; the arrangement of the groups accords with even literary form; the picture falls into incident, episode, dialogue, action, plot, as a drama. The style is eclectic; in the Age of Homer the types and the treatment are derived from Greek marbles and vases; then in the Tower of Babel the severity of the antique gives place to the suavity of the Italian renaissance; while in the Crusades the composition is let loose into modern romanticism, and so the manner descends into the midst of the 19th century. And yet this scholastically compounded art is so nicely adjusted and smoothly blended that it casts off all incongruity and becomes homogeneous as the issue of one mind. But a fickle public craved for change; and so the great master in later years waned in favour, and had to witness, not without inquietude, the rise of an opposing party of naturalism and realism. Yet few men have had a brighter career, or enjoyed a reward better earned. Kaulbach's works are monumental, and will be handed down to future ages as the highest products of the renaissance of the arts in modern Germany. (J. B. A.)

KAUNITZ, WENZEL ANTON (1711–1794), count of Rietberg, Austrian statesman, was born at Vienna, February 2, 1711. As the fifth and youngest son of an Austrian count, he was destined at first for the church, but on the death of his brothers he turned his attention to statesmanship. He was sent by Maria Theresa on embassies to Rome and Florence, and was engaged at Turin in strengthening the alliance between Austria, Sardinia, and Great Britain against the Bourbons. In the meantime he had acquired the countship of Rietberg by marriage. In 1744 he was sent as minister to the court of the duke of Lorraine, governor-general of the Austrian Netherlands. During the duke's absence, Kaunitz administered affairs ably; and, when the French besieged Brussels in 1746, he secured a free retreat for the Austrian troops to Antwerp. After a brief retirement on account of his health, Kaunitz reappeared on the political stage at the congress of Aix-la-Chapelle in 1748, where he laid the foundation of his reputation, and earned the rank of minister of state. During his stay as ambassador at Paris, from 1750 to 1752, he concluded a secret alliance between Austria and France, a diplomatic stroke which involved the complete reversal of the former hostile attitude of the two powers, and which was rewarded by his appointment as chancellor of state or prime minister. In 1756 he was made chancellor of the Netherlands and of Italy. For nearly forty years he continued in this capacity to direct the affairs of Austria, steadily cultivating the French and Russian alliances, and jealously watching the rising power of Prussia, against which he formed the coalition of 1756. At the partition of Poland in 1772 he secured Galicia for Austria; and it was during his ministry also that Bukowina (1776) and the so-called "Inn quarter" came under the Austrian crown. He enjoyed the unbounded confidence of Maria Theresa, and was an active agent in furthering the reforms under her and her son Joseph II. He showed himself a liberal patron of education and art, as well as an accomplished statesman. Under Joseph II. and Leopold II. his influence waned, and he resigned all his offices at the accession of Francis II. in 1792. In 1764 he was created a prince of the empire. He died June 27, 1794.

See the life by Hormayr in the *Oesterreichischer Plutarch*, and *Denkschriften des Fürsten Kaunitz*, Vienna, 1872, by Beer.

KAVA, an intoxicating drink used in the islands of the South Pacific from the Sandwich Islands to Fiji. In Hawaii it is called "kawa"; in the Marquesas "kava kava"; "ava," "ava-ava," and "evava" in Tahiti; and in Fiji "yaquona." It is made from the roots or leaves of *Piper methysticum*, Miq., a species of pepper indigenous in these islands; several varieties are also cultivated by the natives, those growing in a dry soil being considered to be the most active. To prepare the liquid the fresh roots or leaves, after being chewed by young girls or boys, with good teeth, clean mouths, and free from colds, are placed in a large wooden bowl ("umete") on three legs made of the wood of the vesi (*Afzelia bijuga*, Gray), and water or cocoa-nut milk poured over the mass. The liquid is then stirred up, and the woody matter of the root is removed by repeatedly drawing through the infusion long fibres prepared by crushing the green stems of the vau (*Hibiscus*, sp.), and passing them frequently between two pieces of wood. By this means a muddy-looking liquid resembling *café au lait* in appearance, or of a greenish hue if made from the leaves, is left in the bowl, a quantity of fæcula remaining suspended in the fluid. The drink is then distributed into cups made of plantain leaves, by dipping some of the vau fibre into it and squeezing the liquid into the cups, which are handed to the individuals present. As the process of infusion only takes about twenty minutes, it is obvious that no fermentation can take place. The taste of the liquid is at first sweet and then pungent and acrid. The usual dose is half a cupful, equal to about two mouthfuls of the root. Intoxication follows in about twenty minutes, or immediately if twice the usual quantity be taken.

The drunkenness produced by kava differs from that of alcohol in being of a melancholy, silent, and drowsy character, accompanied, if the drink be made from roots growing in a damp soil, with great irritability at the slightest noise. The fit lasts for about two hours, but in persons who only take it occasionally it may continue for six or twelve hours. At Nukahiva kava is said to be used as a daily beverage, probably in small quantities,—its use, however, being forbidden to women and children. In many of the Pacific islands kava is given at official receptions, being the offered and accepted token of hospitality. Formerly the drinking of it preceded warlike enterprises and religious festivals.

The daily use of the drug is sometimes followed by a kind of skin disease, called in Tahiti "arevareva." The effect on those who are addicted to the use of kava for any length of time is to produce obscurity of vision, red conjunctiva, and yellow coloration of the teeth, while the skin where thick becomes dry, scaly, cracked, and ulcerated, and the body becomes emaciated and decrepit. In Nukahiva it is given as a medicine in phthisis and in bronchitis, a small dose being taken before going to bed.

Mr Collie, surgeon to the ship "Blossom," states that he observed the infusion of the root to be useful in certain skin diseases (Beachy, *Voyage of the "Blossom,"* vol. ii. p. 120). Some years ago it was introduced into France as a remedy for various diseases of the mucous membranes (*Annal. de Thérap.*, 1857, p. 61), and it has also been recommended in gout (*Med. Times and Gazette*, 1856, p. 591).

The root contains an essential oil of a yellow colour and agreeable odour, 2 per cent. of a balsamic resin called kawin, and about 49 per cent. of starch, also a neutral crystalline principle discovered in 1844 by Mr J. R. N. Morson, and called *kavahine*, or by Gobley *methysticin*. It is readily soluble in boiling alcohol, crystallizing out on cooling. Hydrochloric acid colours it red, this colour changing to yellow on exposure on the air; concentrated sulphuric acid changes it to a rich purple violet, which on exposure to the air gradually becomes green, or immediately if diluted with water. These tests distinguish it from cubebin and piperin.

See *Pharm. Journ.*, (1) iii. 474, (2) iv. 85, (2) ix. 219, (3) vii. 149; *Comptes Rendus*, l. 436, 598, lii. 206; and *Journ. de Pharm.*, 1860, p. 20, and 1862, p. 218; Seemann, *Flora Vitiensis*, p. 260.

KAVALA, or CAVALLO, a walled town of European Turkey in the vilayet of Saloniki, situated on a promontory stretching southwards into the bay of Kavala, opposite the island of Thaso. Numerous Roman remains have been found in the neighbourhood, of which the chief is the large aqueduct on two tiers of arches, which still serves to supply the town and dilapidated citadel with water from Mount Pangeus. Kavala has a port on each side of its promontory, and exports cotton and tobacco. The Turkish college was founded by Mehemet Ali, pasha of Egypt, who was born in the town in 1769. The population is about 5000.

Kavala has been identified with Neapolis, at which St Paul landed on his way from Samothrace to Philippi, 10 miles to the north (Acts xvi. 11). Neapolis was the port of Philippi, as Kavala now is of Seres; and in the bay on which it stands the fleet of Brutus and Cassius was moored during the battle of Philippi. Some authorities identify Neapolis with Datum (Δάτον), mentioned by Herodotus as famous for its gold mines.

KAVANAGH, Julia (1824–1877), novelist, was born at Thurles in Tipperary, Ireland, in 1824. She was the daughter of Morgan Kavanagh, author of various philological works, and she spent several years of her early life with her parents in Normandy, laying there the foundation of a perfect mastery of the French language and practical insight into French modes of thought, which was perfected by her later frequent and long residences in France. Miss Kavanagh's literary career began with her arrival in London about her twentieth year, and, beyond the publication of her successive works, her uneventful life with her widowed mother affords few incidents to the chronicler. On the outbreak of the Franco-German war the two ladies removed from Paris, where they were living, to Rouen. Thence they subsequently passed to Nice, where on October 28, 1877, Julia Kavanagh died, in her fifty-fourth year. She is described as having been in person extremely small, with large, luminous, brown eyes, and a wealth of splendid hair. She was a devout Roman Catholic.

Julia Kavanagh's first book was *Three Paths*, 1847, a story for the young; but her first work to attract notice was *Madeleine, a tale of Auvergne*, 1848. *A Summer and Winter in the Two Sicilies*, 2 vols., 1858, was the fruit of a journey made about 1853 to France, Switzerland, and Italy. *French Women of Letters*, 2 vols., 1862, and *English Women of Letters*, 2 vols., 1863, are collections of slight biographical essays on lady novelists. She wrote also *Woman in France during the 18th century*, 2 vols., 1850, and *Women of Christianity*, 1852. But Miss Kavanagh is better known by her numerous novels and tales contributed to various magazines. The scenes of these are almost always laid in France, and the authoress handles her French themes with fidelity and skill. Her style is simple and pleasing rather than striking; her characters are interesting without being strongly individualized; and the paucity of incident in the unravelling of her plots sometimes seems to threaten monotony. Her most popular novels are perhaps *Adèle*, 1857; *Queen Mab*, 1863; and *John Dorrien*, 1875. Others are *Nathalie*, 1850; *Daisy Burns*, 1853; *Grace Lee*, 1855; *Rachel Gray*, 1855; *Seven Years*, &c., 1859; *Beatrice*, 1865; *Sibyl's Second Love*, 1867; *Dora*, 1868; *Silvia*, 1870; *Bessie*, 1872; *The Pearl Fountain*, &c. (written along with her mother), 1876; and *Two Lilies*, 1877. *Forget-me-nots*, 2 volumes of shorter tales, appeared after her death.

KÁVERI, or Cauvery, a great river of southern India, famous for its traditional sanctity, its picturesque scenery, and its utility for irrigation. Rising in Coorg, high up amid the Western Gháts, in 12° 25′ N. lat. and 75° 34′ E. long., it flows with a generally south-eastern direction across the plateau of Mysore, and finally pours itself into the Bay of Bengal through two principal mouths in Tanjore district. Its total length is about 475 miles; the estimated area of its basin, 28,000 square miles. It is known to devout Hindus as Dakshini Ganga, or the Ganges of the South, and the whole of its course is holy ground. According to the legend there was once born upon earth a girl named Vishnumáyá or Lopámudrá, the daughter of Brahma; but her divine father permitted her to be regarded as the child of a mortal, called Kávera-muni. In order to obtain beatitude for her adoptive father, she resolved to become a river whose waters should purify from all sin. Hence it is that even the holy Ganges resorts underground once in the year to the source of the Káveri, to purge herself from the pollution contracted from the crowd of sinners who have bathed in her waters. The course of the Káveri in Coorg is very tortuous. Its bed is generally rocky; its banks are high and covered with luxuriant vegetation. On entering Mysore it passes through a narrow gorge, but presently widens to an average breadth of from 300 to 400 yards. Its bed continues rocky, so as to forbid all navigation; but its banks are here bordered with a rich strip of cultivation. In its course through Mysore, the channel is interrupted by twelve anicuts or dams for the purpose of irrigation. From the most important of these, known as the Madadkatte, an artificial channel is led to a distance of 72 miles, irrigating an area of 10,000 acres, yielding a revenue of £7000, and ultimately bringing a water-supply into the town of Mysore. In Mysore state the Káveri forms the two islands of Seringapatam and Sivasamudram, which vie in sanctity with the island of Srírangam lower down in Trichinopoli district. Around the island of Sivasamudram are the celebrated falls of the Káveri, unrivalled for romantic beauty. The river here branches into two channels, each of which makes a descent of about 200 miles in a succession of rapids and broken cascades. After entering the Madras presidency, the Káveri forms the boundary between the Coimbatore and Salem districts, until it strikes into Trichinopoli district. Sweeping past the historic rock of Trichinopoli, it breaks at the island of Srírangam into two channels, which enclose between them the delta of Tanjore, the garden of southern India. The northern channel is called the Coleroon (Kolidam); the other preserves the name of Káveri. On the seaward face of its delta are the open roadsteads of Negapatam and French Kárikal. The only navigation on any portion of its course is carried on in boats of basket-work. It is in the delta that the real value of the river for irrigation becomes conspicuous. The most ancient irrigation work is a massive dam of unhewn stone, 1080 feet long, and from 40 to 60 feet broad, across the stream of the Káveri proper, which is supposed to date back to the 4th century, is still in excellent repair, and has supplied a model to British engineers. The chief modern work is the anicut across the Coleroon, 2250 feet long, constructed by Sir Arthur Cotton between 1836 and 1838.

KAY, John (1742–1826), Scottish caricaturist, was born in April 1742, near Dalkeith, where his father was a mason. At thirteen he was apprenticed to a barber, whom he served for six years. He then went to Edinburgh, where in 1771 he obtained the freedom of the city by joining the corporation of barber-surgeons. For some years he practised his craft with success; but in 1785, induced by the favour which greeted certain attempts of his to etch in aquafortis, he took down his barber's pole and opened a small print shop in Parliament Square. There he continued to flourish, painting miniatures, and publishing at short intervals his sketches and caricatures of local celebrities and oddities, who abounded at that period in Edinburgh society. He died on February 21, 1826. Kay's portraits were collected by Hugh Paton and published under the title *A Series of Original Portraits and Caricature Etchings by the late John Kay, with Biographical Sketches and Illustrative Anecdotes* (Edin., 2 vols. 4to, 1838; 8vo ed., 4 vols., 1842; new 4to ed., with additional plates, 2 vols., 1877), forming a unique record of the social life and popular habits of Edinburgh at its most interesting epoch. The caricatures have little strictly artistic merit, beyond their graphic power; the drawing is always stiff and often false; but they are admitted to have been accurate likenesses, and they possess the evident recommendation of abundant and sly humour.

KAYE, Sir John William (1814–1876), historian, was born in 1814, the son of a solicitor. Educated at Eton and Addiscombe Royal Military College, he served as an officer in the Bengal artillery till 1841, when he exchanged his sword for the pen. In 1856 he entered the service of the East India Company in England; and, when next year the crown assumed the government of India, Kaye succeeded John Stuart Mill as secretary in the political and secret department of the India office. In 1871 he was created a knight of the Star of India. In 1874 his failing health warned him to resign his post; and he died in London, July 24, 1876. To his historical and biographical writings Sir John Kaye brought an historical sagacity, an honesty of purpose, and a military knowledge that make them at once valuable and interesting.

His best known works are his *History of the Sepoy War*, 3 vols., 1864; *History of the War in Afghanistan*, 2 vols., 1851; and his *Life of Lord Metcalfe*, 2 vols., 1854. He was the author also of *Peregrine Pultney* (1844) and *Long Engagements* (1861), two Indian novels; *History of the Administration of the East India Company*, 1853; *Life of Henry Tucker*, 1854; *Life of Sir John Malcolm*, 2 vols., 1856; *History of Christianity in India*, 1859; *Lives of Indian Officers*, 2 vols., 1867; *Essays of an Optimist*, 1870; and numerous contributions to periodicals.

KAZALA, or KAZALINSK, a fort and town, at the point where the Kazala falls into the Jaxartes, about 47 miles from its mouth. It is situated in 45° 45′ N. lat. and 62° 7′ E. long., "at the junction," to quote Schuyler's description, "of all the trade routes in Central Asia, as the road from Orenburg meets here with the Khivan, Bukharan, and Tashkent roads"; and thus, besides carrying on a lively local trade with the Kirghiz of the surrounding country, it is a point of growing importance in the general current of commerce. In other respects the position of the place is far from attractive: the floods on the river make it an island in the spring; in summer it is parched by the sun and hot winds, and hardly a tree can be got to grow. The streets are wide, but the houses, as well as the fairly strong fort known as Fort No. 1, are built of mud bricks. The population, stated at 5000, is on the increase.

KAZAN, a government of European Russia, belonging to the basin of the Volga, and conterminous with the governments of Nizhni Novgorod, Vyatka, Orenburg, Samara, and Simbirsk. The area, according to the government survey, is 23,998 square miles. By the Volga and its tributary the Kama the surface of the government is divided into three regions of differing aspect: the first, to the right of the main river, is traversed by deep ravines sloping to the north-east and by two ranges of hills, one of which, keeping company with the river, has a height of 300 to 500 feet, the second, between the left bank of the Volga and the left bank of the Kama, is an open steppe; and the third, between the left bank of the Volga and the right bank of the Kama, resembles in its eastern part the first region, and in its western part is covered with forest. Marls, limestones, and sandstones, Permian or Triassic, are the main rocks; the Jurassic formation appears in a small part of the Tetyushi district; and Tertiary rocks stretch along the left bank of the Volga. There are no minerals of importance; but mineral springs (iron, sulphur, and naphtha) exist in several places. The Volga is navigable in all the 198 miles of its course through Kazan, as well as the Kama (120 miles); and the Vyatka, the Kazanka, the Rutka, the Tsivil, the Greater Kotshaga, the Ilet, and the Bezdna are not without value as waterways. About four hundred small lakes are enumerated within the government; the Upper and Lower Kaban supply the city of Kazan with water.

About 7,123,610 acres (more than 46 per cent. of the surface) are arable, upwards of 1,324,900 acres (over 8 per cent.) are meadow land, and 5,190,960 acres (nearly 34 per cent.) are under forest. Rye and oats form the principal crops; barley, wheat, buckwheat, and potatoes are also grown. In 1879 the official returns gave 1,048,092 as the number of sheep in the government, and of these 13,748 were of fine woolled breeds; the horned cattle amounted to 359,362, the horses to 426,564, the swine to 192,190, and the goats to 45,822. No fewer than 8066 persons were engaged in beekeeping, and the produce of this department was valued at £29,945. Industrial activity is on the increase; the number of the smaller manufacturing establishments is diminishing, but those which remain (272 in 1879, employing 8399 hands) are greatly increasing in production. The total value of their manufacture in 1879 was £2,034,137. Apart from the regular factories, there is a large industrial activity. The weaving and dyeing of linen and hemp goods gave employment in 1879 to 13,485 men; wool-combing, &c., to 3428; flour and malt making to 3680, and the forest industries, wood-cutting, tar-boiling, &c., to 10,423. The aggregate commerce of the towns is estimated at £3,695,000. Of the seventy-six annual fairs, the chief are the timber fair of Kozmodemyansk, and those of Tchistopol and Tcheboksarui. Administratively Kazan is divided into twelve districts:—Kazan, Sviyazhsk, Tcheboksarui, Tsivilsk, Yadrin, Kozmodemyansk, Tsarevokokshaisk, Mamaduish, Tchistopol, Laisheff, Spassk, Tetyushi. Besides the city of Kazan, the following are the largest towns:—Tchistopol (20,293 inhabitants in 1879), Laisheff (5098), Tcheboksarui (4560), Kozmodemyansk (4508), Mamaduish (4068). The total population of the government in 1879 was 1,872,437 (194,343 in the towns, 1,678,094 in the country districts). The males in the former case numbered 109,915, and the females 84,428; and in the latter the males 820,144, and females 857,950. An increase of 267,732 has taken place since 1862. More than half of the inhabitants are of non-Slavonic origin; and the Mohammedans number over half a million.

The formation of the Kazan government dates from the year 1708; at first it contained a large portion of south-eastern Russia, but in 1781 the present limits were determined. The division into twelve districts was made in 1802.

KAZAN, chief town of the above government, is situated in 55° 48′ N. lat. and 49° 26′ E. long., 528 miles east of Moscow and 970 miles from St Petersburg. The summer course of the Volga lies several miles to the south-west, and is gradually increasing its distance; but when the river is at its height in spring the intervening space is laid under water, and the steamers, which at other times stop at the mouth of the Kazanka, are able to approach the town. Though the hill on which the citadel stands is only about 40 feet high, it forms a striking relief to the level country in front. Contrary to what might be expected from its history, the town is almost completely destitute of Oriental colouring; but the number and brightness of the Greek churches helps to relieve the general air of modern and commonplace regularity. The cathedral of the Annunciation was founded in 1562 by Gury, the first bishop of the diocese of Kazan; and the Bogoroditskii convent was erected in 1579 for the reception of the "Black Virgin of Kazan," which was removed in 1821 to the famous Kazan cathedral in St Petersburg. Of pre-Russian buildings there is hardly a trace; the red brick Sumbek tower, 245 feet high, is an object of great veneration to the Tartars, who consider it as the burial-place of one of their saints; but its similarity to the towers of Moscow proves its Muscovite origin. As an intellectual centre Kazan is the most important city of eastern Russia in Europe. The gymnasium, founded in 1750, was the third national institution for secondary education established in the empire; and the university, which dates from 1801, has become a great seat of Oriental scholarship. It has four faculties, with fifty-six teachers and about seven hundred students. The library contains about 85,000 volumes; but the most valuable part of its manuscript collection has been removed to St Petersburg. There is an astronomical observatory; and from the university press are issued a learned journal (*Izvyestiya i Zapiski*) and a very considerable number of works, especially in Oriental philology. The ecclesiastical academy founded in 1846 contains the old library of the Solovki monastery, of importance for the history of Russian sects. Schools are maintained by the Tartar population, which still occupies some of the suburbs; and Tartar text-books (by Radloff) after the European type have been introduced. As a seat of commerce and industry Kazan holds a respectable place. Its leather goods, especially those of the finer qualities, are in repute; and it also manufactures alcohol, flour, cotton and hemp goods, starch, stearine, tallow, and albumen. The trade connexion of the Tartar merchants more particularly is a very extensive and important one. The population of the town, which was 63,084 in 1863, had increased in 1879 to 134,434, of whom 13,635 are Tartars.

The present government of Kazan was the centre of a great Bulgarian kingdom, the first historical monarchy of north-eastern Russia. On the ruins of this kingdom the Mongolian (Tartar) "kingdom of Kazan" was founded in the 15th century by Ulu-Mahmet, whose descendants continued to rule till the destruction of their city by Ivan the Terrible in 1552. Of the town of Kazan the early notices are of doubtful interpretation; but according to S. M. Shpilevski the Kazan mentioned in 1376 must be Bulgar (the present Bolgarui in the district of Spassk), the "Great Town" of the Bulgarians, the ruins of which are among the most notable in the Kazan region; and the Kazan of even some of the later chronicles is to be identified with Koshan on the Kama. Nor is the present the original of Kazan proper; on the banks of the Kazanka are extensive remains of *Iski* (Tartar for "Old") *Kazan*, near a modern village of the same name. Kazan was laid waste by Pugatcheff, and the conflagrations of 1815 and 1825 were especially destructive. During the French invasion the Moscow university took asylum in the town.

The name of Kazan Tartars is given, not only to those of the government of Kazan, but to those of Ufa, Samara, Vyatka, Saratoff, Penza, Nizhni Novgorod, Orenburg, and Tamboff. In 1870 they amounted altogether to 1,050,000. In many ways they differ considerably from those of Astrakhan, the Crimea, &c. They have pretty certainly incorporated a good deal of Bulgarian blood.

The history of Kazan has been written by Turnerelli (1841), Lepteff, Kurbski, and others. The evidence of Arabic, Tartar, and Russian writers in regard to the antiquities of town and government has been collected by Shpilevski (*Izv. i Zap. Imp. Kaz. Un.*, 1877, pp. 1–585). A bibliography of the Oriental books published in the town is given in the *Bull. of the St Petersburg Academy*, 1867. Compare Louis Leger, "Kazan et les Tartares," in *Bibl. Univ. de Genève*, 1874.

KAZINCZY, Ferencz or Francis (1759–1831), an Hungarian author, known as the most indefatigable agent in the regeneration of the Magyar language and literature at the end of the 18th and beginning of the 19th century, was born 27th October 1759, at Ér-Semlyén, in the county of Bihar, Hungary. After passing through the gymnasium of Sáros-Patak, he studied law at Kassa and Eperies, and in Pest, where he also obtained a thorough knowledge of French and German literature, and made the acquaintance of Gideon Ráday, who allowed him the use of his library, and encouraged him in literary pursuits. In 1784 Kazinczy became subnotary for the county of Abaúj; and in 1786 he was nominated inspector of schools at Kassa. There he began to devote himself to the restoration of the Magyar language and literature by translations from classical foreign works, and by the augmentation of the native vocabulary from ancient Magyar sources. In 1788, with the assistance of Baróti Szabó and John Bacsányi, he started at Kassa the first Magyar literary magazine, *Magyar Muzeum*; the *Orpheus*, which succeeded it in 1790, was of his own creation. Although, upon the accession of Leopold II., Kazinczy, as a non-Catholic, was obliged to resign his post at Kassa, his literary activity in no way decreased, and he not only assisted Gideon Ráday in the establishment and direction of the first Magyar dramatic society, but also enriched the repertoire with several translations from foreign authors. His *Hamlet*, which first appeared at Kassa in 1790, is a rendering from the German version of Schröder. Having become implicated in the democratic conspiracy of the abbot Martinovics, Kazinczy was arrested on the 14th December 1794, conveyed to Buda, tried, and condemned to death; but the sentence was commuted to imprisonment. He was released in 1801, and shortly afterwards married Sophia Török, daughter of his former patron, and retired to his small estate at Széphalom or "Fairhill," near Sátor-Ujhely, in the county of Zemplén. In 1828 he took an active part in the conferences held for the establishment of the Hungarian academy, in the historical section of which he became the first corresponding member. He died of Asiatic cholera, at Széphalom, on the 22d August 1831, in the seventy-second year of his age.

Kazinczy, although possessing great beauty of style, cannot be regarded as a powerful and original thinker; his fame is chiefly due to the felicity of his translations from the masterpieces of Lessing, Goethe, Wieland, Klopstock, Ossian, La Rochefoucauld, Marmontel, Molière, Metastasio, Shakespeare, Sterne, Cicero, Sallust, Anacreon, and many others. He also edited the works of Baróczy (Pest, 1812, 8 vols.) and of the poet Zrinyi (1817, 2 vols.), and the poems of Dayka (1813, 3 vols.) and of John Kis (1815, 3 vols.). A collective edition of his works, consisting for the most part of translations, was published at Pest, 1814–1816, in 9 vols. His original productions, largely made up of letters, were edited by Joseph Bajza and Francis Toldy at Pest, 1836–45, in 5 vols. Editions of his poems appeared in 1858 and in 1863. See Hungary, vol. xii. p. 377.

KEAN, Charles John (1811–1868), tragedian, son of Edmund Kean noticed below, was born at Waterford, Ireland, 18th January 1811. In his fourteenth year he was sent to Eton College, where he remained three years. The name of Kean secured him an engagement at Drury Lane Theatre, where he made his debut 1st October 1827, in the character of Norval, but failed to create a very favourable impression, his talents being such as required long practice and careful study for their development; and his continued failure to achieve popularity led him to leave London in the spring of 1828 for the provinces. After a visit to America in 1830, where he was received with much favour, he in 1833 appeared at Covent Garden as Sir Edmund Mortimer, but his success was not pronounced enough to encourage him to remain long in London, especially as he had already in the provinces won a high position. In January 1838 he returned to Drury Lane, and played Hamlet with a success which gave him a place among the principal tragedians of his time. After his marriage with the actress Miss Ellen Tree in 1842, he paid a second visit to America. Returning to England in 1847, he entered on a successful engagement at the Haymarket, and in 1850, along with Mr Kelly, he became lessee of the Princess Theatre. The most noteworthy feature of his management was a series of gorgeous Shakespearean revivals. Charles Kean cannot be called a great tragic actor. He did all that could be done by the persevering cultivation of his powers, and in many ways manifested the possession of high intelligence and refined taste, but his defects of person and voice made it impossible for him to give a representation at all adequate of the varying and subtle emotions characteristic of pure tragedy. In melodramatic parts such as Louis XI. and the Corsican Brothers his success was unequivocal and complete. From his "tour round the world" Kean returned in 1866 in broken health, and he died at London, January 22, 1868.

The Life and Theatrical Times of Charles Kean, by John William Cole, appeared in 1860 in two volumes.

KEAN, Edmund (1787–1833), an English actor, chiefly celebrated as the impersonator of Shakespearean characters, was born at Chancery Lane, London, November 4, 1787. His reputed father was Aaron Kean, stage carpenter, and his mother was a strolling actress, Ann Carey, granddaughter of Henry Carey, the author of the *National Anthem*, and the natural son of George Savile, marquis of Halifax. When only in his fourth year Kean made his first appearance on the stage as Cupid in one of Noverre's ballets at the opera-house. His fine black eyes, his bright vivacity and cleverness, and his ready affection to those who treated him with kindness, made him in childhood a universal favourite, but the harsh circumstances of his lot, and the want of proper restraint, while they developed strong self-reliance, fostered wayward tendencies. About 1794 a few persons benevolently provided the means of sending him to school, where he mastered his tasks with remarkable ease and rapidity; but finding its restraint intolerably irksome, he shipped himself as a cabin boy at Portsmouth. Soon discovering that he had only escaped to a more rigorous bondage, he counterfeited both deafness and lameness with a bistrionic mastery which deceived even the physicians at Madeira. On his return to England he sought the protection of his uncle Moses Kean, mimic, ventriloquist, and general entertainer, who, besides continuing his pantomimic studies, introduced him to the study of Shakespeare. At the same time Miss Tidswell, an actress who had been specially kind to him from infancy, taught him the principles of acting. On the death of his uncle he was taken charge of by Miss Tidswell, and under her direction he began the systematic study of the principal Shakespearean characters, displaying even at this early period the peculiar originality of his genius by interpretations entirely different from those of Kemble. His brilliant talents and interesting countenance induced a Mrs Clarke of Guildford Street, Russell Square, to adopt him, but the unlucky remark of a visitor so touched his sensitive pride that he suddenly left her house and went back to his old surroundings. In his fourteenth year he obtained an engagement to play leading characters for twenty nights in York Theatre, appearing as Hamlet, Hastings, and Cato. Shortly afterwards, while he was in the strolling troupe of Richardson, the rumour of his abilities reached the ear of King George III., who commanded him to recite at Windsor Castle. It is affirmed that this incident led some gentlemen to send him to Eton College; but the next three years of his life, from 1803 to 1806, are without authentic record. In 1807 he played leading parts in the Belfast theatre along with Mrs Siddons, who said that he "played very very well," but that "there was too little of him to make a great actor." An engagement in 1808 to play leading characters in Beverley's provincial troupe was brought to an abrupt close by his marriage with Miss Chambers, the leading actress, and for several years after his prospects were so dark that, when contemplating the possibility of a debut in London, he was in the habit of exclaiming, "If I succeed I shall go mad." In 1814, however, the committee of Drury Lane theatre, the fortunes of which were then so low that bankruptcy seemed inevitable, resolved to give him a chance among the "experiments" they were making to win a return of popularity. His debut there on the 26th January as Shylock roused the audience to almost uncontrollable enthusiasm, and successive appearances in Richard III., Hamlet, Othello, Macbeth, and Lear only served to demonstrate to the fullest the greatness of his powers and his complete mastery of the whole range of tragic emotion.

Probably the irregular habits of Kean, even from the period when he became famous, were prejudicial to the refinement of his taste, and latterly they tended to exaggerate his special defects and mannerisms. The adverse decision in the divorce case Cox *v.* Kean, and his consequent separation from his wife, roused against him such bitter feeling as almost compelled him to retire permanently into private life. Ultimately he was received with all the old favour, but the contest by its effects both on his bodily health and on his feelings had made him so dependent on the use of stimulants that the gradual deterioration of his gifts was inevitable. Still, even in their decay his great powers triumphed during the moments of his inspiration over the absolute wreck of his physical faculties, and compelled admiration when his gait had degenerated into a weak hobble, when the lightning brilliancy of his eyes had become dull and bloodshot, and the tones of his matchless voice were marred by rough and grating hoarseness. His last appearance on the stage was at Covent Garden, on the 25th March 1833, when he played Othello to his son's Iago. At the words "Villain, be sure" in scene 3 of act iii. he suddenly broke down, and fell insensible into his son's arms. He died at Richmond, 15th May 1833.

It was especially in the impersonation of the great creations of Shakespeare's genius that the varied beauty and grandeur of the acting of Kean were displayed in their highest form, although probably his most powerful character was Sir Giles Overreach, the effect of his first impersonation of which was such that the pit rose *en masse*, and even the actors and actresses themselves were overcome by the terrific dramatic illusion. His only personal disadvantage as an actor was his small stature. His countenance was strikingly interesting and unusually mobile; he had a matchless command of facial elocution; his fine eyes scintillated even the slightest shades of emotion and thought; his voice, though weak and harsh in the upper register, possessed in its lower range tones of penetrating and resistless power, and a thrilling sweetness like the witchery of the finest music; above all, in the grander moments of his passion, his intellect and soul seemed to rise beyond material barriers and to glorify physical defects with their own greatness. Kean specially excelled as the exponent of passion. In Othello, Iago, Shylock, and Richard III., characters utterly different from each other, but in which the predominant element is some form of passion, his identification with the personality, as he had conceived it, was as nearly as possible perfect, and each isolated phase and aspect of the plot was elaborated with the minutest attention to details, and yet with an absolute subordination of these to the distinct individuality he was endeavouring to portray. If the range of character in which Kean attained supreme excellence was narrow, no one except Garrick has been so successful in so many great impersonations. Unlike Garrick, he had no true talent for comedy, but in the expression of biting and saturnine wit, of grim and ghostly gaiety, he was unsurpassed.

See Procter's *Life of Kean*, but especially the *Life of Edmund Kean*, by F. W. Hawkins, 2 vols., 1869, and the authorities therein mentioned. Some interesting details will also be found in Edward Stirling's *Old Drury Lane*, 1881.

KEATS, JOHN, born October 29, 1795, published his first volume of verse in 1817, his second in the following year, his third in 1820, and died of consumption at Rome, February 23, 1821, in the fourth month of his twenty-sixth year. In his first book there was little foretaste of anything greatly or even genuinely good; but between the marshy and sandy flats of sterile or futile verse there were undoubtedly some few purple patches of floral promise. The style was frequently detestable—a mixture of sham Spenserian and mock Wordsworthian, alternately florid and arid. His second book, *Endymion*, rises in its best passages to the highest level of Barnfield and of Lodge, the two previous poets with whom, had he published nothing more, he might most properly have been classed; and this, among minor minstrels, is no unenviable place. His third book raised him at once to a foremost rank in the highest class of English poets. Never was any one of them but Shelley so little of a marvellous boy and so suddenly revealed as a marvellous man. Never has any poet suffered so much from the chaotic misarrangement of his poems in every collected edition. The rawest and the rankest rubbish of his fitful spring is bound up in one sheaf with the ripest ears, flung into one basket with the richest fruits, of his sudden and splendid summer. The *Ode to a Nightingale*, one of the final masterpieces of human work in all time and for all ages, is immediately preceded in all editions now current by some of the most vulgar and fulsome doggrel ever whimpered by a vapid and effeminate rhymester in the sickly stage of whelphood. Shelley, up to twenty, had written little or nothing that would have done credit to a boy of ten; and of Keats also it may be said that the merit of his work at twenty-five was hardly by comparison more wonderful than its demerit at twenty-two. His first book fell as flat as it deserved to fall; the reception of his second, though less considerate than on the whole it deserved, was not more contemptuous than that of immeasurably better books published about the same time by Coleridge, Landor, and Shelley. A critic of exceptional carefulness and candour might have noted in the first book so singular an example of a stork among the cranes as the famous and noble sonnet on Chapman's Homer; a just judge would have indicated, a partial advocate might have exaggerated, the value of such golden grain amid a garish harvest of tares as the hymn to Pan and the translation into verse of Titian's Bacchanal which glorify the weedy wilderness of *Endymion.* But the hardest thing said of that poem by the *Quarterly* reviewer was unconsciously echoed by the future author of *Adonais*,—that it was all but absolutely impossible to read through; and the obscener insolence of the "Blackguard's Magazine," as Landor afterwards very justly labelled it, is explicable though certainly not excusable if we glance back at such a passage as that where Endymion exchanges fulsome and liquorish endearments with the "known unknown *from whom his being sips such darling (!) essence.*" Such nauseous and pitiful phrases as these, and certain passages in his correspondence, make us understand the source of the most offensive imputations or insinuations levelled against the writer's manhood; and, while admitting that neither his love-letters, nor the last piteous outcries of his wailing and shrieking agony, would ever have been made public by merciful or respectful editors, we must also admit that, if they ought never to have been published, it is no less certain that they ought never to have been written; that a manful kind of man or even a manly sort of boy, in his love-making or in his suffering, will not howl and snivel after such a lamentable fashion. One thing hitherto inexplicable a very slight and rapid glance at his amatory correspondence will amply suffice to explain: how it came to pass that the woman so passionately beloved by so great a poet should have thought it the hopeless attempt of a mistaken kindness to revive the memory of a man for whom the best that could be wished was complete and compassionate oblivion. For the side of the man's nature presented to her inspection, this probably was all that charity or reason could have desired. But that there was a finer side to the man, even if considered apart from the poet, his correspondence with his friends and their general evidence to his character give more sufficient proof than perhaps we might have derived from the general impression left on us by his works; though indeed the preface to *Endymion* itself, however illogical in its obviously implied suggestion that the poem published was undeniably unworthy of publication, gave proof or hint at least that after all its author was something of a man. And the eighteenth of his letters to Miss Brawne stands out in bright and brave contrast with such as seem incompatible with the traditions of his character on its manlier side. But if it must be said that he lived long enough only to give promise of being a man, it must also be said that he lived long enough to give assurance of being a poet who was not born to come short of the first rank. Not even a hint of such a probability could have been gathered from his first or even from his second appearance; after the publication of his third volume it was no longer a matter of possible debate among judges of tolerable competence that this improbability had become a certainty. Two or three phrases cancelled, two or three lines erased, would have left us in *Lamia* one of the most faultless as surely as one of the most glorious jewels in the crown of English poetry. *Isabella*, feeble and awkward in narrative to a degree almost incredible in a student of Dryden and a pupil of Leigh Hunt, is overcharged with episodical effects of splendid and pathetic expression beyond the reach of either. *The Eve of St Agnes*, aiming at no doubtful success, succeeds in evading all casual difficulty in the line of narrative; with no shadow of pretence to such interest as may be derived from stress of incident or depth of sentiment, it stands out among all other famous poems as a perfect and unsurpassable study in pure colour and clear melody—a study in which the figure of Madeline brings back upon the mind's eye, if only as moonlight recalls a sense of sunshine, the nuptial picture of Marlowe's Hero and the sleeping presence of Shakespeare's Imogen. Beside this poem should always be placed the less famous but not less precious *Eve of St Mark*, a fragment unexcelled for the simple perfection of its perfect simplicity, exquisite alike in suggestion and in accomplishment. The triumph of *Hyperion* is as nearly complete as the failure of *Endymion;* yet Keats never gave such proof of a manly devotion and rational sense of duty to his art as in his resolution to leave this great poem unfinished; not, as we may gather from his correspondence on the subject, for the pitiful reason assigned by his publishers, that of discouragement at the reception given to his former work, but on the solid and reasonable ground that a Miltonic study had something in its very scheme and nature too artificial, too studious of a foreign influence, to be carried on and carried out at such length as was implied by his original design. Fortified and purified as it had been on a first revision, when much introductory allegory and much tentative effusion of sonorous and superfluous verse had been rigorously clipped down or pruned away, it could not long have retained spirit enough to support or inform the shadowy body of a subject so little charged with tangible significance. The faculty of assimilation as distinguished from imitation, than which there can be no surer or stronger sign of strong and sure original genius, is not more evident in the most Miltonic passages of the revised *Hyperion* than in the more Shakespearean passages of the unrevised tragedy which no radical correction could have left other than radically incorrigible. It is no conventional exaggeration, no hyperbolical phrase of flattery with more sound than sense in it, to say that in this chaotic and puerile play of *Otho the Great* there are such verses as Shakespeare might not without pride have signed at the age when he wrote and even at the age when he rewrote the tragedy of *Romeo and Juliet.* The dramatic fragment of *King Stephen* shows far more power of hand and gives far more promise of success than does that of Shelley's *Charles the First.* Yet we cannot say with any confidence that even this far from extravagant promise would certainly or probably have been kept; it is certain only that Keats in these attempts did at least succeed in showing a possibility of future excellence as a tragic or at least a romantic dramatist. In every other line of high and serious poetry his triumph was actual and consummate; here only was it no more than potential or incomplete. As a ballad of the more lyrical order, *La belle Dame sans Merci* is not less absolutely excellent, less triumphantly perfect in force and clearness of impression, than as a narrative poem is *Lamia.* In his lines on Robin Hood, and in one or two other less noticeable studies of the kind, he has shown thorough and easy mastery of the beautiful metre inherited by Fletcher from Barnfield and by Milton from Fletcher. The simple force of spirit and style which distinguishes the genuine ballad manner from all spurious attempts at an artificial simplicity was once more at least achieved in his verses on the crowning creation of Scott's humaner and manlier genius—Meg Merrilies. No little injustice has been done to Keats by such devotees as fix their mind's eye only on the more salient and distinctive notes of a genius which in fact was very much more various and tentative, less limited and peculiar, than would be inferred from an exclusive study of his more specially characteristic work. But within the limits of that work must we look of course for the genuine credentials of his fame; and highest among them we must rate his unequalled and unrivalled odes. Of these perhaps the two nearest to absolute perfection, to the triumphant achievement and accomplishment of the very utmost beauty possible to human words, may be that to Autumn and that on a Grecian Urn; the most radiant, fervent, and musical is that to a Nightingale; the most pictorial and perhaps the tenderest in its ardour of passionate fancy is that to Psyche; the subtlest in sweetness of thought and feeling is that on

Melancholy. Greater lyrical poetry the world may have seen than any that is in these; lovelier it surely has never seen, nor ever can it possibly see. From the divine fragment of an unfinished ode to Maia we can but guess that if completed it would have been worthy of a place beside the highest. His remaining lyrics have many beauties about them, but none perhaps can be called thoroughly beautiful. He has certainly left us one perfect sonnet of the first rank; and as certainly he has left us but one.

Keats, on high and recent authority, has been promoted to a place beside Shakespeare; and it was long since remarked by some earlier critic of less note that as a painter of flowers his touch had almost a Shakespearean felicity,—recalling, a writer in our own day might have added, the hand of M. Fantin on canvass. The faultless force and the profound subtlety of this deep and cunning instinct for the absolute expression of absolute natural beauty can hardly be questioned or overlooked; and this is doubtless the one main distinctive gift or power which denotes him as a poet among all his equals, and gives him right to a rank for ever beside Coleridge and Shelley. As a man, the two admirers who have done best service to his memory are, first and far foremost, Lord Houghton, and secondly Mr Matthew Arnold. These alone, among all who have written of him without the disadvantage or advantage of a personal acquaintance, have clearly seen and shown us the manhood of the man. That ridiculous and degrading legend which imposed so strangely on the generous tenderness of Shelley, while evoking the very natural and allowable laughter of Byron, fell to dust at once for ever on the appearance of that admirable and unsurpassed biography which gave perfect proof to all time that "men have died and worms have eaten them," but not for fear of critics or through suffering inflicted by reviews. Somewhat too sensually sensitive he may have been in either capacity, but the nature of the man was as far as was the quality of the poet above the pitiful level of a creature whose soul could "let itself be snuffed out by an article"; and in fact, owing doubtless to the accident of a death which followed so fast on his early appearance and his dubious reception as a poet, the insolence and injustice of his reviewers in general have been comparatively and even considerably exaggerated. Except from the chief fountain-head of professional ribaldry then open in the world of literary journalism, no reek of personal insult arose to offend his nostrils; and then as now the tactics of such unwashed malignants were inevitably suicidal; the references to his brief experiment of apprenticeship to a surgeon which are quoted from *Blackwood* in the shorter as well as in the longer memoir by Lord Houghton could leave no bad odour behind them save what might hang about men's yet briefer recollection of his assailant's unmemorable existence. The false Keats, therefore, whom Shelley pitied and Byron despised would have been, had he ever existed, a thing beneath compassion or contempt. That such a man could have had such a genius is almost evidently impossible; and yet more evident is the proof which remains on everlasting record that none was ever further from the chance of decline to such degradation than the real and actual man who made that name immortal. (A. C. S.)

Subjoined are the most important facts in the life of Keats. He was born, as already stated, in London on October 29, 1795. At an early age he was sent to school at Enfield, and in 1810 he was apprenticed to a surgeon at Edmonton. On the completion of his apprenticeship, in 1815, he removed to London for the purpose of walking the hospitals, and soon made the acquaintance of Leigh Hunt, and subsequently that of Haydon, Hazlitt, Shelley, and others. After having published some sonnets in the *Examiner*, of which Hunt was at that time editor, he was encouraged by the praise of his friends to give to the world a volume of *Poems* in 1817, and a second, entitled *Endymion, a Poetic Romance*, in the following year. Meanwhile, symptoms of hereditary lung-disease having shown themselves, he spent some months in visiting the English lake district and portions of Scotland and Ireland, but without re-establishing his failing health; on his return to London the despondency which had fallen upon him on this account was deepened by the death of his younger brother. Soon after this event he first became acquainted with Miss Brawne, and the friendship rapidly grew into a passion which combined with straitened circumstances and the steady progress of disease to give a tragical cast to all that remained of his brief career. In 1820 the results of his literary activity during the two preceding years were published in *Lamia, Isabella, the Eve of St Agnes, and other Poems.* In autumn of the same year, having been advised to winter in a more genial climate, he sailed for Italy. The voyage proved of little advantage, and after some months of suffering he died at Rome on February 23, 1821. *The Life, Letters, and Literary Remains* of Keats were published in two volumes by R. Monckton Milnes in 1848; *The Letters of John Keats to Fanny Brawne*, with introduction and notes by Harry Buxton Forman, appeared in 1878.

KEBLE, JOHN (1792–1866), the poet of the *Christian Year*, was born on St Mark's Day (April 25), 1792, at Fairford, Gloucestershire. He was the second child and eldest son of the Rev. John Keble and Sarah Maule; three sisters and one brother completed the family circle. Descended from a family which had attained some legal eminence in the time of the Commonwealth, John Keble, the father of the poet, was vicar of Coln St Aldwyn, but lived at Fairford, about 3 miles distant from his cure. He was a clergyman of the old High Church school, whose adherents, untouched by the influence of the Wesleys, had moulded their piety on the doctrines of the non-jurors and the old Anglican divines. Himself a good scholar, he did not send his son to any school, but educated him and his brother at home so well that both obtained scholarships at Corpus Christi College, Oxford. John was elected scholar of Corpus in his fifteenth, and fellow of Oriel in his nineteenth year, April 1811. In Easter term 1810 he had obtained double first class honours, a distinction which had been obtained only once before, and that by Sir Robert Peel. After his election to the Oriel fellowship, Keble gained the University prizes, both for the English essay and also for the Latin essay. But he was more remarkable for the rare beauty of his character than even for academic distinctions. Sir John Taylor Coleridge, his fellow scholar at Corpus and his life-long friend, says of him, looking back on his youth, after their friendship of five and fifty years had closed, "It was the singular happiness of his nature, remarkable even in his undergraduate days, that love for him was always sanctified by reverence—reverence that did not make the love less tender, and love that did but add intensity to the reverence." Oriel College was, at the time when Keble entered it, the centre of all the finest ability in Oxford. Copleston, Davison, Whately, were among the fellows who elected Keble; Arnold, Pusey, Newman, were soon after added to the society. In 1815 Keble was ordained deacon, and priest in 1816. His real bent and choice were towards a pastoral cure in a country parish; but he remained in Oxford, acting first as public examiner in the schools, then as tutor in Oriel, till 1823. In summer he sometimes took clerical work, sometimes made tours on foot through various English counties, during which he was composing poems, which afterwards took their place in the *Christian Year*. He had a rare power of attracting to himself the finest spirits, a power which lay not so much in his ability or his genius as in his character, so simple, so humble, so pure, so unworldly, yet wanting not that severity which can stand by principle and maintain what he holds to be the truth. In 1823 he left Oxford, and returned to Fairford, there to assist his father, and with his brother to serve one or two small and poorly endowed curacies in the neighbourhood of Coln. He had made a quiet but deep impression on all who came within his influence in Oxford, and during his five years of college tutorship had won the affection of his pupils, some of whom afterwards rose to eminence. But it was to pastoral work, and not to academic duty, that he thenceforth devoted himself, associating with it, and scarcely placing on a lower level, the affectionate discharge of his duties as a son and brother. Filial piety influenced in a quite unusual degree his feelings and his action all life through. It was in 1827, a few years after he settled at Fairford, that he published the *Christian Year*. The poems which make up that book had been the silent gathering of years. Keble had purposed in his own mind to keep them beside him, correcting and improving them, as long as he lived, and to leave them to be published only "when he was fairly out of the way." This resolution was at length overcome by the importunities of his friends, and above all by the strong desire of his father to see his son's poems in print before he died. Accordingly they were printed in two small volumes in Oxford, and given to the world in June 1827, but with no name on the title page. The book continued to be published anonymously, but the name of the author soon transpired. Probably no book of poetry in this century has had a wider circulation. Between 1827 and 1872 one hundred and fifty-eight editions had issued from the press, and since the latter date it has been largely reprinted both by the original publishers and by others. The author, so far from taking pride in this widespread reputation, seemed all his life long to wish to disconnect his name with the book, and "as if he would rather it had been the work of some one else than himself." This feeling arose from no false modesty. It was because he knew that in these poems he had painted his own heart, the best part of it; and he doubted whether it was right thus to exhibit himself, and by the revelation of only his better self, to win the good opinion of the world, on which he knew that a woe had been pronounced.

Towards the close of 1831 Keble was elected to fill the chair of the poetry professorship in Oxford, as successor to his friend and admirer, Dean Milman. This chair he occupied for ten years, probably the most eventful ten years which Oxford has seen since the Reformation. The professor is required by statute to deliver at least one lecture during each of the three terms that make up the academic year; and during Keble's tenure these lectures were still required to be in Latin. In the course of his professorship he delivered a series of lectures, clothed in excellent idiomatic Latin, in which he expounded a theory of poetry which was original and suggestive, and which grew naturally out of his own character and habits of mind. He looked on poetry as a vent for overcharged feeling, or a full imagination, or some imaginative regret, which had not found their natural outlet in life and action. It was a relief provided for those feelings which are apt to fill the mind too full, and to overburden the heart. This suggested to him a distinction between what he called primary and secondary poets,—the first employing poetry to relieve their own hearts, the second, poetic artists, composing poetry from some other and less impulsive motive. Of the former kind were Homer, Lucretius, Burns, Scott; of the latter were Euripides, Dryden, Milton. This view is set forth in an article contributed to the *British Critic* in 1838 on the life of Scott, and was more fully developed in two volumes of *Prælectiones Academicæ*.

His regular visits to Oxford kept him in intercourse with his old friends in Oriel common room, and made him familiar with the currents of feeling which swayed the university. Catholic emancipation and the Reform Bill had deeply stirred, not only the political spirit of Oxford, but also the church feeling which had long been stagnant. Cardinal Newman writes, "On Sunday July 14, 1833, Mr Keble preached the assize sermon in the University pulpit. It was published under the title of *National Apostasy*. I have ever considered and kept the day as the start of the religious movement of 1833." The occasion of this sermon was the suppression, by Earl Grey's Reform ministry, of ten Irish bishoprics. Against the spirit which would treat the church as the mere creature of the state Keble had long chafed inwardly, and now he made his outward protest, asserting the claim of the church to a heavenly origin and a divine prerogative. About the same time, and partly stimulated by Keble's sermon, some leading spirits in Oxford and elsewhere began a concerted and systematic course of action to revive High Church principles and the ancient patristic theology, and by these means both to defend the church against the assaults of its enemies, and also to raise to a higher tone the standard of Christian life in England. This design embodied itself in what is known as the Tractarian movement, a name it received from the once famous *Tracts for the Times*, which were the vehicle for promulgating the new doctrines. If Keble is to be reckoned, as Dr Newman would have it, as the primary author of the movement, it was from Dr Pusey that it received one of its best known names, and in Dr Newman that it soon found its genuine leader. To the tracts, which did so much to spread High Church views, Keble made only four contributions:—No. 4, containing an argument, in the manner of Bishop Butler, to show that adherence to apostolical succession is the safest course; No. 13, which explains the principle on which the Sunday lessons in the church service are selected; No. 40, on marriage with one who is unbaptized; No. 89, on the mysticism attributed to the early fathers of the church. Besides these contributions from his own pen, he did much for the series by suggesting subjects, by reviewing tracts written by others, and by lending to their circulation the weight of his personal influence.

In 1835 Keble's father died at the age of ninety, and soon after this his son married Miss Clarke, left Fairford, and settled at Hursley vicarage in Hampshire, a living to which he had been presented by his friend and attached pupil, Sir William Heathcote, and which continued to be Keble's home and cure for the remainder of his life.

In 1841 the tracts were brought to an abrupt termination by the publication of Newman's tract No. 90. All the Protestantism of England was in arms against the author of the obnoxious tract. Keble came forward at the time, desirous to share the responsibility and the blame, if there was any; for he had seen the tract before it was published, and approved of it. The same year in which burst this ecclesiastical storm saw the close of Keble's tenure of the professorship of poetry, and thenceforward he was seen but rarely in Oxford. No other public event ever effected Keble so deeply as the secession of his friend Mr Newman to the Church of Rome in 1845. It was to him both a public and a private sorrow, which nothing could repair. But he did not lose heart; at once he threw himself into the double duty, which now devolved on himself and Dr Pusey, of counselling the many who had hitherto followed the movement, and who, now in their perplexity, might be tempted to follow their leader's example, and at the same time of maintaining the rights of the church against what he held to be the encroachments of the state, as seen in such public acts as the Gorham judgment, and the decision on *Essays and Reviews*. In all the ecclesiastical contests of the twenty years which followed 1845, Keble took a part, not loud or obtrusive, but firm and resolute, in maintaining those High Anglican principles with which his life had been identified. These absorbing duties, added to his parochial work, left little time for literature. But in 1846 he published the *Lyra Innocentium*; and in 1863 he completed a life of Bishop Wilson.

In the late autumn of the latter year, Keble left Hursley for the sake of his wife's health, and sought the milder climate of Bournemouth. There he had an attack of paralysis, from which he died on the 29th March 1866. He was buried in his own churchyard at Hursley; and in little more than a month his wife was laid by her husband's side.

It is as a poet that Keble was best known during his life, and it is as a poet that he will be remembered. His poetical works are the *Christian Year* (1827), *A Metrical Version of the Psalter* (1839), *Lyra Innocentium* (1846), and a volume of poems published posthumously.

Keble, though himself childless, was a special lover of children; and the *Lyra Innocentium* expresses this characteristic. It is a book "about children, their ways, and privileges." It begins with their baptism, follows them through their cradle life and infancy, their childhood sports, troubles, encouragements, warnings, the lessons taught them by nature, those taught them by grace, dwells on their sicknesses, and their deaths. It is a book for parents, especially for mothers. The range of subjects is too limited, and the turn of thought often too subtle, to allow it to be widely popular. But Judge Coleridge pronounced it, if not equal to the *Christian Year* as a whole, yet more than equal to it in parts; and Dean Stanley thinks that "it has more of the true fire of genius, more of the true rush of poetic diction." However this may be, it is by the *Christian Year* that Keble won the ear of the religious world, and will retain it. It was a happy thought that dictated the plan of the book, to furnish a meditative religious lyric for each Sunday of the year, and for each saint's day and festival of the English Church. The subject of each poem is generally suggested by some part of the lessons or the gospel or the epistle for the day. One thing which gives these poems their strangely unique power is the sentiment to which they appeal, and the saintly character of the poet who makes the appeal, illumining more or less every poem. That to which the *Christian Year* appeals is the religious and devotional sentiment which, however hidden, exists more or less in most men. In the words of Sir J. T. Coleridge, "to this feeling it makes its unceasing appeal, with a voice so earnest, so sincere, so sad in its hopefulness, so unpretending as to the speaker, yet so authoritative and confident as to the cause it pleads, that for the time it seems irresistible."

The preface begins with observing how important is "a sober standard of feeling in matters of practical religion," and indicates that the object of the book is to calm excitement, and to exhibit the soothing tendency which pervades the Book of Common Prayer. The motto on the title page, "In quietness and confidence shall be your strength," is the keynote to which the whole book is set. The main characteristics which go to make up the charm of this small volume are these:—

1. The peculiar tone of religious feeling that pervades it, at once deep, pure, and tender, sober and severely self-denying. The undertone of the book comes out in verses like this—

"The eye in smiles may wander round,
Caught by earth's shadows as they fleet,
But for the soul no help is found,
Save Him who made it, meet."

Closely connected with this there is a more personal feeling towards our Lord, in His whole nature at once human and divine, than had ever before appeared in English poetry, even in that of Charles Wesley or Cowper. This runs through all the poems; it comes out especially in such verses as these

"Our Saviour's face benign,
Bent on us with transforming power,
Till we, too, faintly shine;"

and again,

"Who loves the Lord aright
No soul of man can worthless find;
All will be precious in his sight,
Since Christ on all hath shined:
But chiefly Christian souls; for they,
Though worn and soiled with sinful clay,
Are yet, to eyes that read them true,
All glistening with baptismal dew."

2. A second note of the *Christian Year* is reverence for the church, and for the pastoral office within it,—a solemn sense of its dignity and its awful responsibility.

3. A third note is the strong and tender affection for home and friends, the filial and fraternal piety, which everywhere pervades it. This appears notably in the poem for St Andrew's Day, in the two opening stanzas of the poem on Whit Monday, in some verses of the poem for the 4th Sunday in Advent, and in many more.

4. A prevailing spirit of modesty and of delicate reserve, very unlike the vanity with which poets are often credited. Combined with this is a special tenderness for those persons and things which the world thinks least of—for those who pine forgotten in hidden nooks, for the downtrodden and the despised. These sympathies appear at every turn of the book,—especially, perhaps, in such poems as that for the 4th Sunday in Lent, that for Visitation of the Sick, and in two well-known stanzas in the poem for St Matthew's Day, not to mention many other like passages.

5. Besides these qualities of Keble's heart as a man, there are others which belong to him especially as a poet. Prominent among these is his love of nature, particularly for the more ordinary and unnoticed features of English landscape. In these he seemed most to delight, as interwoven with home thoughts and sentiments, and because, as he expresses it,

"Homely scenes and simple views
Lowly thoughts may best infuse."

Many a scene from the neighbourhood of Fairford and Oxford, many a fleeting image caught there in casual walks, has been inwrought, naturally and beautifully, into the web of his devout meditations.

6. The intimacy with the Bible which is manifest in the pages of the *Christian Year*, and the unobtrusive felicity with which Biblical sentiments and language are introduced, have done much to endear these poems to all Bible readers; nor this only, but the fidelity with which Biblical scenery is rendered. "The exactness of the descriptions of Palestine, which Keble had never visited, have been noted, and verified on the spot," by Dean Stanley. He points to features of the lake of Gennesareth, which were first touched in the *Christian Year*; and he observes that throughout the book "the Biblical scenery is treated graphically as real scenery, and the Biblical history and poetry as real history and poetry."

As to its style, the *Christian Year* is calm and grave in tone, and subdued in colour, as beseems its subjects and sentiments. The contemporary poets whom Keble most admired were Scott, Wordsworth, and, we may add, Southey; and of their influence traces are visible in his diction. Yet he has a style of language and a cadence of his own, which steal into the heart with strangely soothing power. Some of the poems are faultless, after their kind, flowing from the first verse to the last, lucid in thought, vivid in diction, harmonious in their pensive melody. In others there are imperfections in rhythm, conventionalities of language, obscurities or over-subtleties of thought, which mar the reader's enjoyment. Yet even the most defective poems commonly have, at least, a single verse, expressing some profound thought or tender shade of feeling, for which the sympathetic reader willingly pardons artistic imperfections in the rest.

The real power of the *Christian Year* lies in this, that it brings home to the readers, as few poetic works have ever done, a heart of rare and saintly beauty. We may well believe that ages must elapse ere another such character shall again concur with a poetic gift and power of expression, which, if not of the highest, are still of a high order.

Keble's life was written by his life-long friend the late Mr Justice Coleridge. The following is a complete list of his writings:—(1) Works published in Keble's lifetime:—*Christian Year*, 1827; *Psalter*, 1839; *Prælectiones Academicæ*, 1844; *Lyra Innocentium*, 1846; *Sermons Academical*, 1848; *Argument against Repeal of Marriage Law*, and *Sequel*, 1857; *Eucharistical Adoration*, 1857; *Life of Bishop Wilson*, 1863; *Sermons Occasional and Parochial*, 1867. (2) Posthumous publications:—*Village Sermons on the Baptismal Service*, 1868; *Miscellaneous Poems*, 1869; *Letters of Spiritual Counsel*, 1870; *Sermons for the Christian Year, &c.*, 11 vols., 1875–80; *Occasional Papers and Reviews*, 1877; *Studia Sacra*, 1877; *Outlines of Instruction or Meditation*, 1880. (J. C. S.)

KECSKEMÉT (Lat. *Egopolis*), a royal free town in the county of Pest-Pilis-Solt-Kis-Kun, Hungary, is situated in an extensive plain, on the railway between Szeged (Szegedin) and Budapest, 52 miles south-east of the latter, in 46° 54′ N. lat., 19° 44′ E. long. Kecskemét is a poorly built and straggling town. It contains Roman Catholic, Lutheran, and Calvinist churches, as also a synagogue. Among the educational and other establishments are a Calvinist upper gymnasium (since 1860) and juridical lyceum (1862), possessing a library and collection of pictures, a Roman Catholic (Piarist) upper gymnasium, founded in 1714, a Government technical school dating from 1874, monasteries belonging to the Piarist and Franciscan orders, a royal court of law, a hospital, orphan asylum, and theatre. The soil of the surrounding district, known as the Kecskemét heath, though generally arenaceous, is rendered productive by careful tillage. Soap is manufactured; and trade, promoted by the periodical fairs, is generally thriving. Joseph Katona, the author of the famous historical drama *Bánk Bán*, was born at Kecskemét in 1792. The population in 1880 was 46,505, chiefly Magyars by nationality.

KEELING ISLANDS, or COCOS ISLANDS, also called by Horsburgh the Borneo Coral Islands, a group in the Indian Ocean, about 600 miles south of the coast of Sumatra, in 12° 5′ S. lat. and 90° 55′ E. long., well known as having furnished Mr Darwin with the typical example of an atoll or lagoon island.[1] There are altogether twenty-three small islands, 9½ miles being the greatest width of the whole atoll.[2] The lagoon is very shallow, and the passages between many of the islands of such trifling depth that it is possible to "walk at low tide with some slight wading all the way from Direction island to West island." An opening on the northern side of the reef permits the entrance of vessels into the northern part of the lagoon, which forms a good harbour known as Port Refuge or Port Albion. Since Mr Darwin's visit some of the minor passages have become completely filled up.

The cocoa-nut (as the name Cocos Islands indicates) is the characteristic production, and is cultivated on all the islands. There are a few other trees (Sir E. Owen described seven kinds in 1830) and lesser plants; but the whole flora, exclusive of recent introductions, comprises less than thirty species. Of the twenty species, however, represented in Mr Darwin's collection, "nineteen belonged to different genera, and these again to no less than sixteen families." With the exception of man and the domestic pig, the rat appears to be the only mammal in the islands; and there are no true land birds, except domestic poultry. One of the commonest living creatures is a monstrous crab which lives on the cocoa-nuts; and in some places also there are great colonies of the pomegranate crab, which, to quote Mr Forbes, is "labouring assiduously to make the soft pure white calcareous mud into tree-inhabitable land." The climate is temperate and extremely healthy. Terrific storms sometimes break over the island; and it has been more than once visited by earthquakes. The inhabitants "are well developed, strong, and of a wonderfully healthy appearance"; they belong originally to various parts of the Indian archipelago, Borneo, Sumatra, Celebes, &c.

The Keeling Islands were discovered in 1609 by William Keeling on his way home from the Moluccas.[3] In 1823 Alexander Hare, an English adventurer, settled on the southmost island with a number of slaves. Some two or three years after, a Scotchman, J. Ross, who had commanded a brig during the English occupation of Java, settled with his family on Direction Island, and his little colony was soon strengthened by Hare's runaway slaves. The Dutch Government had in an informal way claimed the possession of the islands since 1829; but they refused to allow Ross to hoist the Dutch flag, and accordingly the place was taken under British protection in 1856. In 1878 it was attached to the government of Ceylon.

Besides Mr Darwin's *Journal of the Voyages of the Beagle* (1860) and the work already mentioned, see Henry O. Forbes in *Proc. Roy. Geog. Soc.*, December 1879 (with a good map); Koner in *Proc. Roy. Geog. Soc.*, 1881; A. van der Jagt in *Verh. Bat. Gen. van K. en W.*, xiii.; J. J. Duintjer in Tindal and Swaart's *Zeewezen*, iv.; *Voyage of Swedish Frigate "Eugenie"* (Berlin, 1856), and Bleeker's papers on ichthyology in *Natuurk. Tijdschr. van Ned. Ind.*, vii., viii., xv., &c.

KEFF, more correctly El-Keff (El Kaf), a town of the regency of Tunis, about 95 miles south-west from the capital, and 75 miles south-east of Bône in Algeria, "on the western declivities of a rocky range of bold hills," 5 or 6 miles to the east of the course of the Wady Medjardak. It is considered the third in importance of the Tunisian towns, ranking after Tunis and Kairwán; and, though distant some twenty-two miles from the Algerian frontier, it is practically a frontier post, and its walls and citadel are kept in a state of defence. Keff is identified with the ancient Roman colony of Sicca Veneria, which appears from the character of its Venus worship (Val. Max., ii. 6, § 15) to have been a Phœnician settlement. Remains of ancient buildings (as, for example, of a temple of Hercules), and a considerable number of ancient Latin inscriptions tend to confirm the identification. Population about 12,000.

See Barth, *Die Küstenländer des Mittelmeeres*, 1849; *Corpus Inscript. Lat.*, vol. viii.; Sombrun in *Bull. de la Soc. de Géog. de Bordeaux*, 1878.

[1] *Geological Observations on Coral Reefs*, London, 1851; new ed., 1874.

[2] The names of the more important are as follows:—Horsburgh or North Island (the most northern of the group); Direction Island or in Malay Pulu Tikus (Mouse Island); Prison Island; Rice (Rijst) or Water Island, in Malay Pulu Tuwan; South Island (Selima or Fairlee); Long, West, or Ross Island.

[3] His narrative is given by Purchas, and epitomized in Astley's *Collection*.

KEIGHLEY, locally Keithley, anciently Keigheley, a market and manufacturing town in the northern division of the West Riding of Yorkshire, is beautifully situated in a deep valley near the junction of the Worth with the Aire. By the Midland Railway it is 95 miles south-east of Carlisle and 222 north of London. A canal between Liverpool and Hull affords it water communication with both west and east coasts. The town is rather irregularly built, and a considerable portion of it consists of workmen's cottages. Its growth has of late years been very rapid. Large reservoirs have been constructed for supplying water to the town. The principal buildings are the parish church of St Andrew in the late Perpendicular (dating from the time of Henry I., modernized in 1710, rebuilt with the exception of the tower in 1805, and again rebuilt in 1878), the Craven bank, the court-house, the mechanics' institute and school of art, the theatre (in the Gothic style, completed in 1870, at a cost of £5000), the baths, the union workhouse, and the Liberal and Conservative clubs. The educational institutions are the Drake and Tonson's school for girls, the trade school for boys, the national schools, and several board schools. The manufactures consist chiefly of worsted and woollen goods, machinery, machine tools, and sewing and wringing machines. Iron-founding is also extensively carried on. The population of the local board district in 1871 was 19,775, and in 1881 had increased to 25,245.

Henry Kigheley, who in the reign of Edward I. possessed the manor of Keighley, obtained for it from that monarch the privilege of a market, a fair, and a free warren. The town in 1645 was the scene of a skirmish between the royal and parliamentary troops.

KEI ISLANDS, a group in the East Indian archipelago, consisting of one large and several smaller islands, situated about 5° 30′ S. lat. and 133° E. long., some 90 miles to the south of the western end of New Guinea, and between the southern Moluccas and the Aru islands. The name, which appears in a great variety of spellings—Kee, Ke, Key, Ki, &c.—has been in use among Europeans from the days of Valentijn downwards, and may be the Spanish Cayo, a rocky island. The natives call the group Evar, the chief island Iut.

The Kei islands have been very frequently visited, but in such a cursory fashion for the most part that there is considerable doubt in regard even to their general cartography. Of Great Kei the outline and extent are known, but as to the other islands—often lumped together under the name of Lesser Kei—even the number of the more important has yet to be determined. Cape Borang, the northern point of Great Kei, lies in 5° 17′. Dullah-Darat, Dullah-Laut, Letman, and Hodjan are believed to be separate islands, though Dullah-Darat and Letman are parted only by a very narrow passage, and Letman and Hodjan may possibly be one. The seat of the rajah recognized by the Dutch Government as the chief authority in the group is Dullah on the west coast of Dullah-Darat.

The inhabitants of the Kei islands are supposed to number 18,000 or 20,000. A certain proportion of them (distinguished by the use of a special language and by the profession of Mohammedanism) are known to be descendants of natives of the Banda islands who had fled eastward before the encroachments of the Dutch. The great bulk of the people are still pagan, with rude statues of local deities and places of sacrifice indicated by flat-topped cairns. In physique the Kei islander is like the Aru islander, but more strongly built.

Cocoa-nuts, sago, fish, limestone, trepang, and timber are the chief productions of the islands. At Eli, on the east coast of Great Kei, there are extensive potteries which furnish earthenware for export as well as for local use.

The native proas are well built, after the shape of a whale-boat.

H. von Rosenberg, *Reis naar de Zuidooster-eilanden*; Guido Cora's *Cosmos*, vol. iii.; Veth, "Geogr. Autcek." (with map), in *Tijdschr. van het. Aardr. Gen.*, ii., 1876.

KEIM, Theodor (1825–1878), a prominent German theologian of the "mediation" school, was born December 17, 1825, at Stuttgart, where he attended the gymnasium, proceeding in 1843 to Tübingen, at which university he continued to study until 1848, F. C. Baur being the teacher who exercised the greatest influence over his thinking. For some time he held a private tutorial appointment, and in 1850 he attended classes at Bonn, returning in 1851 to his alma mater as "repetent." In 1857 he became diaconus at Esslingen, and two years afterwards rose to the rank of archdeacon. From 1860 to 1873 he held the office of professor ordinarius of theology in Zürich, and from 1873 until shortly before his death in November 1878 he occupied a similar post at Giessen.

He wrote *Reformationsgeschichte der Reichsstadt Ulm*, 1851; *Schwäbische Reformationsgeschichte bis zum Reichstage von Augsburg*, 1855; *Reformationsblätter der Reichsstadt Esslingen*, 1860; *Ambrosius Blarer, der Schwäbische Reformator*, 1860; *Der Uebertritt Konstantin's d. Gr. zum Christenthum*, 1862; two volumes of sermons entitled *Freundesworte zur Gemeinde*, 1861–62; and *Celsus' wahres Wort*, 1873. But the works to which he owes the considerable celebrity he possesses among Protestant theologians even outside of Germany are those in which he has investigated, with much patience of independent research and acuteness of discernment as well as with unusual power of noble appreciation, the narrative of the life of Christ contained in the gospels. *Die menschliche Entwickelung Jesu Christi* (1861), *Die geschichtliche Würde Jesu* (1864), and *Der geschichtliche Christus* were followed by what without exaggeration may be called the truly great work, *Geschichte Jesu von Nazara* (3 vols., 1867–72; English translation, 1873–77), of which the *Geschichte Jesu nach den Ergebnissen heutiger Wissenschaft, für weitere Kreise übersichtlich erzählt*, 1873, is a popular abridgment.

KEITH, an old Scotch family which takes its name from the barony of Keith in East Lothian, bestowed, it is said, by Malcolm II. on a member of the house along with the office of hereditary grand marischal in reward of bravery shown in a battle against the Danes. The importance of the family was increased by a grant in 1320 of part of the forfeited estates of the earl of Buchan to Sir Robert Keith for his valour in support of the cause of Robert the Bruce, and by the inheritance in the next century of the lands of the Frasers of Kincardineshire through the marriage of Sir William Keith, who in 1458 was created Lord Keith and Earl Marischal of Scotland. William, earl marischal, great grandson of the first of the line, distinguished himself at the battle of Pinkie in 1547, and was a member of the council of the kingdom during the minority of Queen Mary. By his marriage with his cousin Margaret, daughter of Sir William Keith of Inverugie, he nearly doubled his estates, but, becoming involved in money embarrassments, he lived for some time in seclusion in his castle of Dunnottar, obtaining on that account the sobriquet of "William that kept the tower." He was succeeded in 1581 by his grandson George, fifth earl, who, besides having studied under the direction of Beza at Geneva, had acquired a comprehensive knowledge of the politics and customs of most of the courts of Europe. Probably for this reason he was chosen by King James to negotiate his marriage with Queen Anne of Denmark and bring her to Scotland. Throughout life he showed a keen interest in the advancement of learning. He was one of the commissioners appointed in 1582 to inquire into the management of King's College, Aberdeen, and out of his own private fortune he founded and endowed Marischal College in that city, which received a charter in 1593. He died at Dunnottar, April 5, 1623. The estates of the Keiths were forfeited on account of the part taken by George Keith, tenth earl, and his brother Francis (see next article) in the rebellion of 1715. Through the influence of his brother with Frederick the Great, the earl became governor of Neufchatel. After the reversal of the attainder he returned to Scotland, but soon made his way back to Berlin, where he died in April 1788. Through his death without issue the male line of the house became extinct. From the female line descended the Keith Elphinstones, one of whom, Sir George, was on account of his brilliant naval services created an Irish peer with the title of Baron Keith of Stonehaven Marischal. Sir John Keith, third son of the sixth earl marischal, was created Earl Kintore and Lord Keith of Inverurie and Keith Hall, on account of the part he was supposed to have taken in saving the regalia of Scotland when Dunnottar Castle, where they were deposited, was besieged by Cromwell.

See *Account of the Ancient and Noble Family of Keith*, by P. Buchan, 1828; and Douglas's *Scotch Peerage*.

KEITH, Francis Edward James (1696–1758), generally known as Marshal Keith, son of William the ninth earl marischal (see last article), was the most notable member of the house of Keith. Through his careful education under Bishop Keith, and his subsequent university curriculum at Edinburgh in preparation for the legal profession, he acquired that taste for literature which afterwards secured him the esteem of the most distinguished savants of Europe; but at an early period his preference for a soldier's career was decided and enthusiastic. The rebellion of 1715, in which he displayed qualities that gave some augury of his future eminence, compelled him to seek safety on the Continent. After spending two years in Paris, chiefly in studying at the university, he in 1719 took part in the ill-starred expedition of the Pretender to the Highlands of Scotland. He then passed some time at Paris and Madrid in obscurity and poverty, until he obtained the pay of a colonel from the king of Spain. Finding his Protestantism a barrier to promotion, he obtained from the king of Spain a recommendation to the emperor Peter II. of Russia, from whom he received the command of a regiment of the guards. In several Russian campaigns the calm, intelligent, and watchful valour which was his chief characteristic was displayed to such advantage that he obtained the rank of general and the reputation of being one of the ablest officers in the Russian service. Judging, however, that his rewards were not commensurate with his merits, he in 1747 offered his services to king Frederick of Prussia, who at once gave him the rank of field marshal, and gradually came to cherish towards him a strong personal affection and regard. In the subsequent wars of Frederick he displayed conspicuous ability, manifesting in critical contingencies a remarkable union of circumspection and promptitude. He was killed, 14th October 1758, at the battle of Hochkirch. Keith is described by Carlyle as "sagacious, skilful, imperturbable, without fear and without noise, a man quietly ever ready"; and also as "not given to talk unless there is something to be said, but well capable of it then."

See Varnhagen von Ense, *Leben des Feldmarschalls Jakob Keith*, 1844; *Fragment of a Memoir of Field Marshal James Keith, written by himself*, 1714–1734, edited by Thomas Constable for the Spalding club, 1843; and Carlyle's *Frederick the Great*.

KEJ, the capital of the province of Mekran (the Gedrosia of the Greeks) in Baluchistan, is situated in 26° N. lat. and 62° 50′ E. long. There exists really no town, but a number of small villages dominated by a fort built upon a rock, on the eastern bank of the Kej river. This fort, like many others similarly placed throughout the country, is supposed to be impregnable, but is in fact of no strength except against the matchlocks of the surrounding tribes.

Kej in former days was considered of very great importance by the rulers of Khelat, who have at various times marched large armies into the province with a view to maintaining their supremacy. At the commencement of the present century it had the reputation of being a town of considerable commercial importance, trading through Panjgur with Kandahar, with Kurrachee *via* Beyla, and with Muscat and the Persian Gulf by the seaport of Guader, distant about 80 miles. The present ruler of Khelat is able to exert but a feeble sway over this portion of his dominion, although he appoints a governor to the province. The principal tribe residing around Kej is that of the Gitchki, who claim to be of Rajput origin, and to have settled in Mekran during the 17th century, having been driven out of Rajputana. There are numerous other tribes having very curious traditions as to the time and manner of their settling in the country. The climate during summer is almost unbearable for Europeans. During winter, however, it is temperate. The principal exports consist of dates, which are considered of the finest quality. There is little chance of Kej resuming its former prosperity.

KELAT. See KHELAT.

KELLERMANN, FRANÇOIS CHRISTOPHE (1735–1820), duke of Valmy and marshal of France, was born near Rothenburg, in Bavaria, in May 1735. He entered the French army as a volunteer, and served in the Seven Years' War and in Louis XV.'s Polish expedition of 1771. By 1785 he had attained the rank of maréchal-de-camp. In 1789 Kellermann enthusiastically embraced the cause of the Revolution, and in 1791 he became general of the army in Alsace. In August 1792 he received command of the army of the centre, with orders to effect a junction with Dumouriez in Champagne. The day after he had succeeded in this operation (September 20), he was forced to give battle to the allies on the heights of Valmy. General Kellermann's dash and bravery led his troops to a decisive victory, whose moral effects were of the utmost importance. Transferred next to the army on the Moselle, Kellermann was accused by General Custine of neglecting to support his operations on the Rhine; but from this, as from a similar charge in 1793, he was acquitted at the bar of the Convention in Paris, and was placed at the head of the army of the Alps and of Italy. Shortly afterwards he received instructions to reduce Lyons, then in open revolt against the Convention. The hesitation he displayed in executing that order brought him again into suspicion; and he was imprisoned in Paris for thirteen months. Once more honourably acquitted, he was reinstated in his command, and did good service in maintaining the south-eastern border against the Austrians. When Napoleon came to power Kellermann was named successively senator, marshal of France, and duke of Valmy. In 1814 he voted for the deposition of the emperor, and became a peer under the royal government. After the "Hundred Days" he sat in the high chamber and voted with the Liberals. He died September 12, 1820.

KELLGREN, JOHAN HENRIK (1751–95), Swedish poet and critic, was born at Floby in West Gothland, December 1, 1751. He studied at the university of Åbo, and had already some reputation as a poet when in 1774 he there became a "docent" in æsthetics. Three years after this he removed to Stockholm, where in conjunction with Lenngren he began in 1778 the publication of the journal *Stockholmsposten*, whose chief contributor he continued to be almost throughout the remainder of his life. Kellgren was private librarian to Gustavus III. from 1780, and from 1785 his private secretary. On the institution of the Swedish Academy in 1786 he was appointed by the king one of its first members. He died at Stockholm after a severe illness of two years, April 20, 1795. Early familiar with the models of the French school of Voltaire, Kellgren did not till late in life awake to a sense of the value of the works of Lessing and Goethe. His strong satiric tendency led him into numerous controversies, the chief that with Thorild, against whom he directed his satire *Nyt försök till orimmad vers*, where he sneers at the "raving of Shakespeare" and "the convulsions of Goethe." His lack of humour detracts from the interest of his polemical writings. His poetical works are partly lyrical partly dramatic, but of the latter only the versification belongs to him, all the rest being due to Gustavus III. The songs interspersed in the four operas which they produced in common, viz., *Gustaf Vasa*, *Gustaf Adolf och Ebba Brahe*, *Æneas i Kartago*, and *Drottning Kristina*, are wholly the work of Kellgren. From about the year 1788 a higher and graver feeling pervades Kellgren's verses, partly owing to his increased knowledge of the newer German and English literature, but probably more directly due to his controversy with Thorild. Of his minor poems written before that date the most important are the charming spring-song *Vinterns välde lyktar*, and the satirical *Mina löjen* and *Man eger ej snille för det man är galen*. The best productions of what is called his later period are the satire *Ljusets fiender*, the comic poem *Dumboms lefverne*, the warmly patriotic *Kantat d. 1 jan. 1789*, the ode *Till Kristina*, the fragment *Sigwart och Hilma*, and the beautiful song *Nya skapelsen*, both in thought and form the finest of all his works. Among the lyrics of Kellgren are the choicest fruits of the Gustavian age of Swedish letters. His earlier efforts, indeed, express with great completeness the superficial doubt and pert frivolousness characteristic of his time; but in the works of his riper years he is no mere "poet of pleasure," as Thorild contemptuously styled him, but a worthy exponent of earnest moral feeling and wide human sympathies in the most felicitous and melodious verse. His *Samlade skrifter* (3 vols., 4th ed., Örebro, 1860), revised by himself, were, in accordance with his own direction, published by his friends after his death. His prose works were translated into German by Lappe (Neustrelitz, 1801).

See Wieselgren, *Sveriges sköna literatur*, 1833–49; Atterbom, *Svenska siare och skalder*, 1841–55; C. W. Böttiger in *Transactions of the Swedish Academy*, xlv. 107 *sq.*, 1870; and Gustaf Ljunggren's *Kellgren, Leopold, och Thorild*, and his *Svenska vitterhetens häfder*, 1873, 1877.

KELLS, a market and municipal town of Meath county, Ireland, is situated on the Blackwater and on the Dublin and Meath Railway, 39 miles north-west of Dublin. The prosperity of the town depends chiefly upon its interesting antiquarian remains. The most notable is St Columba's house, originally an oratory, but afterwards converted into a church, the chancel of which was in existence in 1752. The present church is modern, with the exception of the bell-tower, rebuilt in 1578. Near the church there is a very perfect specimen of the ancient round tower, and there are also several ancient crosses, one being situated in the market-place.

Kells was originally a royal residence, whence its ancient name *Ceanannus*, meaning the dun or circular northern fort, in which the king resided, and the intermediate name *Kenlis*, meaning head fort. The other places in Ireland named Kells are probably derived from *Cealla*, signifying church. In the 6th century Kells, it is said, was granted to St Columba. The statement that he founded a monastery at it is probably incorrect; at any rate the town owes its ecclesiastical importance to the bishopric founded about 807, and united to Meath in the 13th century. Until the Act of Union Kells returned two members to parliament. Population of urban sanitary district in 1881, 2820.

KELP (Fr., *varech*) is produced by the incineration of various kinds of sea-weed (*Algæ*) obtainable in great abundance on the west coasts of Ireland and Scotland, and the coast of Brittany in France. It is prepared from the deep-sea tangle (*Laminaria digitata*), sugar wrack (*L.*

saccharina), knobbed wrack (*Fucus nodosus*), black wrack (*F. serratus*), and bladder wrack (*F. vesiculosus*). The Laminarias yield what is termed drift-weed kelp, obtainable only when cast up on the coasts by storms or other causes. The species of *Fucus*, on the other hand, growing within the tidal range, are cut from the rocks at low water, and are therefore known as cut-weeds. In the preparation of kelp, the weeds are first dried in the sun, and are then collected into shallow pits on the ground and burned till they form a fused mass, which while still hot is sprinkled with water in order to break it up into convenient pieces. A ton of kelp is obtained from 20 to 22 tons of wet sea-weed. The average composition may vary as follows:—sulphate of potash, 10 to 12 per cent.; potassium chloride, 20 to 25 per cent.; sodium carbonate, 5 per cent.; other soda and magnesia salts, 15 to 20 per cent.; and insoluble ash from 40 to 50 per cent. The relative richness in iodine of different samples varies largely, good drift kelp yielding as much as 10 to 15 ℔ per ton of 22½ cwts., whilst cut-weed kelp will not give more than 3 to 4 ℔. The rude manner in which kelp is prepared causes much of the iodine to be volatilized; but Mr E. C. C. Stanford has successfully introduced a process for treating sea-weeds by destructive distillation, whereby the whole of that valuable body is saved. See IODINE.

Previous to the introduction of the Leblanc process for the manufacture of sodium carbonate, kelp was the principal source of that substance, as well as a source of potassium salts, and consequently was a raw material of much importance in chemical industries. About the beginning of the 19th century the value of the kelp prepared on the coast and islands of the west of Scotland was not less than £400,000 per annum, representing 20,000 tons of kelp. With the gradual introduction and improvement of the Leblanc process, and the reduction of the duty on salt and other causes, the value of kelp decreased from £20 and upwards to about £2 a ton, a price altogether unremunerative. Towards the middle of the century, however, a new impetus was given to the trade by the rise of the manufacture of iodine, of which kelp was at first the only commercial source. The introduction of Chili saltpetre (*caliche*) as a source of iodine, and the development of the Stassfurth salt-mines for the production of potash salts, have in their turn had a depressing influence on the kelp manufacture, and it is only by the most careful utilization of all the salts contained in the kelp, and the use of most approved methods of preparing the material, that the industry is continued as a remunerative undertaking. The production of kelp in the British Islands varies greatly from year to year. It may be stated to average about 7000 tons, at a value of about £4 per ton. Two-thirds of this quantity is produced in Ireland, and the remainder on the Scottish coast and islands. The quantity produced in France is probably now somewhat less than the British yield.

KELSO, a burgh of barony and market-town of Roxburghshire, Scotland, is situated on the north side of the Tweed near its junction with the Teviot, 45 miles south-east of Edinburgh and 23 south-west of Berwick by rail. The town is embosomed among woods in a pleasantly undulating and fine agricultural country. The principal streets branch out in four directions from the spacious square, where are the principal shops and hotels. From the bridge of five arches, designed by Rennie, a fine view is obtained of the course of the river. Near it stand the picturesque ruins of the ancient abbey church, founded by David I., but demolished by the English in 1545, one of the finest extant examples in Scotland of the Early Norman style. A mile west of Kelso, on the north bank of the river, is Floors Castle, the seat of the duke of Roxburghe, nearly opposite which, on the south bank, stand the ruins of the old fortress of Roxburgh Castle. Kelso possesses a town-hall, a corn exchange, an auction mart, and a collegiate school. About a mile north of the town there is a race course; the fine cemetery and the spacious public park also deserve mention. The trade of the town is chiefly connected with agriculture. There are large nurseries, corn-mills, manure works, coach works, a foundry, and two engineering shops. Kelso was made a burgh of barony in 1634. It is now under the General Public Act. The population in 1881 was 4563.

KEMBLE, CHARLES (1775–1854), a younger brother of John Philip Kemble noticed below, was born at Brecknock, South Wales, 25th November 1775. Like his brother he was educated at Douai. After returning to England in 1792, he obtained a situation in the post-office, but this he soon resigned for the stage, making his debut at Sheffield as Orlando in *As You Like It*. During the early period of his career as an actor, chiefly on account of the great abilities of his sister and brother, he made his way only slowly to public favour. For a considerable time he played along with them, chiefly in secondary parts, and this with a grace and finish which received scant justice from the critics. Ultimately he won independent fame, especially in *comédie larmoyante*. His gifts had been disciplined to the utmost degree of perfection of which they were capable, by his liberal mental culture and by refined social intercourse; and such characters as Archer, Doricourt, Charles Surface, and Ranger he played with an airy grace and polished humour that have never been excelled; while he had sufficient fire and energy to give adequate effect to romantic passion and pathos. In genteel comedy he was ably supported by his wife Miss De Camp, whom he married in 1806. His imposing person, classical countenance, and tuneful voice also enabled him to be highly successful in historical drama, some of his principal parts being Alcibiades, Antony, Henry V., and Orestes. The latter period of his career was clouded by money embarrassments in connexion with his joint proprietorship in Covent Garden Theatre. He formally retired from the stage in December 1836, but his final appearance was on April 10, 1840. For some time he held the office of examiner of plays. He died November 12, 1854.

See *Gentleman's Magazine*, January 1855; and *Records of a Girlhood*, by his daughter Frances Ann Kemble, who has achieved distinction both as a tragedienne and an authoress

KEMBLE, JOHN MITCHELL (1807–1857), Anglo-Saxon scholar and historian, eldest son of Charles Kemble noticed above, was born in 1807. He received his education partly from Dr Richardson, author of the *Dictionary of the English Language*, and partly at the grammar school of Bury St Edmunds, where he obtained in 1826 an exhibition to Trinity College, Cambridge. At school he was distinguished for his miscellaneous knowledge, and at the university his essays on historical subjects gained him high reputation. The historical bent of his studies was confirmed and turned more especially towards the Anglo-Saxon period through the influence of the brothers Grimm, under whom he studied at Göttingen. His thorough knowledge of the Teutonic speeches was shown in his *Beowulf* (1833–37), *Ueber die Stammtafel der Westsachsen* (1836), *Codex Diplomaticus Ævi Saxonici* (1839), and in many contributions to reviews; while his *History of the Saxons in England* (1849) was the first attempt at a thorough examination of the original sources of the early period of English history. He was also for some time editor of the *Foreign Quarterly Review*. In 1857 he published *State Papers and Correspondence illustrative of the Social and Political State of Europe from the Revolution* *to the Accession of the House of Hanover.* He died at Dublin 26th March 1857. His *Horæ Ferales, or Studies in the Archæology of Northern Nations*, was completed by Dr Latham, and published in 1864.

KEMBLE, JOHN PHILIP (1757–1823), tragedian, was the second child of Roger Kemble, a strolling player, and his wife Sarah Ward, the eldest child being Sarah, known as Mrs Siddons. He was born at Prescot, Lancashire, February 1, 1757. In his eleventh year he became an inmate of Sedgely Park Catholic seminary, near Wolverhampton, and after remaining there four years entered the college of Douai with the view of becoming a priest. At the conclusion of the course, however, he discovered that he had no vocation for the priesthood, and, arriving in England in the end of 1775, he joined the theatrical company of Crump and Chamberlain, his first appearance being in the character of Theodosius at Wolverhampton, 8th January 1776. Various stories more or less apocryphal are told of his early hardships, until in 1778 he joined the York company of Wilkinson, where he appeared in Hamlet and other leading parts, besides contributing a drama of his own on the subject of Belisarius. In 1781 he made a decided step in advance, obtaining a "star" engagement in Smock Alley Theatre, Dublin, and achieved astonishing success in the *Count of Narbonne* by Captain Jephson. Gradually he won for himself a high reputation as a careful and finished actor, and this, combined with the greater fame of his sister Mrs Siddons, led to an engagement in Drury Lane Theatre, where he made his debut 30th September 1783, in the part of Hamlet. His appearance was successful, but rather by awakening interest and discussion than enthusiastic approval. His reading of the part, though highly intellectual and elaborated with the most minute care, was stiff and laboured, especially until he acquired the familiarity with the personation obtainable by repetition. In Edward the Black Prince, Richard III., King John, Sir Giles Overreach, and other characters he did not materially advance his reputation. His first decided success was in the character of Macbeth for his own benefit, when he shared in the enthusiasm aroused by Mrs Siddons, and established for himself a reputation among living actors second to hers only. In December 1787 he married Mrs Brereton, the widow of a young actor. His appointment as manager of the theatre in October of the following year gave him full opportunity to experiment with whatever parts might strike his fancy, and of this he took advantage with greater courage than discretion. His smile, as was wittily said, "resembled the plating on a coffin," and it was only in cases where his gravity gave a certain piquancy to the character that his comedy parts were redeemed from failure, notwithstanding his clever mastery of smart repartee. In Coriolanus, however, which was revived during his first season, the character of the "noble Roman" was so exactly suited to his powers that he not only played it with a perfection that has never been approached, but, it is said, unconsciously allowed its influence to colour his private manner and modes of speech. His tall and imposing person, noble countenance, and solemn and grave demeanour were uniquely adapted for the Roman characters in Shakespeare's plays; and, when in addition he had to depict the gradual growth and development of one absorbing passion, his representation gathered a momentum and majestic force that were irresistible. His defect was in flexibility, variety, rapidity; the characteristic of his style was method, regularity, precision, elaboration even of the minutest details, founded on a thorough psychological study of the special personality he had to represent. His elocutionary art, his fine sense of rhythm and emphasis, enabled him to excel in declamation, but physically he was incapable of giving expression to impetuous vehemence and searching pathos. In Coriolanus and Cato he was beyond praise, and possibly he may have been superior to both Garrick and Kean in Macbeth, although it must be remembered that in it part of his inspiration must have been caught from Mrs Siddons. In all the other great Shakespearean characters he was, according to the best critics, inferior to them, least so in Lear and Hamlet, and most so in Shylock and Richard III. On account of the eccentricities of Sheridan, the proprietor of Drury Lane Theatre, Kemble withdrew from the management, and, although he resumed his duties at the beginning of the season 1800–1, he at the close of 1802 finally resigned connexion with it. In 1803 he became manager of Covent Garden, of which he was also part proprietor. The theatre was burned down in 1808, and the raising of the prices after the opening of the new theatre in 1809 led to a persevering succession of riots, which practically suspended the performances for three months. Kemble took his final leave of the stage in the part of Coriolanus, June 23, 1817, his retirement being probably hastened by the increasing popularity of Kean. The remaining years of his life were spent chiefly abroad, first at Toulouse, and after a short stay in London at Lausanne, where he died February 20, 1823.

See Boaden's *Life of John Philip Kemble*, 1825; Fitzgerald, *The Kembles*, 1871.

KEMPIS, THOMAS A (*c.* 1380–1471), is the name by which Thomas Hammerken (Hammerchen, Malleolus) is commonly known. He was born in 1379 or 1380 in the town of Kempen, lying about 15 miles north-west of Düsseldorf, in one of the many patches of territory between the Meuse and the Rhine belonging to the archiepiscopal principality of Cologne. "Ego Thomas Kempis," he says in his chronicle of the monastery of Mount St Agnes, "scholaris Daventriensis, ex diocesi Coloniensi natus." His father was a poor hard-worked peasant; his mother "ad custodiam rei domesticæ attenta, in opere alacris, in victu sobria, in potu abstemia, in verbo pauca, in factis pudica," as her son fondly says, kept a dame's school for the younger children of the town. John and Gertrude Hammerken had two sons, John and Thomas, both of whom found their way to Deventer, and thence to Zwolle and to the convent of Mount St Agnes. Thomas reached Deventer when he was barely twelve years old, was taught by a dame the beginnings of his learning, and in a few months to his great joy entered the classes of Florentius Radewyn. After the fashion of the time he was called Thomas from Kempen, and the school title, as was often the case then, pushed aside the family name. Thomas Hammerken was forgotten; Thomas a Kempis has become known to the whole Christian world.

This school at Deventer had become famous long before Thomas a Kempis was admitted to its classes. It had been founded by Gerhard Groot, a wealthy burgher (see GROOT), who had been won to pious living mainly through the influence of Ruysbroeck, the Flemish mystic. It was at Deventer, in the midst of this mystical theology and hearty practical benevolence, that Thomas a Kempis was trained. Gerhard Groot was his saintly ideal. Florentius Radewyn and Gerhard's other early disciples were his heroes; their presence was his atmosphere, the measure of their lives his horizon. But he was not like them; he was not an educational reformer like Radewyn, nor a man of affairs like Gerhard. He liked books and quiet corners all his days, he says; and so, when conviction of sin and visions of God's grace came to him in the mediæval fashion of a dream of the anger and forgiveness of the Virgin, Florentius told him that a monk's life would suit him best, advised him to join the Augustinian order, and sent him to Zwolle to the new convent of Mount St Agnes, where his brother John was prior. Thomas was received there in 1399, he professed the vows in 1407, received priest's orders in 1413, became sub-prior in 1425, and died on the 8th of August 1471, being ninety-one years old.

The convent of Mount St Agnes was poor, and most of the monks had to earn money to support their household by copying MSS. Thomas was a most laborious copyist: missals, books of devotion, and a famous MS. Bible were written by him; and the weightiest argument of those who deny that he is the author of the *Imitatio Christi* is that he was a copyist. He also wrote a large number of original writings, most of them relating to the convent life, which was the only life he knew. He wrote a chronicle of the monastery and several biographies—the life of Gerhard Groot, of Florentius Radewyn, of a Flemish lady St Louise, of Groot's original disciples; a number of tracts on the monastic life—*The Monk's Alphabet, The Discipline of Cloisters, A Dialogue of Novices, The Life of the Good Monk, The Monk's Epitaph, Sermons to Novices, Sermons to Monks, The Solitary Life, On Silence, On Poverty, Humility, and Patience*; two tracts for young people—*A Manual of Doctrine for the Young*, and *A Manual for Children*; and books for edification—*On True Compunction, The Garden of Roses, The Valley of Lilies, The Consolation of the Poor and the Sick, The Faithful Dispenser, The Soul's Soliloquy, The Hospital of the Poor.* He has also left behind him three collections of sermons, a number of letters, some hymns, and the *Imitatio Christi,* if that be his. These writings help us to see the man and his surroundings, and contemporary pious records make him something more than a shadow. We see a real man, but a man helpless anywhere save in the study or in the convent,—a little fresh-coloured man, with soft brown eyes, who had a habit of stealing away to his cubiculum whenever the conversation became too lively; somewhat bent, for it is on record that he stood upright when the psalms were chanted, and even rose on his tiptoes with his face turned upwards; genial, if shy, and occasionally given to punning, as when he said that he preferred Psalmi to Salmones; a man who perhaps led the most placid uneventful life of all men who ever wrote a book or scribbled letters It was not that he lived in uneventful times: it is impossible to select a stormier period of European history, or a period when the stir of the times made its way so well into the obscurest corners. Bohemia, Huss leading, was ablaze in revolt at one end of Europe; France and England, then France and Burgundy, were at death-grips at the other. Two popes anathematized each other from Avignon and from Rome, and zealous churchmen were at their wit's end to concoct ways and means, by general councils of Constance and Basel and otherwise, to restore peace to a distracted church, and to discipline the clergy into decent living. But Thomas knew nothing about all this. He was intent on his copying, on his little books, and on his quiet conversations. His very biographies are colourless. He had not even the common interest in the little world coming up to the convent gate which most monks may be supposed to have. His brethren made him œconomiæ prefectus, but he was too "simple in worldly affairs" and too absent-minded for the post, and so they deposed him and made him sub-prior once more. And yet it is this placid kindly fresh-coloured old man who is commonly said to be the author of that book the *Imitation of Christ*, which has been translated into more languages than any other book save the Bible, and which has moved the hearts of so many men of all nations, characters, and conditions of life.

Did Thomas a Kempis write the *Imitation of Christ*? Had it not been for his connexion with this famous little book, Thomas would have been no better known than Gerhard Groot, Florentius Radewyn, or Jan van Ruysbroeck. The problem of authorship has given rise to the most interminable controversy the history of literature has ever seen, and one which seems to be still as fresh as it was in the 17th century. It arose in this way. The author of the *Imitatio* sent it forth anonymously. If Thomas was the author he must have written it when he was about forty-five years of age, and it must have found its way into England and France within a very short space of time. Then Thomas was a copyist, a man who spent his life in copying for sale books which he had not composed. These are the only presumptions which make it likely that the *Imitatio Christi* had another author. But down till the beginning of the 17th century Thomas was almost universally esteemed the author of the *Imitatio.* Some MSS. undoubtedly bore the name of St Bernard, and others that of John Gerson; but the great majority of MSS. testified to the authorship of Thomas. In 1604, however, a Spanish student of the *Imitatio* found a sentence from it quoted in what was believed to be a sermon of Bonaventura, who died in 1273, long before either Gerson or Thomas was born. It was afterwards proved that the sermon was not by Bonaventura, but belonged to the end of the 15th century; still for the time it was supposed that Thomas could not have written the *Imitatio,* and learned men looked anxiously for a clue to an earlier author. Just then, in 1605, Bernardin Rossignoli, superior of the Jesuit college at Arona, discovered in the college library a MS. of the *Imitatio* without date, and bearing the title Incipiunt capitula primi libri Abbatis Johannis Gersen, De Imitatione Christi. The college had formerly belonged to the Benedictines, and it was supposed, wrongly as it turned out, that the MS. had been in the old Benedictine library, and was therefore ancient. Here then was an author, Gersen, and a MS. of the date required. The facts were, however, that the MS. was of the beginning of the 16th century, and had been brought to Arona from Genoa in 1579. Constantine Cajetan, famous for his insane devotion to the order of St Benedict, got the Arona MS. printed at Rome, declaring that the author was John Gersen, an abbot of the order of St Benedict. Cajetan next discovered in a copy of the printed Venice edition of the *Imitatio* of 1501 a note in an unknown hand: "This book was not written by John Gerson, but by John, abbot of Vercelli." He also found an MS. bearing the name of John of Canabaco. Weaving these unconnected details together, Cajetan declared that the author of the *Imitation of Christ* was John Gerson of Canabaco, Benedictine abbot of Vercelli. Thus began the famous controversy. It has been a controversy really between the supporters of Thomas a Kempis and the Benedictines, who advocate the claims of John Gersen, a mythical personage whose very existence has been taken for granted and never proved. But, while this is the crux of the dispute, the authorship has been claimed for a great variety of writers:—John Scotus Erigena, Bernard of Clairvaux, Giovanni Gerso (an Italian monk and philanthropist of the close of the 12th century), Pope Innocent III., Scoto Giovanni and Thomas Gallus, both abbots of Vercelli, David of Augsburg, Bonaventura, Ubertin of Cassalis, Peter de Corbario, Ludolf of Saxony, Kalkar, Humbert, Martinus Carthus, Giovanni Michele, Joannes Paumerii (the last four probably transcribers—their names are appended to single MSS. in an early printed edition), John Gerson a brother of the famous chancellor of Paris, John Gerson the famous chancellor himself, John Gersen the supposed Benedictine abbot, Walter Hilton an English monk, Thomas a Kempis, John a Kempis the elder brother of Thomas, and John of Canabaco, probably John of Tambacho, a professor in the university of Prague. It will be sufficient to examine the claims of four of these candidates.

Walter Hilton, a monk of Schene (Sheen) in Surrey, who wrote several devotional books, notably *Scala Perfectionis Christianæ*, is said by Bale (*Illustri. Maj. Brit. Summarium*, published in 1559) to have written a treatise called *De Musica Ecclesiastica*, and this is confirmed by Pits, who wrote much later. The earlier MSS. of the *De Imitatione* are called *De Musica Ecclesiastica*, and the earliest English MS., now in Magdalen College, Oxford, and dated 1438, bears that title. The inference has been drawn that Hilton wrote the first three books of the *Imitation* in England, and that Thomas copied them and added the fourth book (see *Notes and Queries*, March 1881). We have no *contemporary* evidence, however, that Hilton did write a treatise called *De Musica Ecclesiastica*, and this work may have been attributed to him because the MS. copies have been found in volumes also containing some of his devotional writings.

John Gerson, chancellor of Paris (1363–1429, see GERSON), is called the author of the *Imitation* in several undated MSS., and more especially in two MSS. dated 1441 and 1460. His claims have been supported on the ground of MS. evidence, the presence of Gallicanisms in the Latin of the treatise, and the common tradition in France. The evidence to the contrary is so strong, however, that his cause has been given up by all save by Frenchmen who, like Vert, consider it patriotic to declare themselves "pour Gerson, Gerson, et pour la France."

John Gersen, abbot of Vercelli, is supported by the Benedictine order and by others. The first requisite here is to show that such a man ever lived, and this in spite of the pains taken has not yet been done.[1] In all probability Gersen is a mistake of early copyists for Gerson. The MS. evidence is as follows. The earliest *dated* MS. claimed for Gersen gives the author J. Gers., and is dated 1441; the second gives the author's name in the same contracted fashion, J. Gers., and is dated 1464; while two of the earlier undated MSS., those of Florence and Padolirone, call the author J. Gersen, chancellor of Paris. The other MSS. which write the author's name J. Gersen are all late or undated. In short, there is not a vestige of early evidence to connect the *Imitatio* with a John Gersen, and there is no contemporary evidence whatever. Gersen is a creation of Cajetan's for the renown of the Benedictine order, and the motive which has prompted Gersen's supporters finds fitting expression in the dedication to St Benedict of the latest contribution to the controversy, that of Wolfsgruber (Augsburg, 1880).

Thomas a Kempis is acknowledged to be the author by most of the earliest dated MSS., by most of the earliest printed editions of the book, by a great mass of contemporary evidence, and by a great deal of internal evidence, some of a most interesting kind. Of MSS. may be mentioned the Kirchheim MS. of 1425, the autograph of Thomas (1441), the MS. of Innersdorf (1441), and that of Liége (1444). Twenty-two printed editions in the 15th century attributed the *Imitatio* to Thomas. The contemporary witnesses are numerous and convincing. John Buschius of the canons regular of Windesheim, scarcely a league from Mount St Agnes, who had met and conversed with Thomas, calls him the author of the *Imitation*. Brother Herman, living in a monastery of the canons regular near Halle, who had met Thomas at Windesheim, declared that Thomas was the author of the *Imitatio*. Similar testimony is borne by Matthias Farinator, a transcriber of the book, by Peter Schott, by Johann Lambert, either during the lifetime of Thomas or a few years after his death. And Hirsche has produced a new contemporary witness from an old Belgian chronicle ("Chronique de Jean Brandon, avec les additions d'Adrien de But," p. 547, published in *Collect. de Chroniques Belges inédites*), which says that Thomas wrote the *Qui sequitur me* in metre. The proof from internal evidence has been set on quite a fresh basis by the studies of Carl Hirsche, who has discovered from a careful examination of the MS. of 1441 (Bibliothèque de Bourgogne, Brussels, Nos. 5855 and 5861) that the *Imitation* was written and pointed for the purpose of chanting. This discovery has enabled him to compare the book with other writings of Thomas as to punctuation, rhythm, and rhymes, with the result that he has incontestably proved the great similarity between the *Imitation* and the undisputed works of Thomas.

The *Imitatio Christi* is commonly classed among the mystical writings of the 15th century, and in the opinion of writers of the most opposite schools of thought it sums up all that is best of that side of Latin Christianity which includes the theology of the Victorines, of Bernard and Bonaventura, of Eckhart, Tauler, and Ruysbroeck. Mediæval Christianity shows two ideas of the Christian life struggling for the mastery, each with the common watchword of separation from the world. The one was modelled on Augustine's *City of God*, and was fulfilled in Hildebrand's conception of a spiritual empire to be raised on the ruins of political society; the other came to light in the aspirations of Francis of Assisi, and the assimilation of Anselm's maxim that sinners can appropriate the benefits won for them by Christ by imitating the Saviour. Francis's idea of imitation was rudely picturesque. The Bible shows Christ obedient, poor, unmarried; we can imitate the Master by keeping the vows of obedience, poverty, and chastity. This crass idea of an imitation of Christ gave new force to the monastic movement, and put new meaning into its vows, and it spread in various ways through Fratricelli, Spirituales, Wycliffe's poor preachers, &c., far beyond the Franciscan order. This idea of imitation by "evangelical poverty" was almost spent by the 14th century, and was succeeded by the more refined conception of imitation by "renunciation," the watchword of the mystical movement of the 14th and 15th centuries. But by this time the conflict of the Franciscan ideal of the Christian life with Hildebrand's ideal had thoroughly rent mediæval Christendom, and there were two Christianities facing each other, a religious and a political. The breach became wider by the degradation of the papacy, and by the great schism. The "universal" of the church was lost, and had not been discovered again. The new idea of obedience was not obedience to ecclesiastical superiors, but the subordination of the lower part of man's nature to the higher, and of the whole to God. This "renunciation," cut off from practical sympathy with the visible church, feeding itself on a vague idea of union with Christ, might easily have fallen a prey to Buddhist and Averroist notions floating in the European atmosphere (some of the mystics did so fall away) had it not been saved by its clinging to the sacraments, the one mediæval means of grace, and by its contact with practical Christian work. And gradually out of Eckhart through Tauler two schools arose, both of which use "renunciation" as their watchword—imitation by renunciation. The one school, that of Henry Suso, saw Christ's renunciation best exhibited in His passion, and therefore held that men can imitate by suffering; they too have a body to mortify. The other, that of Ruysbroeck, saw Christ's renunciation in His incarnation; so that men can renounce by contemplation, which gives us initiation into the incarnation. Ruysbroeck was Groot's teacher, and Groot taught Thomas, in whom we see the gathered wisdom of that idea of a quest for pardon by imitation of Christ which began with Anselm and came down through Franciscan revivals and mystical movements to him in the 15th century. But Thomas is far more than Ruysbroeck or Groot. He is wider and more sympathetic. He includes Ruysbroeck, Tauler, Eckhart, Bonaventura, the Franciscans, and even the old Victorines. He sums up in his little book the heart religion of Latin Christianity

For the life of Thomas a Kempis see the Nuremberg edition of 1494, *Opera et libri vitæ Thomæ a Kempis*; Heribertus Rosweide, *Vita Thomæ a Kempis*, 1616. The best edition of the collected works is that of Sommalius, *Ven. Viri Thomæ Malleoli a Kempis . . . Opera Omnia . . . in tres tomos distributa*, 1759. The best edition of the *Imitatio* is that of Hirsche, Berlin, 1874. A very complete list of the principal writers in the controversy may be found in Wolfsgruber, *Giovanni Gersen, sein Leben und sein Werk de Imitatione Christi*, 1880, p. 254 *sq.* For authorship by Gerson, see G. Ch. Vert, *Cause de l'Imitation de Jésus-Christ, réplique et conclusions*, Toulouse, 1861. For Thomas as author, see Malou, *Recherches historiques et critiques sur le véritable auteur du livre de l'Imitation de Jesus-Christ*, Tournay, 3d ed., 1858; Carl Hirsche, *Prolegomena zu einer neuen Ausgabe der Imitatio*, Berlin, 1873; and Samuel Kettlewell, *The Authorship of the De Imitatione Christi*, London, 1877. (T. M. L.)

KEMPTEN, a town in the government district of Swabia and Neuburg, Bavaria, is situated on the Iller, about 65 miles south-west of Munich. It is the seat of numerous local and special tribunals, and contains a castle, a gymnasium and a grammar school, two hospitals, and other educational and benevolent institutions. There is a handsome town-house, and the aqueduct is noteworthy. The industries include wool spinning and weaving on a large scale, and the manufacture of paper, beer, machines, hosiery, matches, and wooden wares. As a commercial centre of the Algau, Kempten carries on active trade in linen, timber, and dairy produce. In 1875 the population, including the garrison, was 12,681.

Kempten, identified with the Roman Campodunum, consisted in early times of two towns, the old and the new. The continual hostility that existed between these was intensified by the welcome given by the old town to the Reformed doctrines,—the new town, built round the Benedictine abbey erected in the 8th century, keeping the old faith. The abbot in 1360 had been promoted to the dignity of a prince of the empire by the emperor Charles IV., and the princely abbacy only passed to Bavaria in 1803.

KEN, Thomas (1637–1711), the most eminent of the non-juring bishops, and one of the fathers of modern English hymnology, was born at Little Berkhampstead, Herts, in 1637. He was the son of Thomas Ken of Furnival's Inn, who belonged to an ancient stock,—that of the Kens of Ken Place, in Somersetshire; his mother was a daughter of the now forgotten poet, John Chalkhill, who is called by Walton an "acquaintant and friend of Edmund Spenser." It may be mentioned that Ken's step-sister, Anne, was married to Izaak Walton in 1646, a connexion which brought Ken from his boyhood under the refining influence of this gentle and devout man. In 1652 he entered Winchester College, and in 1656 became a student of Hart Hall, Oxford. He gained a fellowship at New College in 1657, and proceeded B.A. in 1661 and M.A. in 1664. He was for some time tutor of his college; but the most characteristic reminiscence of his university life is the mention made by Anthony Wood that in the musical gatherings of the time "Thomas Ken of New College, a junior, would be sometimes among them, and sing his part." Ordained in 1662, when he was twenty-five years old, he successively held the livings of Little Easton in Essex, Brighstone (sometimes called Brixton) in the Isle of Wight, and East Woodhay in Hampshire; in 1672 he resigned the last of these, and returned to Winchester, being by this time a prebendary of the cathedral, and chaplain to the bishop, as well as a fellow of Winchester College. He remained there for several years,

[1] This mythical personage has been photographed, see *Auteurs présumés de l'Imitation* by Abbé Delaunay.

acting as curate in one of the lowest districts, and fulfilling other duties in the city, but, above all, preparing his *Manual of Prayers for the use of the Scholars of Winchester College*, which was first published in 1674, and composing hymns. It was at this time that he wrote, primarily for the same body as his prayers, his morning, evening, and midnight hymns, the first two of which, beginning "Awake, my soul, and with the sun" and "Glory to Thee, my God, this night," are now household words wherever the English tongue is spoken. The latter is often made to begin with the line "All praise to Thee, my God, this night," but in the earlier editions over which Ken had control, the line is given as above.[1] In 1674 Ken paid a visit to Rome in company with young Izaak Walton, and this journey seems mainly to have resulted in confirming his regard for the Anglican communion. In 1679 he was appointed by Charles II. chaplain to the Princess Mary, wife of William of Orange. While with the court at the Hague, he incurred the displeasure of William by insisting that a promise of marriage, made to an English lady of high birth by a relative of the prince, should be kept; and he therefore gladly returned to England in 1680, when he was immediately appointed one of the king's chaplains. He was once more residing at Winchester in 1683 when Charles came to the city with his doubtfully composed court, and his residence was chosen as the home of Nell Gwynne; but Ken stoutly objected to this arrangement, and succeeded in making the favourite find quarters elsewhere. We find him in August of this same year accompanying Lord Dartmouth to Tangiers as chaplain to the fleet, and Pepys, who was one of the company, has left on record some quaint and kindly reminiscences of him and of his services on board. The fleet returned in April 1684, and a few months after, upon a vacancy occurring in the see of Bath and Wells, Ken, now Dr Ken, was appointed bishop. It is said that, upon the occurrence of the vacancy, Charles, mindful of the high and pure spirit he had shown at Winchester, exclaimed, "Where is the good little man that refused his lodging to poor Nell?" and determined that no other should be bishop. The consecration took place at Lambeth, January 25, 1685; and one of Ken's first duties was to attend the death-bed of Charles, where his wise and faithful ministrations won the admiration of everybody except Bishop Burnet. In this year he published his *Exposition on the Church Catechism*, which is perhaps better known by its sub-title, *The Practice of Divine Love*. His public life as bishop is mainly remembered from the stand he took upon two memorable occasions. In 1688, when James reissued his "Declaration of Indulgence," Ken was one of the "seven bishops" who refused to publish it. He was probably influenced by two considerations:—first, by his profound aversion to Roman Catholicism, to which he felt he would be giving some episcopal recognition by compliance; but, second and more especially, by the feeling that James by his arbitrary action was compromising the spiritual freedom of the church. Along with his six brethren, Ken was committed to the Tower, June 8, 1688, on a charge of high misdemeanour; the trial, which took place on the 29th and 30th of the month, and which resulted in a verdict of acquittal, is matter of history. With the revolution which speedily followed this impolitic trial, new troubles encountered Ken; for, having sworn allegiance to James, he thought himself thereby precluded from taking the oath to William of Orange. Accordingly, he took his place among the non-jurors, and, as he stood firm to his refusal, he was, in August 1691, superseded in his bishopric by Dr Kidder, dean of Peterborough. From this time he lived mostly in retirement, finding a congenial home with Lord Weymouth, his friend from college days, at Longleat in Somersetshire; and, though pressed to resume his diocese in 1703, upon the death of Bishop Kidder, he declined, partly on the ground of growing weakness, but partly no doubt from his love for the quiet life of devotion which he was able to lead at Longleat. His death took place there upon the 19th of March 1711.

Although Ken wrote much poetry, besides his hymns, he cannot be called a great poet; but he had that fine combination of spiritual insight and feeling with poetic taste which marks all great hymn-writers. As a hymn-writer he has had few equals in England; it can scarcely be said that even Keble, though possessed of much rarer poetic gifts, surpassed him in his own sphere (see HYMNS, vol. xii. p. 592). In his own day he took high rank as a pulpit orator, and even royalty had to beg for a seat amongst his audiences; but his sermons are now forgotten. He lives in history, apart from his three hymns, mainly as a man of unstained purity and invincible fidelity to conscience, weak only in a certain narrowness of view which is a frequent attribute of the intense character which he possessed. As an ecclesiastic he was a High Churchman of the old school.

Ken's poetical works were published in collected form by W. Hawkins, his relative and executor, in 1721, and extended to four volumes; his prose works were issued in 1838 in one volume, under the editorship of J. T. Round. A brief memoir was prefixed by Hawkins to a selection from Ken's works which he published in 1713; and a life, in two volumes, by the Rev. W. L. Bowles, appeared in 1830. But the standard biography of Ken is that of J. Lavicount Anderdon (*The Life of Thomas Ken, Bishop of Bath and Wells, by a Layman*, 1851; 2d ed., 1854).

KENDAL, KIRKBY-KENDAL, or KIRKBY-IN-KENDAL, a market-town and parliamentary and municipal borough of Westmoreland, is picturesquely situated in a pleasant valley on the east bank of the Kent or Ken, 44 miles south of Carlisle (50 by rail), and 241 miles from London. The town, which is the largest and most populous in the county, is very irregularly built, but the white-walled houses with their blue-slated roofs, and the numerous trees, give it a very attractive appearance. There are four leading streets, two of which together form a spacious thoroughfare a mile in length. The church of the Holy Trinity, whose oldest part dates from about 1200, is a Gothic edifice with five aisles and a square tower 72 feet high. Kendal contains numerous other churches, a town-hall, a mechanics' institution, a literary and scientific institution, a museum, and a chamber of commerce. Its charities include a hospital (founded 1870), an old maids' hospital, a girls' orphanage, almshouses, &c. The free grammar school is well endowed; and there are also in the town a well-endowed blue-coat school and hospital, a large national school, a school of science and art, and several Sunday schools, among which is the Greencoat Sunday school, founded in 1813. On an eminence to the east of the town are the ruins of Kendal Castle, attributed to the first barons of Kendal. It was the birthplace of Catherine Parr, Henry VIII.'s last queen. On the Castle-law-hill, an obelisk was raised in 1788 in memory of the revolution of 1688. The woollen manufactures of Kendal have been noted since the 14th century, when Edward III. established a colony of Flemish weavers in the town; and, although the coarse cloth known to Shakespeare as "Kendal green" is no longer made, its place is more than supplied by active manufactures of tweeds, linsey-wolsey, railway rugs, horse clothing, knitted woollen caps and jackets, worsted and woollen yarns, and similar goods. Other manufactures of Kendal are machine-made boots and shoes, cards for wool and cotton, agricultural and other machinery, paper, and, in the neighbourhood, gunpowder. There are also important marble-works. There is a large weekly market for grain, and annual horse and cattle fairs. The population in 1881 was 13,696, an increase of only 250 from 1871.

[1] The fact, however, that in 1712—only a year after Ken's death—his publisher, Brome, published the hymn with the opening words "All praise" has been deemed by such a high authority as Lord Selborne sufficient evidence that the alteration had Ken's authority.

Kendal was the head of a barony given by William the Conqueror to Ivo de Talbois. It has given the title of earl to various royal and other personages of English history. The town received its charter from Queen Elizabeth in 1575. A second, granted by Charles I., and confirmed by Charles II., was superseded by the Municipal Act of 1835, according to which the town is governed by six aldermen and eighteen councillors, who select a mayor from among themselves. Quarter sessions are held alternately at Appleby and Kendal. The Reform Act of 1832 assigned one member of parliament to Kendal.

KENILWORTH, a small town of Warwickshire, is pleasantly situated on a tributary of the Avon, on the railway from Coventry to Leamington, 5 miles distant from both towns, and 99 miles north from London The town is only of importance from its antiquarian interest and the magnificent ruins of its old castle. The most probable derivation of its name, which in Domesday is written *Chinewrde*, is from *Cenwulf*, king of the Mercians, and *werthe*, a dwelling-place. The old royal residence of the Saxon kings was destroyed in the wars between Edward and Canute. The manor of Kenilworth was bestowed by Henry I. on Geoffrey de Clinton, afterwards lord chief-justice, who erected the earlier portion of the present castle. By his grandson Henry de Clinton it was given to King John, and it remained a royal residence until the time of Henry III., who granted it to Simon de Montfort, earl of Leicester. After the battle of Evesham, 14th August 1265, at which Simon de Montfort was slain, the rebel forces rallied at the castle, when it sustained a siege of six months, but finally capitulated to Henry III., who bestowed it on his son Edmund. After being used as the prison of Edward II. previous to his removal to Berkeley, it came into the possession of John of Gaunt, by whom it was greatly enlarged. On his son becoming king as Henry IV., it was made a royal residence, and it remained in the possession of the crown until Queen Elizabeth in 1562 granted it to Robert Dudley, earl of Leicester, who spent a large sum in restoring it, and whose splendid entertainments there to Elizabeth are described in Scott's novel of *Kenilworth*. During the civil war it was dismantled by the soldiers of Cromwell, and it was thenceforth abandoned to decay. Since the Restoration it has belonged to the house of Clarendon. The walls of the castle originally enclosed an area of 7 acres. The principal portions of the building still remaining are the gatehouse, now used as a dwelling-house; Cæsar's tower, the only portion built by Geoffrey de Clinton now extant, with massive walls 16 feet thick; the Merwyn's tower of the novel of *Kenilworth*; the great hall built by John of Gaunt with windows of very beautiful design; and the Leicester buildings, which are in a very ruinous condition. Not far from the castle are the remains of an Augustinian monastery founded in 1122, and afterwards made an abbey. Adjoining the abbey is the parish church of St Nicholas, restored in 1865, an old structure of mixed architecture, and containing a fine Norman doorway, which is supposed to have been the entrance of the former abbey church. The town, which possesses large tanneries, is under the government of a local board. Population in 1871, 3880; in 1881, 4150.

KENNEDY, Thomas Francis (1788–1879), a distinguished Scottish Liberal politician, was born near Ayr in 1788. He studied for the bar and passed advocate in 1811. But, having been elected M.P. for the Ayr burghs in 1818, he devoted the greater part of his life to the promotion of those political reforms which the long misgovernment of Scotland by the Tory party had rendered necessary. In this patriotic work he was greatly assisted by Lord Cockburn, then Mr Henry Cockburn, and a volume of correspondence published by Kennedy in 1874 forms a curious and interesting record of the consultations of the two friends on measures which they regarded as requisite for the political regeneration of their native country. One of the first measures of improvement to which he directed his attention was the withdrawal of the power of nominating juries from the judges, and the imparting of a right of peremptory challenge to prisoners. It cost Kennedy several years of persistent urgency upon the legislature before this most reasonable demand was conceded, but at length his energy and perseverance succeeded. Among other subjects he directed his attention to the improvement of the parish schools, of pauper administration, and of several of the corrupt forms of legal procedure which then prevailed. To him also was in a great measure due the freedom which the Scottish people obtained from the domination of certain aristocratic families which had long proved a dead weight on the progress of Liberal principles in Scotland. In the construction of the Scottish Reform Act Kennedy took a very prominent part, and indeed he and Lord Cockburn may almost be regarded as its authors. After the accession of the Whigs to office in 1832 he held various important offices in the ministry, and most of the measures of reform for Scotland, such as burgh reform, the improvements in the law of entail, and the reform of the sheriff courts, owed much to his sagacity and energy. In 1837 he went to Ireland as paymaster of civil services there, and immediately set himself with his accustomed energy to the promotion of various measures of reform. One or two of the blue books published during the period of his administration exhibit with an amusing vividness the sleuth-hound-like keenness and tenacity, characteristic of the man, with which he hunted out several of the abuses and scoundrelisms that he found prevailing. Kennedy retired from public life in 1854, but he never ceased to take the keenest interest in political affairs, and up to the time of his death took a great part in both county and parish business. One of the chief features of his character was a strong, almost stern, love of justice, and a determined hatred of every thing savouring of jobbery or dishonesty. All through his career he preserved the simple straightforwardness and unselfishness of the earlier Liberalism. He died in 1879, having attained the almost patriarchal age of ninety-one. He had married in 1820 the only daughter of Sir Samuel Romilly.

KENNET, White (1660–1728), bishop of Peterborough, a theological writer and learned antiquarian, was born at Dover in 1660. He was educated at Westminster school and at Oxford, where, while still an undergraduate, he published several translations of Latin works, including Erasmus *On Folly*, Pliny's *Trajan*, and Cornelius Nepos. About the year 1685 he became vicar of Amersden. A few years afterwards he returned to Oxford as tutor and vice-principal of St Edmund's Hall, where he gave considerable impetus to the study of antiquities. In 1695 he published *Parochial Antiquities*. In 1700 he resigned the vicarage of Amersden to take charge of the parish of St Botolph, Aldgate, London, and in the following year he was preferred to the archdeaconry of Huntingdon. On account of his eulogistic sermon on the duke of Devonshire he was in 1707 recommended to the deanery of Peterborough. Although he afterwards changed to the Low Church party, strenuously opposed the Sacheverel movement, and in the Bangorian controversy supported with great zeal and considerable bitterness the side of Bishop Hoadly, his intimacy with the bishop of Norwich, who was high in favour with the king, secured him in 1718 promotion to the bishopric of Peterborough. He died at Westminster in September 1728. Kennet published in 1698 an edition of Sir Henry Spelman's *History of Sacrilege*, and he was the author of as many as fifty-seven printed works, chiefly tracts and sermons. His principal publication was a *Compleat History of England*, 3 vols., 1706 (enlarged edition, 3 vols., 1719), chiefly a compilation from other authors, but the part from Charles I. to Queen Anne was written by himself.

The *Life of Bishop White Kennet*, by the Rev. William Kennet, appeared in 1730. See also Nicol's *Literary Anecdotes*, Dibdin's *Quarrels of Authors*, and Disraeli's *Calamities of Authors.*

KENNICOTT, BENJAMIN (1718–1783), an eminent Hebraist, was born at Totnes, Devonshire, on April 4, 1718. His father was parish clerk and master of a charity school, in which latter situation Benjamin was chosen to succeed him at an early age. His talents and acquirements interested some rich friends in his behalf, and by their liberality he was provided with the means of studying at Oxford. Entering himself of Wadham College in 1744, he soon distinguished himself in Hebrew and divinity; and while still an undergraduate published two dissertations, *On the Tree of Life in Paradise, with some Observations on the Fall of Man*, and *On the Oblations of Cain and Abel*, which came to a second edition in 1747, and procured him the honour of a bachelor's degree before the statutable time. Shortly afterwards he was elected fellow of Exeter College, and in 1750 he took his degree of M.A. In 1767 he was appointed keeper of the Radcliffe library, and made D.D. He was also canon of Christ Church and rector of Culham in Oxfordshire, and was subsequently presented to the living of Mynhenyote, Cornwall, which however, being unable to visit it, he resigned two years before his death. He died of a lingering illness at Oxford, on September 18, 1783.

The great work with which his name continues to be associated in the annals of Biblical scholarship is the *Vetus Testamentum Hebraicum cum variis Lectionibus*, 2 vols. fol., Oxford, 1776–80. The course of the studies which resulted in it may be gathered from the nature of the publications by which it was preceded. Two dissertations entitled *The State of the Printed Hebrew Text of the Old Testament considered*, published respectively in 1753 and 1759, were expressly designed to combat the then current ideas as to the "absolute integrity" of the received Hebrew text. The first contains "a comparison of 1 Chron. xi. with 2 Sam. v. and xxiii., and observations on seventy MSS., with an extract of mistakes and various readings"; the second defends the claims of the Samaritan Pentateuch, assails the correctness of the printed copies of the Chaldee paraphrase, gives an account of Hebrew MSS. of the Bible known to be extant, and catalogues one hundred MSS. preserved in the British Museum and in the libraries of Oxford and Cambridge. His labours provoked severe animadversion in some quarters, and even from such men as Warburton and Horne; but they at least had the effect of drawing public attention to the subject to which they related, and in 1760 he issued his proposals for collecting all Hebrew MSS. of date prior to the invention of printing which could be discovered either at home or abroad. Subscriptions to the amount of nearly £10,000 were obtained, and many learned men addressed themselves to the work of collation, Bruns of Helmstadt making himself specially useful as regarded MSS. in Germany, Switzerland, and Italy. Between 1760 and 1769 ten "annual accounts" of the progress of the work were given; in its course six hundred and fifteen MSS. and fifty-two printed editions of the Bible were either wholly or partially collated, and use was also made (but often very perfunctorily) of the quotations in the Talmud. The materials thus collected, when properly arranged and made ready for the press, extended to 30 vols. fol. The text finally followed in printing was that of Van der Hooght,—unprinted however, the points having been disregarded in collation,—and the various readings were printed at the foot of the page. The Samaritan Pentateuch stands alongside the Hebrew in parallel columns. The *Dissertatio Generalis*, appended to the second volume, contains an account of the MSS. and other authorities collated, and also a review of the Hebrew text, divided into periods, and beginning with the formation of the Hebrew canon after the return of the Jews from the exile. Kennicott's great work was in one sense a failure. It yielded no materials of value for the emendation of the received text, and by disregarding the vowel points overlooked the one thing in which some result (grammatical if not critical) might have been derived from collation of Massoretic MSS. But the negative result of the publication and of the *Variæ Lectiones* of De Rossi, published some years later, was important. It showed that the Hebrew text can be amended only by the use of the versions aided by conjecture.

KENOSHA, chief city of Kenosha county, Wisconsin, U.S., is situated in a fertile district on Lake Michigan, about 30 miles south of Milwaukee, with which it is connected by rail. It contains numerous schools, and carries on the manufacture of hardware, wooden wares, machines, and carriages. There are also in the city breweries, foundries, tanneries, planing mills, and other industrial establishments. It possesses a good harbour, and carries on trade in its manufactures and in country produce. The population in 1880 was 5039.

KENSINGTON, a western suburb of London in the parish of Kensington, parliamentary borough of Chelsea, and county of Middlesex, a mile and a half west of Hyde Park Corner. The parish includes the suburbs of Brompton, Earl's Court, part of Little Chelsea, the Gravel Pits, Notting Hill, and part of Kensal Green. Kensington palace and Kensington gardens, however, lie in the parish of St Margaret's, Westminster. The suburb of Kensington, which has developed out of the village of Kensington, lies to the west of Kensington gardens, and consists principally of a long and in places narrow street, the modern improvements of which with the surrounding additions have almost entirely obliterated all traces of the "old court suburb" associated with the distinguished personages of former times. From the High street others branch off at intervals, and the elevated ground to the north is almost wholly occupied with villas embosomed in woods. To the south of the High street is Kensington square, where at one time were the residences of many of the principal attendants on the court. The principal public buildings in the suburb are the parish church in the Decorated style, erected in 1869 at a cost of £35,000, the elegant new town-hall, the vestry-hall, the grammar school, the Roman Catholic college, opened in 1874, several monasteries and convents, and various schools and charities. The site of Old Gore House, at one time the residence of Mr Wilberforce and afterwards of the Countess of Blessington, is now occupied by the Royal Albert Hall and the gardens of the Horticultural Society. These as well as Kensington gardens and the South Kensington museum with its national training schools fall to be noticed under the article LONDON. Kensington palace, a plain and irregular brick structure, originally surrounded by grounds extending to about 350 acres, was at one time the residence of Lord Chancellor Finch, afterwards earl of Nottingham, of whom it was bought by William III. Additions were made to it by William III., George I., George II., and the duke of Sussex. The palace was the birthplace of Queen Victoria. Kensington house, which stood near the palace gate, and was at one time the residence of the duchess of Portsmouth, mistress of Charles II., was pulled down in 1873 to make way for the mansion of Baron Albert Grant. The population of the registration subdistrict in 1871 was 91,664, which in 1881 had increased to 120,125. The population of the parish in 1881 was 162,924.

The manor of Kensington, which is written in Domesday book *Chenesitun*, has an area of 1140 acres. Some trace the origin of the word to the old Saxon name for king, others to a family of the name of Chenesi, others to "Caen," the old name for wood. The manor was originally occupied by the great Middlesex forest, the trees of which were abundant in the time of Henry VIII. In Domesday it is mentioned as being held by Aubrey de Vere of the bishop of Coutances. Soon after this it became the absolute property of the De Veres, who were afterwards created earls of Oxford. In the reign of Elizabeth it passed into the possession of the Argylls, by whom it was sold to Sir Walter Cope, whose daughter married Henry Rich, earl of Holland. Holland House, in the Elizabethan style, the original mansion of the manor of Kensington, was erected by Sir Walter Cope in 1697, and enlarged and adorned by the third Lord Holland (see vol. xii. p. 100). The manor is at present held by Lord Kensington. See Faulkner, *History and Antiquities of Kensington*, 1820; Leigh Hunt, *The Old Court Suburb.*

KENT, a maritime county in the south-eastern corner of England, lies between 50° 54′ and 51° 31′ N. lat., and between 0° 3′ W. long. and 1° 27′ E. long. It is bounded on the N. by the estuary and mouth of the Thames, E. Plate

KENT.

and S.E. by the English Channel, S.W. by Sussex, and W. by Surrey. Its greatest breadth north and south from Sheerness to Dungeness is 35 miles, its length north-west to south-east from London to Dungeness about 60 miles, and its length west to east from Surrey to North Foreland in Thanet 65 miles. The area is 1,004,984 acres, or 1570 square miles.

Coast Line.—About two-thirds of the boundary line of Kent is formed by tidal water. The estuary of the Thames may be said to stretch from London Bridge to Sheerness in the Isle of Sheppey, to the north-west of which the estuary of the Medway cuts off a tongue of land whose extremity is termed the Isle of Grain. Along the banks of the Thames the coast is low and marshy, embankments being in several places necessary to prevent inundation. In the estuary of the Medway there are a number of low marshy islands, but Sheppey presents to the sea a range of chalk cliffs from 80 to 90 feet in height. The marshes extend along the estuary of the Swale to Whitstable, whence stretches a low line of clay and sandstone cliffs, succeeded at the Isle of Thanet by the white chalk cliffs which extend southwards to Pegwell Bay. The coast from Sheppey round to the South Foreland is skirted by numerous flats and sands, the most extensive of which, the Goodwin sands, forming the breakwater of the well-known anchorage of the Downs, are said to have formed part of the estate of Earl Godwine, and to have been submerged as late as 1097. From Pegwell Bay to near Deal the outline of the coast is flat, but thence it rises again into chalk cliffs, which continue round the South Foreland to Folkestone, where they are succeeded by the flat shingly shore bordering Romney Marsh. A considerable portion of Romney Marsh has been reclaimed from the sea since the time of Julius Cæsar, but in nearly every other portion of the coast the sea has been gaining on the land.

Surface and Geology.—Kent abounds in beautiful and finely-wooded valleys with undulating and picturesque uplands. A tract from 7 to 8 miles broad lying to the south of the estuary of the Thames, and extending eastwards as far as Thanet, belongs to the London Tertiary basin, and is formed chiefly either of London or of plastic clay. The London Clay occupies the tongue of land between the estuaries of the Thames and Medway, as well as Sheppey and a district of country about 8 miles wide stretching southwards from Whitstable to Canterbury, and extending eastwards to the Isle of Thanet. It reappears at Pegwell Bay, and in the neighbourhood of London it rises above the plastic clay into the elevation of Shooter's Hill, with a height of about 450 feet, and a number of smaller eminences. The thickness of the formation near London is about 400 feet, and at Sheppey it reaches 480 feet. At Sheppey it is rich in various kinds of fossil fish and shells. The plastic clay, which rests chiefly on chalk, occupies the remainder of the estuary of the Thames, but at several places it is broken through by outcrops of chalk, which in some instances run northwards to the banks of the river. The Lower Tertiaries are represented by three different formations known as the Thanet beds, the Woolwich and Reading beds, and the Oldhaven and Blackheath beds. The Thanet beds resting on chalk form a narrow outcrop rising into cliffs at Pegwell Bay and Reculvers, and consist (1) of a constant base bed of clayey greenish sand, seldom more than 5 feet in thickness; (2) of a thin and local bed composed of alternations of brown clay and loam; (3) of a bed of fine light buff sand, which in West Kent attains a thickness of more than 60 feet; (4) of bluish grey sandy marl containing fossils, and almost entirely confined to East Kent, the thickness of the formation being more than 60 feet; and (5) of fine light grey sand of an equal thickness, also fossiliferous. The middle series of the Lower Tertiaries, known as the Woolwich and Reading beds, rests either on the Thanet beds or on chalk, and consists chiefly of irregular alternations of clay and sand of very various colours, the former often containing estuarine and oyster shells and the latter flint pebbles. The thickness of the formation varies from 15 to 80 feet, but most commonly it is from 25 to 40 feet. The highest and most local series of the Lower Tertiaries is the Oldhaven and Blackheath beds lying between the London Clay and the Woolwich beds. They consist chiefly of flint pebbles or of light-coloured quartzose sand, the thickness being from 20 to 30 feet, and are best seen at Oldhaven and Blackheath. To the south the London basin is succeeded by the North Downs, an elevated ridge of country consisting of an outcrop of chalk which near Westerham on the borders of Surrey reaches an elevation of 812 feet above sea-level, and at several other places more than 600 feet. It extends from Westerham to Folkestone, with an irregular breadth generally of from 3 to 6 miles, but expanding to nearly 12 miles at Dartford and Gravesend and also to the north of Folkestone. After dipping below the London Clay at Canterbury, it sends out an outcrop which forms the greater part of Thanet, and towards the sea is often broken off into precipitous escarpments. To the south of the Downs there is a narrow valley formed by the Gault, a fossiliferous blue clay. This is succeeded by an outcrop of the Lower Greensand, which extends across the country from west to east with a breadth of from 2 to 7 miles, and rises into the picturesque elevations of the Ragstone hills. These in several cases reach a height of over 600 feet, and have a steep slope southwards, overlooking the valley which extends from the borders of Sussex to Hythe. This low ground is occupied chiefly by the Weald clays, which contain a considerable number of marine and freshwater fossils. Along the borders of Sussex there is a narrow strip of country consisting of picturesque sandy hills, whose highest elevation is nearly 400 feet; and the south-west corner of the county is occupied by Romney Marsh, which within a comparatively recent period has been recovered from the sea.

The London Clay is much used for bricks, coarse pottery, and Roman cement. Lime is obtained from the Chalk and Greensand formations. Ironstone is found in the Wealden clays and calcareous ironstone in the Ashdown sand, but the industry has long been discontinued. The last Wealden furnace was put out in 1828.

Rivers.—The Thames, which forms the northern boundary of the county, receives the Ravensbourne at Deptford, and the Darent or Dart, which has a course of 18 miles, and becomes navigable at Dartford. The Medway, which has a course of over 50 miles, and with its tributaries drains a basin having an area of 680 square miles, is formed of several streams that rise in the neighbourhood of Tunbridge Wells, and of East Grinstead in Sussex. After passing Ashurst and Penshurst it receives the Eden from the west, and at Yalding in the Weald the Teise and Beult. At Chatham it widens into an estuary, the greater portion of its waters ultimately joining the Thames at Sheerness, and the other portion passing southwards to the sea through the Swale Channel. The river is tidal as high as Maidstone. The Stour, which has a course of nearly 50 miles, and with its tributary the Little Stour drains an area of about 380 square miles, has its origin in several streams which spring from the Lower Greensand and the Chalk, the two main branches, which have their source near Lenham and near Hythe respectively, uniting at Ashford. At Sarre the Stour separates into two branches which insulate the Isle of Thanet, the smaller portion flowing northward to the sea near Reculver, the other and main portion flowing eastward to Pegwell Bay. The stream is tidal and navigable to Fordwich, near Canterbury. The Little Stour rises in the Lower Chalk near Lyminge, and joins at Stourmouth that branch of the Stour which falls into the sea at Pegwell Bay. The Dour, a small stream which gives its name to Dover, has a course of little more than 3 miles from Ewell to the sea. The Rother, which has its source in Sussex, forms for some distance the boundary between that county and Kent, and along with several of its branches insulates the Isle of Oxney.

The only canals at all in use are that which runs along the borders of Romney Marsh, connecting the Rother with the sea at Hythe, but now partly filled up; and that between Gravesend and Rochester, which is partly occupied by a line of railway.

Climate, Soil, and Agriculture.—The insalubrity of certain portions of the county caused by extensive marshes has been almost wholly removed by draining. In the north-eastern districts the climate is a little uncertain, and damage is often done to early fruit blossoms and vegetation by cold easterly winds. In the large portion of the county sheltered by the Downs the climate is milder and more equable, and vegetation is somewhat earlier. The soil is very various in character, but on the whole rich and under high cultivation. The methods of culture and the kinds of crop produced are perhaps more widely diversified than those of any other county in England. Upon the London Clay the land is generally heavy and stiff, but very fruitful when properly manured and cultivated. The marsh lands along the banks of the Thames, Medway, Stour, and Swale consist chiefly of rich chalk alluvium. The Chalk formation is in some cases overlaid by London Clay, alluvium, or brick-earth, but in the higher chalk districts the soil is often poor and thin, and in some places much mixed with flints. In the Isle of Thanet a light mould predominates, which has been much enriched by fish manure. The valley of the Medway, especially the district round Maidstone, which has been called the garden of England, is the most fertile part of the county, the soil being a deep loam with a subsoil of brick-earth. On the ragstone the soil is occasionally thin and much mixed with small portions of sand and stone; but in some situations the ragstone has a thick covering of clay loam, which is most suitable for the production of hops and fruits. In the district of the Weald marl prevails, with a substratum of clay. The soil of Romney Marsh is a clay alluvium.

According to the agricultural returns for 1881, the total area under crops comprehended 745,215 acres, a percentage of 73·9 instead of 71·7 in 1870; corn crops had an area of 224,211 acres, a percentage of 22·3 instead of 25·1 in 1870; green crops 85,614 acres, a percentage of 8·5 instead of 7·4; rotation grasses 53,421 acres, a percentage of 5·3 instead of 6·2; permanent pasture 327,079 acres, a percentage of 31·8 instead of 28·2. The area under permanent pasture thus exceeds that under corn crops by nearly a third. The area under woods in 1881 was 82,849 acres, under orchards 16,673, under market gardens 4221, and under nursery grounds 670. Of the corn crops the most largely grown is wheat, which in 1881 occupied 84,888 acres, oats coming next with 52,177 acres, and barley and bere occupying only a little less, 50,010 acres. Beans and pease were grown on 17,453 and 19,762 acres respectively, and rye on only 421 acres. In Thanet mustard, spinach, canary seed and a variety of other seeds are raised. Of green crops, turnips and swedes were grown on 27,254 acres, vetches and similar crops on 22,179 acres, potatoes 17,815, mangolds 12,070, cabbage 5843, and carrots 452. Part of the area under green crops is occupied by market gardens, which are very numerous in the neighbourhood of London. The principal orchard districts are the valleys of the Darent and Medway, and the Tertiary soils overlying the Chalk, between Rochester and Canterbury. The county is specially famed for cherries and filberts, but apples, pears, plums, gooseberries, and currants are also largely cultivated. In some cases apples, cherries, filberts, and hops—the special crop of the county—are grown in alternate rows. 41,476 acres were under hops in Kent in 1881, and in the United Kingdom only 64,943 acres. The principal hop districts are the country in East Kent lying between Canterbury and Faversham, the valley of the Medway in Mid Kent, and the district of the Weald. The area under hops in these several districts in 1881 was 11,718, 17,353, and 11,986 acres respectively,—other districts contributing only 419 acres. Much of the Weald, which originally was occupied by a forest, is still densely wooded. There are many fine woods scattered throughout the county, especially in the valley of the Medway, oak and beech being the trees principally grown. A large extent of woodland is ash and chestnut plantations—maintained for the growth of hop-poles.

The following table gives a classification of holdings according to size as returned on the 25th June 1875 and the 4th June 1880, with the acreage of each class of holding for these years:—

Class of holding	50 Acres and under.		50 to 100 Acres.		100 to 300 Acres.		300 to 500 Acres.		500 to 1000 Acres		1000 Acres and upwards.		Total.	
Years	1875.	1880.	1875.	1880.	1875.	1889.	1875.	1880.	1875.	1880.	1875.	1880.	1875.	1880.
Number	6,760	7,281	1,285	1,301	1,814	1,848	368	375	119	108	15	13	10,361	10,926
Area in Acres	92,657	98,228	92,758	93,511	311,188	320,974	136,379	142,269	76,545	70,646	18,587	18,920	728,114	744,548

About two-thirds of the holdings are less than 50 acres in extent, but the largest area—about two-fifths of the whole—is in farms between 100 and 300 acres.

The number of horses in 1881 was 29,450, an average of 3·9 to every 100 acres under cultivation, the average for England and also for Great Britain being 4·4. The number of horses used for agricultural purposes was 24,177. The total number of cattle in 1881 was 73,409, an average of 19·9 (England 16·9, Great Britain 18·4) to every 100 acres under cultivation. The number of cows in milk or in calf was 29,485, and of other cattle 43,924. Cattle are grazed in large numbers on the marsh lands along the estuaries of the rivers, and of course dairy farms are very numerous in the neighbourhood of London. The number of sheep in 1881 was 952,311, an average of 128·9 (England 62·4, Great Britain 76·3) to every 100 acres under cultivation. The number one year old and upwards was 627,124, and below one year 325,187. A breed of sheep peculiar to the district, known as Kents, is grazed on Romney Marsh, but Southdowns are the principal breed raised on the uplands. Pigs in 1881 numbered 55,896, or an average of 7·5 (England 7, Great Britain 6·6) to every 100 acres under cultivation.

According to the landowners' return, 1872-73, the land, exclusive of that in the metropolis, was divided between 34,683 proprietors, and its gross annual value was £3,357,057. Of the owners, 26,925, or more than 77 per cent., possessed less than 1 acre, and the average value per acre over all was £3, 10s. 7½d. There were four proprietors possessing above 10,000 acres each, viz., Viscount Holmsdale, 15,162 acres; Lord Sondes, 14,446; Sir H. Tufton, 13,639; and the Ecclesiastical Commissioners, Whitehall, 10,591. Other seventeen possessed more than 5000 acres each.

Manufactures and Trade.—At one time there were extensive ironworks in the Weald of Kent, and woollen cloth was also largely manufactured, but the former industry is now wholly extinct, and the latter is only prosecuted to a very small extent. Next to the occupations connected with the Government establishments at Deptford, Woolwich, Chatham, and Sheerness (see DOCKYARDS, vol. vii. p. 310), the most important industry of the county is that of paper, which is carried on on the banks of the Cray, Darent, Medway, and other streams in the west of the county. Shipbuilding by private firms is also prosecuted at Greenwich, Gravesend, Dover, Northfleet, and Ramsgate. At Greenwich there are engineering works, soap works, and chemical works; and the carriage and engine works of the South-Eastern Railway are situated at Ashford. Manufactories of silk, cotton, linen, wool, and ribbons give employment in various towns and villages. Bricks, tiles, pottery, and cement are fabricated, especially on the banks of the Swale and Medway. Lime-burning and whiting-making are also carried on. There are powder-mills at Dartford, Faversham, and Tunbridge. The principal ports besides those on the Thames and Medway are Whitstable, Herne Bay, Margate, Broadstairs, Ramsgate, Sandwich, Deal, Dover, and Folkestone. The watering-places are Erith, Greenhithe, Northfleet, Gravesend, Herne Bay, Margate, Westgate, Broadstairs, Ramsgate, Deal, Dover, Folkestone, and Sandgate. Tunbridge Wells is a favourite spa.

Fishing.—Deep-sea fishing is largely prosecuted all round the coast of Kent. Shrimps, soles, and flounders are caught in great numbers in the estuaries of the Thames and Medway and along the coast of Whitstable and Margate as well as at Ramsgate. The principal oyster beds are at Queenborough, Rochester, Milton, Faversham, and Whitstable, and whitebait frequent the Thames in immense shoals below Greenwich.

Railways.—As the main pathway of communication between London and the Continent lies through Kent to Dover, the county at a very early period enjoyed the advantage of railway intercourse; and it is now very completely intersected with railway lines.

Administration.—Kent is divided into five lathes—a partition peculiar to the county, and dating from Anglo-Saxon times. The lathes are St Augustine, Shepway, Scray, Aylesford, and Sutton-at-Hone. The county comprises 61 hundreds, the lowey of Tunbridge, the franchise and barony of Bircholt, the liberty of the Isle of Sheppey, the liberty of New Romney; two cities, Canterbury (21,701) and Rochester (21,590), which are also municipal and parliamentary boroughs; one parliamentary borough, Chatham (46,806); five boroughs which are both municipal and parliamentary, viz., Dover (28,486), Gravesend (m. 23,375, p. 31,355), Hythe (m. 4069, p. 28,066), Maidstone (m. 29,638, p. 30,662), Sandwich (m. 2846, p. 15,566); part of the parliamentary borough of Greenwich and five municipal boroughs, viz., Deal (8422), Faversham (8627), Folkestone (18,887), Margate (15,889), and Tenterden (3620). The liberty of New Romney and all the municipal boroughs except Gravesend and Maidstone are included among the Cinque Ports. The Cinque Port districts in Kent are those of Sandwich, partly in Essex, Dover, Hythe, New Romney, and a portion of Rye, namely, Tenterden (see CINQUE PORTS, vol. v. p. 786). Until 1867 Kent was for parliamentary purposes formed into only two divisions, East and West Kent, but by the Reform Act of that year West Kent was divided into West and Mid Kent. The city of Canterbury, which returns two members, Dover and Sandwich, which return two members each, and Hythe, which returns one member, are included in East Kent, which returns in all nine members. In Mid Kent are included the city of Rochester, returning two members, Maidstone, returning two members, and Chatham and Gravesend, returning one member each; it returns in all eight members. West Kent, which returns two members, includes part of the borough of Greenwich, which returns two members. The total representation of the county, including Greenwich, is thus twenty-one members. The county has one court of general sessions and two of quarter sessions; the number of sessional divisions is sixteen, exclusive of the liberty of Romney Marsh, which has petty and general sessions under its charters. The central criminal court has jurisdiction over certain parishes in the county. The city of Canterbury (a county in itself), the city of Rochester, and the boroughs of Gravesend and Maidstone have commissions of the peace and separate courts of quarter sessions, as have also the ports and boroughs of Deal, Dover, Faversham, Folkestone, Hythe, Margate, Sandwich, and Tenterden. The ancient borough of Queenborough, governed by an old charter, has a recorder and a court of quarter sessions with a separate jurisdiction limited to misdemeanours. Summary cases are dealt with by the mayor and magistrates in petty sessions. With the exception of the portion included in the metropolitan police district, the shire for judicial purposes belongs to the south-eastern circuit, and for police purposes is divided into twelve districts, which are generally identical with the petty sessional divisions. The cities of Canterbury and Rochester, the boroughs of Deal, Dover, Faversham, Folkestone, Gravesend, Hythe, Maidstone, Margate, Sandwich, and Tenterden, and the towns of Ramsgate (22,605) and Tunbridge Wells (24,309) have their own police. Ecclesiastically, with the exception of portions of two parishes, Kent is within the dioceses of Canterbury and Rochester; and it contains thirty-seven civil parishes or places, as well as parts of other parishes extending into adjoining counties.

Population.—Since 1801, when it numbered 308,667, the population has been rapidly and uninterruptedly increasing. In 1821 it was 427,224, and in 1841 it had increased to 549,353, in 1861 to 733,381, in 1871 to 848,294, and in 1881 to 977,585, of whom 477,715 were males and 499,870 females.

History and Antiquities.—A tribe of the Belgæ from Gaul had before the time of Cæsar's invasion taken possession of a large portion of southern Britain, including Kent. The remarkable cromlech, Kit's Coity House, near Aylesford, belongs to this early period, as do numerous earthworks, encampments, stone circles, and excavations on the coast which are now generally regarded as ancient chalk pits. The spot of Cæsar's landing was probably either some part of the coast between Walmer and Thanet—the neighbourhood of Deal finding most supporters—or the *Portus Lemanis* in Romney Marsh, which is identical with the town of Lymne. In his first invasion he did not penetrate farther than Kent, and the absence of lapidary inscriptions is regarded as evidence that its conquest was easily effected. The principal Roman road was the Watling Street, between *Dubris* (Dover) and London, which had much the same course as the present highway. This road was joined at *Durovernum* (Canterbury) by two others, one from the *Portus Lemanis* (Lymne) and the other from *Regulbium* (Reculver). The traces of the road from the *Portus Lemanis* are still well marked throughout its whole extent, but agricultural operations have almost wholly obliterated the traces of that from *Regulbium*. Of two other Roman stations, *Durolevum* and *Vagniacæ*, the site cannot be absolutely determined, but most probably the former was near Faversham, and for the latter, which was somewhere between Rochester and London, most opinions favour Springhead near Gravesend. There are still important remains of Roman fortresses at Dover, Richborough, Reculver, and Lymne; many traces of Roman villas have also been discovered; and portions of Roman structures have frequently been utilized in the construction of churches and other buildings. A great variety of Roman relics have been discovered in nearly every part of the county. The most remarkable are profuse traces of extensive potteries of purple or black ware at Upchurch on the south bank of the Medway, leaden coffins elaborately ornamented, and glass and bronze vessels in various Roman cemeteries. The earliest Teutonic settlement, under Hengest and Horsa, took place in Kent; and, on the arrival of Augustine in 597, Canterbury became the Christian metropolis of the island. Separate kings appear to have occasionally ruled in East and West Kent; and a bishopric was established at Rochester, in West Kent, as well as at Canterbury. Of this period of Kentish history the principal antiquarian remains are the cemeteries; from those at Sarre and Osengal in Thanet, and at Bifrons, Barham, Bishopsbourne, Gilton, and Sittingbourne, a large number of relics of various kinds have been obtained. Some old customs belonging to this period, including that of gavelkind in cases of intestacy, are still extant. Kent in 823 was united by Egbert to the kingdom of the West Saxons. In the 9th, 10th, and 11th centuries it suffered greatly from the ravages of the Danes. After the Conquest the earldom of Kent, which had been held by Godwine and afterwards by Harold, was bestowed by William on his brother Odo bishop of Bayeux. Among other events of historic importance the following may be mentioned:—the capture of Rochester by William Rufus in 1088, an incident connected with the rebellion of Odo, which was subdued in the same year; the murder of Thomas à Becket at Canterbury in 1170; the submission of King John to the pope's legate at Dover in 1215; the capture of Rochester Castle by King John in the same year, and of the same castle by the dauphin of France in 1216, the greater part of Kent formally submitting to him with the exception of Dover Castle; Wat Tyler's insurrection in 1381 and that of Jack Cade in 1450; the encampment of Cornish insurgents at Blackheath in 1497, where they were surprised by Henry VII.; the insurrection of Sir Thomas Wyatt, which was commenced at Maidstone in 1554; the suppression of the Kentish insurrection by Fairfax at Maidstone, June 1, 1648; and the burning of certain ships at Chatham by the Dutch fleet under De Ruyter in 1667 after the fort of Sheerness had been levelled by his guns.

As was to be expected from its connexion with the early history of England, and from its beauty and fertility, Kent possessed a larger than average number of monastic foundations. The earliest were the priory of Christ's Church and the abbey of St Peter and St Paul now called St Augustine's, both at Canterbury, founded by Augustine and the monks who accompanied him to England. In the time of Henry VIII. the other principal religious houses were a priory at Rochester founded in 1089, a priory founded at Folkestone in 1100 on the site of a nunnery originally founded in 630, a nunnery of St Sepulchre at Canterbury, founded about 1100, a nunnery at Minster in Sheppey built in 1130 on the site of a nunnery which was founded in 675, but destroyed by the Danes, St Martin's Priory at Dover established in 1140 in place of one founded in 696 but afterwards dissolved, an abbey at Faversham founded in 1147, and nunneries at Lillechurch in Higham founded before 1151, at Davington founded in 1153, and at Malling founded in the time of William Rufus; the Black Canons possessed a priory at Leeds founded in 1119, an abbey at Westwood in the parish of Erith founded in 1178, a priory at Combwell in Goudherst founded in the reign of Henry II., a priory at Tunbridge founded in the same century, a priory at Bilsington founded in 1253, St Gregory's Priory at Canterbury, changed in the time of Henry I. from one of secular priests, originally founded in 1084; the White Canons had St Radegund's Abbey near Dover, founded in 1193, and an abbey at West Langdon, founded in 1192; houses belonging to the Carmelites existed at Aylesford and Newenden, both founded in 1240, and at Sandwich founded in 1272; one belonging to the Dominicans was founded at Canterbury in 1221, the Franciscans having one at the same city founded in 1225, and the Eremite Friars also one at the same city founded in the time of Edward I or Edward II.; an abbey of Cistercian monks was founded at Boxley in 1146, a preceptory of Knights Templars at Swingfield near Dover some time before 1190, a priory of Trinitarian Friars at Mottenden in the parish of Headcorn in 1224, a nunnery of the order of St Augustine at Dartford about 1355, a cell of Cluniac monks at Monks Horton in the time of Henry II., and a preceptory belonging to the knights of St John of Jerusalem at West Peckham in the time of Henry IV. Of the monastic buildings the principal remains are those of the Benedictine monastery of St Augustine at Canterbury, the priory of Christ's Church, Canterbury, adjoining the cathedral, the Dominican convent, Canterbury, St Radegund's Abbey near Dover, St Martin's Priory, Dover, Horton Priory, Malling Abbey, Aylesford Friary, and the abbeys of Minster in Sheppey and Minster in Thanet. In addition to the cathedrals of Rochester and Canterbury, the churches of special interest are those of Darenth, partly Old English; Lyminge, of very great antiquity; Barfreston, a small but unique specimen of enriched Late Norman work; Patricksbourne, a very beautiful example of Norman; St Margarets-at-Cliffe, with many portions of very rich Norman, the west doorway being one of the finest examples of Norman work in England; New Romney, with the finest Norman tower in Kent; Folkestone, Early English, with some portions almost Norman; St Martin's Church, Canterbury; Brabourne, with some singular Norman work, and possessing several brasses; St Clement's, Sandwich, partly Early English, with enriched Norman tower; Minster in Sheppey, Norman and Early English, with brass of date about 1330; Minster in Thanet, Norman tower and nave, with Early English chancel; Lydd, partly Early English and possessing several brasses; Cobham, Early English, with the finest collection of brasses in England; Hythe, with plain exterior, but possessing a chancel whose interior is one of the finest specimens of Early English work extant; Stone, Early English to Decorated, and in style resembling Lincoln cathedral; Chartham, a fine specimen of the Decorated, and possessing several brasses, one of the date 1306; Ashford, Decorated and Perpendicular, with brass of 1375, and one of the finest towers in Kent.

The principal secular buildings of interest, in addition to the Roman ruins already referred to, are the Norman keeps of Malling, Canterbury, Rochester, Dover, Chilham, and Tunbridge; the castles of Sandown, Deal, and Walmer, built by Henry VIII. for defensive purposes; Hever Castle, the seat of the Boleyns, and the scene of the courtship of Anne Boleyn and Henry VIII.; Allington Castle near Maidstone, the birthplace of Sir Thomas Wyatt; the banquetting hall and gateway of the Royal Palace at Eltham; the castellated mansion of Leeds Castle near Maidstone; Penshurst Castle, the seat of the Sidneys; Knole House near Sevenoaks, formerly one of the palaces attached to the archbishopric of Canterbury, and once the seat of the dukes of Dorset, now of Lord Sackville; the Mote, at Ightham; and Cobham Hall.

A full account of the geology of Kent is comprehended in Topley's *Geology of the Weald*, and Whitaker's *Geology of the London Basin*, forming part of the memoirs of the Geological Survey of the United Kingdom. Among the more ancient books on Kent are Lambard's *Perambulation*, written in 1570, 1st ed. 1576, latest 1826; Kilburne's *Brief Survey*, 1657; and Philipot's *Villare Cantianum*, 1659. The principal histories are those of Harris (1719), Hasted (1778-99), Seymour (1776), Henshall (1798), Ireland (1828-30), Collings (1834), and Dunkin (1856-77). Among the many works treating on Kentish antiquities may be mentioned Somner, *Treatise on the Roman Ports and Forts of Kent*, 1693; Nichols, *Antiquities in Kent*, 1782-83; Parsons, *Monuments of Kent*, 1794; Sandys, *Consuetudines Kanciæ*, 1851; Hussey, *Notes on the Churches of Kent*, 1852; F. H. Appach, *C. J. Cæsar's British Expeditions from Boulogne to the Bay of Apuldore*, 1868; Larking, *Facsimile of Domesday Book relating to Kent*, 1869; Furley, *A History of the Weald of Kent*, 1871-74; Scott-Robertson, *Kentish Archæology*, 1877-81; Glynne, *Notes on Churches of Kent*, 1877. See also Frost, *In Kent with Charles Dickens*, 1880. A very full bibliography of works relating to Kent and its several towns is given in Smith's *Bibliotheca Cantiana*, 1837; see also Anderson's *British Topography*, 1881. The *Archæologia Cantiana*, a periodical publication of the Kent Archæological Society, contains accounts of the latest antiquarian discoveries.

KENT, JAMES (1763-1847), American jurist, was born at Philippi in New York State, July 31, 1763. He graduated at Yale College in 1781, and began to practise law at Poughkeepsie, in 1785 as an attorney, and in 1787 at the bar. In 1790 and 1792 Kent was chosen to represent Dutchess county in the State legislature. In 1793 he removed to New York, where Governor Jay, to whom the young lawyer's Federalist sympathies were a strong recommendation, appointed him a master in chancery for the city. The year 1796 saw Kent again a member of the legislature and professor of law in Columbia College. In 1797 he became recorder of New York, in 1798 judge of the supreme court of the State, in 1804 chief justice, and in 1814 chancellor of New York. In 1822 he became a member of the convention to revise the State constitution. Next year, having attained the age of sixty, Chancellor Kent resigned his office, and was re-elected to his former chair. Out of the lectures he now delivered grew the *Commentaries on American Law* (4 vols., 1826-30), which by their learning, range, and lucidity of style, have won for him a high and permanent place in the estimation of both English and American jurists. Kent rendered most essential service to American jurisprudence while serving as chancellor. Chancery law had been very unpopular during the colonial period, and had received down to his time but little development, and no decisions had been published. His judgments of this class (see Johnson's *Chancery Reports*, 7 vols., 1816-24) cover a wide range of topics, and are so thoroughly considered and developed as unquestionably to form the basis of American equity jurisprudence. Kent was a man of great purity of character, of singular simplicity and guilelessness in his ways, and is altogether a conspicuous and remarkable figure in American annals. He died in New York, December 12, 1847.

To Kent we owe several other works (including a *Commentary on International Law*) of less importance than the *Commentaries*. These have passed through twelve editions, the most recent (1873) being annotated by O. W. Holmes, jun. See Duer's *Discourse on the Life, Character, and Public Services of James Kent*, 1848; and *The National Portrait Gallery of Distinguished Americans*, vol. ii., 1852.

KENT, WILLIAM (1685-1748), "painter, architect, and the father of modern gardening," as Horace Walpole in his *Anecdotes of Painting* describes him, was born in Yorkshire in 1685. Apprenticed to a coach-painter, his ambition soon led him to London, where he began life as a portrait and historical painter. He was fortunate enough to fall in with kind patrons, who sent him in 1710 to study in Italy; and at Rome he made other friends, among them Lord Burlington, with whom he returned to England in 1719. Under that nobleman's roof Kent chiefly resided till his death on April 12, 1748,—enjoying through his patron's influence abundant commissions in all departments of his art, as well as various court appointments which brought him an income of £600 a year. Walpole flatly says that Kent was below mediocrity in painting. He had some little taste and skill in architecture, of which Holkham palace is perhaps the most favourable example. The mediocre statue of Shakespeare in Westminster Abbey sufficiently stamps his powers as a sculptor. His merit in landscape gardening is greater. In Walpole's stilted language, Kent "was painter enough to taste the charms of landscape, bold and opinionative enough to dare and to dictate, and born with a genius to strike out a great system from the twilight of imperfect essays." In short, he was the first in English gardening to vindicate the natural against the artificial. Banishing all the clipped monstrosities of the topiary art in yew, box, or holly, releasing the streams from the conventional canal and marble basin, and rejecting the mathematical symmetry of ground plan then in vogue for gardens, Kent endeavoured to imitate the variety of nature, with due regard to the principles of light and shade and perspective. Sometimes he carried his imitation too far, as when he planted dead trees in Kensington gardens to give a greater air of truth to the scene, though he himself was one of the first to detect the folly of such an extreme. Kent's plans were designed rather with a view to immediate effect over a comparatively small area than with regard to any broader or subsequent results,—doubtless from landscape gardening being then but in its infancy.

KENTIGERN, ST (*c.* 516-603), popularly known as St Mungo, the apostle of Strathclyde and the restorer of Christianity among the Cumbrians, was, according to Jocelyn of Furness, the son of "the daughter of a certain king most pagan in his creed who ruled in the northern parts of Britannia." His mother, probably a nun, was, it is said, when with child sentenced to be thrown from one of the precipices of Dunpelder (Traprain Law, formerly Dumpender Law, in Haddington), but miraculously escaping was exposed in a boat to the mercy of the sea and landed on the sand at Culenross (Culross), where she gave birth to the child. On the spot where the boat reached land there was at one time a small chapel dedicated to St Kentigern. According to the tradition, St Servanus (who however, lived two hundred years after Kentigern) took special care of the mother and child, calling the mother Taneu (Thanew) and the child Kentigern, "head master or lord." Afterwards he also named him, on account of his intelligence and the graces of his character Munghu

(Mungo), "dearest friend." As, however, the favour with which he was regarded by Servanus had awakened the animosity of his fellow pupils, he secretly made his escape, and ultimately found his way to Cathures (Glasgow), near a cemetery which had been long consecrated to St. Ninian. There he dwelt for some time with two brothers named Telleyr and Anguen, when on account of the fame of his manner of life and his miraculous deeds the king and clergy of Cumbria, in order to restore the religion of Christianity to its former influence, called over a bishop from Ireland and caused Kentigern to be consecrated bishop. His cathedral seat he named Glasgu, "the dear family," where he collected a number of friends and disciples who practised continence and lived after the manner of the primitive church. On his life being threatened, he journeyed to Menevia (St. David's) in South Wales, where he founded the monastery of Llanelwy, afterwards St. Asaph's. When Roderick ascended the throne of Cumbria, Kentigern returned, and after establishing his see for some time at Hoddam, Dumfriesshire, he settled finally at Glasgow. He is said to have died on a Sunday, and as his saint's day is the 13th of January, he probably died in 603.

The fragment of a life of St. Kentigern, composed at the instance of Herbert, bishop of Glasgow, who died in 1164, and made use of by John of Fordun, is preserved in a manuscript of the British Museum. It was first printed by Cosmo Innes in the *Registrum Episcopatus Glasguensis*. A life written by Jocelyn, a monk of Furness, about 1180, exists in two MSS., one in the British Museum, the other in the public library of the archbishop of Dublin bound along with a life of St. Servanus in a small quarto volume. An abridgment of the life by Jocelyn was published by Capgrave in *Nova Legenda Angliæ*. The British Museum MS. was published by Pinkerton in the *Vitæ Antiquæ Sanctorum Scotiæ*. The second MS. has been published along with the anonymous fragment, and with translations of both, accompanied with learned notes by Bishop Forbes of Brechin, in vol. v. of *The Historians of Scotland*, 1874. Principally on the earlier fragment have been founded the legends of St. Kentigern and his friends and disciples in the Aberdeen Breviary, which have been published with translations and notes by Rev. William Stevenson, 1874. See also Skene's *Celtic Scotland*, vol. ii., and Montalembert's *Monks of the West*.

KENTUCKY.

KENTUCKY, one of the central States of the Mississippi Valley, in the United States of America, lies between the meridians of 82° 3′ and 89° 26′ W. lon., and between 36° 31′ and 39° 6′ N. lat. Its extreme length from east to west is 458 miles, and its greatest width from north to south is 172 miles. It is bounded on the north by Illinois, Indiana and Ohio, on the east by West Virginia and Virginia, on the south by Virginia and Tennessee, and on the west by Missouri. The area of the State, according to the census of 1880, is 40,400 square miles. The State lies within the Mississippi Valley, and with the exception of about 1,000 square miles, in the sub-valley of the Ohio.

Topography.—Kentucky is divided into two areas of unequal size—the table-land stretching east from the Mississippi and covering about 36,000 square miles; and the mountain district extending over the eastern and southeastern parts of the State. The rivers of the State plough deep furrows through this table-land, and the larger streams, in passing through it, have made for themselves valleys of erosion varying in depth at different points from 25 to 600 feet.

The topography of the State may be regarded as a succession of deeply incised river valleys, having a general northwestern and southeastern direction, with stretches of table-land between having an average elevation of 400 feet above the streams. These river valleys are seldom more than two miles in width. There are few hills in the table-land, although the high steep bluffs along some of the rivers appear like lofty hills from the valleys below. The mountains, in the southern and southeastern parts of the State, have the general characteristics of the Alleghany range; they are regularly recurring curves, quite narrow in width from east to west, but of great length from north to south; Pine Mountain, for example, has an average width of only five miles, while its length is seventy miles.

Rivers.—The State has a river boundary of about 813 miles. The Tug Fork, or main stream of the Big Sandy River, forms the boundary between Kentucky and West Virginia for 120 miles, from the summit of the Cumberland Mountains to Catlettsburg, where the Big Sandy flows into the Ohio. From this point, the Ohio River forms its northern boundary for 643 miles to Cairo, where that river joins the Mississippi. The Mississippi forms its western boundary for a distance of 50 miles. The Cumberland and Tennessee rivers, the two largest tributaries of the Ohio, both rise in the mountainous district of the State, within a few miles of each other, and after making a wide detour to the south, return to the State, and, crossing it, empty into the Ohio River not twenty miles apart. The other affluents of the Ohio are the Green, Salt, Kentucky, Licking, Little Sandy, Clark's and Tradewater rivers. The Mississippi receives a few small tributaries from the State. The Cumberland, Kentucky, Licking, Green and Big Sandy rivers also have tributary streams of considerable size.

Geology.—The geological formations of Kentucky belong to that great system which extends from the Alleghanies on the east, across the Mississippi, and to the Rocky Mountains on the west. Throughout this territory the primary fossiliferous, or Silurian, Devonian, and Carboniferous rocks prevail, with some of the upper formations. These rocks all belong to the class that is termed sedimentary, and they were generally deposited upon the bottom of the primeval ocean. The strata over almost the entire surface of Kentucky lie nearly horizontal, with a few dislocations. They have generally a slight dip. This dip, in the lower strata, seems to be usually in every direction from a point near Cincinnati, on the Ohio river, as a center. At this point the lowest surface rocks of the State are exposed. Up the Ohio River, the other strata in succession crop out, but sink beneath other rocks as they extend eastward, and rise again to the surface on the western slope of the Alleghanies. Down the river, the same succession of rocks is seen, but dipping to the west. In the interior of the State, the rocks dip to the south. Cincinnati seems thus to have been a center of elevation, when this central region was lifted above the waters of the ocean.

First Formation—The Blue Limestone.

The blue limestone formation, which is the lowest exposed in Kentucky, has usually been considered equivalent to the lower Silurian strata of Murchison. In this region it is almost entirely calcareous, being generally composed of thin beds of dark blue-gray fossiliferous limestone, alternating with thin layers of marly shale, or clay; or, in its lower members, such as are exhibited on the Kentucky River at Frankfort, and at several other places on the river above for many miles, appearing in more massive, thick layers of buff granular magnesian limestone—an excellent building stone—and the light bluish-gray or yellowish, brittle and sparry layers, which has been called Kentucky marble, and polished for ornamental and useful purposes. It is believed that what has been called in Ohio and Kentucky the blue limestone formation commences above, with the equivalents of the Hudson River group and the Utica slate, of the New York geologists, and continues downward, in its equivalency, including their Trenton, Black River, Bird's-eye and Chazy limestones, to the equivalent of their calciferous sandstone, which is probably the same as the buff magnesian limestone above mentioned. The so-called Kentucky marble bears a close resemblance to the New York Bird's-eye limestone. This blue limestone formation is one of great importance in Kentucky, as it is the basis of the far-famed blue-grass lands. The main surface exposure of this formation covers a great curved triangular area, having its base on the Ohio River, and its southern apex in Lincoln county, from which only a narrow strip, or axis, occasionally to be observed in the deep cuts of the valleys, can be traced through Casey, Russell and Cumberland counties, to the Cumberland River, in Monroe county. A remarkable fault, or dislocation of the strata of this formation, is found along the great south bend of the Kentucky River, in Madison, Jessamine, Garrard and Mercer counties, and elsewhere, in which the strata on one side of the river stand 350 feet higher than the corresponding ones on the opposite side. This remarkable crack and upheaval, or subsidence of the strata, not only locally altered the dip of the rocks to the north, but changed the topographical configuration, as well as the geological and agricultural features of this region. Here "the so-called Kentucky marble, rising in bold escarpments of 200 to 300 feet," hems in the Kentucky River, and with the superincumbent layers of limestone, makes picturesque bluffs of 400 feet elevation.

On the Ohio River are found the termini of the gray limestone, or cliff limestone formation—always overlying the blue limestone—near the confines of Lewis and Mason counties above, and near those of Trimble and Oldham counties below. From these two points this formation appears as a belt, varying from 22 miles in width, in Jefferson county, to only a fraction of a mile where it enters Tennessee from Monroe county, running in a course more or less meandering from its two termini on the Ohio around the blue limestone formation. Its dip corresponds generally with that of this lower formation. This formation—called by the Ohio geologists "cliff limestone," because the hardness and durability of some of its layers cause it to stand out in bold cliffs, and to be the cause of the falls of water courses—is, in its lower beds, undoubtedly equivalent with the upper Silurian strata of Murchison, and in its upper layers with some portion of his Devonian. In comparison with the New York system, this Kentucky formation appears to stand in the place of a large group of twelve or thirteen important strata of the New York system, comprising sandstones, shales and limestones, extending from the Clinton group, or Niagara group below, to the upper Hilderberg limestone above.

Second Formation—The Gray Limestone, or Cliff Limestone.

This second formation can be examined with great advantage at the Falls of the Ohio when the water is low. The chain coral limestone, which is the lowest, is seen near Beargrass Creek, in Jefferson county; and the coralline falls limestone is beautifully developed, and its numerous corals and other fossils are exposed to view in a silicified coral reef of the Ohio Falls. This coral limestone, about fifty feet in thickness, is capped with an earthy magnesian limestone, which possesses hydraulic properties, and is extensively manufactured into water cements at the falls. Other layers of this formation are magnesian, and furnish some of the best building stones in the State. The general color of the rocks of this formation is light bluish, or greenish-gray, or light-gray buff.

Third Formation—Black Lingula Shale; Black Slate, or Shale; Devonian Shale.

The third formation, resting immediately on the second formation, appears also on the Ohio River at two points—in Lewis county, between the mouth of Quick's and Salt Lick creeks, above, and at the base of the falls of that river, in Jefferson county, below. From these two points, where the Ohio River cuts through these strata, as they pass to the north and west, this formation, like the one below it, sweeps around the gray limestone in a meandering, irregular belt, varying in breadth from eight to ten miles, in parts of Lewis, Bath, Estill and Madison counties, to that of a fraction of a mile, in Casey, Russell, Cumberland and Monroe counties. Like the second formation, it passes into the State of Tennessee, near the Turkey Neck bend of the Cumberland River, in two neighboring narrow zones, lying on each side of the axis described under the head of the first formation; and its two zones, nearly parallel in their northeastwardly course from the Tennessee line to the confines of Lincoln county, begin here to diverge, like those of the second formation, so as to surround and invest that lower formation. Its thickness at the Falls of the Ohio is a little over one hundred feet, but it varies greatly in this respect. This shale is generally quite bituminous, but no workable beds of this mineral have ever been found so low in the strata of the earth as this in America. When this formation sweeps around, bounded on one side by the lower limestones, and on the other by the sandstones which form the "knobs," the land is generally low, wet and heavy, and mineral springs abound. Petroleum has been found in this formation, as well as in the formations below and above it. This black shale of Kentucky is supposed to represent, in the geological strata, the Marcellus, Hamilton and Genessee groups of New York.

Fourth Formation—Knob Sandstone.

This fourth Kentucky formation, which is generally characterized by the presence of those low hills called "knobs," is mainly composed of olive-gray shales, and grits of sandstones of the same tint. It is calculated to be 350 to 550 feet in thickness, and some of the knobs—as for example, the "Sweet Lick knob" of Estill county—rise 500 feet above the level of the streams. This formation also sweeps around the central and lower formations, on the outside of and above the black shale, very much in the same course as already described. The Ohio River valley cuts it in the eastern part of Lewis county above, and in Jefferson county at the base of the falls below. The harder silicious beds of this formation are found very valuable for building purposes and for grindstones. It is very much quarried in Lewis county, as well as in Ohio, where it is called Waverly sandstone. A peculiar *fucoid* fossil, spreading like the tail feathers of a cock, characterizes some of these layers, which are supposed also to belong to the Devonian formation.

Fifth Formation—Cavernous Limestone; Sub-Carboniferous Limestone; Mountain Limestone.

This fifth formation is made up of alternating layers of white, gray, reddish, buff, and sometimes dark-gray colored rocks, varying in quality from the most argillaceous clay stone to the purest limestone. Limestones predominate, however, which, in the southern part of the State, contain numerous caves, of which the celebrated Mammoth Cave, of Edmonson county, is one, and causing many "sinks," in which the drainage water of the country sinks to form underground streams. Clear and copious springs mark the junction of this limestone with the underlying knobstone; and its lower strata contain in many places the dark, flinty pebbles which furnished the arrow heads and various implements of the aborigines. Some of its layers are so compact and close-textured, that they are fit for the lithographer; others are beautifully white, with an oölitic structure. In it are found valuable beds of iron ore, some zinc and lead ore, and large veins of fluor spar. The so-called Barrens of Kentucky are located on this formation; so named, not because the soil is infertile, but on account of the numerous sinks and the former absence of timber. This region, which was an open prairie when Kentucky was first settled, is now covered with forests. Its land is found to be quite productive. This formation is geologically important, as it is the basis of the true coal measures; no workable beds of that mineral have ever been found below this formation in any part of the world. It surrounds the coal fields on all sides, and, like the other lower formations, is believed to extend continuously under them. In Kentucky, its principal surface exposure is in the central portion of the State. The counties of Adair, Allen, Barren, Green, Warren, Logan, Simpson and much of Hart, Edmonson, Todd, Trigg, Christian, Caldwell, Crittenden, Monroe, Butler, Grayson, Ohio, Taylor and Larue, are mainly based upon it. It comes to the Ohio River in Breckenridge and Meade counties in its lower sweep, and in Greenup county in its upper; skirting the western edges of the great eastern coal field down to the Cumberland River.

Sixth Formation—The Carboniferous, or The Coal Measures.

The lower member of this formation, resting on the sub-carboniferous limestone, is usually what is called the *conglomerate, millstone grit*, or *pudding stone*. Its thickness varies from 75 to 300 feet. Two or three workable beds of very good coal are found beneath this formation and above the sub-carboniferous limestone. These are called the *sub-conglomerate coals*. Iron ore is occasionally found with these lower coal beds. The *true coal series*, based upon this rock, are made up of alternating layers of sandstones, shales, conglomerates and limestones, containing various beds of coal, and nodules, and layers of iron ore. Kentucky has two extensive coal fields, one called the eastern coal field, including the whole of that part of the State which lies east of a line running southwest from the Ohio River at Greenupsburg, through Monticello, in Wayne county, to the Tennessee boundary. The other, called the western coal field, occupies the whole of Union, Henderson, Daviess and Hopkins counties, and large portions of Hancock, Ohio, Muhlenburg, Grayson, Todd and Butler counties. It is an extension of the Illinois and Indiana coal field across the Ohio River. The area of the eastern coal field is 8,983 square miles; that of the western is 3,888 square miles. All this immense mineral wealth, as well as that of the abundant iron ores and other minerals of these regions, is as yet but lightly appreciated and feebly developed, lying as it does mostly in the portions of the State that have been measurably neglected. The coals of Kentucky are various in quality, ranging from soft bituminous or coking coal, to splint and cannel coal. Much of it is pure enough to be used for the smelting of iron, like that celebrated block coal of Indiana. These coals are generally quite accessible.

Seventh Formation—The Quaternary Deposits.

There remain the Quaternary deposits to describe. These are loams, marls, clays, etc., found, principally, as a superficial layer in the extreme southwestern counties of the Jackson purchase, situated between the Tennessee and Mississippi rivers. These loams have probably been transported there by the action of water in recent geological time. They are of but little importance, although they contain some local beds of lignite, and the remains of some extinct animals. The soil upon them is generally good.

Minerals.

The coal beds have already been described under the sixth formation. There are several varieties of iron ore found in the State. 1st. The ore of the coal measures. This ore is found in layers, or else in courses of nodules, in the shales or sandstones of the coal fields and is generally an hydrated peroxide of iron. When found in layers, it is readily broken into rectangular blocks; otherwise it is taken from the mine in round lumps of various sizes. 2d. The ore found in connection with the limestone underlying the coal measures. This ore is very abundant, and is extensively worked for furnaces. 3d. The ore of the slate formation. This ore, too, is very abundant, and is found either in continuous strata, or in layers of nodules, in the slate of the third formation. It seems to be a calcareous and argillaceous carbonate of iron and limonite. In many places where the slate has been crumbled to pieces and washed away, it is found abundantly on the surface. All the above ores are worked, more or less extensively, for the furnaces in various sections of the State. Like the coal, the iron in every part of Kentucky is very accessible. The iron district covers about 20,000 square miles, penetrated in every direction by navigable streams, and everywhere accompanied by the fuel necessary for its reduction. In a number of localities veins of lead ore have been found in the blue limestone, but nowhere yet in such abundance as to justify mining operations. The cliff limestone and the cavernous limestone do not appear to be sufficiently developed in Kentucky to furnish any rich veins of this metal. Many salt springs or licks are found in the State. The early deposital rocks were laid down in shallow waters, and absorbed considerable quantities of salt from the brine. In time, springs impregnated with this saline deposit found their way to the surface, usually in some marshy valley. Thither the herbivorous mammals naturally resorted to lick the salt, which had crystallized around the springs. As this practice must have continued for many thousands of years, vast quantities of the remains of these animals are found in the vicinity of these springs. The most remarkable locality of this kind is at Big Bone Lick, in Boone county. Here a large number of bones, perfectly sound and well preserved, have been dug up; the skeletons of the buffalo and deer, and below those of the elephant, the mastodon and mammoth, the fossil elk and a species of musk ox, are among those that have been exhumed. The mineral springs are numerous and various, some of them containing considerable quantities of sulphur. Hydraulic limestone is found in many places in the State, and almost always where shaley argillaceous layers alternate with beds of limestone. Gypsum has not yet been developed in any large quantities, although found in many places. Nitrates are yet to be obtained from the limestone caves, but the manufacture of nitre from them is not now profitable. Silver ore has been found near Cumberland Falls. The caverns of the State form one of its peculiar and most interesting features. Mammoth Cave is the most widely known of the thousands in the State, though possibly not the largest.* These caves occur throughout the entire extent of the sub-carboniferous limestone, covering a region of 5,000 to 8,000 square miles. They are numerous in the region drained by the Green River and its affluents, and it is generally believed that they underlie almost the whole district. In some localities the roofs of the caverns have broken away, precipitating tracts from 50 to 150 feet in diameter, to the floor of the cavern, often 200 or 300 feet below. In some instances these sink holes become partially filled with water; in others the shrubs and trees continue to grow.

Climate.—The climate of the State is somewhat variable, but on the whole mild and pleasant. The mean annual temperature is about 55° Fahr. In winter the mercury occasionally falls to zero, and even below, while in summer it rises to 94°, and at times to 100°. Winter usually continues from the end of November to the beginning of April, but the snows are light and seldom remain long on the ground. Kentucky lies in the district where the annual rainfall is about fifty inches, and its average annual rainfall for thirty years was 50.3 inches. The rainfall is greatest in the Cumberland mountains.

Soils and Vegetation.—As the last glacial period did not extend its sheet of ice over Kentucky, but stayed its course a few miles north of the Ohio River, the State has not the same gravelly soils which characterize the country where the glacier deposited the *debris* of widely separated rocks. The soil of the entire blue grass region may be called a soil of immediate derivation, as it is formed by the disintegration of the rocks of the blue limestone formation. The atmospheric waters, always containing carbonic acid and other solvents have gradually dissolved the upper layers of the limestone in the long course of geological time; leaving the earthy residuum to constitute the soil. This process, still continually going on while it makes the water of all the springs and wells of this region very hard, from the quantity of dissolved limestone it contains, is also the principal means by which the blue-grass soil measureably maintains its productiveness. For the shelly blue limestone is rich in the mineral elements necessary to vegetable growth, and the watery solution of them is continually pervading the soil. But this favored soil presents other conditions of fertility rarely found naturally associated. It is almost perfectly under-drained by the cliffs and caverns in the silurian limestone on which it rests. It has a sub-soil more rich in mineral fertilizers than it is itself. Not only is its chemical composition suitable to productiveness, but the fineness of its texture gives to it great power of absorption of the gases and vapors of the atmosphere for the food of plants, while its great porosity allows excess of water to penetrate it with the greatest facility. Added to these conditions, a favorable climate and suitable meteorological conditions combine to complete its productiveness. The earliest pioneers to Kentucky spoke of the wonderful luxuriance of its vegetable growth, especially in what has since been called the "Blue-grass Region;" and yet, although more than a hundred years have elapsed, and this soil has in many localities been severely taxed by the incessant production of crops, it still exhibits an almost unprecedented fertility, manifested not only in the enormous growth of its staple and vegetable products, but in the finer development of the animals. The region of the sub-carboniferous limestone owes its fertility, which is almost equal to that of the blue-grass country, to the same cause—the disintegration of fossiliferous limestone. These two districts embrace about three-sevenths of the area of the State. The rest of the soil is not so well adapted to the culture of grain and the best grasses. The soils underlaid by the beds between the blue limestone and the carboniferous formations are of average fertility. Within the carboniferous areas the soils are well adapted both for tobacco and fruit culture. With proper care they will produce any crops suited to this climatic belt. But all these lands require a fair quantity of manure, which the blue-grass country does not need. The various kinds of forests in Kentucky manifest the peculiarity of the soils.

Probably two-thirds of the State is still covered by virgin forests of valuable timbers. On the sub-carboniferous limestone there are grand forests on the uplands of the blue ash (*Fraxinus quadrangulata*), and the black walnut (*Juglans nigra*). In other localities are found the yellow poplar (*Liriodendron tulipifera*), white oak (*Q. alba*), and the hickories. Rich but less fertile soils have large forests of beech (*Fagus ferruginea*). In the sandstone soils the forests are of oak, of which there are six or seven species. Other trees on the lower rocks of the lower silurian formation are the black ash (*Fraxinus sambucifolia*) and the shell-bark hickory (*Carya alba*). The open parks, which form so unique a feature of the blue-grass country, are principally of the sugar maple (*Acer saccharinum*), blue ash, pignut hickory, (*C. glabra*), black walnut, mulberry (*Morus rubra*), box elder (*Negundo aceroides*), hackberry (*Celtis occidentalis*), buckeye (*Aesculus glabra*), honey locust (*Gleditschia triacanthus*), and Kentucky coffee-tree (*Gymnocladus*). In the richer lowlands are extensive forests of the tulip tree and the sweet gum (*Liquidambar styraciflua*.) The cypress (*Taxodium distichum*) is found in the swamps of the southwestern part of the State. Limited areas of pine (*Pinus mitis*) occur in the mountainous district of eastern Kentucky. The above named species constitute the most important forest trees in the State. When the State was first settled by the whites, a tract of about 7,000 square miles, known as the "Barrens," lying between the Ohio River and the Tennessee line, and between the 85th and 87th meridians, was open prairie land, having no trees except along the streams. Here only the roots of certain hardy trees had withstood the annual burning of the grass by the Indians. On the suppression of these fires, the saplings springing from these roots soon grew into trees, and this region soon became densely wooded wherever it was not under cultivation.

Agriculture.—Agriculture has been the chief occupation of the people of Kentucky since its first settlement by Virginia and Maryland agriculturists. Kentucky should be one of the best agricultural States in the Union because of the great extent of very fertile soil, its capacity for producing a great diversity of crops, and its excellent facilities for conveying its crops to the best markets. In fact, since 1810, Kentucky has always taken first rank among the States in one or more cereal productions. Still, these great advantages have not been so fully utilized as they might have been, and while Kentucky's position is very creditable, it is to be hoped that the State will soon take the place in agricultural production that belongs to it. Kentucky is the principle tobacco growing State in the Union. Over a third of the total yield in the United States during the year 1880 was credited to Kentucky. Hemp has been raised in Kentucky ever since its first settlement, especially on the blue-grass lands. The yield for 1880 was about 15,000 tons.

The following table gives the farm statistics of Kentucky for the census years 1850-1880:

YEAR.	TOTAL NUMBER OF FARMS.	TOTAL LANDS IN FARMS—ACRES.	IMPROVED LAND FARMS—ACRES.	AVERAGE SIZE OF FARMS—ACRES.	VALUE OF FARMS.	VALUE OF FARMING IMPLEMENTS AND MACHINERY.
1850	74,777	16,949,748	5,968,270	227	$155,021,262	$5,169,037
1860	90,814	19,163,261	7,644,208	211	291,496,955	7,474,573
1870	118,422	18,660,106	8,103,850	158	311,238,960	8,572,896
1880	166,453	21,495,240	10,731,683	129	299,298,631	9,734,634

Following is a table giving general statistics of agriculture for the State of Kentucky in the census years 1850–1880:

YEAR.	TOBACCO—Pounds.	IRISH POTATOES—Bushels.	SWEET POTATOES—Bushels.	VALUE OF LIVE STOCK.	HORSES—Number.	MILCH COWS—Number.	SHEEP—Number.	BUTTER—Pounds.	CHEESE—Pounds.
1850	55,501,196	1,492,487	998,179	$29,661,436	315,682	247,475	1,102,091	9,947,523	213,954
1860	108,126,840	1,756,531	1,057,557	61,868,237	355,701	269,215	938,990	11,716,609	190,400
1870	105,305,869	2,391,062	802,114	66,287,343	317,034	247,615	936,765	11,874,978	115,219
1880	171,120,784	2,269,890	1,017,851	49,670,567	372,648	301,882	1,000,269	18,211,904	58,468

YEAR.	BARLEY—Bushels.	BUCKWHEAT—Bushels.	INDIAN CORN—Bushels.	OATS—Bushels.	RYE—Bushels.	WHEAT—Bushels.	COTTON—Bales.	WOOL—Pounds.	HAY—Tons
1850	95,343	16,097	58,672,591	8,201,311	415,073	2,142,822	758	2,297,433	113,747
1860	270,685	18,928	64,043,633	4,617,029	1,055,260	7,394,809		2,329,105	158,476
1870	238,486	3,443	50,091,006	6,620,103	1,108,933	5,728,704	1,080	2,234,450	204,399
1880	486,326	9,942	72,852,263	4,580,738	668,050	11,356,113	1,367	4,592,576	218,739

* See article on *Mammoth Cave*.

The Kentucky-bred horses are known the world over. This preeminence in the raising of fine stock is due in large measure to the excellence of the blue-grass pasture lands, to the water, and to the climate.

Manufactures.—Kentucky is far behind many of the other States in the extent and variety of its manufactures, although it possesses the best and most lasting water powers in the world, and an abundant supply of coal to generate steam. The greatest increase within a few years has been in the manufacture of corn whisky. In 1880, there were 5,328 mechanical and manufacturing establishments in the State, employing a capital of $45,813,039. The total number of operatives employed was 37,391, of whom 30,949 were males above 16 years, 3,529 females above 15 years, and 2,913 were children and youths. The total amount paid in wages during the year was $11,657,844; the value of materials was $47,461,890; the value of products was $75,483,377.

Railways.—In 1841, there were but 28 miles of railroad in the State, and there was no increase until after 1848. The first road built was in 1831–1834, from Frankfort to Lexington. The most important road at the present time is the Louisville and Nashville, having a length of 436 miles. In 1886* the total length of line of the railroads in the State was 2,763 miles; the length of line operated was 1,934 miles; the capital stock was $75,195,472; the bonded debt, $114,569,254; the unfunded debt, $2,795,708; the cost of railroads and equipment, $158,543,588. The gross earnings from all sources were $11,889,225; the net earnings, $4,653,894.

Population.—In 1880 the population was 1,648,690. The following table shows the population at each census, 1790–1880.

CENSUS YEAR.	WHITE.	FREE COLORED.	SLAVES.	TOTAL.	MALE.	FEMALE.	NATIVE.	FOREIGN.
1790	61,133	114	12,430	73,677	* 32,211	* 28,922	....	.....
1800	179,873	739	40,343	220,955	* 93,956	* 85,915	....	.....
1810	324,237	1,713	80,561	406,511	*168,805	*155,432	....	.....
1820	434,644	2,759	126,732	364,135	293,192	275,125	....	.....
1830	517,787	4,917	165,213	687,917	352,084	335,833	....	.....
1840	590,253	7,317	182,258	779,828	400,088	379,740	. .	..
1850	761,413	10,011	210,981	982,405	502,730	479,675	949,652	31,420
1860	919,484	10,684	225,483	1,155,684	592,321	563,363	1,095,885	59,799
1870	1,098,692	222,210	.....	1,321,011	665,675	655,336	1,257,613	63,398
1880	1,377,179	271,451	.....	1,648,690	832,590	816,100	1,589,173	59,517

* Whites only, enumerated.

1890, the whole population was 1,858,635.

In 1880, there were 41.2 persons to the square mile. The following cities and towns had a population exceeding 4,000 in 1880:

Louisville	132,758	Owensboro	6,231
Covington	29,720	Henderson	5,365
Newport	20,433	Maysville	5,220
Lexington	16,656	Bowling Green	5,114
Paducah	8,036	Hopkinsville	4,229
Frankfort	6,985		

Frankfort is the State capital.

Government, Taxation, etc.—The present constitution of Kentucky was adopted in 1850. The governor, lieutenant-governor, auditor, attorney-general, and superintendent of public instruction, are elected by the people for the term of four years. The governor cannot be his own successor. Senators, 38 in number, are elected from single districts for four years, one-half every two years. Representatives, 100 in number, are elected for two years from single districts. Sessions of the assembly are biennial. The court of appeals is the supreme court of the State. There are also circuit, county and justices' courts. Kentucky is entitled to eleven representatives in Congress. For the year ending October 10, 1880, the gross receipts were $2,445,404, and the gross expenditure, $2,379,343. On July 1, 1887, Kentucky had a funded debt of $680,394, and an unfunded debt of $500,000, but as the State had $530,650 in a sinking fund, it was practically out of debt. The amount raised by taxation in the year ending July 1, 1887, was $2,851,125; the amount of real taxable property, as assessed, was $351,157,063; of personal property, $166,057,238; the taxation on $100 was 47½ cents. During the year 1885–86, the State expended $700,790 on its public schools.

History.—Kentucky was first explored by the Anglo-Saxon race, about the middle of the eighteenth century. It then formed a vast hunting ground, upon which the savage tribes of the south and north killed the elk and buffalo, and occasionally encountered each other in bloody conflict. No permanent settlements existed within its borders. Its dark forests and cane thickets separated the Indian tribes of the Cherokees, Creeks and Catawbas of the south, from the hostile tribes of Shawnees, Delawares and Wyandots of the north. Each and all of these tribes encountered the Anglo-American pioneer, and fiercely disputed the settlement of the country. It is certain, however, that these were not the original occupants of the country lying between the Alleghanies and the Mississippi. Ancient monuments of deep interest, but as yet imperfectly investigated, speak, in unmistaken language, of a race of men who preceded the rude tribes encountered by Boone and Finley. Their origin, language and history are buried in darkness, which, perhaps, may never be dispelled; but the few vestiges they have left behind them enable us to affirm with confidence, that they far surpassed the rude tribes which succeeded them, in arts, civilization and knowledge. They had worked the copper mines of the west, and were in possession of copper tools for use upon wood and stone. Their pipes, and elaborately fashioned household utensils of clay, are far above the rude and clumsy contrivances of their successors; while their large fortifications, constructed of solid masonry and artificially contrived for defense and convenience, show that they had foes to resist, and that they had made considerable progress in the military art. How long they inhabited the country, whence they came, whither they have gone, the present state of our knowledge does not enable us to decide. In relation to time, we can only affirm that the fortifications and cemeteries which have been examined are certainly more than eight hundred years old, but how much older they may be, can only be conjectured. In 1769, Daniel Boone, a native of Pennsylvania, then living in North Carolina, led a company of men into Kentucky and established a settlement where now is Boonesboro. In 1770, Col. James Knox, with a party called the "Long Hunters," explored the middle and southern region of Kentucky. In 1773, Capt. Thomas Bullitt led a party of surveyors down the Ohio to the falls. During this expedition many surveys were executed in Kentucky, and large portions of the country explored, with a view to future settlement. Within the next four or five years other pioneers settled in the territory, and among them such men as Harrod, Henderson, Kenton, Calloway and Logan, all of whom identified themselves with the subsequent history of the State. On May 23, 1775, the settlers, most of whom were from Virginia, met at Boonesboro, and in convention organized themselves as the "Assembly of Transylvania." They passed laws, established courts, and enrolled a militia force; but the Virginia legislature declared their acts null and void, though grants of land were made to these pioneers. In 1776, Kentucky was formed into a county by the legislature of Virginia, embracing all that country between the Big Sandy River and the Mississippi. The county thus became entitled to a separate county court, two justices of the peace, a sheriff, constables, coroner and militia officers. In the spring of 1777 the court of quarter sessions held its first sitting at Harrodsburgh. During the Revolutionary war the settlers increased rapidly in number. Encounters with the Indians were frequent, and the settlers had to go constantly armed. On August 19, 1782, Major McGary led 160 men in a fierce assault upon a band of about 600 Indians, near Blue Lick Springs. The whites were routed. Colonel Boone, who was prominent in the encounter, lost a son in it. Sixty other whites were killed. In the spring of 1783, Kentucky was erected into a district, and a court of criminal, as well as civil, jurisdiction, co-extensive with the district, was erected. In 1784, the people of the district urged that they might be recognized as a State, and that Kentucky might thus become an independent member of the Confederacy. Repeated conventions were held in 1785, 1786 and 1787, and in 1785 the Virginia legislature passed an ordinance granting a separate organization, but with conditions that caused discontent and delay. In January, 1787, a convention was called, in which the people agreed to form a state and adopt a constitution. But Virginia interposed obstacles, and the Spanish viceroy in Louisville and emissaries from Canada attempted to draw away the district from its allegiance to the Union. Just when the prospect seemed fair for a settlement of the difficulties with Virginia, the intelligence was brought that the Constitution of the United States had been accepted and ratified, that the old Congress had declined to act upon the petition of Kentucky, and had referred the question to the new government. A convention—the eighth—assembled in July, 1790, and formally accepted the Virginia act of separation, which thus became a compact between Virginia and Kentucky. A memorial to the President of the United States and to Congress was adopted in December, 1790. President Washington strongly recommended to Congress to admit Kentucky into the Union. On the 4th of February, 1791, an act for that purpose had passed both houses, and received the signature of the President. In December, 1791, the ninth and last convention was elected, which assembled at Danville in April following, and formed the first constitution of Kentucky—under which Kentucky was admitted to the Union as a State on June 1, 1792. At this time the population was about 74,000. Within the next ten years it increased 30 per cent. In the war of 1812, Kentucky took an honorable part, though she suffered a heavy loss in the defeat at the River Raisin and in the barbarous massacre which followed it, and 800 of her best citizens were sacrificed in the miserably managed attempt to relieve Fort Meigs. After the close of the war, the civil history of Kentucky is memorable for the dreadful monetary derangement which led to the passage of the relief laws, and gave rise to the most embittered and violent conflict of parties which has ever occurred in Kentucky. The contest, known as the "Old Court and New Court Controversy," virtually involved the question of repudiation of a debt of doubtful legality by the State. It was at length decided by the maintenance of the State's obligations, though they had been obtained by fraud. In 1820, the total population of Kentucky was 565,317, an increase of 36½ per cent. since 1810. In the Mexican war, the State sent 13,700 men to the field in response to the governor's call for 5,000. In this war the gallant conduct of Kentucky's troops won them lasting renown. In the late civil war Kentucky attempted to maintain a neutral position. On April 16, 1861, the governor refused to furnish the troops demanded by the Federal Government. After the invasion of the Southern troops, in August, 1861, the legislature, after a very exciting discussion, gave its adhesion to the Union, November 27, 1861. The Federal forces held the State almost continually from the beginning to the end of the war, and 91,900 men, in all, were recruited from it for the Federal armies. The State furnished the battlefields for several actions, such as those of Mill Spring, Perryville, and Richmond. About 40,000 Kentuckians joined the Confederate forces. The State suffered from the passage of large forces of hostile troops across its territory, and from repeated raids into and through the State. At the close of the war, the laws passed during the excitement of those times were wiped from the statute-book, and the governor led public sentiment in the effort to grant practical amnesty for the past. Kentucky refused to ratify the fourteenth and fifteenth amendments to the Constitution.

(E. H. F.)

* From Poor's Manual of the Railroads of the United States for 1887.

KENYON, LLOYD KENYON, LORD (1732–1802), an English lawyer and lord chief-justice of England, was descended by his father's side from an old Lancashire family, and his mother was the daughter of a small proprietor in Wales. He was born at Gredington, Flintshire, 5th October 1732. After studying five years at Ruthin grammar school, he was in his fifteenth year articled to an attorney at Nantwich, Cheshire. In 1750 he was entered a student of Lincoln's Inn, London, and in 1756 was called to the bar. As for several years he was left almost unemployed, he utilized his leisure in taking notes of the cases argued in the court of Queen's Bench, which he afterwards published. Through answering the cases of his friend John Dunning, afterwards Lord Ashburton, he gradually became known to the attorneys, after which his success was so rapid that in 1780 he was made king's counsel, his promotion being assisted to some extent through his friendship with Thurlow. He manifested conspicuous ability in the cross-examination of the witnesses at the trial of Lord George Gordon, but his speech was so deficient in tact that the verdict of acquittal was solely due to the extraordinary and brilliant effort of Erskine, the junior counsel. Through the influence of Lord Thurlow, Kenyon in September 1780 entered the House of Commons as member for Hindon, and in April 1782 he was, through the same friendship, appointed attorney-general in Lord Buckingham's administration, an office which he also continued to hold under Pitt. In 1784 he received the mastership of the rolls, and was created a baronet. His position at the bar had been achieved chiefly by hard work, a good knowledge of law, and several lucky friendships. As an advocate he was not only deficient in manner and in ability of statement, but frequently made striking blunders from want of tact. As his rough and irritable temper had also gained him several enemies, his elevation in 1788 to the lord chief-justiceship as successor to Lord Mansfield was by no means popular with the bar. The same year he was raised to the peerage as Baron Kenyon of Gredington. On the bench he not unfrequently displayed a capricious and choleric temper towards both the pleaders and his brother judges. Still he proved himself, not only an able lawyer, but a judge of rare and inflexible impartiality. The decisions of no other judge in the court of Queen's Bench have been more seldom overruled, but, as they were accompanied with only a very imperfect and short statement of his reasons, his judgments are of little value as expositions of the principles of law. He died at Bath, 4th April 1802. See *Life* by Hon. G. T. Kenyon, 1873.

KEOKUK, chief city of Lee county, Iowa, U.S., occupies a lofty site on the west bank of the Mississippi, 2 miles above the mouth of the Des Moines tributary, and about 200 miles above St Louis. It is situated in the extreme south-east corner of the State (whence its name "gate city"); its streets are spacious, and its houses handsome, although mostly of brick. Keokuk contains several churches, a medical college (founded in 1849), a good system of public schools, and a public library. Pork-packing, iron-founding, and smaller industries are carried on. The city is at the junction of seven railways, which, with its advantages of water communication, bring it an important trade. A canal, 9 miles in length, round the lower rapids of the Mississippi, which formerly obstructed the navigation, has been constructed by the United States Government at a cost of $8,000,000. Keokuk has been a port of entry since 1854. Population in 1880, 12,117.

KEPLER, JOHN (1571–1630), one of the founders of modern astronomy, was born, December 27, 1571, at Weil, in the duchy of Würtemberg, of which town his grandfather was burgomaster. He was the eldest child of an ill-assorted and ill-starred union. His father, Henry Kepler, was a reckless soldier of fortune; his mother, Catherine Guldenmann, the daughter of a small proprietor of Leonberg, had a violent temper, unmitigated by even the rudiments of culture. Under these circumstances her husband found campaigning in Flanders under Alva a welcome relief from domestic life; and, after having lost his fortune by a forfeited security and tried without success the trade of tavern-keeping in the village of Elmendingen, he finally, in 1589, severed an irksome tie by the desertion of his family. The misfortune and misconduct of his parents were not the only troubles of young Kepler's childhood. He recovered from small-pox in his fourth year with crippled hands and eyesight permanently impaired; and a constitution enfeebled by premature birth had to withstand successive shocks of severe illness. His schooling began at Leonberg in 1577—the year, as he himself tells us, of a great comet; domestic bankruptcy, however, occasioned his transference to field-work, in which he was exclusively employed for several years. Bodily infirmity, combined with mental aptitude, were eventually considered to indicate a theological vocation; he was accordingly, in 1584, placed at the seminary of Adelberg, and thence removed, two years later, to that of Maulbronn. A brilliant examination for the degree of bachelor procured him, in 1588 admittance on the foundation to the university of Tübingen, where he laid up a copious store of classical erudition, and imbibed Copernican principles from the private instructions of his teacher and life-long friend, Michael Maestlin. As yet, however, he had little knowledge of, and less inclination for, astronomy; and it was with extreme reluctance that he turned aside from the more promising career of the ministry to accept, early in 1594, the vacant chair of that science at Gratz, placed at the disposal of the Tübingen professors by the Lutheran states of Styria.

The best-recognized function of German astronomers in that day was the construction of prophesying almanacs, greedily bought by a credulous public, and quickly belied by the future they pretended to disclose. Kepler thus found that the first duties required of him were of an astrological nature, and set himself with characteristic alacrity to master the rules of the art as laid down by Ptolemy and Cardan. He, moreover, sought in the events of his own life a verification of the theory of planetary influences; and it is to this practice that we owe the summary record of each year's occurrences which, continued almost to his death, affords for his biography a slight but sure foundation. His thoughts, however, were already working in a higher sphere. He early attained to the settled conviction that for the actual disposition of the solar system some abstract intelligible reason must exist, and this, after much meditation, he believed himself to have found in an imaginary relation between the "five regular solids" and the number and distances of the planets. He notes with exultation July 9, 1595, as the date of the pseudo-discovery, the publication of which in *Prodromus Dissertationum Cosmographicarum seu Mysterium Cosmographicum* (Tübingen, 1596) procured him much fame, and a friendly correspondence with the two most eminent astronomers of the time, Tycho Brahe and Galileo.

Soon after his arrival at Gratz, Kepler contracted an engagement with Barbara Von Mühleck, a wealthy Styrian heiress, who, at the age of twenty-three, had already survived one husband and been divorced from another. Before her relatives could be brought to countenance his pretensions, Kepler was obliged to undertake a journey to Würtemberg to obtain documentary evidence of the somewhat obscure nobility of his family, and it was thus not until April 27, 1597, that the marriage was celebrated. In the following year the archduke Ferdinand, on assuming the government of his hereditary dominions, issued an edict of banishment against Protestant preachers and professors. Kepler immediately fled to the Hungarian frontier, but, by the favour of the Jesuits, was recalled and reinstated in his post. The gymnasium, however, was deserted; the nobles of Styria began to murmur at subsidizing a teacher without pupils; and he found it prudent to look elsewhere for employment. He first turned to his native country; but his refusal to subscribe unconditionally to the rigid formula of belief adopted by the theologians of Tübingen permanently closed against him the gates of his *alma mater*. His embarrassment was relieved by a letter from Tycho Brahe offering him the position of assistant in his observatory near Prague, which, after a preliminary visit of four months, he accepted. The arrangement was made just in time; for on August 7, 1600, he received definitive notice to leave Gratz, and, having leased his wife's property, departed with his family for Prague, September 30. His relations with Tycho were not of an entirely agreeable character. The Danish astronomer, though benevolent, was haughty and overbearing; Kepler's natural irritability was aggravated by prolonged fever, by pecuniary anxieties, and by domestic mismanagement. Nevertheless, after one violent quarrel, smoothed over by mutual concessions, they maintained an amicable intercourse, unexpectedly terminated by Tycho's death, October 24, 1601.

A brilliant and prosperous career seemed by this event to be thrown open to Kepler. The emperor Rudolph II. immediately appointed him to succeed his patron as imperial mathematician, although at a reduced salary of 500 florins; the invaluable treasure of Tycho's observations was, after some futile opposition on the part of his heirs, placed at his disposal; and the laborious but congenial task was entrusted to him of completing the tables to which the grateful Dane had already affixed the title of *Rudolphine*. The first works executed by him at Prague were, however, a homage to the astrological proclivities of the emperor. In *De fundamentis astrologiæ certioribus* (Prague, 1602) he declared his purpose of preserving and purifying the grain of truth which he believed the science to contain. Indeed, the doctrine of "aspects" and "influences" fitted excellently with his mystical conception of the universe, and enabled him to discharge with a semblance of sincerity the most lucrative part of his professional duties. Although he strictly limited his prophetic pretensions to the estimate of tendencies and probabilities, his forecasts were none the less in demand. Shrewd sense and considerable knowledge of the world came to the aid of stellar lore in the preparation of "prognostics" which, not unfrequently hitting off the event, earned him as much credit with the vulgar as his cosmical speculations with the learned. He drew the horoscopes of the emperor and Wallenstein, as well as of a host of lesser magnates; but, though keenly alive to the unworthy character of such a trade, he made necessity his excuse for a compromise with superstition. "Nature," he wrote, "which has conferred upon every animal the means of subsistence, has given astrology as an adjunct and ally to astronomy." He dedicated to the emperor in 1603 a treatise on the "great conjunction" of that year (*Judicium de trigono igneo*); and he published his observations on a brilliant star which appeared suddenly, September 30, 1604, and remained visible for seventeen months, in *De stella nova in pede Serpentarii* (Prague, 1606). While sharing the opinion of Tycho as to the origin of such bodies by condensation of nebulous matter from the Milky Way, he attached a mystical signification to the coincidence in time and place of the sidereal apparition with a triple conjunction of Mars, Jupiter, and Saturn.

The main task of his life was not meanwhile neglected. This was nothing less than the foundation of a new astronomy, in which physical cause should replace arbitrary hypothesis. A preliminary study of optics led to the publication, in 1604, of his *Astronomiæ pars optica*, containing important discoveries in the theory of vision, and a notable approximation towards the true law of refraction. But it was not until 1609 that, the "great Martian labour" being at length completed, he was able, in his own figurative language, to lead the captive planet to the foot of the imperial throne. From the time of his first introduction to Tycho he had devoted himself to the investigation of the orbit of Mars, which, on account of its relatively large eccentricity, had always been especially recalcitrant to theory, and the results appeared in *Astronomia nova αἰτιολογητός, seu Physica cœlestis tradita commentariis de motibus stellæ Martis* (Prague, 1609). In this, the most memorable of Kepler's multifarious writings, two of the cardinal principles of modern astronomy—the laws of elliptical orbits and of equal areas—were established;[1] important truths relating to gravity were enunciated, and the tides ascribed to the influence of lunar attraction; while an attempt to explain the planetary revolutions in the then backward condition of mechanical knowledge produced a theory of vortices closely resembling that afterwards adopted by Descartes. Having been provided, in August 1610, by Ernest, archbishop of Cologne, with one of the new Galilean instruments, Kepler began, with unspeakable delight, to observe the wonders revealed by it. He had welcomed with a little essay called *Dissertatio cum Nuncio Sidereo* Galileo's first announcement of celestial novelties; he now, in his *Dioptrice* (Augsburg, 1611). expounded the theory of refraction by lenses, and suggested the principle of the "astronomical" or inverting telescope. Indeed the work may be said to have founded the branch of science to which it gave its name.

The year 1611 was marked by Kepler as the most disastrous of his life. The death by small-pox of his favourite child was followed by that of his wife, who, long a prey to melancholy, was at last, July 3, carried off by typhus. In his review of their conjugal life, remorse for frequent outbursts of impatience towards his shiftless though well-meaning helpmate took the place of regret for her loss. Public calamity was added to private bereavement. On the 23d of May 1611 Matthias, brother of the emperor, assumed the Bohemian crown in Prague, compelling Rudolph to take refuge in the citadel, where he died on the 20th of January following. Kepler's fidelity in remaining with him to the last did not deprive him of the favour of his successor. Payment of arrears, now amounting to upwards of 4000 florins, was not, however, in the desperate condition of the imperial finances, to be hoped for; and he was glad, while retaining his position as court astronomer, to accept (in 1612) the office of mathematician to the states of Upper Austria. His residence at Linz was troubled by the harsh conduct of the pastor Hitzler, in excluding him from the rites of his church on the ground of supposed Calvinistic leanings—a decision confirmed, with the addition of an insulting reprimand, on his appeal to Würtemberg. In 1613 he appeared with the emperor Matthias before the diet of Ratisbon as the advocate of the introduction into Germany of the Gregorian calendar; but the attempt was for the time frustrated by anti-papal prejudice. The attention devoted by him to chronological subjects is evidenced by the publication about this period of several essays in which he sought to prove that the birth of Christ took place five years earlier than the commonly accepted date.

Kepler's second courtship forms the subject of a highly characteristic letter addressed by him to Baron Stralendorf,

[1] See ASTRONOMY, vol. ii. p. 752.

in which he reviews the qualifications of eleven candidates for his hand, and explains the reasons which decided his choice in favour of a portionless orphan girl named Susanna Reutlinger. The marriage was celebrated at Linz, October 30, 1613, and seems to have proved a happy and suitable one. The abundant vintage of that year drew his attention to the defective methods in use for estimating the cubical contents of vessels, and his essay on the subject (*Nova Stereometria Doliorum*, Linz, 1613) entitles him to rank among those who prepared the discovery of the infinitesimal calculus. His observations on the three comets of 1618 were published in *De Cometis*, contemporaneously with the *Harmonice Mundi* (Augsburg, 1619), of which the first lineaments had been traced twenty years previously at Gratz. This extraordinary production is memorable as having announced the discovery of the "third law"—that of the sesquiplicate ratio between the planetary periods and distances. But the main purport of the treatise was the exposition of an elaborate system of celestial harmonies depending on the various and varying velocities of the several planets, of which the sentient soul animating the sun was the solitary auditor. The work exhibiting this fantastic emulation of extravagance with genius was dedicated to James I. of England, and the compliment was acknowledged with an invitation to that island, conveyed through Sir Henry Wotton. Notwithstanding the distracted state of his own country, however, he refused to abandon it, as he had previously, in 1617, declined the post of successor to Magini in the mathematical chair of Bologna.

The insurmountable difficulties presented by the lunar theory forced Kepler, after an enormous amount of fruitless labour, to abandon his design of comprehending the whole scheme of the heavens in one great work to be called *Hipparchus*, and he then threw a portion of his materials into the form of a dialogue intended for the instruction of general readers. The *Epitome Astronomiæ Copernicanæ* (Linz and Frankfort, 1618–21), a lucid and attractive text-book of Copernican science, was remarkable for the prominence given to "physical astronomy," as well as for the extension to the Jovian system of the laws recently discovered to regulate the motions of the planets. The first of a series of ephemerides, calculated on these principles, was published by him at Linz in 1617; and in that for 1620, dedicated to Napier, he for the first time employed logarithms. This important invention was eagerly welcomed by him, and its theory formed the subject of a treatise entitled *Chilias Logarithmorum*, printed in 1624, but circulated in manuscript three years earlier, which largely contributed to bring the new method into general use in Germany.

His studies, were, however, interrupted by a painful family trouble. The restless disposition and unbridled tongue of Catherine Kepler his mother created for her numerous enemies in the little town of Leonberg; while her unguarded conduct exposed her to a species of calumny at that time but too readily circulated and believed. As early as 1615 suspicions of sorcery began to be spread against her, which she, with more spirit than prudence, met with an action for libel. The suit was, by the connivance of the judicial authorities, purposely protracted, and at length, August 5, 1620, the unhappy woman, then in her seventy-fourth year, was arrested on a formal charge of witchcraft. Kepler immediately hastened to Würtemberg, and devoted a whole year to the zealous advocacy of her cause. It was owing to his indefatigable exertions that, contrary to general expectation, she was acquitted after having suffered thirteen months' imprisonment, and endured with undaunted courage the formidable ordeal of "territion," or examination under the imminent threat of torture. She survived her release only a few months, dying April 13, 1622.

Kepler's whole attention was now devoted to the production of the new tables. "Germany," he wrote, "does not long for peace more anxiously than I do for their publication." Financial difficulties, however, combined with civil and religious convulsions, long delayed the accomplishment of his desires. From June 24 to August 29, 1626, Linz was besieged, and its inhabitants reduced to the utmost straits by bands of insurgent peasants. The pursuit of science needed a more tranquil shelter; and accordingly, on the raising of the blockade, Kepler obtained permission to transfer his types to Ulm, where, in September 1627, the *Rudolphine Tables* were at length given to the world. Although by no means free from errors, their value appears from the fact that they ranked for a century as the best aid to astronomy. Appended were tables of logarithms and of refraction, together with Tycho's catalogue of 777 stars, enlarged by Kepler to 1005.

The work of Kepler's life was now virtually completed, but not so its vicissitudes. His claims upon the insolvent imperial exchequer amounted by this time to 12,000 florins. The emperor Ferdinand II., too happy to transfer the burden, countenanced an arrangement by which Kepler entered the service of the duke of Friedland (Wallenstein), who assumed the full responsibility of the debt. In July 1628 Kepler accordingly arrived with his family at Sagan in Silesia, where he applied himself to the printing of his ephemerides up to the year 1636, and whence he issued, in 1629, a *Notice to the Curious in Things Celestial*, warning astronomers of approaching transits. That of Mercury was actually seen by Gassendi in Paris. November 7, 1631 (being the first passage of a planet across the sun ever observed); that of Venus, predicted for the 6th of December following, was invisible in western Europe. Wallenstein's promises to Kepler were but imperfectly fulfilled. In lieu of the sums due, he offered him a professorship at Rostock, which Kepler declined, being unwilling to compromise his claim. An expedition to Ratisbon, undertaken for the purpose of representing his case to the Diet, terminated his life. Shaken by the journey, which he had performed entirely on horseback, he was attacked with fever, and died at Ratisbon, November 15 (N. S.), 1630, in the fifty-ninth year of his age. An inventory of his effects found among his papers showed him to have been possessed of no inconsiderable property at the time of his death. It is true that he had often been severely straitened; but there is reason to believe that his complaints on the subject were to some extent exaggerated. By his first wife he had five, and by his second seven children, of whom only two, a son and a daughter, reached maturity.

The character of Kepler's genius was one of which it is especially difficult to arrive at a just estimate. His irresistible tendency towards mystical speculation formed a not less fundamental quality of his mind than its strong grasp of positive scientific truth. Without assigning to each element its due value, no sound comprehension of his modes of thought can be attained. His idea of the universe was essentially Pythagorean and Platonic. He started with the conviction that the arrangement of its parts must correspond with certain abstract conceptions of the beautiful and harmonious. His imagination, thus kindled, animated him to the severe labours of which his great discoveries were the fruit. His demonstration that the planes of all the planetary orbits pass through the centre of the sun, coupled with his clear recognition of the sun as the moving power of the system, entitles him to rank as the founder of physical astronomy. But the fantastic relations imagined by him of planetary movements and distances to musical intervals and geometrical constructions seemed to himself discoveries no less admirable than the achievements which have secured his lasting fame. Outside the boundaries of the solar system, the metaphysical side of his genius, no longer held in check by experience, fully asserted itself. The Keplerian like the Pythagorean cosmos was threefold, consisting of the centre, or sun, the surface, being the sphere of the fixed stars, and the intermediate space, filled with ethereal matter. It is a mistake to suppose that he regarded the stars as so many suns. He quotes indeed the opinion of Giordano Bruno to that effect, but with dissent. Among his happy conjectures may be mentioned that of the sun's axial rotation, postulated by him as the physical cause of the revolutions of the planets, and soon after confirmed by the discovery of sun-spots; the suggestion of a periodical variation in the obliquity of the ecliptic; and the explanation as an effect of a solar atmosphere of the radiance observed to surround the totally eclipsed sun.

It is impossible to consider without surprise the colossal amount of work accomplished by Kepler under numerous disadvantages. His health was uncertain, his powers of calculation indifferent, his interruptions numerous, his cares at times overwhelming. But his iron industry counted no obstacles, and secured for him the highest triumph of genius, that of having given to mankind the best that was in him. In private character he was amiable and affectionate; his generosity in recognizing the merits of others secured him against the worst shafts of envy; and a life marked by numerous disquietudes was cheered and ennobled by sentiments of sincere piety.

Kepler's extensive literary remains, purchased by the empress Catherine II. in 1724 from some Frankfort merchants, and long inaccessibly deposited in the observatory of Pulkowa, have at length been completely brought to light, under the able editorship of Dr Ch. Frisch, in the first complete edition of Kepler's works. This important publication (*Joannis Kepleri opera omnia*, Frankfort, 1858–71, 8 vols. 8vo) contains, besides the works already enumerated and several minor treatises, a posthumous scientific satire entitled *Joh. Keppleri Somnium* (first printed in 1634), and a vast mass of his correspondence. A careful biography is appended, founded mainly on his private notes and other authentic documents.

The reader may also usefully consult Reuschle, *Kepler und die Astronomie*, Frankfort, 1871; Goebel, *Ueber Kepler's astronomische Anschauungen*, Halle, 1871; Apelt, *Johann Kepler's astronomische Weltansicht*, Leipsic, 1849; Breitschwert, *Johann Kepler's Leben und Wirken*, Stuttgart, 1831; W. Forster, *Johann Kepler und die Harmonie der Sphären*, Berlin, 1862; R. Wolf, *Geschichte der Astronomie*, Munich, 1877. (A. M. C.)

KERAK, a town of Syria, situated about 10 miles east of the southern end of the Dead Sea, on the summit of a rocky hill some 3000 feet above sea-level. It stands upon a platform forming an irregular triangle with sides of 800 to 1000 yards in length, and separated by deep ravines from the higher encircling ranges on all sides except one, where a narrow neck connects it with a neighbouring hill. The whole place was formerly surrounded by a wall with five towers, with only two entrances through tunnels in the side of the cliff. The town is an irregular mass of about six hundred flat mud-roofed houses. The Christian quarter contains the Greek church of St George; and the present mosque still bears marks of its Christian origin. On the north-west is the tower or castle of Bibars (see vol. vii. p. 755), with an inscription bearing his name. The great castle at the southern angle was built as a crusading fortress about 1131. Relics of the Roman occupation of Kerak have been found. The inhabitants are estimated at 8000, of whom about one-fourth are Greek Christians. They are fierce and truculent; and, though they were formerly renowned for hospitality, their rapacious treatment of their European visitors has brought them into very bad repute.

Kerak is the ancient Kir-Hareseth or Kir-Moab (2 Kings iii. 25; Isa. xv. 1, xvi. 7). The name Kerak (Syriac Karkâ, fortress) is as old as 2 Macc. xii. 17. In crusading times Kerak was a highly important point. In 1188 it was captured by Saladin (vol. vii. p. 753), and under his dynasty the town prospered. In the early part of the present century Kerak was governed by a powerful sheikh, paying nominal homage to the Wahhaby kingdom; it is now the residence of a Turkish official and garrison under the wály of Jerusalem, but the authority of the government is weak. A considerable trade is carried on by merchants from Hebron.

See Burckhardt's *Syria*, 1822, p. 377 *sq.*; Tristram's *Land of Moab*, 1873; Bädeker-Socin's *Handbook*; Le Quien, *Or. Chr.*, iii. 730.

KERBELA, or MESHHED-HOSEIN, a town of Asiatic Turkey, in the vilayet of Baghdad, is situated in a fertile and well-cultivated district about 60 miles south-south-west of Baghdad, and about 20 miles west of the Euphrates, from which a very ancient canal extends to it. It is surrounded by a dilapidated brick wall 24 feet high, and contains a fine market-place, with one broad street leading to the governor's residence. The other streets are narrow and dirty. Of the five mosques in the town the largest is the mosque of Hosein with a large gilded dome and minarets; it contains the tomb of Hosein, son of the caliph 'Aly (see ARABIA, vol. ii. p. 258), whose sanctity makes Kerbela in the eyes of Shiites less sacred only than Mecca. Some 200,000 pilgrims from all parts of Islam journey annually to Kerbela, many of them carrying the bones of their relatives to be buried in its sacred soil. The moullahs, who fix the burial fees, derive an enormous revenue from the faithful. At one time Kerbela was an inviolable sanctuary for criminals, but it has ceased to be so since 1843, when the inhabitants revolted against the Turks, and were reduced with great slaughter. The enormous influx of pilgrims naturally creates brisk trade in Kerbela and the towns on the route thither,—a fact which makes the Turkish Government anxious not to divert the stream elsewhere, as some years ago was partially done by sanitary and other regulations. The population, necessarily fluctuating, was estimated in 1878 at 60,000; Mr Clements Markham, writing in 1874, put it at 20,000.

KERGUELEN'S LAND, KERGUELEN ISLAND, or DESOLATION ISLAND, an island in the Southern Ocean, to the south-east of the Cape of Good Hope and south-west of Australia, and nearly half-way between them. To the south is Heard Island, and west-north-west the Crozets and the Marion Group. Kerguelen lies between 48° 39′ and 49° 44′ S. lat., and 68° 42′ and 70° 35′ E. long. Its extreme length is about 85 miles, and its extreme breadth 79, but the area is only about 2050 square miles. The island is throughout mountainous, presenting from the sea in some directions the appearance of a series of jagged peaks. The various ridges and mountain masses are separated by steep-sided valleys, which run down to the sea, forming deep fjords, so that no part of the interior is more than 12 miles from the sea. The chief mountain peaks are Mount Ross (6120 feet), Mount Richards (4000), Mount Crozier, (3258), Mount Wyville Thomson (3160), Mount Hooker (2600), Mount Moseley (2400). The coast-line is extremely irregular, many of the fjords being bounded by long, steep rocky promontories. These, at least on the north, east, and south, form a series of well-sheltered harbours; as the prevailing winds are westerly, the safest anchoring ground is on the north-east. Christmas Harbour on the north and Royal Sound on the south are noble harbours, the latter with a labyrinth of islets interspersed over upwards of 20 miles of landlocked waters. The scenery is generally magnificent, and often singularly picturesque. A district of considerable extent in the centre of the island is occupied by snowfields, whence glaciers descend east and west to the sea. The whole island, exclusive of the snowfields, abounds in freshwater lakes and pools in the hills and lower ground. Hidden deep mudholes are frequent.

Kerguelen's Land is of undoubted volcanic origin, the prevailing rock being basalt, sometimes intersected by trap, and indeed an active volcano and hot springs are said to exist on the south-west of the island. Judging from the abundant fossil remains of trees, the island must at one time have been thickly clothed with woods and other vegetation, of which it has no doubt been denuded by volcanic action and submergence, and possibly by change of climate. It presents evidences of having at one time been subjected to powerful glaciation, and to subsequent immersion and immense denudation. The soundings made by the "Challenger" and "Gazelle," and the affinities which in certain respects exist between the islands, seem to point to the existence at one time of an extensive land in this quarter, of which Kerguelen, Prince Edward's Islands, the Crozets, St Paul, and Amsterdam are the remains. The Kerguelen plateau rises in many parts to within 1500 fathoms of the surface of the sea. Beds of coal and of red earth are found at some places. The summits of the flat-topped hills about Betsy Cove, in the south-east of the island, are formed of caps of basalt. Sir J. D. Hooker points out that the vegetation of Kerguelen's Land must be of great antiquity, and may have originally reached it from the American continent; it has no affinities with Africa. The present climate is not favourable to permanent vegetation: the island lies within the belt of rain of all seasons of the year, and is reached by no drying winds; its temperature is kept down by the surrounding vast expanse of sea; and it lies within the line of the cold Antarctic drift. The temperature is, however, very equable. During the transit expedition, the lowest winter temperature was seldom less than 32°, while the summer temperature occasionally approached 70°. Tempests and squalls are frequent, and the weather is rarely calm. On the lower slopes of the mountains a rank vegetation exists, which, from the conditions just mentioned, is constantly saturated with moisture. A rank grass, *Festuca Cookii*, grows thickly in places up to 300 feet, with *Azorella*, *Cotula plumosa*, &c. Sir J. D. Hooker enumerates twenty-one species of flowering plants, and seven of ferns, lycopods, and *Characeæ*; at least seventy-four species of mosses, twenty-five of *Hepaticæ*, and sixty-one of lichens are known, and there are probably many more. Several of the marine and many species of freshwater algæ are peculiar to the island. The characteristic feature of the vegetation, however, is the Kerguelen cabbage (*Pringlea antiscorbutica*), a perennial cruciferous plant, in appearance somewhat like the garden cabbage. This cabbage and *Azorella* are found growing at a height of 1000 feet, while on the higher rocks a very handsome conspicuous lichen (*Neuropogon Taylori*), of a mingled bright sulphur-yellow and black colour, is found abundantly. Fur seals are still found in Kerguelen, though their numbers have been greatly reduced by reckless slaughter. One of the most characteristic animals of the island is the sea elephant (*Macrorhinus leoninus*), which is found in considerable abundance even far up the streams that flow into the fjords. The sea-leopard (*Ogmorrhinus leptonyx*) is pretty abundant on the coasts. All parts of the coast and even the lower slopes are covered with penguins of various species, mainly the Johnny penguin (*Pygoscelis tæniata*), rock-hopper (*Eudyptes saltator*), and king penguin (*Aptenodytes longirostris*). A teal (*Querquedula Eatoni*) peculiar to Kerguelen and the Crozets is also found in considerable numbers, and crowds of petrels, especially the giant petrel (*Ossifraga gigantea*), *Halobæna cærulea*, and *Prion desolatus* frequent the island, as also skuas, gulls, sheathbills (*Chionis minor*), albatross, terns (*Sterna virgata* ?), cormorants (*Phalacrocorax verrucosus*), and Cape pigeons. The island shelters a considerable variety of insects, many of them with remarkable peculiarities of structure, and with a predominance of forms incapable of flying. The island is frequented by sealers and whalers, but has no permanent inhabitants. Kerguelen's Land was discovered by the French navigator Kerguelen Tremarec (born 1745, died 1797), on February 13, 1772, and partly surveyed by him in the following year. It was subsequently visited by Captain Cook, and also by Sir James C. Ross in 1840 in the "Erebus" and "Terror." It has occasionally formed a refuge for shipwrecked sailors. The "Challenger" spent some time at the island, and its staff visited and surveyed various parts of it in January 1874. Later in the same year it was occupied for several months (October 1874 to February 1875) by the expeditions sent from England, Germany, and the United States to observe the transit of Venus. Still the interior is all but unexplored, and we have only vague notions of a considerable part of the coast. The Admiralty chart is based chiefly on mining surveys and information obtained from whalers.

Perry's *Notes of a Voyage to Kerguelen*.

KERKÚK, or KERKOOK, a town of Asiatic Turkey, in the vilayet of Baghdad, is situated on the right bank of the Khasa Tshai, about 140 miles north of the city of Baghdad. A suburb, Mahalle, on the left bank of the stream, which is spanned by a bridge, contains the residence of the pasha. The citadel stands east of the river upon an artificial mound, 130 feet high, which in Niebuhr's time was still surrounded by an earthen rampart. The citadel hill is the residence of the old Nestorians, now adherents of the Church of Rome. Round the foot of this hill run the dirty, crooked, and narrow streets of the lower town, with their flat-roofed, ugly houses, built partly of wood and partly of stone. The only large building is occupied by the bazaar, with passages one hundred paces long. Owing to its position at the junction of several routes, Kerkúk has a brisk transit trade in hides, Persian silks and cottons, colouring materials, fruit, and timber, on the way from Suleimanieh to the north. The natural warm springs at Kerkúk are used to supply baths. The surrounding country is fertile and well-cultivated; the petroleum and naphtha springs near the town are its most valuable commercial resource. Till lately the petroleum was used as fuel by the Turkish steamers on the Tigris; but English coal has now superseded it. The official designation of Kerkúk is Shahr Zul. The inhabitants, from twelve to fifteen thousand in number, are chiefly Mohammedan Kurds; there is a Jewish quarter beneath the citadel. The reputed sarcophagi of Daniel and the Hebrew children are shown in one of the mosques.

Kerkúk is the ancient metropolitan city Karká a' Beth Slôk ("fortress of the house of Seleucia").

KERMES (Arabic, *kirmis*), a crimson dye, now superseded by cochineal, obtained from *Coccus ilicis*, L. (*Coccus vermilio*, G. Planchon), an hemipterous insect found in Spain, Italy, the south of France, and other parts of the Mediterranean region, feeding on *Quercus coccifera*, a small shrub from 2 to 5 feet high. The discovery of the animal nature of kermes is due to Emeric, Garidel, and Cestoni. Until the year 1714 it was thought to be a gall or excrescence.

Like other members of the group to which it belongs, the female kermes insect is wingless, and furnished with a beak or sucker attached to its breast, by which it fixes itself immovably on its food plant, and through which it draws its nourishment. The male insect is unknown, two insects mistaken for it being, according to Planchon, parasitic hymenoptera of the chalcidian group, living in the kermes grains. In the month of May, when full grown, the insects are globose, 6 to 7 millim. in diameter, of a reddish-brown colour, and covered with an ash-coloured powder. They are found attached to the twigs or buds by a circular lower surface 2 millim. in diameter, and surrounded by a narrow zone of white cottony down. At this time there are concealed under a cavity, formed by the approach of the abdominal wall of the insect to the dorsal one, thousands of eggs of a lively red colour, and smaller than poppy seed, which are protruded and ranged regularly beneath the insect. At the end of May or the beginning of June the young escape by a small orifice, near the point of attachment of the parent. They are then of a fine red colour, elliptic and convex in shape, but rounded at the two extremities, and bear two threads half as long as their body at their posterior extremity. At this period they are extremely active, and swarm with extraordinary rapidity all over the food plant, and in the course of two or three days attach themselves to fissures in the bark or buds, but rarely to the leaves. In warm and dry summers the insects breed again in the months of August and September, according to Eméric, and then they are more frequently found attached to the leaves. Usually, however, they remain immovable and apparently unaltered until the end of the succeeding March, when their bodies become gradually distended and lose all trace of abdominal rings. They then appear full of a reddish juice resembling discoloured blood. In this state, or when the eggs are ready to be extruded, the insects are collected. In some cases the insects from which the young are ready to escape are dried in the sun on linen cloths—care being taken to prevent the escape of the young from the cloths until they are dead. The young insects are then sifted from the shells, made into a paste with vinegar, and dried on skins exposed to the sun, and the paste packed in skins is then ready for exportation to the East under the name of "pâte d'écarlate."

In the pharmacopœia of the ancients kermes triturated with vinegar was used as an outward application, especially in wounds of the nerves. From the 9th to the 16th century this insect formed an ingredient in the "confectio alkermes," a well known medicine, at one time official in the London pharmacopœia as an astringent and corroborant in doses of 20 to 60 grains or more. Syrup of kermes was also prepared. Both these preparations have now fallen into disuse, the latter being replaced by the syrup of cochineal.

To dye spun worsted with kermes, the material is first boiled for half an hour with bran in water, and then for two hours in a fresh bath containing one-fifth of Roman alum and one-fifth of tartar, to which "sour water" is commonly added. It is then taken out and laid in a linen bag for some days in a cool place. In order to obtain a full colour it is then put in a warm bath as at the first boiling, the bath containing as much kermes as is equal to three-fourths or even the whole weight of the worsted used. For cloth one-fourth less of the salt and kermes was required. The colour imparted by kermes has much less bloom than the scarlet made with cochineal. hence the former has fallen into disuse.

Mineral kermes is an amorphous tersulphide of antimony, prepared by a variety of processes, and containing a variable proportion of teroxide of antimony and sometimes a little alkaline antimonite. The oldest method consists in boiling the finely powdered sulphide with a solution of an alkaline carbonate and leaving the hot filtered solution to cool, the kermes being deposited on cooling. In another method dilute nitric acid was added to the alkaline solution to precipitate the kermes mineral. Mineral kermes is a brown red powder becoming blackish-grey when washed with boiling water. By fusion and slow cooling it is converted into a clay-like mass devoid of crystalline structure, in which it differs essentially from the pure amorphous sulphide.

Planchon, *Le Kermes du Chêne*, Montpellier, 1864; Watts's *Dictionary of Chemistry*, i. p. 330–33, iii. p. 446; Gmelin, *Handbook of Chemistry*, iv. p. 340–49; Lewis, *Materia Medica*, 1784, pp. 71, 365; *Memorias sobre la grana Kermes de España*, Madrid, 1788; Adams, *Paulus Ægineta*, iii. 180; Beckmann, *History of Inventions*.

KERNER, Justinus Andreas (1786–1862), a German poet and medical writer, was born in Ludwigsburg, Würtemberg, on the 18th of September 1786. He received his early education in the Latin school of Ludwigsburg and in the cloister school of Maulbronn. After the death of his father, who was an upper bailiff and government councillor in Ludwigsburg, Kerner was obliged to accept a position in a cloth manufactory; but in 1804, aided by Pastor Conz, who had some reputation as a poet, he was able to enter the university of Tübingen, where he studied medicine. At Tübingen he made the acquaintance of Uhland, who was about his own age; and the two young men encouraged each other in their first efforts in poetry. Having completed his studies in 1809, Kerner spent some time in travel. In 1815 he received a medical appointment in Gaildorf, and in 1819 was transferred to Weinsberg, where he spent the rest of his life. Weinsberg is a pretty little town in Würtemberg, and was formerly a free imperial city. Here the emperor Conrad III. is said to have besieged the castle of Count Welf; and, according to the well-known legend, the women, having obtained permission to retire with their most valuable possessions, stumbled out, each with her husband on her back. Kerner built a house under the shadow of the castle ("Weibertreue"); and through his exertions measures were taken for the preservation of the ruins and the laying out of the surrounding grounds in public gardens. He also occupied himself with the history of the town, and published a work in two volumes describing *The Storming of Weinsberg in* 1525. He was troubled with an affection of the eyes, and becoming almost blind he resigned his office and medical practice in 1851. He died on the 21st of February 1862. Kerner takes rank as one of the best of the Swabian school of poets, who had in some respects a close affinity to the Romantic school, but aimed at greater simplicity and clearness.

He attracted attention by his *Reiseschatten von dem Schattenspieler Lux* (1811), and co-operated with Uhland, Schwab, and other writers in producing the *Poetischer Almanach* (1812) and the *Deutscher Dichterwald* (1813). In 1826 he issued a collection of his poems, to which he added many new lyrics in subsequent editions. He also published two other volumes of poetry, *Der letzte Blütenstrauss* (1852) and *Winterblüten* (1859). His lyrics are remarkable for the intermingling of quaint humour and delicate pathos, while in his ballads, which are written with great spirit and in a thoroughly popular tone, he prefers to represent such scenes of horror and mystery as the romantic school delighted in. He devoted much study to abnormal conditions of the brain, and wrote several popular works on animal magnetism and kindred subjects. Of more importance than these labours were his investigations on the influence of sebacic acid on animal organisms, and his work *Das Wildbad im Königreich Würtemberg*. In his *Bilderbuch aus meiner Knabenzeit* he gave a vivid and interesting description of the circumstances of his youth. See K. Mayer in the *Album Schwäbischer Dichter*, and D. Strauss, *Kleine Schriften*.

KERRY, a maritime county of Ireland, in the province of Munster, between 51° 41′ and 52° 23′ N. lat., and between 9° 7′ and 10° 30′ W. long., bounded on the W. by the Atlantic Ocean, N. by the estuary of the Shannon, which separates it from Clare, E. by Limerick and Cork, and S.E. by Cork. Its greatest length from north to south is 60 miles, and its greatest breadth from east to west 58 miles. The area comprises 1,159,358 acres, or 1811 square miles.

Geology.—Kerry, with its combination of mountain, sea, and plain, possesses some of the finest scenery of the British Islands. The portion of the county south of Dingle Bay consists of mountain masses intersected by valleys formed by narrow bands of carboniferous rocks. These masses are composed chiefly of red and green sandstones, grits, and slates, with beds of conglomerate in which are sometimes found pebbles of bright red jasper. The formation is almost entirely unfossiliferous, but on the Geological Survey maps it is marked as Old Red Sandstone. At one time the mountains were covered by a great forest of fir, birch, and yew, which was nearly all cut down to be made use of in smelting iron, and the constant pasturage of cattle prevents the growth of young trees. In the north-east, towards Killarney, the formation rises abruptly from the Carboniferous Limestone rocks into the rugged range of Macgillicuddy's Reeks, the highest summit of which, Carntual, has a height of 3414 feet. The next highest summit to Carntual is Caper, 3200 feet, and several others are over 2500 feet. Lying between the precipitous sides of the Tomies, the Purple Mountains, and the Reeks is the famous gap of Dunloe. A small portion of country at the south-west of the Dingle promontory is occupied by Upper Silurian strata, which in the middle of the promontory are covered by vast strata of grits, slates, and sandstones known as the Dingle beds, but of unknown age. This formation attains at Brandon Hill a height of 3127 feet. Resting unconformably on these beds are the Old Red Sandstone strata which occupy the remainder of the promontory and also a small tract of country at Kerry Head. The remainder of Kerry is occupied by the Coal-measures which are separated from the mountain masses of Old Red Sandstone by a narrow and irregular band of Carboniferous Limestone or Carboniferous Slate, which abounds in fossils. The Coal-measures, which rest conformably on the Carboniferous Limestone, form a succession of undulating hills rising sometimes to a height of over 1000 feet. All the three measures of coal are represented, but the seams of coal are very thin, and the workable portions are outside the limits of the county. In the upper part of the Kenmare valley some copper veins occur in the Old Red Sandstone, but they are workable only when they enter the limestone. Silver with zinc and lead with zinc are found in a few places. In the coal formation there are some veins both of iron and lead. The Valentia flags and slates are largely exported to England. Amethysts were at one time obtained near Kerry Head.

Coast Line.—The sea-coast, which for the most part is wild and mountainous, is much indented by inlets, the largest of which, Tralee Bay, Dingle Bay, and Kenmare River, lie in synclinal troughs, the anticlinal folds of the rocks forming extensive promontories. Between Kenmare River and Dingle Bay the land is separated by mountain ridges into three valleys. The extremity of the peninsula between Dingle Bay and Tralee Bay is very precipitous, and Mount Brandon, rising abruptly from the ocean, is skirted at its base by a road from which magnificent views are obtained. From near the village of Ballybunion to Kilconey Point near the Shannon there is a remarkable succession of caves, which have evidently been excavated by the sea. The principal islands are the picturesque Skelligs, Valentia Island, and the Blasquet Islands.

Rivers and Lakes.—The principal rivers are the Blackwater, which, rising in the Dunkerran mountains, forms for a few miles the boundary line between Kerry and Cork, and falls into the Kenmare River; the Ruaughty, which with a course resembling the arc of a circle falls into the head of the Kenmare River; the Inny and Ferta, which flow westward, the one into Ballinskellig Bay and the other into Valentia Harbour; the Flesk, which flows northward through the lower lake of Killarney, after which it takes the name of the Laune, and flows north-westward to Dingle Bay; the Cara, which rises in the mountains of Dunkerran, and after forming several lakes falls into Castlemaine Harbour; the Maine, which flows from Castle Island southwestwards to the sea at Castlemaine Harbour, receiving in its course the northern Flesk, which rises in the mountains that divide Cork from Kerry; and the Feale, Gale, and Brick, the junction of which forms the Cashin, a short tidal river which flows into the estuary of the Shannon. The lakes of Kerry are not numerous, and none of them are of great size, but those of Killarney form one of the most important features in the striking and picturesque mountain scenery amidst which they are situated. (See KILLARNEY.) The other principal lakes in the county are Lough Currane near Ballinskellig, and Lough Cara near Castlemaine Harbour. Near the summit of Mangerton Mountain an accumulation of water in a deep hollow forms what is known as the Devil's Punchbowl, the surplus water, after making a succession of cataracts, flowing into Lough Kittane at the foot of the mountain. There are chalybeate mineral springs near Killarney, near Valentia Island, and near the mouth of the Inny; sulphurous chalybeate springs near Dingle, Castlemaine, and Tralee; and a saline spring at Magherybeg in Corkaguiney, which bursts out of clear white sand a little below high water mark.

Climate and Agriculture.—Owing to the vicinity of the sea and the height of the mountains, the climate is very moist and unsuitable for the growth of cereals, but it is so mild even in winter that the pasturage on the mountains retains perpetual greenness. Arbutus and other trees indigenous to warm climates grow in the open air, and several flowering plants are found which are unknown in England. In the northern parts of the county the land is generally coarse and poor, except in the valleys, where a rich soil has been formed by rocky deposits. In the Old Red Sandstone valleys there are many very fertile regions, and several extensive districts now covered by bog admit of easy reclamation so as to form very fruitful soil, but other tracts of boggy land scarcely promise a profitable return for labour expended on their reclamation. The lower slopes of the mountains afford a very rich pasturage for cattle even in winter, while large flocks of sheep and goats graze on the upper ridges.

According to the classified summary of owners for 1876 there were no fewer than twenty-eight proprietors who possessed upwards of 10,000 acres, and ten possessed upwards of 20,000 acres, viz., Francis C. Bland, 25,576; Sir Edward Denny, Baronet, 21,479; Robert Drummond, 29,780; Edward Bouchier Hartopp, 24,222; Henry A. Herbert, 47,238; earl of Kenmare, 91,080; marquis of Lansdowne, 94,983; earl of Listowel, 25,964; Richard Mahoney, 26,173; Lord Ventry, 93,629. Altogether the number of owners was 1116, possessing 1,153,373 acres, at an annual valuation of £283,198. Of the owners 637, or 57 per cent., possessed less than 1 acre, the total possessed by these owners being only 172 acres. The average annual valuation was 4s. 10d. per acre.

The following table shows the number of the various classes of holdings in 1850 and 1880:—

	1 Acre.	Between 1 and 5 Acres.	Between 5 and 15 Acres.	Between 15 and 30 Acres.	30 Acres and upwards.	Total.
1850	623	1,024	3,071	4,391	9,508	18,617
1880	1,078	1,267	2,689	3,655	10,058	18,747

In some of the larger farms the best modern systems of agriculture are practised, but especially on the small farms the primitive form of lazy-bed culture is that almost wholly in use, with alternate crops of oats and potatoes. The total area under crops in 1881 was 165,568 acres, 14·2 per cent. of the acreage of the county. In 1880 there were 586,600 acres (50·6 per cent.) under grass, 18,348 were woods, 105,884 bogs, 248,808 mountain, and 39,392 water, roads, and fences. There has been an increase in the area under crops since 1850 of 16,694 acres, but this is wholly due to an increase of 37,906 in the area under meadow and clover, which in 1881 was 90,068, while between 1851 and 1880 the area under grass increased by 133,489, or more than a fourth. The area under cereals in 1881 was 33,169 acres, a decline of 18,849, or more than a third since 1850, wheat declining from 4502 to 1032, and oats from 30,190 to 27,533. Between 1850 and 1880 the diminution has been very slight in the area under green crop, from 43,129 acres to 41,968, that under potatoes increasing from 30,963 to 31,179, but that under turnips declining from 10,434 to 5723. Flax occupied 300 acres in 1850, and only 39 in 1881.

Horses have increased from 13,129 in 1850 to 15,367 in 1881. The number of horses used for agricultural purposes in 1881 was 11,159. Mules between 1850 and 1881 increased from 1871 to 2311, while asses increased from 3417 to 8765. Cattle in 1850 numbered 147,748, and in 1881 had increased to 209,733. Cows numbered 104,971, dairy farming being very largely followed. The Kerry breed of cattle—small finely-shaped animals, black or red in colour, with small upturned horns—are famed for the quality both of their flesh and milk, and are now in considerable demand for the parks surrounding mansion houses. The "dexter," a cross between the Kerry and an unknown breed, is larger but without its fine qualities. Sheep between 1850 and 1871 had risen from 59,931 to 129,618, but in 1881 they had declined to 82,929. Little regard is paid to the breed, but those in most common use have been crossed with a merino breed from Spain. Goats, which share with sheep the sweet pasturage of the higher mountain ridges, have increased between 1850 and 1881 from 17,382 to 23,442. Pigs since 1850 have increased from 36,246 to 45,630. Poultry have more than doubled in numbers, increasing from 183,115 to 485,076.

Feræ Naturæ.—As may be supposed from the wild and mountainous character of a great part of Kerry, foxes are numerous, and otters and badgers are not uncommon. The alpine hare is very abundant. The red deer inhabits the mountains round Killarney. The golden eagle was at one time frequently seen in the higher mountain regions, but is now rarely met with. The sea eagle haunts the lofty marine cliffs, the mountains, and the rocky islets. The osprey is occasionally seen, and also the peregrine falcon. The merlin is common. The common owl is indigenous, the long-eared owl resident, and the short-eared owl a regular winter visitor. Rock pigeons breed on the sea-cliffs, and the turtle dove is an occasional visitant. The common quail is becoming rare. The great grey seal is found in Brandon and Dingle Bays.

Manufactures.—At the beginning of the century there was a considerable linen trade in Kerry, but this is now nearly extinct, the chief manufacture being that of coarse woollens and linens for home use. At Killarney a variety of articles are made from the wood of the arbutus. A considerable trade in agricultural produce is carried on at Tralee, Dingle, and Kenmare, and in slate and stone at Valentia.

Fisheries.—The number of vessels engaged in the deep sea and coast fisheries is about 600, employing about 2500 men and boys. From the passing of the Act 37 and 38 Vict. up to 31st December 1880 the total amount of money advanced on loan for fishery purposes in Kerry has been £10,872, and up to the same date the repayments have amounted to £6879. The loans during the year 1880 amounted to £2146. The sum advanced for Kerry fisheries is more than one-third of the whole sum advanced for Ireland. Perhaps on no part of the coast are the fishing localities so numerous, or such fish as herring, pilchards, cod, hake, and ling so abundant. There is, however, a great want of boats, tackle, and nets, although the stations of Dingle and Kenmare are prosperous and well provided. Fine salmon are obtained in the rivers and in some of the larger lakes. The shellfish are large and abundant.

Railways.—A branch of the great southern and western line passes by Killarney to Tralee.

Administration.—The county comprises nine baronies, and contains eighty-five civil parishes and two parts of parishes, and 2682 townlands. There are six poor-law unions wholly within the county, viz., Cahirciveen, Dingle, Kenmare, Killarney, Listowel, and Tralee, and part of one, namely Glin, the remaining portion being in Limerick. The county includes one parliamentary borough, Tralee, which in 1881 had a population of 9664, the township of Killarney, and the towns of Dingle and Listowel. There are in the county twenty-four petty sessions districts and one part of a petty sessions district. Assizes are held at Tralee, and quarter sessions are held in the towns of Dingle, Kenmare, Killarney, Listowel, and Tralee. The county is within the Cork military district, and there is a barrack station at Tralee. The headquarters of the constabulary force is at Tralee, and subinspectors are stationed at Cahirciveen, Dingle, Kenmare, Killarney, and Listowel. Previous to the Union the county returned eight members to parliament, two for the county, and two for each of the boroughs of Tralee, Dingle, and Ardfert. At the Union the number was reduced to three, two for the county and one for the borough of Tralee.

Population.—At the census of 1659 the population of Kerry was 8390, of whom 7824 were Irish and 566 English. De Burgo estimates it at 56,628 in 1760, and the census of 1821 gives it as 216,185. In 1841 it had increased to 294,095, but in 1851 had diminished to 238,619, in 1861 to 201,800, and in 1871 to 196,586. The increase to 200,448 in 1881, notwithstanding that Kerry has suffered severely from agricultural distress, is sufficiently accounted for by an increase in the number of the smaller class of holdings. The number of males in 1881 was 100,715, and of females 99,733. The annual rate of marriages in 1880 to every 1000 of estimated population was 2·4, of births 27·5, of deaths 17·5, and of emigration 26·4. The total number who emigrated from 1st May 1851 to 31st December 1880 was 121,826. The number of persons not of Irish birth in Kerry at the census of 1841 was 615, and in 1871 it was 1194. The number in 1871 who could speak Irish only was 1209, and the number who could speak Irish and English 69,959. The number of Roman Catholics in 1881 was 193,917, of Protestant Episcopalians 5767, of Presbyterians 224, of Methodists 271, and of all other persuasions 264.

History.—The county is said to have derived its name from Ciar, who, along with his tribe the *Ciarraidhe*, is stated to have inhabited about the beginning of the present era the territory lying between Tralee and the Shannon. That portion lying south of the Maine was at a later period included in the kingdom of Desmond. Kerry suffered frequently from invasions of the Danes in the 9th and 10th centuries, until they were finally overthrown at the battle of Clontarf in 1014. In 1172 Dermot MacCarthy, king of Cork and Desmond, made submission to Henry II. on certain conditions, but was nevertheless gradually compelled to retire within the limits of Kerry, which was made shire ground in 1210. An English adventurer Raymond le Gros received from this MacCarthy a large portion of the county round Lixnaw. Thomas, grandson of Raymond, and king's sheriff in the counties of Cork, Waterford, and Kerry, was in 1295 made lord chief-justice of Ireland. Of his two sons John the eldest was created earl of Kildare, and Maurice in 1329 became earl of Desmond, and with certain exceptions received all the royal liberties which the king had in the county of Kerry. After the attainder of Thomas, earl of Desmond, in 1467, his kinsmen took up arms against the English, until at last the king was glad to guarantee the earl's elder son the full possession of his father's privileges. In consequence, however, of the rebellion of Gerald the sixteenth earl, the estates of the Desmonds, 574,628 acres in extent, were in 1583 forfeited to the crown, and parcelled into manors and seignories of 12,000, 8000, 6000, and 4000 acres, which were divided among English noblemen and gentlemen. The Irish took advantage of the disturbed state of England at the time of the Puritan revolution to attempt the overthrow of the English rule in Kerry, and ultimately obtained possession of Tralee, but in 1652 the rebellion was completely subdued, and a large number of estates were afterwards confiscated.

Antiquities.—There are remains of a round tower at Aghadoe near Killarney, another, a small cell at Lough Currane, and a third, one of the finest and most perfect specimens of the round tower in Ireland, at Rattoo, not far from Ballybunion. On the summit of a hill to the north of Kenmare River is the remarkable stone fortress known as Staigue Fort. There are several stone cells in the principal Skellig island, where at one time there were monastic remains which have now been swept away by the sea. The principal groups of sepulchral stones are those on the summits of the Tomie mountains, a remarkable stone fort at Cahirciveen, a circle of stones with cromlech in the parish of Tuosist, and others with inscriptions near Dingle. The most notable monastic ruins are those of Innisfallen, founded by St Finian, a disciple of St Columba, and the fine remains of Muckross Abbey, founded by the Franciscans, but there are also monastic remains at Ardfert, Castlemaine, Derrynane, Kilcoleman, Lislaghtin, and O'Dorney. Among old ruined churches of interest may be mentioned those of Aghadoe, Kilcrohane, Lough Currane, Derrynane, Kilmakilloge, and Muckross. The cathedral of Ardfert, founded probably in 1253, was partly destroyed during the Cromwellian wars, but was restored in 1831. Some interesting portions of the old building still remain. There are a large number of old feudal castles.

See Smith, *Ancient and Present State of the Counties of Cork, Waterford, and Kerry*, Dublin, 1746-56; Cusack, *History of the Kingdom of Kerry*, 1871.

KERTCH, the ancient Panticapæon, a seaport town of Russia in the government of Taurida, situated at the eastern extremity of the Crimea, on the Cimmerian Bosphorus (Strait of Yenikale or Strait of Kertch). It is 133 miles north-east of Simpheropol and 50 miles from Theodosia, in 45° 21′ N. lat. and 36° 30′ E. long. Like most towns built by ancient Greek colonists, it occupies a beautiful situation clustering round the foot and climbing the sides of the hill (now named after Mithradates) on which stood the ancient acropolis. In 1876 it contained twelve churches (including one Catholic and one Armenian), two synagogues, and a mosque, a local bank, two hospitals (one at Yenikale), three prisons, two gymnasiums, and a "noble maidens' institute." The church of John the Baptist, which, according to an inscription, was founded in 717 A.D., presents a good example of the purely Byzantine style of architecture. The church of Alexander Nevski was formerly the famous Kertch museum of local antiquities, founded in 1825. The more valuable objects were afterwards removed to the Hermitage at St Petersburg, and those which remained were wantonly scattered during the English occupation of the town. The present "museum" is a small collection in a private house. Among the products of local industry are leather, tobacco, cement, beer, aerated waters, lime, candles, and soap. Fish-curing is carried on, and there are steam saw-mills and flour-mills. Previous to the deepening of the Strait of Yenikale so as to admit vessels drawing 17 feet of water (1876), the harbour was visited by a large number of vessels which now pass on to the Azoff ports. The imports comprise coal, wines, olive oil, &c.; and grain, fish, linseed, rapeseed, wool, and hides are exported. The harbour was improved by dredging at the same time as the strait. A promenade extends along the sea-wall, and beyond the town lie public gardens. About 6 miles to the north-east is the town and old Turkish fortress of Yenikale, which is united with Kertch to form a separate administrative circle or mayoralty, including, according to the surveys of 1843–44, an area of 42,103 acres. In 1876 the population of Kertch, exclusive of the temporary garrison of 13,745, amounted to 21,211.

The Greek colony of Panticapæon was founded about the middle of the 6th century B.C., by the people of Miletus. From about 438 B.C. till the conquest of this region by Mithradates the Great about 100 B.C., the town and territory formed the so-called kingdom of the Bosphorus, ruled over by an independent dynasty. Phanaces, the son of Mithradates, became the founder of a new line under the protection of the Romans, which continued to exist till the middle of the 4th century A.D., and extended their power over the maritime parts of the Tauris. After this time the town—which had already begun to be known as Bosphora or Bospora—passed into the hands of the Eastern empire, of the Khazars, and of various barbarian tribes. In 1318 the Tartars, who had come into possession in the previous century, ceded the town to the Genoese, who soon raised it into new importance as a commercial centre. They usually called the place Cerchio, by a corruption of the Russian name K'rtcheff (whence Kertch), which appears in the 11th century inscription of Tmutorokansk. Under the Turks, whose rule dates from the end of the 15th century, Kertch was a military port; and as such it plays a part in the Russo-Turkish wars. Captured by the Russians under Dolgorakoff in 1771, it was ceded to them along with Yenikale by the peace of Kertchuk-Kainardji, and it became a great centre of Russian naval activity. Its importance was greatly impaired by the rise of Odessa and Taganrog; and in 1820 the fortress was dismantled. Opened to foreign commerce and made a quarantine station, it attained a certain degree of prosperity, but again suffered severely during the Crimean War.

Archæologically Kertch is of particular interest, the kurgans or sepulchral mounds of the town and vicinity having yielded a rich variety of the most beautiful works of art. Since 1825 (the date of Blaramberg's discoveries) a large number of tombs have been opened. In the so-called Zolotai (*i.e.*, Golden) kurgan, or Abtrimoba, was found a great stone vault similar in style to an Egyptian pyramid; and within, among many objects of minor note, were golden dishes adorned with griffins and beautiful arabesques. In the Kul-oba, or Mound of Cinders (opened in 1830–31 by Dubrux), was a similar tomb, in which were found what would appear to be remains of one of the kings of the Bosphorus, of his queen, his horse, and his groom. The ornaments and furniture were of the most costly kind; the king's bow and buckler were of gold; his very whip intertwined with gold; the queen had golden diadems, necklace, and breast-jewels, and at her feet lay a golden vase. In the Pavlovskoi kurgan (opened in 1858) was the tomb of a Greek lady, containing among other articles of dress and decoration a pair of fine leather boots (a unique discovery) and a beautiful vase on which is painted the return of Persephone from Hades and the setting out of Triptolemus for Attica. In a neighbouring tomb was what is believed to be "the oldest Greek mural painting which has come down to us," dating probably from the 4th century B.C. Among the minor objects discovered in the kurgans perhaps the most noteworthy are the fragments of engraved boxwood, the only examples known of the art taught by the Sicyonian painter Pamphilus.

Archéologique*, St Petersburg; L. Stephani, *Die Alterthümer vom Kertsch*, 1880; C. T. Newton, *Essays on Art and Archæology*, 1880.

KÉSMÁRK, or KÄSMARK, an ancient town in the cis-Tisian county of Szepes (Zips), Hungary, is situated on the Poprád, 11 miles north-west of Löcse (Leutschau), in 49° 8′ N. lat., 20° 28′ E. long. The trade is chiefly in linen, wine, and cereals. Owing to the vicinity of the Carpathians the rainfall is high, and the climate frequently tempestuous and inclement. At the end of 1880 the population amounted to 4477, chiefly Germans and Slovaks.

Késmárk (Latin *Forum Caseorum*) is probably a Magyarized form of the German *Käsemarkt*. In 1380, during the reign of Louis I., it was raised to the dignity of a royal free town. As the most important of the Saxon settlements in the north of Hungary, Késmárk in 1440 became the seat of the counts of Szepes (Zips). In 1464 King Matthias Corvinus granted the town the so-called *jus gladii*, its civic blazon, and the right of holding weekly markets. In 1530 Késmárk fell into the power of John Zápolya, and later it suffered much at the hands of the Polish leader Hieronymus Lasky, and from Sebastian Toköli. In 1655 the town was re-established by the emperor Ferdinand III. in all its ancient rights; and it remained a royal free town until the recent administrative changes of 1876. An international exhibition of linen goods was held at Késmárk in the summer of 1881.

KESTREL (French *Cresserelle* or *Crécerelle*, Old French *Quercerelle* and *Quercelle*, in Burgundy *Cristel*), the English name[1] for one of the smaller Falcons, originating probably from its peevish and languid cry. This bird, though in the form of its bill and length of its wings one of the true Falcons, and by many ornithologists placed among them under its Linnæan name of *Falco tinnunculus*, is by others referred to a distinct genus *Tinnunculus* as *T. alaudarius*—the last being an epithet wholly inappropriate. We have here a case in which the propriety of the custom which requires the establishment of a genus on structural characters may seem open to question. The differences of structure which separate *Tinnunculus* from *Falco* are of the slightest, and, if insisted upon, in the way some systematists have done, must lead to including in the former birds which obviously differ from Kestrels in all but a few characters arbitrarily chosen; and yet, if structural characters be set aside, the Kestrels form an assemblage readily distinguishable by several peculiarities from all other *Falconidæ*, and an assemblage that the instinct of real ornithologists (though this is treading upon dangerous ground) does not hesitate to separate from the true Falcons of the genus *Falco*, with its subsidiary groups *Æsalon*, *Hypotriorchis*, and the rest (see FALCON, vol. ix. p. 2). Scarcely any one outside the walls of an ornithological museum or library would doubt for a moment whether any bird shewn to him were a Kestrel or not; and Mr Gurney believes (*Ibis*, 1881, p. 277) that the aggregation of species placed by Mr Sharpe (*Cat. Birds Brit. Museum*, i. pp. 423–448) under the generic designation of *Cerchneis* (which should properly be *Tinnunculus*) includes "three natural groups sufficiently distinct to be treated as at least separate subgenera, bearing the name of *Dissodectes*, *Tinnunculus*, and *Erythropus*." Of these we may say that the first and last are not at all Kestrels, but are perhaps rather related to the Hobbies (*Hypotriorchis*).

The ordinary Kestrel of Europe, *Falco tinnunculus* or *Tinnunculus alaudarius*, is by far the commonest bird of prey in the British Islands, and is too common and well-known a bird to need any description. It is almost entirely a summer migrant, coming from the south in early spring and departing in autumn, though examples (which are nearly always found to be birds of the year) occasionally occur in winter, some arriving on the eastern coast in autumn. It is most often observed while practising its habit of hanging in the air for a minute or two in the same spot, by means of short and rapid beats of its wings, as, with head pointing to windward and expanded tail, it is looking out for prey,—which consists chiefly of mice, but it will at times take a small bird, and the remains of frogs, insects, and even earth-worms have been found in its crop. It generally breeds in the deserted nest of a Crow or Pie, but frequently in rocks, ruins, or even in hollow trees—laying four or five eggs, mottled all over with dark brownish-red, sometimes tinged with orange and at other times with purple. Though it may occasionally snatch up a young Partridge or Pheasant,[2] the Kestrel is quite the most harmless bird-of-prey, if it be not, from its destruction of mice and cockchafers, a most beneficial species. It is a species of very wide range, extending over nearly the whole of Europe from 68° N. lat., and the greater part of Asia—though the form which inhabits Japan and is abundant in north-eastern China has been by some writers deemed distinct and called *T. japonicus*—and it also pervades the greater part of Africa, becoming, however, scarce in southern latitudes, and unknown beyond Fantee on the west and Mombasa on the east coast (*Ibis*, 1881, p. 457). The southern countries of Europe have also another and smaller species of Kestrel, *T. tinnunculoides* (the *T. cenchris* and *T. naumanni* of some writers), which is widely spread in Africa and Asia, though specimens from India and China are distinguished as *T. pekinensis*.

Three other species are found in Africa as well—*T. rupicola*, *T. rupicoloides*, and *T. alopex*—the first of which is a common bird in the Cape Colony, while the others occur in the interior. Some of the islands of the Ethiopian region have peculiar species of Kestrel, as the *T. newtoni* of Madagascar, *T. punctatus* of Mauritius, and *T. gracilis* of the Seychelles; while, on the opposite side, the Kestrel of the Cape Verd Islands has been separated as *T. neglectus*.

[1] Other English names are Windhover and Standgale (the last often corrupted into Stonegale and Stannell), from a habit to be presently mentioned.

[2] When what are called "tame" Pheasants are bred, a Kestrel will often contract the bad habit of infesting the coops and carrying off the young birds. This evil may easily be stopped, but it should not lead to the relentless persecution of the species, especially when it is remembered that the Kestrel is in the first place attracted to the spot by the presence of the mice which come to eat the Pheasants' food.

The next species deserving of notice is that of America, *T. sparverius*, commonly known in Canada and the United States as the "Sparrow-Hawk"—a beautiful little bird, though not more courageous than the rest of its relations. Various attempts have been made to recognize several species, more or less in accordance with locality, but the majority of ornithologists seem unable to accept the distinctions which have been elaborated chiefly by Mr Sharpe (*ut supra*) and Mr Ridgway (*North American Birds*, iii. pp. 159–175), the former of whom recognizes six species, while the latter now admits but three, *T. sparverius*, *T. leucophrys*, and *T. sparverioides*, with five geographical races of the first, viz., the typical *T. sparverius* from the continent of North America, except the coast of the Gulf of Mexico; *T. australis* from the continent of South America, except the North Atlantic and Caribbean coasts; *T. isabellinus*, inhabiting continental America from Florida to Cayenne; *T. dominicensis* from the Lesser Antilles as far northwards as St Thomas; and lastly *T. cinnamominus* from Chili and western Brazil. *T. leucophrys* is said to be from Hispaniola and Cuba; and *T. sparverioides* peculiar to Cuba only. This last has been generally allowed to be a good species, though Dr Gundlach, the best authority on the birds of that island, in his latest work, published in 1876 (*Contribucion á la Ornitologia Cubana*, p. 48) will not allow its validity. More recently it has been found (*Ibis*, 1881, pp. 547–564) that *T. australis* and *T. cinnamominus* cannot be separated, that Mr Ridgway's *T. leucophrys* should properly be called *T. dominicensis*, and his *T. dominicensis* *T. antillarum*, while that gentleman has recorded the supposed occurrence of *T. sparverioides* in Florida.[1] Of other Kestrels it remains to say that *T. moluccensis* is widely spread throughout the islands of the Malay archipelago, while *T. cenchroides* seems to inhabit the whole of Australia, and has occurred in Tasmania (*Proc. Roy. Soc. Tasmania*, 1875, pp. 7, 8). No Kestrel is found in New Zealand, but an approach to the form is made by the very peculiar *Hieracidea* (or *Harpe*) *novæ-zelandiæ* (of which a second race or species has been described, *H. brunnea* or *H. ferox*) the "Sparrow-Hawk," "Quail-Hawk," and "Bush-Hawk" of the colonists—a bird of much higher courage than any Kestrel, and perhaps exhibiting the more generalized and ancestral type from which both Kestrels and Falcons may have descended. (A. N.)

KESWICK, a market-town of Cumberland, is situated on the left bank of the Greta, close to Derwentwater or Keswick Lake, about 30 miles south of Carlisle, and 300 miles from London by rail. It is one of the centres for visitors to the Cumberland lakes, and is the point whence the ascent of Skiddaw is usually begun. In the parish church of Crosthwaite, three quarters of a mile off, there is a monument to the poet Southey, whose residence for many years, Greta Hall, stands at the end of the main street, close by the river. Keswick was formerly noted for its manufacture of lead pencils; and the plumbago (locally wad) used to be supplied by the mines in Borrowdale. Lead is still found in the neighbouring hills. Char, caught in the neighbouring lakes, are potted at Keswick in large quantities during the season, and sent to all parts of England. The population in 1881 was 3220.

KESZTHELY, a market-town in the trans-Danubian county of Zala, Hungary, is picturesquely situated near the western extremity of Lake Balaton, about 97 miles south of Pozsony (Pressburg), in 46° 47′ N. lat., 17° 15′ E. long. Keszthely is chiefly noted for its well-organized agricultural institute, founded by Count George Festetics, and known as the "Georgicon." At the source of the Héviz brook there is a warm sulphur spring. The trade is principally in grain, fruit, and wine. The population at the end of 1880 was 5341, mostly Magyars by nationality, and Roman Catholics by creed.

KETCHUP, a sauce or relish prepared principally from the juice of mushrooms and of many other species of edible fungi, salted for preservation and variously spiced. The term ketchup, written also catsup and katchup, is said to be of Japanese origin. The following may be taken as a typical example of the ingredients and method of preparation of ordinary ketchup. Freshly gathered mushrooms are placed in a wooden vessel and sprinkled with salt. They are left for two or three days, during which time they are repeatedly stirred and turned over. The juice is then squeezed out, and to every gallon of the juice there is added of crushed cloves and mustard seed half an ounce each, and of black pepper, ginger, and allspice each an ounce. The mixture is boiled gently, decanted, and left to macerate for about two weeks, after which it is strained off and bottled. Should it show any tendency to putrefaction it is again boiled with the addition of salt and spices. It is of the utmost consequence to avoid copper, lead, and pewter vessels or implements in the preparation of ketchup; as far as possible glazed earthenware vessels alone should be used. The juices of various fruits, such as cucumbers, tomatoes, and especially green walnuts, are used as a basis of ketchup, and shell-fish ketchup, from oysters, mussels, and cockles, is also made; but in general the term is restricted to sauces having the juice of edible fungi as their basis.

KETI, a town and port in Kurrachee district, Sind, India, situated on the Hajámro branch of the Indus, in 24° 8′ 30″ N. lat., 67° 28′ 30″ E. long. Population (1872), 3199. The town is a large seat of river trade, and ranks next to Kurrachee among the ports of Sind. The sea-going exports comprise grain, pulses, oilseeds, wool, cotton, drugs, dyes, saltpetre, and firewood. The imports include cocoanuts, cotton piece goods, metals, sugar, spices, coir, and shells.

KETTERING, a market-town of Northamptonshire, is built on a slope near the Ise, a tributary of the Nen, 14 miles north-east of Northampton, and 75 miles north-west of London. The principal buildings are the church of SS. Peter and Paul, a good specimen of the Perpendicular style, with a tower and spire; the church of St Andrew, built in 1870, in the Decorated style; the town-hall and corn-exchange; the temperance hall; and the union workhouse. The water-works were erected in 1872 at a cost of £12,000. The chief manufactures of Kettering are boots, shoes, brushes, stays, clothing, and agricultural implements. There are iron-works in the immediate neighbourhood. The privilege of market was granted in 1227 by a charter of Henry III. The population in 1881 was 11,093.

KEUNJHAR, or KEUNJUR, a petty state in Orissa, India, lying between 21° 1′ and 22° 9′ 30″ N. lat., and 85° 14′ and 86° 24′ 35″ E. long, with an area of 3096 square miles, and a population in 1872 of 181,871. The state originally formed part of Morbhanj; but about two hundred years ago the tribes of this part, finding it a great hardship to travel through the perilous forests of Morbhanj to obtain justice from their prince, separated themselves, and set up the brother of the Morbhanj rájá as their independent ruler. The last prince rendered good service during the Kol rebellion in 1857, and was rewarded with the title mahárájá. A Government elephant establishment is maintained at Keunjhar.

KEUNTHAL, a petty hill state in the Punjab, India, between 30° 55′ 30″ and 31° 6′ N. lat., and 77° 10′ and 77° 26′ E. long., with an area of 116 square miles, and an estimated population of 50,000. The chief, a Rajput,

[1] The absence of any species of Kestrel from Jamaica is a most curious fact, considering the abundance of the former in other parts of the West Indies.

received the title of rájá in 1857. After the Gurkhá war, a portion of Keunthál, which had been occupied by the Gurkhás, was sold to the mahárájá of Patiála, the remainder being restored to its own chief. In consideration of this, no tribute is paid by the Keunthál rájá. In 1823 the district of Punár was added to the Keunthál state. The rájá exercises rights of lordship over the petty states of Kothi, Theog, Madhan, and Ratesh.

KEW, a village and parish in the county of Surrey, England. The village is pleasantly situated on the south bank of the Thames, 6 miles by road west-south-west of Hyde Park corner. It has communication with London by steamer and by several railway routes. By a stone bridge of seven arches, erected in 1789, it is connected with Brentford on the other side of the river. The village consists chiefly of a row of houses with gardens attached, situated on the north side of a green, to the south of which is the church and churchyard, and at the west the principal entrance to Kew gardens. In the vicinity there are many fine villas. From remains found in the bed of the river near Kew bridge it has been conjectured that the village is an old British settlement. The name first occurs in a document of the reign of Henry VII., where it is spelt Kayhough. The free school originally endowed by Lady Capel in 1721 received special benefactions from George IV., and the title of "the king's free school."

The estate of Kew House about the end of the 17th century came into the possession of Lord Capel of Tewkesbury, and in 1721 of Samuel Molyneux, secretary to the prince of Wales, afterwards George II. After his death it was leased by Frederick, prince of Wales, son of George II., and it continued to be the residence of members of the royal family until the estate was purchased about 1789 by George III., who devoted his chief leisure to its improvement. The old house was pulled down in 1802. Dutch House, adjoining Kew House, afterwards sold by Robert Dudley, earl of Leicester, to Sir Hugh Portman, a Dutch merchant, was purchased by George III. as a nursery for the royal children. It is a plain brick structure, and is now known as Kew Palace. The Royal Botanic Gardens of Kew originated in the exotic garden formed by Lord Capel and greatly extended by the princess dowager, widow of Frederick, prince of Wales, and by George III., aided by the skill of the Aitons and of Sir Joseph Banks. In 1840 the gardens were adopted as a national establishment, and transferred to the department of woods and forests. The gardens proper, which originally contained only about 11 acres, have been increased to 75 acres, and the pleasure grounds or arboretum adjoining extend to 270 acres.

A catalogue of the plants in the exotic garden of Kew was published by Dr Hill in 1768, 2d ed. 1769; and in 1789 William Aiton published *Hortus Kewensis*, in 3 vols. 8vo. See Oliver's *Guide to the Royal Botanic Gardens and Pleasure Grounds, Kew*, 26th edition, 1881.

KEW-KEANG FOO, a prefecture and prefectural city in the province of Keang-se, China. The city, which is situated on the south bank of the Yang-tsze Keang, 15 miles above the point where the Kan Keang flows into that river from the Po-yang lake, stands in 29° 42′ N. lat. and 116° 8′ E. long. The north face of the city is separated from the river by only the width of a roadway, and two large lakes lie on its west and south fronts. The walls are from 5 to 6 miles in circumference, and are more than usually strong and broad. As is generally the case with old cities in China, Kew-Keang has repeatedly changed its name. Under the Tsin dynasty (265–420 A.D.) it was known as Sin-Yang, under the Leang dynasty (502–557) as Keang Chow, under the Suy dynasty (589–618) as Kew-Keang, under the Sung dynasty (960–1127) as Ting-Keang, and under the Ming dynasty (1368–1644) it assumed the name it at present bears. Kew-Keang has played its part in the history of the empire, and has been repeatedly besieged and sometimes taken. The last time this worst fate overtook it was in February 1853, when the Tai-ping rebels gained possession of the city. After their manner they looted and utterly destroyed it, leaving only the remains of a single street to represent the once flourishing town. The position of Kew-Keang on the Yang-tsze Keang and its proximity to the channels of internal communication through the Po-yang lake, more especially to those leading to the green-tea-producing districts of the provinces of Keang-se and Gan-hwuy, induced Lord Elgin to choose it as one of the treaty ports to be opened under the terms of his treaty (1861). Unfortunately, however, it stands above instead of below the outlet of the Po-yang lake, and the 15 miles which separate it from that channel form one of the swiftest parts of the lower Yang-tsze Keang. This has proved to be a decided drawback to its success as a commercial port, but nevertheless the customs returns show a steady annual increase in the trade carried on. The immediate effect of opening the town to foreign trade was to raise the population in one year from 10,000 to 40,000, and at the present time the census declares it to be peopled by 48,000 souls. The foreign settlement extends westward from the city, along the bank of the Yang-tsze Keang, and is bounded on its extreme west by the P'un river, which there runs into the Yang-tsze. The bund, which is 500 yards long, was erected by the foreign community at a cost of 1700 taels. The climate is considered to be good, and though hot in the summer months is invariably cold and bracing in the winter. According to the latest customs returns the value of foreign imports into Kew-Keang in 1878 was 2,514,302 taels as against 2,954,286 in 1880; during the same period native imports showed an increase from 649,109 taels to 962,364 taels; and the value of exports declined from 8,924,436 taels to 8,824,966 taels. 1653 piculs of opium were imported in 1878, and 2290 in 1880; and the revenue returns show that while the duties levied in 1872 amounted to 585,883 taels, in 1880 the sum received from the same source was 764,571 taels.

KEY WEST (Spanish, *Cayo Hueso*, Bone Reef), a coral island, 7 miles long, from 1 to 2 miles broad, and 11 feet above sea-level, lies 60 miles south of Cape Sable, the most southerly point of the mainland of Florida. It belongs to Monroe county, Florida, and forms one of the Florida Keys. The soil is thin, but supports a tolerably dense tropical vegetation, including various fruits. In the absence of fresh springs, the water supply is derived from rain and distillation. The healthy climate attracts an annually increasing number of invalids from the north. The inhabitants are chiefly of Cuban and Bahaman extraction, and speak a Spanish patois.

KEY WEST, chief city of Monroe county, covers nearly one-half of Key West island. It has broad streets, arranged on the rectangular plan; and the houses, almost all wooden, are picturesquely surrounded by tropical shrubs and plants. The chief buildings are the Government naval and judicial edifices, the masonic hall, and the opera house. There is also a convent, and several churches and schools. The position of Key West in relation to Cuba, the Gulf of Mexico, and the coast of the United States gives it commercial advantages that are seconded by the possession of one of the finest harbours in the Union south of the Chesapeake. Key West shows much the largest tonnage in Florida of vessels clearing and entering; and it has frequent and good steam communication with the mainland. Described as being "to Cuba what Gibraltar is to Ceuta, to the Gulf of Mexico what Gibraltar is to the Mediterranean," Key West is one of the chief naval stations of the United States, and is strongly fortified. The principal manufacture is that of cigars, begun in 1867, and steadily prospering. Previous to 1874, when a hurricane destroyed the works, 30,000 bushels of salt were annually produced on the island by solar evaporation. Fishing, sponge-gathering, and turtle-catching occupy many of the inhabitants; and a large number of small vessels are employed in "wrecking," *i.e.*, in saving goods and rendering assistance to vessels that have failed to clear the dangerous Florida reef. The population of the city in 1880 was 9890.

KHABAROVKA, the chief town of the Maritime Province, in eastern Siberia, is situated on high crags, on the right bank of the Amoor, amidst wide forests and marshes, at the confluence of the Ussuri. It was but a poor settlement with 700 inhabitants when it took the place of Nikolaievsk as the seat of the military administration of the Maritime Province and of the various establishments connected with the Amoor fleet. Since its foundation in 1857 it has always been the chief centre for the trade in sables, purchased yearly from the aborigines to the average amount of 20,000 pieces, and sent to Irkutsk and to Russia.

KHAIRÁBÁD, or KHYRABAD, the chief town of Sitápur district, Oudh, India, situated 5 miles south of Sitápur civil station and cantonment, 27° 31′ 30″ N. lat., 80° 47′ 35″ E. long. It is the fifth largest town in Oudh, with a population in 1869 of 15,677, made up of Hindus and Mohammedans in about equal numbers. The town contains forty mosques and thirty Hindu temples, besides a beautiful group of sacred Mohammedan buildings. A large fair is held here in January, lasting ten days, and attended by an average of 60,000 persons. A second fair is held at the *Dasahára* festival, attended by about 15,000 persons. The annual value of *bázár* sales is about £34,000.

KHAIRPUR, or KHYRPOOR, a native state in Sind, India, lying between 26° 10′ and 27° 46′ N. lat., and 68° 14′ and 70° 13′ E. long., bounded on the N. by Shikárpur district, S. by Jáisalmír state, E. by Hyderabad district, and W. by the Indus river, with an area of 6109 square miles. Like other parts of Sind, Khairpur consists of a great alluvial plain, very rich and fertile in the neighbourhood of the Indus and the irrigation canals, the remaining area being a continuous series of sand-hill ridges covered with a stunted brushwood, where cultivation is altogether impossible. A small ridge of limestone hills passes through the northern part of the state, being a continuation of a ridge known as the Ghar, running southwards from Rohri. The state is watered by five canals drawn off from the Indus, besides the Eastern Nára, a canal which follows an old bed of the Indus. In the desert tracts are pits of *natron*, forming a source of revenue to the chief; as many as a thousand camel loads are annually exported to northern and central India, as well as to the seaboard, each load being taxed at 5s.

A census taken in 1872 returned the population at 130,350, or 21 per square mile. The Moslems chiefly belong to the Rájur tribe. The Hindus are principally Rájputs of the Soda Thákur clan, who inhabit the extreme eastern part of the state. They are a well-built and sturdy race, of nomadic habits, their wealth consisting in herds of camels, oxen, sheep, and goats. The principal food grain crops are *joár* (*Holcus sorghum*), *bájrá* (*Holcus spicatus*), wheat, gram, and pulses. Indigo is largely cultivated, and cotton to a less extent. Fruits consist of the mango, mulberry, apple, pomegranate, date, &c. Several varieties of forest trees are grown in the mír's game preserves. The annual value of the export trade is estimated at about £52,000, and the imports at £25,000. Cotton and silk fabrics, silver ware, lacquered wood-work, boots, shoes, horse trappings, swords, matchlocks, and pottery are the chief manufactures. A small quantity of salt and saltpetre is also manufactured. The revenue of the state, which is collected in kind, the mír receiving one-third of the produce, is estimated to amount to about £50,000. The climate is agreeable during about four months of the year, and fiercely hot during the remaining eight. The principal diseases are fever, ophthalmia, and cutaneous affections.

The chief or mír of Khairpur belongs to a Baluchi family, known as the Tálpur, which rose on the fall of the Kalhorá dynasty of Sind. About 1813, during the troubles in Cabul incidental to the establishment of the Bárakzái dynasty, the mírs were able to refuse the tribute which up to that date had been somewhat irregularly paid to the rulers of Afghánistán. In 1832 the individuality of the Khairpur state was recognized by the British Government in a treaty, under which the use of the river Indus and the roads of Sind were secured. When the first Cabul expedition was decided on, the mír of Khairpur, Alí Murád, cordially supported the British policy; and the result was that, after the battles of Miani and Daba had put the whole of Sind at the disposal of the British, Khairpur was the only state allowed to retain its political existence under the protection of the paramount power.

KHÁMGAON, a town in Akola district, Berar, India, in 20° 42′ 30″ N. lat., 76° 37′ 30″ E long., with a population in 1867 of 9432. The cotton market—the largest in the province—was established about 1820. A branch line of 8 miles, opened in 1870, connects Khámgáon with the Great Indian Peninsula Railway. In fair seasons above 100,000 bullock-loads of cotton are brought into Khámgáon on the weekly market day. To the east of the town is a large enclosed cotton-market. The factories of the Berár Ginning Company and the Mofussil Pressing Company possess steam machinery for full-pressing cotton.

KHÁNDESH, or CANDEISH, a district of Bombay Presidency, India, lying between 20° 15′ and 22° N. lat., and 73° 37′ and 76° 24′ E. long., bounded on the N. by the Sátpura hills, E. by Berar, S. by the Sátmála or Ajanta hills, S.W. by Násik district, and W. by Baroda territory, with an area of 10,162 square miles. The chief town is Dhulia. The principal natural feature is the Tápti river, which enters at the south-east corner of the district, and flows in a north-westerly direction, dividing Khándesh into two unequal parts. Of these the larger lies towards the south, and is drained by the river Girna. Northwards beyond the alluvial plain, which contains some of the richest tracts in Khándesh, the land rises towards the Sátpura hills. In the centre and east the country is level, save for some low ranges of barren hills, and has in general an arid, unfertile appearance. Towards the north and west, the plain rises into a difficult and rugged country, thickly wooded, and inhabited by wild tribes of Bhíls, who chiefly support themselves on the fruits of the forests and by the profits of wood-cutting. The drainage of the district centres in the Tápti, which receives thirteen principal tributaries in its course through Khándesh. None of the rivers are navigable, and the Tápti flows in too deep a bed to be made use of for irrigation. The district on the whole, however, is fairly well supplied with surface water. Khándesh is not rich in minerals. A large area is under forest; but the jungles have been robbed of most of their valuable timber. Wild beasts are numerous. As late as 1858 tigers abounded; but since then they have been very closely hunted, and driven almost entirely out of the plains into the rough hilly country.

The census of 1872 returned the population at 1,028,642 (males 530,610, and females 498,032),—Hindus, 948,279; Musalmáns, 79,359; Pársis, 61; Christians, 517; Jews, 36; Sikhs, 59; "others," 331. Of the aboriginal tribes the Bhils are the most important. They number 122,092, and formerly were a wild and lawless robber tribe. Since the introduction of British rule, the efforts made by kindly treatment, and by the offer of suitable employment, to win the Bhils from their disorderly life have been most successful. Many of them are now employed in police duties and as village watchmen. The total area of Government cultivable land is returned at 3,453,549 acres, of which 2,218,355 acres were under cultivation in 1875–76. Food grains take up 52 per cent.; pulses, 5¾ per cent.; fibres, 28 per cent.; oil seeds, 11 per cent.; miscellaneous crops, 3¼ per cent. of the cultivated area. Irrigation is more extensively practised in Khándesh than in the Deccan and the southern Marhattá country. Owing to the liability of the district to river-floods, almost every year is marked by some failure of the crops. The chief exports are food grains, oil seeds, butter, indigo, wax, and honey; and the imports salt, spices, metal, piece goods, cotton yarn, and sugar. There are ten steam cotton presses, and one steam spinning and weaving factory. Many Bombay mercantile houses have established agencies in the district; and towards the east, in the rich Tápti valley, Jalgáon and Bhusáwal are rising into important centres of trade. The trunk road from Bombay to Agra and the Great Indian Peninsula Railway intersect the district, and of late years roads have been made all along the chief lines of traffic. The total revenue in 1876–77 amounted to £422,291, of which £303,706 was made up of the land tax. The same year there were 272 schools, with 16,249 pupils. The average annual rainfall for the five years ending 1875–76 was 25 inches. Fevers and cutaneous affections are the prevailing diseases.

KHANDPÁRA, a petty state in Orissa, India, lying between 20° 11′ and 20° 25′ N. lat., and 85° 1′ and 85° 25′ E. long., with an area of 244 square miles, and a population in 1872 of 60,877, mostly Hindus. Khandpára originally formed a part of the neighbouring state of Nayágarh, and was separated from it about two hundred years ago by a brother of the Nayágarh rájá, who established his independence. The present chief, a Rájput by caste, is the eighth in descent from the founder. The country forms a very valuable territory, and is one of the best cultivated of the Orissa states. Fine *sál* timber abounds in the hilly parts, and magnificent banian and mango trees stud the plain. It is intersected by the Kuariá and Danka rivers, small tributaries of the Mahánadi. The estimated annual revenue of the chief is £2258; tribute to the British government, £421.

KHANDWA, or CUNDWAH, the chief town and headquarters station of Nimár district, Central Provinces, India, 21° 50′ N. lat., 76° 23′ E. long. Population (1877), 14,119. Khandwa is perhaps the most rising town in the Central Provinces. It is the station on the Great Indian Peninsula Railway, where the whole traffic of Central India towards Bombay meets the line. It has entirely superseded Burhanpur, the ancient centre of trade between Málwá, the Nerbudda valley, and the Deccan. Extensive barracks have been built for the relays of troops which pass through in the cold season, and there is also a good travellers' bungalow with a spacious *sarái* or native rest-house.

The Arabian geographer, Al Birúní (*circa* 1000 A.D.), mentions Khandwa; and a century later, it was a great seat of Jain worship. The mound on which the town stands has supplied many finely carved pillars, cornices, and other remains of the old Jain buildings, which have been built into Bráhmanical temples, the walls of the Marhattá fort, and other structures. It also formed a quarry for the Sivaite temples surrounding the four *kunds* or water reservoirs, one of which is on each side of the town, that on the west side bearing the date 1132 A.D.

KHARKOFF, a government of European Russia, surrounded by those of Kursk, Poltava, Ekaterinoslaff, and Voronezh, and belonging partly to the basin of the Don and partly to that of the Dnieper. The area is estimated at 21,035 square miles. In general terms the government may be described as a table-land with an elevation of from 300 to 460 feet traversed by deep-cut river valleys. The soil is for the most part of high fertility, about 47 per cent. of the surface being arable land and 30 per cent. natural pasture; and though the winter is rather severe the summer heat is sufficient for the ripening of grapes and melons in the open air. The bulk of the population is engaged in agricultural pursuits, and the breeding of sheep, cattle, and horses, though various manufacturing industries have also received a rapid development, more especially since the middle of the present century. The ordinary cereals, maize, buckwheat, millet, hemp, flax, tobacco, poppies, and beetroot are all grown, and bee keeping and silk-worm rearing are of considerable importance. In 1879 the horses numbered 258,711, the cattle 475,217, the sheep 1,059,596, of which 376,777 were of fine-fleeced varieties. Beetroot sugar factories, cotton mills, woollen factories, iron-works, and tanneries are the leading industrial establishments; their whole production in 1879 was estimated at 23,939,147 roubles (about £3,790,000). The mass of the people are Little Russians, but there are also Great Russians, Calmucks, Germans, Jews, and Gipsies. In 1867 the total population was 1,681,486, and in 1879 2,036,949—4119 of these being Raskolniks (dissidents), 1960 Roman Catholics. 2732 Protestants, and 3079 Jews. The government is divided into eleven districts—Kharkoff, Akhtuirka, Bogodukhoff, Izyum, Kupyansk, Lebedyin, Zmieff, Starobyelsk, Sumui, Valki, and Voltchansk. In 1879 there were eight towns with populations above 5000—Kharkoff, Izyum (15,741), Starobyelsk (12,581), Voltchansk (11,107), Slavansk (10,558), Tchugueff (9418), Valki (7001), Zolotcheff (5038). Ecclesiastically the government is a separate eparchy or diocese of the Greek Church. The Roman Catholics are subject to the bishop of Tiraspol in Kherson.

KHARKOFF, the chief town of the above government, is situated in 50° 37′ N. lat. and 25° 5′ E. long., in the valley of the Donets, 462 miles from Moscow and 137 miles from Kursk. It has railway communication northward by Kursk and southward to Mariupol on the Sea of Azoff and to Odessa by Poltava and Balta. The four annual fairs are among the busiest in Russia, more especially the Krestchenskaya or Epiphany fair, which is opened on the 6th (18th) January. The turn-over is estimated at from £3,000,000 to £4,000,000. Thousands of horses are bought and sold. At the Trinity (Troitsa) fair in June an extensive business (£800,000) is done in wool. A great variety of manufactured goods are produced in the town—linen, felt, sugar (especially from beetroot), tobacco, brandy, soap, candles, cast-iron. Besides a flourishing university, instituted in 1805, and attended in 1879 by 720 male and 163 female students, Kharkoff possesses an observatory, a large veterinary college, a botanical garden, a theological seminary, and several important institutions of beneficence. The university building was formerly a royal palace. The library contained in 1878 98,000 volumes; and the zoological collections are especially rich in the birds and fishes of southern Russia. Extensive barracks are maintained in the town. Public gardens occupy the site of the ancient military works; and the Government has a model farm in the neighbourhood. Of the Orthodox churches one has the rank of cathedral. The population of Kharkoff was 59.968 in 1867, and 101,175 in 1879.

The foundation of Kharkoff is assigned to the year 1650, and the name is at least popularly connected with that of Khariton, the Cossack originator of the settlement; but there is archæological evidence of a much earlier occupation of the district, if not of the site. The Cossacks of Kharkoff remained faithful to the czar during the rebellions of the latter part of the 17th century; in return they received a variety of privileges, and continued to be a strong advance guard of the Russian power, till the final subjugation of all the southern region. Along with other military settlements Kharkoff was placed on a new footing in 1765; and at the same time it became the administrative centre of the Ukraine. It has been the government town from the establishment of the government in 1780. For plan see Reclus, *Géographie Universelle*, vol. v. p. 807.

KHARPUT (officially MA'MURAT-EL-'AZÍZ), a town of Armenia, the seat of a mutasarrif, is situated about 60 miles north of Diarbekir on the highway to Siwas, and occupies a peculiarly picturesque position on a rocky eminence rising above the great plain through which the waters of the eastern Euphrates describe a devious passage. Besides the imposing ruins of the castle on the height, it possesses an ancient Jacobite church and convent, and is the seat of an important American missionary college and schools. The population may be estimated at 25,000 or rather more, as there are 5000 households in the town (70 Jacobite, 500 Armenian, and the rest Turkish).

There is epigraphic evidence for the existence of a town on this site in the time of Nero (see Mordtmann in *Hermes*, 1880), and by some it is identified with Carcathiocerta, the capital of the province of Sophene. Kharput (Armenian, *Kharpert, i.e.*, Castle Rock; Χάρποτε of Cedrenus; Arabic, *Khartabirt*) appears in the older Arabic literature as Hisn Ziyád. It is the Quart Piert or Quart Pierre of William of Tyre, the scene of the tragical story of the imprisonment of Baldwin II. by the emír Balak. See Tozer, *Turkish Armenia*, &c., London, 1881.

KHARTÚM or KHARTOUM (erroneously Kartum), the chief town of the Egyptian Súdán, situated in 15° 37′ N. lat., and 32° 54′ E. long., on the peninsula formed by the junction of the White and the Blue Nile. The level of the stream just below the town is 1240 feet. The principal landing-place and the dockyards are on the Blue river. The surrounding country is flat and open, the forest described by the first European visitors having disappeared for a considerable distance up the river, but there are many gardens within and around the town planted with date-palms, fig and orange trees, &c. The town, though consisting chiefly of mean mud-built huts, has a considerable number of substantial modern buildings, the most imposing of which is the stone-faced palace of the governor. As the centre of the great caravan routes from the interior of Africa, Khartúm carries on a good legitimate trade, but the inhabitants have always shown a preference for slave traffic when the governor has proved indulgent or inefficient. Khartúm is the seat of a Roman Catholic mission founded by Pope Gregory XVI. in 1846, and long conducted by Dr Ignaz Knoblecher, of Protestant missions, and of several European consulates. The British consulate, established in 1849, and latterly held by Petherick, was abolished in 1864 under circumstances which gave rise to much comment. The population amounts to 50,000, including in addition to the natives the usual medley elements of an Egyptian town.

Khartúm was founded by Mohammed Aly in 1823. In 1859 the population was estimated at 40,000. In 1869–70 the disturbed state of the country had brought the number down to 15,000, but since then the recovery has been rapid.

See Lord Prudhoe in *Journ. R. Geog. Soc.* 1832; G. Melly, *Khartoum*, &c., 1851; Heuglin, *Reise n. Abessinien*, 1868; Schweinfurth, *Heart of Africa*, 1873; Hansal, *Briefe aus Chartum*, 1856 and 1880. Details regarding the Roman Catholic mission will be found in the last work; in *Jahresberichte* of the Marienverein; and in *Zeitschr. f. allg. Erdk.*, 1858 and 1861.

KHÁSI AND JÁINTIA HILLS, a district in Assam, India, lying between 25° 1′ and 26° 14′ N. lat., and 90° 47′ and 92° 52′ E. long., and bounded on the N. by Kámrúp and Nowgong districts, E. by Cachar and the Nágá Hills, S. by Sylhet, and W. by the Gáro Hills. Its approximate area is 6157 square miles.

The district consists of a succession of steep ridges running east and west, with elevated table-lands between. On the southern side, towards Sylhet, the mountains rise precipitously from the valley of the Bárák. The first plateau is about 4000 feet above sea-level. Farther north is another plateau, on which is situated the station of Shillong, 4900 feet above the sea; behind lies the Shillong range, of which the highest peak rises to 6449 feet. On the north side, towards Kámrúp, are two similar plateaus of lower elevation. The general appearance of all these table-lands is that of undulating downs, covered with grass, but destitute of large timber. At 3000 feet elevation the indigenous pine predominates over all other vegetation, and forms almost pure pine forests. The highest ridges are clothed with magnificent clumps of timber trees, which superstition has preserved from the axe of the woodcutter. The characteristic trees in these sacred groves chiefly consist of oaks, chestnuts, magnolias, &c. Beneath the shade grow rare orchids, rhododendrons, and wild cinnamon. The streams are merely mountain torrents. As they approach the plains, they form rapids and cascades, and many of them pass through narrow gorges of wild beauty. From time immemorial, Lower Bengal has drawn its supply of lime from the Khási Hills, and the quarries along their southern slope are literally inexhaustible. Coal of excellent quality crops out at several places, but has not yet been remuneratively worked. Ironstone exists in abundance, and in former days the Khásias were renowned as smelters of iron. Among other natural products may be mentioned beeswax, lac, and caoutchouc. Wild animals abound, including the elephant, rhinoceros, tiger, buffalo, *mithun* or wild cow, and many varieties of deer.

Both as regards history and administration the Khási (Khasiá or Cossya) and Jáintia or Jayntiyá Hills constitute two separate tracts. The Khási Hills are occupied by a collection of petty states, each governed by an elective ruler. The chiefs have not been brought completely under British administration, and still retain marks of semi-independence. The headquarters of the British political agent for the Khási Hills is at Chára Púnjí (Cherra Poonjee). The Jáintia Hills, on the other hand, are purely British territory. The inhabitants call themselves Syntengs, and first became British subjects in 1835 (see JÁINTIA HILLS, vol xiii. p. 554).

An enumeration in 1872 disclosed a total population in the Khási and Jáintia Hills of 141,838—aboriginal tribes, 141,283; Hindus, 365; Mohammedans, 62; Christians, 128. The two races of Khásias and Syntengs have succeeded in preserving to the present day their primitive isolation, free from the interference of Hinduism. They have only given way somewhat to Hindu prejudices as regards purity of food. The Khásias have no written character or literature, nor even any traditions of their own. The most curious of their social customs is the importance attached to female descent and female authority. The husband marries into the wife's family, the wife or her mother is regarded as the head of the household, and all property descends in the female line—a survival of the polyandric institutions still kept up in full force by the Nairs, and other non-Aryan tribes of India. The ashes of the dead are buried under cromlechs consisting of four upright slabs of stone, covered over by a fifth slab. The only places in the Khási and Jáintia Hills above the rank of hamlets are Shillong, the headquarters station, Jowái, and Chára Púnjí.

The principal cereal crop is rice, but even of this they do not grow sufficient for their own consumption. Sugar cane, cotton, and potatoes are also grown; and fruits such as oranges, limes, and pine-apples are raised in large quantities for export to Calcutta. The land is the absolute property of the cultivators, who pay no rent or revenue either to the British Government or to their own chiefs. Blights, floods, and droughts are almost unknown. Of a total area of 6157 square miles, only 286 are estimated as under cultivation, but other 3896 are returned as available for tillage. The trade of the hills is considerable. The estimated exports in 1876–77 were valued at £160,000, chiefly potatoes, limestone, cotton, stick-lac, bay leaves, oranges, and betel nuts. The imports were valued at £157,000. By far the greater portion of the trade is conducted at a row of markets along the southern foot of the hills, of which Chhatak in Sylhet district is the most important.

The Khási and Jáintia Hills constitute a political agency, independent of the ordinary jurisdiction. The Khási petty states, twenty-five in number, are presided over by elective chiefs, having jurisdiction over their own subjects in all cases except homicide. The British Government undertakes the management of the natural products of the country, such as lime, coal, timber, and elephants, and pays over to the chiefs a half share of the profits. Their other sources of revenue are market dues, court fines, and various cesses. Their aggregate income is approximately estimated at £5000, of which £2300 is derived from lime quarries. The total revenue of the district to the British Government in 1875 was £13,383, of which the larger portion came from royalties on lime quarries and the house tax; the expenditure was £9692. Education is conducted through the agency of the Welsh Calvinistic mission, and in 1874–75 there were seventy-three schools open, attended by 1666 pupils. Female education is making progress among the Khásias. The climate of the district is mild and equable, though in some parts excessively humid. At Shillong the thermometer rarely exceeds 80° Fahr., and falls as low as 38°. Shallow water occasionally freezes, but snow never falls. The rainfall at Chára Púnjí is the heaviest recorded in the world. The average during the three years ending 1876 is returned at 368·41 inches; and 805 inches are said to have fallen in 1861, including 366 inches in the single month of July. At Shillong the annual rainfall declines to about 85 inches; and at Jowái, which occupies an intermediate position, the average is 150 inches. The district is liable to shocks of earthquake. Generally speaking, the climate is healthy, both for natives and Europeans. Cholera never prevails, unless directly imported from the plains.

KHATMÁNDU, the capital of the kingdom of Nepál, India, situated on the bank of the Vishnumati river at its junction with the Bághmati, 27° 36′ N. lat., 85° 24′ E. long. The town, which is said to have been founded by Rájá Gunakámadeva about 723, now contains a population estimated at about 50,000, occupying 5000 houses made of brick, and usually from two to four stories high. Many of the houses have large projecting wooden windows or balconies, richly carved. The mahárájá's palace, a huge, rambling, ungainly building, stands in the centre of the city, which also contains numerous handsome temples. The streets are extremely narrow, and the whole town very dirty. A British resident, with a small staff and escort, is stationed about a mile to the north of the city.

KHAZARS. This vanished people, who appear also as Chozars, as Ἀκάτζιροι or Χάζαροι in Byzantine writers, as Khazirs in Armenian and Khwalisses in Russian chronicles, Ugri Bielii in Nestor, and Kosa (?) in Chinese, occupied a prominent place amongst the secondary powers of the Byzantine state-system. In the epic of Firdousi "Khazar" is the representative name for all the northern foes of Persia, and legendary invasions long before the Christian era are vaguely attributed to them. But the Khazars are an historic figure upon the borderland of Europe and Asia for at least nine hundred years (190–1100 A.D.). The three hundred and fifty years 600–950 A.D. mark the epoch of their greatness, but their rise can be traced for four centuries before, and their decline for one hundred and fifty years to follow. Their home was in the spurs of the Caucasus and along the shores of the Caspian—the "sea of the Khazars"; and their cities, all of them populous and civilized commercial centres, were *Itil*, the capital, upon the delta of the Volga, the "river of the Khazars," *Semender* (Tarkhu), the older capital, *Khamlidje* or *Khalendsch*, *Belendscher*, the outpost towards Armenia, and *Sarkel* on the Don. They were the Venetians of the Caspian and the Euxine, the organizers of the transit between the two basins, the universal carriers between East and West; and Itil was the meeting-place of the commerce of Persia, of Byzantium, of Armenia, of Russia, and of the Bulgarians of the middle Volga. The tide of their dominion ebbed and flowed repeatedly during their history, but the normal Khazaria may be taken as the territory included between the Caucasus, the Volga, and the Don, with the outlying province of the Crimea or "Little Khazaria." The southern boundary never greatly altered; it did at times reach the Cyrus and the Araxes, but on that side the Khazars were confronted by the great powers of Byzantium and Persia, and were for the most part restrained within the passes of the Caucasus by the fortifications of Dariel. Amongst the nomadic Ugrians and agricultural Slavs of the north their frontier fluctuated widely, and in its zenith Khazaria extended from the Dnieper to Bolgari upon the middle Volga, and along the eastern shore of the Caspian to Asterabad.

Ethnology.—Few points have been more disputed than the origin of this interesting people; and there is still no consent amongst authorities upon the subject. They are assigned to the Turkish stock by Latham and Howorth, to the Ugrian by Klaproth and Vivien St Martin, and have even been claimed as Jews on account of their use of the Hebrew character and the profession of the Hebrew faith amongst them. But their geographical position, their history, and the contemporary witness we have as to their physical character, their language, and their own national tradition, may be accepted as conclusive proof that the Khazars were an indigenous people of the Caucasus, and near akin to the Armenians and the Georgians.

Their king Joseph, in answer to the inquiry of the Rabbi Chasdai Ibn-Shafrût of Cordova (*circ.* 958) stated that his people sprang from Thogarmah, grandson of Japhet, and the supposed ancestor of the other peoples of the Caucasus. The Arab geographers who knew the Khazars best connect them either with the Georgians (Ibn el Athîr) or with the Armenians (Dimishqy, ed. Mehren, p. 263); whilst Ahmed ibn Fadlân, who passed through Khazaria on a mission from the caliph Moktadir (921 A.D.), positively asserts that the Khazar tongue differed not only from the Turkish, but from that of the bordering nations, which were Ugrian.

Nevertheless there are many points connected with the Khazars which indicate a close connexion with Ugrian or Turkish peoples. The official titles recorded by Ibn Fadlân are those in use amongst the Tartar nations of that age, whether Huns, Bulgarians, Turks, or Mongols. The names of their cities can be explained only by reference to Turkish or Ugrian dialects (Klaproth, *Mém. sur les Khazars*; Howorth, *Khazars*). Some too amongst the mediæval authorities (Ibn Haukal and Istakhry) note a resemblance between the speech in use amongst the Khazars and the Bulgarians; and the modern Magyar—a Ugrian dialect—can be traced back to a tribe which in the 9th century formed part of the Khazar kingdom. These characteristics, however, are accounted for by the fact that the Khazars were at one time subject to the Huns (448 A.D. *et seq.*), at another to the Turks (*circ.* 580), which would sufficiently explain the signs of Tartar influence in their polity, and also by the testimony of all observers, Greeks, Arabs, and Russians, that there was a double strain within the Khazar nation. There were *Khazars* and *Kara* (black) *Khazars*. The "Khazars" were fair-skinned, black-haired, and of a remarkable beauty and stature; their women indeed were sought as wives equally at Byzantium and Baghdad; while the "Kara Khazars" were ugly, short, and were reported by the Arabs almost as dark as Indians. The latter were indubitably the Ugrian nomads of the steppe, akin to the Tartar invaders of Europe, Huns, Bulgarians, and Hungarians, who filled the armies and convoyed the caravans of the ruling caste. But the Khazars proper were a civic commercial people, the founders of cities, remarkable for somewhat elaborate political institutions, for persistence, and for good faith—all qualities foreign to the Hunnic character.

They are identified with good reason (by Zeuss, V. St Martin, Howorth, Latham) with the Ἀκάτζιροι (perhaps Ak-Khazari, "White Khazars") who appear upon the lower Volga in the Byzantine annals, and thence they have been deduced, though with less convincing proof, either from the Ἀγάθυρσοι or the Κατίαροι of Herodotus, iv. 104 (Latham, V. St Martin). There was throughout historic times a close connexion which eventually amounted to political identity between the Khazars and the Barsileens (the Passils of Moses of Chorene) who occupied the delta of the Volga; and the Barsileens can be traced through the pages of Ptolemy (*Geog.*, v. 9), of Pliny (iv. 26), of Strabo (vii. p. 306), and of Pomponius Mela (ii. c. 1, p. 119) to the so-called Royal Scyths, Σκύθαι βασιλῆες, who were known to the Greek colonies upon the Euxine, and whose political superiority and commercial enterprise led to this rendering of their name. Such points, however, need not here be further pursued than to establish the presence of this white race ("La Race Blonde" of Klaproth) around the Caspian and the Euxine throughout historic times. They appear in European history as White Huns (Ephthalites), White Ugrians (Sar-ogours), White Bulgarians. They were the carriers between Europe and the farthest East. Owing to climatic causes (see ASIA) the tract they occupied was slowly drying up. They were the outposts of civilization towards the encroaching desert, and the Tartar nomadism that advanced with it. They held in precarious subjection the hordes whom the conditions of the climate and the soil made it impossible to supplant. They bore the brunt of each of the great waves of Tartar conquests, and were eventually overwhelmed.

History.—From out of the mass of this white race of the steppe the Khazars can be first historically distinguished at the end of the 2d century of our era. They burst into Armenia with the Barsileens, 198 A.D. They were repulsed and attacked in turn, but thenceforth Khazar wars occupy a prominent place in the Armenian annals for eight hundred years. The pressure of the nomads of the steppe, the quest of plunder or revenge, these seem the only motives of these early expeditions; but in the long struggle between the Roman and Persian empires, of which Armenia was not seldom the battlefield, and eventually the prize, the attitude of this powerful people of the Caucasus assumed political importance. Armenia inclined to the civilization and ere long to the Christianity of Rome, whilst her Arsacid princes maintained an inveterate feud with the Sassanids of Persia. It became therefore the policy of the Persian kings to call in the Khazars to neutralize or to chastize the efforts of the Armenians in every collision with the empire (200–350). During the 4th century, however, the growing power of Persia culminated in the annexation of eastern Armenia. The Khazars, endangered by so powerful a neighbour, passed from under Persian influence into that remote alliance with Byzantium which thenceforth characterized their policy, and they aided Julian in his invasion of Persia (363). Simultaneously with the approach of Persia to the Caucasus the terrible empire of the Huns sprang up among the Ugrians of the northern steppes. The Khazars straitened on every side remained passive till the danger culminated in the accession of Attila (434). The emperor Theodosius, with reason terrified for civilization, sent envoys to bribe the Khazars (Ἀκάτζιροι) to divert the Huns from the empire by an attack upon their flank. But there was a Hunnic party amongst the Khazar chiefs. The design was betrayed to Attila; and he extinguished the independence of the nation in a moment. Khazaria became the appanage of his eldest son, and the centre of government amongst the eastern subjects of the Hun (448). Even the iron rule of Attila was preferable to the time of anarchy that succeeded it. Upon his death (454) the wild immigration which he had arrested revived. The Khazars and the Sarogours (*i.e.*, White Ogors, possibly the Barsileens of the Volga delta) were swept along in a flood of mixed Tartar peoples which the conquests of the Jouan Jouan (the Avars) had set in motion. The Khazars and their companions broke through the Persian defences of the Caucasus. They appropriated the territory up to the Cyrus and the Araxes, and roamed at large through Iberia, Georgia, and Armenia. The Persian king, deeming the floodgates of the steppes opened, implored the emperor Leo I. to help him defend Asia Minor at the Caucasus (457), but Rome was herself too hard pressed, nor was it for fifty years that the Khazars were driven back, and the pass of Derbend fortified against them (*circ.* 507).

Throughout the 6th century Khazaria was the mere highway for the wild hordes to whom the Huns had opened the passage into Europe, and the Khazars took refuge (like the Venetians from Attila) amongst the seventy mouths of the Volga. The rise of the first Turk empire in Asia (554) precipitated the Avars upon the West. The conquering Turks followed in their footsteps (560–580). They beat down all opposition, wrested even Bosphorus in the Crimea from the empire, and by the annihilation of the Ephthalites completed the ruin of the White Race of the plains from the Oxus to the Don. The empires of Turks and Avars, however, ran swiftly their barbaric course, and the Khazars arose out of the chaos to more than their ancient renown. They issued from the land of Barsilia, and extended their rule over the Bulgarian hordes left masterless by the Turks, compelling the more stubborn to migrate to the Danube (641). The agricultural Slavs of the Dnieper and the Oka were reduced to tribute, and before the end of the 7th century the Khazars had annexed also the Crimea, had won complete command of the Sea of Azoff, and, seizing upon the narrow neck which separates the Volga from the Don, had organized the portage which has continued since an important link in the traffic between Asia and Europe. The alliance with Byzantium was revived. Simultaneously and, we cannot doubt, in concert with the Byzantine campaign against Persia (589), the Khazars had reappeared in Armenia, though it was not till 625 that this people, long known to Persians and Armenians as Khazirs and to the Romans as Akatzirs, take their place as Khazars in the Byzantine annals. They are then described as "Turks from the East," a powerful nation which held the coasts of the Caspian and the Euxine, and took tribute of the Viatitsh, the Severians, and the Polyane. The khakan, enticed by the promise of an imperial princess, furnished Heraclius with 40,000 men for his Persian war, who shared in the victory over Chosroes at Nineveh.

Meanwhile a power had arisen which transformed the whole course of Eastern politics and committed the Khazars to a struggle for life which lasted two hundred years. Mohammed had proclaimed his faith, and the Saracens were advancing to enforce it. The Persian empire was struck down (637), and the Moslems poured into Armenia. The khakan had defied the summons sent him by the invaders, and he now aided the Byzantine patrician in the defence of Armenia. The allies were defeated; and ere long the Moslems undertook the subjugation of Khazaria (651). It was the beginning of eighty years of ceaseless, obstinate, ineffectual warfare. Ten great invasions of Khazaria through the pass of Derbend are recorded, and many a retributive raid upon the Moslems; but in the end their fanaticism and enormous superiority in numbers prevailed. The khakan and his chieftains were captured and compelled to embrace Islam (737), and till the decay of the Mohammedan empire Khazaria with all the other countries of the Caucasus paid an annual tribute of children and of corn (737–861). Nevertheless, though overpowered in the end, the Khazars had protected the plains of Europe from the Mohammedans, and made the Caucasus the limit of their conquests.

In the interval between the decline of the Mohammedan empire and the rise of Russia the Khazars reached the zenith of their power. The merchants of Byzantium, Armenia, and Baghdad met in the markets of Itil (whither since the raids of the Mohammedans the capital had been transferred from Semender), and traded for the wax, furs, leather, and honey that came down the Volga. So important was this traffic held at Constantinople that, when the portage to the Don was endangered by the irruption of a fresh horde of Turks (the Petchenegs), the emperor Theophilus himself despatched the materials and the workmen to build for the Khazars a fortress impregnable to their forays (834). Famous as the one stone structure is in that stoneless region, the post became known far and wide amongst the hordes of the steppe as Sar-kel or the White Abode. Merchants from every nation found protection, justice, and perfect good faith in the Khazar cities. The Jews, expelled from Constantinople, sought a home amongst them, developed the Khazar trade, and contended with Mohammedans and Christians for the theological allegiance of the pagan people. The dynasty accepted Judaism (*circ.* 740), but there was equal tolerance for all, and each man was held amenable to the authorized code and to the official judges of the faith which he professed. At the Byzantine court the khakan was held in high honour. The emperor Justinian Rhinotmetus took refuge with him during his exile and married his daughter, 702. Justinian's rival Bardanes in turn sought an asylum in Khazaria, and in Leo IV. (775) the grandson of a Khazar sovereign ascended the Byzantine throne. Khazar troops were amongst the bodyguard of the imperial court; they fought for Leo VI. against Simon of Bulgaria (888); and the khakan was honoured in diplomatic intercourse with the seal of three solidi, which marked him as a potentate of the first rank, above even the pope and the Carlovingian monarchs. Indeed his dominion became an object of uneasiness to the jealous statecraft of Byzantium, and Constantine Porphyrogenitus, writing for his son's instruction in the government, carefully enumerates the Alans, the Petchenegs, the Uzes, and the Bulgarians as the forces he must rely on to restrain it.

It was, however, from a power that Constantine did not consider that the overthrow of the Khazars came. Long before, when a band of Slav prisoners was brought into the Khazar camp, a sage had prophesied—"These men's swords have two edges; ours have but one. We conquer now; but some day they will conquer us." The arrival of the Varangians amidst the scattered Slavs (862) had now united them into a nation and launched them upon that career of conquest which within a hundred years carried the Russian arms to the Balkans and the Caucasus. The advance of the Petchenegs from the East gave the Russians their opportunity. Before the onset of those fierce invaders the precarious suzerainty of the khakan broke up. By calling in the Uzes, the Khazars did indeed dislodge the Petchenegs from the position they had seized in the heart of the kingdom between the Volga and the Don, but only to drive them inwards to the Dnieper. The Hungarians, severed from their kindred and their rulers, migrated to the Carpathians, whilst Oleg, the Russ prince of Kieff, passed through the Slav tribes of the Dnieper basin with the cry "Pay nothing to the Khazars" (884). The kingdom dwindled rapidly to its ancient limits between the Caucasus, the Volga, and the Don, whilst the Russian traders of Novgorod and Kieff supplanted the Khazars as the carriers between Constantinople and the north. When Ibn Fadlân visited Khazaria forty years later, Itil was even yet a great city, with baths and market-places and thirty mosques. But there was no domestic product nor manufacture; the kingdom depended solely upon the now precarious transit dues; and the king or great khakan was a *roi fainéant* hidden from the sight of men, the actual administration being in the hands of a major domus also called khakan. At the assault of Swiatoslav of Kieff the rotten fabric crumbled into dust. His troops were equally at home on land and water. Sarkel, Itil, and Semender surrendered to him (965–969). He pushed his conquests to the Caucasus, and established Russian colonies upon the Sea of Azoff. The principality of Tmoutorakan, founded by his grandson Mstislav (988), replaced the kingdom of Khazaria, the last trace of which was extinguished by a joint expedition of Russians and Byzantines (1016). The last of the khakans, George Tzula, was taken prisoner. A remnant of the nation took refuge in an island of the Caspian (Siahcouyé), others retired to the Caucasus; part emigrated to the district of Kasakhi in Georgia, and appear for the last time joining with Georgia in her successful effort to throw off the yoke of the Seljuk Turks (1089). But the name is thought to survive in "Kadzaria," the Georgian title for Mingrelia, and in "Kadzaro," the Turkish word for the Lazes. Till the 13th century the Crimea was known to European travellers as "Gazaria"; the "ramparts of the Khazars" are still distinguished in the Ukraine; and the record of their dominion survives in the names of Kazarek, Kazaritshi, Kazarinovod, Kozar-owka, Kozari, and Kazan (Schafarik, ii. 65).

Authorities.—Khazar: The letter of King Joseph to R. Chasdai Ibn Shafrût, first published by J. Akrish, *Kol Mebasser*, Constantinople, 1577, and often reprinted in editions of Jehuda hal-Levy's *Kuzari*. German translations by Zedner (Berlin, 1840) and Cassel, *Magyar. Alterth.*, Berlin, 1848; French by Carmoly, *Rev. Or.* (1841). Comp. Harkavy, *Russische Revue*, iv. 69; Graetz, *Geschichte*, v. 364; and Carmoly, *Itineraires de la Terre Sainte*, Brussels, 1847. *Armenian*: Moses of Chorene; comp. Saint-Martin, *Mémoires Historiques et Géographiques sur l'Armenie*, Paris, 1818. *Arabic*: The account of Ibn Fadlân (921) is preserved by Yâkût, ii. 436 *sq.* See also Istakhry (ed. de Goeje, p. 220 *sq.*), *Mas'ûdy*, chap. xvii. 406 *sq.* of Sprenger's translation; *Ibn Haukal* (ed. de Goeje, p. 279 *sq.*), and the histories of Ibn el Athir and Tabary. Much of the Arabic material has been collected and translated by Fraehn, "Veteres Memoriæ Chasarorum," in *Mem. de St Pet.*, 1822; Dorn (from the Persian Tabary), *Mém. de St Pet.*, 1844; Dufrémery, *Journ. As.*, 1849. KHELAT, the capital of Baluchistan, and the residence of the reigning khan, is situated, at an elevation of 6800 feet above the sea, in 29° N. lat., and 66° 40′ E. long., in a narrow valley, which is bounded to the east by the mountain ranges extending to the province of Cutch Gundava; to the west is the Sha Mirdan, on the northern slope of which hill the town is built; to the south the valley is closed by low hills, while to the north it is of sufficient breadth to allow space for two or three small villages. Through the centre of this valley runs a mountain torrent, which is generally dry, but after heavy rain pours down a considerable body of water. The town is surrounded by a mud wall about 30 feet in height, which is pierced by three gateways. The houses are built of mud, and number from three to four hundred; the streets are narrow and tortuous; it possesses a tolerably well supplied bazaar. A miri or citadel, having an imposing appearance, dominates the town, and contains within its walls the palace of the khan. It was in an upper room of this residence that Merab Khan, then ruler of Baluchistan, was killed during the storming of the town and citadel by the British troops at the close of the first Afghan war in 1839. The suburbs of Khelat are comparatively extensive, and contain from 10,000 to 12,000 inhabitants, which number, however, fluctuates according to the season, as well as with the political events passing in the country. There are to be found both in the town and suburbs residents representing many of the countries of Asia, viz., Hindus, Brahoes, Dehwars, Babé, Afghans, Persians, and Baluchis. The Hindu community forms the principal trading class, a fair proportion of which, however, includes the Babé tribe, while agriculture is almost entirely in the hands of the Dehwar tribe. The town is well supplied with excellent water, principally from a spring situated in the eastern side of the valley; this water is also used for irrigating the numerous enclosed gardens studded about, in which are grown most of the fruit trees to be found in European climates, including the vine, apricot, apple, and mulberry; vegetables of all descriptions thrive to perfection. The climate of Khelat is peculiarly dry and pure, nor is there heat during the summer months that can be called oppressive. The citadel, although offering an imposing appearance, has in reality no military value, and could offer no resistance to the artillery in use at the present day. It is quite impossible to give an idea of the period of the building of Khelat, though there can be no doubt that it is of very ancient origin, long prior to the Mohammedan era; but, as political events have now brought England into close friendly relations with the Baluch state, we may look forward to the unravelling of many traditions which now surround and obscure the history of Baluchistan and its capital.

KHERI, a district of Oudh, India, lying between 27° 41′ and 28° 42′ N. lat., and 80° 4′ 30″ and 81° 23′ E. long., bounded on the N. by the river Mohan, separating it from Nepál, E. by the Kauriála river, separating it from Bharáich district, S. by Sítápur district, and W. by Sháhjahánpur district in the North-Western Provinces, with an area of 2963 square miles.

Kheri district consists of a series of fairly elevated plateaus, separated by rivers flowing from the north-west, each of which is bordered by a belt of alluvial land. The rivers are, commencing from the east, the Kauriála, Suheli, Daháwar, Chauka, Ul, Jamwári, Kathna, Gumti, and Sukheta. North of the Ul, the country is considered very unhealthy. This tract probably formed in ancient times the bed of a lake, through which flow two rivers, the Kauriála and Chauka, changing their courses constantly, so that the whole surface is seamed with deserted river beds much below the level of the surrounding country. The vegetation is very dense, and the stagnant waters are the cause of endemic fevers. The people reside in the neighbourhood of the low ground, as the soil is more fertile and less expensive to cultivate than the forest-covered uplands. South of the Ul, the scene changes. Between every two rivers or tributaries stretches a plain, considerably less elevated than the tract to the north. There is very little slope in any of these plains for many miles, and marshes are formed, from which emerge the head-waters of many secondary streams, which in the rains become dangerous torrents, and frequently cause devastating floods. The general drainage of the country is from north-west to south-east. Several large lakes exist, some formed by the ancient channels of the northern rivers being fine sheets of water, from 10 to 20 feet deep and from 3 to 4 miles long; in places they are fringed with magnificent groves. In the south there are some other large natural lakes. The whole north of the district is covered with vast forests—occupying an area of 650 square miles, of which 423 square miles are now Government reserves. *Sál* occupies about two-thirds of the whole forest area. *Kankar* (nodular limestone) of good quality is met with, and saltpetre is manufactured in large quantities. The wild animals include tigers, leopards, black buck, spotted deer, hogdeer, and *nílgái*.

At the census of 1869 the population was returned at 746,350 (males 403,837, females 342,513)—Hindus, 671,686; Mohammedans, 74,307; Christians, 96; "others," 261. Allowing for recent transfers, the latest return (based on the above census) gives the population at 739,283. All the towns now existing are of recent foundation, none dating earlier than the 16th century. Of their origin, one common tale is told. The Musalmán or Rájput founder came through the woods and marshes, and seized upon the slight hills or hummocks upon which some Pási or Ahír patriarch ruled over a few mud huts. The rightful owner fled deeper into the forest, and the intruder built a block house or a brick fort to guard against his return. Only three towns in 1869 contained upwards of 5000 inhabitants, namely, Kheri, Muhamdi, and Oel, with an aggregate population of 19,087. Lakhimpur, the civil station, is the only municipality in the district. The area under the chief agricultural products is returned as follows:—rice, 166,811 acres; wheat, 135,081; other food grains, 851,133; oil-seeds, 29,380; sugar-cane, 41,065; cotton, 6739; tobacco, 8265; vegetables, 6644; fibres, 419 acres. Poppy and indigo are also cultivated. District manufactures are confined to weaving and cotton printing for local requirements. Grain of all kinds is exported, as also are turmeric, tobacco, timber, sugar, syrup, hides, bullocks, and *ghí*. Catechu is made in large quantities throughout the north of the district, from the *khair* tree (*Acacia Catechu*), the heart-wood of which is chopped out and boiled down by a caste called Khairís. *Khaskhas* (*Andropogon muricatum*), the roots of which are used for matting *tatti* screens, is exported in large quantities to Benares and Patna. Two great annual religious trading fairs are held at Gola Gokarannáth—one in January attended by about 50,000 people, and the other in February, lasting about fifteen days, at which 150,000 persons are said to assemble. This great fair is increasing rapidly in importance, goods to the value of about £15,000 being sold annually by traders from all parts of India. The imports, which consist mainly of cotton, salt, country cloth, and English piece goods, considerably exceed the exports in value. The district revenue in 1870 amounted to £74,132, of which £62,471 was derived from the land-tax. In respect of education, Kheri is the most backward district in Oudh. The mean annual temperature is about 79° Fahr.; the mean rainfall during the eleven years ending 1874 was 47·3 inches.

The present district only dates its history as an administrative unit from 1858. At the time of the mutiny of 1857 it was divided between the districts of Muhamdi and Mallápur, and was not constituted a separate district till the reorganization of the province on the pacification of the country.

KHERSON, a government of European Russia, on the borders of the Black Sea, and conterminous with Bessarabia, Podolia, Kieff, Ekaterinoslaff, and Taurida. The area is estimated at 27,455 square miles. Especially in the south the general aspect of the country is that of an open steppe, and almost the whole government is destitute of forest. The Dniester marks the western and the Dnieper the eastern boundary, and the Bug, the Ingul, and several minor streams traverse the intermediate territory. Along the shore lie a number of extensive lagoons. Chalk, saltpetre, salt, sandstone, and a limestone conglomerate largely used for building are the principal minerals. Besides the ordinary cereals, maize, hemp, flax, tobacco, and mustard are pretty commonly grown; the fruit trees of general cultivation include the cherry, the plum, the peach, and the mulberry; and gardening receives a large amount of attention. The agricultural condition of the government has been greatly improved by the presence of numerous German colonies. Cattle-breeding, horse-breeding, and sheep farming are pursued on a large scale. Some of the sheep farmers have as many as 30,000 or 40,000 merinos, and only a very small proportion of the 2,500,000 sheep in the government are of unimproved varieties. The value of the total industrial production has been estimated at upwards of £2,500,000,—the more important departments being the manufacture of wool, hemp, leather, and flour. The ports of Kherson, Otchakoff, Nikolaieff, and more especially Odessa are among the great outlets of Russian commerce; and Berislaff, Alexandriya, Elizabethgrad, Vozneseusk, Olviopol, and Tiraspol play an important part in the inland traffic. In 1871 the total population of the government was 1,661,892; and besides Great and Little Russians it comprised Roumanians, Servians, Poles, Greeks, Germans, Gipsies, while no fewer than 44,107 were returned as Roman Catholics, 48,902 as Protestants, 3183 as Armenians, and 128,312 as Jews. There are six administrative districts—Alexandriya, Ananieff, Elizabethgrad, Kherson, Odessa, and Tiraspol. The towns with more than 5000 inhabitants are Odessa (184,820 in 1873), Nikolaieff (82,800), Elizabethgrad (35,200), Tiraspol (16,700), Ananieff (16,000), Alexandriya (10,520), Novo-Georgievsk or Kruiloff (10,225), Voznesensk (9450), Berislaff (8080), Bobrinetz (7150), Gregoriopol, Dubosarui, Novo-Mirgorod, Olviopol, and Otchakoff.

Kherson, the chief town of the above government, is situated on the right bank of the Dnieper, about 19 miles from its mouth. Founded by Prince Potemkin in 1778 as a naval station and seaport, it had become by 1786 a place of 10,000 inhabitants, and, although its progress was checked by the rise of Odessa and the removal (in 1794) of the naval establishments to Nicolaieff, it has still a population of more than 46,000. The Dnieper at this point breaks up into several arms, forming islands overgrown with reeds and bushes; it is difficult to maintain a deep navigable channel, and vessels of burden must anchor at Stanislavskoe Selo, a good way down the stream. Of the traffic on the river the largest share is due to the timber trade, and wool-dressing is the only extensive local industry. Kherson is a substantial and regular town. The cathedral is interesting as the burial-place of Potemkin, and near the church of the Assumption lie the remains of John Howard, the English philanthropist. The fortifications have fallen into decay. The name Kherson was given to the town from the supposition that the site had formerly been that of Chersonesus Heracleotica, the famous Greek city founded by the Dorians of Heraclea.

KHIVA, an independent Uzbeg khanate of Turkestan, which occupies the fertile oasis stretching in a band of varying width along the left bank of the lower Oxus between Pitniak and the Sea of Aral. The inhabited district, which lies between 41° and 43° N. lat., and 59° and 61° 30′ E. long., and practically forms the limits of the khanate, is about 200 miles in length and has an average breadth of 25 to 30 miles—an area therefore of some 5000 to 6000 square miles.

This tract of territory is but a meagre relic of the great kingdom which under the name of Chorasmia, Kharezm (Khwârizm), or Urgentch held the keys of the mightiest river in Central Asia, and formed in consequence a precious jewel for rivalry among Eastern potentates from an early period of the world's history. Great alterations, geographically and politically, have taken place since those times. The Oxus has changed its outlet, and no longer forms a water-way to the Caspian and thence to Europe. A great European power has arisen which has made gradual but important encroachments in Asia, and between this power on the north and the independent Turcoman tribes on the south the authority of the khan of Khiva has been dwarfed and circumscribed within the narrow limits above indicated.

From the establishment of the Russians on the lower Jaxartes in 1847 dates the decline in power of the khan of Khiva. Prior to that year the khan claimed sovereignty from the Caspian on the west to the confines of Khokand and Bokhara on the east, and from the northern margin of the Ust Urt and the Jaxartes on the north to the mountain range forming the Persian frontier on the south, including Merv. Within these limits his authority was recognized, although towards the extremities this was merely nominal. Since that year the Russians have annexed the country between the lower Jaxartes and Oxus, established the large trans-Caspian military district on the east shore of the Caspian, and conquered the Akhal Tekke country, thereby hemming in the Khivans on all sides. The Russians have, moreover, by imposing a large indemnity (two millions of roubles) for the campaign of 1873, so crippled the finances of the state that the khan, though nominally independent, is in reality a vassal and in a state of complete subjection to his more powerful neighbours. A Russian military force now watches the khanate from Forts Petro-Alexandrovsk and Nukus on the right bank of the Oxus, the former fort being within 35 miles of the capital.

History.—It would be impossible to trace here, even in the briefest manner, the changes through which Kharezm has passed, under the successive waves of migration and conquest which have swept across the country in ancient and historic times. The present insignificance and the eventual disappearance of the khanate from the map of Turkestan in the near future being intimately connected with the extension eastward of Russia, it will be more profitable to trace its history after its first connexion with that power.

Russia commenced her relations with Khiva in the 17th century. The warlike Cossacks of the Yaik during their raids across the Caspian learnt of the existence of the rich territory of Khiva, and made an expedition to the chief town, Urgentch, at a time when the khan and his troops were absent. They carried off a large number of women and a rich booty, but were overtaken on their road home by the Khivans and killed to a man. Two subsequent expeditions under Atamans Nechai and Shemai proved equally disastrous to the Cossacks. These three expeditions were simply the raids of freebooters. In 1717, however, Peter the Great, having heard of the presence of auriferous sand in the bed of the Oxus, and desiring also to "open mercantile relations with India through Turan" and to release from slavery some Russian subjects, sent a properly equipped military force to Khiva. The command of the expedition, which consisted of 3300 men and six guns, with three months' provisions, was entrusted to Prince Bekovitch Tcherkassky. After establishing a fortified base of operations on the east shore of the Caspian, Bekovitch collected his forces at the mouth of the Ural and thence marched across the Ust Urt into Khivan territory. When within 100 miles of the capital he was encountered by the forces of the khan. The battle lasted three days, and ended in victory for the Russian arms. The Khivans, however, induced the victors to break up their force into small detachments in order to facilitate supply, and then treacherously annihilated them in detail. This disaster did not prevent the Russians from sending embassies from time to time to the khan, but the representations of the envoys did not induce him to desist from enslaving Russian subjects or even to free those already in bondage. The Persian campaign which subsequently followed, the designs in other parts of Central Asia, and the constant embroilment of Russia in European wars caused Khivan affairs to recede temporarily to the background, and it was not until the third decade of the 19th century that the attention of the Muscovite Government was again directed to the khanate. In 1839 a force under General Perovsky, consisting of three and a half battalions, three Cossack regiments, and twenty-two guns, in all 4500 men, with a large train of camels, moved from Orenburg across the Ust Urt to the Khivan frontiers, in order to occupy the khanate, liberate the captives, and open the way for trade. This expedition likewise terminated in disaster. The inaccessibility of Khiva was once more her safeguard. Before the force reached half-way towards its destination it was forced to return, in consequence of the severity of the weather and the loss of life among the men and animals. These expeditions had convinced the Russians that for the effective control of the relations of Khiva a nearer position must be sought. In 1847 they founded the Raim fort at the mouth of the Jaxartes. As this advance deprived the Khivans not only of territory, but of a large number of tax-paying Kirghiz, while the establishment of a fort gave the Russians a base for further operations, a collision became sooner or later inevitable. For the next few years, however, the attention of the Russians was taken up with Khokand, their operations on that side culminating in the capture of Tashkend in 1865. Free in this quarter, they directed their thoughts once more to Khiva. In 1869 Krasnovodsk on the east shore of the Caspian was founded, and in 1871–72 the country leading to Khiva from different parts of Russian Turkestan was thoroughly explored and surveyed. In 1873 an expedition to Khiva was carefully organized on a large scale. The forces placed at the disposal of General v. Kaufmann started from three different bases of operation—Krasnovodsk, Orenburg, and Tashkend. The whole force consisted of more than 10,000 men. Khiva was occupied by the Russians almost without opposition. All the territory (35,700 square miles, and 110,000 souls) on the right bank of the Oxus was annexed to Russia and formed into the Amu Daria sub-district, while a heavy war indemnity was imposed upon the khanate. The difficult position financially in which the khan is thereby placed has more than once impelled him to beg the Russians to take the country under their administration. Russia, however, prefers the present arrangement of maintaining Khiva semi-independent instead of in complete subjection, for, not only does the collection of the indemnity fall upon the Khivan authorities, but the country shields the Russian possessions on the Oxus from the attacks of the Turcomans, which if made must first come in contact with the intervening territory of Khiva.

Topography.—The Khivan oasis is indebted for its fertility to the waters of the Oxus, which by means of irrigating canals and ditches penetrate into what was at one time barren steppe. Where this water reaches the land teems with life; where it ends all is death and a waste. The area of sandy desert reclaimed by the Oxus is estimated by the late Major Wood, Madras Engineers, at $1\frac{1}{2}$ millions of acres. The soil of the khanate is a tenacious clay of a red and grey colour, more or less impregnated with sand, —the detritus brought down by the river. Black earth is seldom seen; but earth strongly impregnated with salt is frequently found. The oasis is generally level, except some unimportant heights and sand-hills.

That part of the Oxus which waters the khanate has at Pitniak a north-west direction, and flows within a single bed. Below Kipchak it bends sharply to the west, and, after describing part of a semicircle to Hodjeili and giving off the Laudan, which with the Usboi forms the ancient course of the Oxus, resumes its north-west course to Kungrad. There it takes a north direction, dividing into two branches, the Taldyk and Ulkun, the latter the principal arm, and ultimately disembogues by many channels into the Sea of Aral. The banks of the river are generally low and in midsummer do not stand more than 6 to 20 feet above the level of the water. The river is in flood three or four times a year, the chief periods being in April and May, when it overflows its banks and does much damage to the canal dams. The average velocity is about 3 miles an hour, but at times of inundation the current becomes much more rapid. The breadth of the river at ordinary times varies from $\frac{1}{4}$ to $\frac{2}{3}$ mile, but increases to 3 or more miles at inundations. There are no obstacles to navigation in the shape of rapids, but the shifting of the sand banks acts as an impediment. The water of the Oxus is wholesome, although of a yellowish-brown colour, which is due to particles in suspension. These particles are gritty, and unlike the mud of the Nile do not fertilize the ground. The deposit from the water when dried is used by the Khivans to form their dams. In consequence of the large body of matter brought down, the irrigating canals require constant clearing. These canals vary from 20 to 150 feet in breadth, and from 10 to 20 feet in depth, and are sometimes as much as 80 miles long. They have a current of about 2 miles an hour, and are mostly navigable by boats. The direction of the canals is west and north-west, from which it may be concluded that the left bank of the river has a natural slope towards the Caspian. By actual measurement it has been found that the fall of the ancient bed is 400 feet from the point near Kipchak where it had its origin to Balkhan Bay in the Caspian,—a distance of 500 miles.

From the statement of Abulghazi Khan and other proofs there can be little doubt that two hundred and fifty years ago the Oxus flowed into the Caspian through the Usboi, which was connected with the present channel by at any rate three arms—Daudan, Daryalik, and Lauzan or Laudan. The alteration in the course of the river was probably due to the gradual elevation of the land where the old bed passed, from which naturally resulted a diminution in the velocity of the stream, and at the same time a silting of the channel. From this cause the waters of the Oxus found for themselves another outlet. Whether the Russians will be able to carry out their scheme of forcing the Oxus to resume its old course to the Caspian it would be premature to offer an opinion, but the surveys at present are not favourable. The advantages to Russia would be great, as she would have a continuous waterway from the Volga to Afghanistan.

The khanate has numerous lakes, especially towards the Aral, connected together by affluents and canals. They are usually covered with reeds. Lake Aibugir, once a large inlet of the Aral, is now dry.

The means of communication in the khanate is by road and by water. The roads are usually narrow, but some are as much as 70 feet wide. In spring and autumn, at the time of inundations, they are in bad order. Internal trade is carried on by camels and by carts.

Government.—The government is an absolute despotism, and, subject to a certain moral control exercised by the proximity of the Russians, is entirely in the hands of the khan. The chief secular officials are (1) the *kush-begi* or vizier, prime minister; (2) *mehter*, chancellor of the exchequer; (3) *inakh*, four in number, local governors; (4)

metch-mehrem and *batchman*, controller and collector of customs respectively; (5) *biy*, the khan's supporter in battle; (6) *minbashi, yuzbashi*, and *onbashi*, belonging to the military class, now fast disappearing. The *ulema* or priests, of whom the nakib is the chief, are subdivided as follows:—(1) *kazi kelan* and *kazi*, judicial functionaries; (2) *alem*, chief of the five muftis; (3) *reis*, *mufti*, and *akhond*. The acknowledged religion is the Suni form of Mohammedanism. Justice is administered in the mosques and in the private dwellings of the cadis and muftis, but every Khivan subject has the right to prefer his complaint before the governor or even before the khan.

Revenue.—The khan's revenue is derived from (1) the land-tax, paid in coin by all sedentary Khivan subjects, and in cattle (2½ per cent.) by nomads; (2) a customs due on all incoming and outgoing caravans, and on the sale of cattle—2½ per cent. *ad valorem*; (3) the rent of crown lands. The revenue of certain districts is set aside for the support of the relatives of the reigning khan, and of the rest the greater part is exhausted in paying the large indemnity imposed by the Russians after the campaign of 1873.

Population.—The inhabitants are partly sedentary and partly nomad. They include Uzbegs, Karakalpaks, Turcomans, Sarts, Kizilbashes, and Arabs—the first three of Mongol origin, the rest of Aryan descent. The Uzbegs come from a Turk stock, and constitute the dominant class. Some few live in towns, but the bulk reside on their farms, where they occupy themselves in agriculture, gardening, silk cultivation, and fishing. Very few engage in trade. They are divided into tribes. The Karakalpaks, or "black-hats," are supposed to be a clan of Uzbegs. They inhabit the lower part of the Oxus, and are mostly stock-breeders; they are divided into tribes, and are nearly all nomadic. The Turcomans are of similar origin to the Uzbegs, and are divided into tribes, of which the chief are the Yomud, Karadashli, Goklen, Ersari, Chaudor, and Imrali. They are all engaged in breeding horses and stock and in agriculture. Some are sedentary, while others migrate to the steppe in summer. The Sarts or Tajiks, who were probably the original inhabitants of the country, live chiefly in the large towns and are engaged in trade or in handicrafts, some in agriculture and silk cultivation. The Kizilbashes are liberated Persian slaves, and are distributed over the khanate, but more particularly inhabit the Tashauz district. Of the Semitic race we find Arabs in small numbers at Shavat. They form the living monuments of the Arab conquest.

Owing to the absence of any census it is impossible to give more than a very rough estimate of the population of the Khivan oasis. Major Wood, a competent observer, estimated it in 1875 at 300,000 souls, of whom two-thirds are Uzbegs and Tajiks. Liberated Persians and other slaves make up 50,000, while the remainder is composed of sedentary Turcomans who occupy cultivated lands or who nomadize about the western borders of the khanate.

There is no marked division of the people into castes or classes. A Khivan may be a merchant, an agriculturist, or craftsman as he pleases; he may possess land or other real property, but for this privilege he must fulfil his obligation to the state, pay taxes, and furnish labourers for digging or repairing canals, upon which the life of the oasis may be said to depend. Only the military class, the priesthood, and the khodjas are exempt from the payment of taxes. The khodjas consider themselves descendants of the prophet; they pay no taxes and render no military service, nor do they furnish canal labour. They are derived from the same stock as the khodjas of Turkestan, and according to tradition came to Khiva six hundred years ago. Agriculture, trade, and handicrafts constitute their chief employment.

Towns.—Khivan towns are nothing more than agglomerations of houses without plan or regularity; the streets are so crooked and narrow that two carts can only pass with difficulty or not at all. The towns are usually surrounded by a defensive wall, in a more or less dilapidated state; sometimes there is also a wet ditch. Outside the walls stretches an extensive suburb. Each town contains usually a bazaar, a caravanserai, and one or more medresses (ecclesiastical colleges) and mosques. The population consists of government officials, shopkeepers, mechanics, and a very few agriculturists. There are no villages as we understand the term,—only farmsteads dotted at intervals along the banks of the canals. The security against Turcoman raids which is given to the townspeople by the wall and ditch is replaced in the case of the farming class by small round guard-houses (karachi-khane) constructed along the same canals where the farmsteads are placed.

The chief towns are Khiva (the present capital and residence of the khan); Khazarasp, spoken of by the Arab geographers as a strong place in the 10th century, a reputation it still maintains; New Urgentch, the chief trading town; Tashauz, another strong place; Gurlen, Hazavat, Ilalli, Kipchak, Khanka, Hodjeili, Kungrad, Pitniak, Kunia Urgentch (once the capital, but destroyed first by Jenghiz Khan, and afterwards by Timur), and Kiat, which up to the 15th century was the capital of Kharezm, but is now a place of little importance.

Climate.—The climate is quite continental, but is healthy, and the people are long-lived. The prevailing ailments are small-pox, inflammation of the eyes, and ague. Cholera is a rare visitant. Winter begins in November and lasts until February. At this season the thermometer sometimes falls to 20° Fahr., and the Oxus freezes to a depth of 6 to 12 inches. At the end of March the vine, pomegranate, and fig commence to bud, and in the first days of April are covered with green. Wheat harvesting commences early in July; about this time apricots and plums ripen. Leaves begin to grow yellow and fall in the first half of November. The west wind is distinguished by its violence, but it only rages in spring. At this season the north wind also blows strongly. When the wind is in these quarters dews are abundant. Severe storms and earthquakes are of rare occurrence; and, generally speaking, there is little rain, snow, or hail.

Products.—The chief agricultural products are wheat, jugara, rice, sesamum, millet, chigin (a variety of millet), barley, mash (a pulse), linseed, cotton, hemp, lucerne, tobacco, poppy, and madder. The gardens furnish the melon, cucumber, pumpkin, capsicum, garlic, onion, beet, radish, carrot, turnip, potato, and cabbage. Of fruits the mulberry, apple, pear, cherry, plum, date, peach, pomegranate, and grape are in abundance. Of trees we find in small quantities the poplar, black poplar, plane, elm, willow, karaman (a sort of elm), and narvan (a species of oak). Saksaul (*Holoxylon ammodendron*) is found in quantities, and furnishes excellent fuel. Shrubs of various kinds are indigenous, and the reed grass, in the absence of meadow-land, affords good fodder for cattle.

Khiva furnishes no metals, but sulphur and salt are present in sufficient quantities to satisfy home demands.

The domestic quadrupeds are camels, horses, asses, horned cattle, sheep, and goats. Of wild animals are found the hog, giraffe, panther, jackal, fox, wolf, and hare. The feathered tribe is represented by the wild goose, swan, crane, pelican, duck, moorhen, bustard, pheasant, quail, snipe, partridge, magpie, crow, sparrow, nightingale (in large numbers), and lark, besides domestic fowls and pigeons. The fish include sturgeon, sterlet, bream, pike, carp, and sandre.

Trade and Industry.—The trade of Khiva, in the Middle

Ages very considerable, has in the present day declined to insignificant proportions. At the epoch when Arab trade flourished, and in the time of Jenghiz Khan, Kharezm possessed important trade routes. Along these routes were dug deep stone-lined wells, and they were moreover dotted at intervals with caravanserais; so that, in the words of a historian of the 14th century, the traveller from Khiva to the Crimea need make no provision for his journey, for all that was needful could be procured from caravanserais on the way. In this latter half of the 19th century the trade is unimportant, and even the ruins of the caravanserais and wells are to be detected with difficulty. The merchants of New Urgentch, it is true, take their wares as far as the great Russian fair of Nijni-Novgorod on the west, to Bokhara on the east, and to Persia on the south, but the caravans are small and money is scarce. The chief articles of trade are horned cattle, camels, horses, sheep, cereals, khalats, silk and cotton cloth, clothing, gunpowder, arms, agricultural implements, two-wheeled carts, saddlery, harness, boats, wood, potash, salt, &c. These wares are sometimes bartered, sometimes sold for money. Dried fish is also an article of export for the Bokhara market. The cotton is of excellent quality, and the silk of Khazarasp is renowned in Central Asia.

Of manufactures there are none in the true sense of the word. The Khivans weave in their hand-looms cotton and silk cloth sufficient to satisfy their home necessities. In handicraft they are specially clever as armourers, smiths, and founders. The fuel used is saksaul.

Currency.—The money of the country is the gold tilla, the silver tenghe, and the copper pul. The tilla is worth 28 to 35 tenghe, or from sixteen shillings to a pound, according to the exchange; while the tenghe, value about sevenpence, is equivalent to about 35 to 50 puls. Russian, Persian, and Bokharian money are also in circulation.

KHIVA, a fortified city, capital of the khanate of the same name, situated between two canals derived from the Oxus, and in the midst of green fields, orchards, and high poplars. It lies in 41° 22′ 30″ N. lat. and 60° 25′ E. long., about 400 miles east of Krasnovodsk on the Caspian, 350 miles north of Meshhed in Persia, and 700 miles north-north-west of Kandahar. The city is girt with two mud walls. The inner wall, which surrounds the main town, is built on a low eminence, and forms a tolerably regular parallelogram with four towers at the angles. This wall is about 24 feet high, and has a perimeter of some 2500 yards. Three gates lead into the inner town. The outer wall, 10 feet high, was built in 1842 to enclose a former suburb, and has an irregular perimeter of 7200 yards. Twelve gates pierce this outer wall. In the main or inner town are two palaces of mean appearance, seventeen mosques, twenty-two educational seminaries, a caravanserai, a covered bazaar of some one hundred and twenty shops, and two hundred and sixty other shops distributed over the place. The principal mosques are those erected in honour of the saints Polvan Ata and Seid Bai. (F. C. H. C.)

KHOI, a town and district in the province of Azerbijan, Persia, towards the extreme north-west frontier, between Lake Urumiyah and the river Aras. The town lies in 38° 37′ N. lat., 45° 15′ E. long., 77 miles north-west of Tabriz on the great trade route between the Euxine and Persia, and on the Kotura, a tributary of the Aras, crossed here by a seven-arched bridge. The fortifications, which are in a ruinous state, consist of an outer line of bastions, redans, glacis, ditch and covered way, and an inner high wall flanked with towers, the intervening space being occupied with gardens and mud hovels. But the central part forms one of the best laid out towns in Persia, cool streams and lines of willows running along its broad regular streets. Here are a few good buildings, including the governor's palace, several mosques, a large brick bazaar second only to those of Shiraz, and a fine caravanserai. There is a large transit trade, and considerable local traffic across the Turkish border. Ophthalmia is very prevalent, about 10 per cent. of the inhabitants suffering from inflammation of the eyes. The chief manufactures are copper wares and worsted socks. Here the Turks under Selim I. gained a great victory over the Persians in 1514, but with such heavy losses to themselves that the battle was long after known as the "day of doom." In September 1881 Khoi was visited by a series of violent earthquakes, the seismic waves running north-west and south-east in the direction of the main mountain ranges. The population numbers about 30,000, including many Armenians, who occupy a separate quarter. The district consists of an elevated plateau 60 miles by 10 to 15, highly cultivated by a skilful system of drainage and irrigation, producing a series of fertile oases laid out in meadows, gardens, and tillage, and yielding rich crops of wheat and barley, besides apples, pears, cherries, walnuts, chestnuts, and unrivalled mulberries.

KHOJEND, or HODJENT, chief town of the Khojend and Jizak district in the province of Sír Daria, in Russian Turkestan, is situated on the left bank of the Sír Daria or Jaxartes, 96 miles south-east from Tashkend, and on the direct road from Bokhara to Khokand. The Russian quarter lies between the river and the native town. Near the river is the old citadel, built on the top of an artificial square mound, about 100 feet high, which Mr Schuyler suspected to be a mere hollow wooden framework, only half filled in with earth. The bazaar of Khojend is very large in proportion to the size of the town. There is a wooden bridge over the Jaxartes, whose banks at this point are so high as to make the river useless to the town in the absence of pumping gear; so that when the little stream Khoja Bakargan dries up in summer, there is much suffering from want of water. The great heat intensifies the distress. There is now no very great trade in Khojend. Formerly the entire commerce between the khanates of Bokhara and Khokand passed through it, but since the Russian occupation much of that has been diverted. Silk worms are reared, and silk goods are manufactured in the town. A coarse sort of ware is made in imitation of the Chinese porcelain. Lignite is carried to Tashkend from the neighbourhood of Khojend. The surrounding district is tolerably well cultivated; immediately about the town the ground is taken up with cotton plantations and vineyards. The majority of the inhabitants are Tajiks. They are sociable and pleasure-loving, and the whole air of the town is agreeable. The population for 1873 is put down by Mr Schuyler at 30,000.

Khojend has always been a bone of contention between Khokand and Bokhara; and, although belonging from very ancient times to the former, it has often been seized by the latter. When the ameer of Bokhara assisted Khudayer Khan to regain his throne in 1864, he kept possession of Khojend. In 1866 it was stormed by the Russians; and during the war with Khokand in 1875 it played an important part.

KHOKAND, a city of Turkestan, was, previous to the Russian conquest, the capital of an independent khan, but, owing mainly to the fact that those who reside in it are subject to goitre, it has not been made the administrative centre of the Russian province (FERGHANA, *q.v.*). The town is situated on the skirts of the Kashgar Devan ridge, which separates Kashgar from Ferghana, and it is traversed by three mountain gullies which send their scanty waters to the Jaxartes. Dating only from the reign of Saur Khan, about the early part of the 18th century, Khokand has within the 10 miles circuit of its mud walls a greater amount of space to spare than is to be found in any other city of Central Asia; some of the market-places are of great extent, and the bazaar is built on a more handsome scale than that even of Tashkend. The palace erected by the last khan is after the style of the palace at Samarkand, and rivals it in the rich colouring of its enamels and the general effect of its relief. The audience chamber now serves as a Russian church and the women's apartments are occupied by the Russian governor of the fortress. The mosques, according to native exaggeration, number 600, and there are fifteen colleges. The gardens, especially those of the palace, are conspicuous for their rich foliage. Silk weaving and papermaking are the chief industries. Coins bearing the inscription "Khokand the Charming," and known as khokands, have a wide currency. Population about 75,000.

See Schuyler's *Turkistan*, 1876; Khoroshkin's narrative translated in *Recueil d'itinéraires et de voyages dans l'Asie Centrale*, Paris, 1878; Ujfalvy, "L'Asie Centrale," in *Tour du Monde*, 1880.

KHONSAR, a town in the province of Irak-Adjemi, Persia, 92 miles north-west of Ispahan on the Hamadan route, in a gorge of the hills, which here approach so close that all the intervening space is occupied by the houses and their garden plots. The town straggles some 6 miles along the gorge, with a mean breadth of scarcely half a mile. There is good water from the hills, and a great profusion of fruits, the apples yielding a kind of cider, which does not keep. The climate is cool in summer but excessively cold in winter. Population 2500 families, or about 12,500 souls.

KHORAMABAD, a town and fortress of Persia, capital of the province of Luristan, in 33° 32′ N. lat., 47° 43′ E. long., 138 miles west-north-west of Ispahan, 117 south-east of Kirmánsháhán. The fort is perched on an isolated steep rock in the middle of a difficult pass, and is 1000 yards in circuit. The modern town lies at the south-west foot of the fort in a narrow valley watered by the broad but shallow and rapid river Kashgan. A rich plain stretching thence southwards yields abundance of supplies. Population about 6000.

KHORÁSAN, *i.e.*, "land of the sun," a geographical term originally applied to the eastern quarter of the four, named from the cardinal points, into which the ancient monarchy of the Sassanians was divided.[1] After the Arabic conquests the name was retained both as the designation of a definite province and in a looser sense. Under the new Persian empire the expression has gradually become restricted to the north-eastern portion of Persia proper, of which it now forms the largest province. The boundaries of this vast region have scarcely anywhere been accurately determined, and have constantly fluctuated, especially towards the north and east. Speaking generally, however, the province is conterminous on the east with Afghanistan and Sistan, north with Astrabad and the recently organized Russian trans-Caspian territory, north-east with the Turkoman country, west with Mazandaran and Irak-Adjemi, south with Farsistan and Kirman. It lies mainly within 33° 30′–38° 30′ N. lat. and 53°–61° E. long., extending 500 miles north-west and south-east and 300 north and south, with total area of about 150,000 square miles, and a population estimated at from 800,000 to over 1,000,000.

The surface in the north, south-west, and partly in the east is distinctly mountainous to a far greater extent than is commonly supposed. The ranges generally run in two or more parallel ridges, enclosing extensive longitudinal valleys, and running in the normal direction from north-west to south-east. The whole of the north is occupied by an extensive highland system forming a continuation of the Hindu Kush and Paropamisus, and stretching from the Herat valley between the Iranian plateau and the Turkestan depression north-west to the south-east corner of the Caspian. This system, for which there is no general name, but which is now sometimes spoken of collectively as the Kuren-Dagh or Kopet-Dagh, from its chief sections, forms in the east three ranges, the Hazar-Masjid, Binalud-Kuh, and Jagatai, enclosing the Meshhed-Kuchan valley and the Jagatai plain. The former is watered by the Kashaf-rud, or river of Meshhed, flowing east to the Hari-rud, their junction forming the Tejend, which sweeps round the Daman-i-Koh, or northern skirt of the outer range in the direction of the Caspian or Usboi (old bed of the Oxus), but now losing itself in the desert long before reaching them. The Jagatai plain is watered by the Kal-Mura river, formed by the junction of the Kara-su and several other head streams, and flowing south-west to the Great Salt Desert. In the west the northern highlands also develop three branches, the Kuren-Dagh stretching through the Great and Little Balkans to the Caspian at Krasnovodsk Bay, the Ala-Dagh forming a continuation of the Binalud-Kuh and the Astrabad mountains merging south-westwards in the Elburz system. The Kuren and Ala Daghs enclose the valley of the Atrek, which flows mainly west to the Caspian at Hasan Kuli bay. The western offshoots of the Ala Dagh and the Astrabad mountains enclose in the same way the valley of the Gurgan, which also flows westwards to the south-east corner of the Caspian. The outer range has probably a mean altitude of 8000 feet, the highest known summits being the Hazar-Masjid (10,500 feet) and the Kara-Dagh (9800); it is crossed by the Maidan-Kuni and Allaho-Akhbar (4200 feet) passes leading from Kuchan north to the Daragez district. The central range seems to be still higher, culminating with the Shah Jahan Kuh (11,000 feet), the Kuh Ala Dagh (12,300), and Kuh Khorkhud (12,500). The southern ridges, although generally much lower, have the highest point of the whole system in the Shah-Kuh (13,000 feet) at the junction of the Astrabad and Elburz ranges.

Another system runs diagonally right across the province from Yezd in the south-west to the Hari-rud valley in the north-east, throwing off the Kuh Shorab, Kuh Shutari (10,000 feet), and Kuh Nastanji (8000 feet) in the Tabbas district. Towards Sistan the country is also very mountainous, with several nearly parallel ridges stretching from near Tún south-east to the Hamun lake or swamp.

Beyond the Atrek and others watering the northern valleys there are scarcely any rivers, and most of these are brackish and intermittent, losing themselves in the Dasht-i-Kavír or Great Salt Desert, which occupies the central and western parts of the province, and which is separated by the diagonal range from the more sandy and drier desert of Lut in the south. The true character of the kavír, which forms the distinctive feature of east Persia, has scarcely yet been determined, some regarding it as the bed of a dried-up sea, others as developed by the saline streams draining t it from the surrounding highlands. Collecting in the central depressions, which have a mean elevation of scarcely more than 500 feet above the Caspian, the water of these streams is supposed to form a saline efflorescence with a thin whitish crust beneath which the moisture is retained for a considerable time, thus producing those dangerous and slimy quagmires which in winter are covered with brine, in summer with a thick incrustation of salt. "The waters of all springs and rivers contain salts in minute quantities, but the rivers of Persia are often so salt as to be undrinkable. The salts brought down by the rivers are deposited in the marsh, which thus gets salter year by year. It dries up during the fierce summer heats, to become a marsh again when the winter floods occur This process is repeated for ages, and in the course of time

[1] See Nöldeke's translation of Ṭabari, p. 155.

the whole soil over which the marsh extends becomes encrusted with salt."[1]

The surface of Khorasan thus consists mainly of highlands, saline swampy deserts, and fertile well-watered upland valleys. Of the last, occurring mainly in the north, the chief are the longitudinal valley stretching from near the Herat frontier through Meshhed, Kuchan, and Shirvan to Bunjnrd, and the Daragez district, which lies on the northern skirt of the outer range projecting into the Akhal Tekke domain, now Russian territory. These fertile tracts produce rice and other cereals, some cotton, tobacco, saffron, and especially melons and other fruits in great profusion, 45 ℔ of splendid grapes being sold in Daragez for ninepence. Other products are manna, gums, and great quantities of asafœtida, which is not used by the natives but exported to India. The chief manufactures are the famous Khorasan sabres, firearms, stoneware, armour, fine carpets and rugs, velvets, woollens, cottons, and sheepskin pelisses.

The population is far from homogeneous, consisting of Iranians (Tajiks, Kurds, and Baluchis), Mongols, Tatars, and Arabs, as under:—

Races.	District.	Population.	Speech.
Tajiks (Persians)	Towns and agricultural districts.	400,000	Persian.
Kurds	N. frontier.	250,000	Persian mostly.
Baluchis.	East frontier.	10,000	Baluchi.
Mongols. Taemuri Aimaks,	South and E. frontiers.	250,000	Persian.
Mongols. Hazarahs.	Herat frontier.	50,000	Persian.
Tatars ... Turkomans, Afshars, Kajars, &c.[2]	North and W. mainly.	100,000	Turki and Persian.
Arabs	S.&W. mainly.	100,000	Persian.[3]
		1,160,000	

The Persians proper have always represented the settled, industrial, and trading elements, and to them the Kurds (removed to the north by Shah Ismail) and the Arabs have become largely assimilated. Even many of the Tatar nomad tribes, collectively called Iliat,[4] have become *Shahr-nishin, i.e.*, "townsfolk," or settled. But all the Baluchis are not only still *Sahra-nishin, i.e.*, "country or desert folk," but have lately resumed their old predatory habits, covering incredible distances on their swift camels, and harassing the country as far west as the Yezd district. On the other hand the raids of the Turkoman marauders have almost entirely ceased since the reduction of the Akhal Tekke Turkomans by the Russians in the spring of 1881. In religion great uniformity prevails, all except the Baluchis and Turkomans having conformed to the national Shiah sect.

The administrative divisions of the province seem to be Daragez, Kuchan, Turshiz, Tabbas, Ghayn, Khaf, Meshhed, Nishapur, Shahrud, and Damgan. The chief towns are Meshhed, Kuchan, Mohammadabad, Shirvan, Bostan, Turshiz, Tún, Tabbas, Khaf, and Ghayn. (A. H. K.)

KHOSRU. See PERSIA.

[1] Colonel C. E. Stewart, in *Proc. Roy. Geog. Soc.*, September 1881. This traveller visited the north frontier of Persia in 1880-81, disguised as an Armenian horse-dealer from Calcutta.

[2] The Kajars are the royal tribe to which the present dynasty belongs; hence the reigning shah's title, Násir ed-dín Shah Kájár. But Nadir Shah, though commonly called a Kajar, was an Afshar.

[3] Some travellers have stated that the Khorasan Arabs still speak Arabic as well as Persian—a mistake due probably to the fluency with which they repeat passages from the Koran. The great bulk of them have long been "Parsivan" or "Persian-speaking."

[4] Iliat (plural of Ili) simply means "tribes," and is applied indifferently to all the nomads of Persia, whatever their affinities may be.

KHOTAN, a city and district of eastern Turkestan, lying between the northern slopes of the Kuenlun mountains and the eastern portion of the Gobi (Takla Makan) desert. The district is well watered by a number of rivers, the most important of which, the Karakash and the Khotan Daria, meet to the north of the city. Both soil and climate are excellent, and the vegetation is characterized at once by variety and luxuriance. Indian corn, barley, jowar, buckwheat, rice, olives, pears, peaches, apricots, mulberries, grapes, currants, melons, the charas plant, the cotton plant, are all produced in abundance. Willows, poplars, and tamarisks are the ordinary trees; in some parts they form extensive forests. Of the mineral wealth of the country glowing accounts are given,—gold, copper, iron, antimony, salt, sulphur, coal, jade, and a variety of precious stones being the principal items. Upwards of twenty gold mines are known to exist, and those of Sorghak and Kappa are worked by 4000 and 3000 men respectively. Jade is obtained, more especially in the Karakash district. Among the wild animals are goats, wolves, jackals, foxes, and hares; and the Khotanese keep camels, horses, mules, asses, goats, sheep, geese, ducks, and fowls (the goats and the fowls being particularly numerous). The total number of the inhabitants is variously estimated at from 130,000 to 250,000, and the country is capable of maintaining a much denser population. Females preponderate to as much as 25 per cent. There are six districts, each with a town of its name—Khotan or Ilchi (42,000), Karakash (7000), Yurung Kush (7000), Tchira (28,000), Kiria (28,000), and Naya (3500). The city of Khotan (in Chinese Hu-tan, locally Ilchi) is situated 150 miles south-east of Yarkand and 90 miles due east of Sanju, and is only 6 miles distant from the borders of the desert. It has long been celebrated as a great industrial centre, silks, felts, rich carpets (of either silk or wool), paper, and articles in jade being the chief productions; and its traders maintain an active traffic with Tibet.

As early as the 1st century the town contained (according to Chinese authorities) 3300 families. Cotan, as he calls it, was one of the places visited by Marco Polo. In modern times the first European who reached the city was Mr Johnson in 1865. At that time it was governed by a local khan, the Chinese having been expelled by their Mohammedan subjects, in 1863; and since then it has been subjugated by Yakub Khan of Kashgar (who perpetrated a terrible massacre at his capture of the place), and again recovered by the Chinese forces.

See Johnson, *J. R. G. S.*, 1867; Sir T. D. Forsyth, *Mission to Yarkund*, Calcutta, 1875.

KHOTIN, or KHOTEEN (this is the Russian form of the name, which appears in a great variety of disguises—partly dialectal—such as Khotchim, Chotchim, Choczim, and Chocim), a fortified town of 21,000 inhabitants, in the government of Bessarabia, Russia, situated in 48° 30′ N. lat. and 26° 30′ E. long., on the right bank of the Dniester, near the Austrian (Galician) frontier, and opposite Podolian Kamenetz. Though it possesses a few manufactures and carries on a considerable trade both legitimate and contraband, Khotin has all through its history been of importance mainly as a military post. In the Middle Ages it was the seat of a Genoese colony; and it has passed through periods of Polish, Turkish, and Austrian possession. The chief facts in its annals as a fortress are the defeat of the Turks in 1621 by Ladislaus IV., in 1673 by John Sobieski, and in 1739 by the Russians under Münnich; the defeat of the Russians by the Turks in 1768; the capture by the Russians in 1769; and the occupation by the Russians in 1806. It finally passed to Russia along with Bessarabia in 1812 by the peace of Bucharest.

KHULNA, or CULNA, a town in Jessor district, Bengal, India, situated at the point where the Bhairab river debouches on the Sundarban delta, in 22° 49′ N. lat., 89° 57′ E. long., may be described as the capital of the Sundarbans, and for the last hundred years at least has been a place of considerable importance. It was the headquarters of the salt department under the East Indian Company. The whole boat traffic from the east and north-east passes here on its way to Calcutta; from Calcutta the principal cargo is Liverpool salt, the trade in which is very considerable. There are numerous sugar refineries.

KHURJA, an important trading town and station on the East Indian Railway in Bulandshahr district, North-Western Provinces, India, 28° 15′ N. lat., 77° 54′ E. long. The population in 1872 was 26,858—15,543 Hindus and 11,315 Mohammedans. A large business in raw cotton is carried on, of which about 70,000 cwts. are annually exported to Cawnpur, Mírzápur, and Calcutta; eight cotton presses are at work in the town. There is a local trade in cotton, safflower, indigo, sugar, molasses, grain, rice, and *ghí*.

KHUSHÁB, or KOSHAUB, a town in Sháhpur district, Punjab, India, situated on the river Jhelum, 32° 18′ N. lat., 72° 24′ E. long.; population (1868) 8509. A flourishing trade is carried on with Mooltan, Sakkar, Afghánistán, and the Deráját. The exports consist of grain, cotton, wool, *ghí*, and country cloth; and the imports of English piece goods, metal, dried fruits, sugar, and molasses. It is the chief mart for the trade of the Salt Range. Coarse cloth and cotton scarfs are manufactured; there are six hundred weaving establishments.

KHÚZISTAN, a province of West Persia, bounded N. and N.E. by Luristan, S.E. by Fars, S. by the Persian Gulf, W. by Turkey, lies mainly within 30°–33° N. lat. and 47°–51° E. long., stretching about 200 miles north and south, with a mean breadth of 80 to 100 miles, and an area of 25,677 square miles. In the south is the rich alluvial lowland tract of Arabistan, "the most extensive and fertile plain in Persia." Elsewhere the surface is very mountainous, being traversed by the lofty Bakhtiari ranges, which form a south-eastern continuation of the Pusht-i-Koh highlands, and which preserve a remarkable parallelism throughout their entire length, while increasing in elevation from 8000 to 16,000 feet as they advance inland to the Kuh-Dinár. They are broken by several deep and romantic gorges, through which the Karkhah, Karún, Jarahi, and Tab rivers escape to the Euphrates delta or to the coast, watering several fertile upland valleys on their winding course seawards. The climate on the coast is excessively hot, and in some low-lying swampy districts very unhealthy; in the highlands severe winters and hot summers are followed by genial springs and autumns; the prevailing winds are north-west and south-east, the latter bearing much moisture from the Indian Ocean. The lowlands take the name of Arabistan from the Arabs, who form the bulk of their population. Many of the Kaʿb Arabs have been assimilated in speech and religion to the Persians; but most of the great Beni-Lám nation, comprising in Khúzistán and Baghdad 17 branches, 85 septs, and 30,000 families, are still in the nomad state. The highlands are mainly occupied by the Feili, Bakhtiari, Kohgelu, Mamaseni, and other Luri tribes of Kurd stock and speech, also nomads and addicted to brigandage. The staples of food are dates and fish in the south, elsewhere the produce of the herds and flocks. The chief products are rice, tobacco, cotton, indigo, silk, maize, barley; the trade is mainly with Baghdad and Bussorah. The manufactures include coarse woollens, cottons, tents, red cloth. Dyeing is extensively carried on in Dizful, which, besides Shaster and Mohammrah, is the only place worthy the name of town.

Khúzistán is the Biblical ELAM (*q.v.*), the classical Susiana. The name appears in the great inscription of Darius as Uvaja, corresponding to the Uxii of classical writers. The transition to the modern Khúz, Khúzistán, appears in the name Beth Khûzâyê, used by Syriac writers of the Sassanian period.

KHYRPOOR. See KHAIRPUR.

KIACHTA, or KIAKHTA, a mercantile town of Siberia, and one of the chief centres of trade between Russia and China, is situated upon the Kiachta, an affluent of the Selenga, and on an elevated and barren expanse of country surrounded by mountains, in the Russian government of Transbaikal, about 280 miles south-west of the capital Tchita, and close to the Chinese frontier, in 50° 20′ N. lat., 106° 40′ E. long. Besides the lower town or Kiachta proper, the municipal jurisdiction comprises the fortified upper town of Troitskosavsk, about 2 miles to the north, and the settlement of Ust-Kiachta, 10 miles further distant. The upper town, which is substantially built, contains the public offices, barracks, a stone church, and many large warehouses, &c., and is the headquarters of the commandant of the Transbaikal Cossacks. The lower town, lying directly opposite to the Chinese emporium of Maimaichin, consists of several stores and about a hundred houses inhabited mostly by merchants. Prior to 1727 the trade of Kiachta was a Government monopoly, but from that year it was open to private merchants, and continued to improve until 1860, when the right of commercial intercourse was extended along the whole Russian Chinese frontier in conformity with the treaty of Pekin. The annual December fairs for which Kiachta was formerly famous, and which were resorted to by merchants from a great distance, and also the regular commercial traffic passing through the town, have considerably fallen off since that date. The Russians exchange here leather, sheep-skins, furs, horns, woollen cloths, coarse linens, and cattle for teas, porcelain, rhubarb, manufactured silks, nankeens, and other Chinese produce. In 1873 the population, including Ust-Kiachta, was 9050.

KIDDERMINSTER, a market-town and municipal and parliamentary borough of Worcestershire, England, is situated in the north-west corner of the county, on the Stour, near its junction with the Severn, on the Staffordshire and Worcestershire canal, and on the West Midland branch of the Great Western Railway, 14 miles north from Worcester and 18 miles south-west from Birmingham. The streets are rather irregular, and the houses for the most part small and mean in appearance, but of late years great improvements have been made by the paving and widening of the streets and the construction of shops and houses of a better class. A new system of drainage has also been completed, and the town is now well supplied with water. Besides the churches, the principal buildings of Kidderminster are the corporation buildings, the infirmary, the town hall in the Renaissance style, erected in 1876, the masonic hall and club, and the buildings of the school of art. The parish church of St Mary, a fine old structure in the Perpendicular style, containing several ancient monuments, was lately extensively repaired. The town is adorned by a statue erected in 1875 to Richard Baxter, who was for some time minister in Kidderminster, and another to Sir Rowland Hill, completed in 1881, and by a beautiful drinking fountain. There is a free grammar school founded in 1637, besides board schools and others connected with some of the churches. A new cemetery for the town was opened in 1878. At an early period Kidderminster had a large manufacture of broad-cloths, but it is now chiefly celebrated for its carpets (see CARPETS, vol. v. p. 129), the manufacture of which was introduced about the year 1735. At first Scotch carpets were the only variety made, but in 1745 the manufacture of Wilton and Brussels carpets was commenced, and since that period the carpets manufactured at Kidderminster, on account of the permanency of their colour, due it is supposed to peculiar properties of the water of the Stour, have retained an exceptional reputation. Worsted spinning and dyeing, are also carried on extensively, and there are iron foundries, tinplate works, breweries, malthouses, tanneries, flour-mills, and a paper-mill. The population of the municipal borough in 1871 was 19,473, and that of the parliamentary borough 20,814; in 1881 the corresponding numbers were 24,270 and 25,634.

The ancient name of Kidderminster was Chiderminster, that is, the minster or church on the brow of the hill. From the time of the Conquest until the time of Henry II. it was a royal manor. Among the private owners who subsequently held possession of it was the poet Waller. Kidderminster returned a member to parliament in the reign of Edward I., but the privilege was subsequently lost. In the 12th year of Charles I. it received a charter of incorporation, and by the Reform Act of 1832 it again obtained the privilege of returning a member to parliament. It is now governed according to the Municipal Act of 1835.

KIDNAPPING is defined by Blackstone as the forcible abduction or stealing away of a man, woman, or child from their own country and sending them into another. The term is, however, more commonly applied to the offence of taking away children from the possession of their parents. By 24 and 25 Vict. c. 100, "whosoever shall unlawfully, by force or fraud, lead or take away or decoy or entice away or detain any child under the age of fourteen years with intent to deprive any parent, guardian, or other person having the lawful care or charge of such child of the possession of such child, or with intent to steal any article upon or about the person of such child, to whomsoever such article may belong, and whosoever shall with any such intent receive or harbour any such child, &c.," shall be guilty of felony. The abduction or unlawfully taking away an unmarried girl under the age of sixteen years out of the possession and against the will of her father or mother, or any other person having the lawful care or charge of her, is a misdemeanour under the same Act. The term is used in much the same sense in the laws of the United States. Bishop states the more correct acceptation of the word to be false imprisonment aggravated by the intent to carry the person away to another place, but not necessarily to another country.

KIEFF, KIYEFF, or KIEV, a south-western government of European Russia, conterminous with those of Minsk, Poltava, Tchernigoff, Podolia, Kherson, and Volhynia. The area is estimated at 31,664 square miles. In the north we find a low-lying district characterized by marsh and woodland; in the east a series of hills keeps company with the Dnieper; and in the west are several outliers from the Carpathian system. The central region is a kind of steppe. It is only in a very few places that the altitude exceeds 900 feet. Granite with underlying syenite is the prevailing rock in the west and south-west of the government; in the east there are various Eocene formations. Iron-ore, fireclay, sandstone, and lignite are among the useful minerals. Towards the southern and the central parts the surface is covered by a deep rich "black earth." Nearly the whole of the government belongs to the basin of the Dnieper, that river forming part of its eastern boundary. In the southwest are a few small tributaries of the Bug. Besides the Dnieper the only navigable stream is its confluent the Pripyat, but two or three of the rest are available for rafts. About a fourth of the surface is occupied by woods, very unequally distributed throughout the territory. Rye is the commonest of the cereals; and next follow oats and wheat. In the growing of beetroot the government is the first in Russia, and its factories for the production of beetroot sugar are the largest in the empire. The whole industrial activity of the district has rapidly developed since about the middle of the century: in 1879 there were 602 establishments, with 35,306 workmen, and a production worth £10,000,000. In the 75 sugar factories large numbers of Tartars from Tamboff and Penza find employment; and next in importance are the flour-mills, leather works, and tobacco factories. The population of the government has increased from 2,017,262 in 1862 to 2,266,000 in 1875. Little Russians form 80 per cent. of the aggregate; Jews, 13 per cent.; Poles, 4 per cent.; White Russians, 2½ per cent.; and there are a few thousand Great Russians. There are twelve districts:—Radomuisl, Kieff, Kaneff, Tcherkasui, Tchigirin, Vasilkoff, Berditcheff, Lipovets, Skvira, Tarashtcha, Uman, Zvenigorodka. Besides the government town the following have upwards of 5000 inhabitants:—Berditcheff, 52,560; Vasilkoff, 16,597; Uman, 15,393; Tcherkasui, 13,914; Tarashtcha, 11,420; Zvenigorodka, 11,375; Skvira, 10,061; Tchigirin, 9677; Kaneff, 7418; Lipovets, 6710; Radomuisl, 5905, to which may be added the large Jewish village of Zlatopol, 10,000. The exarchate or diocese of Kieff and Galitsch is the oldest in Russia, and comprises 1421 churches, 12 cathedrals, and 30 monasteries.

In 1708 a Kieff government was founded which included the whole eastern Ukraine and an extensive region in Central Russia containing thirty-six towns—Orel, Kursk, &c. The Kieff lieutenantship, founded in 1782, consisted of parts of the present governments of Kieff, Poltava, and Tchernigoff. In 1796 the present government was practically constituted, though several slight changes in regard to the district towns have since taken place.

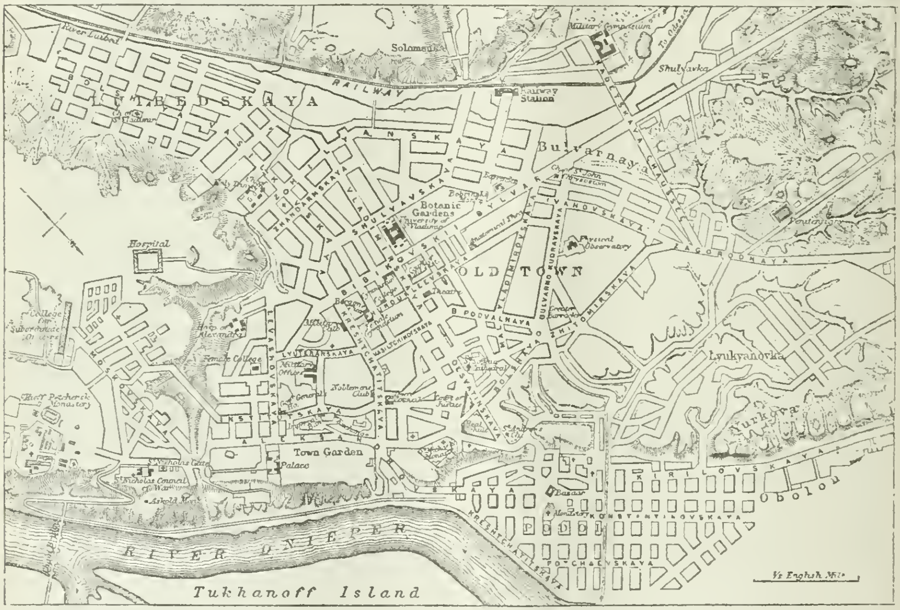
KIEFF, capital of the above province, the "mother city" and Canterbury of Russia, is situated on the right or western bank of the Dnieper, in 50° 26′ N. lat. and 30° 37′ E. long., 800 miles from St Petersburg, and 566 miles from Moscow on the highway between Moscow and Odessa. By railway it is connected on the one hand with Kursk and on the other hand with Odessa. The site of the greater part of the town consists of a succession of hills or bluffs separated from each other by ravines and hollows, the elevation of the central portions being from 350 to 365 feet above the ordinary level of the Dnieper. On the opposite side of the river the country spreads out low and level like a sea. Having by this time received all its important tributaries, the Dnieper is a large and navigable stream; but as it approaches the town it breaks up into two currents and forms a low grassy island of considerable extent called Tukhanoff. During the spring floods there is a rise of 16 or even 20 feet, and not only the whole island but the country along the left bank and the lower grounds on the right bank are laid under water. The bed of the river is sandy and shifting, and it is only by costly engineering works that the main stream has been kept from returning to the more eastern channel which it formerly occupied. Opposite the southern part of the town, where the currents have again united, the river is crossed by a wrought-iron bar-chain suspension bridge, which at the time of its erection (1851) was the largest enterprise of the kind in Europe. It is about half a mile in length and 52½ feet in breadth, and the four principal spans are each 440 feet. The bridge was designed by Mr Vignoles, and the whole of the iron (3500 tons) employed in the construction was prepared in England. The cost was about £400,000.[1]

Owing to the natural character of the site, Kieff is broken up into several distinct portions; and from no point is it possible to get a view of the city as a whole. Up to 1837 the town proper consisted of the Old Town, Petchersk, and Podol; but in that year three districts were added, and in 1879 the limits were extended so as to include Kurenevka, Lukyanovka, Shulyavka, and Solomenka, and the whole was divided into eight districts. The administrative area of the town, as thus defined, is about 12,404 acres, or 18 square miles; but these figures give a very exaggerated notion of the place, as there are extensive suburbs and large intervals of unoccupied ground. Wood is still the most

[1] Views of the bridge will be found in *Official Catalogue of the Great Exhibition*, 1851, vol. i. p. 321.

usual building material; no less than 64·68 per cent. of the houses existing in 1874 were of wood alone, and 14·75 per cent. of wood and stone. The number of clay huts is no less than 8·57 per cent.

The Old Town. or Old Kieff quarter (Starokievskaya Tchast) occupies the highest of the range of hills. It is here that the houses are the most closely built, and that stone structures are most abundant. In some of the principal streets—as Vladimir's, Vasiltchikoff's—buildings of three to five stories, a comparatively rare thing in Russia, have been erected. In the 11th century the area was enclosed by earthen ramparts, with bastions and gateways; but of these the only remnant is the so-called Golden Gate. In the centre of the Old Town stands the cathedral of St Sophia, the oldest cathedral in the Russian empire. The statement frequently repeated that it was a copy of St Sophia's in Constantinople has been shown by Zakrevski to be a mistake. The building measures in length only 118 feet, while its breadth is 173 feet. But if the plan shows no imitation of the great Byzantine church, the decorations of the interior (pictures, mosaics, &c.) indicate direct Byzantine influence. During the occupation of the church by the Uniats in the 17th century these were covered with a coating of whitewash, and a thorough-going restoration was rendered a matter of necessity; but the chapel of the Three Pontiffs has been left untouched to show how carefully the old style has been preserved or copied. Among the mosaics is a colossal representation of the Virgin, 15 feet in height, which, like the so-called "indestructible wall" in which it is inlaid, dates from the time of Yaroslaff. It was this prince who founded the church in 1037 in gratitude for his victory over the Petchenegs. His sarcophagus, curiously sculptured with palms, fishes, &c., is still preserved. The church of St Andrew occupies the spot where, according to Russian tradition, the apostle stood when as yet Kieff was not, and declared that the hill



Plan of Kieff.

would become the site of a great city. The present building dates only from 1744–1767. The church of the Tithes, restored in 1842, was originally founded in the close of the 10th century by Vladimir in honour of two martyrs whom he had put to death; and the monastery of St Michael (or of the Golden Heads—so called from the fifteen gilded cupolas of the original church) claims to have been built in 1108 by Svyatopolk II., and restored in 1655 by Bogdan Khmelnitski.

Up to 1820 the south-eastern district of Petchersk was the industrial and commercial quarter; but it has been greatly altered in carrying out fortifications commenced in that year by Nicholas I. Most of the houses are small and old-fashioned. The monastery—the Kievo-Petcherskaya—is the chief establishment of its kind in Russia; it is visited every year by about 350,000 pilgrims. From the books of the conventual inns it is shown that shelter is given to 150,000 persons per annum; and the numbers for whom there is no accommodation is often very great,—72,000, for example, were counted lying under the open sky on the night of 15th August 1872. Of the ten or twelve conventual churches the chief is that of the Assumption. There are four distinct quarters in the monastery, each under a superior, subject to the archimandrite: the Laura proper or New Monastery, that of the Infirmary, and those of the Nearer and the Further Caves. These caves or catacombs are the most striking characteristic of the place; the name Petchersk, indeed, is connected with the Russian *peshtchera*, a cave. The first series of these caves, dedicated to St Antony, contains about eighty saints' tombs; the second, dedicated to St Theodosius, about forty-five. The bodies were formerly exposed to view; but the pilgrims who now pass through the gloomy galleries, candle in hand, see nothing but the draperies and the inscriptions. Among the more notable names are those of Nestor the chronicler, and Ilia of Murom, the Old

Cossack of the Russian epics. The foundation of the monastery is ascribed to two saints of the 11th century—Antony of Lyubeth, and Hilarion, metropolitan of Kieff. By the middle of the 12th century it had become wealthy and beautiful, but, completely ruined by Batu in 1240, it remained deserted for more than two centuries. Prince Simeon Olblkovitch was the first to start the restoration. A conflagration laid the buildings waste in 1716, and their present aspect is largely due to Peter I. The monastery contains a school of picture-makers of ancient origin, whose productions are widely diffused throughout the empire, and a printing press from which have issued a variety of liturgical and religious works, the oldest known examples bearing the date 1616.

The Pödol quarter, as the name indicates, lies on the low ground at the foot of the bluffs. It is the industrial and trading quarter of the town, and the seat of the great fair of the "Contracts," the transference of which from Dubno in 1797 largely stimulated the commercial prosperity of the city. The present regular arrangement of its streets arose after the great fire of 1811. Lepki district (from the lepki or lime trees, destroyed in 1833) is of recent origin, and is mainly inhabited by the well-to-do classes. It is sometimes called the palace quarter, from the royal palace erected between 1868 and 1870, on the site of the older structure dating from the time of Elizabeth. Gardens and parks abound; the palace garden is exceptionally fine, and in the same neighbourhood are the public gardens with the place of amusement known as the Château de Fleurs.

In the New Buildings, or the Luibed quarter, are the university and the botanical gardens. The Ploskaya Tchast (Flat quarter) or Obolon contains the lunatic asylum; the Lukyanovka Tchast, the penitentiary and the camp and barracks; and the Bulvarnaya Tchast, the military gymnasium of St Vladimir and the railway station.

Kieff is the seat of the governor-general of the three provinces of Kieff, Podolia, and Volhynia, and as such possesses a large number of administrative institutions. In 1862 it was made the headquarters of a great military district including the same provinces. As a centre of intellectual activity it ranks among the principal cities of Russia. The university of St Vladimir, transferred from Vilna after the Polish insurrection of 1831, possessed 94 professors in 1878, and was attended by 771 students; and the library contained 150,000 volumes. The theological academy and theological seminary are large institutions; and the ordinary educational establishments include three male and four female gymnasiums. A daily paper, founded in 1864, and nine other periodicals are published in the town. Of the learned societies the more important are the medical (1840), the naturalists' (1869), the juridical (1876), the historical of Nestor the chronicler (1872), the horticultural (1875), and the dramatical (1879), the archæological commission (1843), and the society of church archæology. There are three considerable theatres.

In 1862 the population of Kieff was returned as 70,341; of this number 8604 were Roman Catholics, 1411 Jews, and 976 Protestants. In 1874 the total was given as 127,251,—77·43 per cent. being members of the Greek Church, 10·85 per cent. Jews, 8·18 per cent. Catholics, and 2·45 per cent. Protestants. The clergy—regular and secular—amounted to no less than 3505. Russian and its dialects were spoken by four-fifths of the inhabitants. For 1881 the total population is estimated at 165,000.

The history of Kieff cannot be satisfactorily severed from that of Russia. According to Nestor's well-known legend it was founded in 864 by three brothers Ke, Shtchek, and Khoriff. It was in the waters of the Dnieper opposite the town that Vladimir, the first saint of the Russian Church, caused his people to be baptized; and Kieff became the seat of the first Christian church, of the first Christian school, and of the first library in Russia. For three hundred and seventy-six years it was an independent Russian city; for eighty years it was subject to the Tartars; for two hundred and forty-nine years it belonged to the Lithuanian principality; and for ninety-eight years to Poland. It was finally united to the Russian empire in 1667. In 1833 the headquarters of the first army corps, with all the departments of the general staff, were transferred to Kieff from Mogileff. The Magdeburg rights, which the city had previously enjoyed, were abolished in 1835, and the ordinary form of town government introduced; and in 1840 it was made subject to the common civil law of the empire.

A long list of works relating to Kieff will be found in Semenoff, *Slov. Ross. Imp.* Of more recent publication are the following:—Rambaud's *La Russie épique*, Paris, 1876; Avenarius' *Kniga o Kievskikh Bogatuiryakh*, St Petersburg, 1876, dealing with the early Kieff heroes; Zakrevski, *Opisanie Kieva*, 1868; the materials issued by the temporary commission for the investigation of the ancient records of the city; Ikonnikoff, *Gorod Kieff*, Kieff, 1881. See also Rambaud in *Rev. de Deux Mondes*, 1874. The standard geological map of the government is Theophilaktoff's (see *Bull. Soc. imp. de Nat. de Moscou*, 1872).

KIEL, the chief town of the province of Schleswig-Holstein in Prussia, is picturesquely situated at the southern end of the Kieler Föhrde, about 66 miles north-east of Hamburg by rail. It consists of a somewhat cramped old town and a better built and more spacious newer part, increased since 1869 by the inclusion of Brunswick and Düsternbrook. In the old town stands the palace, built in the 13th century, and enlarged by Catherine II. of Russia in the 18th; it contains the university library of 150,000 volumes, and a small collection of casts of antique sculpture and of Thorwaldsen's works. Other interesting buildings are the church of St Nicholas, dating from 1240, with a lofty tower; the old town-house; the prison and court-house; the observatory; the theatre; the Government naval offices; and the Thaulaw museum, opened in 1877. The university, founded in 1665 by Christian Albert, duke of Schleswig, and named after him Christiana Albertina, had in 1881 a teaching-staff of 69, with 380 students. The new university buildings were completed in 1876. A naval academy was opened in 1875. Among the public charities there are three hospitals, a blind asylum, an orphanage, an idiot asylum, and a large institution for poor citizens and their widows. Kiel is the most important naval harbour of Germany, and the station of the German Baltic fleet; the port and its approaches are very strongly fortified. The land defences, not yet completed, are to consist of eleven forts, completely encircling the town. The imperial dockyards on the east side of the haven include two large basins (one 235 yards square, the other 271 yards by 235 yards), connected by a canal 70 yards long, four dry docks (each 100 to 120 yards long by 24 or 25 yards wide), and a wet dock. Near them are the yards of a large shipbuilding company. The excellence and safety of Kiel harbour, whose only drawback is that it is frozen in winter, have made the town one of the principal ports of the Baltic. It carries on a very active trade with the Danish islands as well as with the Continent. The chief imports are grain, coal, timber, and cattle; the chief exports, timber, coal, fish, and agricultural produce. Iron-founding and the manufacture of machinery, wooden wares, carpets, tobacco, and oil form the leading industries after the shipping trade. In 1879 there entered at Kiel 3074 ships representing 279,099 tons; 3021 cleared, representing 275,600 tons. Near the town are large steam corn-mills. Kiel possesses a sea-bathing establishment, and is surrounded by fine scenery. The population in 1875, including the garrison, was 37,246.

The name of Kiel appears as early as the 10th century in the form Kyl. Kiel is mentioned as a city in the next century; in 1242 it received the Lübeck rights; in the 14th century it acquired other privileges, and in 1363 entered the Hanseatic league. It suffered much from neighbouring barons; and in the wars in which Schleswig was involved Kiel had its share of siege and capture. In recent times the name of Kiel has been associated with the peace concluded in 1814 between Great Britain and Denmark, and Sweden and Denmark, by which Norway was ceded to Sweden.

KIELCE, the chief town of a government in Russian Poland, is situated about 50 miles north-east of Cracow, in the mountainous district of the Lysa Gora. The copper mines which were in the 16th century the main support of the place are no longer worked; but it has iron-works and sugar factories of considerable importance. The principal buildings are the cathedral, the bishop's palace, and a nunnery in which is an ancient statue of St Barbara fashioned out of a single piece of galena. In 1873 the population was 7838. Bishop Gedcow of Cracow is said to have founded Kielce in 1173.

KIERKEGAARD, SÖREN (1813-1855), the greatest philosophical writer that Scandinavia has produced, was born at Copenhagen, May 5, 1813, and was the seventh child of a respectable Jutland hosier. He was a very serious and precocious boy, weak in health, morbid in character. Of his mother, singularly enough, he has said no word in his copious autobiographical remains, although he was in his twenty-second year when she died; she had been his father's servant. Kierkegaard became a student at the university of Copenhagen, and took up theology as a profession, but never became a priest. He lived in great retirement, deeply oppressed with melancholy and physical suffering, and was at first very little known to his contemporaries. In 1838 he published his first volume, *Papers of a Still Living Man*, a very poor attempt to characterize Hans Andersen. Two years later he took his degree, with a treatise *On Irony*, which contains the germs of his later speculations. In 1840 he engaged himself to a young lady, and shortly after broke off the engagement, an extraordinary step for which he has given many extraordinary reasons. It was not until 1842 that he began the composition of his greatest work, *Enten—Eller* (" Either—Or "), on which his reputation mainly rests; this appeared in 1843, and was immediately followed by a rapid succession of philosophical works, which formed at once an epoch in the history of Danish literature. From 1849 to 1854, however, he was silent as an author. In the last-mentioned year he published a polemical tract against Bishop Martensen, and the short remainder of his life was spent in a feverish agitation against the theology and practice of the state church. But his health, which had always been miserable, was growing worse and worse. In October 1855 he took up his abode in one of the chief hospitals of Copenhagen, where he died, on the 11th of November, at the age of forty-two. His life has been written, with great skill and brilliance, by Dr Georg Brandes (1877). Kierkegaard published about thirty distinct books during his life-time, and left at his death about an equal amount of MS.; a competent analysis of these multifarious labours is given in Brandes's admirable biography.

KILDARE, an inland county of Ireland, in the province of Leinster, is situated between 52° 51′ and 53° 26′ N. lat., and between 6° 28′ and 7° 11′ W. long., and is bounded on the W. by Queen's county and King's county, N. by Meath, E. by Dublin and Wicklow, and S. by Carlow. The area is 418,497 acres, or 654 square miles.

Geology.—The greater part of Kildare belongs to the carboniferous plain which occupies the central portion of Ireland. In the east of the county this plain is bounded by elevations belonging to the clay slate formations bordering on the granite mountains of Dublin and Wicklow; in the south it is encroached upon by the granite formations of Carlow; and in the centre it is interrupted by an elevated plateau terminated on the south by the hills of Dunmurry, consisting chiefly of grauwacke and clay slates, and on the north by the Hill of Allen, a conical rock of porphyry and greenstone, which rises abruptly from the Bog of Allen to the height of 300 feet. Marble of very fine quality is obtained in the quarries to the west of the town of Kildare, and copper ore is said to have been found in the hills of Dunmurry.

Rivers.—The principal rivers are the Boyne, which with its tributary the Blackwater rises in the north part of the county, but soon passes into Meath; the Barrow, which forms the boundary of Kildare with Queen's county, and receives the Greese and the Lane shortly after entering Kildare; the Lesser Barrow, which flows southward from the Bog of Allen to near Rathangan; and the Liffey, which enters the county near Ballymore Eustace, and flowing north-west and then north-east quits it at Leixlip, having received the Morrel between Celbridge and Clane, and the Ryewater at Leixlip. The northern border of the county is traversed by the Royal Canal, which connects Dublin with the Shannon at Cloondara. Further south the Grand Canal, which connects Dublin with the Shannon at Shannon Harbour, occupies the valley of the Liffey until at Sallins it enters the Bog of Allen, passing into King's county near the source of the river Boyne. Several branch canals connected with it afford communication with the southern districts of the county.

Climate and Agriculture.—Owing in a considerable degree to the large extent of bog, the climate of the northern districts is very moist, and fogs are frequent, but the eastern portion is drier, and the climate of the Liffey valley is very mild and salubrious. The soil, whether resting on the limestone or on the clay slate, is principally a rich deep loam inclining occasionally to clay, easily cultivated and very fertile if properly drained, which too often is not the case. About 40,000 acres in the northern part of the county are included in the Bog of Allen, which is, however, intersected in many places by elevated tracts of firm ground. To the south of the town of Kildare is the Curragh, an undulating down of about 8000 acres in extent, and presenting to the eye a beautiful sward of vivid green unbroken by a single tree or shrub. The common is the property of the crown, and is occupied as a sheep walk, while a portion of it forms the principal race-course of Ireland. It is now also the headquarters of a military division. The most fertile and highly cultivated districts of Kildare are the valleys of the Liffey and a tract in the south watered by the Greese. The demesne lands along the valley of the Liffey are finely wooded. More attention is paid to drainage and the use of manures on the larger farms than is done in many other parts of Ireland, but the small farms are mostly cultivated in the usual slovenly manner. The pastures which are not subjected to the plough are generally very rich and fattening.

The following table gives a classification of holdings according to size in 1850 and 1880, as contained in the agricultural returns:—

	1 Acre.	1 and under 5.	5 and under 15.	15 and under 30.	30 and upwards.	Total.
1850	1,295	2,513	2.145	1,539	3,854	10,346
1880	1,414	1,764	1,682	1,166	2,931	8,957

The total area under crop in 1881 was 120,953 acres, or 29 per cent. of the whole acreage of the county. In 1880 239,406 acres, a percentage of 57·2, were under grass, 360 acres lay fallow, 7332 were woods, 37,540 bog and marsh, 985 barren mountain land, and 15,404 water, roads, and fences. The area under crop in 1850 was 147,507 acres, the diminution in 1881 being more than accounted for by a fall of 34,932 in the area under cereals. On the other hand, the area under grass increased between 1850 and 1881 by 47,156 acres. Between 1850 and 1881 the area under wheat, for which the rich deep soil in the valley of the Liffey is well suited, declined from 22,737 to 4120, and that under oats from 45,791 to 23,761, or nearly one-half, while the area under barley was nearly doubled, being 13,883 in 1881. The area under potatoes declined from 12,158 acres in 1850 to 9348 acres in 1881, and, notwithstanding a large increase in pasturage and in the number of cattle, the area under turnips only increased from 9622 to 11,501.

Horses have increased from 13,521 in 1855 to 13,795 in 1881. The number used for agricultural purposes was 8205. Little attention is paid to the breed, and the supply is obtained chiefly outside the limits of the county. Cattle in 1855 numbered 74,480, and in 1881 had increased to 92,252. Milch cows numbered only 12,578, and have diminished since 1855 by 3612. There has been great improvement in the breeds of cattle, crosses with the shorthorned or the Durham being now the most common. Sheep numbered 127,614 in 1855, 133,996 in 1880, and 117,760 in 1881. They are grazed chiefly on the Curragh, and are now principally Leicesters or crosses with that breed. Pigs have diminished since 1855 from 15,993 to 12,936. Goats in 1881 numbered 3835, and poultry 224,310.

According to the corrected summary of the return of owners of land in Ireland, 1878, the county in 1873 was divided among 1768 owners, possessing altogether 412,490 acres, with a rateable valuation of £338,233. Of the owners 848, or 48 per cent., possessed 1 acre and upwards and the average rateable valuation all over was

16s. 4½d. The duke of Leinster owned 67,227 acres; the marquis of Drogheda, 16,609; Sir G. G. Aylmer, 15,396; John La Touche 11,282; and seven other estates exceeded 5000 acres.

Manufactures.—Though possessing a good supply of water-power, the county is almost wholly destitute of manufactures; but there are a few small cotton, woollen, and paper mills, as well as breweries and distilleries, and several corn mills. Large quantities of turf are exported to Dublin by the canal.

Railways.—The Great Western line crosses the county at its northern boundary near Leixlip, Maynooth, Kilcock, and Enfield, and the Great Southern and Western passes through nearly its whole extent by Naas, Newbridge, Kildare, Monasterevan, and Athy.

Administration.—The county comprises fourteen baronies, and contains 107 civil parishes, five parts of parishes, and 1240 townlands. Judicially it is within the home circuit, and is divided into fourteen petty sessions districts and three parts of petty sessions districts. Assizes are held at Naas, and quarter sessions at Athy, Kildare, Maynooth, and Naas. The county contains portions of the six poor-law unions of Athy, Baltinglass, Carlow, Celbridge, Edenderry, and Naas. The military stations at Newbridge and the Curragh constitute the Curragh military district, and the barracks at Athy and Naas are included in the Dublin military district. There are three townships—Athy, Naas, and Newbridge. The principal other towns are Maynooth (which is the seat of a Roman Catholic college), Celbridge, Kildare, Monasterevan, Kilcullen, Leixlip, Kilcock, Castledermot, Ballymore Eustace, and Rathangan. Previous to the Union Kildare returned ten members to parliament, of whom eight represented boroughs; but now it sends only two, who sit as members for the county.

Population.—According to the census return of 1659 the population amounted to only 13,825, of whom 796 were English and 13,029 Irish. In 1760 it was estimated at 51,726. According to the parliamentary return of 1821 it was 99,065, and by 1841 it had increased to 115,190, but in 1851 had diminished to 96,495, in 1861 to 90,946, in 1871 to 83,614, and in 1881 to 76,102, of whom 40,859 were males and 35,243 females. In several other counties there is an excess of males over females, but it is much larger in Kildare than in any other, which is the more remarkable that between 1851 and 1880 there has been also an excess of male emigrants, the total number of emigrants being 13,651 males and 11,765 females, or 27·9 per cent. of the population of 1861. The rate of marriages in 1880 to every 1000 of the population was 3·6, of births 22·0, and of deaths 16·9, the rates for Ireland being 3·8, 24·0, and 19·3. The number of natives of England and Wales residing in the county in 1841 was 406, and in 1871 they had increased to 5270; of natives of Scotland there were 151 in 1841 and 574 in 1871. The number of Roman Catholics in 1881 was 66,184; of Protestant Episcopalians, 8616; of Presbyterians, 754; of Methodists, 344. In 1871 there were none who spoke Irish only, but 554 spoke Irish and English. The number who could read and write in 1871 was 43,783; 11,472 could read but could not write, and 28,359 could neither read nor write.

History.—The early inhabitants of the county are perhaps to be identified with Ptolemy's Coriondi. Afterwards it formed part of the district of Caellan or Galen, which also included portions of Wicklow and Carlow, the principal chieftain being a representative of the family of Hy Caellan or M'Kelly, who had their residence at the moat of Ardscull near Naas. According to a tale in the Book of Leinster the original name of Kildare was *Druim Criaidh* (Drumcree), which it retained until the time of St Brigit, after which it was changed to *Cilldara*, the church of the oak, from a very old oak under whose shadow the saint had constructed her cell. For some centuries it was under the government of the Macmurroughs, kings of Leinster, but along with the remainder of Leinster it was granted by Henry II. to Strongbow. On the division of the palatinate of Leinster among the five granddaughters of Strongbow, Kildare fell to Sibilla, the fourth daughter, who married William de Ferrara, earl of Derby. Through the marriage of the only daughter of William de Ferrars it passed to William de Vescy—who, when challenged to single combat by John Fitz Thomas, baron of Offaly, for accusing him of treason, fled to France. His lands were thereupon in 1297 bestowed on Fitz Thomas, who in 1316 was created earl of Kildare, and in 1317 was appointed sheriff of Kildare, the office remaining in the family until the attainder of Gerald, the ninth earl, in the reign of Henry VIII. Kildare was a liberty of Dublin until 1296, when an Act was passed constituting it a separate county.

Antiquities.—In the county there are several old gigantic pillar stones, the principal being those at Punchestown, Harristown, Jigginstown, and Mullamast. Among the more remarkable earthworks are the raths at Mullamast, Knockcaellagh near Kilcullen, Ardscull near Naas, and elsewhere, and the numerous sepulchral mounds in the Curragh. Of the round towers the finest is that of Kildare, which is 130 feet high; there are remains of others at Taghadoe, Kilcullen, Oughterard, and Castledermot. At one time there were an immense number of religious houses in the county. There are remains of a Franciscan abbey at Castledermot. At Graney there are the ruins of an Augustinian nunnery and also portions of a building said to have belonged to the Knights Templars. The town of Kildare has ruins of no less than four monastic buildings, among others the nunnery founded by St Brigit. The site of a monastery at Old Kilcullen, said to date from the time of St Patrick, is marked by two stone crosses, one of which is curiously sculptured. The fine abbey of Monasterevan is now the seat of the marquis of Drogheda. On the Liffey are the remains of Great Connel Abbey near Celbridge, of St Wolstan's near Celbridge, and of New Abbey. At Moone, where there was at one time a Franciscan monastery, there are the remains of a very old cross with curious sculpturings. Among the old castles may be mentioned those of Athy and Castledermot, built about the time of the Anglo-Norman invasion; Maynooth Castle, built by the Fitzgeralds; Kilkea, originally built by the seventh earl of Kildare, and restored within the present century; and Timolin, erected in the reign of King John.

KILIA, a seaport town of Roumania, formerly in the province of Moldavia, situated on the northern bank of the northern arm of the lower Danube, 20 miles from its mouth. The inhabitants, between 6000 and 7000 in number, are mainly engaged in the river trade and fisheries. Kilia was occupied by the Russians in 1790, and bombarded by the English and French in 1854. Old Kilia is on the opposite side of the river. A plan of the present town will be found in the maps published by the European Commission of the Danube.

KILIAN, St, the apostle of Franconia, was, according to Hrabanus Maurus, a native of Ireland, whence along with his companions he went to eastern Franconia. After having preached the gospel in Würzburg, the whole party were put to death by the orders of an unjust judge of the name of Gozbert. Notker Balbulus (*c.* 912) relates that Kilian's mission emanated from the pope, and that Gozbert was the duke of Franconia, who, after receiving baptism, had been persuaded to put away his wife (Geila) because she was his brother's widow. Geila in revenge caused Kilian and his comrades, Coloman and Totman, to be secretly put to death. Later accounts assign the mission to the time of Conon (686). In the *Martyrologies* Saints Kilian (Kyllena, Chilianus), Coloman, and Totman are commemorated on July 8. Their relics lie in the cathedral (St Kiliansmünster) at Würzburg.

KILIMANJARO, a great snow-topped mountain in eastern Africa, in 3° 5′ S. lat. and 37° 22′ E. long., has a height of 18,715 feet, and is believed to be the loftiest eminence of the whole continent. It stands completely apart from all the neighbouring heights, but is only "one of many summits that crown the eastern edge of the great plateau of equatorial Africa." At a distance of 100 miles to the north, across the wide expanse of the Kaptei and Kikuyu plains, lie the less known mountains Kenia and Lemeru; and due west, at a distance of about 30 or 40 miles, rises the noble mass of Mount Meru.

As the natives believe that the summit of Kilimanjâro is composed of silver, it is possible that Aristotle's reference to "the so-called Silver Mountain" from which the Nile flows was based on indistinct reports about this mountain; but the real discovery of its existence was made only in 1848 by Mr Rebman of the Church Missionary Society (*Church Missionary Intelligencer*, 1849). His account, though fully borne out by Dr Krapf, was at first received with great incredulity by professional geographers. The matter has been finally set at rest by the visits paid to the mountain by Von der Decken (1861 and 1862) and Mr Charles New (1867), the latter of whom reached the lower edge of the snow. Kilimanjâro has two principal summits. The eastern, Kibo or Bareni, is a magnificent dome with a smooth and regular outline; the other, Kimawenzi, is a dark and rugged peak; and between the two stretches a saddle-like ridge several miles in extent. Trachytes, basalt, and obsidian were obtained by Von der Decken from the upper part of the mountain. Mr New distinguished six clearly marked zones of vegetation. The first was the region of the banana and maize, the surface, when not under cultivation, being clothed with a close turf exceedingly rich in clover; above this lay a belt of jungle; the jungle was succeeded by a forest of gigantic trees with a dense and varied undergrowth, and an extraordinary profusion of moss both on the ground and on the stems and branches; beyond the trees was a region of hills covered with rich grass and clover; beyond the grass came heath; and this gradually dwindled away into a region of bare wind-swept rocks. Among the fifty species of plants collected on the mountain Dr Hooker found only a few of those European forms which are known to exist in the Cameroons and the Abyssinian mountains.

From the southern slopes of Kilimanjâro descend a great many streams—the Weri-Wari, the Rau, the Ganu, &c.—which, uniting with the Jipe from Lake Jipe, ultimately form the Rufu or Pangani, an important river reaching the Indian Ocean about 5° 30′ S. lat. The hilly country round the southern skirts is occupied by the Jaggas or Chaggas, who cultivate maize, millet, and pulse, and keep cattle. Their chief villages are Kilema and Moche.

See R. Thornton (the geologist of Von der Decken's party) in *Proc. of Roy. Geog. Soc.*, 1861–62; Krapf, *Travels in East Africa*, 1860; New, *Life . . in East Africa*, 1873; Hooker in *Journal of Linnean Society*, 1875; and for further literature, Petermann's *Mittheilungen*, 1866, pp. 75–76.

KILKENNY, an inland county of Ireland, in the province of Leinster, is situated between 52° 14′ and 52° 52′ N. lat., and between 6° 56′ and 7° 38′ W. long. It is bounded on the N. by Queen's county, E. by Carlow and Wexford, S. by Waterford, and W. by Waterford and Tipperary. Its greatest length from north to south is about 45 miles, and its greatest breadth from east to west about 25 miles. The area is 507,254 acres, or about 793 square miles.

The greater part of Kilkenny is a continuation forming the south-eastern extremity of the Carboniferous Limestone plain of Ireland, but in the south-east this is bounded partly by the Cambro-Silurian rocks which run into the county from Wexford, and partly by a continuation of the granite mountains of Wicklow and Carlow, and it is interrupted in the north by an extensive hilly region forming part of the Castlecomer coal-field, which extends also into Queen's county and Tipperary. The field lies in the form of a broad basin, and rests on flagstone and black shale. The coal is anthracite, and the most productive portions of the bed are in the centre of the basin at Castlecomer. Besides a large number of fossil plants, crustaceans of a rare species and also several peculiar reptilian remains have been found in the measures. The field is believed to contain nearly 80,000,000 tons of workable coal, and at present the annual yield is about 80,000 tons,—the annual yield of Ireland being only about 130,000 tons. On the granite the limestone has the form of a bedded dolomite, and this is also principally the form of the central division to the north-west of Kilkenny. In other places the limestones are bluish or black, the latter being the best quality for burning, and are often associated with shales of a considerable thickness. Cherty beds frequently occur between the limestone and the Coal-measures. Hematitic iron of a rich quality is found in the Cambro-Silurian rocks at several places. Tradition has it that silver shields were made about 850 B.C. at Argetros or Silverwood on the Nore, and at Ballygunnion there were very ancient mines associated with the lead. The shelly black marble obtained near the town of Kilkenny has gained wide fame, and is used for tombstones, chimney-pieces, and picture frames. Manganese is obtained in some of the limestone quarries, and also near the Barrow. Marl is abundant in various districts. Pipeclay and potter's clay are found, and also yellow ochre. Copper occurs near Knocktopher.

Rivers.—The principal rivers, the Suir, the Barrow, and the Nore, have all their origin in the Slieve Bloom mountains, and after a widely divergent course southwards discharge their waters into Waterford Harbour. The Suir forms the boundary of the county with Waterford, and is navigable for sloops to Carrick. The Nore, which is navigable to Innistioge, enters the county at its north-western boundary, and flows by Kilkenny to the Barrow, 9 miles above Ross, having received in its course the King's river at Jerpoint and the Argula near Innistioge. The Barrow, which is navigable beyond the limits of Kilkenny into Kildare, forms the eastern boundary of the county from near New Bridge. There are no lakes of any extent, but turloughs are occasionally formed by the bursting up of underground streams.

Climate and Agriculture.—On account of the slope of the country and the nature of the soil, the surface occupied by bog or wet land is very small, and the air is dry and very salubrious. So temperate is it in winter that the myrtle and arbutus grow in the open air. There is less rain than at Dublin, and vegetation is earlier than in the adjacent counties. Along the banks of the Suir, Nore, and Barrow a very rich soil has been formed by alluvial deposits. Above the Coal-measures in the northern part of the county there is a moorish tract devoted chiefly to pasturage. The soil above the limestone is for the most part a deep and rich loam admirably adapted for the growth of wheat. The heath-covered hills afford honey with a flavour of peculiar excellence.

The following table gives a classification of holdings according to size in 1850 and in 1880, as contained in the agricultural returns:—

	1 Acre.	1 and under 5.	5 and under 15.	15 and under 30.	30 and upwards.	Total.
1850	1,932	3.583	4.109	3.802	5.206	18,632
1880	1,734	1,816	2,508	2,662	5.325	14,045

The total area under crops in 1881 was 159,304 acres, a percentage of 31·4 of the whole acreage of the country. In 1880, 293,252 acres, a percentage of 57·8, were under grass, 2196 fallow, 10,799 wood, 10,746 bog, 13,515 mountain, and 21,661 water, roads, and fences. The area under crops in 1850 was 195,923. The area under cereals declined from 112,220 acres in 1850 to 65,232 in 1881, wheat decreasing from 47,343 acres to 11,843, and oats from 52,236 to 35,878, while in other cereals, of which the chief is barley, there has been an increase from 12,641 acres to 17,511. Between 1851 and 1880 the area under grass increased by 40,530 acres. Almost nothing has been done to improve the pasturage of the hilly districts, which are still largely covered with heath. The area under meadow and clover, which includes a large portion of rich soil on the banks of the Nore and Suir, increased from 42,482 acres in 1850 to 62,079 in 1881. Green crops diminished in area from 41,189 acres in 1850 to 31,993 in 1881, potatoes from 26,321 acres to 18,269, and turnips from 11,613 to 9929. Horses since 1850 declined from 17,161 to 16,933. The number in 1881 used for agricultural purposes was 11,606. Mules since 1850 have increased from 687 to 1054, and asses from 3355 to 5345. Cattle in 1850 numbered 72,998, and in 1881 had increased to 120,594. Cows numbered 37,695, or about a third of the total number of cattle, dairy-farming being largely followed, especially in the hilly districts to the south. The most common species of cattle is a cross between the old Irish breed and the longhorn, but Kerry cows are considerably in demand for dairies. For winter-feeding pounded furze tops are frequently used, but in many cases the cattle graze outside in winter. Sheep, the breed of which has been much improved by crossing, increased from 40,450 in 1850 to 85,393 in 1881. Pigs have declined in numbers from 45,763 to 39,777, while goats have increased from 5958 to 6376, and poultry from 197,955 to 410,524.

According to the corrected summary of owners of land, 1878, the land in 1873, exclusive of the county of the city of Kilkenny, was divided among 1150 proprietors, of whom 827 possessed less than 1 acre. The annual rateable valuation is stated in the return of 1876 as £340,696, giving an average value of 13s. 9d. per acre. There were forty-seven owners who possessed upwards of 2000 acres, twelve who possessed upwards of 5000 acres, and six upwards of 10,000 acres, viz., Viscount Clifden, 35,288; Earl of Bessborough, 23,967; Charles Wandesforde, 22,232; Col. W. F. Tighe, 11,970; Marquis of Ormonde, 11,960; and Viscount Mountgarret, 11,919.

Manufactures.—The linen manufacture introduced into the county in the 17th century by the duke of Ormonde to supersede the woollen manufacture gradually became extinct, and the woollen manufacture now carried on is also very small. There are, however, breweries, distilleries, tanneries, and flour-mills, as well as marble polishing works.

Railways.—The county is intersected from north to south by the Maryborough and Waterford line, which is joined near Kilkenny by the South-Eastern Railway from Carlow. The Great Southern and Western Railway skirts the south-western boundary of the county.

Administration.—The county comprises 10 baronies, 124 civil parishes and 15 parts of parishes, and 1601 town-lands. The county of the city contains one parish and four parts of parishes. There are three poor-law unions wholly within the county, viz., Castlecomer, Kilkenny, and Thomastown, and portions of five, viz., Callan, Carrick-on-Suir, New Ross, Urlingford, and Waterford. The county includes the parliamentary borough of Kilkenny, part of that of New Ross, and the township of Callan. There are in the county and city sixteen petty sessions districts. Assizes are held at Kilkenny, and quarter sessions at Kilkenny, Pilltown, Urlingford, Castlecom

Grace's Old Castle, Callan, and Thomastown. The county is within the Cork military district, and there are barrack stations at Kilkenny and Castlecomer. Previous to the Union Kilkenny returned sixteen members to Parliament, two representing the county. Since that period two members have been returned for the county, one for the city of Kilkenny, and one for New Ross, which, however, is situated chiefly in Wexford.

Population.—According to the census of 1659, the total population of the county was 18,427, of whom 1442 were English and 16,985 Irish. In 1760 it was estimated at 62,832. In 1821 it had increased to 158,716, and in 1841 to 202,746, but in 1851 it had diminished to 159,514, in 1871 to 109,379, and in 1881 to 99,064, of whom 48,682 were males and 50,382 females. The total number of emigrants from 1st May 1851 to 31st December 1880 was 55,402, or 44·5 per cent. of the population in 1861. The marriage rate in 1880 to every 1000 of the population was 3·2, the birth-rate 22·1, and the death rate 20·0. In 1881 the Roman Catholics numbered 93,699; Protestant Episcopalians, 4963; Presbyterians, 197; Methodists, 131; and all other denominations, 74. There were resident in 1871 in the county 805 natives of England and 160 of Scotland. In 1871 the number of persons who spoke Irish only was 316, while 6424 could speak Irish and English. 44,779 could read and write, 15 369 could read but could not write, and 36,521 could neither read nor write.

History.—Kilkenny received its name from St Cannech or Canice, abbot of Aghaboe in Queen's county, who died in 598, and whose see was removed to Kilkenny in the beginning of the 11th century. In the time of Ptolemy the county was inhabited by the Brigantes and the Cauoi. Afterwards it formed part of the kingdom of Uisraigagh, modernized into Ossory, which was tributary sometimes to Leinster and sometimes to Munster. In 1210 Kilkenny was formed into a county by King John. During the Revolution it was held by the Irish, and it also strongly adhered to the cause of James II. against William III.

Antiquities.—Circular groups of stones of very ancient origin are to be seen on the summits of Slieve Grian and the hill of Cloghmanta. There is a remarkable cromlech at Kilmogue and a large number of cromlechs as well as raths in various parts of the county. Besides numerous forts and mounds there are five round towers, one adjoining the cathedral of Kilkenny, and others at Tulloherin, Kilree, Fertagh, and Aghaviller respectively. The monastic remains in the city of Kilkenny are mentioned under the notice of the town. There are interesting remains of a Cistercian monastery at Jerpoint, said to have been founded by Dunnough, king of Ossory, and of another belonging to the same order at Graig, founded by the earl of Pembroke in 1212. The Dominicans had an abbey at Roshercon founded in 1267, and another at Thomastown, of which there are still some remains. The Carmelites had a monastery at Knocktopher. There was an Augustinian monastery at Innistioge, and priories at Callan and Kells, of all of which there are still some remains. Of the old castles the most remarkable is Graney or Grandison Castle in Iverk, which is supposed to have been founded by the eighth earl of Ormonde in 1521, and of which three towers and the walls still remain. See Robertson, *Antiquities and Scenery of the County of Kilkenny*, 1851.

KILKENNY, the chief town of the above county, a market-town, county of a city, and parliamentary borough, is finely situated on the Nore, and on the Great Southern and Western Railway, 73 miles south-west of Dublin and 32 north of Waterford. It consists of two distinct portions, Englishtown or Kilkenny proper and Irishtown, separated from each other by a small rivulet, but although Irishtown still retains its name it is now included in the corporation of Kilkenny. The city is irregularly built, but possesses several spacious streets with many good houses, while its beautiful environs and several imposing ancient structures give it an unusually interesting and picturesque appearance. The Nore is crossed by two handsome bridges erected towards the close of last century. The old cathedral of St Canice, from whom the town takes its name, dates from 1052, and with the exception of the cathedral of St Patrick in Dublin is the largest ecclesiastical building in Ireland, having a length from east to west of 226 feet, and a breadth along the transepts from north to south of 123 feet. It occupies a commanding position on an eminence at the western extremity of Irishtown. It is a cruciform structure in the Early English style, with a low massive tower supported on clustered columns of the black marble peculiar to the district. The building was lately restored at a cost of £15,000. It contains a large number of old sepulchral monuments. On the eastern side of the north transept is the parish church, and a short distance from the south transept are the remains of a round tower, rising to the height of 100 feet. The episcopal palace near the east end of the cathedral was erected in the time of Edward III. and enlarged in 1735. Besides the old cathedral, the principal other churches are the Episcopal church of St Mary, a plain cruciform structure; that of St John, containing a portion of the old abbey of St John; and the Roman Catholic cathedral, erected in 1857 at a cost of £30,000, a cruciform structure in the late First Pointed style, with a massive central tower 186 feet in height. There are important remains of three old monasteries—the preceptory of St John's, founded in 1211; the Dominican abbey, founded in 1225, and now used as a Roman Catholic church; and the Franciscan abbey on the banks of the Nore, founded about 1230. But, among the ancient buildings, that next in importance and interest to the cathedral is the castle, occupying a commanding position on the summit of a precipice above the river Nore. It was originally built by Strongbow, but rebuilt by William le Mareschal in 1175, and again restored in the present century, and transformed into the princely residence of the marquis of Ormonde. The grammar school or college, which was originally founded by Pierce, earl of Ormonde, and re-endowed in 1684 by the duke of Ormonde, stands on the banks of the river opposite the castle. In it Swift, Farquhar, Congreve, and Bishop Berkeley received part of their education. Adjoining the city is the Roman Catholic college of St Kyran, a Gothic building completed about 1840 at a cost of £20,000. The other principal public buildings are the new court-house, the tholsel or city court, the city and county prison, the barracks, and the county infirmary. There is still a small manufacture of coarse woollens and linens. In the neighbourhood there are large collieries, as well as quarries for marble, the manufactures connected with which are an important industry of the town. It also possesses corn-mills, breweries, and a tannery. The population of the county of the city of Kilkenny in 1851 was 19,973, of the town proper 15,808; in 1871 the numbers were 15,748 and 12,710; and in 1881 they were 14,964 and 12,182.

The town of Kilkenny proper owes its origin to an English settlement which took place in the time of Strongbow, and it received a charter from William le Mareschal, who married Strongbow's daughter. This charter was confirmed by Edward III., and from Edward IV. Irishtown received the privilege of choosing a portrieve independent of Kilkenny. By Elizabeth the boroughs, while retaining their distinct rights, were constituted one corporation, which in 1608 was made a free borough by James I., and in the following year a free city. From James II. the citizens received a new charter, constituting the city and liberties a distinct county, to be styled the county of the city of Kilkenny, the burgesses of Irishtown continuing, however, to elect a portrieve until the passing of the Municipal Reform Act. Frequent parliaments were held at Kilkenny in the 14th century, and so late as the reign of Henry VIII. it was the occasional residence of the lord-lieutenant. In 1642 it was the meeting-place of the assembly of confederate Catholics. In 1648 Cromwell in the hope, by means of a plot, of obtaining possession of the town, advanced towards it, but before his arrival the plot was discovered. In 1650 it was, however, compelled to surrender after a long and resolute defence. At a very early period Kilkenny and Irishtown returned each two members to parliament, but since the Union one member only has been returned for the city of Kilkenny.

KILLARNEY, a market-town of Ireland, county of Kerry, is situated on a branch line of the Dublin and Cork Railway, 180 miles south-west from Dublin and 47 miles north from Cork. On account of the beautiful scenery in the neighbourhood, the town is much frequented by tourists. Within late years it has been greatly improved in appearance, and the streets are now spacious and well-paved, while many good houses and several imposing public buildings have been erected. The principal buildings are the court-house, the Roman Catholic cathedral and bishop's palace, designed by Pugin, the episcopal church lately rebuilt, the lunatic asylum, erected at a cost of £30,000, and the railway hotel. Adjoining the town is the fine mansion of the earl of Kenmare. The only manufacture of any importance now carried on at Killarney is that of fancy articles from the wood of the arbutus; but it owed its origin to iron-smelting works, for which abundant fuel was obtained from the neighbouring forests.

The lakes of Killarney, about a mile and a half distant from the town, are situated in a basin between several lofty mountain groups, some rising abruptly from the water's edge, and all clothed with trees and shrubbery almost to their summits. The lower lake, or Lough Leane, which has an area of 5001 acres, is studded with finely wooded islands, on the largest of which, Ross Island, are the ruins of Ross castle, an old fortress of the O'Donoghues; and on another island, the "sweet Innisfallen" of Moore, are the picturesque ruins of an abbey founded by St Finian the leper at the close of the 6th century. Between the lower lake and the middle or Torc lake, which is 680 acres in extent, stands Muckross Abbey, built by the Franciscans about 1440. With the upper lake, which is 430 acres in extent, thickly studded with islands, and closely shut in by mountains, the lower and middle lakes are connected by the Long Range, a winding and finely wooded channel, 2½ miles in length, and commanding magnificent views of the mountains. Midway in its course is a famous echo caused by the Eagle's Nest, a lofty pyramidal rock. The population of the urban sanitary district in 1881 was 6546.

KILLDEER, a common and well-known American Plover, so called in imitation of its whistling cry, the *Charadrius vociferus* of Linnæus, and the *Ægialitis vocifera* of modern ornithologists. About the size of a Snipe, it is mostly sooty-brown above, but showing a bright buff on the tail coverts, and in flight a white bar on the wings; beneath it is pure white except two pectoral bands of deep black. It is one of the finest as well as the largest of the group commonly known as Ringed Plovers or Ring Doterels,[1] forming the genus *Ægialitis* of Boie. Mostly wintering in the south or only on the sea-shore of the more northern States, in spring it spreads widely over the interior, breeding on the newly-ploughed lands or on open grass-fields. The nest is made in a slight hollow of the ground, and is often surrounded with small pebbles and fragments of shells. Here the hen lays her pear-shaped, stone-coloured eggs, four in number, and always arranged with their pointed ends touching each other, as is indeed the custom of most Limicoline birds. The parents exhibit the greatest anxiety for their offspring on the approach of an intruder: the hen runs off with drooping wings and plaintive cries, while the cock sweeps around, gesticulating with loud and angry vociferations. It is the best-known bird of its Family in the United States, throughout which it is found in all suitable districts, but less abundantly in the north-east than further south or west. In Canada it does not range further to the northward than 56° N. lat., and it is not known to occur in Greenland, or hardly in Labrador, though it is a passenger in Newfoundland every spring and autumn.[2] In winter it finds its way to Bermuda and to some of the Antilles, but it is not recorded from any of the islands to the windward of Porto Rico. However, in the other direction it goes very much further south, travelling down the Isthmus of Panama and the west coast of South America to Peru. The Killdeer has several other congeners in America, among which may be noticed *Æ. semipalmata*, so curiously resembling the ordinary Ringed Plover of the Old World, *Æ. hiaticula*, except that it has its toes connected by a web at the base; and *Æ. nivosa*, a bird inhabiting the western parts of both the American continents, which in the opinion of some authors is only a local form of the widely-spread *Æ. alexandrina* or *cantiana*, best known by its English name of Kentish Plover, from its discovery near Sandwich towards the end of the last century, though it is far more abundant in many other parts of the Old World. The common Ringed Plover, *Æ. hiaticula*, has many of the habits of the Killdeer, but is much less often found away from the sea-shore, though a few colonies may be found in dry warrens in certain parts of England many miles from the coast, and in Lapland at a still greater distance. In such localities it has the curious habit of paving its nest with small stones (whence it is locally known by the name of "Stone-hatch"), a habit almost unaccountable unless regarded as an inherited instinct from shingle-haunting ancestors.

About thirty species all apparently referable with propriety to the genus *Ægialitis* have been described, but probably so many do not exist. Some, as the Kentish Plover above named, have a very extended distribution, for that, letting alone its supposed American habitat, certainly occurs in greater or less numbers on the coasts of China, India, and Africa generally. On the other hand there is one, the *Æ. sanctæ-helenæ*, which seems to be restricted to the island whence it takes its scientific name, and where it is called the "Wire-bird" (*Ibis*, 1873, p. 260). Nearly allied to *Ægialitis* are two genera peculiar to the New Zealand subregion—*Thinornis*, which does not call for any particular remark, and the extraordinary *Anarhynchus*, which deserves a few words. Of this there is but one species, *Æ. frontalis*, the Wrybill, so called from its bill being congenitally bent in the middle and diverted to the right side—a formation supposed to give the bird greater facility in seeking its food, chiefly arthropods that lurk under stones, round which it may be seen running from left to right. Mr Buller (*B. New Zealand*, p. 219) connects with this habit the curious fact that the black pectoral band worn by the bird is "narrower and of a less decided colour on the left side of the breast," whence he infers that "the law of natural selection has operated to lessen the colouring on the side of the bird more exposed to Hawks and other enemies while the *Anarhynchus* is hunting for its daily food." Be that as it may, it does not detract from the wonderful nature of this asymmetry of the bill, which is comparable indeed with that found in so large a number of Cetaceans among mammals, but with nothing known among birds, for in the CROSSBILLS (*q.v.*) the bones of the mandibles are not affected, and in certain Owls (*Nyctala*) the distortion of the ear-bones is not externally visible. (A. N.)

KILLIZ, or KILIS, a town of Syria, in the Turkish vilayet of Aleppo, in 37° 2′ N. lat. and 37° 2′ E. long., 60 miles north of the city of Aleppo. It is situated in an extremely fertile plain or plateau, completely surrounded with olive groves, the produce of which is reckoned the finest oil of all Syria; and its position on the regular route from Birejik on the Euphrates to southern Caramania gives it considerable traffic. The bazaars are unusually fine, and gunmaking is a common craft in the town. The population, variously estimated at 12,000 and 6000, consists largely of Arabs, the town lying just on the northern rim of the Arab territory.

KILMARNOCK, a market-town, and parliamentary and municipal burgh, in the district of Cunningham,

[1] The word Doterel seems properly applicable to a single species only, the *Charadrius morinellus* of Linnæus, which, from some of its osteological characters, may be fitly regarded as the type of a distinct genus, *Eudromias*. Whether any other species agree with it in the peculiarity alluded to is at present uncertain.

[2] A single example is said to have been shot near Christchurch, in Hampshire, in April 1857 (*Ibis*, 1862, p. 276).

Ayrshire, Scotland, is situated on both sides of the Kilmarnock water, near its junction with the Irvine, 21 miles south-west of Glasgow by rail. The town is long and narrow, but its principal streets are well-built and spacious. Among the chief buildings are the town-house, the court-house, the corn exchange buildings (including the Albert tower, 110 feet high, and various public offices), the observatory, and the academy, built in 1876 at a cost of £5000 to accommodate six hundred children. Kilmarnock also possesses the endowed Kay schools, an industrial school in the once famous Kilmarnock House, a school of art, an athenæum, a public library, an opera-house, and an infirmary. In the Kay park of 40¾ acres, purchased from the duke of Portland for £9000 (with a legacy left by a native of the town in 1866), stands the Burns Monument, inaugurated in August 1879. Kilmarnock rose into importance in the 17th century by its production of striped woollen "Kilmarnock cowls" and broad blue bonnets. Knitted woollen bonnets are still manufactured to an annual value of about £25,000, but by far the most important textile industry is carpet-weaving. When trade is good, the annual turn out of Brussels and Scotch carpets is valued at about £100,000. There are several spinning mills in connexion with the carpet factories. Tweeds, blankets, shawls, and tartans are produced to a limited but rapidly increasing extent; the manufacture of wincey is larger. Calico-printing, once important, has dwindled. The boot and shoe trade is prosperous; and there are very extensive iron and engineering works in the town. Situated in a highly cultivated region, Kilmarnock is famous for its dairy produce; and the largest cheese-show in Scotland is held there annually. The neighbourhood abounds in freestone and coal. The burgh is governed by a provost, six bailies, and eighteen councillors. It unites with Dumbarton, Port-Glasgow, Renfrew, and Rutherglen in returning one member to parliament. The population in 1881 was 23,901.

KILSYTH, a burgh of barony in Stirlingshire, Scotland, is situated about 12 miles north-east of Glasgow. It is ill built and dingy. On August 15, 1645, the Covenanters under Baillie were defeated at Kilsyth by Montrose with great slaughter. Kilsyth is further interesting as the centre of remarkable religious revivals in 1742–43 and 1839. The present village dates from the middle of the 17th century. It became a burgh of barony in 1826 by charter from George IV. The inhabitants are chiefly engaged in the neighbouring coal and iron works; but weaving and paper-making are also carried on. The population in 1881 was 5402.

KILWINNING, a market-town in Cunningham district, Ayrshire, Scotland, is situated on the right bank of the Garnock, 26 miles south-west of Glasgow by rail. The houses are neat, but somewhat straggling. The chief buildings are the parish church (with a handsome detached Gothic tower erected in 1815 in place of an older one, 103 feet high, which fell in 1814), the Free church, and the board school. The greatest interest of the place centres in its ruined abbey, originally one of the richest in Scotland. Founded about 1140 by Hugh de Morville, lord of Cunningham, it was dedicated to St Winning, who lived on the spot during the 8th century, and has given his name to the town. This beautiful specimen of Early English was destroyed in 1561; and its lands were granted to the earl of Eglinton and others. Kilwinning is the traditional birthplace of Scottish freemasonry; and Kilwinning lodge, said to have been founded by the foreign architects and masons who came to build the abbey, is still looked up to as the mother-lodge in Scotland. The royal company of archers of Kilwinning—dating, it is said, as far back as 1488—used till recently to meet annually to shoot at the papingo, or popinjay, in the manner described in Scott's *Old Mortality*; and in 1881 an attempt has been made to revive the custom. The former industry in weaving shawls and lighter fabrics has quite died out. The large iron, coal, and fire-clay works in the neighbourhood employ most of the working inhabitants. A woollen-mill, with sixty hands, but capable of employing three hundred, was opened in 1881. The population of the parish in 1881 was 7037; of the town, 3469. About a mile from Kilwinning is Eglinton Castle, the principal seat of the earl of Eglinton, where the famous Eglinton tournament was held in 1839.

KIMBERLEY, formerly called New Rush, one of the mining towns of the diamond district of South Africa, situated in Griqualand West, to the east of the Orange river, 520 miles north-east of Cape Town. Though it dates only from 1872, and has much of the temporary character to be expected from the conditions that gave it existence it bids fair to be a permanent settlement, having a number of buildings of stone and brick, a market-place, banks, churches, &c., and publishing a *Diamond News*. Although in 1874 the population left almost *en masse* for the gold-mines of Leydenberg (in Transvaal), the town was estimated in 1881 to have something like 10,000 inhabitants, besides a floating native population about equal in number. See Holub, *Seven Years in South Africa*, 1881.

KIMHI. ReDaK, *i.e.*, Rabbi David Ḳimḥi or Kimchi,[1] was born at Narbonne after 1155, and died probably in the same city about 1235. His father Rabbi Yoseph, or his grandfather Rabbi Isaac (Yiṣḥak) Ibn Ḳimḥi, had immigrated into Provence from Spain, where Arab fanaticism had compelled the Jews to flee from the sword of tyranny. In Provence the family took the Gentile surname of *Petit*.[2] Rabbi David lost his father (who was himself a grammarian, Bible commentator, and poet of no mean order) very early; but his elder and only brother, Rabbi Mosheh (a fair scholar, but famous chiefly through his younger brother), was his principal oral teacher. The valuable literary treasures of his father, however, falling into his hands, Redak grew strong by studying them, and, as we know, eclipsed them completely, although he lacked his father's originality. But, if Rabbi David lacked originality, he had abundance of instinct for finding out the best in the works of his predecessors, and abundance of genius for digesting and assimilating it till it became his own in a peculiar way. Although preceded by Ḥayyúj, Ibn Janáḥ, and others, and succeeded by Abraham de Balmes, Elias Levita, and others, Ḳimḥi has maintained the position of the greatest Jewish grammarian and lexicographer for six hundred and fifty years. And, although much inferior as a Biblical scholar and talmudist to Rashi, and as a critic and philosopher to Abraham Ibn Ezra, he has outstripped both in the eyes, not only of the Christians, but to some extent even of the Jews, and thus reigned supreme for more than half a millennium, as a commentator on the Bible. The fact is, he united in his own person the child-like simplicity of Rashi and the incisive criticism of Ibn Ezra. Add to this that he was master of the Targums and Aggadoth as few before or after him, that he had Hebrew, Arabic, and Greek philosophy at his fingers' ends, and that he was endowed with a truly poetical soul, and the mystery is explained how the merely reproductive scholar could cause original scholars of the highest eminence, but who were one-sided, to be all but forgotten. Not only have his works, in whatever field they are to be found, been printed and reprinted, but the most important of them are translated

[1] Not Kamchi. Compare קימחית in the Talmud Yerushalmi, *Horayoth*, iii. 2.

[2] From these circumstances Ḳimḥi is known as *Hassephardi* (the Spaniard), as *Ibn* Ḳimḥi, or as *Maistre Petit*. *Petit* is, to a certain extent, an equivalent of Ḳimḥi (from קֶמַח, grain ground small).

into Latin,[1] into Judæo-German,[2] and even into English.[3] The following is a list of Ḳimḥi's works, which, however, lays no claim to perfection:—

Grammar.—מכלול, part i.:—(1) Constantinople, 1532–34, folio; (2) Constantinople, 1532–34, 8vo; (3) with Latin translation by Agathius Guidacerius, Paris, 1540, 8vo; (4) with additamenta by Elias Levita, Venice, 1544, 8vo.[4] and again (5) 1545, folio; (6) with the same additions, Venice, 1545, 8vo; (7) with the same additions and commentary by Mosheh העכים (Hechingen?), Fürth, 1793, 8vo; (8) with additions from MSS. by Rittenberg, Lyck, 1862, 8vo. In addition to these have appeared *Compendia* from this grammar by Pagninus, Paris, 1549, 4to; and by Baynus, Paris, 1554, 4to.

Lexicon.—מכלול, part ii.:—(1) without place and date, but before 1480, folio; (2) with a Biblical index on the margin, Naples, 1490, folio; (3) with a Biblical index inserted, Naples, 1491, folio; (4) without pagination, Constantinople, 1513, folio; (5) Venice, 1529, folio; (6) with corrections from MSS., Salonika, 1532–33, folio; (7) Venice, 1546, folio; (8) with notes by Elias Levita, Venice, 1546–48, folio; (9) with Latin translation of the roots, Venice, 1546–48, folio; (10) the text revised from three MSS., Berlin, 1847, 4to.

Commentaries.—(1) *On the Greater Part of Genesis*,[5] Pressburg, 1842, 8vo. (2) *On the Prophets and the Psalms*, in the first Rabbinic Bible, Venice, 1517, folio. (3) *On the Prophets and the Chronicles*, in the third and all subsequent Rabbinic Bibles, Venice, 1548, 1568, 1617–19; Basel, 1618–19; Amsterdam, 1724; Warsaw, 1860–68; 1866–76. (4) *On the Former Prophets, Jeremiah and Ezekiel*, in the second Rabbinic Bible, Venice, 1524–25, folio. (5) *On the Former Prophets*, Soncino, 1485; Leiria, 1494; Pesaro, 1511; Salonika, 1535, all in folio. (6) *On the Latter Prophets*, Guadalaxara, 1482; Soncino, 1485–86; Pesaro, 1515, all in folio. (7) *On Isaiah and Jeremiah*, Lisbon, 1492, folio. (8) *On the Minor Prophets*, Paris, 1539–40, 4to. (9) *On Hosea, Joel, Amos, Obadiah, and Jonah*, Paris, 1556, 4to. (10) *On Hosea*, with the Latin translation of Mercier abridged by Coddæus, Leyden, 1621, 4to; with the sacred text, Helmstädt, 1702–3, 4to; by Hermann von der Hardt, Göttingen, 1775, 4to. (11) *On Joel and Malachi*, by Münster, Basel, 1570, 12mo. (12) *On Joel and Obadiah*, Utrecht, 1657, 8vo. (13) *On Amos*, with a letter by Elias Levita, Basel, 1531, 8vo. (14) *On Obadiah*, Bremen, 1673, 4to; Jena, 1678, 8vo. (15) *On Jonah*, Utrecht, 1656, 8vo; Leipsic, 1683, 8vo; Utrecht, 1692, 8vo; Frankfort-on-the-Main, 1697, 4to. (16) *On Haggai, Zechariah, and Malachi*, by Thomas Neale, Paris, 1557, 4to. (17) *On Malachi*, Basel, 1530, 8vo; Rostock, 1637, 4to; Leipsic, 1679, 8vo. Besides these editions it ought to be mentioned that the *Haphtaroth*, or "Prophetic Portions," read on sabbaths, festivals, &c., are to be found attached to the Pentateuch, Constance, 1505, folio; Venice, 1516, folio; Constance, 1522, folio; Cremona, 1566, folio; Venice, 1568, folio; Cracow, 1588, folio; Basel, 1618, folio; Berlin, 1705, folio; Wilmersdorf, 1713, folio; Amsterdam, 1726, folio; Frankfort-on-the-Main, 1730, folio; Metz, 1766, 4to. (18) *On the Psalms* without place (but, no doubt, Bologna), 1477, folio; in the *Hagiographa*, Naples, 1486–87, folio; in the first Rabbinic Bible, as above; Salonika, 1522, folio; Isny, 1541, folio; Cremona, 1561, 8vo; Venice, 1566, 8vo; Venice, 1596; Amsterdam, 1681, 4to; Zolkiew, 1696, 4to; Frankfort-on-the-Main, 1712, 8vo; Dyhernfurt, 1714, 4to; Amsterdam, 1765, 4to; Berlin, 1767, 4to; Amsterdam, 1777, 16mo; as part of prayer-book, Amsterdam, 1796, 18mo; Amsterdam, 1816, 8vo; a part of a Bible, Fürth, 1842–47, 8vo; Zitomir, 1867, 16mo. In addition to these there ought to be mentioned *The First Ten Psalms*, &c., Constance, 1544, folio, and *An Extract from Kimchi on the Psalms*, &c., Wilmersdorf, 1725, 4to.

Miscellaneous Works.—(1) *Et Sopher on the Massoreth and the Accents*, Lyck, 1864, 8vo. (2) *Antichristiana*:—(*a*) in the *Milchemeth Chobah*, Constantinople, 1710, 8vo; and (*b*) in the *Nitzzachon*, Nuremberg, 1644, 4to; Amsterdam, 1709, 16mo; Amsterdam, 1711, 16mo; Amsterdam, 1827, 16mo; Königsberg, 1848–50, 24mo. The "Antichristiana" contained in the *Nitzzachon* are the "Answers to the Christians," from the author's commentary on the *Psalms*, which are omitted in most of the editions. (3) *Religious Philosophy*.—The "explanation of the *Merkabah* (first chapter of Ezekiel) in a mystic way," is, although attached to the author's commentary on Ezekiel, a separate essay. In all the editions it is to be found after that commentary.

[1] As, *e.g.*, the commentary *On Isaiah*, by Malanimeus, Florence, 1774, 4to; *On Hosea*, by Mercier, Leyden, 1621, 4to; *On Joel*, by Leusden, Utrecht, 1657, 8vo; *On Obadiah*, by Crocius, Bremen, 1673, 4to; *On Obadiah*, by Bedwell, London, 1601, 4to; *On Jonah*, by Leusden, Utrecht, 1656, 8vo; *On Haggai, Zechariah, and Malachi*, by Neale, Paris, 1557, 4to; *On Malachi*, by Bohl, Rostock, 1637, 4to; *On the Psalms*, by Janvier, Paris, 1666, 4to; *On Psalms* i.–x., by Fagius, Constance, 1544, folio, and with Janvier's translation in Reland's *Analecta Rabbinica*, Utrecht, 1723, 8vo; *On Psalm* iv., by Bourdelot, Paris, 1619, 4to; and on *Psalm* xix., by Philipp. d'Aquino, 1629, 8vo.

[2] That, for instance, *On Isaiah*, Cracow, 1586, 4to.

[3] As that *On Zechariah*, by M'Caul, London, 1837, 8vo.

[4] Dr W. Aldis Wright, Fellow of Trinity College, Cambridge, possesses this edition, printed by Cornelio Adelkind at Bombergi's house, with the remarkable date on the title-page—אתק ומד לגאולתינו (*sic*), *i.e.*, 1544 of our redemption, showing that the editor was a baptized Jew. Of this edition no other copy is known to us.

[5] This was, no doubt, Ḳimḥi's last production.

KIMPULUNG, a town of Roumania, in that part of the country formerly known as Great Wallachia, is situated at the foot of the Transylvanian Alps on the banks of one of the left hand tributaries of the Danube, about 80 miles north-west of Bucharest. Its position near the Törzburg pass gives it a considerable share of the trade between Hungary and Roumania. Population about 9000.

KINCARDINE, or The Mearns, a maritime county in the east of Scotland, is situated between 56° 46′ and 57° 9′ N. lat., and between 2° 3′ and 2° 47′ W. long. It is bounded on the E. by the German Ocean, on the N.W. by Aberdeenshire, and on the S.W. by Forfarshire. Its length along the coast from the mouth of the North Esk to that of the Dee is 31 miles, and its breadth east to west from Dunnottar to Mount Battock 22 miles. The total area is 248,284 acres, or about 388 square miles.

Geology.—The Grampian range of mountains intersects the county from east to west, and occupies a breadth of about 8 miles in the western and north-western districts, terminating in the north-eastern corner in the promontory of Girdleness. To the north the county slopes into the picturesque and finely wooded valley of the Dee, and towards the south into the "How (or hollow) of the Mearns," a continuation of the valley of Strathmore, but it rises again into smaller eminences towards the coast. The highest summit of the Grampians in Kincardineshire is Mount Battock, 2465 feet, but a considerable number range from 1500 to a little above 2000 feet. The southern part of the coast from the North Esk is rocky but low, with considerable stretches of sand; from Bervie to Stonehaven it rises into an almost unbroken line of perpendicular cliffs ranging from 100 to 250 feet in height; from Stonehaven to the mouth of the Dee it is still more bold and rocky, but at the same time more frequently interrupted by creeks and bays, which form natural harbours for a number of fishing villages. The greater part of the county belongs to the Upper Silurian strata of the Highlands, consisting chiefly of gneiss, but towards the west there is a large eruption of granite, and the southern half of the county belongs to the upper strata of Old Red Sandstone. Conglomerate occurs on the coast, and porphyry, sandstone, and whinstone in the southern part of the county. Lime is found, but not in amount sufficient to meet agricultural wants, and large quantities are imported.

Rivers and Lakes.—The principal rivers are the Dee, which skirts the northern boundary of the county, and receives the Feugh at Banchory, where are the beautiful falls of Feugh; the North Esk, which after entering it from Forfarshire, receives the tributary of the Luther, and forms a portion of the south-western boundary of the shire; the Bervie, which rises in the Grampians, and after flowing south-eastwards for about 10 miles, falls into the sea at Bervie; and the Carron and Cowie, which flow the one eastward and the other south-eastward to the sea at Stonehaven. The principal lakes are the Loch of Drum, lately reduced from 300 to 100 acres, and Loirston Loch, 2? acres.

Climate, Soil, and Agriculture.—The climate is healthy, but, except on the north side of the Dee, often cold even on the low grounds, owing both to exposure to east winds, especially near the sea-coast, and to the proximity of bleak and chilly uplands. It has, however, been greatly improved by extensive drainage of the marshes. The mean annual is 45° Fahr., that of summer being 58°, and of winter

A great part of the mountainous district is unsuitable for either pasturage or tillage, and is occupied chiefly by deer forests and grouse moors; but the land in the valley of the Dee, in the "How," and along the coast is very productive, and is cultivated according to the most advanced methods. A considerable portion of the "How" is, however, on account of the difficulty of drainage, still occupied by moor and moss. The land in this district is richer and stronger than that in the valley of the Dee, but the most fertile region is that along the sea-coast, the soil consisting more generally of a deep loam resting on clay, although in some places it is poor and thin, or stiff and cold.

According to the agricultural returns for 1881, the total area under crops was 120,631 acres, a percentage of 48·6, that for 1870 being 47·1. The area under corn crops was 44,803; under green crops, 22,476; under rotation grasses, 46,645; under permanent pasture, 6552 acres. The area under woods was 27,850 acres, while 12 acres were under nursery grounds, and 23 under market gardens. About two-thirds of the area under corn crops is occupied by oats, which in 1881 covered 31,430 acres, while 12,120 acres were under barley, and 577 acres, chiefly in the neighbourhood of the sea-coast, were under wheat, the area of which has been rapidly declining, 55 under rye, 581 under beans, and 40 under pease. Of green crops about four-fifths of the area is under turnips and swedes, which in 1881 occupied 18,304 acres, 3696 being occupied by potatoes, 450 by vetches and similar crops, 17 by carrots, and 8 by cabbage. Flax occupied 1 acre, and there were 184 acres fallow. Great improvements have lately been effected in regard to farm buildings and drainage.

The total number of horses, many of which are well-bred Clydesdales, in 1881 was 4798. Of these, 3893 are stated to be used solely for agricultural purposes, and 905 to be kept solely for breeding purposes. Cattle in 1881 numbered 25,013, or an average of 21 to every 100 acres under cultivation, the average for Scotland being 23·9. Much attention is paid to the rearing of stock, and cattle feeding is carried on according to the most advanced methods. The most common breed is the shorthorn, which are bought in for feeding from Ireland, but a few Canadian cattle have also lately been bought. The more common home-bred stock is a cross between shorthorned and polled; but there are also many valuable herds of the pure polled breed. Sheep in 1881 numbered 24,966, an average of 20·7 to every 100 acres under cultivation, the average for Scotland being 141·3. Blackfaced sheep are of course those chiefly kept on the hill pastures, but on the lowland farms Cheviots or a cross with Leicesters are not uncommon. The number of pigs in 1881 was 1967.

The following table gives a classification of holdings according to size in 1875 and 1880, with the total area under each class of holding:—

	50 Acres and under.		From 50 to 100 Acres.		From 100 to 300 Acres.		From 300 to 500 Acres.		From 500 to 1000 Acres.		Above 1000 Acres.		Total.	
	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.
1875	1,200	15,604	301	22,583	362	60,730	41	15,254	10	6,281	...	...	1,914	120,452
1880	1,081	14,705	808	23,113	370	63,333	89	14,692	8	4,489	...	...	1,806	120,332

It will thus be seen that about three-fifths of the holdings are under 50 acres in extent, but that their number has within recent years been diminishing. According to the *Owners of Lands and Heritages Return*, 1872–73, the land was divided among 1384 proprietors, possessing 244,585 acres, with a gross annual value of £253,393. Of the owners, 1189 possessed less than 1 acre, and the average value per acre was £1, 0s. 6½d. Sir Thomas Gladstone owned 45,062 acres; Earl of Kintore, 17,370; James Young, 16,659; Viscount Arbuthnott, 13,560; Sir J. H. Burnett, 12,025; R. W. Duff, 8722; Mrs Badenoch Nicolson, 8481; W. N. Forbes, 6528. A comprehensive account of the agriculture of Kincardineshire, by James Macdonald, is contained in the *Transactions of the Highland and Agricultural Society* for 1881.

Manufactures.—Woollen manufactures are carried on at Stonehaven, and flax-spinning and weaving at Bervie, Laurencekirk, and a few other places. There are several breweries, tanneries, and distilleries. Fishing gives employment to a number of persons in the sea-coast villages. The rental of the salmon fishings on the coast is £7000, and of those on the rivers £1250 per annum. There is some shipping at Stonehaven.

Railways.—The Caledonian Railway traverses the county from Marykirk to the mouth of the Dee, and a branch line runs along the sea-coast as far north as Bervie.

Administration.—The county comprises eighteen parishes and three parts of parishes; one royal burgh, Bervie, which received its constitution from David II. in return for the hospitality of the inhabitants when he landed there through stress of weather; and one burgh of barony, Stonehaven, which, since 1600, has been the capital of the county, the former capital, Kincardine, in the parish of Fordoun, at which there was at one time a royal castle, having now declined to the position of a mere hamlet. The county is now joined to the sheriffdom of Aberdeen, weekly courts being held at Stonehaven. One member of parliament is returned for the county, and Bervie is united with the Montrose district of burghs, which returns one member.

Population.—The population between 1801 and 1851 increased from 26,349 to 34,598. In 1871 it was 34,466, and in 1881 it was 34,460, of whom 16,972 were males and 17,488 females. The population of Stonehaven in 1871 was 3396, and in 1881 it was 3948. Laurencekirk in 1881 had a population of 1454, Johnshaven 1039, and Bervie 1094.

History and Antiquities.—Anciently Kincardine belonged to the district of Pictavia. Cairns and stone circles are frequent in nearly every part of the shire, and there are numerous traces of Roman camps. According to some the county received the name Mearns from having been granted to Mernia, a Scottish king, brother of the Angus who received the neighbouring county of Forfar. The only old building of special interest is Dunnottar Castle near Stonehaven, the old seat of the Keiths, earl marischals of Scotland. The castle stands on a high projecting rock about 150 feet above the sea, by which it is nearly surrounded, and was formerly an extensive fortress of great strength. In the reign of James II. it was used as a prison for Nonconformists. Among the eminent persons connected with Kincardine may be mentioned John of Fordoun the historian, George Wishart, Robert Barclay the Quaker, Bishop Burnet, Dr John Arbuthnott, Dr James Beattie, Dr Thomas Reid, and Lord Monboddo.

See the *History and Traditions of the Lands of the Lindsays*, 1853; *History and Antiquities of the Mearns*, 1858; and *Memorials of Angus and the Mearns*, 1861,—all by A. Jervise.

KINDERGARTEN, a German word meaning "garden of children," is the name given by Friedrich Froebel (see FROEBEL) to a kind of "play-school" invented by him for furthering the physical, moral, and intellectual growth of children between the ages of three and seven. Froebel's observation of the development of organisms and his fondness for analogies drawn from trees and plants made him attach especial importance to our earliest years, years in which, as he said, lies the tap-root of much of the thought and feeling of after life. Although the analogies of nature had constantly been referred to before Froebel's days ("First the blade, then the ear, then the full corn in ear"), and Bacon, speaking of education, had said that the gardener bestows the greatest care on the young plants, the Renaissance left the imparting theory of education so firmly fixed on the mind of Europe that for two hundred years the developing theory could hardly get a hearing, and little was done to reduce it to practice before the attempt of Pestalozzi. Pestalozzi and other great thinkers (notably Comenius), who attached much importance to the first years of life, looked to the mother as the sole educator. But in the case of the poor the mother might not have time to attend to her children; so towards the end of the last century Pestalozzi planned and Oberlin formed day-asylums for young children, the benefit of which was intended no less for the mother than the child. Schools of this kind took in the Netherlands the name of "play school," and in England, where they have especially thriven, of "infant schools." But Froebel's idea of the "Kindergarten" differed essentially from that of the infant schools. He maintained that there was something to do for young children which even the ideal mother in the ideal family could not do. The child required to be prepared for society by being early associated with its equals; and young children thus brought together might have their employments, especially their chief employment, play, so organized for them as to draw out their capacities of feeling and thinking, and even of inventing and creating.

According to the development theory all education must be based on study of the nature to be developed. Froebel's study of the nature of children showed him that their great characteristic was restlessness. This was, first, restlessness of body, delight in mere motion of the limbs; and, secondly, restlessness of mind, a constant curiosity about whatever came within the range of the senses, and especially a desire to examine with the hand every unknown object within reach. Children's fondness for using their hands was specially noted by Froebel, and he found that they delighted, not merely in examining by touch, but also in altering whatever they could alter, and further that they endeavoured to imitate known forms whether by drawing or by modelling in putty or clay. Besides remarking in them these various activities, he saw that children were sociable and needed the sympathy of companions. There was, too, in them a growing moral nature, passions, affections, and conscience, which needed to be controlled, responded to, cultivated. Both the restraints and the opportunities incident to a well-organized community would be beneficial to their moral nature, and prove a cure for selfishness.

Froebel held that the essence of all education was to be found in rightly directed but spontaneous action. So the children must be employed; and at that age their most natural employment is play, especially, as Wordsworth has pointed out, games in which they imitate and "con the parts" they themselves will have to fill in after years. Froebel agreed with Montaigne that the games of children were "their most serious occupations," and with Locke that "all the plays and diversions of children should be directed towards good and useful habits, or else they will introduce ill ones" (*Thoughts concerning Education*, § 130). So he invented a course of occupations, most of which are social games. Many of the games are connected with the "gifts," as he called the series of simple playthings provided for the children, the first being the ball, "the type of unity." The "gifts" are chiefly not mere playthings but materials which the children work up in their own way, thus gaining scope for their power of doing and inventing and creating. The artistic faculty was much thought of by Froebel, and, as in the education of the ancients, the sense of rhythm in sound and motion was cultivated by music and poetry introduced in the games. Much care was to be given to the training of the senses, especially those of sight, sound, and touch. Intuition or first-hand experience (*Anschauung*) was to be recognized as the true basis of knowledge, and though stories were to be told, and there was to be much intercourse in the way of social chat, instruction of the imparting and "learning-up" kind was to be excluded. Froebel sought to teach the children not what to think but how to think, in this following in the steps of Pestalozzi, who had done for the child what Bacon nearly two hundred years before had done for the philosopher. Where possible the children were to be much in the open air, and were each to cultivate a little garden.

To judge by all appearances at the present date (1881), the kindergarten will be an important institution in the education of the future. The first kindergarten was opened at Blankenburg, near Rudolstadt, in 1840, but after a needy existence of eight years was closed for want of funds. In 1851 the Prussian Government declared that "schools founded on Froebel's principles or principles like them could not be allowed." But the idea had far too much vitality to be starved or frowned down. Although its progress has not been rapid, it has been constant. As early as 1854 it was introduced into England by the then famous Ronges, and Henry Barnard reported on it that is was "by far the most original, attractive, and philosophical form of infant development the world has yet seen" (*Report to Governor of Connecticut*, 1854). But the attempt failed, and though there are now a Froebel Society, an institution for training young women to conduct kindergartens, and also some good kindergartens, Froebel's idea has hardly yet found a home in Britain. The great propagandist of Froebelism, the Baroness Marenholtz-Bülow, drew the attention of the French to the kindergarten from the year 1855, and Michelet declared that Froebel had "solved the problem of human education." In the department of the Seine the "Salles d'asile" now consist of a class for children from two to four years old, and a "Froebel class" of children from four to six. In Italy the kindergarten has been introduced by Madame Salis-Schwabe, and is used in the education of the poor. In Austria it is recognized and regulated by the government, though the Volks-Kindergarten are not numerous. But by far the greatest developments of the kindergarten system are in the United States and in Belgium. Dr William T. Harris, assisted by Miss Blow, tried the experiment of making the kindergarten a part of the public education in St Louis eight years ago, and there are now no less than 8000 children, all over five years of age, in the St Louis public kindergartens. In Belgium the mistresses of the "Écoles gardiennes" have for some time been instructed in the "idea of the kindergarten" and "Froebel's method," and in 1880 the minister of public instruction, Van Humbeeck, issued a programme for the "Écoles Gardiennes Communales," which is both in fact and in profession a kindergarten manual. This programme attributes the improvement in infant schools to "le souffle puissant de Froebel"; and, after explaining that the method to be adopted is based on the laws which govern the development of the child, the minister continues: "In its great principles as well as in its main applications this method is that created by the genius of Froebel." This estimate of Froebel's principles contrasts strangely with the Prussian minister's thirty years earlier.

Literature.—Henry Barnard's volume, *Froebel's Kindergarten*, Hartford, U.S.A., 1881, contains a large collection of papers on the subject, original and translated; W. T. Harris's *Reports* give full accounts of the adaptation of the Kindergarten to public education at St Louis. Kindergartens in Germany are described in Joseph Payne's *Visit to German Schools*, 1876. Practical guides published in England are J. and B. Ronge's, 3d ed., 1855; E. Wiebe's *Paradise of Children*; and Miss Lyschinska's, 1880. Other literature is cited in Steiger's *Cyclopædia of Education*; and in L. Walter's *Die Fröbelliteratur*, 1881. (R. H. Q.)

KINEMATICS. See MECHANICS.

KING, WILLIAM (1650–1729), a political and religious writer, and successively bishop of Derry and archbishop of Dublin, was born at Antrim in 1650. He was educated at Trinity College, Dublin, and after being presented to the parish of St Werburgh, Dublin, in 1679, was elected dean of St Patrick's, Dublin, in 1688, bishop of Derry in 1691, and archbishop of Dublin in 1702. He died in 1729. King was the author of *The State of the Protestants in Ireland under King James's Government*, 1691, but is best known by his *De Origine Mali*, 1702 (English translation, 1731), an endeavour to reconcile the presence of evil with the existence and goodness of an Omnipotent Being, which was deemed worthy of a reply by Bayle and Leibnitz. He also published a sermon entitled *Divine Predestination and Foreknowledge consistent with the Freedom of Man's Will*, 1709, and various other small treatises.

KING-BIRD, the *Lanius tyrannus* of Linnæus, and the *Tyrannus carolinensis* or *T. pipiri* of most later writers, a common and characteristic inhabitant of North America, ranging as high as 57° N. lat. or further, and westward to the Rocky Mountains, beyond which it goes to Oregon, Washington Territory, and British Columbia, though apparently not occurring in California. In Canada and the northern States of the Union it is a summer visitor, wintering in the south, but also reaching Cuba; and, passing through Central America, it has been found in Bolivia and eastern Peru. Both the scientific and common names of this species are taken from the way in which the cock will at times assume despotic authority over other birds, attacking them furiously as they fly, and forcing them to divert or altogether desist from their course. Yet it is love of his mate or his young that prompts this bellicose behaviour, for it is only in the breeding season that he indulges in it; but then almost every large bird that approaches his nest, from an Eagle downwards, is assaulted, and those alone that possess greater command of flight can escape from his repeated charges, which are accompanied by loud and shrill cries. On these occasions it may be that the King-bird displays the emblem of his dignity, which is commonly concealed; for, being otherwise rather plainly coloured—dark ashy-grey above and white beneath—the erectile feathers of the crown of the head, on being parted, form as it were a deep furrow, and reveal their base, which is of a bright golden-orange in front, deepening into scarlet, and then passing into silvery-white. This species seems to live entirely on insects, which it captures on the wing, and is in bad repute with bee-masters,[1] though, according to Dr Coues, it "destroys a thousand noxious insects for every bee it eats." It builds, often in an exposed situation, a rather large nest, coarsely constructed outside, but neatly lined with fine roots or grasses, and lays five or six eggs of a pale salmon colour, beautifully marked with blotches and spots of purple, brown, and orange, generally disposed in a zone near the larger end.

King-Bird.

Nearly akin to the King-bird is the Petchary or Chicheree, so called from its loud and petulant cry, *T. dominicensis*, or *T. griseus*, one of the most characteristic and conspicuous birds of the West Indies, and the earliest to give notice of the break of day. In habits, except that it eats a good many berries, it is the very counterpart of its congener, and is possibly even more jealous of any intruder. At all events its pugnacity extends to animals from which it could not possibly receive any harm, and is hardly limited to any season of the year.

In several respects both of these birds, with several of their allies, resemble some of the Shrikes; but it must be clearly understood that the likeness is but of analogy, and that there is no near affinity between the two Families *Laniidæ* and *Tyrannidæ*, which belong to wholly distinct sections of the great Passerine Order; and, while the former is a comparatively homogeneous group, much diversity of form and habits is found among the latter. Similarly many of the smaller *Tyrannidæ* bear some analogy to certain *Muscicapidæ*, with which they were at one time confounded (see FLYCATCHER, vol. ix. p. 351); but the difference between them is deep seated.[2] Nor is this all, for out of the seventy genera, or thereabouts, into which the *Tyrannidæ* have been divided, comprehending perhaps three hundred and fifty species, all of which are peculiar to the New World, a series of forms can be selected which find a kind of parallel to a series of forms to be found in the other group of *Passeres*; and the genus *Tyrannus*, though that from which the Family is named, is by no means a fair representative of it; but it would be hard to say which genus should be so accounted. The birds of the genus *Muscisaxicola* have the habits and almost the appearance of Wheatears; the genus *Alectorurus* calls to mind a Water-Wagtail; *Euscarthmus* may suggest a Titmouse, *Elainea* perhaps a Willow-Wren; but the greatest number of forms have no analogous bird of the Old World with which they can be compared; and, while the combination of delicate beauty and peculiar external form possibly attains its utmost in the long-tailed *Milvulus*, the glory of the Family may be said to culminate in the king of King-birds, *Muscivora regia*. (A. N.)

KINGFISHER—*Königsfischer*, Germ.[3]; *Roi-pêheux* (=*pêcheur*), Walloon—the *Alcedo ispida* of ornithologists, one of the most beautiful and well-known of European birds, being found, though nowhere very abundantly, in every country of this quarter of the globe, as well as in North Africa and South-Western Asia as far as Sindh. Its blue-green back and rich chestnut breast render it conspicuous as it frequents the streams and ponds whence it procures its food, by plunging almost perpendicularly into the water, and emerging a moment after with the prey—whether a small fish, a crustacean, or an aquatic insect—it has captured. In hard frosts it resorts to the sea-shore, but a severe winter is sure to occasion a great mortality in the species, for many of its individuals seem unable to reach the tidal waters where only in such a season they could obtain sustenance; and to this cause rather than any other (though, on account of its beauty and the utility of its feathers in making artificial flies, it is shot and netted in great numbers) is perhaps to be ascribed its general scarcity. Very early in the year it prepares its nest, which is at the end of a tunnel bored by itself in a bank, and therein the six or eight white, glossy, translucent eggs are laid, sometimes on the bare soil, but often on the fish-bones which, being indigestible, are thrown up in pellets by the birds; and, in any case, before incubation is completed these *rejectamenta* accumulate so as to form a pretty cup-shaped structure that increases in bulk after the young are hatched, but, mixed with their fluid excretions and with decaying fishes brought for their support, soon becomes a dripping fetid mass.

The Kingfisher is the subject of a variety of legends and superstitions, both classical and mediæval. Of the latter one of the most curious is that having been originally a plain grey bird it acquired its present bright colours by flying towards the sun on its liberation from Noah's ark, when its upper surface assumed the hue of the sky above it and its lower plumage was scorched by the heat of the setting orb to the tint it now bears.[4] More than this, the Kingfisher was supposed to possess many virtues. Its dried body would avert thunderbolts, and if kept in a wardrobe would preserve from moths the woollen stuffs

[1] It is called in some parts the Bee-Martin.

[2] This is not the place to dwell upon the essential nature of the difference; but two easy modes of discriminating them externally may be mentioned. All the *Laniidæ* and *Muscicapidæ* have but *nine* primary guides in their wings, and their tarsi are covered with scales in front only; while in the *Tyrannidæ* there are *ten* primaries, and the tarsal scales extend the whole way round. The more recondite distinction in the structure of the trachea seems to have been first detected by Macgillivray, who wrote the anatomical descriptions published in 1839 by Audubon (*Orn. Biography*, v. pp. 421, 422); but its value was not appreciated till the publication of Johannes Müller's classical treatise on the vocal organs of Passerine Birds (*Abhandl. k. Akad. Wissensch. Berlin*, 1845, pp. 321, 405).

[3] But more commonly called *Eisvogel*, which finds its counterpart in the Anglo-Saxon *Isern* or *Isen*.

therein laid, or hung by a thread to the ceiling of a chamber would point with its bill to the quarter whence the wind blew. All readers of Ovid (*Metam.*, bk. xi.) know how the faithful but unfortunate Ceyx and Alcyone were changed into Kingfishers—birds which bred at the winter solstice, when through the influence of Æolus, the wind-god and father of the fond wife, all gales were hushed and the sea calmed so that their floating nest might ride uninjured over the waves during the seven proverbial "Halcyon Days"; while a variant or further development of the fable assigned to the Halcyon itself the power of quelling storms.[1]

The common Kingfisher of Europe is the representative of a well-marked Family of birds, the *Alcedinidæ* or *Halcyonidæ* of ornithologists, which is considered by some authorities[2] to be closely related to the *Bucerotidæ* (see HORNBILL, vol. xii. p. 169); but the affinity can scarcely be said as yet to be proved; and to the present writer there seems to be at least some ground for believing that a nearer alliance is to be found in the *Galbulidæ* (see JACAMAR, vol. xiii. p. 531), *Momotidæ* (MOTMOT, *q.v.*), *Meropidæ*, and perhaps some other Families—though all may possibly be discovered to belong to one and the same larger group. Be that as it may, the present Family forms the subject of a work by Mr Sharpe,[3] which, though still incomplete as regards their anatomy,[4] is certainly one of the best of its class, and reflects infinite credit on its then youthful author, whose treatment of his subject was most successful. Herein are described one hundred and twenty-five species, nearly all of them being beautifully figured by Mr Keulemans, and that number may be taken even now as approximately correct; for, while the validity of a few has been denied by some eminent men, nearly as many have since been made known, and it seems likely that two or three more described by older writers may yet be rediscovered. These one hundred and twenty-five species Mr Sharpe groups in nineteen genera, and divides into two Sub-families, *Alcedininæ* and *Daceloninæ*,[5] the one containing five and the other fourteen genera. With existing materials perhaps no better arrangement could have been made, but in the absence of anatomical knowledge it is certainly not to be deemed conclusive, and indeed the method since published by Sundevall (*Tentamen*, pp. 95, 96) differs from it not inconsiderably. Here, however, it will be convenient to follow that of Mr Sharpe. Externally, which is almost all we can at present say, Kingfishers present a great uniformity of structure. One of their most remarkable features is the feebleness of their feet, and the union (syndactylism) of the third and fourth digits for the greater part of their length; while, as if still further to show the comparatively functionless character of these members, in two of the genera, *Alcyone* and *Ceyx*, the second digit is aborted, and the birds have but three toes. In most forms the bill does not differ much from that of the common *Alcedo ispida*, but in *Syma* its edges are serrated, while in *Carcineutes*, *Dacelo*, and *Melidora* the maxilla is prolonged, becoming in the last a very pronounced hook. Generally the wings are short and rounded, and the tail is in many forms inconspicuous; but in *Tanysiptera*, one of the most beautiful groups, the middle pair of feathers is greatly elongated and spatulate, while this genus possesses only ten rectrices, all the rest having twelve. Sundevall relies on a character not noticed by Mr Sharpe, and makes his principal divisions depend on the size of the scapulars, which in one form a mantle, and in the other are so small as not to cover the back. The *Alcedinidæ* are a cosmopolitan Family, but only one genus, *Ceryle*, is found in America, and that extends as well over a great part of the Old World, though not into the Australian Region, which affords by far the greater number both of genera and species, having no fewer than ten of the former and fifty-nine of the latter peculiar to it.[6]

In habits Kingfishers display considerable diversity, though all, it would seem, have it in common to sit at times motionless on the watch for their prey, and on its appearance to dart upon it, seize it as they fly or dive, and return to a perch where it may be conveniently swallowed. But some species, and especially that which is the type of the Family, are not always content to await at rest their victim's showing itself. They will hover like a Hawk over the waters that conceal it, and, in the manner already described, precipitate themselves upon it. This is particularly the way with those that are fishers in fact as well as in name; but no inconsiderable number live almost entirely in forests, feeding on insects, while reptiles furnish the chief sustenance of others. The last is characteristic of at least one Australian form, which manages to thrive in the driest districts of that country, where not a drop of water is to be found for miles, and the air is at times heated to a degree that is insupportable by most animals. The limits of this article forbid an entrance upon details of much interest, but the Belted Kingfisher of North America, *Ceryle alcyon*, is too characteristic a bird of that country to be passed in silence, though its habits greatly resemble those of the European species before described; and the so-called "Laughing Jackass" of New South Wales and South Australia, *Dacelo gigas*—with its kindred forms, *D. leachi*, *D. cervina*, and *D. occidentalis*, from other parts of the country—likewise requires special notice. Attention must also be called to the speculations of Mr Sharpe (*op. cit.*, pp. xliv.-xlvii.) on the genetic affinity of the various forms of *Alcedinidæ*, and it is to be regretted that hitherto no light has been shed by palæontologists on this interesting subject, for the only fossil referred to the neighbourhood of the Family is the *Halcyornis toliapicus* of Professor Owen (*Br. Foss. Mamm. and Birds*, p. 554) from the Eocene of Sheppey—the very specimen said to have been previously placed by König (*Icon. foss. sectiles*, fig. 153) in the genus *Larus*. (A. N.)

KINGLET, a name applied in many books to the bird called by Linnæus *Motacilla regulus*, and by most modern ornithologists *Regulus cristatus*, the Golden-crested or Golden-crowned Wren of ordinary persons. This species is the type of a small group which has been generally placed among the *Sylviidæ* or true Warblers, but by certain systematists it is referred to the Titmouse-Family, *Paridæ*. That the Kinglets possess many of the habits and actions of the latter is undeniable, but on the other hand they are not known to differ in any important points of organization or appearance from the former—the chief distinction being that the nostril is covered by a single bristly feather directed forwards. The Golden-crested Wren is the smallest of British birds, its whole length being about 3 inches and a half, and its wing measuring only 2 inches from the carpal joint. Generally of an olive-green colour, the top of its head is bright yellow, deepening into orange, and bounded on either side by a black line, while the wing

[1] In many of the islands of the Pacific Ocean the prevalent Kingfisher is the object of much veneration.

[3] *A Monograph of the* Alcedinidæ *or Family of the Kingfishers*, by R. B. Sharpe, 4to, London, 1868–71.

[4] Some important anatomical points are briefly noticed by Professor Cunningham (*Proc. Zool. Soc.*, 1870, p. 280).

[5] The name of this latter Sub-family as constituted by Mr Sharpe would seem to be more correctly *Ceycinæ*—the genus *Ceyx*, founded in 1801 by Lacépède, being the oldest included in it. The word *Dacelo*, invented by Leach in 1815, is simply an anagram of *Alcedo*, and, though of course without any etymological meaning, has been very generally adopted.

[6] *Cf.* Wallace, *Geog. Distr. Animals*, ii. p. 315.

coverts are dull black, and some of them tipped with white, forming a somewhat conspicuous bar. The cock has a pleasant but weak song. The nest is a beautiful object, thickly felted of the softest moss, wool, and spiders' webs, lined with feathers, and usually built under and near the end of the branch of a yew, fir, or cedar, supported by the interweaving of two or three laterally diverging and pendent twigs, and sheltered by the rest. The eggs are from six to ten in number, of a dull white sometimes finely freckled with reddish-brown. The species is particularly social, living for the most of the year in family-parties, and often joining bands of any species of Titmouse in a common search for food. Though to be met with in Britain at all seasons, the bird in autumn visits the east coast in enormous flocks, apparently emigrants from Scandinavia, while hundreds perish in crossing the North Sea, where they are well known to the fishermen as "Woodcock's Pilots." A second and more local European species is the Fire-crested Wren, *R. ignicapillus*, easily recognizable by the black streak on each side of the head, before and behind the eye, as well as by the deeper colour of its crown. A third species, *R. maderensis*, inhabits the Madeiras, to which it is peculiar; and examples from the Himalayas and Japan have been differentiated as *R. himalayensis* and *R. japonicus*. North America has two well-known species, *R. satrapa*, very like the European *R. ignicapillus*, and the Ruby-crowned Wren, *R. calendula*, which is remarkable for a loud song that has been compared to that of a Canary-bird or a Sky-lark, and for having the characteristic nasal feather in a rudimentary or aborted condition. Under the name of *R. modestus*, or "Dalmatian Regulus" of many English authors, two very distinct species are now known to have been confounded, both belonging really to the group of Willow-Wrens, and having nothing to do with *Regulus*. One, which has occurred in Britain, is the *Motacilla superciliosa* of old or *Phylloscopus superciliosus* of modern authors, and is a native of northern Asia, visiting Europe nearly every year, and the other, also of Asiatic origin, is the *Motacilla* or *Phylloscopus proregulus*. (A. N.)

KINGS, The First and Second Books of, which form the last part of the series of Old Testament histories known as the Earlier Prophets, were originally reckoned as a single book (Josephus; Orig. *ap.* Eus., *H. E.*, vi. 25; Peshito; Talmud), though modern Hebrew Bibles follow the bipartition which we have derived from the Septuagint. In that version they are called the third and fourth books of kingdoms (βασιλειῶν), the first and second being our books of Samuel. The division into two books is not felicitous, and even the old Hebrew separation between Kings and Samuel must not be taken to mean that the history from the birth of Samuel to the exile was treated by two distinct authors in independent volumes. We cannot speak of the author of Kings or Samuel, but only of an editor or successive editors whose main work was to arrange in a continuous form extracts or abstracts from earlier books. The introduction of a chronological scheme and of a series of editorial comments and additions, chiefly designed to enforce the religious meaning of the history, gives a kind of unity to the book of Kings as we now read it; but beneath this we can still distinguish a variety of documents, which, though sometimes mutilated in the process of piecing them together, retain sufficient individuality of style and colour to prove their original independence. Of these documents one of the best defined is the vivid and exact picture of David's court at Jerusalem (2 Sam. ix.–xx.), of which the first two chapters of 1 Kings are manifestly an integral part.[1] As it would be unreasonable to suppose that the editor of the history of David closed his work abruptly before the death of the king, breaking off in the middle of a valuable memoir which lay before him, this observation leads us to conclude that the books of Samuel and Kings are not independent histories. They have at least one source in common, and a single editorial hand was at work on both. But the division which makes the commencement of Solomon's reign the beginning of a new book is certainly ancient; it must be older than the insertion of the appendix 2 Sam. xxi.–xxiv., which now breaks the continuity of the original history of David's court. From an historical point of view the division is very convenient. The subject of the book of Samuel is the creation of a united Israel by Samuel, Saul, and David. Under Solomon the creative impulse has already died away; the kingship is divorced from the sympathies of the nation; and the way is prepared for the formation of the two kingdoms of Ephraim and Judah, the fortunes of which up to their extinction by the great empires of the East form the main subject of the book of Kings. It is probable, however, that the editor who made the division had another reason for disconnecting Solomon from David and treating his reign as a new departure. The most notable feature in the extant redaction of the book is the strong interest shown in the Deuteronomic "Law of Moses," and especially in the centralization of worship in the temple on Zion as prescribed in Deuteronomy and enforced by Josiah. This interest did not exist in ancient Israel, and is quite foreign to the older memoirs incorporated in the book; amidst the great variety in style and manner which marks the several parts of the history it is always expressed in the same stereotyped phrases and unvarying style; in brief, it belongs to the editorial comments, not to the original sources of the history. To the Deuteronomistic editor, then, the foundation of the temple, which is treated as the central event of Solomon's reign, is a religious epoch of prime importance (see especially his remarks in 1 Kings iii. 2 *sq.*), and on this ground alone he would naturally make Solomon's reign commence a new book—the history of Israel under the one true sanctuary.[2]

When we say in general that the book of Kings was thrown into its present form by a Deuteronomistic redactor we do not affirm that he was the first who digested the sources of the history into a continuous work. Indeed the selection of materials, especially in the earlier parts of the narrative, has been thought to point to an opposite conclusion. Nor, on the other hand, must we ascribe absolute finality to his work. He gave the book a definite shape and character, but the recognized methods of Hebrew literature left it open to additions and modifications by later hands. Even the redaction in the spirit of Deuteronomy seems itself to have had more than one stage, as Ewald and other critics recognize. The book was not closed till far on in the exile, after the death of Nebuchadnezzar and Jehoiachin (2 Kings xxv. 27 *seq.*); and the fall of the kingdom of Judah is presupposed in such passages as 2 Kings xvii. 19, 20, xxiii. 26, 27. But these passages are mere interjected remarks, which seem to be added to adapt the context to the situation of the Jews in captivity. The main redaction, though subsequent to the reformation of Josiah, which forms the standard with which all previous kings are compared ("the high places were not removed"), does not point to the time of the captivity. Thus, for example, the words "unto this day," 2 Kings viii. 22, xiv. 7, xvi. 6, are part of the "epitome" composed by the main redactor (see below), and imply that he wrote before the destruction of the Judæan state.

[1] See this proved in detail, Wellhausen-Bleek, *Einl.*, § 114. The verses 1 Kings ii. 1–12 have no connexion with the rest of the chapter, and are due to a later hand.

[2] With this it agrees that the later appendix 2 Sam. xxi.–xxiv. does not seem to have passed under the hand of the Deuteronomic redaction. See Wellhausen-Bleek, § 134.

Even the second redaction did not absolutely fix a single authoritative recension of the book, as appears in detail by comparison of the LXX. version with the Hebrew text.

The LXX. of Kings is not a corrupt reproduction of the Hebrew *receptus*, but represents another recension of the text. Neither recension can claim absolute superiority. The defects of the LXX. lie on the surface, and are greatly aggravated by the condition of the Greek text, which has suffered much in transmission, and particularly has in many places been corrected after the later Greek versions that express the Hebrew *receptus* of the 2d century of our era. Yet the LXX. not only preserves many good readings in detail, but throws much light on the long-continued process of redaction at the hand of successive editors or copyists of which the extant Hebrew of Kings is the outcome. Even the false readings of the Greek are instructive, for both recensions were exposed to corrupting influences of precisely the same kind. The following examples will serve to illustrate the treatment through which the book has passed.

1. Minor detached notices such as we should put in footnotes or appendices are inserted so as to disturb the natural context. Thus 1 Kings iv. 27 (Heb., v. 7) must be taken continuously with iv. 19, and so the LXX. actually reads. In like manner the LXX. omits 1 Kings vi. 11–14, which breaks the context of the description of the temple. Again, in the LXX., 1 Kings ix. 26 follows on ver. 14, so that Solomon's dealings with Hiram are continuously recorded. The notices intervening in vers. 15–25 (in a very unnatural order) belong to a class of floating notes about Solomon and his kingdom which seem to have got stranded almost by chance at different points in the two recensions.

2. There are direct or indirect indications of transpositions and insertions on a larger scale. Thus in the LXX. the history of Naboth (1 Kings xxi.) precedes chap. xx. And in fact chaps. xx. and xxii. are parts of one narrative, obviously quite distinct from the history of Elijah. Again the story of Abijah's sickness and Ahijah's prophecy (1 Kings xiv.) is not found in the LXX.,[1] but another version of the same narrative appears at xii. 24, in which there is no reference to a previous promise to Jeroboam through Ahijah, but the prophet is introduced as a new character. This version, which places the prophecy of the destruction of Jeroboam's house between his return from Egypt and his elevation to the throne, is no doubt a mere legend, but it goes to prove that there was once a version of the history of Jeroboam in which chap. xi. 29–39 had no place. In truth, after xi. 26–28 there must once have stood some account of a rebellion in which Jeroboam "lifted up his hand" against King Solomon. To such an account, not to the incident of Ahijah and the cloak related in vers. 29–39, ver. 40 is the natural sequel. Thus all that is related of Ahijah falls under suspicion of being foreign to the original history, and it is noteworthy that in a passage peculiar to the LXX. the incident of the tearing of the cloak is related of Shemaiah and placed at the convention at Shechem, showing how much fluctuation there was in the tradition.

These instances show that there was a certain want of definiteness about the redaction. The mass of disjointed materials, not always free from inconsistencies, which lay before the editor in separate documents or in excerpts already partially arranged by an earlier hand, could not have been reduced to real unity without critical sifting, and an entire recasting of the narrative in a way foreign to the ideas and literary habits of the Hebrews. The unity which the editor aimed at was limited to chronological continuity in the events recorded and a certain uniformity in the treatment of the religious meaning of the narrative. Even this could not be perfectly attained under the circumstances, and the links of the history were not firmly enough rivetted to prevent disarrangement or rearrangement of details by later scribes.

3. The continued efforts of successive redactors can be traced in the chronology of the book. The chronological method of the narrative appears most clearly in the history after Solomon, where the events of each king's reign are thrown into a kind of stereotyped framework on this type:—"In the twentieth year of Jeroboam, king of Israel, Asa began to reign over Judah, and reigned in Jerusalem forty-one years." . . . "In the third year of Asa, king of Judah, Baahsa began to reign over Israel in Tirzah twenty-four years." The history moves between Judah and Israel according to the date of each accession; as soon as a new king has been introduced everything that happened in his reign is discussed, and wound up by another stereotyped formula as to the death and burial of the sovereign; and to this mechanical arrangement the natural connexion of events is often sacrificed. In this scheme the elaborate synchronisms between contemporary monarchs of the north and south give an aspect of great precision to the chronology. But in reality the data for Judah and Israel do not agree, and Wellhausen, following Ewald, has shown that the synchronisms were not in the sources, but were calculated from the list of the years of each king (*Jahrb. f. D. Theol.*, 1875). It appears further that these latter data are not all derived from historical tradition, but are in part due to conjectural subdivision of the cycle 480 (twelve generations of forty years) which appears in 1 Kings vi. 1 as the period from the Exodus to the foundation of the temple, and according to the Judæan list of kings as the period from the foundation of the temple to the end of the captivity (536 B.C.).[2] In the early part of the Judæan history the first dates not accessions are connected with the temple, and apparently derived from temple records. Of these the most important is the twenty-third year of Joash, which the chronological scheme makes the one hundred and sixty-first year of the temple, trisecting the four hundred and eighty years cycle. Other one hundred and sixty years bring us to the death of Hezekiah, and the last third of the cycle begins with the accession of Manasseh, whose sins are treated as the decisive cause of the exile. Within these limits a few dates were given by the sources; the rest, as can easily be shown, were filled in with reference to a unit of forty years.[3] Again the duration of the kingdom of Israel, according to the northern lists, was two hundred and forty completed years, viz., eighty years before the first expedition of Benhadad, eighty years of Syrian wars, forty of prosperity under the victorious Jeroboam II., whose first year belongs to the period of war, and forty years of decline. The trisections in each case and the round numbers of 480 and 240 point strongly to a systematization of the chronology on the basis of a small number of given dates, and the proof that it is so is completed when we learn from the exactly kept lists of Assyrian chronology that the siege of Samaria fell in 722, whereas the system dates the captivity from 737 (535 + 480 − 37 − 241).

The key to the chronology is 1 Kings vi. 1, which, as Wellhausen has shown, was not found in the original LXX., and contains internal evidence of post-Babylonian date. In fact the system as a whole is necessarily later than 535 B.C., the fixed point from which it counts back.

4. Another aspect in the redaction may be called theological. Its characteristic is the application to the old history of a standard belonging to later developments of the Old Testament religion. Thus, as we have already seen, the redactor in 1 Kings iii. regards worship in high places as sinful after the building of the temple, though he knows that the best kings before Hezekiah made no attempt to suppress these shrines. So too his unfavourable judgment on the whole religion of the northern kingdom was manifestly not shared by Elijah and Elisha, nor by the original narrator of the history of these prophets. This feature in the redaction displays itself, not only in occasional comments or homiletical excursuses, but in that part of the narrative in which all ancient historians allowed themselves free scope for the development of their reflexions—the speeches placed in the mouths of actors in the history. Here also there is textual evidence that the theological element is somewhat loosely attached to the earlier narrative, and underwent successive additions. We have seen that the LXX. omits 1 Kings vi. 11–14, and that both prophecies of Ahijah belong to the least certain part of the textual tradition. So too an indication that the long prayer of Solomon, 1 Kings viii. 14–53, the Deuteronomic colour of which is recognized by all critics, did not stand in the oldest account of the dedication of the temple is preserved in the fact that the ancient fragment, vers. 12, 13, which in the Hebrew text is imperfect, appears in the LXX. after ver. 53 in completer form and with a reference to the book of Jashar as source (βιβλίον τῆς ᾠδῆς = ספר השיר = ספר הישר). The redactional insertion displaced it in one recension and led to its mutilation in the other. The older parts of this chapter have also been retouched in conformity with later (even post-exile) ritual and law. The Levites who appear at ver. 4 in contrast to the priests, in a way unknown to the pre-exile history, are not named in the LXX., and the post-exile "congregation" (ʿēdah) at ver. 5 is also wanting. The processes illustrated by these examples were doubtless at work in many places where external evidence fails us, and may often be detected by a careful use of internal evidence alone. See especially Wellhausen's detailed analysis in the last edition of Bleek's *Einleitung*.

To gain an exacter idea of the main redaction of Kings and of the nature of the original sources, we may divide the history into three sections:—(1) the conclusion of the "court history," 1 Kings i. ii., the further consideration of which belongs to the criticism of SAMUEL (*q.v.*); (2) Solomon, 1 Kings iii.–xi.; (3) the kingdoms of Ephraim and Judah. For (2) the main source, as we learn from 1 Kings xi. 41, was a book called *Acts of Solomon*. This work can hardly have been a regular chronicle, for the history founded on it contains no continuous narrative. All that is related of Solomon's reign is grouped round the description of the

[1] In the Alex. and other MSS. it is added from the version of Aquila.

[2] Compare Krey's investigations in *Z. f. w. Th.*, 1877, p. 404 *sq.*

[3] See the details in an article by W. R. Smith. *Journal of Philology*, vol. x. No. 20.

royal buildings, particularly of the temple, and the account of the dedication of the house (chaps. vi.-ix. 9); and the greater part of the latter account is either due to the redactor or largely rewritten. The whole section is descriptive rather than narrative, and the accurate details might have been got by actual observation of the temple at a date long subsequent to Solomon. In fact, they are not all due to a single hand. Thus we can still reconstruct a shorter text of vi. 17–21, which says only that "the house before the oracle was forty cubits long, and the oracle in the midst of the house within where the ark of Jehovah's covenant was to be placed was twenty cubits in length, breadth, and height; and he overlaid it with gold and made an altar of cedar [the table of shewbread] before the oracle and overlaid it with gold." The original author used the book of Jashar for the account of the dedication, and had access to some exact particulars as to dates, the artist Hiram, &c., which may have been contained in the temple records. The immediate environment of this section, if we set aside the floating elements in chap. ix. already referred to, is occupied with Solomon's dealings with King Hiram, who aided him in his architectural schemes and in the commercial enterprises which procured the funds for such costly works (chap. v. [Heb., v. 15–32] and ch. ix. 10 *sq.*). On each side of this context lies a complex of various narratives and notices illustrating Solomon's wisdom and greatness, but also, in chap. xi., his weakness and the incipient decay of his kingdom. It is evident that the rise of the adversaries who, according to xi. 25, troubled Solomon through all his reign cannot originally have been related as the punishment of the sins of his old age. The pragmatism as usual belongs to the redactor (xi. 4). We have seen that there was once another version of the history of Jeroboam.

In the history of the divided kingdom the redactor, as we have seen, follows a fixed scheme determined by the order of accessions, and gives a short epitome of the chief facts about each king, with an estimate of his religious character, which for the schismatic north is always unfavourable. The epitome, as the religious standpoint shows, belongs to the same hand throughout, *i.e.*, to the Deuteronomistic redactor; but so much of it as relates to Judah is plainly based on good written sources, which from the nature of the particulars recorded may be identified with the book of Royal Chronicles referred to under each reign, which seems to have been a digest of official notices.

A similar chronicle is named for the kings of Israel, but if it actually lay before the editor he at least did not make such excerpts from it as we find in the Judæan history, for the epitome for Ephraim is very bare of concrete details. Besides the epitome, however, and the short excerpts from the Judæan chronicles which go with it, the history includes a variety of longer narratives, which alike in their subject-matter and their treatment are plainly distinct from the somewhat dry bones of the official records. The northern narratives are all distinguished in a greater or less degree by the prominence assigned to prophets. In the southern kingdom we hear less of the prophets, with the great exception of Isaiah; but the temple occupies a very prominent place.

The history of the man of God from Judah (1 Kings xiii.) is indubitably of Judæan origin. Its attitude to the altar at Bethel—the golden calf does not appear as the ground of offence—is not only diverse from that of Elijah and Elisha, but even from that of Hosea.[1] The other narratives that deal with the history of Ephraim are all by northern authors (see, for example, 1 Kings xix. 3; 2 Kings ix. 6), and have their centre in the events of the Syrian wars and the persons of Elijah and Elisha. But they are not all of one origin, as appears most clearly by comparing the account of the death of Naboth in the history of Elijah, 1 Kings xxi., and the history of Elisha and Jehu, 2 Kings ix. In the latter narrative Naboth's "field" lies a little way from Jezreel, in the former it is close to Ahab's palace (*query*, in Samaria?—see ver. 18 and variants of LXX. in ver. 1), and is described as a vineyard. The "burden" quoted by Jehu is not in the words of 1 Kings xxi., and mentions the additional fact that Naboth's sons were killed.[2] In other words, the history of Jehu presupposes events recorded in the extant accounts of Elijah, but not these accounts themselves. And the narrative in 2 Kings seems to be the more accurate; it contains precise details lacking in the other.

Now it is plain that 1 Kings xxi. belongs to the same history of Elijah with chaps. xvii.–xix. The figure of the prophet is displayed in the same weird grandeur, and his words (omitting the addition already noted in verses 20b *sq.*) have the same original and impressive force. That history, a work of the highest literary art, has come down to us as a fragment. For in 1 Kings xix. 15 Elijah is commanded to take the desert route to Damascus, *i.e.*, the route east of the Jordan. He could not, therefore, reach Abel Meholah in the Jordan valley, near Bethshean, when he "departed thence" (ver. 19), if "thence" means from Horeb. The journey to Damascus, the anointing of Hazael and Jehu, must once have intervened; but they have been omitted because another account ascribed these acts to Elisha (2 Kings viii. ix.). Now there is no question that we possess an accurate historical account of the anointing of Jehu. Elisha, long in opposition to the reigning dynasty (2 Kings iii.), and always keeping alive the remembrance of the murder of Naboth and his sons (vi. 32), waited his moment to effect a revolution. It is true that the prime impulse in this revolution came from Elijah; but, when the history in 1 Kings represents Elijah as personally commissioned to inaugurate it by anointing Jehu and Hazael as well as Elisha, we see that the author's design is to gather up the whole contest between Jehovah and Baal in an ideal picture of Elijah and his work. In doing this he also places Ahab in a different light from that in which he appears in the other extant histories. Had we only his account we might suppose that Ahab had altogether rejected Jehovah and aimed at introducing a new national worship. But, in fact, we learn from the other records that, while like Solomon before him he gave countenance to his wife's religion, Ahab still regarded Jehovah as the God of Israel, consulted His prophets, and gave to his sons names expressive of devotion to the old faith. The ideal delineation of Elijah conveys a vivid picture of his imposing personality and permanent influence; but it records the impression he left behind him rather than the literal details of his life, and is no doubt of younger date than the more photographic picture of the accession of Jehu, though prior to the rise of the new prophecy under Amos and Hosea.[3]

[1] The expression "cities of Samaria" (ver. 32) reappears only after the deportation of Ephraim (2 Kings xvii. 24, 26), and seems to have come in here from 2 Kings xxiii. 19. Even in that passage the last clause of ver. 18, which alone refers to details of the history of 1 Kings xiii., is clearly erroneous; the old prophet did not come from Samaria. Another and later Jewish prophet foretold the fall of the altar of Bethel, viz., Amos of Tekoa.

[2] The standing phrases common to 1 Kings xxi. 20b *sq.*, 2 Kings ix. 7–10a, belong to the redaction, as is plain in the latter case from ix. 3.

[3] Some expressions that point to a later date are certainly added by another hand, *e.g.*, the last part of xviii. 18. In old Israel, up to the time of Hosea, the Baalim (pl.) are the golden calves, which have no place in this context. A late insertion also is the definition of time by the stated oblation in the temple at Jerusalem, xviii. 29, 36. At ver. 36 this is lacking in the LXX.; at ver. 29 the longer insertion of the LXX. reveals the motive for the interpolation, viz., to assimilate Elijah's sacrifice to the legal service. The true text says that, when noon was

The episode of Elijah and Ahaziah, 2 Kings i., is certainly by a different hand, as is seen even from the new feature of revelation through an angel; and the ascension of Elijah, 2 Kings ii., is related as the introduction to the prophetic work of Elisha.

The narratives about Elisha are not all by one hand; for example, iv. 1–7 is separated from the immediately subsequent history by a sharply marked grammatical peculiarity (the suffix כי); moreover, the order is not chronological, for vi. 24 cannot be the sequel to vi. 23; and in general those narratives in which the prophet appears as on friendly terms with the king, and possessed of influence at court (*e.g.*, iv. 13, vi. 9, vi. 21 compared with xiii. 14), plainly belong to the time of Jehu's dynasty, though they are related before the fall of the house of Omri. In this disorder we can distinguish portions of an historical narrative which speaks of Elisha in connexion with events of public interest, without making him the central figure, and a series of anecdotes of properly biographical character. The historical narrative embraced 2 Kings iii., vi. 24–vii. 20, ix. 1–x. 28, in fact, the whole account of the reign of Joram and the revolution under Jehu; and, as 2 Kings iii. has much affinity to the history of Ahab and Jehoshaphat in 1 Kings xxii., we may add the earlier history of the Syrian wars (1 Kings xx., xxii.) to the series. The evidence of style is hardly sufficient to assign all these chapters to a single hand (for example, רכב is a single chariot in the history of Jehu, but in 1 Kings xx. a collective, the single chariot being מרכבה); but they are all full of fresh detail and vivid description, and their sympathy with the prophets of the opposition, Micaiah and Elisha, and with the king of Judah, who takes the prophets' part, does not exclude a genuine interest in Ahab and Joram, who are painted in very human colours, and excite our pity and respect. To the historian these chapters are the most valuable part of the northern history; and the most surprising details have received striking verification from modern research. The stone of Mesha supplies details to 2 Kings iii. 5; the method of obtaining water suggested by Elisha (iii. 16, 17) is that which still gives its name to W. el-Hasá at the southern end of the Dead Sea (see Wetzstein in Delitzsch, *Gen.*, 4th ed., p. 567); and the sudden retreat of the Syrians in 2 Kings x. is very intelligible when we know that they were already at that time pressed by the Assyrians (see on all these points Wellhausen, *op. cit.*).

In the more biographical narratives about Elisha we may distinguish one circle connected with Gilgal, Jericho, and the Jordan valley to which Abel-meholah belongs (iv. 1–7?, 38–44; ch. v.?; vi. 1–7). Here Elisha appears as the head of the prophetic guilds, having his fixed residence at Gilgal. Another circle, which presupposes the accession of the house of Jehu, places him at Dothan or Carmel, and represents him as a personage of almost superhuman dignity. Here there is an obvious parallelism with the history of Elijah, especially with his ascension (compare 2 Kings vi. 17 with ii. 11; xiii. 14 with ii. 12); and it is to this group of narratives that the ascension of Elijah forms the introduction.[1]

Of the Judæan narratives there is none to rival the northern histories in picturesque and popular power. The history of Joash, 2 Kings xi., xii., of Ahaz's innovations, xvi. 10 *sq.*, and of Josiah's reformation, xxii. 3–xxiii. 27, have their common centre in the temple on Zion, and may with great probability be referred to a single source. The details suggest that this source was based on official documents. Besides these we have a full history of Hezekiah and Sennacherib and of Hezekiah's sickness, xviii. 13–xx. 19, repeated in a somewhat varying text in Isa. xxxvi.–xxxix. (compare ISRAEL, vol. xiii. p. 413 *sq.*). The history of Amaziah and Joash in 2 Kings xiv., with the characteristic parable from vegetable life, may possibly be of northern origin.

When we survey these narratives as a whole we receive an increased impression of the merely mechanical character of the redaction by which they are united. Though editors have added something of their own in almost every chapter, generally from the standpoint of religious pragmatism, there is not the least attempt to work the materials into a history in our sense of the word; and in particular the northern and southern histories are practically independent, being merely pieced together in a sort of mosaic in consonance with the chronological system, which we have seen to be really later than the main redaction. It is very possible that the order of the pieces was considerably readjusted by the author of the chronology; of this indeed the LXX. still shows traces. But with all its imperfections, as judged from a modern standpoint, the redaction has the great merit of preserving the older narratives in their original colour, and bringing us much nearer to the actual life of the old kingdom than any history written throughout from the standpoint of the exile could possibly have done.

Literature.—Since Ewald's *History*, vols. i. and iii., and Kuenen's *Onderzoek*, the most thorough and original investigation of the structure of the book is that in Wellhausen's edition of Bleek's *Einleitung* (1878), with which the corresponding section of his *Geschichte* (1878) should be compared. There are modern commentaries by Thenius (Leipsic, 1849, 2d ed. 1873) and Keil (2d ed. 1876, English translation, 1872); by Bähr in Lange's *Bibelwerk* (1868, English translation, 1877); by Rawlinson in the *Speaker's Commentary*; and in Reuss's *Bible*. The Assyrian material, which is of the highest value, but requires to be still further sifted, is collected in Schrader's *Keilinschriften und altes Testament* (Giessen, 1872), Smith's *Assyrian Eponym Canon*, and other works. Translations of the chief inscriptions are given in *Records of the Past*, London, *v.y.* (W. R. S.)

KING'S COUNTY, an inland county in the province of Leinster, Ireland, is situated between 52° 50′ and 53° 25′ N. lat., and between 6° 59′ and 8° 1′ W. long., and is bounded on the N. by Meath and Westmeath, on the W. by Roscommon, Galway, and Tipperary, on the S. by Tipperary and Queen's county, and on the E. by Kildare. It is oblong in shape, but of very irregular outline. Its greatest breadth from north to south is 39 miles, and its greatest length from east to west 45 miles. The area is 493,019 acres, or about 770 square miles.

Geology.—The greater part of the county is occupied by the limestone strata of the central plain. In the south-east the Slieve Bloom mountains, composed of clay-slate surrounded by sandstone, form the boundary between King's county and Queen's county, and run into the former county from south-west to north-east for a distance of about 20 miles, consisting of a mass of lofty and precipitous crags through which there are two narrow passes, the Black Gap and the Gap of Glandine. In the north-east Croghan Hill, a beautiful green eminence consisting of trap conglomerate, rises to the height of over 700 feet. The remainder of the county is flat, but a range of low limestone hills crosses its north-eastern division to the north of the Barrow. In the centre of the county from east to west a large portion is occupied by the Bog of Allen. Along the Slieve Bloom mountains iron is found in small

past and there was no answer to the prophets of Baal, Elijah intervened. Thus we get time for the events which as the text stands could not have all happened the same evening. In 2 Kings iii. 20 for המנחה read השחר.

[1] The Gilgal of Elisha is near the Jordan—comp. vi. 1 with iv. 38, ישבים לפניו,—and cannot be other than the great sanctuary 2 miles from Jericho, the local holiness of which is still attested in the *Onomastica*. It is true that in 2 Kings ii. 1 Bethel seems to lie between Gilgal and Jericho; but ver. 25 shows that Gilgal was not originally represented as Elisha's residence in this narrative, which belongs to the Carmel-Dothan series. Hence Robinson's Gilgal (Jiljilia) seems not to be Biblical.

quantities, and also manganese, ochre, chalk, and potter's clay. Excellent clay-slate flags are quarried. In several places there are bands of foliated limestone, of a greenish hue and granular in texture, which forms a very useful manure.

Rivers.—The county shares in the advantage of the navigation of the Shannon, which skirts its western side and forms its boundary line with Roscommon and Galway. The Brosna, which issues from Loch Ennell in West Meath, enters the county near the town of Clara, and flowing south-westwards across its north-west corner, discharges itself into the Shannon after receiving the Clodagh and the Broughill. A small portion of the north-eastern extremity is skirted by the Boyne. The Barrow forms the south-eastern boundary with Queen's county. The Little Brosna, which rises in the Slieve Bloom mountains, forms the boundary of King's county with Tipperary, and falls into the Shannon.

Climate, Soil, and Agriculture.—Notwithstanding the large area occupied by bogs, the climate is generally salubrious, and it is less moist than that of several neighbouring districts. The soil naturally is not of great fertility except in special cases, but is capable of being rendered so by the judicious application of bog and lime manures according to its special defects. It is generally either a deep bog or a shallow gravelly loam. On the former soil corn crops are late in ripening during wet seasons, which on the other hand are specially suitable for the gravelly soils. On the borders of the Slieve Bloom mountains there are some very rich and fertile pastures, and there are also extensive grazing districts on the borders of West Meath, which are chiefly occupied by sheep. Along the banks of the Shannon there are some fine tracts of meadow land. With the exception of the tract occupied by the Bog of Allen, the remainder of the county is nearly all under tillage, the most productive portion being that to the north-west of the Hill of Croghan.

The following table gives a classification of holdings according to size in 1850 and 1880:—

	Under 1 Acre.	1 to 5 Acres.	5 to 15 Acres.	15 to 30 Acres.	30 Acres and upwards.	Total.
1850	1,400	2,755	3,614	2,476	3,078	13,323
1880	1,718	1,930	2,395	2,075	3,333	11,451

The total area under crops in 1881 was 119,751 acres—24·2 per cent. of the total acreage of the county. In 1880 238,667 acres (48·4 per cent.) were under grass, 424 fallow, 8551 woods, 108,773 (the large percentage of 22·1) bog, 6043 mountain, and 16,327 water, roads, and fences. The area under corps in 1850 was 138,538 acres, or 24,814 more than in 1880 and 18,787 more than in 1881. The area under cereals declined between 1850 and 1881 from 70,668 to 40,263, that under wheat decreasing from 20,410 to only 1436, that under oats from 38,787 to 23,082; but that under other cereals, of which nearly the whole acreage is under barley, increased from 11,471 to 15,745. Between 1851 and 1880 the area under grass increased by 46,427 acres, a change due in a considerable degree to reclamation. The area under meadow and clover only increased from 40,348 to 44,765 acres. The area under green crops between 1851 and 1881 diminished from 30,561 to 29,178 acres, that under potatoes diminishing from 17,907 to 15,762, while that under turnips increased from 9418 to 9863. Anciently nearly the whole of the county was covered by a vast forest, and on the borders of Tipperary it is still richly wooded.

Horses, which are a much better breed than the average of Ireland, increased from 12,990 in 1850 to 13,505 in 1881. The number in 1881 used for agricultural purposes was 8889. Mules increased from 817 to 1209, and asses from 4212 to 6221. Cattle in 1850 numbered 47,978, and in 1881 had increased to 68,165. Cows in 1881 numbered 14,749. Dairies are numerous in the northern part of the county on the borders of Meath, but in other districts cattle-feeding is more largely prosecuted than dairy farming. Sheep, which are pastured chiefly on the hilly districts, and have been much improved by crossing, in 1850 numbered 68,552, and in 1880 had increased to 97,570. Goats since 1850 have declined in numbers from 4032 to 3910. Pigs have increased from 15,450 to 20,526, and poultry from 158,154 to 271,873.

According to the corrected summary for 1878 of the landowners return, the land in 1873 was divided among 1140 owners, of whom 353, or 31 per cent., possessed less than 1 acre. The annual rateable valuation was £243,204, giving an average value per acre of 9s. 11d. Forty-six proprietors possessed more than 2000 acres, thirteen had upwards of 5000 acres, and five upwards of 10,000 acres, viz., Lord Digby, 29,722; Earl of Rosse, 22,513; Earl of Charleville, 20,032; Marquis of Downshire, 13,679; and Col. T. Bernard, 18,153.

Railways, &c.—A branch of the Great South-Western Railway traverses the county by Portarlington, Clara, and Banagher, and there is also a branch of the same line from Roscrea to Parsonstown. The Grand Canal traverses the county from Edenderry in the east to the Shannon in the west.

Administration.—The county comprises twelve baronies, forty-two civil parishes and nine parts of parishes, and 1160 townlands. It contains portions of five poor-law unions, viz., Edenderry, Mountmellick, Parsonstown, Roscrea, and Tullamore. The county includes part of the parliamentary borough of Portarlington (the remainder being in Queen's county), and two townships, Parsonstown and Tullamore. Assizes are held at Tullamore and quarter-sessions at Parsonstown, Philipstown, and Tullamore. King's county is in the Dublin military district, and there are barrack stations at Parsonstown, Banagher, Philipstown, Shannon Bridge, and Tullamore. Previous to the Union, King's county returned six members to parliament, two for the county, and two for each of the boroughs of Philipstown and Banagher, but since then only the two county members have been returned.

Population.—The total population of the county in 1659 was 8310, of whom 7085 were Irish and 1225 English. The estimate of De Burgo in 1760 made it 45,618. In 1821 it had increased to 131,088 and in 1841 to 147,551, but in 1851 it had diminished to 112,798, in 1871 to 75,900, and in 1881 to 72,668, of whom 36,942 were males and 35,726 were females. The number of emigrants from 1st May 1851 to 31st December 1880 was 41,798, or 46·4 per cent. of the population in 1861, 21,437 being males and 20,361 females. The marriage rate in 1880 to every 1000 of the estimated population was 3·9, the birth rate 23·5, and the death rate 18·2. In 1881 the Roman Catholics numbered 64,984, the Protestant Episcopalians 6750, the Presbyterians 285, the Methodists 421, and all other denominations 228. The number of natives of England and Wales in the county in 1841 was 293, which had increased in 1871 to 1087; the natives of Scotland in the same years were 109 and 203. The number in 1871 who could speak Irish and English was 245, and in 1861 it was 396. In 1871 there were 34,360 persons who could read and write, 13,157 who could read but could not write, and 28,383 who could neither read nor write.

History.—King's county, with portions of Tipperary, Queen's county, and Kildare, at an early period formed one kingdom under the name of Hy Falgia or Offalia, a title which it retained after the landing of the English. Subsequently it was known as Glenmallery, Western Glenmallery pretty nearly corresponding to the present King's county, and Eastern Glenmallery to Queen's county. The principal septs of the district were the O'Connors and the O'Carrolls, whose estates and those of the other leading families were forfeited about the middle of the 16th century. By a statute of 1557 the western district was constituted a shire under the name of King's county in honour of Philip—the principal town, formerly the seat of the O'Connors, being called Philipstown; and the eastern district at the same time received the name of Queen's county in honour of Mary. The subjugation of King's county was, however, not completely accomplished till about the beginning of the 17th century, when the O'Connors and their followers were totally routed and dispersed by Sir Oliver Lambert. After the Cromwellian wars a large number of estates were forfeited on account of the insurrectionary action taken by the leading gentry.

Antiquities.—Perhaps the oldest antiquarian relic is the large pyramid of white stones in the Slieve Bloom mountains called the Temple of the Sun or the White Obelisk. There are a considerable number of Danish raths, and a chain of moats commanding the passes of the bogs extended throughout the county. The most important ecclesiastical ruins are those of the seven churches of Clonmacnoise on the Shannon in the north-west of the county, where an abbey was founded by St Kieran in 548. Afterwards it was formed into a see, which was united with that of Meath in 1568. Within the old walls there are several small chapels erected over the graves of ancient chieftains, and also one or two richly ornamented crosses. Adjoining the ecclesiastical ruins are the remains of round towers and of an old castle. Amongst the more famous religious houses in addition to Clonmacnoise were Durrow Abbey, founded by St Columba in 550; Monasteroris, founded in the 14th century by John Bermingham, earl of Louth; and Seirkyran Abbey, founded in the beginning of the 5th century. The principal old castles are Rathmore, probably the most ancient in the county; Banagher, commanding an important pass on the Shannon; Leap Castle, in the Slieve Bloom mountains; and Birr or Parsonstown, now the seat of the earl of Rosse, whose father erected there the well-known great telescope.

KINGSLEY, CHARLES (1819–1875), an English clergyman, poet, and novelist, was born on the 12th June 1819, at Holne vicarage, Dartmoor, Devon. His early years were spent at his father's living in the Fen country, and afterwards in North Devon. The scenery of both made a great impression on his mind, and was afterwards described with singular vividness in his writings. He was educated at private schools and at King's College, London, after his father's promotion to the rectory of Chelsea. In 1838 he entered Magdalene College, Cambridge, where he took his degree in 1842, first-class in classics, and senior optime in mathematics. In the same year he was ordained to the curacy of Eversley in Hampshire, to the rectory of which he was not long afterwards presented, and this was his home for the remaining thirty-three years of his life, although his residence there was much broken by various domestic circumstances as well as, in later years, by promotion to other offices in the church.

In 1844 he married Fanny, daughter of Pascoe Grenfell, and in 1848, when aged twenty-nine, he published his first volume, *The Saint's Tragedy.* In 1860 he was appointed to the professorship of modern history in the university of Cambridge, which he resigned in 1869, and was soon after appointed to a canonry at Chester. In 1873 this was exchanged for a canonry at Westminster. He died at Eversley, after a short illness, on the 23d January 1875.

It will be seen that his life had but few incidents. With the exception of occasional changes of residence in England, generally for the sake of his wife's health, one or two short holiday trips abroad, a tour in the West Indies, and another in America to visit his eldest son settled there as an engineer, his life was spent in the peaceful, if active, occupations of a clergyman who did his duty earnestly, and of a vigorous and prolific writer. But in spite of this outward peace he was for many years one of the most prominent men of his time, who both personally and by his works had no little influence on the thought of his generation. Though at no time profoundly learned, he was a man of wide and various information, whose interests and sympathies embraced almost all branches of human knowledge as well as speculations on subjects on which men but slowly learn that speculation avails them nothing. Gifted with great powers of language, both written and in conversation, with a keen wit, and a fund of knowledge far above the average, there were few subjects in which he did not shine, and many in which he excelled. The inherited peculiarities of his opinions and temperament, which made him seemingly though not really inconsistent, excited curiosity, and were in part the reason of his great attractiveness. Sprung on the father's side from an old English race of country squires, and on his mother's side from a good West Indian family who had been slaveholders for generations, he had the keen love of sport and the exceeding sympathy with country folk often fostered by such pursuits, while he had at the same time much of the aristocratic scorn for lower races to be found among those who have been in a dominant position among them.

With the sympathetic organization which made him keenly sensible of the wants of the poor, he threw himself heartily into the movement known as Christian Socialism, of which Mr Maurice was the recognized leader, and for many years he was considered as an extreme radical in a profession which holds as a rule but few such. While in this phase of mind he wrote his novels *Yeast* and *Alton Locke,* in which, though he pointed out unsparingly the folly of extremes, his sympathies were unmistakably shown to be, not only with the poor as in their strife against the rich, but with much that was done and said by the leaders in the Chartist movement. Yet even then he considered that the true leaders of the people were a peer and a dean, and there was no real inconsistency in the fact that at a later period he was among the most strenuous defenders of Governor Eyre in the measures adopted by him to put down the Jamaican disturbances. In politics he might therefore have been described as a Tory aristocrat tempered by sympathy, or as a Radical tempered by hereditary scorn of subject races. The like seeming but not real inconsistencies were to be found in his attitude as a clergyman. He was a man of earnest piety, and lived so near in his own mind to the great realities of the unseen world that he could even afford to speak of serious subjects in a way which in one less reverent than he would have seemed to lack reverence; and, while he held in many respects what would be called a liberal theology, the church, its organization, its creed, its dogma, had ever an increasing hold upon him. Although at one period he certainly shrunk from reciting the Athanasian creed in church, he was towards the close of his life found ready to join an association for the defence of this symbol. With these two influences at work in his mind, it was not unnatural that the more orthodox and conservative should gain the upper hand as time went on, but the careful students of him and his writings will find a deep conservatism underlying all the most radical utterances of his earlier years, while a passionate sympathy for the poor, the afflicted, and the weak held possession of him till the last hour of his life.

Both as a writer and in his personal intercourse with men Kingsley was a thoroughly stimulating teacher. He would not probably have wished to found a school, and most certainly never did so. As with his own teacher Mr Maurice, his influence on other men rather consisted in the fact of his inducing them to think for themselves than that he led them to adopt his own views. Perhaps these were at no time quite definite enough to have been reduced to such system as is demanded for one who would make his disciples think as himself. But his healthy and stimulating influence went far beyond the boundaries of his parish, his canonries, and his wide circle of friends, and was largely attributable to the fact that he gave utterance to the thoughts which were stirring in many minds during the time of his own most vigorous life. His originality, which was great, lay rather in his manner of crystallizing the current thoughts of men, and giving them apt expression, than in any new discoveries in the matters of which he treated. Just because he was completely the product and the mouthpiece of his own time, it may be doubted whether his influence on the future will be very great, and it is possible that men who may read his works by chance some years hence will fail to understand how wide was the influence he exercised.

As a preacher he was vivid, eager, and earnest, equally plain-spoken and uncompromising when preaching to a courtly congregation or to his own village poor. One of the very best of his writings is a sermon called *The Message of the Church to Working Men*; but as a rule his sermons cannot be read with the interest with which they were heard, and none of his later published sermons equal the little volume of *Twenty-five Village Sermons* which he preached in the early years of his Eversley life.

As a novelist his chief power lay in his descriptive faculties. *Yeast* and *Alton Locke* were written out of the heat of strong conviction, and dealt in a brilliant manner with great social questions, but the later novels seem to have been written rather because he wished to say something than because he had something to say, and in spite of new and ever new editions it may be doubted whether the real interest felt in these works is considerable. Few persons read them twice, although it is fair to say that this may partially arise from the fact that the story is so vividly told that it is not forgotten, and therefore needs no second reading. But the descriptions of South American scenery in *Westward Ho*, of the Egyptian desert in *Hypatia*, of the North Devon scenery in *Two Years Ago*, are among the most brilliant pieces of word-painting in English prose writing, and the American scenery is even more vividly and more truthfully described when he had seen it only by the eye of his imagination than in his work *At Last*, which was written after he had visited the tropics.

As a poet he wrote but little, but that little he wrote with singular facility, and there are passages in the *Saint's Tragedy*, and many isolated lyrics, which ought to take their place in all future standard collections of English literature. *Andromeda* is a very successful attempt at naturalizing the hexameter as a form of English verse, and reproduces with great skill the sonorous roll of the Greek original.

In person Charles Kingsley was tall and spare, sinewy rather than powerful, and of a restless excitable temperament. His complexion was swarthy, his hair dark, and his eye bright and piercing. His temper was hot, kept under rigid control, his disposition tender, gentle, and loving as that of a woman, with flashing scorn and indignation against all that was ignoble and impure; he was a good husband, father, and friend.

Kingsley's life has been written by his widow, in two volumes, entitled *Charles Kingsley, his Letters and Memories of his Life*, and presents a very touching and beautiful picture of her husband, but perhaps hardly does justice to his humour, his wit, his overflowing vitality and boyish fun.

The following is a list of Kingsley's writings:—*Saint's Tragedy*, a drama, 1848; *Alton Locke*, a novel, 1849; *Yeast*, a novel, 1849; *Twenty-five Village Sermons*, 1849; *Phaeton, or Loose Thoughts for Loose Thinkers*, 1852; *Sermons on National Subjects*, 1st series, 1852; *Hypatia*, a novel, 1853; *Glaucus, or the Wonders of the Shore*, 1854; *Sermons on National Subjects*, 2d series, 1854; *Alexandria and her Schools*, 1854; *Westward Ho!* a novel, 1855; *Sermons for the Times*, 1855; *The Heroes*, Greek fairy tales, 1856; *Two Years Ago*, a novel, 1857; *Andromeda and other Poems*, 1858; *The Good News of God*, sermons, 1859; *Miscellanies*, 1859; *Limits of Exact Science applied to History* (Inaugural Lectures), 1860; *Town and Country Sermons*, 1861; *Sermons on the Pentateuch*, 1863; *Water-babies*, 1863; *The Roman and the Teuton*, 1864; *David and other Sermons*, 1866; *Hereward the Wake*, a novel, 1866; *The Ancient Régime* (Lectures at the Royal Institution), 1867; *Water of Life and other Sermons*, 1867; *The Hermits*, 1869; *Madam How and Lady Why*, 1869; *At Last*, 1871; *Town Geology*, 1872; *Discipline and other Sermons*, 1872; *Prose Idylls*, 1873; *Plays and Puritans*, 1873; *Health and Education*, 1874; *Westminster Sermons*, 1874; *Lectures delivered in America*, 1875. He was a large contributor to periodical literature; many of his essays are included in *Prose Idylls* and other works in the above list. But no collection has been made of some of his more characteristic writings in the *Christian Socialist* and *Politics for the People*, many of them signed by the pseudonym he then assumed, "Parson Lot." (C. K. P.)

KINGSTON, the chief city of Ulster county, New York, United States, is situated on the west bank of the Hudson, about 90 miles north of New York. Its harbour is formed by the navigable portion of Rondout Creek. Among the chief buildings are the city hall, the music-hall, the almshouses, and the county buildings. Kingston is a very busy shipping centre, with 4 miles of wharfage, and steam and other shipping representing a considerable aggregate tonnage. As the centre of the blue stone region, Kingston ships an immense quantity of that mineral; and, possessing the largest cement factory in the country, its out-turn of that material together with bricks, ice, lime, timber, and other goods swells the amount of its exports to upwards of a quarter of a million tons per annum. The manufactures of the town include salt, tobacco, glue, carriages, beer, boats, and bricks. The population in 1880 was 18,342.

Kingston city was incorporated in 1872. The first settlement on the spot was made about 1665. At Kingston was framed the first Constitution of New York State, in 1777. In September 1777 the British, under Sir Henry Clinton, scattered the State legislature which had met at Kingston, and in October burned the village.

KINGSTON, the chief city of Frontenac county, Ontario, Canada, is situated at the north-eastern extremity of Lake Ontario, at the point where the St Lawrence issues from it, and at the mouth of the Cataraqui Creek, about 160 miles east of Toronto by the Grand Trunk Railway. Of the many fine buildings the chief are the city-hall, the market, the custom-house, the court-house and jail, the post-office, and the university. Among the charities are a hospital, an orphanage, a combined hospital and orphanage, a house of industry, and a house of refuge. The penitentiary and the lunatic asylum are at a little distance from the city. Kingston is the seat of Queen's university and college, and of a medical college affiliated to the university. The Roman Catholic Regiopolis college has been closed since 1869. The royal military college of the Dominion is at Kingston. The harbour is deep, spacious, and sheltered, and brisk trade is carried on. As a naval station Kingston occupies an important position. It commands the entrance to the Rideau Canal, and is strongly fortified. Shipbuilding, iron-founding, and the manufacture of locomotives, steam-engines, and machinery, leather, soap and candles, boots and shoes, cotton, and wooden goods are carried on by the inhabitants. Kingston is the seat of an Anglican and of a Roman Catholic bishop. The population in 1881 was 14,093.

Kingston occupies the site of the old French fort Frontenac. It received its present name after it was taken by the British in 1762. For three years (1841–44) it was the capital of Canada.

KINGSTON, the capital of Jamaica. See JAMAICA.

KINGSTON-ON-THAMES, a municipal borough and market-town of England, county of Surrey, extends for about a mile and a half along the right bank of the Thames, and is distant from London about 20 miles by the river and 12 miles by rail and road. The ancient wooden bridge over the river, which was in existence as early as 1224, was superseded by a structure of stone in 1827. The town is irregularly built, but its suburbs contain many fine houses and villas embosomed in trees, and of late years it has been rapidly increasing. Public walks and gardens have been constructed along the river. The parish church of All Saints, chiefly Perpendicular in style, contains several brasses of the 15th century; the grammar school, rebuilt in 1878, was originally founded as a chantry by Edward Lovekyn in 1305, and converted into a school by Queen Elizabeth. Near the parish church stood until 1779 the chapel of St Mary, where, it is alleged, the Saxon kings were crowned. The ancient stone said to have been used as a throne at these coronations was removed to the market-place in 1850. A town-hall in the Italian style was erected in 1840, the former building having been a very ancient structure. There are several foundation schools and a large number of charities. The growth of the town has been owing chiefly to the increasing number of London business men who have made it their residence, its proximity to Richmond park and Hampton Court no doubt aiding its popularity. There are large market gardens in the neighbourhood, and the town possesses oil-mills, flour-mills, breweries, and brick and tile works. A little distance up the river are the works of several London water companies. An annual cattle fair is held in November, and county assizes are held at Lent. The population of the municipal borough in 1881 was 19,875.

Kingston doubtless derived its name from the fact that at an early period it was a royal demesne. On digging the foundation for the new bridge a large number of important Roman remains were discovered, and on this account many believe that it was at this spot that Cæsar crossed the Thames when in pursuit of Cassivelaunus. In 838 it was the seat of a witenagemot convened by King Egbert. From Edwin in 901 to Ethelred in 978 it was the place where the Anglo-Saxon kings were crowned. Kingston returned members to parliament from the 4th of Edward II. to the 47th of Edward III. It received a charter of incorporation from King John, which was confirmed and extended by several subsequent monarchs. In 1264 the castle of Kingston, no trace of which now remains, was taken by Henry III. In 1648 it was made the rendezvous of forces designed for the release of Charles I. from the Isle of Wight, but in the skirmish near the town the Royalists were defeated, and Lord Francis Villiers was killed.

See Roots, *Charters of the Town of Kingston*, 1797, and the histories of the town by Anderson, 1818, and Biden, 1852.

KINGSTON-UPON-HULL. See HULL, vol. xii. p. 340.[1]

KINGSTON, WILLIAM HENRY GILES (1814-1880), boys' novelist, was born in London, February 28, 1814. Much of his youth was spent at Oporto, where his father was a merchant, but when he joined his father in business, and afterwards when he carried on business for himself, he lived chiefly in London. In 1844 his first book, *The Circassian Chief*, appeared, and its success led to the publication in 1845 of *The Prime Minister, a Story of the Days of the Great Marquis of Pombal*. The *Lusitanian Sketches* that appeared soon after describe Kingston's travels in Portugal. In 1851 *Peter the Whaler*, his first book for boys, came out. That and its immediate successors were received with such unequivocal popularity that Kingston retired from business, and devoted himself to the production of tales of adventure for boys. Within thirty years he wrote upwards of one hundred and thirty such books. He travelled at various times in many of the countries of Europe, and lived for a while in Portugal during the civil war there. His *Western Wanderings*, published in 1856, describes a tour in Canada. In all philanthropic schemes Kingston took deep interest; he was the promoter of the mission to seamen; and he acted as secretary of a society for promoting an improved system of emigration. He was a supporter of the volunteer movement in England from the first. For his services in bringing about a commercial treaty between Portugal and Britain he was knighted by the queen of Portugal; and his literary merits were recognized at home by a grant from his own sovereign. He died at Willesden, August 5, 1880.

Kingston's boyish ambition had been to enter the navy, and he always kept his affection for the sea. As he advanced in life he had opportunities of cruising in men-of-war, besides sailing in merchantmen and his own yacht; and it was thus that he gained the knowledge of practical seamanship that he used so graphically in his books. Most of his stories are stories of the sea; and he generally laid his plots in the old romantic days before England's wooden walls had given place to iron-clads. He was a master of the simple romance in which boys delight, and knew well how to draw the peculiar compound of valour and magnanimity that forms the hero to healthy boyhood. He had great assimilative power in using the accounts of travellers in countries where he had never been; and his imagination supplied him abundantly with gallant adventures, thrilling dangers, and hairsbreadth escapes. His books are useful in insinuating knowledge whilst they are giving pleasure, and they are valuable inasmuch as their whole tone is pure, wholesome, and manly. Characteristic specimens of his works are *The Three Midshipmen*; *The Three Lieutenants*; *The Three Commanders*; and *The Three Admirals*. Occasionally his books were not in the form of a story; and some of them are designed for adult readers.

KINGSTOWN, a seaport town of Ireland, in the county of Dublin, is situated at the south-eastern extremity of Dublin Bay, 6 miles south-east from Dublin by railway. It is a large seaport and favourite watering-place, and possesses several fine streets and terraces commanding picturesque sea views. The original name of Kingstown was Dunleary, which was exchanged for the present designation after the embarkation of George IV. at the port on his return from Ireland in 1821, an event which is also commemorated by a granite obelisk erected near the harbour. The town was a mere fishing village until the construction of an extensive harbour, begun in 1817 from designs by Rennie, and finally completed in 1859, at a cost of £825,000. The eastern pier has a length of 3500 feet, and the western of 4950 feet, the total area enclosed being about 250 acres, with a varying depth of from 15 to 27 feet. Kingstown is the station of the mail packets to Holyhead in connexion with the London and North-Western Railway. It has a large export and import trade both with Great Britain and foreign countries, but as its shipping returns are now included in those of the port of Dublin, it is impossible to give accurate details. The principal exports are cattle, and the principal imports corn and provisions. The harbour revenue exceeds £2000 annually. By the Towns' Improvement Act of 1854, Kingstown, with several surrounding districts, was formed into a township, having an area of 1450 acres. The population in 1861 was 14,257, which in 1871 had increased to 16,378, and in 1881 to 18,230.

KING-TIH CHIN, a town near Foo-leang Heen in the province of Keang-se, China, and the principal seat of the porcelain manufacture in that empire. Being situated on the south bank of the river Chang, it was in ancient times known as *Chang-nan Chin*, or "town on the south of the river Chang." It is unwalled, and stretches along the bank of the river in a somewhat straggling way. The streets are narrow, and crowded with a population which is reckoned at a million, the vast majority of whom find employment at the porcelain factories. Since the Ch'in dynasty (557-589) this has been the great trade of the place, which was then called by its earlier name. In the reign of King-tih of the Sung dynasty (1004-1007) a manufactory was founded there for making vases and objects of art for the use of the emperor. Hence its adoption of its present title. Since the time of the Ming dynasty a magistrate has been specially appointed to superintend the factories and to despatch at regulated intervals the imperial porcelain to Peking. The town is situated on a vast plain surrounded by mountains, and boasts of three thousand porcelain furnaces. These constantly burning fires are the causes of frequent conflagrations, and at night give the city the appearance of a place on fire. The people are as a rule orderly, though they have on several occasions shown a hostile bearing towards foreign visitors. This is probably to be accounted for by a desire to keep their art as far as possible a mystery, and is after all only an extreme interpretation of the law which forbids strangers to lodge in the town. This feeling appears less unreasonable when it is remembered that the two kinds of earth of which the porcelain is made are not found at King-tih Chin, but are brought from K'i-mun in the neighbouring province of Gan-hwuy, and that there is therefore no reason why the trade should be necessarily maintained at that place. The two kinds of earth are known at pih-tun-tsze, which is a fine fusible quartz powder, and kaou-lin, which is not fusible, and which it is said gives strength to the ware (see KAOLIN). Both materials are prepared in the shape of bricks at K'i-mun, and are brought down the Chang to the seat of the manufacture.

KINO, an astringent drug introduced into European medicine in 1757 by Fothergill, an eminent physician and patron of economic botany. When described by him it was believed to have been brought from the river Gambia

[1] The population of the municipal borough amounted in 1881 to 154,250, and that of the parliamentary borough of Hull to 161,519.

in West Africa. According to Moore (1733), a factor to the Royal African Company, the tree yielding the drug is known in the Mandingo language as "kano." When first imported, however, it was sold in England as *Gummi rubrum astringens Gambiense.* It was introduced into the Edinburgh pharmacopœia in 1776 under the above name, and into the London pharmacopœia in 1787 under the name of *Resina kino.* Specimens of the plant sent home by Mungo Park in 1805 were recognized as identical with *Pterocarpus erinaceus*, Poiret. In 1811 the African drug was no longer to be met with in English commerce, its place being supplied by several other kinds.

The drug which is at present recognized as the legitimate kind is East Indian, Malabar, or Amboyna kino, and is obtained from *Pterocarpus Marsupium*, Roxb. (*Leguminosæ*). It is collected in the Government forests of the Malabar coast, the collectors being required to pay a small fee for the privilege, and to perform the tapping carefully and without injuring the timber. The mode of obtaining the kino is by making a perpendicular incision, with lateral ones leading into it, in the trunk, a vessel being placed at the foot of the incision to receive the juice. When exuding it resembles red currant jelly,[1] but hardens in a few hours after exposure to the air and sun. When sufficiently dried it is packed into wooden boxes for exportation. When these are opened it breaks up into angular brittle fragments of a blackish-red colour and shining surface. In cold water it is only partially dissolved, leaving a pale flocculent residue, which is soluble in boiling water, but deposited again on cooling. In spirit of wine, sp. gr. ·838, it is entirely soluble, affording a solution having an acid reaction, but the liquid by long keeping assumes a gelatinous condition. It is also soluble in caustic alkalis and to a large extent in a saturated solution of sugar, but is wholly insoluble in ether. In chemical composition kino appears to be nearly allied to Pegu catechu, but differs from it in not yielding catechin when exhausted by ether, but only a minute quantity of scaly prismatic crystals of a substance which is soluble in cold water, and thus more nearly resembles pyrocatechin. Pyrocatechin is, however, not present in the fresh bark or wood of the tree. Etti (1878) states that he has obtained kinoin, $C_{14}H_{12}O_6$, from Malabar kino, while Hanbury and Fluckiger failed to obtain it from that drug, but found it in Australian kino. According to Bentley, kino-tannic acid, catechin (or probably pyrocatechin), and kino red are the essential constituents of Malabar kino. The first of these is precipitated from an aqueous solution of the drug by dilute mineral acids, and the last by boiling an aqueous solution of kino-tannic acid for some time, when it separates as a red precipitate. The chemical constitution of Malabar kino is therefore only imperfectly known. The quantity of kino collected in Madras is comparatively small, and is supposed not to exceed a ton or two annually, but it is often shipped from Cochin.

Bengal, Butea, or Palas kino—obtained from *Butea frondosa*, Roxb. (*Leguminosæ*), a native of India and Burmah, well known under the name of the Palas or Dhak tree, and remarkable for its large orange papilionaceous flowers—also finds its way occasionally into British commerce. A portion is also obtained from *Butea superba*, Roxb., and *Butea parviflora*, Roxb. Butea kino does not stick to the teeth when chewed like ordinary kino, although like the latter it gives a red tinge to the saliva. It is usually more or less mixed with small fragments of bark. It is almost completely soluble in water, and to the extent of 46 per cent. in boiling alcohol, but different specimens vary in solubility. It is believed to contain about half its weight of kino-tannic acid, the remainder consisting of a soluble mucilaginous substance, and a minute quantity of pyrocatechin, which can be extracted by ether. In India Butea kino is used instead of the Malabar kino, and is called by the Hindus kueni or kuenee.

[1] African kino is very liquid and of an extremely pale red colour when it first flows out, but soon coagulates and becomes of a deep blood-red hue.

Botany Bay, Australian, or Eucalyptus kino is a more or less resinous astringent exudation obtained from several species of *Eucalyptus.* It is found in flattened cavities in the trunks, and is mostly collected by sawyers and wood-splitters. It frequently comes into the London market, and the best variety, probably the product of *E. corymbosa*, Sm., is used under the name of "red gum" in the preparation of astringent lozenges for sore throat. According to Wiesner of Vienna, Australian kino contains a little catechin (a statement doubted by Fluckiger) and pyrocatechin, no pectinous matter, but a gum nearly allied to that of acacia. Fluckiger also obtained from it kinoin, $C_{14}H_{12}O_6$, which he regards as the methylated gallic ether of pyrocatechuic acid, viz., $C_6H_4(OCH_3)C_7H_5O_5$.

Between 1808 and 1820 a substance was met with in French commerce under the name of Jamaica kino, which is said to have been prepared by inspissating the juice of the seaside grape, *Coccoloba uvifera*, L. (*Polygonaceæ*). When powdered it has a somewhat bituminous odour and an astringent slightly bitter taste. It is but little soluble in cold water or alcohol, but dissolves almost entirely in boiling water, and to the extent of about 75 per cent. in hot alcohol. In thin laminæ it is only semi-transparent, the fragments usually met with in commerce being quite opaque. In 1835 an article appeared in French commerce under the name of "kino de la Colombie," which is stated in *Histoire des Drogues* to be in all probability an extract of the bark of *Rhizophora Mangle*, L. A liquid kino is obtained from *Pterocarpus indicus*, which does not harden like that obtained from *P. Marsupium.* Although used in India it is not imported into Europe. Other varieties of kino are mentioned in the same work, but they must be regarded rather in the light of curiosities than as articles of commerce.

Kino is used in medicine as an astringent, chiefly in the form of tincture; but, owing to its tendency to gelatinize, that preparation is much less used than formerly.

Moore, *Travels into the Inland Parts of Africa*, 1737, p. 160, 209, 267; *Histoire des Drogues*, 7th ed., tom. iii. p. 426–439; Lewis, *Materia Medica*, 1784, p. 366; Daniell, *Pharmaceutical Journal*, (1) xiv. p. 55; *Pharmacographia*, 2d ed., p. 195; Pereira, *Mat. Med.*, 4th ed., vol. ii., pt. ii., p. 325; Bentley and Trimen, *Medicinal Plants*, Nos. 79–81.

KINROSS, a small inland county of Scotland, is situated between 56° 8′ and 56° 18′ N. lat., and 3° 14′ and 3° 35′ W. long. It is of an irregular circular form, and in outline somewhat resembles a toothed wheel, lying between Perthshire on the north-west and Fife on the south-east. Its breadth from west to east is about 12 miles, and its length from north to south about 10 miles; the area is 49,812 acres, or about 78 square miles. Next to Clackmannan it is the smallest county in Scotland.

The surface consists principally of an oval and level plain, which is bounded on the N.W. by the Ochils, on the E. by Bishop Hill and the Lomonds, on the S. by Benarty Hill, and on the S.W. by the Cleish Hills. This plain opens out on the west along the Devon valley towards Stirling, on the north-east towards the valley of the Eden, and more narrowly on the south between the Cleish Hills and Benarty. Kinross is touched by the river Devon at the Crook of Devon, not far from the Rumbling Bridge; and the river Leven, which has its source in the loch of that name, flows for about half a mile in Kinross before entering Fife. Of the streams which flow into Lochleven the principal are the Gairney, the South Queich, and the North

Queicu. Lochleven, the area of which has been lessened by extensive reclamation works undertaken in 1826, has still a surface of 3406 acres, and its trout fishing is the best of any loch in Scotland. The loch contains several islands, the principal being Queen Mary's Island, 8 acres in extent, Reed Bowers, 1 acre, and the island of St Serf, 80 acres.

Geology and Agriculture.—The greater part of the county belongs to the upper strata of the Old Red Sandstone, but a portion in the north-west to the porphyry formation of the Ochils, while on the east there is a narrow boundary of the Coal-measure slightly interrupted by trap. Coal is wrought in the southern part of the county, but only to a small extent; limestone is very abundant, and sandstone is obtained for building purposes.

The lower part of the county is generally well sheltered, and suitable for all kinds of crops. In this region the soil is generally of a mossy character, but when well drained and cultivated is very fertile. The eminences are devoted chiefly to the pasturage of sheep and the rearing of cattle. Much land has been reclaimed within recent years, and the methods of farming are now quite equal to those of the most advanced districts of Scotland.

A great proportion of the land is held in fee by small proprietors who farm their own properties. The following table gives a classification of holdings according to size in 1880 and 1875:—

	50 Acres and under.		From 50 to 100 Acres.		From 100 to 300 Acres.		From 300 to 500 Acres.		From 500 to 1000 Acres.		Above 1000 Acres.		Total.	
	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.
1880	136	1,068	32	7.823	102	18,680	21	2.361	2	1.445	...	...	293	31.377
1875	143	1,543	29	2,074	118	21,556	25	9.307	1	530	...	...	316	35.010

According to the agricultural returns for 1881, the total area under crops was 31,459 acres, of which 7296 acres were under corn crops, 3698 under green crops, 11,348 under rotation grasses, 9100 permanent pasture, and 17 fallow. 2576 acres were under woods. The percentage of cultivated area in 1870 was 67·9, and in 1880 it was 63·0. The area under permanent pasture has increased very much of late years, while there is an unusually large percentage under rotation grasses. 5801 acres, or more than two-thirds of the area under corn crops, is occupied by barley and bere, while oats had 1350 and wheat only 112 acres. Nearly the whole area under green crops was occupied either by turnips and swedes or potatoes, turnips and swedes having 2663 and potatoes 957 acres.

The total number of horses in 1881 was 1039. Of these 699 were used solely for agricultural purposes, and 340, a very large proportion, were unbroken horses or mares kept solely for breeding. Cattle in 1881 numbered 5555. Milch cows numbered 984, less than one-fifth of the whole. A considerable number of cattle are pastured on the lowland farms. They are chiefly a native breed, which has been much improved by crossing. Sheep in 1881 numbered 26,530. They are chiefly pastured on the hills, but a considerable number are also wintered on the lowland farms. Pigs in 1881 numbered 504.

In 1872–73 the land was divided between 728 proprietors, and its gross annual value was £64,671, 14s. Of the owners, 468 or 64·3 per cent. possessed less than 1 acre, and the average value per acre was £1, 8s. 10½d. There were nine proprietors who held more than 1000 acres, the largest estates being those of the Right Hon. W. P. Adam, 2869 acres, and Sir Graham Montgomery, 2336.

Manufactures and Trade.—Tartan plaids, shawls, and other woollen goods are manufactured at Kinross, which also possesses corn-mills and a brewery. There is a large linen factory at Milnathort, as well as manufactories for woollen goods.

Administration.—The county sheriff courts are held weekly or fortnightly. Kinross is now joined with Clackmannan and Linlithgow in one sheriffdom, and quarter sessions are held on the first Tuesday of March, July, August, and October. The county unites with Clackmannan in returning a member to parliament.

Population.—Kinross has the smallest population of any county in Scotland. From 6725 in 1801 it rose to a maximum of 9072 in 1831, from which it fell in 1841 to 8763, and, although in 1851 it rose to 8924, it gradually diminished till in 1871 it was 7198, while in 1881 it was 6699, of whom 3112 were males and 3587 females. The principal villages are Kinross (population in 1881, 1960), the capital of the county and a market-town; Milnathort (1269), with linen and woollen manufactures; Kinnesswood (250); and a portion of Kelty, the remainder being in Fife.

History and Antiquities.—The early history of Kinross-shire is given in the article FIFE. There are traces of an ancient fort or camp on the top of the hill of Dumglow in the parish of Cleish, and a remarkable cairn called Cairn-a-vain on a hill on the northern boundary of the parish of Orwell, in the centre of which a rude stone cist was discovered with an urn full of bones and charcoal. In 1857 a hoard of seven hundred Roman coins was dug up in the vicinity of the county town. The priory of Portmoak, properly situated on the island of St Serf in Lochleven, although the prior and canons often resided at Kinnesswood, was originally the oldest Culdee establishment in Scotland,—being a gift of the Pictish kings after their conversion. Some time before 961 it was made over to the bishop of St Andrews, and shortly after 1144 a body of canons regular was established in it in connexion with the priory of canons regular established in that year at St Andrews. The castle of Lochleven was a royal residence as far back as 1257. In it Archibald, earl of Douglas, was imprisoned in 1429, and Queen Mary from June 16th 1567 to May 2d 1568. A short distance north-east of Kinross stands the ruined castle of Burleigh.

KINSALE, a parliamentary borough and seaport town of Ireland, in the county of Cork, is situated on the estuary of the Bandon, 24 miles south from Cork by rail. The town occupies chiefly the acclivity of Compass Hill, and, while possessing a striking and picturesque appearance, is built in a very irregular manner, the streets being narrow and so precipitous that in many instances conveyances have to take a very circuitous course. The principal buildings are the castle fort, completed by the duke of Ormonde at a cost of £70,000, and captured by the earl of Marlborough in 1690; the parish church, an ancient but inelegant structure erected as a conventual church about the 14th century; the assembly-rooms, the barracks, the Carmelite friary, and the convent of the sisters of mercy. Kinsale is much frequented by summer visitors, and is also an important fishery station, the number of boats employed in the division of which it is the principal port being about 350, employing over 1700 men and boys. It possesses also a commodious harbour, but the trade has become almost extinct owing to the proximity of Cork. The population in 1881 was 4976.

Kinsale is said to derive its name from *ccan taile*, the headland in the sea. At an early period the town belonged to the De Courceys, a representative of whom was created baron of Kinsale in 1181. It received a charter of incorporation from Edward III., having previously been a borough by prescription, and its privileges were confirmed and extended by various subsequent sovereigns. For several centuries previous to the Union it returned two members to parliament, but since then it has returned only one. It was the scene of an engagement between the French and English fleets in 1380, was forcibly entered by the English in 1488, was partly consumed by fire in 1594, was captured by the Spaniards and retaken by the English in 1601, was entered by the English in 1641, who expelled the Irish inhabitants, was the scene of the landing of James II. and of the French army sent to his assistance in 1689, and was taken by the English in the following year.

KIÔTO, KIYÔTO, MIAKO, or SAIKIO, the ancient sacred capital of Japan, is situated on the main island of the Japanese archipelago. It occupies the level bottom of a valley between the ridges Hujei-zan and Higushiyama on the east, and of Tenno-san on the west, and is so girt by the streams Kamogawa and Kalunagawa as to have an almost insular position. With Tôkiô, to the north-east, it is connected by two highways, the Tôkaidô, 307 miles long, and the Nakasendô, 323 miles long. To Ôzaka on the coast a railway line was opened in 1877. Kiôto is regularly and compactly built on the rectangular system, the immense number of Shintô and Buddhist shrines and temples being almost entirely beyond the city proper. The large suburb beyond the Kamogawa, which is crossed by many bridges, is the finest in respect of inns and temples. The houses, chiefly of wood, are small, and are further dwarfed by the great width of the streets. Tea-houses and pleasure-gardens abound, and the whole air of the city is pleasant. "With its schools, hospitals, lunatic asylum, prisons, dispensaries, alms-houses, fountains, public-parks, and gardens, exquisitely beautiful cemeteries, and streets of almost painful cleanliness, Kiyôto is the best-arranged and best-managed city in Japan."[1] The chief building is, of course, the imperial palace surrounded by beautiful gardens. Formerly forbidden to even most natives, it is now occupied as a museum of Japanese arts and manufactures. Among the other buildings are the former residences of the taikun and of the mikado's nobility, the various normal training and other schools for both sexes and all ages, the hospital, &c. Under the city government of Kiôto there was founded in 1870 an industrial department to foster the industries of the place. There are divisions for the encouragement of gardening, shoe-making, silk and other weaving, paper-making, leather-making, the manufacture of mineral waters, and many other branches of industry. Kiôto supports also a pauper colony. The silk-factories, though on a small scale, are numerous. Crape, bronze goods, and porcelain (largely for the English market) are also produced in the city. The population in 1870 was estimated at 370,000.

Kiôto is much the oldest of the three great cities of Japan, but both Tôkio and Ôzaka have far outstripped it in importance. In the reign of the emperor Kuwammu, towards the end of the 8th century, Nara was superseded as the capital by Kudzuno, afterwards called Kiôto, and sometimes Miako; and this last town became identified with the mikado, as Yedo was with the shôgun. It was the scene of the first contests of the Taira and Minumoto clans. In the 16th century Xavier preached in its streets; and in the 17th Kaempfer twice visited it. In 1864 a fierce contest, followed by a conflagration, resulted from an attack upon it by the Chôsiu clan and Kiheitai. After the revolution in 1869 the mikado and his court migrated to Yedo, thenceforth called Tôkio or eastern capital. Kiôto also received an alternative name,—Saikio, or western capital; but it is never used. Kiôto is not a treaty port; and foreigners are not allowed to reside in it unless they are in Japanese employ.

KIPPIS, Andrew (1725–1795), a learned and laborious compiler, was born at Nottingham, March 28, 1725. From school at Sleaford in Lincolnshire he passed at the age of sixteen to spend a five years' course in the Dissenting academy at Northampton, of which Dr Doddridge was then president. In 1746 Kippis became minister of a church at Boston; in 1750 he removed to Dorking in Surrey; and in 1753 he became pastor of a dissenting congregation at Westminster, where he remained till his death on 8th October 1795. Kippis took a prominent part in the affairs of the body with which he was connected. From 1763 till 1784 he was classical and philological tutor in Coward's training college; and when another institution of the same kind was opened at Hackney he was prevailed upon, somewhat against his will, to serve as tutor there for a few years. In 1767 he received the degree of D.D. from Edinburgh university; in 1778 he was elected a fellow of the Antiquarian Society, and a fellow of the Royal Society in 1779. He left a reputation for piety, learning, and active virtue.

Kippis was a very voluminous writer. He contributed largely to *The Gentleman's Magazine*, *The Monthly Review*, and *The Library*; and he had a good deal to do with the establishment and conduct of *The New Annual Register*. He published also a number of sermons and occasional pamphlets; and he prefixed a life of the author to a collected edition of Dr Nathaniel Lardner's *Works* (11 vols. 8vo, 1788). He wrote a life of Dr Doddridge, also, which is prefixed to Doddridge's *Exposition of the New Testament* (6 vols. 8vo, 1792). His chief work is his edition of the *Biographia Britannica*, of which, however, he only lived to publish 5 vols. (folio, 1778–1793). Many new lives were inserted, written for the most part by the editor himself; and extensive additions and corrections were made. These last were given in the form of footnotes to the original text,—a plan which often gives the work the air of a long controversy, and swelled it beyond reasonable bounds. As a monument of the painstaking erudition of the editor the work is interesting; and as a mere storehouse of facts it possesses a genuine value. Kippis's *Life and Voyages of Captain James Cook* was reprinted from this book, 4to, 1788. See notice by A. Rees, D.D., in *The New Annual Register* for 1795.

KIRBY, William (1759–1850), entomologist, was born at Witnesham in Suffolk, September 19, 1759. From the village school of Witnesham he passed to Ipswich grammar school, and thence to Caius College, Cambridge, where he graduated B.A. in 1781, not becoming M.A. till 1815. Taking orders in 1782, he spent his entire life in the peaceful seclusion of an English country parsonage, till 1796 as curate, afterwards as rector, of Barham in Suffolk. Although Kirby was once and again induced to use his pen against the spirit of free-thinking then reacting from France upon England, he had little taste for controversy. His favourite study was natural history; and eventually entomology engrossed all his leisure. His first work of importance was his *Monographia Apum Angliæ* (2 vols. 8vo, 1802), which as the first scientific treatise on its subject brought him into notice with the leading entomologists of his own and foreign countries. Latreille, Fabricius, Illiger, and Walckenaer were among his correspondents; and his opinion and advice were sought by many less illustrious. The practical result of a friendship formed in 1805 with Mr Spence, a scientific gentleman of Hull, was the jointly written *Introduction to Entomology* (4 vols. 8vo, 1815–26, 7th ed. 1856), one of the most popular books of science that have ever appeared, and still highly valuable. In 1830 Kirby was chosen to write one of the *Bridgewater Treatises*, his subject being *The History, Habits, and Instincts of Animals*. This, published in 2 vols. in 1835, undeniably fell short of his earlier works in point of scientific value. On July 4, 1850, William Kirby died, after a long life of piety, benevolence, and diligence. He was an original member of the Linnean Society; and his name was on the rolls of all the chief scientific associations in England and abroad.

Besides the books already mentioned, Kirby was the author of many papers in *The Transactions of the Linnean Society*, *The Zoological Journal*, and other periodicals; of *Strictures on Sir James Smith's Hypothesis respecting the Lilies of the Field of our Saviour and the Acanthus of Virgil*, 1819; of *Seven Sermons on our Lord's Temptations, &c.*, 1829; and of the sections on insects in the *Account of the Animals seen by the late Northern Expedition while within the Arctic Circle*, 1821, and in *Fauna Boreali-Americana*, 1837. The *Life of the Rev. William Kirby, M.A.*, by Rev. John Freeman, was published in 1852. It contains a list of Kirby's works.

KIRCHER, Athanasius (1602–1680), a learned scholar and accomplished mathematician, was born May 2, 1602, at Geisa near Fulda, was educated at the Jesuit college of Fulda, and entered upon his noviciate in that order at Mainz in 1618. After continuing his studies at Paderborn, Münster, Cologne, Coblenz, and Mainz, he became professor of philosophy, mathematics, and Oriental languages at Würzburg, whence he was driven (1631) by the troubles of the Thirty Years' War to Avignon. Through the influence of Cardinal Barberini he next (1635) settled in Rome, where for eight years he taught mathematics in the Collegio Romano, but ultimately resigned this appointment in order that he might devote the closing years of his life entirely to the study of hieroglyphics and other archæological subjects. He died November 28, 1680.

Kircher was a man of wide and varied learning, but singularly devoid of judgment and critical discernment. His voluminous writings in philology, natural history, physics, and mathematics often accordingly have a good deal of the historical interest which attaches to pioneering work, however imperfectly performed; otherwise they now take rank as curiosities of literature merely. They include *Ars Magnesia*, 1631; *Magnes, sive de arte magnetica opus tripartitum*, 1640; and *Magneticum naturæ regnum*, 1667; *Prodromus Coptus*, 1636; *Lingua Ægyptiaca restituta*, 1643: *Obeliscus*

[1] Miss Bird, *Unbeaten Tracks in Japan*, vol. ii. p. 252.

Pamphilius, 1650; and *Œdipus Ægyptiacus, hoc est universalis doctrinæ hieroglyphicæ instauratio*, 1652–55,—works which may claim the merit of having first called the attention of the learned to the Egyptian hieroglyphics; *Ars magna lucis et umbræ in mundo*, 1645–46; *Musurgia universalis, sive ars magna consoni et dissoni*, 1650; *Polygraphia, seu artificium linguarum quo cum omnibus mundi populis poterit quis respondere*, 1663; *Mundus subterraneus, quo subterrestris mundi opificium, universæ denique naturæ divitiæ, abditorum effectuum causæ demonstrantur*, 1665–78; *China illustrata*, 1667; *Ars magna sciendi*, 1669; and *Latium*, 1669, a work which may still be consulted with advantage. The *Specula Melitensis Encyclica* (1638) gives an account of what may be described as a kind of calculating machine of his invention. The valuable collection of antiquities which he bequeathed to the Collegio Romano has been described by Buonanni (*Musæum Kircherianum*, 1709; republished by Battara in 1773).

KIRCHHEIM-UNTER-TECK, chief town of a district in the Danube circle of Würtemberg, is prettily situated on the Lauter, not far from the Teck, and about 15 miles south-east of Stuttgart. Its castle was built in 1538. The manufactures include cotton goods, damask, pianofortes, machinery, lanterns, chemicals, cement, &c. The town also has wool-spinning establishments and breweries, and a corn exchange. It is the most important wool market in South Germany, the annual turn-over averaging about 1,650,000 ℔. The population in 1875 was 6197.

KIRGHIZ, a large and wide-spread division of the Mongolo-Tatar family, of which there are two main branches, the Kara-Kirghiz of the uplands and the Kirghiz-Kazaks of the steppe. To the same group belong the Kipchaks, forming a connecting link between the nomad and settled Turki peoples of Ferghana and Bokhara, and the Kara-Kalpaks on the south-east side of the Aral Sea, who are intermediate between the Kazaks and Uzbegs. The Kirghiz jointly number about 3,000,000, and occupy an area of perhaps the same number of square miles, stretching from Kulja westwards to the lower Volga, and from the head streams of the Ob southwards to the Pamir and the Turkoman country. In the Mongolo-Tatar family their position is peculiar, they being closely allied ethnically to the Mongolians and in speech to the Tatars. To understand this phenomenon, it should be remembered that both Mongols and Tatars belonged themselves originally to one racial stock, of which the former still remain the typical representatives, but from which the latter have mostly departed and become largely assimilated to the regular "Caucasian" type. But the Kirghiz have either remained nearly altogether unmixed, as in the uplands, or else have intermingled in the steppe mainly with the Volga Calmucks in the west, and with the Zungarian nomads in the east, all alike of Mongol stock. Hence they have everywhere to a large extent preserved the common Mongolian features, while retaining their primitive Tatar speech. Physically they are a middle-sized, square-built race, inclined to stoutness, especially in the steppe, mostly with long black hair, scant beard or none, small, black, and oblique eyes, though blue or grey also occur in the south, broad Mongoloid features, high cheek bones, broad, flat nose, small mouth, brachycephalous head, very small hands and feet, dirty brown or swarthy complexion, often yellowish, but also occasionally fair. These characteristics, while affiliating them directly to the Mongol stock, also betray an admixture of foreign elements, probably due to Finnish or Chudic influences in the north, and Tajik or Iranian blood in the south. Their speech also, while purely Turkic in structure, possesses, not only many Mongolian and a few Persian and even Arabic words, but also some terms unknown to the other branches of the Mongolo-Tatar linguistic family, and which should perhaps be traced to the Kiang-Kuan, Wu-sun, Ting-ling, and other extinct Chudic peoples of South Siberia partly absorbed by them These relations to the surrounding Asiatic races will be made clearer in the subjoined detailed account of the Kara-Kirghiz and Kirghiz-Kazaks.

The Kara-Kirghiz.—The Kara or "Black" Kirghiz, so called from the colour of their tents, are known to the Russians either as Chernyie ("Black") or Dikokammenyie ("Wild Stone" or "Rocky") Kirghiz, and are the Block Kirghiz of some English writers. They are on the whole the purest and best representatives of the race, and so true is this that, properly speaking, to them alone belongs the distinctive national name Kirghiz or Krghiz. This term is commonly traced to a legendary chief, Kirghiz, sprung of Oghuz-Khan, ninth in descent from Japhet. It occurs in its present form for the first time in the account of the embassy sent in 569 by Justin II. to the Uighur Khan, Dugla-Ditubulu, where it is stated that this prince presented a slave of the "Kerghiz" tribe to Zemark, head of the mission. In the Chinese chronicles the word assumes the form Ki-li-ki-tz', and the writers of the Yuan dynasty (1280–1367) place the territory of these people 10,000 li north-west of Pekin, about the head streams of the Yenisei. In the records of the Thang dynasty (618–907) they are spoken of under the name of Kha-kia-tz' (pronounced Khaka, and sometimes transliterated Haka), and it is mentioned that these Khakas were of the same speech as the Khoei-khu. From this it follows that they were of Mongolo-Tatar stock, and are wrongly identified by some ethnologists with the Kiang-Kuan, Wu-sun, or Ting-ling, all of whom are described as tall, with red hair, "green" or grey eyes, and fair complexion, and must therefore have been of Finnish stock, akin to the present Soyotes of the upper Yenisei.

The Kara-Kirghiz are by the Chinese and Mongolians called *Burut*, where *ut* is the Mongolian plural ending, as in Tangut, Yakut, modified to *yat* in Buryat, the collective name of the Siberian Mongolians of the Baikal district. Thus the term *Bur* is the common Mongolian designation both of the Baikal Mongols and of the Kara-Kirghiz, who occupied this very region and the upper Yenisei valley generally till comparatively recent times. For the original home of their ancestors, the Khakas, lay in the south of the present governments of Yeniseisk and Tomsk, stretching thence southwards beyond the Sayan range to the Tannu-ola hills in Chinese territory. Here the Russians first met them in the 17th century, and by the aid of the Kazaks exterminated all those east of the Irtish, driving the rest further west and south-westwards. Most of them took refuge with their kinsmen, the Kara-Kirghiz nomad highlanders, whose homes, at least since the 13th century, have been the Ala-tau range, the Issik-kul basin, the Tekes, Chu, and Talass river valleys, the Tian-shan range, the uplands draining both to the Tarim and to the Jaxartes and Oxus, including Khokand, Karategin, and Shignan southwards to the Pamir table-land, visited by them in summer. They thus occupy most of the uplands along the Russo-Chinese frontier, between 35° and 50° N. lat. and between 70° and 85° E. long., where they have been recently joined by some Chiliks, Kipchaks, Naimans, and Kitars from Andijan and the Kazak steppes.

The Kara-Kirghiz are all grouped in two main sections—the On or "Right" in the east, with seven branches (Bogu, Sary-Bagishch, Son-Bagishch, Sultu or Solye, Cherik, Sayak, Bassinz), and the Sol or "Left" in the west, with four branches (Kokche or Kuchy, Soru, Mundus, Kitai or Kintai). The Sol section occupies the region between the Talass and Oxus head streams in Ferghana (Khokand) and Bokhara, where they come in contact with the Galchas or Highland Tajiks. The On section lies on both sides of the Tian-shan, about Lake Issik-kul, and in the Chu, Tekes, and Narin (upper Jaxartes) valleys.

Each of the On tribes comprises a number of stocks or septs, which are further divided into auls or families, of which, however, the lists are complete for the Bogu and Sary-Bagishch alone. Of the Bogu there are six stocks, with 11,000 tents, and numbering 55,000 to 60,000 souls. Of the Sary-Bagishch there are four stocks, with 16,500 tents, or 80,000 to 90,000 souls. The Sayak numbers 10,000 tents, or about 50,000 souls, making a total of 200,000 in Russian territory. The Sol section, with the independent On tribes, are roughly estimated at about 200,000, making 400,000 Kara-Kirghiz altogether.

All are essentially nomads, occupied mainly with stock breeding, chiefly horses of a small but hardy breed, sheep of the fat-tailed species, oxen used both for riding and as pack animals, some goats, and camels of both species. Agriculture is limited chiefly to the cultivation of wheat, barley, and millet, from the last of which a coarse vodka or brandy is distilled. Trade is carried on chiefly by barter, cattle being taken by the dealers from China, Turkestan, and Russia in exchange for manufactured goods.

The Kara-Kirghiz are governed by the "manaps," or tribal rulers, who enjoy almost unlimited authority, and may even sell or kill their subjects. In religious matters they differ little from the Kazaks, whose practices are described below. Although generally recognizing Russian sovereignty since 1864, they pay no taxes, and merely furnish certain raw products to the Russian troops on their passage through the country.

The Kazaks.—Though not unknown to them, the term Kirghiz is never used by the steppe nomads, who always call themselves simply Kazaks, that is, "riders," as the word is commonly interpreted. The first authentic reference to this name is by Firdousi (1020), who speaks of the Kazak tribes as much dreaded steppe marauders, all mounted and armed with lances. From this circumstance the term Kazak came to be gradually applied to all freebooters similarly equipped, and it thus spread from the Aralo-Caspian basin to South Russia, where it still survives under the form of "Kossak." Hence though Kazak and Cossack are originally the same word, the former now designates a Mongolo-Tatar nomad race, the latter various members of the Great and Little Russian Slav family. No satisfactory explanation of its origin has been given. Since the 18th century the Russians have used the compound expression Kirghiz-Kazak, chiefly in order to distinguish them from their own Cossacks, at that time overrunning Siberia. Herbertstein (1520) is the first European who mentions them by name, and it is noteworthy that he speaks of them as "Tartars," that is, a people rather of Turki than Mongolian stock. In their present homes, the so-called "Kirghiz steppes," they are far more numerous and wide-spread than their Kara-Kirghiz kinsmen, stretching almost uninterruptedly from Lake Balkash round the Aral and Caspian Seas westwards to the lower Volga, and from the river Irtish southwards to the lower Oxus and Ust-Urt plateau. Their domain, which is nearly 2,000,000 square miles in extent, thus lies mainly between 45° and 55° N. lat. and from 45° to 80° E. long. Here they came under the sway of Jenghiz Khan, after whose death they fell to the share of his son Juchi, head of the Golden Horde, but continued to retain their own khans. When the Usbegs acquired the ascendency, many of the former subjects of the Juchi and Jagatai hordes fell off and joined the Kazaks. Thus were formed about 1500 two powerful states in the Kipchak and Cheteh steppes, the Moghul-Uluss and the Kazak, the latter of whom, under their khan Arslane, are said by Sultan Baber to have had as many as 400,000 fighting men. Their numbers continued to be swollen by voluntary or enforced accessions from the fragments of the Golden Horde, such as the Kipchaks, Naimans, Konrats, Jalairs, Kankly, whose names are still preserved in the tribal divisions of the Kazaks. And as some of these peoples were undoubtedly of true Mongolian stock, their names have given a colour to the statement that all the Kazaks were rather of Mongol than of Turki origin. But the universal prevalence of a nearly pure variety of the Turki speech throughout the Kazak steppes is almost alone sufficient to show that the Tatar element must at all times have been in the ascendant.

The Kirghiz-Kazaks have long been grouped in three large "hordes" or encampments, further subdivided into a number of so-called "races," which are again grouped in tribes, and these in sections, branches, and auls, or communities of from five to fifteen tents. The division into hordes has been traditionally referred to a powerful khan, who divided his states amongst his three sons, the eldest of whom became the founder of the Ulu-Yuz, or Great Horde, the second of the Urta-Yuz, or Middle Horde, and the third of the Kachi-Yuz, or Little Horde. The last two under their common khan Abulkhair voluntarily submitted in 1730 to the czarina Anne. Most of the Great Horde were subdued by Yunus, khan of Ferghana, in 1798, and all the still independent tribes finally accepted Russian sovereignty in 1819. The races, range, and numerical strength of these hordes are shown in the following table:—

Races.	Range.	Tents.	Souls.
GREAT HORDE.—*Uisiûn, Tulatai, Sargan, Konrat.*	Chiefly south of Lake Balkash and near the Tian-Shan; between Semipalatinsk and Semiryechensk.	85,000	450.000
MIDDLE HORDE.—*Arghyne, Naiman, Kipchak, Uvak-Ghirei.*	Chiefly on the low hilly watershed between the Ob and Aralo-Caspian basins, from Aral Sea to Lake Balkash; governments of Semipalatinsk and Akmolinsk, West Siberia.	175,000	1,100,000
LITTLE HORDE.—*Alimuly, Baiuly, Jetiruug.*	From Kara-Kum desert to lower Volga, north of Aral Sea, and in governments of Orenburg, Uralsk, Turgay, and Astrakhan.	170,000	1,000,000

Since 1801 a fourth division, known as the Inner or Bukeyevskaya Horde, from the name of their first khan, Bukei, has been settled in the Orenburg steppe. It is estimated at 40,000 tents or 200,000 souls, giving for all the Kazaks 470,000 tents and 2,750,000 souls.

But these divisions affect the common people alone, all the higher orders and ruling families being broadly classed as White and Black Kost or Bones. The White Bones comprise only the khans and their descendants, besides the issue of the khojas or Moslem "saints." The Black Bones include all the rest, except the *Telengut* or servants of the khans, and the *Kûl* or slaves.

The Kazaks are an honest and trustworthy people, but heavy, sluggish, sullen, and unfriendly. Even the hospitality enjoined by the Koran is displayed only towards the "faithful," that is, exclusively to the members of the orthodox Sunnite sect. So essentially nomadic are all the tribes that they cannot adopt a settled life without losing the very sentiment of their nationality, and becoming rapidly absorbed in the Slav population. They dwell exclusively in the kibitka or yurt, a semi-circular tent consisting of a light wooden framework, and red cloth or felt covering, with an opening above for light and ventilation. It is usually furnished with a large family clothes chest, felt carpet, wooden bedstead, leather bottles for kumis (fermented mare's milk), a tea service, and a few domestic utensils. Yet it may easily be pitched or struck in half an hour, and is rapidly transported on camels across the steppe. The camp life of the Kazaks seems almost unendurable to Europeans in winter, when they are confined altogether to the tent, and exposed to endless discomforts. In summer the day is spent mostly in sleep or drinking kumis, followed at night by feasting and the recital of tales, varied with songs accompanied by the music of the flute and balalaika. But horsemanship is the great amusement of all true Kazaks, who may almost be said to be born in the saddle. Hence, though excellent riders, they are bad walkers, and, though hardy and long-lived, uncleanly in their habits and often decimated by small-pox and Siberian plague. They have no fixed meals, and live mainly on mutton and goat and horse flesh, and instead of bread use the so-called balamyk, a mess of flour fried in dripping and diluted in water. The universal drink is kumis, which is wholesome, nourishing, and a specific against all chest diseases.

The dress consists of the chapân, a flowing robe of which one or two are worn in summer and several in winter, fastened with a silk or leather girdle, in which are stuck a knife, tobacco pouch, seal, and a few other trinkets. Broad silk or cloth pantaloons are often worn over the chapân, which is of velvet, silk, cotton, or felt, according to the rank of the wearer. Large black or red leather boots, with round white felt pointed caps, complete the costume, which is much the same for both sexes.

Like the Kara-Kirghiz, the Kazaks are nominally Sunnites, but Shamanists at heart, worshipping, besides the Kudai or good divinity, the Shaitan or bad spirit. Their faith is strong in the *talchi* or soothsayer and other charlatans, who know everything, can do everything, and heal all disorders at pleasure. But they are not fanatics, though holding the abstract doctrine that the "Kafir" may be lawfully oppressed, including in this category, not only Buddhists and Christians, but even Mohammedans of the Shiah sect. There are no fasts or ablutions, mosques or mollahs, or regular prayers. Although Mussulmans since the beginning of the 16th century, they have scarcely yet found their way to Mecca, their pilgrims visiting instead the more convenient shrines of the "saints" scattered over eastern Turkestan. Unlike the Mongolians, the Kazaks treat their dead with great respect, and the low steppe hills are often entirely covered with monuments raised above their graves.

Letters are neglected to such an extent that whoever can merely write is regarded as a savant, while he becomes a prodigy of learning if able to read the Koran in the original. Yet the Kazaks are naturally both musical and poetical, and possess a considerable number of national songs, which are usually repeated with variations from mouth to mouth.

The Kazaks still choose their own khans, who, though confirmed by the Russian Government, possess little authority beyond their respective tribes. The real rulers are the elders or umpires and sultans, all appointed by public election. Brigandage and the *barantas* or raids arising out of tribal feuds, which were formerly recognized institutions, are now severely punished, sometimes even with death. Capital punishment, usually by hanging or strangling, is inflicted for murder and adultery, while three, nine, or twenty-seven times the value of the stolen property is exacted for theft.

The domestic animals, daily pursuits, and industries of the Kazaks differ but slightly from those of the Kara-Kirghiz. Some of the wealthy steppe nomads own as many as 20,000 of the large fat-tailed sheep. Goats are kept chiefly as guides for these flocks; and the horses, though small, are hardy, swift, light-footed, and capable of covering from 50 to 60 miles at a stretch. The total live-stock was thus estimated in 1872 by Tillo:—camels, 120,000; horses, 1,720,000; oxen, 600,000; sheep, 2,000,000; goats, 180,000. Amongst the Kazaks there are a few workers in silver, copper, and iron, the chief arts besides being skin dressing, wool spinning and dyeing, carpet and felt weaving. Trade is confined mainly to an exchange of live stock for woven and other goods from Russia, China, and Turkestan.

Since their subjection to Russia, the Kazaks have become less lawless, but scarcely less nomadic. A change of habit in this respect is opposed alike to their tastes and to the climatic and other outward conditions. Hence the progress of culture can here lead only to the depopulation of the steppe wherever incapable of being irrigated, and to the gradual extinction or absorption of the Kirghiz-Kazaks by their Slav rulers.

Literature.—Alexis Levshin, *Description des Hordes et des Steppes des Kirghiz-Kazaks*, translated from the Russian by Ferry de Cigny, 1840; Radloff, *Proben der Volksliteratur der Türkischen Stämme Südsiberiens*; Ch. de Ujfalvy, *Le Kohistan, le Ferghanah, et Kouldja*; also *Bul. de la Soc. de Géo.*, 1878–79; Semenoff, paper in Petermann's *Mittheilungen*, 1859, No. 3; Valikhanov's *Travels in* 1858–59; Madame de Ujfalvy, papers in *Tour du Monde*, 1874; Vambéry, *Die primitive Cultur des Turko-Tatarischen Volkes.* (A. H. K.)

KIRIN, GIRIN, or in Chinese CHWEN-CHANG, the chief town of the province of Central Manchuria or Kirin, is situated at the foot of the Lau-Ye-Ling mountains, at the edge of a wide and well-wooded plain, and on the left bank of the Girin-ula or Sungari, there 300 yards in breadth. The situation is one of exceptional beauty; but the streets are narrow and irregular. Tobacco is the principal article of trade, the kind grown in the province being greatly prized throughout the Chinese empire under the name of "Manchu leaf." Formerly ginseng was also an important staple, but the supply from this quarter of the country has been exhausted. Outside of the town lies a plain "thickly covered with open coffins containing the dead bodies of Chinese emigrants exposed for identification and removal by their friends; if no claim is made during ten years the remains are buried on the spot." Kirin was chosen by the emperor Kanghi as a military post during the wars with the Eleuts; and it owes its Chinese name of Chwen-chang, *i.e.*, Naval Yard, to his building there the vessels for the transport of his troops. The population was estimated at 300,000 in 1812; at present it is about 120,000.

See Palladius, "Expedition through Manchuria," in *Journ. Roy. Geog. Soc.*, 1872; Williamson, *Journeys in North China.*

KIRKCALDY, a royal and parliamentary burgh and seaport on the south-east coast of Fifeshire, Scotland, 12 miles north from Edinburgh. The chief topographical feature of the town is its length, which is nearly 4 miles within the municipal boundary, as extended by Act of Parliament in 1876. Formerly there was little besides one main street with lanes and shorter streets branching from it, but during the last five-and-twenty years a large number of new streets and villas have been built along the high ground to the north. The parish, however, is a very small one, the landward part (now Abbotshall) having been disjoined in 1650. In population and most other statistical respects Kirkcaldy is the principal town in the county, and the tenth in Scotland, ranking next after Perth and Kilmarnock. The valuation of the burgh in 1881, including railways, was £87,622, and the census of the same year showed a population of 23,632. Besides some importations of flax, timber, whiting, &c., the chief regular trade of the port is that carried on by means of coasting vessels with Leith, Glasgow, and London. The annual harbour revenue is about £2000, and that of the custom-house £52,000.

The linen manufacture, begun in the early part of the 18th century, has long been the staple industry, the town being one of the chief centres of the trade in Scotland. The spinning of flax by machinery was introduced into the district in 1792, and in 1807 steam was added as a motive power. At present there are six mills with 18,830 spindles, employing when in full operation about 1450 persons. There is also an extensive net factory. Twelve power-loom factories, with an aggregate of 2100 looms, broad and narrow, employ fully that number of operatives. In these, as in the spinning mills, a large proportion of the workers, about 80 per cent., are females. Hand-loom weaving has almost entirely disappeared. The principal fabrics manufactured are sheetings, ticks, hollands, towellings, diapers, dowlas, &c.; and one or two firms are now making cotton goods to some extent. There are three bleachfields, with 180 workpeople. Next in importance to the various branches of the linen manufacture are the floor-cloth works. First introduced by the late Mr Michael Nairn, the production of floor-cloth at Kirkcaldy has for some years been the largest in the world. There are six factories employing about 930 workpeople. The linoleum manufacture has also been successfully established. In 1877 the Messrs Nairn built the first factory in Scotland for this branch of industry, and its success has resulted in the formation of other two companies. The three firms employ an aggregate of nearly 450 hands. A large amount of machinery, including steam-engines, boilers, sugar-mills, rice-mills, and the like, is also manufactured in Kirkcaldy. There are eight works in operation, several of them extensive, and about 800 men and lads are employed. Among miscellaneous works may be noted two potteries (one of them including a tile-work with 400 operatives), malting barns, flour-mills, several dye-works, a brewery, and a large printing and lithographic business.

The educational, ecclesiastical, and literary institutions of Kirkcaldy are numerous. There are seven public schools, with 3490 children on the roll, and nearly as many private and ladies' schools, with about 350 in attendance. In addition there are three schools belonging to Philp's trust, at which 500 children receive gratuitous education and clothing; the revenue of the trust for the purposes of these three schools was £2115 in 1880. There are twenty-six churches,—the finest architecturally being St Brycedale Free church. The town has two public libraries, one of them with nearly 10,000 volumes; and there are three weekly newspapers.

For much of its recent prosperity Kirkcaldy is indebted to the water scheme, for which an Act was obtained in 1867, and an Amendment Act in 1870. The sum authorized to be expended by these bills was £53,000, but an Extension Act was passed in 1881 giving power to raise £40,000 additional when required. An extensive system of drainage is also in process. A sheriff-substitute has recently been appointed for the Kirkcaldy district.

Kirkcaldy, with Dysart, Kinghorn, and Burntisland, returns one member to parliament.

An *Ecclesia de Kirkcaldie* is mentioned in the list printed by Sibbald of the churches in the county of Fife in the year 1176. In 1240 it was bestowed by David, bishop of St Andrews, on the abbey of Dunfermline. The name of Kirkcaldy also occurs in the map of the civil divisions of Scotland in the 13th century prefixed to Professor Cosmo Innes's *Scotland in the Middle Ages.* In 1334 the town, with its harbour, was given by David II. to the abbey of Dunfermline, and in 1450 it was "disponed" by Richard, abbot of Dunfermline, to the bailies and council of Kirkcaldy.

The commerce of the place has suffered many fluctuations. In 1573, as we learn from the *Register of the Privy Council*, the district of Kirkcaldy had the largest manufacture of salt in Scotland, and about 1650 it was assessed as the sixth town in the kingdom. About 1644 there were one hundred ships belonging to the port, in 1760 only three, in 1792 the number had risen to twenty-nine, and in 1843 to ninety-one. Since then, chiefly owing to the abandonment of the whale-fishing, and the insufficiency of the harbour to admit large vessels, the trade of the port has considerably declined. The number of vessels belonging to it may be stated at twenty-seven. A considerable extension of the present harbour is among the possibilities of the future.

Adam Smith, whose great work *The Wealth of Nations* formed an era in the history of political economy; James Oswald of Dunnikier, a schoolfellow of Adam Smith, and a statesman of much promise; George Gillespie, a leading member of the Westminster Assembly; and Balnaves of Halhill, a lord of session in the time of Queen Mary, were natives of Kirkcaldy. Michael Scot, of wizard fame, was born about a mile from the burgh boundary. (T. H.)

KIRKCUDBRIGHT, a maritime county of Scotland, known as the "Stewartry of Kirkcudbright," and also as East Galloway, is situated between 54° 43′ and 55° 19′ N. lat., and between 3° 33′ and 4° 34′ W. long., and is bounded on the N. and N.W. by Ayr, E. and N.E. by Dumfries, S. by the Solway Firth and the Irish Sea, and W. by Wigtownshire and Wigtown Bay. Its extreme length from north-west to south-east is about 45 miles, and its breadth varies from 21 to 31 miles. The total area comprises 610,343 acres, or about 954 square miles.

The larger half of the county in the north-west direction consists of a rugged and mountainous table-land, with lofty summits of every variety of aspect, intersected often by deep glens. The scenery of this region is for the most part wild and bleak, its solitary desolation being heightened by the presence of many small lochs and tarns, but almost totally unrelieved by a single tree or shrub, although the peat deposits give evidence that the district was at one time covered by an extensive forest. The most elevated regions are generally covered with heath, but at the northern boundary there is a range of grassy hills. Many of the mountains have an elevation of over 2000 feet, the highest summits being Mearroch (2762 feet) in the parish of Minnigaff, and Corserine (2668), Carlin's Cairn (2650), and Cairnsmure in Carsphairn (2612)—all in the parish of Carsphairn. The south-eastern half of the county is for the most part level but undulating, its uniformity being broken by frequent rocky knolls or small rounded hills, and in the south-eastern corner rising into several elevated summits, the highest of which is Criffel, 1867 feet. The greater part of this district is finely wooded, and abounds in picturesque scenery, especially towards the sea-coast and in the neighbourhood of the rivers and numerous lochs. The southern coast is usually bold and rocky, and is much indented by the estuaries of various rivers, which form a number of natural harbours. Owing to the shallowness of the sea-bed, large stretches of sand are exposed in the Solway Firth at ebbtide, and the rapid flow of the tide has often occasioned loss of life to the unwary.

Geology.—Geologically Kirkcudbright forms part of the Silurian belt of the south of Scotland, but this formation is interrupted in the county by several upheavals of granite, one in the north-west south of Loch Doon, another near the centre immediately west of Loch Ken, and a third round Criffel on the shores of the Solway Firth. The lofty table-land is supposed to have been at one time the seat of an immense ice-bed (see paper by W. Jolly, in *Trans. Edin. Geol. Soc.*, 1868), whose action has doubtless in part created the isolated round-backed ridges of granite in the valley of the Urr, the finest example in Scotland of the *Roches moutonnées*, which constitute a peculiar feature in alpine scenery (A. Somervail in *Trans. Edin. Geol. Soc.*, 1879). A more striking result of the glacial action was the dispersion of Kirkcudbrightshire granite to Cumberland, to North Wales, and even so far south as the neighbourhood of Wolverhampton (D. Mackintosh in *Quart. Journ. Geol. Soc.*, 1879). The Silurian strata are for the most part of a slaty character, but in some places are composed of a species of red sandstone. Especially in the neighbourhood of the granite the strata are very much contorted, and give evidence of having at one time been subjected to the action of immense heat. The granite is principally of a pale grey resembling that of Aberdeen, but a red variety also occurs. The principal quarries are at Dalbeattie and Creetown. Strata of lead are believed to stretch between Minnigaff and the Leadhills in Dumfriesshire, but the metal is very little worked. Iron ore exists in different parts of the county, but from the absence of coal is almost wholly unutilized. Copper and barytes are also found, especially in the parish of Urr. Marl is obtained in large quantities from a number of the lochs.

Rivers.—The Nith, which rises in Ayrshire and flows through Dumfriesshire, forms for about 12 miles the boundary between Dumfries and Kirkcudbright, an equal distance of boundary to the north-west being formed by its tributary the Cluden water. The Urr, which rises in Loch Urr on the borders of Dumfriesshire, flows south-eastward by Dalbeattie to the Solway Firth, where it forms a small bay. The Ken rises in Dumfriesshire, and after being joined from the west by the Deugh water flows south-east into Loch Ken, the stream that issues from the loch taking the name of the Dee, and after a beautiful course south-westwards falling into the Solway Firth. The Fleet, which rises in Loch Fleet, after a course of about 7 miles, falls into Wigtown Bay, where it forms an estuary. The Cree, which has its origin in two streams in Ayrshire, and forms the boundary of Kirkcudbright with Ayrshire and afterwards with Wigtownshire, flows south-east by Minnigaff and Newton Stewart, and falls into Wigtown Bay at Creetown.

Agriculture.—A considerable proportion of the land in the higher regions of Kirkcudbright is unsuitable for tillage, and yields a very small return as pasturage. In many cases also the soil is very marshy. In the lower regions it is generally dry but rocky. Much has been done of late years to increase the value of the land by draining the swamps, by the removal of stones, and by deepening the soil and enriching it with manures. Generally the climate and soil are not adapted for the rearing of grain, but are specially suited for grass and green crops.

According to the agricultural returns for 1881 the area under crops was 179,237 acres, or 29 per cent. of the whole area. The area under corn crops was 32,349 acres; under green crops, 18,091; under rotation grasses, 71,091; under permanent pasture, 57,471 acres. The area under woods was 19,741 acres. The system of cropping is generally as follows:—first year, in breaking up fro-pasture, oarley or more generally oats; second year, green crop; third year, wheat, oats, or barley; fourth year, hay or pasture, which is generally continued for three additional years. It is now becoming a very common practice to sow out in grass after turnips without taking a corn crop, the soil being also frequently allowed the advantage of the manure of the sheep which have eaten the turnips on the ground. Of corn nearly the whole area is under oats, which in 1881 occupied 31,061 acres, while only 933 were under barley and bere, and 146 under wheat. Of green crops the area under turnips and swedes in 1881 was 14,596 acres, under potatoes 2847, mangolds 91, carrots 38, cabbage, kohl-rabi, and rape 402, and vetches 117.

The total number of horses in 1881 was 5395. Of these 3789 are stated to be used solely for agricultural purposes, and 1606 to be unbroken horses and mares kept solely for breeding. The breeding of Clydesdale horses has of late years been increasing. Cattle in 1881 numbered 40,737 The Ayrshire breed of cattle was introduced into Galloway about the beginning of the century, and has risen rapidly in favour, being now the principal stock in West Galloway. Polled or Galloway cattle is a common breed in East Galloway, especially on inferior farms, and is still preferred for dairy purposes on many low country farms. The number of cows in 1881 was 12,071, of other cattle above two years of age 14,002, and of cattle under two years of age 14,664. The number of cattle to every 100 acres under cultivation was 22·8, the average for Scotland being 23. Within recent years the increase in the number of cows has been very great, cheese-making, in which much progress has been made, now occupying the chief attention of the farmer. Cattle feeding is also largely practised, and for this purpose large quantities of lean cattle are imported from Ireland. Sheep in 1881 numbered 362,289, an average of 202·1 to every 100 acres under cultivation, the average for Scotland being 141·3. Blackfaced sheep are the most common on the high grounds, and even on the lower parts the Cheviot breed is decreasing owing to the low price of wool. In some districts crosses of a Leicester tup with a blackfaced or Cheviot ewe are common. Pigs, which are kept principally on dairy farms, are generally fed on whey and Indian corn. In 1881 they numbered 5667.

The following table gives a classificatiou of holdings according to size in 1875 and 1880:—

	50 Acres and under.		From 50 to 100 Acres.		From 100 to 300 Acres.		From 300 to 500 Acres.		From 500 to 1000 Acres.		Above 1000 Acres.		Total.	
	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.	No.	Acres.
1875	761	11,377	265	19,874	416	75,218	113	43,049	29	18,453	1	2,014	1,585	169,985
1880	775	11,458	254	19,481	451	82,601	120	45,699	25	15,844	1	2,022	1,696	177,105

In 1872-73 the land was divided among 2386 proprietors, and amounted to 571,950 acres, with a gross annual value of £360,960. Of the owners 1908, or 79 per cent., possessed less than 1 acre, and the average value was 12s. 8d. per acre. There were three proprietors who possessed upwards of 40,000 acres, viz., the earl of Galloway, 55,981; H. G. Murray Stewart, 45,367; and William Forbes, 40,445. Other eight possessed upwards of 10,000 acres.

Manufactures.—The principal ports are Kirkcudbright, Creetown, and Gatehouse. Linen, woollen, and cotton goods are manufactured in the towns and villages, and there are also breweries, distilleries, tanneries, and paper-mills. Shipbuilding is carried on to a small extent at Kirkcudbright. Lead is obtained at Woodhead and Minnigaff; there are extensive granite works at Dalbeattie and Creetown; and at Dalbeattie there are brick and tile works. Deep-sea fishing is prosecuted in the Solway, and salmon fisheries at the mouths of the rivers.

Railways.—A line from Dumfries to Castle Douglas is continued by Gatehouse and Creetown to Newton Stewart, and a branch line runs south from Castle Douglas to Kirkcudbright.

Administration.—The county includes twenty-eight parishes. Quarter sessions are held on the first Tuesday of March, May, and August, and the last Tuesday of October; and justice of peace small debt courts are held at Kirkcudbright, New Galloway, Castle Douglas, Maxwelltown, Gatehouse of Fleet, and Creebridge. The county forms a portion of the sheriffdom of Dumfries and Galloway. A sheriff court is held twice a week. A sheriff circuit small debt court is held at Castle Douglas, Maxwelltown, New Galloway, and Creetown, and a small debt court for the whole stewartry at Kirkcudbright. The county returns one member to parliament, and the burgh of Kirkcudbright unites with Annan, Dumfries, and Lochmaben in returning another, New Galloway uniting with Wigtown, Stranraer, and Whithorn in returning a third, while Maxwelltown, a portion of which is in the county, forms part of the burgh of Dumfries.

Population.—From 29,211 in 1801 the population gradually increased till it was 43,121 in 1851. Since then it decreased in 1861 to 42,495 and in 1871 to 41,859, but in 1881 it was 42,126, of whom 19,796 were males and 22,330 females. None of the towns exceed 3000 in population. Kirkcudbright, a royal and parliamentary burgh, has a population of 2571. New Galloway, Maxwelltown, Castle Douglas, Dalbeattie, and Gatehouse are police burghs. The principal villages are Auchencairn, Creetown, Crossmichael, Dalry, Haugh of Urr, Kirkpatrick-Durham, and New Abbey.

History and Antiquities.—Anciently Kirkcudbrightshire formed part of the kingdom of Strathclyde, being occupied partly by the Novantæ, who held the whole of Galloway westward from the Dee, and partly by the Selgovæ, whose territory stretched eastward from the Dee to Northumbria. One of the towns of the Selgovæ, Carbantorigum, in all probability occupied the site of the stronghold called the Moat of Urr. In 79 B.C. Agricola landed on the shores of the Solway Firth and overran Strathclyde, but the district was not completely subjugated by the Romans till the building of the wall of Severus in 208. Many traces of Roman camps are still to be seen, and a very perfect one exists at Pulcree in the parish of Anwoth. Some suppose that the important indications of human occupation in the caves on the coast were due to the fact that some of the inhabitants betook themselves to these during the Roman occupation (see "Accounts of the Exploration of the Borness Cave" in *Proc. Soc. Antiq. Scot.*, 1874, 1875, 1877). The Pictish tribe which, according to Bede, inhabited Galloway in 608, is supposed by Skene to have been the original *Novantæ*,—a tribe, he thinks, of Gaedel or Gaelic Fichts who retained their independence because of the isolated position of the country. In the 7th century the region was invaded by the Angles, but their rule over it ceased about the end of the 8th century. In 740 Alpin, king of the Scots of Dalraida, was slain in battle, probably near the site of the present town of Kirkcudbright. The name Galloway, by which the country occupied by Kirkcudbright and Wigtownshire is now known, seems first to have been applied to it while it formed part of the Anglian kingdom of Northumbria, the word Galwetha being formed from Galwyddel the Welsh equivalent of Gallgaidhel, the word meaning the Gaels under the dominion of foreigners. Of the ancient inhabitants of Galloway there are in Kirkcudbrightshire a large number of relics. In several of the lochs crannogs or lake dwellings as well as canoes and a variety of implements and other remains have been found. Druidical circles are very common, and among the numerous cairns may be mentioned that of Drumlawhinnie on the moor of Barclay in Minnigaff parish, which is 891 feet in circumference. Of the Pictish kilns there are several specimens in the parish of Minnigaff and in other places. The most notable old forts are a very ancient one on a sea-cliff near Borgue, an old Pictish tower at Rattra in the same parish, a circular fort with vitrified walls at Castle Gower, parish of Buittle, and others on the hill of Halfarne, Crossmichael, the hill of Dunguile, Kelton, and on Benarty hill. An old wall known as the Devil's dyke, supposed to have been built previous to the Roman invasion, passed through Galloway from Lochryan into Dumfriesshire. In the 9th century the district was invaded by the Danes, and so much harassed that many of the inhabitants emigrated to Wales. In the following century Galloway along with Strathclyde was subdued by Edmund and brought under the rule of Malcolm I. of Scotland. Some time in the 11th century it was subdued by the Danes and the Norwegians, but in the beginning of the 12th century they were overpowered by a Celtic chief Fergus, who founded a line of lords of Galloway, some of whom asserted their independence of the Scotch crown. The line became extinct in the male branch in 1234, after which Galloway was for some time under the rule of Edward I. of England. The lordship in the female line became divided between two families, one of whose representatives, John Baliol, laid claim to the crown of Scotland, but in 1308 the district was freed of the English and brought under allegiance to Robert Bruce, after which the lordship of Galloway was conferred upon Edward Bruce. Later in the 14th century Galloway again espoused the pretensions of the Baliols to the throne of Scotland, but the district was finally completely subjugated in 1353 by Sir William Douglas, whose descendant Archibald received from the crown in 1371–72 the lordship of Galloway. After the forfeiture of the estates of the Baliols, Kirkcudbright was placed under the immediate rule of the crown, and was governed by the royal steward, whence it has still the name of the "stewartry," but it appears that the stewardship was afterwards transferred to the Douglases, and was not restored to the crown until the forfeiture of their estates in 1455.

The principal old castles are Threave Castle on the Dee, the seat of the Douglases, for the reduction of which during the siege of 1455 it is said that the famous cannon Mons Meg was manufactured; Cardross Castle, on the west side of the Fleet; and the castle of Kirkcudbright, which belonged to the lords of Galloway, and was frequently the residence of royalty.

The principal monastic buildings were the Cistercian abbey of Dundrennan, founded in 1142; Tongland Abbey, founded by the Premonstratensians under the auspices of Fergus in the reign of David I.; the priory of St Mary's Isle, founded also by Fergus, and subsequently united as a dependent cell to the abbey of Holyrood; the New Abbey founded for Cistercian monks in 1275; the priory of Lincluden, founded by Uchtred, lord of Galloway, for Benedictine nuns; a convent for Franciscans or Greyfriars, founded at Kirkcudbright in the reign of Alexander II.; and a nunnery in the parish of Kirkcudbright.

See Symson, *A Large Description of Galloway*, 1684, new ed. 1823; Murray, *Literary History of Galloway*, 1822; and the *Histories of Galloway* by Mackenzie, 1841, and Mackerlie, 1870–78.

KÍRKÍ, or KIRKEE, a town and military cantonment in Poona district, Bombay, India, 18° 33′ N. lat., 73° 54′ E. long. The town, with its adjoining suburbs and the military cantonments, contains a total population of upwards of 31,000 inhabitants.

KIRKINTILLOCH, a burgh of barony and market-town of Dumbartonshire, Scotland, about 7 miles north of Glasgow. The town is rather irregularly built. The cruciform parish church dates from 1644. The Broomhill house for incurables is situated near the town. Traces of the wall of Antoninus are to be discerned behind the church. The inhabitants are chiefly employed in the chemical and iron-works on the banks of the Forth and Clyde Canal, and in coal-mining, which is being rapidly developed in the district. Weaving to a small extent is also carried on. Kirkintilloch became a burgh of barony by grant of William the Lion. Since 1871 it has been under the General Police Act of 1862. The population in 1881 was 10,582.

KIRK-KILISSIA, or KIRK-KILISSEH, a town in the vilayet of Adrianople, Turkey, is situated on a feeder of the Erkene, which is an affluent of the Maritza, about 35 miles east of Adrianople. It has its chief importance from its position at the southern outlet of the Fakhi defile over the Strandja mountains, through which passes the shortest road from Shumla to Constantinople. It contains six mosques, several Greek churches, and a large bazaar. A special kind of confection is made at Kirk-Kilissia; and a considerable quantity of butter and cheese is sent thence to Constantinople. The population is estimated at about 16,000.

KIRKWALL, a royal and parliamentary burgh of Scotland, and the chief town of the Orkney Islands, is situated near the centre of the island group, at the south-east corner of a well-sheltered bay on the east side of the island of Pomona, 240 miles north of Edinburgh by steamer, 58 north of Wick, and 54 north of Thurso. It consists principally of an irregular street about a mile in length running along the margin of the bay, and so narrow that carts and similar vehicles in many places cannot pass each other. The houses are generally substantially built, with the gables facing the street nearly as frequently as the fronts. In courts leading from the main street there are many ancient buildings, formerly occupied during winter by the leading families of the islands. The more modern portion of the town is built with great regularity, and in the suburbs there are several good villas surrounded by gardens. The most prominent feature of the town is the cathedral, dedicated to St Magnus, the patron saint of Orkney, a stately cruciform structure with a length of 226 feet from east to west and a breadth of 56 feet. It was founded by Earl Ronald in 1137, and the older portion, embracing the greater part of the present building, is in the Norman style of architecture. The choir was lengthened by Bishop Stewart in 1511, and the western extremity of the nave was completed by Bishop Reid, who succeeded to the bishopric in 1540. The building has undergone extensive repairs during the present century. The choir is used as the parish church. The bells were presented by Bishop Maxwell, the predecessor of Bishop Reid, but the larger or tenor bell was recast in 1862. The cathedral contains a number of old monuments. Adjoining it are the ruins of the bishop's palace, where King Haco died in 1263, and also the earl's palace, which after the forfeiture of the earl of Orkney was given to the bishops for their residence. There is a grammar school, which was endowed by Bishop Reid, and also several charitable institutions. The town has no manufactures of importance, and its prosperity depends chiefly on its being the capital and principal port of the islands. It is often touched by ships passing to Norway and the Baltic. The harbour is amply sufficient for the shipping of the port, and a fine iron pier was erected in 1867. There is regular steam communication with Lerwick, and with Leith by Aberdeen and Wick. Kirkwall (a name derived from *kirk*, church, and *vágr* or *vaag*, bay), was a place of some size when the islands were in the possession of the Norsemen, and by James III. it was created a royal burgh. It unites with the other burghs in the Wick district in returning a member to parliament. The population of the parliamentary burgh in 1881 was 3923.

KIRMÁN, the ancient Karmania, a province of south Persia, bounded on the E. by Sistán and Balúchistán, on the W. by Farsistán, N. by Khórásán, on the S. by Láristán, Makrán, and the Strait of Ormuz. It is of very irregular shape, expanding in the north towards Khorásán, and gradually contracting in the south to the narrow coast district of Mogistan; the extreme length between Sistán and Fars east and west is 400 miles; the greatest breadth from south of Yezd to the coast at Bandar-Abbas is 300 miles; and the total area is estimated at 55,000 to 60,000 square miles. It is generally described as consisting of two parts, an uninhabitable desert region in the north, and a habitable mountainous region in the south. But the recent explorations of Khanikoff, Goldsmid, Lovett, St John, and others require this view to be considerably modified. There are mountains and desert tracts in all parts, while much of what appears on the maps as forming the western portion of the great Kirmán desert consists of the fertile upland plateau of the Kuh-Banán, stretching along the eastern base of the lofty range which runs from Yezd south-east to Khabís. West of and parallel to this range are two others, one culminating north of Bam in the Kuh-Hazár, 14,550 feet, the other continued at about the same elevation under the name of the Jamal Báris south-eastwards to the Kohistán highlands on the Makrán frontier. These chains traverse the fertile Nurmanshahr district, dividing it into several longitudinal valleys of considerable length, but not averaging more than 12 miles in width. Snow lies on their slopes to a great depth for the better part of the year, feeding the springs and "karez" or underground irrigation rills, by means of which large tracts in this almost rainless region in summer are kept under cultivation. Still further west the Kuh-Dinár range is continued from Farsistán also in a south-easterly direction to the valley of the Mináb, which is the only river worthy of the name in the whole province.

Between the south-western highlands and the Jamal Barís there is much arid and unproductive land. But the true desert of Kirmán lies mainly in the north and north-east, where it merges northwards in the desert of Lut,[1] which stretches far into Khórásán. These southern deserts differ from the Great Kavír, or Salt Desert of North Khórásán, mainly in three respects:—they are far less saline, are more sandy and drier, and present in some places tracts of from 80 to 100 miles almost absolutely destitute of vegetation. Yet they are crossed by a well-known track

[1] The term *lut* means simply arid, waterless, and has nothing to do with the Lot of Holy Writ, as some have supposed.

running from Kirmán north-eastwards to Herát, which is traversed by couriers at great risk in about eighteen days. It appears from recent observation that these sandy wastes are continually encroaching on the fertile districts, and this is the case even in Nurmanshahr, which is being invaded by the sands of the desolate plains stretching thence westwards to Bam. There are also some "kafeh" or salt swamps, answering to the kavír of Khórásán, but occurring only in isolated depressions, and nowhere of any great extent. The desert of Kirmán lies about 500 or 600 feet above the sea, apparently on nearly the same level as the desert of Lut, from which it cannot be geographically separated.

The climate, which varies much with the relief of the land, has the reputation of being the most unhealthy in Persia, the fever-stricken districts of the Caspian alone excepted. The cool air from the snowy ranges is usually attended by chills and agues, so that the people on the whole prefer the sultry heat of the plains. Still some of the sheltered upland valleys in Nurmanshahr and elsewhere enjoy a genial climate like that of Shíráz.

The chief products are cotton, wheat, barley, gums, dates of almost unrivalled flavour from Mogistan, and wool both of sheep and goats (*kurk*) noted for its extreme softness. This wool is used in the manufacture of the Kirmán shawls, which yield in delicacy of texture only to those of Kashmír, while often surpassing them in design, colour, and finish. A shawl of the finer quality, 3 yards long, is sold on the spot for from £20 to £24. Spinning and dyeing are also practised, so that the province completes the manufacture of its own raw material. Its carpets and felts are also unsurpassed for richness of texture and durability. Besides these woven goods it exports mainly cotton, grain, and dates, receiving in return from India chintzes, muslins, indigo, tea, gold-cloth, china, glass, sugar; from Turkestan madder, rhubarb, drugs, gums, furs, silks, Bokhara furs, steel, copper, tea. Bandar-Abbas is the natural outport; but, since shipping has shown a preference for Bushire further north, the trade of Kirmán has greatly fallen off.

The inhabitants, numbering altogether about 500,000, consist of Tajiks in the towns and agricultural districts, some Túrki, Rind, and Balúchi nomads in the east and south-east, and numerous Kúrd tribes, here called Leks. Shiel gives a list (incomplete) of twenty-one of these Lek tribes, dwelling partly in houses partly in tents, and numbering altogether about 200,000 souls.

The chief towns are Kirmán (the capital), Regan, Kruk, Kúm, Bam, Khabís, Khánú, and Bandar-Abbas.

KIRMANSHÁHÁN, or KERMANSHAH (Arabic, *Karmísín*), a town and district of west Persia, lying between Ardelán and Lúristán north and south. The town is the chief place in what is known as Persian Kúrdistán, an expression, however, which has no administrative significance. It lies in 34° 18′ N. lat. and 46° 37′ E. long., on a rising ground connected with the Zagros hills, which stretch south-eastwards to the Bakhtiari range. Here it occupies an important strategical position near the right bank of the river Kernah, 250 miles south-west of Tehrán, 262 north-west of Ispahán, 220 north-east of Baghdad, and 280 south of Tabríz. Although surrounded by fortifications with five gates and 3 miles in circuit, it is now practically an open town, for the walls are in ruins and the moat choked with rubbish. During Muhammad Ali Mirza's administration it was a very flourishing place, with a population of 35,000 and a large local and transit trade between Baghdad and Tehrán. Since then it has suffered more than most towns in Persia from misgovernment, under which its few buildings have gone to decay, its bazaars have become empty, and its trade reduced to a local traffic in the excellent fruits produced in the surrounding gardens and orchards. The rich and beautiful carpets and rugs for which it was formerly noted are no longer to be had, and the population has fallen to about 12,000, exclusive of a garrison of 5000 usually maintained at this important frontier station.

Kirmánsháhán is governed by a royal prince, with jurisdiction over the district, which occupies an extensive tract between Mount Elwend and the Turkish border. Here the plains are well watered and very fertile, while the hills are covered with rich pastures which support large flocks of sheep and goats, besides horses of a good breed crossed with Arab blood. About 70,000 sheep are yearly taken to Tehrán by the Kúrd shepherds, who form the vast majority of the inhabitants of the district, residing some in houses some in tents, and numbering altogether about 180,000.

KIRRIEMUIR, a burgh of barony and market-town of Forfarshire, Scotland, is beautifully situated on an eminence, above the glen through which the Gairie flows. It lies about 5 miles north-west of Forfar, and about 62 miles north of Edinburgh. The town, consisting of several narrow diverging streets, is tolerably well built. Its educational advantages are good; by the Henry bequest a number of boys are maintained at the public school; and by the Webster bequest a school has been endowed and erected. The special industry of the town is linen-weaving, for which large power-loom factories have recently been built. The population in 1881 was 6588.

KIRSANOFF, a town of Russia, in the government of Tamboff, 61 miles east of the government town, near the junction of the Pursavka with the Vorona, with a station on the railway between Saratoff and Kozloff. The population, which increased from 5699 in 1862 to 7200 in 1872, is mainly engaged in agriculture and trade, the only manufactures of importance being those of wax and tallow. There is a nunnery with nearly one hundred nuns in the town. Kirsanoff owes its origin to the opening of iron-works in 1733. It became a district town in 1779.

KISFALUDY, KÁROLY or CHARLES (1788–1830), one of the most genial, prolific, and gifted poets of Hungary, and especially celebrated as the regenerator of the national drama, was born on the 6th of February 1788, at Tét, in the county of Győr. His birth cost his mother her life, which unfortunate circumstance preyed upon the father's mind and caused him to view the child with feelings akin to aversion. The austerity of his father and the loss of his mother were, however, in a great measure made amends for to Károly by the love of his elder sister Teréz, who tended him during his early years with maternal care, and remained devoted to him through his whole life. In 1799 he was sent to the gymnasium at Győr (Raab), where he made only moderate progress in his studies, whilst the impetuosity of his disposition often involved him in trouble. Placed as a cadet in Duke Eszterházy's regiment in 1804, he saw a good deal of service, rising to the rank of captain. In 1811 he quitted the army with the intention of marrying. Offended at this step, his father withdrew from him all support, and his affianced bride rejected him upon finding him at variance with his father. His sister, then the wife of Captain Gábor Farkas, offered him an asylum in her home, where he remained during the winter of 1811–12; but, unwilling to eat the bread of dependence, Károly removed to Pest and afterwards to Vienna, where he tried to live by his skill in painting. He at this time began assiduously to study the works of Shakespeare, Schiller, and Lessing, became a frequent visitor at the Vienna theatre, and made the acquaintance of its official poet Theodore Körner, whose drama *Zrínyi* was written at Kisfaludy's suggestion. Rendered impatient by ill success, he soon left Vienna, and for over four years wandered, mostly on foot, through Germany, Switzerland, France, and Italy as far as Rome, obtaining as before a precarious livelihood as an artist. At length subdued by misfortune, and longing for his home and a more honourable career, he in 1817 sought by the aid of his sister reconciliation with his father, who, though still hard to be entreated, allowed him a slight pecuniary assistance. Although not without friends at Pest, where he now took up his abode, he continued to support himself by his brush until the spring of 1819. It was on the 3d of May in this year that the successful performance at Pest of his national drama, in five acts, *The Tatars in Hungary*, placed the name of Károly Kisfaludy on the roll of literary fame. It was rapidly followed by other dramas, all of which met with popular favour. Not only was he now admired by his own countrymen, but by means of the German translations of Gaal in the *Theater der Magyaren* (Brünn, 1820) he soon became known abroad. Freed from pecuniary embarrassment, Károly Kisfaludy was now able to devote his best energies to literature, poetry, and the drama. In 1822 he started an annual under the name of *Aurora*, which he continued to edit until the year of his death. Although its success was great and his popularity continued to increase, he became ever more and more critical with regard to his own productions; and, if his earlier pieces must be regarded rather as the outcome of natural talent than as the result of matured consideration, his later productions bear evidence to the high culture of his mental powers. In recognition of his exceptional literary merit, he was in 1826 rewarded with the prize of the Marczibányi foundation; about this time also he came into possession of the estate at Tét through the death of his father. Towards the close of 1829 his health began to fail, and, though he rallied for a time, consumption, accelerated by the news of his sister's death, brought his career to a close on the 21st November 1830, at the early age of forty-two, while his friends were rejoicing at the tidings of his election as a member of the Hungarian academy of sciences. The first edition of his collected works was published by Toldy in 10 vols. (Buda, 1831). To the *Kisfaludy Károly élete*, prefixed to the Pest edition of 1872, we are indebted for many of the foregoing particulars.

KISFALUDY, Sándor or Alexander (1772–1844), elder brother of Károly Kisfaludy, whom he excels as a lyric poet though not as a dramatist, was born on the 27th of September 1772 at Sümeg in the county of Zala, Hungary. Choosing the career of a soldier, he entered the army in 1793, and was soon appointed to a lieutenancy in the Hungarian life guards at Vienna. There he employed his spare time in literary pursuits, and especially in the study of Italian poets. Upon the death of his patron Prince Anton Eszterházy, Kisfaludy was sent back to Hungary. Soon after this, at a vintage festival in Badacsony, he made the acquaintance of Rozalia Szegedy, whom, notwithstanding a subsequent long estrangement, he eventually married, and who under the name of Liza is the subject of his *Himfy*. During the Italian campaign of 1796 Kisfaludy was stationed at Milan, and upon the surrender of that city he was sent as a prisoner of war to Vaucluse, where he began to write the series of love sonnets for which he afterwards became so famous, and which were suggested to his mind by the songs of Petrarch. After his release at the peace of Campo Formio (17th October 1797), Kisfaludy was posted as captain in a regiment quartered at Würtemberg, and in 1799 he took part in the battles of Stockach, Winterthur, and Zürich. In 1800 he left the army, and stayed for five years at Kám in the county of Vas, subsequently removing to his native place Sümeg, where he devoted himself to agricultural and literary pursuits. By this time Kisfaludy had gained the highest reputation as a lyric poet by his *Loves of Himfy*, the first part of which, published anonymously at Buda in 1801, was received with such applause as had never before been accorded to any Magyar work. The second part appeared under his own name in 1807. On the "insurrectio," or general rising of the Hungarian nobles against Napoleon, in 1809, Kisfaludy accepted the post of major of cavalry, and was also nominated by the palatine one of his adjutants. After his return to private life Kisfaludy wrote several dramatic pieces, and from 1820 contributed largely to his brother's annual *Aurora*. In 1818 he gained the Marczibányi prize for his *Ballads* (2d edition, Buda, 1818), which work was translated into German by Gaal (Vienna, 1820); and in 1831 he was elected member of the Hungarian academy of sciences, in the formation of which he had taken an active part. He died on the 28th of October 1844, at the age of seventy-two. His collective works, in 6 vols., were published at Pest in 1847 by Toldy. Exquisite metrical English renderings of several verses from the *Himfy* will be found in Sir John Bowring's *Poetry of the Magyars* (London, 1830).

See J. Ferenczy, *Magyar Irók. Életrajz-Gyujtemény*, Pest, 1856.

KÍSH, or Kais (the first form is Persian and the second Arabic), an island in the Persian Gulf, which rose to importance in the 12th and 13th centuries, and flourished on the fall of Síráf as a chief station of the Indian trade with the West. Edrísí in the 12th century describes it as the capital of a pirate chief who had acquired great wealth and power, and ravaged the coasts far and wide. He also drew a tribute from the pearl fisheries of the gulf. In the following century Yákút describes it from personal observation as a beautiful and flourishing island, the seat of the lord of 'Omán, sovereign of those seas, and the station for ships trading between India and Fársistán. The lord of Kísh was respected even in India for his wealth and maritime power. According to Ibn el Athír he was at constant war with the sovereign of Hormuz, and the rise of the latter port seems to have been fatal to the importance of Kísh (Ibn Batuta, i. 244, and note in Paris edition; Kazwíní, ed. Wüstenf., ii. 161). The island is generally identified with the modern Kenn and the Kataia of Arrian. See Vincent, *Voyage de Néarque*; Ouseley's *Travels*, i. 169 *sq.*

KISHANGARH, or Krishnagarh, a native state in Rájputána, India, lying between 26° 17′ and 26° 59′ N. lat., 74° 43′ and 75° 13′ E. long., with an area of about 724 square miles, and an estimated population of 105,000. It was founded in the reign of the emperor Akbar, by a younger son of the rájá of Jodhpur. In 1818 Kishangarh first came into direct relations with the British Government, by entering into a treaty together with the other Rájput states, having for its object the suppression of the Pindári marauders by whom the country was at that time overrun. The estimated revenue in 1875 was £30,000.

KISHINEFF, the Kishlanew of the Moldavians, a town of Russia, capital of the province of Bessarabia, on the right bank of the Byk, a tributary of the Dniester, situated on the railway between Odessa and Jassy in Roumania, 118 miles north-west from the former. At the beginning of this century it was but a poor village, and in 1812, when it was acquired by Russia from Moldavia, it had but 7000 inhabitants; twenty years later its population numbered 35,000, while in 1862 it had, with suburbs, 92,000 inhabitants, and now its population is more than 110,000, composed of the most varied nationalities—Moldavians, Wallachs, Russians, Jews, Bulgarians, Tartars, Germans, and Tsigans. The town consists of two parts—the old or lower town, on the banks of the Byk, and the new or high town, situated on high crags, 450 to 500 feet above the level of the river. The wide suburbs are remarkable for their gardens, which occupy about 12,000 acres, and produce great quantities of fruits (especially plums, which are dried and exported), tobacco, and wine. The buildings of the town are, however, very plain, and the streets remain mostly unpaved. Kishineff is the seat of the archbishop of Bessarabia, and has an ecclesiastical seminary with 800 students, a college, and several secondary and primary schools. There are several tallow-melting houses, steam flour-mills, candle and soap works, distilleries, and tobacco factories. The trade is very active and yearly becomes more important, Kishineff being now a centre for the whole Bessarabian trade in grain, wine, tobacco, tallow, wool, and skins, exported to Austria and to Odessa. The fairs, which are held twice a week, are very animated, and their yearly return is estimated at £300,000. The town played an important part in the late war between Russia and Turkey, as the chief centre of the Russian invasion.

KISHM, or Ṭawílah (*i.e.*, Long Island), an island at the mouth of the Persian Gulf, separated from the coast of the Persian province of Kirmán by Clarence Strait, which at its narrowest point has a breadth of less than 2 miles. The island has a length of about 55 miles, its main axis running north-east and south-west; and the area is estimated at 640 square miles. A range of hills from 300 to 600 feet in height, and with strongly marked escarpments, runs nearly parallel to the southern coast; they are largely composed, like those of Hormuz and the neighbouring mainland, of rock salt, which is regularly excavated in one or two places, and forms one of the chief products of the island, finding its way first to Muscat and thence to India and Africa. The rest of the island consists of sandstones and marls. In its general aspect it is parched and barren-looking, like the south of Persia, but it contains fertile portions which produce grain, dates, grapes, melons, &c. Naphtha springs exist near the village of Saluk on the south coast. Kishm, the largest of the towns, lies at the eastern extremity of the island; Bassidore, the next in importance, at the western extremity; and Láft (Luft, Leit) about midway along the northern coast. The town of Leit was reduced by a British fleet in 1809. Politically the island belongs to Persia, but the shah has long farmed it to the sultan of Muscat. The inhabitants are reckoned at 5000 or 6000.

Kishm is the ancient Oaracta, or Uorochtha, a name said to survive in a village called Brokt. The old Arabic word is Barkáwán or Bany-Káwán. Mas'ūdy (ch. x.), who mentions its capture by 'Amr ibn el 'Āṣ, says that it also bore the name of Láfit.

See Wellsted's *Travels to the City of the Caliphs*, 1840, vol. i. p. 65 *sq.*; Pelly, in *Journ. Roy. Geog. Soc.*, 1864; Sprenger, *Alte Geog. Arabiens*, p. 119 *sq.*; and Ouseley's *Travels*, i. 162.

KISSINGEN, the chief town of a department in the government district of Lower Franconia and Aschaffenburg, Bavaria, is situated on the Franconian Saale, 656 feet above sea-level, and about 62 miles east of Frankfort-on-the-Main. Its streets are regular, and its houses attractive. A stone bridge spans the Saale at the town. It has a local court, a commercial school, a theatre, and various benevolent institutions, besides all the usual buildings for the lodging, cure, and amusement of the 10,000 annual visitors who are attracted to this, the most popular watering-place in Bavaria. In the Kurgarten, a tree-shaded expanse between the Kurhaus and the handsome colonnaded Conversations-Saal, are the three principal springs, Rakoczi, Pandur, and Maxbrunnen, of which the first two, strongly impregnated with iron and salt, have a temperature of 51°·26 Fahr.; and the last (50°·72), is like Selters or Seltzer water. At short distances from the town are the intermittent artesian spring Soolensprudel, the Schonbörnsprudel, and the Theresienquelle; and in the same valley as Kissingen are the minor spas of Bocklet and Brückenau. The waters of Kissingen are prescribed for both internal and external use in a great variety of diseases, such as chronic catarrh, rheumatism, scrofula, affections of the bowels, of the lungs, and also of the eyes and ears. They are all highly charged with salt, and productive Government salt-works were at one time stationed near Kissingen. The manufactures of the town, chiefly carriages and furniture, are unimportant. The population in 1875 was 3471.

The salt springs were known in the 9th century, and their medicinal properties were recognized in the 16th, but it was only within the first half of the 19th century that Kissingen became a popular resort. On July 10, 1866, the Prussians defeated the Bavarians with great slaughter near Kissingen. The town was the scene of the attempted assassination of Prince Bismarck by Kullman, July 13, 1874.

KISTNA, or Krishna, a district in the Madras Presidency, India, lying between 15° 35′ and 17° 10′ N. lat., and between 79° 14′ and 81° 34′ E. long., and bounded on the N. by Godávari, on the E. by the Bay of Bengal, on the S. by Nellore, and on the W. by the Nizám's Dominions and Karnúl. Kistna is, speaking generally, a flat country, but the interior is broken by a few low hills, the highest being 1857 feet above sea-level. The principal rivers are the Kistna, which cuts the district into two portions known as the Masulipatam and Gantúr divisions, and the Munyeru, Paleru, and Naguleru (tributaries of the Gundlakamma and the Kistna); the last only is navigable. The Kolar Lake, which covers an area of 21 by 14 miles, and the Romparu swamp are natural receptacles for the drainage on the north and south sides of the Kistna respectively. Iron and copper exist, and at one time the mines were worked; but the smelting of copper is now a thing of the past, and that of iron is also dying out. Diamond mines are still worked, to a very slight extent, in five villages belonging to the nizám; and at other places there are traces of mines which were abandoned long ago. Garnets and small rubies are also found. There are no forests in the district. Every variety of the game birds of India, except the pheasant, woodcock, and hill partridge, abounds. The most deadly of poisonous snakes, the Russell viper, is common about Masulipatam. The cobra, carpet snake, and one kind of *bangaras* (*Arcuatus*) are also met with.

The census of 1871 returned the population of Kistna district at 1,452,374 (1,373,089 Hindus, 78,937 Mohammedans, 90 Europeans, 218 Eurasians, and 36 "others"). As a whole the people are poor, except in the fertile Godávari delta. The cultivated area, exclusive of *zamindári* estates, in 1875–76, was returned at 1,907,213 acres, cultivable but not under tillage 981,377 acres, and waste 1,215,853 acres. The principal agricultural products are rice, maize, *rágí*, pulses, hemp, flax, cotton, tobacco, gingelly, oil-seeds, chilies, wheat, garlic, indigo. The delta is irrigated by the Kistna river, which in 1875 watered 218,029 acres. A considerable trade is carried on in dressed hides at Bezwára. The inland villages carry on weaving from native hand-made cotton or silk thread. The chief exports are cotton and indigo. The total revenue in 1870–71 amounted to £548,469, of which £359,172 was derived from the land. The number of cultivators' holdings in 1871 was 137,880, owned by 169,036 proprietors or coparceners.

The early history of Kistna is inseparable from that of the northern Circars and Godávari district. Dharánikotá and the adjacent town of Amarávati were the seats of early Hindu and Buddhist Governments; and the more modern Rájámahendri (Rajahmundry) owed its importance to later dynasties. The Chalukyas here gave place to the Ganapatis, who in turn were ousted by the Reddi chiefs, who flourished during the 14th century, and built the forts of Bellamkondá, Kondavír, and Kondápalli. On the death of one of these, at the commencement of the 15th century, Deva Ráyalu, of the Vijayanagar dynasty, seized the country and held it until Mohammed II. (1463–86), a Moslem king of the Báhmani line, wrested this portion of his kingdom from him. The power of the Báhmani dynasty failed towards the end of the 15th century. Kulí Kutab Sháh became king of Golconda about 1512 A.D., and his kingdom included the whole of what is now the Masulipatam portion of Kistna district. On the other side of the Kistna, Narasinha Deva Ráyalu ruled at this time. His territory, which included Gantúr, was annexed to Golconda by Kutab Sháh's great-grandson, about 1600. This line of kings ended with Tanisha, who was dethroned by Aurangzeb in 1687. Meantime the English had, in 1622, established a small factory at Masulipatam, where they traded with varying fortune till 1750, when the French took possession of it. From 1759, when it was recaptured by Colonel Forde, with a force sent by Lord Clive from Calcutta, the power of the English in the greater part of the district was complete. In 1765 the entire administration was assumed by the Company; but the absolute right of sovereignty was not obtained until 1823.

KISTNA, or KRISHNA, a large river of southern India, stretching almost across the entire peninsula from west to east. It rises near the Bombay sanatarium of Mahábaleshwar in the Western Ghats, only about 40 miles from the Arabian Sea. Its source is held sacred, and is frequented by pilgrims in large numbers. From Mahábaleshwar the Kistna runs southwards in a rapid course into the Nizám's Dominions, then turns to the east, and ultimately falls into the sea by two principal mouths. Along this part of the coast runs an extensive strip of land, which has been entirely formed by the detritus washed down by the Kistna and Godávari. The river channel is throughout too rocky and the stream too rapid to allow even of small native craft. In utility for irrigation the Kistna is also inferior to its two sister streams, the Godávari and Káveri (Cauvery). By far the greatest of its irrigation works is the Bezwára anicut, commenced in 1852. Bezwára is a small town at the entrance of the gorge by which the Kistna bursts through the Eastern Gháts, and immediately spreads over the alluvial plain. The channel there is 1300 yards wide. During the dry season the depth of water is barely 6 feet, but sometimes it rises to as much as 36 feet, the maximum flood discharge being calculated at 1,188,000 cubic feet per second. Of the two main canals connected with the dam, that on the left bank breaks into two branches, the one running 39 miles to Ellore, the other 49 miles to Masulipatam. The canal on the right bank proceeds nearly parallel to the river, and also sends off two principal branches, to Nizámpatam and Comamur. The total length of the main channel is 254 miles, and the total irrigated area 226,000 acres, yielding a revenue of £89,000.

KIT-CAT-CLUB, a convivial association of Whig wits, painters, politicians, and men of letters, founded in the reign of James II. The name, according to Defoe, was derived from the keeper of the house in which the club met, Christopher Catt, a pastry cook in Shire Lane, which now no longer exists, but formerly ran parallel with Chancery Lane near Temple Bar. The pies of Christopher were the principal dish of the club, and the *Spectator* (No. 9) derives the name, not from the maker of the pies, but from the pies themselves, which were of a species generally known as "kit-cats." According to another authority, the meeting place of the club was at the sign of the Cat and Fiddle in Gray's Inn Lane, kept by a person of the name of Christopher. The locale of the club was afterwards changed to the Fountain tavern in the Strand, and latterly to a room specially built for the purpose at Barn Elms, the residence of the secretary, Jacob Tonson. In summer the club met at the Upper Flask, Hampstead Heath. The club consisted of thirty-nine noblemen and gentlemen, and included among other distinguished men the duke of Marlborough, Lords Halifax and Somers, Sir Robert Walpole, Vanbrugh, Congreve, Steele, and Addison. The portraits of many of the members were painted by Sir Godfrey Kneller, himself also a member, of a uniform size, less than half length, which is known as the kit-cat size. The club was dissolved about 1720.

KITE,[1] Anglo-Saxon *Cyta*, the *Falco milvus* of Linnæus and *Milvus ictinus* of modern ornithologists, once perhaps the most familiar bird-of-prey in Great Britain, and now one of the rarest. Three or four hundred years ago foreigners were struck with its abundance in the streets of London, and the evidence of two of them, one being the eminent naturalist Belon, has been already given (BIRDS, vol. iii. p. 736, note). It was doubtless the scavenger in ordinary of that and other large towns (as a kindred species now is in Eastern lands), except where its place was taken by the Raven; for Sir Thomas Browne (*circa* 1662) wrote of the latter at Norwich—"in good plentie about the citty which makes so few Kites to be seen hereabout." Wolley has well remarked of the modern Londoners that few "who see the paper toys hovering over the parks in fine days of summer, have any idea that the bird from which they derive their name used to float all day in hot weather high over the heads of their ancestors." Even at the beginning of the present century the

> "Kites that swim sublime
> In still repeated circles, screaming loud,"

formed a feature of many a rural landscape in England, as they had done in the days of Cowper. But an evil time soon came upon the species. It must have been always hated by the henwife, but the resources of civilization in the shape of the gun and the gin were denied to her. They were, however, employed with fatal zeal by the gamekeeper; for the Kite, which had long afforded the supremest sport to the falconer, was now left friendless,[2] and in a very few years it seems to have been exterminated throughout the greater part of England, certain woods in Huntingdonshire and Lincolnshire and in the Western Midlands, as well as Wales, excepted. In these latter a small remnant still exists; but the well-wishers of this beautiful species are naturally chary of giving information that might lead to its further persecution. In Scotland there is no reason to suppose that its numbers suffered much diminution until about 1835 or even later, when the systematic destruction of "vermin" on so many moors was begun. In that kingdom, however, it is now as much restricted to certain districts as in England or Wales, and those districts it would be most inexpedient to indicate.

The Kite is, according to its sex, from 25 to 27 inches in length, about one half of which is made up by its deeply-forked tail, capable of great expansion, and therefore a powerful rudder, enabling the bird while soaring on its wide wings, more than 5 feet in extent, to direct its circling course with scarcely a movement that is apparent to the spectator below. Its general colour is pale reddish-brown or cinnamon, the head being greyish-white, but almost each feather has the shaft dark. The tail-feathers are broad, of a light red, barred with deep brown, and furnish the salmon-fisher with one of the choicest materials of his "flies." The nest, nearly always built in the crotch

[1] *Glede*, cognate with glide, is also another English name.

[2] George, third earl of Orford, died in 1791, and Colonel Thornton, who with him had been the latest follower of this highest branch of the art of falconry, broke up his hawking establishment not many years after. There is no evidence that the pursuit of the Kite was in this or any other country reserved to kings or privileged persons, but the taking of it was quite beyond the powers of the ordinary trained Falcons, and in older days practically became limited to those of the sovereign. Hence the Kite had attached to it, especially in France, the epithet of "royal," which has still survived in the specific appellation of *regalis* applied to it by many ornithologists. The scandalous work of Sir Antony Weldon (*Court and Character of King James*, p. 104) bears witness to the excellence of the Kite as a quarry in an amusing story of the "British Solomon," whose Master-Falconer, Sir Thomas Monson, being determined to outdo the performance of the French king's falconer, who, when sent to England to show sport, "could not kill one Kite, ours being more magnanimous then the French Kite," at last succeeded, after an outlay of £1000, in getting a cast of Hawks that took nine Kites running—"never missed one." On the strength of this, James was induced to witness a flight at Royston, "but the Kite went to such a mountee as all the field lost sight of Kite and Hawke and all, and neither Kite nor Hawke were either seen or heard of to this present."

of a large tree, is formed of sticks intermixed with many strange substances collected as chance may offer, but among them rags[1] seem always to have a place. The eggs, three or four in number, are of a dull white, spotted and blotched with several shades of brown, and often lilac. It is especially mentioned by old authors that in Great Britain the Kite was resident throughout the year; whereas on the Continent it is one of the most regular and marked migrants, stretching its wings towards the south in autumn, wintering in Africa, and returning in spring to the land of its birth.

There is a second European species, not distantly related, the *Milvus migrans* or *M. ater* of most authors,[2] smaller in size, with a general dull blackish-brown plumage and a less forked tail. In some districts this is much commoner than the red Kite, and on one occasion it has appeared in England. Its habits are very like those of the species already described, but it seems to be more addicted to fishing. Nearly allied to this Black Kite are the *M. ægyptius* of Africa, the *M. govinda* (the Pariah Kite of India),[3] the *M. melanotis* of Eastern Asia, and the *M. affinis* and *M. isurus*; the last is by some authors removed to another genus or sub-genus as *Lophoictinia*, and is peculiar to Australia, while *M. affinis* also occurs in Ceylon, Burmah, and some of the Malay countries as well. All these may be considered true Kites, while those next to be mentioned are more aberrant forms. First there is *Elanus*, the type of which is *E. cæruleus*, a beautiful little bird, the Black-winged Kite of English authors, that comes to the south of Europe from Africa, and has several congeners—*E. axillaris* and *E. scriptus* of Australia being most worthy of notice. An extreme development of this form is found in the African *Nauclerus riocourii*, as well as in *Elanoides furcatus*, the Swallow-tailed Kite, a widely-ranging bird in America, and remarkable for its length of wing and tail, which gives it a marvellous power of flight, and serves to explain the unquestionable fact of its having twice appeared in Great Britain. To *Elanus* also *Ictinia*, another American form, is allied, though perhaps more remotely, and it is represented by *I. mississippiensis*, the Mississippi Kite, which is by some considered to be but the northern race of the Neotropical *I. plumbea*. *Gampsonyx*, *Rostrhamus*, and *Cymindis*, all belonging to the Neotropical Region, complete the series of forms that seem to compose the sub-family *Milvinæ*, though there may be doubt about the last, and some systematists would thereto add the Perns or Honey-Buzzards, *Perninæ*. (A. N.)

KITTO, JOHN (1804–1854), the author of various works connected with Biblical literature, was the son of a mason at Plymouth, where he was born December 4th, 1804. In childhood he was weak and sickly, and he received only a very meagre school education; but his untoward and miserable circumstances did not prevent the growth of a passionate love of books and an eager thirst for learning. By a fall sustained while assisting his father in his trade he received severe general injuries and lost permanently the sense of hearing. No longer able to support himself by manual labour, he endeavoured to do so by preparing rude drawings and coloured cards in large capital letters, but at last in November 1819 he found it necessary to seek refuge in the workhouse, where he was employed in making list shoes. In 1821 he was bound apprentice to a shoemaker in Plymouth, who, however, treated him with such oppressive tyranny that he appealed to the magistrates, and got his indenture cancelled, upon which he again obtained admission to the workhouse. Not long afterwards a fund was raised in his behalf, and in 1823 he was sent to board with the clerk of the guardians, having his time at his own disposal, and the privilege of making use of a public library. After preparing a small volume of miscellanies, which was published by subscription, he became a pupil of Mr Groves, a dentist in Exeter, and in this art rapidly acquired proficiency. Through the same gentleman he in 1825 obtained more congenial employment in the printing office of the Church Missionary Society at Islington, from which he was after two years transferred to the same society's establishment at Malta. There he remained only six months, but shortly after his return to England he accompanied Mr Groves in the capacity of tutor to his two sons on a Christian mission to Baghdad, where he obtained that personal knowledge of Oriental life and habits which he afterwards applied with such tact and skill in the illustration of Biblical scenes and incidents. On account of the ravages of the plague the missionary establishment was broken up, and in 1832 Kitto returned to England. On arriving in London he was engaged in the preparation of various serial publications of the Society for the Diffusion of Useful Knowledge, the most important of which were the *Pictorial History of Palestine* and the *Pictorial Bible*. Henceforth his life was one of congenial but incessant literary labour. The *Cyclopædia of Biblical Literature*, edited under his superintendence, appeared in two volumes, 1843–45, and has passed through three editions; and his *Daily Bible Illustrations* (8 vols., 1849–53) still retain a wide popularity among general readers. On the morning after he had finished the last volume of this work Kitto was seized with a paralytic stroke, and from that time he was incapacitated for literary work. In 1850 he had received an annuity of £100 from the royal civil list; and on his illness an additional fund was raised on his behalf. In the autumn of 1854 he removed with his family to Cannstatt on the Neckar, where on the 25th November he was seized with an attack which in a few hours proved fatal.

See Dr Kitto's own work *The Lost Senses*, 1845; Ryland's *Memoirs of Kitto*, 1856; and Eadie's *Life of Kitto*, 1857.

KITZINGEN, a town in the government district of Lower Franconia and Aschaffenburg, Bavaria, is situated on the Main, 95 miles south-east of Frankfort by rail. A bridge, 950 yards long, connects it with its suburb Etwashausen on the left bank of the river. A railway bridge also spans the Main at this point. Kitzingen has walls and towers, an old church of the 15th century, a trade school and a grammar school, a town house, a hospital (since 1344), and two old convents. Breweries (with large export of beer), a steam-mill for grain, tan, and timber, and manufactories of casks, chocolate, &c., employ the inhabitants. Considerable trade in wine, fruit, grain, and timber is carried on by boats on the Main. The population in 1875 was 6393.

KIUNG-CHOU-FOO. See HAINAN.

KIWI, or KIWI-KIWI, the Maori name—first apparently introduced to zoological literature by Lesson in 1828 (*Man. d'Ornithologie*, ii. p. 210, or *Voy. de la "Coquille," Zoologie*, p. 418), and now very generally adopted in English—of one of the most characteristic forms of New Zealand birds, the *Apteryx* of scientific writers. This remarkable bird was unknown till Shaw, as almost his latest labour, very fairly described and figured it in 1813 (*Nat. Miscellany*, pls. 1057, 1058) from a specimen brought to him from the southern coast of that country by Captain

[1] Thus justifying the advice of Autolycus (*Winter's Tale*, act iv. sc. 3)—"When the Kite builds, look to lesser linen"—very necessary no doubt to the laundresses of former days when the bird commonly frequented their drying grounds.

[2] Mr Sharpe (*Cat. Birds Brit. Museum*, i. p. 322) calls it *M. korschun*; but the figure of S. G. Gmelin's *Accipiter korschun*, whence the name is taken, unquestionably represents the Moor-Buzzard, *Circus æruginosus*.

[3] The Brahminy Kite of India, *Haliastur indus*, seems to be rather a fishing Eagle

Barcley of the ship "Providence." At Shaw's death, in the same year, it passed into the possession of the then Lord Stanley, afterwards thirteenth Lord Derby, and president of the Zoological Society, and it is now with the rest of his collection in the Liverpool Museum. Considering the state of systematic ornithology at the time, Shaw's assignment of a position to this new and strange bird, of which he had but the skin, does him great credit, for he said it seemed "to approach more nearly to the Struthious and Gallinaceous tribes than to any other." And his credit is still greater when we find the venerable Latham, who is said to have examined the specimen with Shaw, placing it some years later among the Penguins (*Gen. Hist. Birds*, x. p. 394), being apparently led to that conclusion through its functionless wings and the backward situation of its legs. In this false allocation Stephens also in 1826 acquiesced (*Gen. Zoology*, xiii. p. 70). Meanwhile in 1820 Temminck, who had never seen a specimen, had assorted it with the Dodo in an Order to which he applied the name of *Inertes* (*Man. d'Ornithologie*, i. p. cxiv.). In 1831 Lesson, who had previously (*loc. cit.*) made some blunders about it, placed it (*Traité d'Ornithologie*, p. 12), though only, as he says, "par analogie et *a priori*," in his first

Kiwi.

division of Birds, "Oiseaux Anomaux," which is equivalent to what we now call *Ratitæ*, making of it a separate Family "Nullipennes." At that time no second example was known, and some doubt was felt, especially on the Continent, as to the very existence of such a bird[1]—though Lesson had himself when in the Bay of Islands in April 1824 (*Voy.* "*Coquille*," *ut supra*) heard of it; and a few years later Dumont d'Urville had seen its skin, which the naturalists of his expedition procured, worn as a tippet by a Maori chief at Tolaga Bay (Houa-houa),[2] and in 1830 gave what proves to be on the whole very accurate information concerning it (*Voy.* "*Astrolabe*," ii. p. 107). To put all suspicion at rest, Lord Derby sent his unique specimen for exhibition at a meeting of the Zoological Society, 12th February 1833 (*Proc. Zool. Society*, 1833, p. 24), and a few months later (*tom. cit.*, p. 80) Yarrell communicated to that body a complete description of it, which was afterwards published in full with an excellent portrait (*Trans. Zool. Society*, i. p. 71, pl. 10). Herein the systematic place of the species, as akin to the Struthious birds, was placed beyond cavil, and the author called upon all interested in zoology to aid in further research as to this singular form. In consequence of this appeal a legless skin was within two years sent to the society (*Proceedings*, 1835, p. 61) obtained by Mr W. Yate of Waimate, who said it was the second he had seen, and that he had kept the bird alive for nearly a fortnight, while in less than another couple of years additional information (*op. cit.*, 1837, p. 24) came from Mr T. K. Short to the effect that he had seen two living, and that all Yarrell had said was substantially correct, except underrating its progressive powers. Not long afterwards Lord Derby received and in March 1838 transmitted to the same society the trunk and viscera of an *Apteryx*, which, being entrusted to Professor Owen, furnished that eminent anatomist, in conjunction with other specimens of the same kind received from Drs Lyon and George Bennett, with the materials of the masterly monograph laid before the society in instalments, and ultimately printed in its *Transactions* (ii. p. 257, iii. p. 277). From this time the whole structure of the Kiwi has certainly been far better known than that of nearly any other bird, and by degrees other examples found their way to England, some of which were distributed to the various museums of the Continent and of America.[3]

In 1847 much interest was excited by the reported discovery of another species of the genus (*Proceedings*, 1847, p. 51), and though the story was not confirmed, a second species was really soon after made known by Gould (*tom. cit.*, p. 93; *Transactions*, iii. p. 379, pl. 57) under the name of *Apteryx oweni*—a just tribute to the great master who had so minutely explained the anatomy of the group. Three years later Mr Bartlett drew attention to the manifest difference existing among certain examples, all of which had hitherto been regarded as specimens of *A. australis*, and the examination of a large series led him to conclude that under that name two distinct species were confounded. To the second of these, the third of the genus (according to his views), he gave the name of *A. mantelli* (*Proceedings*, 1850, p. 274), and it soon turned out that to this new form the majority of the specimens already obtained belonged. In 1851 the first Kiwi known to have reached England alive was presented to the Zoological Society by Mr Eyre, then lieutenant-governor of New Zealand. This was found to belong to the newly described *A. mantelli*, and some careful observations on its habits in captivity were published by Wolley and another (*Zoologist*, pp. 3409, 3605).[4] Subsequently the society has received several other live examples of this form, besides one of the real *A. australis* (*Proceedings*, 1872, p. 861), some of *A. oweni*, and one of a supposed fourth species, *A. haasti*, characterized in 1871 by Mr Potts (*Ibis*, 1872, p. 35; *Trans. N. Zeal. Institute*, iv. p. 204; v. p. 195).[5]

The Kiwis form a group of the Subclass *Ratitæ* to which the rank of an Order may fitly be assigned, as they differ in many important particulars from any of the other existing forms of Ratite birds. The most obvious feature the *Apteryges* afford is the presence of a back toe, while the

[1] Cuvier in the second edition of his *Règne Animal* only referred to it in a footnote (i. p. 498).

[2] Cruise in 1822 (*Journ. Residence in New Zealand*, p. 313) had spoken of an "Emeu" found in that island, which must of course have been an *Apteryx*.

[3] In 1842, according to Broderip (*Penny Cyclopædia*, xxiii. p. 146), two had been presented to the Zoological Society by the New Zealand Company, and two more obtained by Lord Derby, one of which he had given to Gould. In 1844 the British Museum possessed three, and the sale catalogue of the Rivoli Collection, which passed in 1846 to the Academy of Natural Sciences at Philadelphia, includes a single specimen—probably the first taken to America.

[4] This bird in 1859 laid an egg, and afterwards continued to lay one or two more every year. In 1865 a male of the same species was introduced, but though a strong disposition to breed was shown on the part of both, and the eggs, after the custom of the *Ratitæ*, were incubated by him, no progeny was hatched (*Proceedings*, 1868, p. 329).

[5] A fine series of figures of all these supposed species is given by Rowley (*Orn. Miscellany*, i. pls. 1–6). Some others, as *A. maxima*, *A. mollis*, and *A. fusca* have also been indicated, but proof of their validity has yet to be adduced.

extremely aborted condition of the wings, the position of the nostrils—almost at the tip of the maxilla—and the absence of an after-shaft in the feathers, are characters nearly as manifest, and others not less determinative though more recondite will be found on examination. The Kiwis are peculiar to New Zealand, and it is believed that *A. mantelli* is the representative in the North Island of the southern *A. australis*, both being of a dark reddish-brown, longitudinally striped with light yellowish-brown, while *A. oweni*, of a light greyish-brown transversely barred with black, is said to occur in both islands. About the size of a large domestic Fowl, they are birds of nocturnal habit, sleeping, or at least inactive, by day, feeding mostly on earth-worms, but occasionally swallowing berries, though in captivity they will eat flesh suitably minced. Mr Buller writes (*B. New Zealand*, p. 362):—

"The Kiwi is in some measure compensated for the absence of wings by its swiftness of foot. When running it makes wide strides and carries the body in an oblique position, with the neck stretched to its full extent and inclined forwards. In the twilight it moves about cautiously and as noiselessly as a rat, to which, indeed, at this time it bears some outward resemblance. In a quiescent posture, the body generally assumes a perfectly rotund appearance; and it sometimes, but only rarely, supports itself by resting the point of its bill on the ground. It often yawns when disturbed in the daytime, gaping its mandibles in a very grotesque manner. When provoked it erects the body, and, raising the foot to the breast, strikes downwards with considerable force and rapidity, thus using its sharp and powerful claws as weapons of defence. . . . While hunting for its food the bird makes a continual sniffing sound through the nostrils, which are placed at the extremity of the upper mandible. Whether it is guided as much by touch as by smell I cannot safely say; but it appears to me that both senses are used in the action. That the sense of touch is highly developed seems quite certain, because the bird, although it may not be audibly sniffing, will always first touch an object with the point of its bill, whether in the act of feeding or of surveying the ground; and when shut up in a cage or confined in a room it may be heard, all through the night, tapping softly at the walls. . . . It is interesting to watch the bird, in a state of freedom, foraging for worms, which constitute its principal food: it moves about with a slow action of the body; and the long, flexible bill is driven into the soft ground, generally home to the very root, and is either immediately withdrawn with a worm held at the extreme tip of the mandibles, or it is gently moved to and fro, by an action of the head and neck, the body of the bird being perfectly steady. It is amusing to observe the extreme care and deliberation with which the bird draws the worm from its hiding-place, coaxing it out as it were by degrees, instead of pulling roughly or breaking it. On getting the worm fairly out of the ground, it throws up its head with a jerk, and swallows it whole."

The foregoing extract refers to *A. mantelli*, but there is little doubt of the remarks being equally applicable to *A. australis*, and probably also to *A. oweni*, though the different proportion of the bill in the last points to some diversity in the mode of feeding. Did space allow much more should be said of the Kiwis—perhaps to ornithologists the most interesting group of birds now existing, and the more interesting in regard to the melancholy doom of extinction which almost inevitably awaits them. (A. N.)

KIZLIAR, KIZLYAR, or KIZLAR, a town of Russia, in the government of Stavropol, 325 miles east of the government town, in the low-lying delta of the river Terek, about 35 miles from the shores of the Caspian. It lies to the left of the main stream between two of the larger secondary branches, and the whole is subject to flooding. The town proper, which spreads out round the citadel, has its Tartar, Georgian, and Armenian quarters; the Russians for the most part live in the soldiers' "sloboda" or village. Of the public buildings it is sufficient to mention the Greek cathedral, dating from 1786; the Greek nunnery of the Elevation of the Cross, founded by the Georgian chief Daniel in 1736; the Armenian church of SS. Peter and Paul, remarkable for its size and riches. The population, which has increased from 8309 in 1861 to 9176 in 1872, is mainly supported by the gardens and vineyards irrigated by canals fed by the river. A Government vineyard and school of viticulture are situated 3½ miles from the town. About 1,200,000 gallons of Kizliar wine are sold annually at the fair of Nizhni Novgorod. Kizliar is mentioned as early as 1616, but the most notable accession of inhabitants (Armenians, Georgians, and Persians) took place in 1715; and its importance as a fortress dates from 1736, when it received the garrison formerly stationed at Sv. Kresta on the Sulak in Daghestan. In 1785 it was made a district town. The incursion of Kazni Mulla in 1821, and the inundation in 1863, are the chief facts of more recent note. The fortress is no longer kept in repair.

KLADNO, a mining town in the district of Smichov, Bohemia, lies about 15 miles west-north-west of Prague, with which it is connected by the Buschtierad line of railway. There are few buildings of special interest, and the importance of the town is mainly due to the wealth of its iron-mines and coal-fields, which afford employment for some three thousand men. The average annual yield of iron is from 25,000 to 30,000 tons, and of coal 300,000 tons. About 2 miles to the north is the imperial chateau of Buschtierad. Population in 1880, 14,085.

KLAGENFURT, capital of the duchy of Carinthia, Austria, and seat of the provincial administration, financial direction, and court of appeal, is situated upon a plain at an elevation of 1450 feet above the sea-level, and about 40 miles north-north-west of Laibach, with which, as with Vienna, Gratz, Innsbruck, and other centres, it is connected by railway, in 46° 37′ N. lat., 14° 19′ E. long. Klagenfurt is for the most part well and symmetrically built, and comprises an inner town quadrangular in form, and four suburbs—St Veit (north), Viktring (south), Völkermarkt (east), and Villach (west), the last communicating with Lake Wörth by means of the Lend Canal. Among the more noteworthy edifices are the parish church of St Ægidius (erected 1709), with a tower 298 feet in height; the cathedral of SS. Peter and Paul (1582–93, burnt 1723, restored 1725); the churches of the Benedictines (1613), of the Capuchins (1646), and of the order of St Elizabeth (1710); and the fine structure standing in the Villach suburb, and belonging to the Protestant community. To these must be added the palace of the prince bishop of Gurk, originally built for the sisters of the emperor Joseph II., and containing in its chapel some fine fresco paintings completed in 1798 by the Carinthian artist Joseph von Pichler; the municipal hospital; the lunatic asylum; the *burg* or castle, existing in its present form since 1777; and the *Landhaus* or house of assembly, dating from the end of the 14th century, and containing a museum of natural history, and the Klagenfurt Historical Society's library, and collection of minerals, antiquities, seals, paintings, and sculptures. The most interesting public monument is the great *Lindwurm* or Dragon, standing in the principal square (1590). Among the many educational establishments of Klagenfurt are an upper and lower gymnasium with public library; a theological seminary for priests; monastic and conventual houses; agricultural, industrial, technical, and mining schools; and an asylum for the instruction of the deaf and dumb. The industrial establishments comprise factories for the preparation of white lead, tobacco, woollen cloth, muslins, silk fabrics, and leather; also machine and iron foundries. Klagenfurt possesses, moreover, several banks, a chamber of industry and commerce, a central board of mining control, and a few scientific associations. The transit trade, which is considerable owing to the wealth of the mineral products of the province, is much facilitated by the position of Klagenfurt at a junction of the Crown-Prince-Rudolph and Austrian Southern Railways. The civil population in 1880 was 16,592; with the military, it was 18,749.

Upon the Zollfeld to the north of the city once stood the ancient Roman town of Virunum. In the middle of the 7th century the surrounding country was overrun by the Avars. During the Middle Ages Klagenfurt became the property of the crown, but by a patent of Maximilian I. of the 24th April 1518, it was conceded to the Carinthian estates, and has since then taken the place of St Veit as capital of Carinthia. In 1535, 1636, 1723, and 1796 Klagenfurt suffered from destructive fires, and in 1690 from the effects of an earthquake. On March 29, 1797, the French took the city, and upon the following day it was occupied by Napoleon as his headquarters. The fortifications constructed in 1580 were destroyed by the French in 1809, and the ground that they formerly occupied is now laid out as a public promenade.

See Amthor and Jaborneggg-Gamsenegg, *Kärntnerführer*, Gera, 1874; G. von Ankershofen, *Handbuch der Geschichte des Herzogthums Kärnten*, Klagenfurt, 1857-74, bd. i.-iv.; *Umgebungskarte von Klagenfurt*, Vienna, 1873.

KLAPROTH, HEINRICH JULIUS VON (1783–1835), one of the founders of Oriental scholarship in Europe, was born at Berlin, October 11, 1783. His father, Martin Heinrich Klaproth (1743–1817), not only desired him to pursue the chemical studies by which he had himself attained to position and fame, but did all in his power to frown away what he deemed a foolish attachment to a profitless subject. But the boy-philologist received from a more indulgent or wiser mother the means of secretly satisfying his natural instinct, and by the time that in ordinary course he ought to have passed the gymnasial examination he was able to retort, when upbraided with ignorance of the usual subjects, that at least he knew Chinese. He was still in his teens when he published his *Asiatisches Magazin* (Weimar, 1802); and immediately after he was called to St Petersburg as an adjunct to the academy of Oriental languages. In 1805 he accompanied Count Golowin's embassy to China; and though the travellers were stopped at the frontier he had a splendid opportunity of becoming acquainted with the tribes and languages of southern Asiatic Russia. On his return he was despatched by the academy to the Caucasus for the purpose of ethnographical and linguistic exploration (1807–1808), and when this mission was completed he was employed for several years in connexion with the academy's Oriental publications. In 1811 he came to Berlin; but in 1815 he settled in Paris, and in 1816 W. von Humboldt procured him from the king of Prussia the title and salary of professor of Asiatic languages and literature, with permission to remain in Paris as long as was requisite for the publication of his works. He died in that city August 23, 1835.

The principal feature of Klaproth's erudition was the vastness of the field which it embraced. To enormous industry he joined a somewhat reckless intellectual aggressiveness, and where more solid footing failed was ready to bridge the chasm by adventurous hypothesis. His great work *Asia polyglotta* (Paris, 1823, with *Sprachatlas*) not only served as a resumé of all that was known on the subject, but formed a new departure for the classification of the Eastern languages, more especially of the Russian empire. To a great extent, however, his work is now superseded. That he was sometimes not over-scrupulous in the use he made of his erudition is matter of more than suspicion. The *Itinerary of a Chinese Traveller*, which he published in 1821, a series of documents in the military archives of St Petersburg purporting to be the travels of George Ludwig von ——, and a similar series obtained from him in the London Foreign Office, are all judged to be spurious; and the learning displayed in the forgery was possessed by no one but himself.

A list of Klaproth's works will be found in *Nouv. Journ. Asiat.*, vol. xvii., and in Quérard, *La France littéraire*, vol. vi. Compare M. C. Landresse's "Notice" in *Nouv. Journ. Asiat.*, 1835.

KLATTAU (Latin, *Clatovia*; Bohemian, *Klatovy*), chief town of a district of the same name in Bohemia, lies about 70 miles south-west of Prague, and on the railway between Pilsen and Eisenstein, in 49° 23′ N. lat., 13° 22′ E. long. Klattau has six churches, an upper gymnasium, two hospitals, a large steam brewery, and an old-fashioned town-hall dating from the 16th century, and containing in its tower a bell weighing over 5 tons. Population 8067.

Klattau was an ancient Bohemian fortress, and afterwards became a royal free town. In 1421 it was desolated by the Bohemian leader Ziska. Having refused to assist the emperor Ferdinand I., it was in 1546 deprived of many of its privileges. In 1620 it was taken by the emperor Maximilian. Until the early part of the 17th century it was a thriving place; but the depredations committed by the Swedes in 1641, 1645, and 1648, and the many conflagrations which from time to time ravaged it, so seriously affected the town that it has never recovered its former prosperity.

KLAUSENBURG, or CLAUSENBURG (Hungarian, *Kolozsvár*; Latin, *Claudiopolis*), a royal free town of Hungary, the capital of the county of Kolozs, and also of the whole Transylvanian circle, is situated in a picturesque valley on the banks of the Little Szamos, and on the Hungarian eastern railway, 72 miles north-north-west of Hermannstadt, in 46° 44′ 8″ N. lat., 23° 34′ 51″ E. long. Klausenburg is the seat of a Unitarian bishop, of the superintendent of the Calvinists for the Transylvanian circle, of a royal court of justice, of a chamber of commerce, and of the county administration, as also the headquarters of the *honvéd* (militia) and regular infantry regiments of the military district. Klausenburg consists of an inner town (quadrangular in form, and divided into the old and new towns) and five suburbs now united with it in consequence of the removal of the old walls. With the exception of the old quarter, Klausenburg is generally well laid out, and contains many broad and fine streets, several of which diverge at right angles from the principal square or market-place, where stands a fine old Roman Catholic church, often described as a cathedral (Gothic style), dedicated to St Michael, and founded by king Sigismond in the year 1414. Besides several other Roman Catholic, Calvinist, Lutheran, Unitarian, Greek Catholic, and Greek Orthodox churches, and a Jewish synagogue, Klausenburg comprises among its public edifices a national museum, county and town halls, a national theatre, several hospitals, a workhouse, and barracks. The educational establishments include the university (with four faculties, founded in 1872), the Unitarian college (with seminary), Calvinist and Roman Catholic upper gymnasia, training institutes, and many others. A special feature of Klausenburg is the large number of elegant private mansions belonging to the Transylvanian nobles who reside here during the winter months. The greater part of the town lies on the right bank of the river, while upon the other side is the so-called "Bridge Suburb" and the citadel. Klausenburg bears in general more the character of a seat of learning than of a business centre; but there are factories for the preparation of woollen and linen cloth, paper, tobacco, candles, and bone dust, as well as breweries, distilleries, oil mills, and beetroot sugar refineries; and furrying, and hat, cap, and boot making are largely carried on. The fairs are well attended, especially for the purchase of horses, and prepared skins, dressed furs, felt goods, delf, and crockery ware. The chief agricultural products of the neighbourhood are wheat, beetroot, and forage. On the more elevated portions of the communal lands are extensive vineyards and woods. At the end of 1880 the civil population amounted to 29,929 (with military it was 30,869); by far the greater majority were Magyars by nationality, the remainder being composed of Roumanians, Germans, Armenians, and Jews. Outside the town, upon the slope of the citadel hill, there is a Gipsy quarter.

Klausenburg is believed to occupy the site of a Roman settlement named *Claudia*, whence its modern Latin appellation of *Claudiopolis*. Colonized by Saxons in 1178, it then received its German name of *Klausenburg* from the old word *Klause*, signifying a "mountain pass." In 1443 Matthias Corvinus, king of Hungary, was born here. Subsequent to the defeat of the Hungarians by the Turks at Mohács (1526), Transylvania came under the protection of the Porte, and owing to the trade from the East passing through the principality to Dantzic, the prosperity of Klausenburg much increased. Between the years 1545 and 1570 large numbers of the Saxon population left the town in consequence of the introduction of Unitarian doctrines. In 1603 it fell into the hands of the usurper Moses Székely, but was soon regained by the imperialists under General Basta. In 1662 it was ineffectually besieged by the Transylvanian prince Michael Apaffi I., but two years later it came into his power. The burg or citadel was erected between 1715–23, during the reign of King Charles III. (as emperor, Charles VI.). In 1798 the town was to a great extent destroyed by fire. As capital of Transylvania and the seat of the Transylvanian diets, Klausenburg from 1830–48 became the centre of the national movement in the grand principality; and in December 1848 it was taken and garrisoned by the Hungarians under the Polish General Bem. After the conclusion of the war it was degraded from its position as capital of Transylvania, and subordinated to Nagyszeben (Hermannstadt), but in 1861 it was reinstated in its former rank. The official name is *Kolozsvár*.

KLAUSTHAL, or CLAUSTHAL, in the circle of Zellerfeld and the district of Hildesheim, Prussia, is the chief town and mining centre of the Upper Harz. It is situated on a bleak plateau, 1860 feet above sea-level, and unites to form one town with Zellerfeld on the opposite bank of the Zellbach. The streets are broad, opportunity for improvement having been given by fires in 1844 and 1854; the houses are mostly of wood. Klausthal has a famous mining college, with a mineralogical museum, and a mine-surveying and a mining school. There is also a disused mint. The men of the town are mainly employed in the neighbouring mines and smelting works; of the latter the most important is the Frankenscharner silver smelting house, where American as well as German ore is worked. The population in 1875 was 8539; including Zellerfeld, it was 12,799.

Klausthal was founded about the middle of the 16th century, after the erection of the Benedictine monastery at Cella. Mining was carried on by the monks, and more energetically by the dukes of Brunswick, who brought miners from Franconia.

KLÉBER, JEAN BAPTISTE (1753–1800), was born at Strasburg in 1753 or 1754, where his father was a builder. He was meant to be an architect, but his opportune assistance to two German nobles in a tavern brawl obtained for him a nomination to the military school of Munich. He soon obtained a commission, but resigned it in 1783 on finding his humble birth in the way of his promotion. On returning to France he was appointed inspector of public buildings at Belfort, where he studied fortification and military science. In 1792 he enlisted in the Haut-Rhin volunteers, and was from his military knowledge at once elected adjutant. At the siege of Mainz under Merlin de Thionville, he so distinguished himself that he was made general of brigade in July 1793. In that capacity he commanded in the Vendean war, and was instrumental in winning the victories of Torfou, Chollet, Le Mans, and Savenay. For openly expressing his opinion that lenient measures ought to be pursued towards the Vendeans he was recalled; but in April 1794 he was made general of division, and sent to the army of the North. Under Jourdan he commanded the left wing at Fleurus, June 26, 1794, and Aldenhaven, October 2, and took Maestricht after a short siege on November 8. During the winter of 1794–95 he besieged Mainz, and on June 4, 1796, gained the victory of Altenkirchen over the prince of Würtemberg. Kléber now considered he had a fair claim to a command in chief, and, not receiving one in the spring of 1797, he resigned his division in disgust, and retired to Paris. There he allied himself with the reactionary party, and, according to Mathieu Dumas even offered to command any forces that could be raised against the coup d'état of Fructidor 1797, but there were no forces to command. He gladly accepted a division in the expedition to Egypt under Bonaparte, but was wounded in the head at Alexandria in the very first engagement, which prevented his taking any further part in the campaign of the Pyramids; and caused him to be appointed governor of Alexandria. In the Syrian campaign of 1799, however, he commanded the vanguard, took El-Arish, Gaza, and Jaffa, and bore the brunt of the battle of Mount Tabor, April 15, 1799. Being left by Bonaparte in command of the army in Egypt, he made the convention of El-Arish, and, when Lord Keith refused to ratify the terms, attacked the Turks at Heliopolis, though with but 10,000 men against 60,000, and utterly defeated them on March 20, 1800. He then retook Cairo, which had revolted from the French, and was assassinated there by a fanatic on June 14, 1800, the very day on which Desaix fell at Marengo. Kléber was undoubtedly one of the greatest generals of the French revolutionary epoch, but hardly had a chance of showing his powers against a capable adversary; Napoleon's ejaculation on hearing of his death was "Eh bien; a rival the less."

Ernouf, the grandson of Jourdan's chief of the staff, published in 1867 a valuable biography of Kléber. See also Reynaud's *Life of Merlin de Thionville*, Ney's *Memoirs*, Dumas's *Souvenirs*, Napoleon's *Memoirs*, dictated at St Helena, and Martha-Becker's *Desaix*.

KLEIN, JULIUS LEOPOLD (1804–1876), a German writer of Jewish origin, was born at Miscolcz, in Hungary, in 1804. He was educated at the gymnasium in Pest, and studied medicine in Vienna and Berlin. After travelling in Italy and Greece, he settled as a man of letters in Berlin, where he remained until his death in 1876. He was the author of many dramatic works, among others the historical tragedies *Maria von Medici*, *Luines*, *Zenobia*, *Moreto*, *Maria*, *Strafford*, and *Heliodora*, and the comedies *Die Herzogin*, *Ein Schützling*, and *Voltaire*. These plays were published between 1841 and 1867. The tendency of Klein as a dramatist was to become bombastic and obscure, but many of his characters are vigorously conceived, and in nearly all his tragedies there are passages of brilliant rhetoric. He is chiefly known as the author of an elaborate *Geschichte des Dramas* (1865–1876), in which he undertook to record the history of the drama both in ancient and in modern times. He died when about to enter upon the Elizabethan period, to the treatment of which he had looked forward as the chief part of his task. The work, which is in 12 bulky volumes, gives proof of immense learning, but is marred by many eccentricities of style.

KLINTZY, a town in Russia, situated in the government of Tchernigoff, 203 miles north-east of the capital of the province. It is one of the most important industrial centres in Little Russia. Its 8000 inhabitants are engaged in the manufacture of woollen cloth and knitted woollen goods (to the value of more than £100,000 per annum), morocco-leather, leather, and cast-iron wares.

KLOPSTOCK, FRIEDRICH GOTTLIEB (1724–1803), German poet, was born at Quedlinburg on the 2d of July 1724. He was educated partly at the gymnasium of his native town, partly at Schulpforta. After studying theology for a short time at Jena, he went in 1746 to the university of Leipsic, where he made the acquaintance of Cramer, Schlegel, Rabener, and other young men of letters, who were conducting the *Bremische Beiträge*. At Schulpforta Klopstock had become conscious of a talent for poetry, and had resolved to write a great epic. His original intention was to make Henry the Fowler his hero, but this was soon abandoned in favour of the scheme to which he devoted the best years of his life. The first three cantos of *The Messiah*, which were planned in prose in Jena, he finished in Leipsic; and they were published anonymously in the *Bremische Beiträge* in 1748. The name of the author was soon known, and Klopstock suddenly found himself the most popular poet of his generation. In 1748 he accepted the position of tutor to a private family in Langensalza, and in 1750 he went to Zürich, whither he was invited by Bodmer, the translator of *Paradise Lost*, who had been deeply impressed by the early cantos of *The*

Messiah. In Zürich Klopstock received from Frederick V. of Denmark, on the recommendation of his minister Count Bernstorff, an invitation to settle in Copenhagen with a pension of 400 thalers. The invitation was accepted; and on his way to the Danish capital he met at Hamburg the lady who, in 1754, became his wife—Margarethe (Meta) Moller, an enthusiastic admirer of his poetry. She died in 1758; and after her death Klopstock edited her writings, which give evidence of a tender, sensitive, and deeply religious spirit. In 1771 Klopstock left Copenhagen, and followed his friend Count Bernstorff to Hamburg, where, in 1773, he issued the last five cantos of *The Messiah.* After spending about a year at the court of the margrave of Baden in Carlsruhe, he returned to Hamburg with the title of hofrath and a pension, which he retained along with the pension of the king of Denmark. During the rest of his life he remained in Hamburg, where in 1792 he married Johanna Elizabeth von Winthem, a widow who had been for many years one of his most intimate friends. He died on the 14th of March 1803, and was buried beside his first wife in the village of Ottensen, near Hamburg. Besides *The Messiah* he wrote many odes; and in several dramas he celebrated the deeds of the ancient German hero, Arminius, while in others he dealt with the earliest narratives of the Old Testament. He was also the author of *Fragmente über Sprache und Dichtkunst*, *Grammatische Gespräche*, and a book entitled *Gelehrtenrepublik.* In these works he made important contributions to philology and to the history of German poetry. Klopstock's dramatic writings are without value; many of his odes, especially those on subjects taken from northern mythology, are so vague as to be hardly intelligible; and *The Messiah* lacks plastic force, unity of conception, and precision of style. His best odes, however, and many passages of *The Messiah* are still admitted to be marked by lyrical genius of a high order; and all German critics recognize that he exercised a salutary influence on the literature of his age by helping to deliver it from slavish adherence to foreign models.

An edition of his works in 12 octavo volumes was published in Leipsic, 1798–1817; and among later editions may be mentioned one in 12 volumes, 1823–26, another in 9 vols., 1839, and a third in 11 vols., 1844–45. Klopstock's writings are included in Hempel's *Nationalbibliothek*, and there is a new edition, with notes, by Bock (Stuttgart, 1876). See K. F. Cramer, *Klopstock, er und über ihn*; and *Klopstock's Jugendgeschichte* in the *Kleine Schriften* of D. F. Strauss.

KLOSTERNEUBURG, a town in the official district of Hernals, Austria, is situated on the right bank of the Danube, 5½ miles north-west of Vienna. It is divided by a small stream into an upper and a lower town, in the former of which are the ruins of a mediæval fortress. The town has a local court, a hospital, an asylum for the insane, and a convent of Mekhitarists; among the schools is an academy of wine and fruit cultivation. As an important pioneer station, it has various military buildings and stores. On a hill rising directly from the banks of the Danube, stand the magnificent buildings (erected 1730–1834) of the Augustine canonry, founded in 1106 by Margrave Leopold the Holy. This foundation is the oldest and richest of the kind in Austria; it owns much of the land upon which the north-western suburbs of Vienna stand. Among the points of interest within it are the old chapel of 1318, with Leopold's tomb and the altar of Verdun, the treasury and relic-chamber, the library with 30,000 volumes and many MSS., the picture gallery, the collection of coins, the theological hall, and the wine-cellar, containing an immense tun like that at Heidelberg. The inhabitants of Klosterneuburg are mainly occupied in making wine, of excellent quality. There is a large cement factory outside the town. The population in 1869 was 5330, but has increased. In Roman times the castle of Citium stood in the region of Klosterneuburg. The town was founded by Charlemagne.

KNARESBOROUGH, a market-town and parliamentary borough in the West Riding of Yorkshire, is finely situated on a rocky elevation on the left bank of the Nidd, 17 miles west by north of York and 207 north of London. It is a station on the North-Eastern Railway, which crosses the valley near the town by a lofty viaduct. The town is built chiefly of stone, and contains several good streets and a spacious market-place. The parish church of St John is an old cruciform structure chiefly Perpendicular in style, restored in 1872; the free grammar school was founded in 1616. Knaresborough Castle, now in ruins, but originally of great strength, was founded in 1170 by Serlo de Burgh. After the battle of Marston Moor it was taken by Fairfax, and in 1648 it was ordered to be dismantled. To the south of the castle is St Robert's chapel, an excavation in the rock constructed into an ecclesiastical edifice in the reign of Richard I. A little further down the river is St Robert's cave, which is supposed to have been the residence of the hermit, and in 1744 was the scene of the murder of Daniel Clarke by Eugene Aram. Opposite the castle is a petrifying spring called the "Dropping Well." Before the rise of Harrogate Knaresborough was a favourite watering-place, but it is now dependent chiefly on its manufacture of towels, sheetings, and similar linen fabrics, and of wool rugs. There are also flour-mills and a considerable trade in corn. From the first year of the reign of Mary until 1867 Knaresborough returned two members to parliament, but since then it has returned only one. The area of the parliamentary borough and local board district, which includes part of Scriven with Tentergate, is 481 acres, and the population, which in 1871 was 5205, was exactly 5000 in 1881.

KNELLER, Sir Godfrey (1648–1723), a portrait painter whose celebrity belongs chiefly to England, was born in Lübeck in the duchy of Holstein, of an ancient family, on August 8, 1648. He was at first intended for the army, and was sent to Leyden to learn mathematics and fortification. Showing, however, a marked preference for the fine arts, he studied in the school of Rembrandt, and under Ferdinand Bol in Amsterdam. In 1672 he removed to Italy, directing his chief attention to Titian and the Caracci; Carlo Maratti gave him some guidance and encouragement. In Rome, and more especially in Venice, Kneller earned considerable reputation, by historical paintings as well as portraits. He next went to Hamburg, painting with still increasing success. In 1674 he came over to England at the invitation of the duke of Monmouth, was introduced to Charles II., and painted that sovereign, much to his satisfaction, several times. Charles also sent him to Paris, to take the portrait of Louis XIV. When Lely died in 1680, Kneller, who produced in England little or nothing in the historical department, remained without a rival in the ranks of portrait painting; there was no native-born competition worth speaking of. Charles appointed him court painter; and he continued to hold the same post into the days of George I. Under William III. (1692) he was made a knight, under George I. (1715) a baronet, and by order of the emperor Leopold I. a knight of the Roman empire. Not only his court favour but his general fame likewise was large: he was lauded by Dryden, Addison, Steele, Prior, Tickell, and Pope. Kneller's gains also were very considerable, aided by habits of frugality which approached stinginess: he left property yielding an annual income of £2000. His industry was maintained till the last. His studio had at first been in Covent Garden, but in his closing years he lived in Kneller Hall, Twickenham. He died of fever, the date being generally given as 7th November 1723, though some accounts say 1726. He was buried in Twickenham church, and has a monument in Westminster Abbey. An elder brother, John Zachary Kneller, an ornamental painter, had accompanied Godfrey to England, and had died in 1702. The style of Kneller as a portrait painter represented the decline of the art as practised by Vandyck; Lely marks the first grade of descent, and Kneller the second. His works have much freedom, and are well drawn and coloured; but they are essentially slight in manner, and to a great extent monotonous, this arising partly from the habit which he had of lengthening the oval of all his heads. The colouring may be called brilliant rather than true. He indulged much in the commonplaces of allegory; and, though he had a quality of dignified elegance not unallied with simplicity, genuine simple nature is seldom to be traced in his works. His fame has greatly declined now, and could not but do so after the advent of Reynolds. Among Kneller's principal paintings are the Forty-three Celebrities of the Kit-Cat Club, and the Ten Beauties of the Court of William III., now at Hampton court; these were painted by order of the queen; they match, but match unequally, the Beauties of the Court of Charles II., painted by Lely. He executed altogether the likenesses of ten sovereigns. It is said that Kneller's own favourite performance was the portrait of the Converted Chinese in Windsor Castle. His works are confined almost entirely to England, not more than two or three specimens having gone abroad after he had settled there.

KNIGHT, Charles (1791–1873), publisher and author, was the son of a bookseller and printer at Windsor, where he was born 15th March 1791. After acquiring some knowledge of Latin and French at a common day school, he was sent at the age of twelve to the classical school of Dr Nicholas of Ealing. There, according to his own account, he imbibed such a tincture of learning as made him desirous to be a scholar; and it was very much in opposition to his wishes that in 1805 he was withdrawn from school to be bound apprentice to his father. In editing *The Windsor and Eton Express*, commenced by his father in 1812, some gratification was afforded to his literary ambition, and this received additional stimulus when he became the publisher of *The Etonian*, edited by Praed, with Macaulay, Moultrie, and Derwent and Nelson Coleridge as principal contributors. After editing *The Guardian* from 1820 to 1822, Knight was induced by the Etonians already mentioned, now undergraduates at Cambridge, to set up in business at Pall-Mall East, and to become for them editor of *Knight's Quarterly Magazine*. As far as the magazine was concerned the venture was unsuccessful, for it was brought to a close with its sixth number, but it initiated for Knight a literary career as publisher and author which extended over forty years, and the unselfish enterprise of which conferred lasting intellectual benefit on the general mass of his fellow countrymen. In 1827 Knight became the superintendent of the publications of the Society for the Diffusion of Useful Knowledge, for whom he projected and edited *The British Almanac and Companion*, commenced in 1828. In 1829 he began the publication of *The Library of Entertaining Knowledge*, he himself writing several volumes of the series. 1832 and 1833 saw respectively the commencement of *The Penny Magazine* and *The Penny Cyclopædia*, two literary ventures which so far as circulation was concerned were highly satisfactory in their results, but the latter of which, on account of the heavy excise duty, was completed at a great pecuniary sacrifice. Besides a considerable number of illustrated editions of other standard works, Knight completed in 1842 *The Pictorial Shakespeare*, which, although now superseded in regard to critical scholarship, is still valued for the research and taste displayed in its illustrations. *The Pictorial Shakespeare* was followed by various other editions of the same author. The energy of Knight also found scope in the compilation of a variety of illustrated series, such as *Old England* and *The Land We Live in*. In 1853 he became editor of *The English Cyclopædia*, and conjointly with the multifarious duties of such an office he was also engaged in writing his *Popular History of England*, published in eight volumes, 1854–61. In 1864 he withdrew from the business of publisher, but he continued his active literary career nearly to the close of his long life, publishing *The Shadows of the Old Booksellers* (1865), an autobiography under the title *Passages of a Working Life During Half a Century* (3 vols., 1864–65), an historical novel *Begg'd at Court* (1868) and subsequently various papers in *The British Almanac and Companion*. He died at Addlestone, Surrey, March 9, 1873.

KNIGHTHOOD

KNIGHTHOOD and CHIVALRY are two words which are nearly but not quite synonymous; that is, they may often, although they cannot always, be used precisely in the same way and exactly in the same sense. What we mean by the order of knighthood is to all intents and purposes what we mean by the order of chivalry. But in some of the more special applications of the several terms diversities in their respective significations manifest themselves. We could not, for example, say of anybody that he had received the honour of chivalry, or that he had lived in the age of knighthood. Again, we should speak of lands as held in chivalry not in knighthood, and of the rank or degree of knighthood not of chivalry. But taken together the two words knighthood and chivalry designate a single subject of inquiry, which presents itself under three different although connected and in a measure intermingled aspects. It may be regarded in the first place as a mode or variety of feudal tenure, in the second place as a personal attribute or dignity, and in the third place as a scheme of manners or social arrangements. It is under these three general aspects that the subject is to be dealt with here. For the more important religious as distinguished from the military orders of knighthood or chivalry the reader is referred to the headings St John (Knights of), Teutonic Knights, and Templars.

Derivation of *knight*

Our words *knight* and *knighthood* are merely the modern forms of the Anglo-Saxon or Old English *cniht* and *cnihthád*. Of these the primary signification of the first was a boy or youth, and of the second that period of life which intervenes between childhood and manhood. But some time before the middle of the 12th century they had acquired the meaning they still retain of the French *chevalier* and *chevalerie*. In a secondary sense *cniht* meant a servant or attendant answering to the German *Knecht*, and in the Anglo-Saxon Gospels a disciple is described as a *leorning cniht*. In a tertiary sense the word appears to have been occasionally employed as equivalent to the Latin *miles*—usually translated by *thegn*—which in the earlier Middle Ages was used as the designation of the domestic as well as of the martial officers or retainers of sovereigns and princes or great personages.[1] Sharon Turner suggests that *cniht* from meaning an attendant simply may have come to mean more especially a military attendant, and that in this sense it may have gradually superseded the word thegn.[2] But the word thegn

[1] Du Cange, *Gloss.*, *s.v.* "Miles."

[2] *History of England*, vol. iii. chap. 12.

itself, that is, when it was used as the description of an attendant of the king, appears to have meant more especially a military attendant. As Dr Stubbs says, "the thegn seems to be primarily the warrior gesith"—the gesiths forming the chosen band of companions (*comites*) of the German chiefs (*principes*) noticed by Tacitus—"he is probably the gesith who had a particular military duty in his master's service"; and he adds that from the reign of Athelstan "the gesith is lost sight of except very occasionally, the more important class having become thegns, and the lesser sort sinking into the rank of mere servants of the king."[1] It is pretty clear, therefore, that the word *cniht* could never have superseded the word thegn in the sense of a military attendant, at all events of the king. But besides the king, the ealdormen, bishops, and king's thegns themselves had their thegns, and to these it is more than probable that the name of *cniht* was applied. Under the singular system of joint responsibility and suretyship which was characteristic of the Anglo-Saxon government, the practice of commendation had attained to extraordinary dimensions. He who was unattached to some superior—the lordless man—was indeed regarded as a kind of outlaw; and, if he refused or neglected to choose a lord for himself, his kindred were bound to present him to the county court and select a lord for him. Hence a relation which was for the most part merely personal, but which only required the addition of land holding—an addition, it can scarcely be doubted, sometimes made—to render it in all respects feudal, was widely and firmly established in England long before the Norman Conquest. The mutual rights and obligations of lord and man, in a far more advanced condition than they appear as between hlaford and gesith at an earlier period, were perfectly familiar to the Anglo-Saxons, and it was only in part due to the influence of the Normans that they were subsequently transformed into the mutual rights and obligations of lord and tenant. Around the Anglo-Saxon magnates were collected a crowd of retainers and dependants of all ranks and conditions; and there is evidence enough to show that among them were some called *cnihtas* who were not always the humblest or least considerable of their number.[2] The testimony of Domesday also establishes the existence in the reign of Edward the Confessor of what Dr Stubbs describes as a "large class" of landholders who had commended themselves to some lord, and he regards it as doubtful whether their tenure had not already assumed a really feudal character. But in any event it is manifest that their condition was in many respects similar to that of a vast number of unquestionably feudal and military tenants who made their appearance after the Norman Conquest. If consequently the former were called *cnihtas* under the Anglo-Saxon régime, it seems sufficiently probable that the appellation should have been continued to the latter—practically their successors—under the Anglo-Norman régime. And if the designation of knights was first applied to the military tenants of the earls, bishops, and barons—who although they held their lands of mesne lords owed their services to the king—the extension of that designation to the whole body of military tenants need not have been a very violent or prolonged process. Assuming, however, that *knight* was originally used to describe the military tenant of a noble person, as *cniht* had sometimes been used to describe the thegn of a noble person, it would, to begin with, have defined rather his social status than the nature of his services. But those whom the English called *knights* the Normans called *chevaliers*, by which term the nature of their services was defined, while their social status was left out of consideration. And at first *chevalier* in its general and honorary signification seems to have been rendered not by *knight* but by *rider*, as may be inferred from the Saxon Chronicle, wherein it is recorded under the year 1085 that William the Conqueror "dubbade his sunu Henric to ridere."[3] But, as Mr Freeman says, "no such title is heard of in the earlier days of England. The thegn, the ealdorman, the king himself, fought on foot; the horse might bear him to the field, but when the fighting itself came he stood on his native earth to receive the onslaught of her enemies."[4] In this perhaps we may behold one of the most ancient of British insular prejudices, for on the Continent the importance of cavalry in warfare was already abundantly understood. It was by means of their horsemen that the Austrasian Franks established their superiority over their neighbours, and in time created the Western empire anew, while from the word *caballarius*, which occurs in the *Capitularies* in the reign of Charlemagne, came the words for knight in all the Romance languages.[5] In Germany the chevalier was called *Ritter*, but neither *rider* nor *chevalier* prevailed against *knight* among ourselves. And it was long after *knighthood* had acquired its present meaning with us that *chivalry* was incorporated into our language. It may be remarked too in passing that in official Latin, not only in England but all over Europe, *miles* held its own against both *eques* and *caballarius*.

Origin of mediæval knighthood.

Concerning the origin of knighthood or chivalry as it existed in the Middle Ages,—implying as it did a formal assumption of and initiation into the profession of arms,—nothing beyond more or less probable conjecture is possible. The mediæval knights had nothing to do in the way of derivation with the "equites" of Rome, the knights of King Arthur's Round Table, or the Paladins of Charlemagne. But there are grounds for believing that some of the rudiments of chivalry are to be detected in early Teutonic customs, and that they may have made some advance among the Franks of Gaul. We know from Tacitus that the German tribes in his day were wont to celebrate the admission of their young men into the ranks of their warriors with much circumstance and ceremony. The people of the district to which the candidate belonged were called together; his qualifications for the privileges about to be conferred upon him were inquired into; and, if he were deemed fitted and worthy to receive them, his chief, his father, or one of his near kinsmen presented him with a shield and a lance. Another custom apparently common to the Goths and the Franks was the ceremony of adoption by arms. By means of a solemn investiture with warlike weapons, the two parties to the formality or rite thenceforth acquired the artificial characters of father and son, not, as in the Roman practice of adoption, for any purpose of succession or inheritance, but in a purely honorary and complimentary manner. Selden and Du Cange concur in tracing the ceremony of "dubbing to knighthood" directly to the ceremony of the "adoptio per arma." Among the Lombards the sons of their kings were forbidden to sit at the tables of their fathers until they had been invested with arms, and this, it is further said, by some foreign prince or potentate.[6] But among the Franks we find, from the authorities cited by Du Cange, Charlemagne girding his son Louis the Pious, and Louis the Pious girding his son Charles the Bald with the sword, when they arrived at manhood.[7] These cases can hardly be referred, as the Lombard usages may, to the "adoptio per arma." Yet it is indisputable that in the investiture of Louis and Charles with the sword some ceremony was observed which was deemed worthy of record,

not for its novelty, but as a thing of recognized importance. It does not follow that a similar ceremony extended to personages less exalted than the sons of kings and emperors. But if it did we must naturally suppose that it applied in the first instance to the mounted warriors who formed the most formidable portion of the warlike array of the Franks. It was among the Franks indeed, and possibly through their experiences in war with the Saracens, that cavalry first acquired the pre-eminent place which it long maintained in every European country. In early society, where the army is not a paid force but the armed nation, the cavalry must necessarily consist of the noble and wealthy, and cavalry and chivalry, as Mr Freeman observes,[1] will be the same. Since then we discover in the *Capitularies* of Charlemagne actual mention of "caballarii" as a class of warriors, it may reasonably be concluded that formal investiture with arms applied to the "caballarii," if it was a usage extending beyond the sovereign and his heir apparent. "But," as Hallam says, "he who fought on horseback and had been invested with peculiar arms in a solemn manner wanted nothing more to render him a knight;" and so he concludes, in view of the verbal identity of "chevalier" and "caballarius," that "we may refer chivalry in a general sense to the age of Charlemagne."[2] Yet, if the "caballarii" of the *Capitularies* are really the precursors of the later knights, it remains a difficulty that the Latin name for a knight is "miles," although "caballarius" became in various forms the vernacular designation.

Knighthood in England. Before it was known that the chronicle ascribed to Ingulf of Croyland is really a fiction of the 13th or 14th century, the knighting of Heward or Hereward by Brand, abbot of Burgh (now Peterborough), was accepted from Selden to Hallam as an historical fact, and knighthood was supposed, not only to have been known among the Anglo-Saxons, but to have had a distinctively religious character which was contemned by the Norman invaders. The genuine evidence at our command altogether fails to support this view. When William of Malmesbury describes the knighting of Athelstan by his grandfather Alfred the Great, that is, his investiture "with a purple garment set with gems and a Saxon sword with a golden sheath," there is no hint of any religious observance. In spite of the silence of our records, Dr Stubbs thinks that kings so well acquainted with foreign usages as Ethelred, Canute, and Edward the Confessor could hardly have failed to introduce into England the institution of chivalry then springing up in every country of Europe; and he is supported in this opinion by the circumstance that it is nowhere mentioned as a Norman innovation. Yet the fact that Harold received knighthood from William of Normandy[3] makes it clear either that Harold was not yet a knight, which in the case of so tried a warrior would imply that "dubbing to knighthood" was not yet known in England even under Edward the Confessor, or, as Mr Freeman thinks, that in the middle of the 11th century the custom had grown in Normandy into "something of a more special meaning" than it bore in England. William of Normandy was knighted by his overlord Henry I. of France, and of the Conqueror's sons he himself, as we have already seen, knighted Henry Beauclerc,[4] while William Rufus was knighted by Archbishop Lanfranc.[5] It was under William Rufus, according to Mr Freeman, that the chivalrous and financial sides of feudalism sprang together into sudden prominence in England—the first as represented by the Red King, and the second as represented by his minister Ranulf Flambard.[6]

In one sense tenure in chivalry was practically co-extensive with European feudalism, while in another sense it was strictly speaking peculiar to England after the Norman Conquest, and Ireland after the English Conquest. We have no earlier information of the details of the feudal organization of Normandy than we have of the feudal organization of England, and therefore it is impossible to say how far the second was copied from the first, or the first assimilated to the second. But at all periods there was apparently sufficient difference between the Norman "fief de hauberc" and the English knight's fee to prevent the one from being pronounced in the proper meaning of the term the counterpart of the other. Into Ireland, however, the English system of tenures was imported without change of conditions.[7] But the process of feudalization commenced in England under William I. was only completed under Henry II., and at the time of the subjugation of Ireland there was already established a distinction between the feudal arrangements which had been made before and after the death of Henry I., as the "old" and the "new" feoffments. That Henry II.'s method of dealing with the conquered lands of Ireland was an exact imitation of William I.'s method of dealing with the conquered lands in England cannot therefore be assumed. But both kings had at their disposal a large extent of territory which they granted to their vassals on terms necessarily very similar. In the reign of Henry II. the knight's fee was what may be called the "unit" of the system of tenures which had grown up in England since the Norman Conquest. In the *Modus Tenendi Parliamenti*,[8] for instance, a treatise which pretended to date from the 11th and which really dates from the 14th century, it is laid down that an earldom consisted of twenty knights' fees, and that a barony consisted of thirteen and a third knights' fees, a statement which seems to have been accepted without misgiving until it was refuted by Selden.[9] It is, however, beyond question that some, although not all, of the feudal services and obligations of the tenants of earldoms and baronies were determined by the number of the knights' fees which they comprised. It was certainly not a fixed number, for it varied in every or nearly every recorded example.[10] But it was in each instance a specified number, by which the earl's or baron's military contribution to the king's army was settled and the amerciaments payable in the event of its being absent or incomplete were computed.[11] Hallam is inclined to attribute the invention of what he terms the "reasonable and convenient" principle of the knight's fee to the administrative genius of William the Conqueror.[12] But Domesday proves that at the time when the survey was made nothing approaching to a regular distribution of the country into knights' fees had been attempted. On two occasions indeed the expression "servitium unius militis," which was afterwards the technical designation of a knight's fee in legal phraseology, is

[4] The Saxon Chronicle so records. But Ordericus Vitalis says that he received his arms from Lanfranc, and Dr Stubbs seems to think that both statements may be true (*Const. Hist.*, vol. i. p. 367).
[5] William of Malmesbury is the authority for the knighting of William Rufus by Archbishop Lanfranc. "Accessit etiam favori ejus maximum rerum momentum archiepiscopus Lanfrancus eo quod eum nutrierat et militem fecerat, quo auctore et annitente die Sanctorum Cosmæ et Damiani coronatus."—*Gesta Regum Anglorum*, lib. iv. sec. 305. Dr Stubbs notices, in this connexion, that abbots were forbidden to make knights in the Council of London in 1102. He adds that "Thomas Becket knighted the count of Guisnes, and William, bishop of Ely, knighted Ralph Beauchamp as late as 1191" (*Const. Hist.*, vol. i. p. 367).

employed. But even the word "miles" had not as yet acquired the special meaning which was subsequently assigned to it. Among the "milites" of Domesday are persons of very various conditions, from ordinary soldiers and the inferior tenants of manors to Hamo the sheriff and the earl of Eu.[1] But when the returns contained in the Black Book of the Exchequer were made in the reign of Henry II., both the principle and system of knights' fees were fully and definitively established. Hence this change must have been effected in the interval between the compilation of these two records. It cannot be supposed that the numerous grants of land made by William I. to his adherents were exempt from military obligation of one kind or another. But no original grant of his or of either of his immediate successors to any lay vassal is in existence to inform us what the exact nature of those military obligations was; and, arguing from the grants to various ecclesiastical vassals, Dr Stubbs regards it as unlikely that such gifts were made on any expressed condition or accepted with a distinct pledge to provide a certain contingent of knights for the king's service.[2] Before the Norman Conquest, he contends, all landholders having been bound to the duty of national defence, and a certain quantity of land having customarily furnished a fully armed man, the old rate of military obligation was in all probability continued in the case of the new grantees after the Conquest. Nothing in Domesday implies that the conditions of military service differed under the old and the new monarchy, and hence Dr Stubbs concludes that "the form in which knights' fees appear when called on by Henry II. for scutage was most probably the result of a series of compositions by which the great vassals relieved their lands from a general burden by carving out particular estates the holders of which performed the services due from the whole; it was a matter of convenience and not of tyrannical pressure." And, although Selden, and Madox after him, adhere to the common and ancient tradition that William the Conqueror made his grants conditional on the service of some particular number of knights in every case, they substantially agree in regarding the knight's fee in its special meaning as the consequence of subinfeudation. From the reign of Henry II. to the reign of Edward I., indeed, what may be called grants in gross from the king and grants in detail from the mesne lords were the ordinary methods of erecting knights' fees and providing for the discharge of the personal and pecuniary obligations with which they were burdened.

Although the feudal services and incidents of a knight's fee appear to have been ascertained with perfect clearness, the exact nature of a knight's fee itself—what it was or in what it consisted—has been the subject of a great deal of controversy. As the demands both personal and pecuniary which were made on the holder of each knight's fee were uniform, it is reasonable to conclude that all such fees were in some way equivalent to one another. But whether their equivalence was inferred from the quantity of land they contained or from the amount of revenue derived from them has been much debated, and cannot be said to be even now finally settled. Selden, indeed, roundly affirms that "the legal value of knights' fees was never in truth estimable either by any certain number of acres or quantity of revenue (though some have erroneously determined them by both), but only by the services or number of knights reserved."[3] But if this were the case it is difficult to understand how parts of a knight's fee such as a half or a third could have been held, as they unquestionably were held, under reduced burdens calculated in proportion to the full burdens of a whole knight's fee. According to the analogies of the Anglo-Norman policy in other departments of its manifestation, it might have been expected with some degree of confidence that the knight's fee would have been a combination of the property qualification of the thegn and the feudal attributes of the "fief de hauberc," that is, of the latter superinduced upon the former. Before the Norman Conquest the property qualification of a thegn was five hides of land, for which a fully equipped warrior was to be furnished for the national defence in the king's host or "fyrd"; and there is no evidence to rebut the presumption that after the Norman Conquest a similar rate of military obligation was continued. It is not, however, without hesitation that Dr Stubbs arrives at what seems to be rather a provisional than a final determination on the subject. In one passage he observes that "the name of thegn covers the whole class which after the Conquest appears under the name of knights, with the same qualification in land and nearly the same obligations."[4] In another passage, on the contrary, he says that "it cannot even be granted that a definite area of land was necessary to constitute a knight's fee; for although at a later period and in local computations we may find four or five hides adopted as a basis of calculation, where the particular knight's fee is given exactly, it affords no ground for such a conclusion."[5] On the whole he thinks it must be held that its extent was determined not by acreage but by rent or valuation, and that "the common quantity was really expressed in the twenty librates, the twenty pounds' worth of annual value, which until the reign of Edward I. was the qualification for knighthood." That this was the established appraisement of the knight's fee very soon after the Norman Conquest Dr Stubbs infers from the circumstance that Archbishop Lanfranc maintained ten knights to answer for the military service due from the convent of Christ Church in consideration of land worth two hundred pounds a year which on that account was assigned to him.[6] But, although, as Coke says, the annual value of a knight's fee was twenty pounds at the enactment of both Magna Charta and the statute "De Militibus," he cites various writs for distraint of knighthood which, if indeed some of them were not merely writs of array, would show that it varied irregularly from ten to forty pounds in amount between the reigns of Edward I. and Henry VI.[7] It was computed at forty pounds in the reign of Elizabeth, and again when Charles I. resorted to "knight-money" as a means of raising a revenue. The aggregate number of knights' fees throughout England in feudal times is very variously stated by tradition. The assertion of Ordericus Vitalis in the reign of Stephen that the Conqueror settled his military fiefs so as to provide 60,000 knights for his service was accepted, not only

"There is no ground," says Mr Freeman, "for thinking that William directly or systematically introduced any new kind of tenure into the holding of English lands. There is nothing to suggest any such belief either in the chronicles of his reign, in the survey which is his greatest monument, in the genuine, or even in the spurious, remains of his legislation. The code of laws which bears William's name, but which is assuredly none of his enacting, is in all but a very few points a mere confirmation of the old English law. And the few points of innovation have nothing to do with feudal tenures. But when we come to the reign next but one we are met by a document which shows us that within thirteen years after the Conqueror's death not only the military tenures but the worst abuses of the military tenures were in full force in England. The great charter of Henry I., the groundwork of the greater charter of John, and thereby the groundwork of all later English legislation, is filled with promises to abolish the very same class of abuses which were at last swept away by the famous statute of Charles II." popularly and in an uncritical age, but by writers of weight from Selden to Hallam. But 60,000 knights' fees at £20 a year gives about twelve times the whole national income from land as it appears in Domesday; or, if the knight's fee is reckoned at five hides, the aggregate amounts to thirty millions of acres, leaving something more than two millions for royal demesnes, all other tenures, forests, waste, and the rest.[1] The Red Book of the Exchequer, which dates from the first third of the 13th century, mentions a tradition, which the compiler himself rejects as unsupported by evidence, that William I. created not 60,000 but 32,000 knights' fees.[2] According to the Black Book of the Exchequer the number of knights furnished at the date of its compilation by the tenants in chief of twenty counties taken at random was 3991, and of the ten counties south of the Thames and Avon 2047.[3] As it is probable that these ten counties contained about a fourth of the population, and as the proportion of knights' fees is not very materially departed from in the twenty unselected counties, we should not be far wrong in assuming perhaps that the entire number of knights' fees in the kingdom was between eight and nine thousand.[4]

All tenure in chivalry was founded on homage and fealty, to which were added the various services and liabilities under which the different fiefs or tenements were held. Homage consisted in the mutual acknowledgment by the lord and tenant that the latter was the vassal or man of the former, accompanied as evidence thereof by certain solemn acts of obeisance on the one hand and of acceptance and patronage on the other. Hence homage could be done only by the tenant in person to the lord in person. Connected with and following on homage was fealty, which was an undertaking or oath on the part of the tenant that he would be true and faithful to his lord in consideration of the lands which he held of him, and that he would duly and fully observe the several conditions of his tenure, which declaration might be received on behalf of the lord by anybody whom he might appoint for the purpose. Every tenant in chivalry owed service to his lord in peace as well as in war, and was bound to attend him in his court not less than in the field. The civil obligations of tenants by knight-service were to assist their lords in the administration of justice and to support them on occasions of ceremony and display. The chief vassals of the king, the earls and barons, were the homagers and peers of the great court-baron of the kingdom, and in turn their under-tenants were the homagers and peers of their palatine and baronial courts. The military obligations of tenants by knight-service were discharged either in the king's armies or in the castles of the king and his principal feudatories. In the first case the holder of a knight's fee was bound to serve in the royal host fully equipped and on horseback at his own expense for forty days in every year when called upon,—a tenant in chief serving under the direct command of the sovereign or his officers, and an under tenant in the martial retinue of his immediate lord. But in the second case the duties of the tenant were not defined by any general rule or custom, and the terms of his service of "castle guard" depended on the special stipulations of his grant or feoffment.[5] Besides all this, however, tenants by knight-service were subjected to various other burdens which in course of time became the most important incidents of their tenure. On the death of a tenant, his heir, if he was of full age, was compelled on taking up his inheritance to pay a fine to his lord. This was called a relief if he was an under tenant, or "primer seisin" if he was a tenant in chief, and amounted in the first instance to one quarter's profits, and in the second to one whole year's profits, of his estate.[6] The tenant was also liable to render what were called aids to his lord for three purposes, namely, to ransom him from captivity, to make his eldest son a knight, and to provide a portion for his eldest daughter on her marriage. Of these three aids ransom was only a very rare and exceptional demand, while those "pur faire fitz chivaler" and "pur file marier" were of course of frequent and ordinary occurrence. Wardship and marriage, however, were the main incidents of tenure by knight-service after the military obligations which formed its essential characteristic, and they were always the most unpopular and oppressive of them. When on the death of the tenant the heir was under the age of twenty-one or the heiress under the age of fourteen, the lord became the "guardian in chivalry" of his or her person and lands until he reached the age of twenty-one or she reached the age of sixteen, when on the payment of half a year's income of their estate in lieu of all reliefs and "primer seisins" the wards were entitled to sue out their livery or "ousterlemain." In the meantime the lord had all the profits of the lands, and was not bound to render any account of them, while he was at liberty to assign or sell his guardianship with its attendant rights and immunities unimpaired. Moreover, he was entitled to dispose of his male, as well as his female, wards in marriage to any person of equal or similar rank to their own, and if they rejected the match recommended by him, or married without his consent, they incurred the forfeiture to him of a sum of money equivalent to what was termed the value of their marriage, that is, the price which was to have been given or might have been reasonably expected to be given for it. Nor could the tenant by knight-service part with his lands without the payment of a fine on alienation to his lord, to whom they altogether passed on his neglect to fulfil his feudal obligations or on the extinction of his heirs. Again, whether he was an under tenant or a tenant in chief, his lands escheated to the king if he was convicted of treason, while if he was convicted of any other felony they escheated to his immediate lord, the king—if he were not the immediate lord—entering into possession of them for a year and a day. It had also become customary from a comparatively early period to compel the tenants of knights' fees to take upon themselves the honorary distinction of knighthood, and it is remarkable that this appears to have been most systematically insisted on after the actual render of military service had been universally commuted to a money equivalent, and when even that money equivalent itself under its original name of escuage or scutage was passing or had passed away.[7] Neglect or refusal to be knighted by any

[7] "In the nineteenth of Henry III., all the sheriffs of England were commanded by close writs under the great seal to make proclamation that all they who held of the king in chief one knight's fee or more and were not as yet knighted should get themselves knighted before the ensuing Christmas, as they loved the tenements and fees they held of the king. Two years before the king had seized the lands and chattels of Roger de Sumery, including the honour of Dudley, because he did not come to the king to be girded with the belt of knighthood" (Madox, *Baronia Anglica*, p. 130). "There can be no doubt," Dr Stubbs says, "that this practice was one of the influences which blended the minor tenants-in-chief with the general body of the free holders; possibly it led also to the development of the military spirit which in the following century [he is speaking of the reign of Edward I.] sustained the extravagant designs of Edward III., and was glorified under the name of chivalry" (*Const. Hist.*, vol. ii. p. 282). The statute "De Militibus" was passed in the reign of Edward II., just at the period when scutage was being abandoned as a special mode of taxation (Stubbs, *Const. Hist.*, vol. ii. p. 522).

tenant in chivalry who was thereunto commanded by the king's writ subjected the offender, if he was capable of bearing arms, and between the ages of twenty-one and sixty, to a fine. And thus in the progress of events knight-service tended to become more and more divorced from its primary uses and intentions, and to survive merely as a series of oppressive exactions and idle ceremonies. During the centuries which followed the enactment of the statute of "Quia Emptores," the king gradually added the character of immediate lord over nearly all the lands held in chivalry within the realm to the character of lord paramount which had been his from the beginning. When feudalism was as firmly established and as fully developed as it ever was in England, a single officer in each county, called the king's escheator, who was appointed annually by the lord treasurer, was considered sufficient to watch over the royal "droits of seignory" and to prevent the evasion of them. But when nothing save the name and the hardships of feudalism remained, the Court of Wards and Liveries was erected, and the scandals and abuses to which its jurisdiction gave rise under the Tudors and the first two Stuarts speedily assumed the proportions of an almost intolerable grievance. Towards the end of the reign of James I. the general discontent resulted in an attempt to abolish tenures in chivalry altogether, compensation being proposed to the king and the mesne lords in the form of a fixed rent in the place of their feudal dues, "which motion, though it proceeded not to effect," says Coke, "yet we thought it well to remember, hoping that so good a motion . . . will some time or other . . . take effect and be established."[1] This hope was in part realized by the Long Parliament, which by resolution of both Houses in 1645 put an end to the Court of Wards and Liveries, and converted all tenures in chivalry into free and common soccage. But it was not until eleven years later that, by an Act of the Commonwealth in 1656, legislative sanction was conferred on these ordinances. Their substance, however, had been embodied in one of the articles of the treaty of Newport between Charles I. and the Parliamentarians, and the king was then to have been indemnified by means of a revenue charged on the lands relieved, amounting to a hundred thousand pounds a year. At the Restoration a tax on lands held in chivalry was proposed in place of knight-service, but an alternative scheme for an excise on beer and some other liquors received the preference. It was not, however, until the abolition of purveyance as well as knight-service had been included in the measure, since known as the 12th Charles II. cap. 24, by way of concession to the claims of the yeomanry and peasantry, that it was permitted to pass, and then only amid vigorous protests from many quarters.

Regarded as a method of military organization, the feudal system of tenures was always far better adapted to the purposes of defensive than of offensive warfare. Against invasion it furnished a permanent provision both in men-at-arms and strongholds; nor was it unsuited for the campaigns of neighbouring counts and barons which lasted for only a few weeks, and extended over only a few leagues. But when kings and kingdoms were in conflict, and distant and prolonged expeditions became necessary, it was speedily discovered that the unassisted resources of feudalism were altogether inadequate. The barons and knights who fought on horseback were in their own country attended by the yeomen and townsmen who fought on foot. But in foreign wars the feudal cavalry alone were available, and the infantry were nearly all and always mercenary troops. Again, although the period for which the holders of fiefs were bound to military service had originally been uncertain and unlimited, it gradually became an established rule, to which the exceptions were everywhere trifling and rare, that it should be restricted in various countries to from forty to sixty days in each year.[2] Hence warlike operations on anything like an extended scale would have been impossible if the terms of the feudal engagement had been strictly observed. In these circumstances it became customary to retain the feudal tenants under arms as stipendiaries after their ordinary and legitimate obligations had been fulfilled. But this arrangement was exceedingly inconvenient in practice to sovereigns and their feudatories alike. It implied to the former the expenditure of large sums of money, then very difficult to raise, on what was frequently an inferior commodity, and to the latter the neglect of their estates and of all their peaceful duties and diversions. It became therefore the manifest interest of both parties that personal services should be commuted into pecuniary payments. In the early times of feudalism the refusal or omission to discharge the military obligations attached to a fief entailed immediate forfeiture. But the usage of fining the delinquents in such cases, at first arbitrarily and afterwards in a fixed amount, grew up all over Europe, while in England from the reign of Henry II. to the reign of Edward II. escuage or scutage was regularly levied, originally as an amerciament and subsequently as an ordinary war-tax on tenants by knight-service.[3] In this way funds for war were placed at the free disposal of sovereigns, and, although the feudatories and their retainers still formed the most considerable portion of their armies, the conditions under which they served were altogether changed. Their military service was now the result of special agreement, by which they undertook in consideration of certain payments to themselves and their followers, with whom they had entered into similar arrangements, to attend in a particular war or campaign with a retinue of stipulated composition and strength. In the reign of Edward I., whose warlike enterprises after he was king were confined within the four seas, this alteration does not seem to have proceeded very far, and Scotland and Wales were subjugated by what was in the main if not exclusively a feudal militia raised as of old by writ to the earls and barons and the sheriffs.[4] But the armies of Edward III., Henry V., and Henry VI. during the century of intermittent warfare between England and France were recruited and sustained entirely on the principle of contract. On the Continent the systematic employment of mercenaries was both an early and a common practice. But the transition from the feudal régime to the régime of standing armies was everywhere sudden and abrupt as compared with the same process among ourselves.

Besides consideration for the mutual convenience of sovereigns and their feudatories, there were other causes which materially contributed towards bringing about the changes in the military system of Europe which were finally accomplished in the 13th and 14th centuries. During the crusades vast armies were set on foot in which feudal rights and obligations had no place, and it was

[1] *Institutes* 4, vol. iii. p. 203.

[2] Du Cange, *Gloss.*, *s.v.* "Hostis"; Brussel, *Usage Général des Fiefs*, p. 162 *sq.*

[3] Henry II. adopted the knight's fee instead of the hide as the basis of rating (in levying taxes) for the knights and barons, and under him escuage or scutage became "an honourable commutation for personal service." Littleton defines knight-service as tenure by "homage, fealty, and escuage"; and, although scutage may have been the name for the personal service represented by the tax, it had of course long been replaced by the tax itself when he wrote in the reign of Henry VI. See Coke-Littleton. bk. ii. chap. 4, sect. 103; Madox, *Baronia Anglica*, pp. 216-226; Pearson, *Early and Middle Ages*, vol. i. p. 591; Stubbs, *Constitutional History*, vol. i. pp. 581-590.

[4] Stubbs, *Const. Hist.*, vol. ii. p. 278; also compare Grose, *Military Antiquities*, vol. i. p. 65 *sq.*

seen that the volunteers who flocked to the standards of the various commanders were not less but even more efficient in the field than the vassals they had hitherto been accustomed to lead. It was thus established that pay, the love of enterprise, and the prospect of plunder,—if we leave zeal for the sacred cause which they had espoused for the moment out of sight,—were quite as useful for the purpose of enlisting troops and keeping them together as the tenure of land and the solemnities of homage and fealty. Moreover, the crusaders who survived the difficulties and dangers of an expedition to Palestine were seasoned and experienced although frequently impoverished and landless soldiers, ready to hire themselves to the highest bidder, and well worth the wages they received. Again, it was owing to the crusades that the church took the profession of arms under her peculiar protection, and thenceforward the ceremonies of initiation into it assumed a religious as well as a martial character. Nor was this by any means a merely gratuitous patronage of bloodshed on her part. In the ages of faith and chivalry, magic and sorcery were the terrors alike of the pious and the brave, and the blessings of the priest on the warrior, his weapons, and his armour were always regarded as the surest safeguards against the influence of hostile spells and enchantments. To distinguished soldiers of the cross the honours and benefits of knighthood could hardly be refused on the ground that they did not possess a sufficient property qualification,—of which perhaps they had in fact denuded themselves in order to their own and their retinue's equipment for the Holy War. And thus the conception of knighthood as of something wholly distinct from and independent of feudalism both as a social condition and a personal dignity arose and rapidly gained ground. It was then that the analogy was first detected which was afterwards more fully developed between the order of knighthood and the order of priesthood, and that an actual union of monachism and chivalry was effected by the establishment of the religious orders of which the Knights Templars and the Knights Hospitallers were the most eminent examples. As comprehensive in their polity as the Benedictines or Franciscans, they gathered their members from, and soon scattered their possessions over, every country in Europe. And in their indifference to the distinctions of race and nationality they merely accommodated themselves to the spirit which had become characteristic of chivalry itself, already recognized, like the church, as a universal institution which comprised and knit together the whole warrior caste of Christendom into one great fraternity irrespective alike of feudal subordination and territorial boundaries. Somewhat later the adoption of hereditary surnames and armorial bearings marked the existence of a large and noble class who either from the subdivision of fiefs or from the effects of the custom of primogeniture were very insufficiently provided for. To them only two callings were generally open, that of the churchman and that of the soldier, and the latter as a rule offered greater attractions than the former in an era of much licence and little learning. Hence the favourite expedient for men of birth, although not of fortune, was to attach themselves to some prince or magnate in whose military service they were sure of an adequate maintenance, and might hope for even a rich reward in the shape of booty or of ransom.[1] It is probably to this period and these circumstances that we must look for at all events the rudimentary beginnings of the military as well as the religious orders of chivalry. Of the existence of any regularly constituted companionships of the first kind there is no trustworthy evidence until between two and three centuries after fraternities of the second kind had been organized. Soon after the greater crusading societies had been formed similar orders, such as those of St James of Compostella, Calatrava, and Alcantara, were established to fight the Moors in Spain instead of the Saracens in the Holy Land. But the members of these orders were no less monks than knights, their statutes embodied the rule of the cloister, and they were bound by the ecclesiastical vows of celibacy, poverty, and obedience. From a very early stage in the development of chivalry, however, we meet with the singular institution of brotherhood in arms; and from it the ultimate origin if not of the religious fraternities at any rate of the military companionships is usually derived.[2] By this institution a relation was created between two or more knights by voluntary agreement which was regarded as of far more intimacy and stringency than any which the mere accident of consanguinity implied. Brothers in arms were supposed to be partners in all things save the affections of their "lady-loves." They shared in every danger and every success, and each was expected to vindicate the honour of another as promptly and zealously as his own. Their engagements usually lasted through life, but sometimes only for a specified period or during the continuance of specified circumstances, and they were always ratified by oath, occasionally reduced to writing in the shape of a solemn bond and often sanctified by their reception of the eucharist together. Romance and tradition speak of strange rites—the mingling and even the drinking of blood—as having in remote and rude ages marked the inception of these martial and fraternal associations.[3] But in later and less barbarous times they were generally evidenced and celebrated by a formal and reciprocal exchange of weapons and armour. In warfare it was customary for knights who were thus allied to appear similarly accoutred and bearing the same badges or cognizances, to the end that their enemies might not know with which of them they were in conflict, and that their friends might be unable to accord more applause to one than to another for his prowess in the field. It seems likely enough therefore that, at or soon after the period when the crusades had initiated the transformation of feudalism into chivalry as a military system, bodies banded together by engagements of fidelity, although free from monastic obligations, wearing a uniform or livery, and naming themselves after some special symbol or some patron saint of their adoption, were neither unknown nor even uncommon. And such bodies raised by or placed under the command of a sovereign or grand master, regulated by statutes, and enriched by ecclesiastical endowments would have been precisely what in after times such orders as the Garter in England, the Golden Fleece in Burgundy, the Annunciation in Savoy, and the St Michael and Holy Ghost in France actually were.[4] The knight too who had "won his spurs" was very differently esteemed from the knight who succeeded to them as an incident of his feudal tenure. In rank and the external ensigns of rank under the sumptuary regulations of the age they were equal. But it was the first and not the second who was welcomed in court and camp, who was invited to the "round tables" which the Arthurian romances brought into fashion among the potentates of mediæval Europe, and more particularly Edward III. and Philip VI. And thus it became the ambition of every aspirant to knighthood to gain it by his exploits rather than to claim it merely as his right by virtue of his position and estate. But there was one qualification for knighthood

which was theoretically exacted even in England, and which was rigorously exacted abroad. Nobody could be legitimately created a knight who was not a gentleman of "name and arms," that is, who was not descended on both sides at the least from grandparents who were entitled to armorial bearings. And this condition is embodied in the statutes of every order of knighthood, religious or military, which can trace its origin to a period when chivalry was a social institution.[1]

During the 14th and 15th centuries, as well as somewhat earlier and later, the general arrangements of a European army were always and everywhere pretty much the same.[2] Under the sovereign the constable and the marshal or marshals held the chief commands, their authority being partly joint and partly several. Attendant on them were the heralds, who were the officers of their military court, wherein offences committed in the camp and field were tried and adjudged, and among whose duties it was to carry orders and messages, to deliver challenges and call truces, and to identify and number the wounded and the slain. The main divisions of the army were distributed under the royal and other principal standards, smaller divisions under the banners of some of the greater nobility or of knights banneret, and smaller divisions still under the pennons of knights or, as in distinction from knights banneret they came to be called, knights bachelors. All knights whether bachelors or bannerets were escorted by their squires. But the banner of the banneret always implied a more or less extensive command, while every knight was entitled to bear a pennon and every squire a pencel. All three flags were of such a size as to be conveniently attached to and carried on a lance, and were emblazoned with the arms or some portion of the bearings of their owners. But while the banner was square the pennon, which resembled it in other respects, was either pointed or forked at its extremity, and the pencel, which was considerably less than the others, always terminated in a single tail or streamer.[3] As we have already indicated, it became the custom from the time of the crusades to seek out and as far as possible to establish analogies between the institutions of chivalry and the church. In the military grades of the squire, the knight, and the banneret, therefore, were of course seen the representatives of the clerical grades of the deacon, the priest, and the bishop.[4] But despite that the ceremonies of ordination were unquestionably imitated in the ceremonies of knighting, there is no reason for supposing that the resemblance, such as it was, which obtained between the chivalrous and the ecclesiastical series of degrees was otherwise than accidental. Moreover, it failed in at least two material respects, namely, that squirehood although the usual was not the necessary preliminary to knighthood, and that in all the attributes of knighthood as knighthood a knight bachelor was as fully and completely a knight as a knight banneret. If indeed we look at the scale of chivalric subordination from another point of view, it seems to be more properly divisible into four than into three stages, of which two may be called provisional and two final. The bachelor and the banneret were both equally knights, only the one was of greater distinction and authority than the other. In like manner the squire and the page were both in training for knighthood, but the first had advanced further in the process than the second. It is true that the squire was a combatant while the page was not, and that many squires voluntarily served as squires all their lives owing to the insufficiency of their fortunes to support the costs and charges of knighthood. But in the ordinary course of a chivalrous education the successive conditions of page and squire were passed through in boyhood and youth, and the condition of knighthood was reached in early manhood. Every feudal court and castle was in fact a school of chivalry in which the sons of the sovereign and his vassals, or of the feudatory and his vassals, together commonly with those of some of their allies or friends, were reared in its principles and habituated to its customs and observances. And, although princes and great personages were rarely actually pages or squires, the moral and physical discipline through which they passed was not in any important particular different from that to which less exalted candidates for knighthood were subjected.[5] The page, or, as he was more anciently and more correctly called, the "valet" or "damoiseau," commenced his service and instruction when he was between seven and eight years old, and the initial phase continued for seven or eight years longer. He acted as the constant personal attendant of both his master and mistress. He waited on them in their hall and accompanied them in the chase, served the lady in her bower and followed the lord to the camp.[6] From the chaplain and his mistress and her damsels he learnt the rudiments of religion, of rectitude, and of love;[7] from his master and his squires the elements of military exercise, to cast a spear or dart, to sustain a shield, and to march with the measured tread of a soldier; and from his master and his huntsmen and falconers the "mysteries of the

[1] Being made to "ride the barriers" was the penalty for anybody who attempted to take part in a tournament without the qualification of name and arms. Hence the importance of the descents in geometrical progression commonly referred to as "sixteen quarters," beginning with "three descents" in England, "four lines" in France, "four quarters" in the empire, and "four branches" in Scotland. The books where this subject may be pursued are far too numerous to mention. Guillim (*Display of Heraldry*, p. 66) and Nisbet (*System of Heraldry*, vol. ii. p. 147) speak of it as concerning England and Scotland. See also Ashmole's *Order of the Garter*, p. 284. But in England knighthood has always been conferred to a great extent independently of these considerations. At almost every period there have been men of obscure and illegitimate birth who have been knighted. Ashmole cites Sandars's *Flandria Illustrata* to the effect that "the degree of knighthood is of so great splendour and fame that it bestows gentility not only upon a man meanly born but also upon his descendants, and very much increaseth the honour of those who are well descended." And he adds that "it is a maxim laid down by a learned civilian (Tiraquel, *De Nobilitate*) that knighthood ennobles, insomuch that whosoever is a knight it necessarily follows that he is also a gentleman (*Militia nobilitat ut quisquis est Miles is quoque continuo sit nobilis*), for, when a king gives the dignity to an ignoble person whose merit he would thereby recompense, he is understood to have conferred whatsoever is requisite for the completing of that which he bestows." By the common law, if a villain were made a knight he was thereby enfranchised and accounted a gentleman, and if a person under age and in wardship were knighted both his minority and wardship terminated.—*Order of the Garter*, p. 43; Nicolas, *British Orders of Knighthood*, vol. i. p. v.

[7] "Le petit Jehan de Saintré" is the great example on this point, especially the homily addressed to him by La Dame des Belles-Cousines. Therein she instructs him how he ought to love *par amours*. But Sir Walter Scott says that "so pure was the nature of the flame which she recommended that she maintained it to be inconsistent even with the seventh sin of chambering and wantonness to which it might seem too nearly allied. The least dishonest thought or action was, according to her doctrine, sufficient to forfeit the chivalrous lover the favour of his lady. It seems, however, that the greater part of her charges concerning incontinence is levelled against such as haunted the receptacles of open vice, and that she reserved an exception (of which in the course of the history she made liberal use) in favour of the intercourse which in all love, honour, and secrecy might take place when the favoured and faithful knight had obtained by long service the boon of amorous mercy from the lady whom he loved *par amours*" (article CHIVALRY in 7th and 8th editions of the *Encyclopædia Britannica*).

woods and rivers," or in other words the rules and practices of hunting and hawking. When he was between fifteen and sixteen he became a squire. But no sudden or great alteration was made in his mode of life. He continued to wait at dinner with the pages, although in a manner more dignified according to the notions of the age. He not only served but carved and helped the dishes, proffered the first or principal cup of wine to his master and his guests, and carried to them the basin, ewer, or napkin when they washed their hands before and after meat. He assisted in clearing the hall for dancing or minstrelsy, and laid the tables for chess or draughts, and he also shared in the pastimes for which he had made preparation. He brought his master the "vin de coucher" at night, and made his early refection ready for him in the morning. But his military exercises and athletic sports occupied an always increasing portion of the day. He accustomed himself to ride the "great horse," to tilt at the quintain, to wield the sword and battle-axe, to swim and climb, to run and leap, and to bear the weight and overcome the embarrassments of armour. He inured himself to the vicissitudes of heat and cold, and voluntarily suffered the pains or inconveniences of hunger and thirst, fatigue, and sleeplessness. It was then too that he chose his "lady-love," whom he was expected to regard with an adoration at once earnest, respectful, and the more meritorious if concealed. And when it was considered that he had made sufficient advancement in his military accomplishments, he took his sword to the priest, who laid it on the altar, blessed it, and returned it to him.[1] Afterwards he either remained with his early master, relegating most of his domestic duties to his younger companions, or he entered the service of some valiant and adventurous lord or knight of his own selection. He now became a "squire of the body," and truly an "armiger" or "scutifer," for he bore the shield and armour of his leader to the field, and, what was a task of no small difficulty and hazard, cased and secured him in his panoply of war before assisting him to mount his courser or charger. It was his function also to display and guard in battle the banner of the baron or banneret or the pennon of the knight he served, to raise him from the ground if he were unhorsed, to supply him with another or his own horse if his was disabled or killed, to receive and keep any prisoners he might take, to fight by his side if he was unequally matched, to rescue him if captured, to bear him to a place of safety if wounded, and to bury him honourably when dead. And after he had worthily and bravely borne himself for six or seven years as a squire, the time came when it was fitting that he should be made a knight.

Two modes of conferring knighthood appear to have prevailed from a very early period in all countries where chivalry was known. In both of them the essential portion seems to have been the accolade. But while in the one the accolade constituted the whole or nearly the whole of the ceremony, in the other it was surrounded with many additional observances. As soon as we have any historical evidence of their separate and distinct existence, we discover them as severally appropriated, the first to time of war and the second to time of peace.[2] In one of the oldest records of chivalry quoted by Selden, under the heading of "Comment on doit faire et creer ung Chivalier," it is stated that, "quant ung Escuier que a longement voyage et este en plusiers faicts d'armes et que a de quoy entretenir son estate et qu'il est de grant maison et rich et qu'il se trouve en un battaile on recounter il doit adviser le chiefe de l'armé ou vaillant chivalier. Alors doit venir devant luy et demander 'chivalier au nom de Dieu et de Sainct George donnez moy le ordre' et le dit chivalier ou chiefe de guerre doit tirer l'espee nue vers le dict demaundeur et doit dire en frappant trois fois sur icculy: 'Je te fais chivalier au nom de Dieu et de mon seigneur Sainct George, pour la foy et justice loyalment garder et l'eglise, femes, vesves, et orphelins defender."[3] But the words of creation were various as well as the words of the exhortation. Sometimes the first were "avancez chevalier au nom de Dieu," or "au nom de Dieu, Saint Michel, et Saint George je te fais chevalier"; and the second "soyez preux, hardi, et loyal," "be a good knight in the name of God"; or "soyez bon chevalier," or "be a good knight," merely. In this form a number of knights were made before and after almost every battle between the 11th and the 16th centuries, and its advantages on the score of both convenience and economy gradually led to its general adoption both in time of peace and time of war. On extraordinary occasions indeed the more elaborate ritual continued to be observed. But recourse was had to it so rarely that among us about the beginning of the 15th century it came to be exclusively appropriated to a special kind of knighthood. When Segar, garter king of arms, wrote in the reign of Queen Elizabeth, this had been accomplished with such completeness that he does not even mention that there were two ways of creating knights bachelors. "He that is to be made a knight," he says, "is striken by the prince with a sword drawn upon his back or shoulder, the prince saying, 'Soys Chevalier,' and in times past was added 'Saint George.' And when the knight rises the prince sayeth 'Avencez.' This is the manner of dubbing knights at this present, and that term 'dubbing' was the old term in this point, not 'creating.' This sort of knights are by the heralds called knights bachelors."[4] In our days when a knight is personally made he kneels before the sovereign, who lays a sword drawn, ordinarily the sword of state, on either of his shoulders, and says, "Rise," calling him by his Christian name with the addition of "Sir" before it.[5]

Very different were the solemnities which attended the creation of a knight when the complete procedure was observed. "The ceremonies and circumstances at the giving this dignity," says Selden, "in the elder time were of two kinds especially, which we may call courtly and sacred. The courtly were the feasts held at the creation, giving of robes, arms, spurs, and the like, whence in the stories of other nations so in those of ours 'armis militaribus donare' or 'cingulo militari,' and such more phrases are the same with 'militem facere' or to make a knight. The sacred were the holy devotions and

[1] Sainte Palaye, *Mémoires*, vol. i. p. 11 *sq.*:—"C'est peut-être à cette cérémonie et non à celles de la chevalerie qu'on doit rapporter ce qui se lit dans nos historiens de la première et de la seconde race au sujet des premières armes que les Rois et les Princes remettoient avec solemnité au jeunes Princes leurs enfans."

[2] There are several obscure points as to the relation of the longer and shorter ceremonies, as well as the origin and original relation of their several parts. There is nothing to show whence came "dubbing" or the "accolade." It seems certain that the word "dub" means to strike, and the usage is as old as the knighting of Henry by William the Conqueror (*supra*, pp. 111, 112). So, too, in the empire a dubbed knight is "ritter geschlagen." The "accolade" may etymologically refer to the embrace, accompanied by a blow with the hand, characteristic of the longer form of knighting. The derivation of "adouber," corresponding to "dub," from "adoptare," which is given by Du Cange, and would connect the ceremony with "adoptio per arma," is certainly inaccurate. The investiture with arms, which formed a part of the longer form of knighting, and which we have seen to rest on very ancient usage, may originally have had a distinct meaning. We have observed that Lanfranc invested Henry I. with arms, while William "dubbed him to rider." If there was a difference in the meaning of the two ceremonies, the difficulty as to the knighting of Earl Harold (*supra*, p. 112) is at least partly removed.

[5] Nicolas, *British Orders of Knighthood*, p. vii.

what else was used in the church at or before the receiving of the dignity, whence also 'consecrare militem' was to make a knight. Those of the first kind are various in the memories that preserve them, and yet they were rarely or never without the girding with a sword until in the later ages wherein only the stroke on the neck or shoulder according to the use at this day hath most commonly supplied it."[1] Of these "ceremonies and circumstances" Selden gives several examples, especially those of the knighting of Geoffrey of Anjou by Henry I., of Alexander III. of Scotland by Henry III. of England, and of Edward Prince of Wales (afterwards Edward II.) by his father Edward I. But the leading authority on the subject is an ancient tract written in French, which will be found at length either in the original or translated by Segar, Dugdale, Byshe, and Nicolas, among other English writers.[2] Daniel explains his reasons for transcribing it, "tant à cause du detail que de la naiveté du stile et encore plus de la bisarrerie des ceremonies que se faisoient pourtant alors fort serieusement," while he adds that these ceremonies were essentially identical in England, France, Germany, Spain, and Italy.

The process of inauguration was commenced in the evening by the placing of the candidate under the care of two "esquires of honour grave and well seen in courtship and nurture and also in the feats of chivalry," who were to be "governors in all things relating to him." Under their direction, to begin with, a barber shaved him and cut his hair. He was then conducted by them to his appointed chamber, where a bath was prepared hung within and without with linen and covered with rich cloths, into which after they had undressed him he entered. While he was in the bath two "ancient and grave knights" attended him "to inform, instruct, and counsel him touching the order and feats of chivalry," and when they had fulfilled their mission they poured some of the water of the bath over his shoulders, signing the left shoulder with the cross, and retired.[3] He was then taken from the bath and put into a plain bed without hangings, in which he remained until his body was dry, when the two esquires put on him a white shirt and over that "a robe of russet with long sleeves having a hood thereto like unto that of an hermit." Then the "two ancient and grave knights" returned and led him to the chapel, the esquires going before them "sporting and dancing" with "the minstrels making melody." And when they had been served with wines and spices they went away leaving only the candidate, the esquires, "the priest, the chandler, and the watch" who kept the vigil of arms until sunrise, the candidate passing the night "bestowing himself in orisons and prayers." At daybreak he confessed to the priest, heard matins, and communicated in the mass, offering a taper and a piece of money stuck in it as near the lighted end as possible, the first "to the honour of God" and the second "to the honour of the person that makes him a knight." Afterwards he was taken back to his chamber, and remained in bed until the knights, esquires, and minstrels went to him and aroused him. The knights then dressed him in distinctive garments, and they then mounted their horses and rode to the hall where the candidate was to receive knighthood; his future squire was to ride before him bareheaded bearing his sword by the point in its scabbard with his spurs hanging from its hilt. And when everything was prepared the prince or subject who was to knight him came into the hall, and, the candidate's sword and spurs having been presented to him, he delivered the right spur to the "most noble and gentle" knight present, and directed him to fasten it on the candidate's right heel, which he kneeling on one knee and putting the candidate's right foot on his knee accordingly did, signing the candidate's knee with the cross, and in like manner by another "noble and gentle" knight the left spur was fastened to his left heel. And then he who was to create the knight took the sword and girded him with it, and then embracing him he lifted his right hand and smote him on the neck or shoulder, saying, "Be thou a good knight," and kissed him. When this was done they all went to the chapel with much music, and the new knight laying his right hand on the altar promised to support and defend the church, and ungirding his sword offered it on the altar. And as he came out from the chapel the master cook awaited him at the door and claimed his spurs as his fee, and said, "If you do anything contrary to the order of chivalry (which God forbid), I shall hack the spurs from your heels."

As may be gathered from Selden, Favyn, La Colombiere, Menestrier, and Sainte Palaye, there were several differences of detail in the ceremony at different times and in different places. But in the main it was everywhere the same both in its military and its ecclesiastical elements. In the *Pontificale Romanum*, the old *Ordo Romanus*, and the manual or Common Prayer Book in use in England before the Reformation forms for the blessing or consecration of new knights are included, and of these the first and the last are quoted by Selden.[4] But the full solemnities for conferring knighthood seem to have been so largely and so early superseded by the practice of dubbing or giving the accolade alone that in England it became at last restricted to such knights as were made at coronations and some other occasions of state. And to them the particular name of knights of the bath was assigned, while knights made in the ordinary way were called in distinction from them knights of the sword, as they were also called knights bachelors in distinction from knights banneret.[5] It is usually supposed that the first creation of Knights of the Bath under that designation was at the coronation of Henry IV.; and before the Order of the Bath as a companionship or capitular body was instituted the last creation of them was at the coronation of Charles II. But all knights were also knights of the spur or "equites aurati," because their spurs were golden or gilt,—the spurs of squires being of silver or white metal,—and these became their peculiar badge in popular estimation and proverbial speech. In the form of their solemn inauguration too, as we have noticed, the spurs together with the sword were always employed as the leading and most characteristic ensigns of knighthood.[6]

With regard to knights banneret various opinions have been entertained as to both the nature of their dignity and the qualifications they were required to possess for receiving it at different periods and in different countries. On the Continent the distinction which is commonly but incorrectly made by us between the nobility and the gentry has never arisen, and it was unknown here while chivalry existed and heraldry was understood. Here, as elsewhere in the old time, a nobleman and a gentleman meant the

[1] Selden, *Titles of Honor*, p. 639.

[2] Daniel, *Histoire de la Milice Françoise*, vol. i. pp. 99–104; Byshe's Upton, *De Studio Militari*, pp. 21–24; Dugdale, *Warwickshire*, vol. ii. pp. 708–710; Segar, *Honor Civil and Military*, p. 69 *sq.*; and Nicolas, *Orders of Knighthood*, vol. ii. (*Order of the Bath*), p. 19 *sq.* It is given as "the order and manner of creating Knights of the Bath in time of peace according to the custom of England," and consequently dates from a period when the full ceremony of creating knights bachelors generally had gone out of fashion. But as Ashmole, speaking of Knights of the Bath, says, "if the ceremonies and circumstances of their creation be well considered, it will appear that this king [Henry IV.] did not institute but rather restore the ancient manner of making knights, and consequently that the Knights of the Bath are in truth no other than knights bachelors, that is to say, such as are created with those ceremonies wherewith knights bachelors were formerly created" (Ashmole, *Order of the Garter*, p. 15). It is singular that Dugdale in his translation of this ancient formulary has accidentally omitted the actual dubbing or accolade. See also Selden, *Titles of Honor*, p. 678; and the *Archæological Journal*, vol. v. p. 258 *sq.*

[3] In another formulary in the Cotton MSS. (Tib. E. viii. f. 72), which is printed in full in the *Archæological Journal*, vol. v. p. 267 *sq.*, the shoulders of the candidate are to be signed with the sign of the cross, and in still another formulary among the Astley MSS. the cross was to be signed on the candidate's left shoulder only by the senior of the ancient and grave knights "in nomine patris," &c. In both, however, the cross is to be kissed by the officiating knight after he had signed it with the water.

[4] *Titles of Honor*, pp. 369 and 648. See also p. 367 for the ceremonies observed at the knighting of William, count of Holland, when he was elected king of the Romans in 1247, and Selden's remarks and authorities with respect to the disuse of the ancient form of investiture with arms in the empire.

[5] Selden, *Titles of Honor*, p. 678; Ashmole, *Order of the Garter*, p. 15; Favyn, *Théâtre d'Honneur*, vol. ii p. 1055.

[6] "If we sum up the principal ensigns of knighthood, ancient and modern, we shall find they have been or are a horse, gold ring, shield and lance, a belt and sword, gilt spurs, and a gold chain or collar." —Ashmole, *Order of the Garter*, pp. 12, 13.

same thing, namely, a man who under certain conditions of descent was entitled to armorial bearings. Hence Du Cange divides the mediæval nobility of France and Spain into three classes:—first, barons or ricos hombres; secondly, chevaliers or caballeros; and thirdly, écuyers or infanzons; and to the first, who with their several special titles constituted the greater nobility of either country, he limits the designation of banneret and the right of leading their followers to war under a banner, otherwise a "drapeau quarré" or square flag.[1] Selden mentions as an instance of "the nearness and sometimes community of the title of banneret and baron" the "bannerherr" or "dominus vexillifer" of the empire. And he also shows especially from the parliament rolls that the term banneret has been occasionally employed in England as equivalent to baron, where, for example, in the reign of Richard II. among "divers other earls and barons there mentioned by name 'plusiers autres barons et bannerets esteants au dit parlament assemblez'" are referred to.[2] In Scotland even as late as the reign of James VI., lords of parliament were always created bannerets as well as barons at their investiture, "part of the ceremony consisting in the display of a banner, and such 'barones majores' were thereby entitled to the privilege of having one borne by a retainer before them to the field of a quadrilateral form."[3] In Scotland, too, lords of parliament and bannerets were also called bannerents, banrents, or baronets, and in England banneret was often corrupted to baronet. "Even in a patent passed to Sir Ralph Fane, knight under Edward VI., he is called 'baronettus' for 'bannerettus.'"[4] In this manner it is not improbable that the title of baronet may have been suggested to the advisers of James I. when the Order of Baronets was originally created by him, for it was a question whether the recipients of the new dignity should be designated by that or some other name.[5] But there is no doubt that as previously used it was merely a corrupt synonym for banneret, and not the name of any separate dignity. On the Continent, however, there are several recorded examples of bannerets who had an hereditary claim to that honour and its attendant privileges on the ground of the nature of their feudal tenure.[6] And generally, at any rate to commence with, it seems probable that bannerets were in every country merely the more important class of feudatories, the "ricos hombres" in contrast to the knights bachelors, who in France in the time of St Louis were known as "pauvres hommes." In England all the barons or greater nobility were entitled to bear banners, and therefore Du Cange's observations would apply to them as well as to the barons or greater nobility of France and Spain. But it is clear that from a comparatively early period bannerets whose claims were founded on personal distinction rather than on feudal tenure gradually came to the front, and much the same process of substitution appears to have gone on in their case as that which we have marked in the case of simple knights. According to the *Sallade* and the *Division du Monde*, as cited by Selden, bannerets were clearly in the beginning feudal tenants of a certain magnitude and importance and nothing more, and different forms for their creation are given in time of peace and in time of war.[7] But in the French *Gesta Romanorum* the warlike form alone is given, and it is quoted by both Selden and Du Cange. From the latter a more modern version of it is given by Daniel as the only one generally in force. "Quand un bachelier," says the ceremonial in question, "a grandement servi et suivi la guerre et que il a terre assez et qu'il puisse avoir gentilshommes ses hommes et pour accompagner sa bannière il peut licitement lever bannière et non autrement; car nul homme ne doit lever bannière en bataille s'il n'a du moins cinquante hommes d'armes, tous ses hommes, et les archiers et les arbelestriers qui y appartiennent, et s'il les a, il doit à la première bataille ou il se trouvera apporter un pennon de ses armes et doit venir au connetable ou aux maréchaux ou à celui qui sera lieutenant de l'ost pour le prince et requirir qu'il porte bannière, et s'il lui octroyent doit sommer les herauts pour temoignage et doivent couper la queue du pennon."[8] The earliest contemporary mention of knights banneret is in France, Daniel says, in the reign of Philip Augustus, and in England, Selden says, in the reign of Edward I. But in neither case is reference made to them in such a manner as to suggest that the dignity was then regarded as new or even uncommon, and it seems pretty certain that its existence on one side could not have long preceded its existence on the other side of the Channel. Sir Alan Plokenet, Sir Ralph Daubeney, and Sir Philip Daubeney are entered as bannerets on the roll of the garrison of Caermarthen castle in 1282, and the roll of Carlaverock records the names and arms of eighty-five bannerets who accompanied Edward I. in his expedition into Scotland in 1300. Selden quotes some and refers to many of the wardrobe accounts of Edward II. in which contracts with and payments to bannerets are mentioned, observing that "under these bannerets divers knights bachelors and esquires usually served, and according to the number of them the bannerets received wages."[9] What the exact contingent was which they were expected to supply to the royal host is doubtful. In the authorities collected by Selden, Du Cange, and Daniel it varies from ten and twenty-five to fifty men-at-arms with their attendants. Grose seems to prefer the medium estimate of a hundred mounted combatants in all, that number forming a square of ten in each face, and being the lowest equivalent of the more modern squadron.[10] But, however this may be, in the reign of Edward III. and afterwards bannerets appear as the commanders of a military force raised by themselves and marshalled under their banners—although paid through them by the sovereign—who were moreover always persons of property and soldiers of distinction. At the same time their status and their relations both to the crown and their followers were the consequences of voluntary contract not of feudal tenure. It is from the reigns of Edward III. and Richard II. also that the two best descriptions we possess of the actual creation of a banneret have been transmitted to us. During Edward the Black Prince's expedition of 1367 into Spain, Sir John Chandos, one of the founder Knights of the Garter, was made a banneret on the morning of the day on which the battle of Navarrete was fought. When the troops were drawn up in order before the action commenced, "Sir John Chandos," says Froissart, "advanced in front of the battalions with his banner uncased in his hand. He presented it to the prince, saying, 'My lord, here is my banner; I present it to you that I may display it in whatever manner shall be most agreeable to you; for, thanks to God, I have

now sufficient lands to enable me to do so and maintain the rank which it ought to hold.' The prince, Don Pedro, being present took the banner in his hands, which was blazoned with a sharp stake gules on a field argent; after having cut off the tail to make it square, he displayed it, and returning it to him by the handle said, 'Sir John, I return you your banner; God give you strength and honour to preserve it.' Upon this Sir John left the prince, went back to his men with the banner in his hand, and said to them, 'Gentlemen, behold my banner and yours; you will therefore guard it as it becomes you.' His companions taking the banner replied with much cheerfulness that 'if it pleased God and St George they would defend it well and act worthily of it to the utmost of their abilities.'"[1] At a later period some distinction appears to have been made between bannerets who were created under the royal standard, the king himself being present with his army in open war, and bannerets who were created only by the king's lieutenants, as Sir John Chandos and Sir Thomas Trivet were created. But no such distinction seems to have existed in the reigns of Edward III. and Richard II.; and, although it was doubtless of more ancient origin, the earliest contemporary evidence of its existence is of the reign of James I., when bannerets whether of one or two classes had practically disappeared. Sir Thomas Smith, writing towards the end of the 16th century, says, after noticing the conditions to be observed in the creation of bannerets, "but this order is almost grown out of use in England;"[2] and during the controversy which arose between the new order of baronets and the crown early in the 17th century respecting their precedence[3] it was alleged without contradiction in an argument on behalf of the baronets before the privy council that "there are not bannerets now in being, peradventure never shall be."[4] Sir Ralph Fane, Sir Francis Bryan, and Sir Ralph Sadler were created bannerets by the Lord Protector Somerset after the battle of Pinkie in 1547, and the better opinion is that this was the last occasion on which the dignity was conferred. It has been stated indeed that Charles I. created Sir John Smith a banneret after the battle of Edgehill in 1642 for having rescued the royal standard from the enemy. But of this there is no sufficient proof. It was also supposed that George III. had created several naval officers bannerets towards the end of the last century, because he knighted them on board ship under the royal standard displayed.[5] This, however, is unquestionably an error. Knights bannerets were not distinguished from knights bachelors merely because they were created under the standard or banner of the sovereign, but further because their own pennons were converted into or exchanged for banners.

On the Continent the degree of knight bachelor disappeared with the military system which had given rise to it. It is now therefore peculiar to the United Kingdom, where, although very frequently conferred by letters patent, it is yet the only dignity which is still even occasionally created—as every dignity was formerly created—by means of a ceremony in which the sovereign and the subject personally take part. Everywhere else dubbing or the accolade seems to have become obsolete, and no other species of knighthood, if knighthood it can be called, is known except that which is dependent on admission to some particular order. It is a common error to suppose that baronets are hereditary knights. Baronets are not knights unless they are knighted like anybody else; and, so far from being knights because they are baronets, one of the privileges granted to them shortly after the institution of their dignity was that they, not being knights, and their successors and their eldest sons and heirs apparent should, when they attained their majority, be entitled if they desired to receive knighthood.[6] It is a maxim of the law indeed that, as Coke says, "the knight is by creation and not by descent," and, although we hear of such designations as the "knight of Kerry" or the "knight of Glin," they are no more than traditional nicknames, and do not by any means imply that the persons to whom they are applied are knights in a legitimate sense. Notwithstanding, however, that simple knighthood has gone out of use abroad, there are innumerable grand crosses, commanders, and companions of a formidable assortment of orders in almost every part of the world,[7] from that of the Golden Fleece of Spain and Austria to those of St Charles of Monaco and of King Kamehameha of the Sandwich Islands. But, with the exception of the orders of the Golden Fleece founded by Philip II., duke of Burgundy, in 1429, and of the Annunciation founded by Charles III., duke of Savoy, in 1518—now that the orders of St Michael founded by Louis XI. and of the Holy Ghost founded by Henry III. of France, in 1469 and 1578, are either extinct or in abeyance—none of the foreign military as distinguished from the religious orders of knighthood have any actual historical connexion with chivalry. The orders of the Genet of France and the Oak of Navarre of course are to be classed as mere fictions with the order of the Round Table of Britain. But the pretensions of almost every other foreign order to extreme antiquity, as for example of the Elephant and Danneborg of Denmark, the White Eagle of Poland, or the Seraphim of Sweden, if they are less obviously extravagant, are not more susceptible of verification. It has nearly always been the practice even in modern days to represent the establishment as the revival or reorganization of an order. We ourselves have seven orders of knighthood, the Garter, the Thistle, St Patrick, the Bath, the Star of India, St Michael and St George, and the Indian Empire; and, while the first is undoubtedly the oldest as well as the most illustrious anywhere existing, a fictitious antiquity has been claimed

[1] Froissart, bk. i. chap. 241. The other case is that of Sir Thomas Trivet in 1380 (Froissart, bk. ii. chap. 53).

[2] *Commonwealth of England*, p. 48, ed. 1640.

[3] By the decree of 1612 on the precedence of baronets they are placed after the younger sons of viscounts and barons, who came next to "bannerets made by the sovereign in person under the royal standard displayed in an army royal in open war," and immediately before "bannerets not made by the sovereign in person," and are still so ranked in all the "Tables of Precedence" (see Selden, *Titles of Honor*, p. 749, 750).

[4] *State Papers*, Domestic Series, James the First, vol. lxvii. p. 119.

[5] "Thursday, June 24th: His Majesty was pleased to confer the honour of knights banneret on the following flag officers and commanders under the royal standard, who kneeling kissed hands on the occasion: Admirals Pye and Sprye, Captains Knight, Bickerton, and Vernon" (*Gentleman's Magazine*, vol. xliii. p. 299, 1773). Sir Harris Nicolas remarks on these and the other cases (*British Orders of Knighthood*, p. xliii.), and Sir William Fitzherbert published anonymously a pamphlet on the subject, *A Short Inquiry into the Nature of the Titles conferred at Portsmouth*, &c., which is very scarce, but is to be found under the name of "Fitzherbert" in the catalogue of the British Museum Library.

[6] "Sir Henry Ferrers, Baronet, was indicted by the name of Sir Henry Ferrers, Knight, for the murther of one Stone whom one Nightingale feloniously murthered, and that the said Sir Henry was present aiding and abetting, &c. Upon this indictment Sir Henry Ferrers being arraigned said he never was knighted, which being confessed, the indictment was held not to be sufficient, wherefore he was indicted *de novo* by the name of Sir Henry Ferrers, Baronet." Brydall, *Jus Imaginis apud Anglos, or the Law of England relating to the Nobility and Gentry*, p. 50, London, 1675. After the dispute between the baronets and the younger sons of viscounts and barons for precedence in 1612, it was declared by James I., among other concessions to them, that "his Majesty is pleased to knight the present baronets that are no knights," and that for the future all baronets and their eldest sons and heirs apparent should be knighted if they pleased to apply for knighthood when they came or were of age.—*Patent Rolls*, 10 Jac. I., part x. No. 18; Selden, *Titles of Honor*, p. 687.

[7] Louis XIV. introduced the practice of dividing the members of military orders into several degrees when he established the order of St Louis in 1693.

and is even still frequently conceded to the second and fourth, although the third, fifth, sixth, and seventh appear to be as contentedly as they are unquestionably recent.

It is, however, certain that the "most noble" Order of the Garter at least was instituted in the middle of the 14th century, when, to use Hallam's words, the court of England "was the sun as it were of that system which embraced the valour and nobility of the Christian world," when "chivalry was in its zenith, and in all the virtues which adorned the knightly character none were so conspicuous as Edward III. and the Black Prince." But in what particular year this event occurred is and has been the subject of much difference of opinion. All the original records of the order until after 1416 have perished, and consequently the question depends for its settlement not on direct testimony but on inference from circumstances. The dates which have been selected vary from 1344 to 1351, and it is a matter of some historical interest and importance to determine so far as it is practicable which of them is probably accurate, since Dr Stubbs cites the fact of "Edward III. celebrating his great feast on the institution of the Order of the Garter in the midst of the Black Death" as a "typical illustration" of the heartlessness and want of sympathy between classes which he holds to have been characteristic of the age.[1] The Black Death made its appearance on the coast early in August 1348, reached the capital in the following November, and spreading over the country raged until the end of September 1349. Hence Dr Stubbs apparently agrees with Ashmole (who based his opinion on the preamble to the two earliest but evidently not contemporary copies of the statutes) in referring the institution of the order and the accompanying feast to St George's Day in the April of the second of these two years.[2] Mr Longman thinks that the order was "finally established" in 1347,[3] Mr Beltz contends that it was founded in 1344, as Froissart, who wrote in the reign of Edward III. and Richard II., affirms, while Sir Harris Nicolas maintains that, although it is not impossible that Edward III. may have determined to found an order of knighthood in 1344, when he invited knights of all countries to jousts at Windsor and revived the feast of the Round Table, of which Froissart speaks, yet "the details of the Order of the Garter were not settled (even if the institution itself was contemplated), the companions appointed, nor the name or ensigns established until the latter part of 1347 or early in 1348."[4] And, without going fully into the evidence, which may be examined at length in Nicolas and Beltz, it is indisputable that in the wardrobe account from September 1347 to January 1349, the 21st and 23d Edward III., the issue of certain habits with garters and the motto embroidered on them is marked for St George's Day, that similar vestments for the king and others on occasions not connected with the order are recorded as having been delivered in 1347 at the Christmas games at Guildford and the tournaments at Bury, Windsor, Lichfield, and Eltham, that the letters patent relating to the preparation of the royal chapel of Windsor are dated in August 1348, and that in the treasury accounts of the Prince of Wales there is an entry in November 1348 of the gift by him of "twenty-four garters to the knights of the Society of the Garter."[5] But that the order, although from this manifestly already fully constituted in the autumn of 1348, was not in existence before the summer of 1346 Sir Harris Nicolas holds on the ground that nobody who was not a knight could under its statutes have been admitted to it, and that neither the Prince of Wales nor several others of the original companions were knighted until the middle of that year. Mr Beltz, following a suggestion of Anstis, had endeavoured to overcome this difficulty by assuming that the Black Prince had been knighted in his infancy, and that he was made a banneret at the age of fifteen. But, although it was not unusual for the sons of sovereigns and great feudatories to be knighted when they were children, and even at their baptism, it is beyond question, as Sir Harris Nicolas points out, that in England only commoners could be formally created bannerets. All knights of or above the rank of a baron were at once entitled to bear their banners in the field. And that the Prince of Wales was knighted on the landing of Edward III.'s expedition against France at La Hogue in July 1346 there can be no doubt. It seems pretty clear, however, that the Order of the Garter was instituted and the great feast celebrated, not in the midst of the Black Death, but at any rate some months before its ravages commenced. Regarding the occasion there has been almost as much controversy as regarding the date of its foundation. The "vulgar and more general story," as Ashmole calls it, is that of the countess of Salisbury's garter. But commentators are not at one as to which countess of Salisbury was the heroine of the adventure, whether she was Katherine Montacute or Joan the Fair Maid of Kent, while Heylyn rejects the legend as "a vain and idle romance derogatory both to the founder and the order, first published by Polydor Vergil, a stranger to the affairs of England, and by him taken upon no better ground than *fama vulgi*, the tradition of the common people, too trifling a foundation for so great a building," and Anstis says that "it is now no more credited than the absurd, ridiculous relation of Micheli Marquez that this order, termed from the Greek language Periscelidis Ordo, was erected to the memory of one Periscelide, a true fairy queen, or the whimsical dream of Mr Joshua Barnes in his far-fetched derivation of it from the Cabiri among the Samothracians."[6] Ashmole, however, while denying that any such accident became the principal cause of creating the order, will not altogether repudiate the allegation that "the king may have picked up a garter at some solemn ball or festivity,"—the queen's garter, as some have said,—while she and not he made use of the memorable words "Honi soit qui mal y pense."[7] Another legend is that contained in the preface to the Register or Black Book of the order, compiled in the reign of Henry VIII., by what authority supported is unknown, that Richard I., while his forces were employed against Cyprus and Acre, had been inspired through the instrumentality of St George with renewed courage and the means of animating his fatigued soldiers by the device of tying about the legs of a chosen number of knights a leathern thong or garter, to the end that being thereby reminded of the honour of their enterprise they might be encouraged to redoubled efforts for victory. This was supposed to have been in the mind of Edward III. when he fixed on the garter as the emblem of the order, and it was stated so to have been by Taylor, master of the rolls, in his address to Francis I. of France on his investiture in 1527.[8] According to Ashmole the true account of the matter is that, "King Edward having given forth his own garter as the signal for a battle which sped fortunately (which with Du Chesne we conceive to be that of Cressy, fought almost three years after the setting

up of the Round Table at Windsor, rather than with the author of the 'Nouveau Théâtre du Monde' that of Poictiers, which happened above seven years after the foundation of the order and whereat King Edward was not present), the victory, we say, being happily gained, he thence took occasion to institute this order, and gave the garter (assumed by him for the symbol of unity and society) pre-eminence among the ensigns of it, whence that select number whom he incorporated into a fraternity are frequently styled 'equites aureæ periscelidis' and vulgarly knights of the garter."[1] Ashmole and Beltz also see in the order a reference to the king's French claims, and remark that the colour of the garter is the tincture of the field of the French arms. But, as Sir Harris Nicolas points out,—although Ashmole is not open to the correction,—this hypothesis rests for its plausibility on the assumption that the order was established before the invasion of France in 1346. And he further observes that "a great variety of devices and mottoes were used by Edward III.; they were chosen from the most trivial causes and were of an amorous rather than of a military character. Nothing," he adds, "is more likely than that in a crowded assembly a lady should accidentally have dropped her garter; that the circumstance should have caused a smile in the bystanders; and that on its being taken up by Edward he should have reproved the levity of his courtiers by so happy and chivalrous an exclamation, placing the garter at the same time on his own knee, as 'Dishonoured be he who thinks ill of it.' Such a circumstance occurring at a time of general festivity, when devices, mottoes, and conceits of all kinds were adopted as ornaments or badges of the habits worn at jousts and tournaments, would naturally have been commemorated as other royal expressions seem to have been by its conversion into a device and motto for the dresses at an approaching hastilude."[2] Moreover, Sir Harris Nicolas contends that the order had no loftier immediate origin than a joust or tournament. It consisted of the king and the Black Prince, and twenty-four knights divided into two bands of twelve like the tilters in a hastilude—at the head of the one being the first, and of the other the second; and to the companions belonging to each, when the order had superseded the Round Table and had become a permanent institution, were assigned stalls either on the sovereign's or the prince's side of St George's Chapel. That Sir Harris Nicolas is accurate in this conjecture seems probable from the selection which was made of the "founder knights." As Mr Beltz observes, the fame of Sir Reginald Cobham, Sir Walter Manny, and the earls of Northampton, Hereford, and Suffolk was already established by their warlike exploits, and they would certainly have been among the original companions had the order been then regarded as the reward of military merit only. But, although these eminent warriors were subsequently elected as vacancies occurred, their admission was postponed to that of several very young and in actual warfare comparatively unknown knights, whose claims to the honour may be most rationally explained on the assumption that they had excelled in the particular feats of arms which preceded the institution of the order. The order was dedicated to St George of Cappadocia and St Edward the Confessor, and its feast or solemn annual convention was kept at Windsor on St George's Day, the 23d of April, with little interruption from the reign of Edward III. to the reign of Queen Elizabeth. But a few years after the Restoration the celebration was altogether discontinued. The original companionship had consisted of the sovereign and twenty-five knights, and no change was made in this respect until 1786, when the sons of George III. and his successors were made eligible notwithstanding that the chapter might be complete. In 1805 another alteration was effected by the provision that the lineal descendants of George II. should be eligible in the same manner, except the Prince of Wales for the time being, who was declared to be "a constituent part of the original institution"; and again in 1831 it was further ordained that the privilege accorded to the lineal descendants of George II. should extend to the lineal descendants of George I. The power of making and modifying the statutes of the order as exemplified in these innovations had from the beginning belonged to the whole fraternity, and it was only in the reign of Charles II. that it was surrendered to the sovereign. But the knights still continued at any rate formally to elect their companions, and the gorgeous and elaborate ceremonies of installation were still regarded as requisite to the full reception of knights elect. Since the beginning of the reign of George III., however, both chapters and installations became more and more occasional, and it is now the established custom for the sovereign altogether to dispense with them. Although, as Sir Harris Nicolas observes, nothing is now known of the form of admitting ladies into the order, the description applied to them in the records during the 14th and 15th centuries leaves no doubt that they were regularly received into it. The queen consort, the wives and daughters of knights, and some other women of exalted position, were designated "Dames de la Fraternité de St George," and entries of the delivery of robes and garters to them are found at intervals in the Wardrobe Accounts from the 50th Edward III. (1376) to the 10th of Henry VII. (1495), the first being Isabel, countess of Bedford, the daughter of the one king, and the last being Margaret and Elizabeth, the daughters of the other king. The effigies of Margaret Byron, wife of Sir Robert Harcourt, K.G., at Stanton Harcourt, and of Alice Chaucer, wife of William de la Pole, duke of Suffolk, K.G., at Ewelme, which date from the reigns of Henry VI. and Edward IV., have garters on their left arms. At a chapter in 1637 an attempt was made to revive the practice of issuing the ensigns of the order to ladies. Sir James Palmer, acting as deputy for Sir Thomas Rowe, the chancellor of the order, moved the sovereign that the wives of the knights companions might have the privilege of wearing "a garter of the order about their arms and an upper robe at festival times, according to ancient usage." The matter was referred by Charles I. to the queen, and another chapter was appointed for the purpose of taking it into final consideration. But owing to the civil war nothing further was done in the matter. At present the officers of the order are five—the prelate, chancellor, register, king of arms, and usher—the first, third, and fifth having been attached to it from the commencement, while the fourth was added by Henry V. and the second by Edward IV. The prelate has always been the bishop of Winchester; the chancellor was formerly the bishop of Salisbury, but is now the bishop of Oxford; the registership and the deanery of Windsor have been united since the reign of Charles I.; the king of arms, whose duties were in the beginning discharged by Windsor herald is garter principal king of arms; and the usher is the gentleman usher of the Black Rod.

The other orders of knighthood subsisting in the British empire must be spoken of more briefly. The "most ancient" Order of the Thistle was founded by James II. in 1687, and dedicated to St Andrew. It consisted of the sovereign and eight knights companions, and fell into abeyance at the Revolution of 1688. In 1703 it was revived by Queen Anne, when it was ordained to consist of the sovereign and twelve knights companions, the number being increased to sixteen by statute in 1827 The "most illustrious" Order

[1] *Order of the Garter*, p. 183.

[2] *Orders of Knighthood*, vol. i. p. lxxxiii.

of St Patrick was instituted by George III. in 1788, to consist of the sovereign, the lord lieutenant of Ireland as grand master, and fifteen knights companions, enlarged to twenty-two in 1833. The "most honourable" Order of the Bath was established by George I. in 1725, to consist of the sovereign, a grand master, and thirty-six knights companions. This was a pretended revival of an order supposed to have been created by Henry IV. at his coronation in 1399. But, as we have before shown, no such order existed. Knights of the Bath, although they were allowed precedence before knights bachelors, were merely knights bachelors who were knighted with more elaborate ceremonies than others and on certain great occasions. After the so-called revival the grand mastership merged in the crown on the death of John, duke of Montagu, the first tenant of the office in 1749, and in 1815 and again in 1847 the constitution of the order was remodelled. Exclusive of the sovereign, royal princes, and distinguished foreigners, it is limited to fifty military and twenty-five civil knights grand crosses, one hundred and twenty-three military and eighty civil knights commanders, and six hundred and ninety military and two hundred and fifty civil companions. The "most distinguished" Order of St Michael and St George was founded by the prince regent, afterwards George IV., in 1818, in commemoration of the British protectorate of the Ionian Islands, "for natives of the Ionian Islands and of the island of Malta and its dependencies, and for such other subjects of his majesty as may hold high and confidential situations in the Mediterranean." By statute of 1832 the lord high commissioner of the Ionian Islands was to be the grand master, and the order was directed to consist of fifteen knights grand crosses, twenty knights commanders, and twenty-five cavaliers or companions. After the repudiation of the British protectorate of the Ionian Islands, the order was placed on a new basis, and by letters patent of 1868 and 1877 it was extended and provided for such of "the natural born subjects of the crown of the United Kingdom as may have held or shall hold high and confidential offices within her Majesty's colonial possessions, and in reward for services rendered to the crown in relation to the foreign affairs of the empire." It is now limited to fifty knights grand crosses, of whom the first or principal is grand master, exclusive of extra and honorary members, of one hundred and fifty knights companions, and two hundred and sixty companions. It ranks between the "most exalted" Order of the Star of India and the Order of the Indian Empire, of both of which the viceroy of India for the time being is *ex officio* grand master. Of these the first was instituted in 1861 and enlarged in 1876, and the second was established in 1878 in commemoration of the Queen's assumption of the imperial style and title of the empress of India. Of the Star of India there may be thirty knights grand commanders, seventy-two knights commanders, and one hundred and fifty-four companions, while of the Indian Empire there may be an unlimited number of companions, among whom the councillors of her majesty for her Indian empire are included by virtue of their office and for life.

It has been the general opinion, as expressed by Sainte Palaye and Mills, that formerly all knights were qualified to confer knighthood.[1] But it may be questioned whether the privilege was thus indiscriminately enjoyed even in the earlier days of chivalry. It is true that as much might be inferred from the testimony of the romance writers; historical evidence, however, tends to limit the proposition, and the sounder conclusion appears to be, as Sir Harris Nicolas says, that the right was always restricted in operation to sovereign princes, to those acting under their authority or sanction, and to a few other personages of exalted rank and station.[2] In several of the writs for distraint of knighthood from Henry III. to Edward III. a distinction is drawn between those who are to be knighted by the king himself or by the sheriffs of counties respectively, and we have seen that bishops and abbots could make knights in the 11th and 12th centuries.[3] At all periods the commanders of the royal armies had the power of conferring knighthood; as late as the reign of Elizabeth it was exercised among others by Sir Henry Sidney in 1583, and Robert, earl of Essex, in 1595, while under James I. an ordinance of 1622, confirmed by a proclamation of 1623, for the registration of knights in the college of arms, is rendered applicable to all who should receive knighthood from either the king or any of his lieutenants.[4] Many sovereigns, too, both of England and of France, have been knighted after their accession to the throne by their own subjects, as, for instance, Edward III. by Henry, earl of Lancaster, Edward VI. by the Lord Protector Somerset, Louis IX. by Philip, duke of Burgundy, and Francis I. by the Chevalier Bayard. But when in 1543 Henry VIII. appointed Sir John Wallop to be captain of Guisnes, it was considered necessary that he should be authorized in express terms to confer knighthood, which was also done by Edward VI. in his own case when he received knighthood from the duke of Somerset.[5] In like manner Henry, earl of Arundel, under special commission from the queen, created the Knights of the Bath and other knights at the coronation of Elizabeth in 1559, and in the patent from James II. nominating Christopher, duke of Albemarle, governor of Jamaica in 1686 he is empowered to confer knighthood on any persons "not exceeding six in number within the said island whom he may think deserving of the same in the king's service."[6] But at present the only subject to whom the right of conferring knighthood belongs is the lord-lieutenant of Ireland, and to him it belongs merely by long usage and established custom. It was called in question in 1821 by the Lords of the Admiralty on the occasion of Earl Talbot knighting Sir John Phillimore, a captain in the navy, and the point, having been submitted to the law officers of the crown in England and Ireland, was the subject of contradictory opinions from them. In 1823, however, it was referred by order in council to the English judges, who unanimously reported in favour of the lord-lieutenant of Ireland's claims.[7] But, by whomsoever conferred, knighthood at one time endowed the recipient with the same status and attributes in every country wherein chivalry was recognized. In the Middle Ages it was a common practice for sovereigns and princes to dub each other knights much as they were afterwards, and are now, in the habit of exchanging the stars and ribands of their orders. Henry II. was knighted by his great-uncle David I. of Scotland, Alexander III. of Scotland by Henry III., Edward I. when he was prince by Alphonso X. of Castile, and Ferdinand of Portugal by Edmund of Langley, earl of Cambridge.[8] And, long after the military importance of knighthood had practically disappeared, what may be called its cosmopolitan character was maintained. Writing in the 17th century, Mr Justice Doddridge lays it down as a principle of law in which he is supported by all the older

authorities that "the highest and the lowest dignities are universal, for if the king of a foreign nation come into England by leave of the king of this realm (as it ought to be), in this case he shall sue and be sued by the name of a king, so shall he sue and be sued by the name of a knight wheresoever he received that degree of dignity, but otherwise it is as of a duke, marquess, earl, or other title of honour given by any foreign king."[1] The well-known story told by Camden about Queen Elizabeth and Sir Thomas Arundel afterwards Lord Arundel of Wardour, and her disinclination that "her sheep should bear a stranger's mark," and "dance after the whistle of every foreigner," had reference to a countship of the empire, and not to knighthood or an order of chivalry. Even to the end of the last century indeed any knight duly dubbed abroad was fully accepted as a knight in England. Hence when in 1792, at the request of the king of Sweden, George III. invested Sir Sidney Smith with the grand cross and collar of the Swedish Order of the Sword, it was expressly announced that he "was not knighted on this occasion, that ceremony having been performed by his late Swedish majesty."[2] By certain regulations, however, made in 1823, and repeated and enlarged in 1855, not only is it provided that the sovereign's permission by royal warrant shall be necessary for the reception by a British subject of any foreign order of knighthood, but further that such permission shall not authorize "the assumption of any style, appellation, rank, precedence, or privilege appertaining to a knight bachelor of the United Kingdom." Moreover, no permission of the kind will be granted "unless the foreign order shall have been conferred in consequence of active and distinguished service before the enemy either at sea or in the field," or unless the person receiving it shall have been "actually and entirely" employed beyond the British dominions "in the service of the foreign sovereign by whom the order is conferred."[3]

Since knighthood was accorded either by actual investiture or its equivalent, a counter process of degradation was regarded as necessary for the purpose of depriving anybody who had once received it of the rank and condition it implied. And in this respect there can be no doubt that the order of chivalry was designedly assimilated to the order of priesthood.[4] Hence, as Selden points out, "as by the canon laws the ceremony of degradation from any degree of any order is by the solemn taking away those things from the clerk wherewith he was so invested at his taking the order from which he is to be degraded, so the ceremonies of degradation of a knight were in ancient times such as that the sword with which he was girt at his knighting and the spurs that were put on him were to be publicly taken off from him, and some other solemnities were sometimes in it."[5] The cases in which a knight has been formally degraded in England are exceedingly few, so few indeed that two only are mentioned by Segar, writing in 1602, and Dallaway says that only three were on record in the College of Arms when he wrote in 1793. But in illustration of the statement of Coke that "when a knight is degraded one of his punishments is 'quod clypeus suus gentilicius reversus erit,' and how his arms be reversed that he beareth none," Sir Harris Nicolas states that in an illuminated copy of Matthew Paris's *Historia Major*, among the royal manuscripts in the British Museum, there is a representation of Sir William de Marisco, who was convicted of treason in the reign of Henry III., with his sword and the staff of his banner broken and his shield hewn asunder.[6] With this exception, however, the earliest known example of degradation from knighthood is that of Sir Andrew Harclay, who was created earl of Carlisle by Edward II., and was attainted of high treason in the year following his creation. He was tried and condemned at Carlisle in 1323 by special commission under Edmund of Woodstock, earl of Kent, the king's half-brother. A part of his sentence, as preserved in the record, was in the following words: "que vous soietz degrade, que vous perdetz noun de count pur vous et pur vous heirs a touts jours que vous soietz deceynt del espée que vous esporeuns d'orrees soient coupez de talouns," which having been done, according to Holingshed, Sir Anthony Lucy, the sheriff of Cumberland, said to him, "Andrew, thou art no knight, but thou art a knave," when judgment for treason was pronounced on him, and he was immediately beheaded.[7] The next case was that of Sir Ralph Grey, which occurred in the reign of Edward IV. He was tried and convicted of treason, before John Tiptoft, earl of Worcester, constable of England in 1468, but the sentence as preserved by Stowe seems to indicate that the ceremonies of degradation were to be remitted.[8] The last case was that of Sir Francis Michell in 1621, whose spurs were hacked from his heels, his sword belt cut, and his sword broken over his head by the heralds in Westminster Hall.[9] The ceremony of degrading a knight who is a companion of an order which as a capitular body has a chapel assigned to it applies to his achievements therein displayed more markedly than to him in person. On the degradation of a Knight of the Garter, indeed, a deputation of the companions are (Ashmole says) to go to him, attended by Garter king of arms, who "in a solemn manner first takes from him his George and riband and then his garter."[10] But the principal observances are that his banner, helm, and armorial plate are torn down from above and from off his stall by the officers of arms, and are by them spurned or kicked out of the building.[11] From the Order of the Garter William Lord Paget, who was subsequently reinstated, was degraded in 1552, "chiefly," according to the diary of Edward VI., "because he was no gentleman of blood neither of father's side or mother's side."[12] The degradation in due form of James, duke of Monmouth, and of James, duke of Ormond, for treason occurred severally in 1685 and 1716 Thomas Lord Cochrane and Sir Eyre Coote were similarly degraded from the Order of the Bath in 1814 and 1816. But in all these cases the knights retained their knighthood, although they were expelled from the orders to which they had belonged.

Roughly speaking, the age of chivalry properly so called may be said to have extended from the beginning of the crusades to the end of the Wars of the Roses. Within the limits of that period, which comprised about four hundred years, all that was peculiarly characteristic of it arose, attained to maturity, and fell into decay. It is true that some of its spirit and many of its external forms lingered on throughout the greater part of the 16th century. But the chivalry of Francis I. and Charles V. bore much the same relation to the chivalry of Edward III. and the Black Prince that the romance of Don Quixote bears to the romance of Amadis de Gaul. As a practical military system chivalry was entirely at an end. The revolu-

tion in the mode of warfare which had commenced under Edward III. was completed under Henry VIII., and it was on their infantry and artillery rather than on their cavalry that commanders had come principally to rely. Knights still disported themselves in the lists as bravely and gallantly as of old, but neither their arms nor their armour availed them aught against the cannon and muskets they were compelled to encounter in the field. And even in the way of pageantry and martial exercise chivalry was not destined to be of long continuance. In England tilts and tourneys, in which her father had so much excelled, were patronized to the last by Queen Elizabeth, and were even occasionally held until after the death of Henry, Prince of Wales. But on the Continent the Comte de Montgomerie's lance proved as fatal to them as it did to the French king Henry at Paris. By that time, however, chivalry had ceased to exist as a social institution as well as a military régime. Its standard of conduct, the code of honour, indeed remained as it in some measure still remains, the test of propriety and the guide of manners in the higher ranks of society all over Europe. But the order of knighthood as an order formally and particularly dedicated to the service of "God and the Ladies,"—"I blush," says Gibbon, "to unite such discordant names,"—and bound by solemn and express engagements to vindicate justice, to avenge wrong, and to defend the weak, the unprotected, and the oppressed, had disappeared. It was under this shape, however, that chivalry manifested itself during the earlier and more vigorous stages of its development, and played its part among the chief and certainly among the most remarkable of those influences which moulded the form and directed the course of Western civilization in mediæval times. The common offspring of feudalism and the church, it derived its resources and its sanctions from each of its parents in turn, and stood forth as at once the spiritual representative of the one and the temporal representative of the other. Whatever may have been its inherent vices and defects, it is at any rate indisputable that it embodied some of the noblest sentiments and engendered many of the worthiest actions of contemporary mankind. It animated poetry and art; it created romance and heraldry; it determined individual ethics, modified the policy of states, and generally inspired the energies while it controlled the destinies of all those nations, especially England and France, which were then as they now are the most enlightened as well as the most powerful in the world. Under ecclesiastical teaching war came to be regarded from a judicial standpoint as, to use the words of Bacon, "the highest trial of right when princes and states that acknowledge no superior on earth shall put themselves upon the justice of God for the deciding of their controversies by such success as it please Him to give on either side."[1] Battles were commenced with religious celebrations, and armies esteemed themselves happy if they marched beneath a consecrated standard. Even in the field and while engaged in mortal conflict Christian knights acknowledged the duties and courtesies of their order. And if they were taken prisoner they could count on consideration from their captors, and on their freedom when they paid their stipulated ransom. Moreover, when they took prisoners they knew that they could safely release them on parole to raise their ransom, and that they would return to captivity if their ransom could not be raised.[2] It is indeed from the customs of chivalry that the best and most humane portions of the laws of war in so far as actual combatants are concerned have their origin. But war, although it was the principal, was not the exclusive or the continuous occupation of mediæval knighthood. When not in the camp the home of the knight was in the court or the castle, and it was there that his prowess in the past campaign or present tournament was rewarded, often it might be rather generously than discreetly by the ladies in whose cause he was partly enrolled. Hence, although at no period were women held in greater outward respect by men, it is probable that at no period did more licence in the association of the sexes prevail; and it is a strange comment on the manners of the times that the single word "gallantry" should have grown to signify both bravery and illicit love.[3] But, if chastity was not among the cardinal virtues of chivalry, the catalogue of them included valour, loyalty, courtesy, and munificence; and, had they been practised with the zeal with which they were inculcated, they would have gone far towards redeeming the dissoluteness of private manners with which they were connected. Valour was of course the primary qualification of a knight, and the imputation of cowardice the most damaging that could be cast upon him. But loyalty, which implied the strictest fidelity to all his engagements to his sovereign or lord, his "lady-love," and his friends and foes alike, was only second to it in importance. Next came courtesy, which meant not only ceremonious politeness but also spontaneous modesty of carriage, self-denial, and careful respect for the feelings of others. And last came munificence, a disdain for money, readiness to relieve want and reward services, hospitality, and liberality in all things. In a celebrated passage Burke describes chivalry as "the unbought grace of life, the cheap defence of nations, the nurse of manly sentiment and heroic enterprise." "Never never more," he says, "shall we behold that generous loyalty to rank and sex, that proud submission, that dignified obedience, that subordination of the heart which kept alive even in servitude itself the spirit of an exalted freedom;" and, he adds, "that sensibility of principle, that chastity of honour which felt a stain like a wound, which inspired courage whilst it mitigated ferocity, which ennobled whatever it touched, and under which vice itself lost half its evil by losing all its grossness."[4] A very different estimate of chivalry is expressed by Mr Freeman. "The chivalrous spirit," he contends, "is above all things a class spirit. The good knight is bound to endless fantastic courtesies towards men and still more towards women of a certain rank; he may treat all below that rank with any degree of scorn and cruelty. The spirit of chivalry implies the arbitrary choice of one or two virtues to be practised in such an exaggerated degree as to become vices, while the ordinary laws of right and wrong are forgotten. The false code of honour supplants the laws of the commonwealth, the law of God, and the eternal principles of right. Chivalry again in its military aspect not only encourages the love of war for its own sake without regard to the cause for which war is waged, it encourages also an extravagant regard for a fantastic show of personal daring which cannot in any way advance the objects of the siege or campaign which is going on. Chivalry in short is in morals very much what feudalism is in law: each substitutes purely personal obligations, obligations devised in the interests of an exclusive class, for the more homely duties of an honest man and a good citizen."[5] Between these two views,—which, indeed, may be taken to represent the extremes of praise and of depreciation,—it may be assumed that at all events an approximation to the truth concerning the ethical effects of chivalry or knighthood is somewhere to be found. KNITTING is the art of forming looped fabrics or textures with the use of needles or wires and a single continuous thread. Crochet is an analogous art, differing from knitting in the fact that the separate loops are thrown off and finished successively, whereas in knitting the whole series of loops which go to form one length or round of the fabric are retained on one or more needles while a new series is being formed from them on a separate needle. The origin and history of the art of knitting are referred to under the heading HOSIERY, vol. xii. p. 299. The wires, needles, or pins used are of different lengths and gauges, according to the work for which they are intended, and are made either of steel, ivory, bone, or wood. Some are headed, to prevent loops from slipping over their ends, but on these can be woven only flat pieces of work; others are pointed at both ends, and with the use of three or more of these circular webs can be made. The materials used in knitting are specially twisted for the purpose, and consist of twines, threads, cotton, silk, wools, and worsteds, the latter being the most important and largely used substance. Ordinary stockings and socks, which are the staple hand-knit articles, are worked in "lambswool," "fingering," and "wheeling" worsteds respectively, these differing in size and fineness of quality; and for other articles of underclothing and fancy knitting the worsteds most commonly used are "fleecy," "Berlin," and "Lady Betty" wool. Shetland wool is a thin hairy undyed and very tenacious and strong worsted, spun in the Shetland Islands from the wool of the native sheep, and very extensively used in the knitting of fine shawls, veils, scarfs, and small articles by the islanders, among whom the industry is of much local consequence. "Crewels" are closely twisted coloured worsteds of the same size as Shetland wool, and capable consequently of being knit into the same fabric. Much spun silk is also knit into patterns and articles similar in form and appearance to Shetland wool goods. In Ayrshire the hand-knitting of Scotch caps is extensively prosecuted as a domestic industry, the knit work being collected and "waulked" or felted and otherwise finished in factories. The methods by which, with plain knitting, "purling," "slipping" loops, "taking up" and "casting off," &c., materials can be shaped and worked into varied and variegated forms are endless, and patterns and directions for working are to be found in all magazines and papers devoted to ladies' work, as well as in numerous special cheap publications.

Standard works, from which many of the patterns and directions in smaller manuals are copied, are Mrs Gaugain's *Knitting and Crochet Work*, and Esther Copley's *Comprehensive Knitting Book*, London, 1849.

KNOLLES, RICHARD (*c.* 1545–1610), author of the *History of the Turks*, was a native of Northamptonshire, and was born about 1545. In 1560 he entered Lincoln's College, Oxford, of which four years later he was elected fellow. After graduating M.A. he left Oxford to become master of the free school at Sandwich in Kent, where he died in 1610.

In 1603 Knolles published *A General History of the Turks*, a second edition of which appeared in 1610. The work was continued up to date in several editions subsequently published, the best known being that by Sir Paul Rycaut, 1687–1700, who gives a continuation to 1699. The history of Knolles was highly praised by Dr Johnson, and, though now entirely superseded, it has for the time in which it was written considerable merits at least as regards style and arrangement. Knolles also published a translation of Bodin's *Respublica* in 1606, but the *Grammaticæ Latinæ, Græcæ, et Hebraicæ Compendium*, and the *Rudiments of Hebrew Grammar*, attributed to him by Anthony Wood and in most works of reference, were, as is shewn in the *Athenæum* of August 6th, 1881, the works of the Rev. Hanserd Knollys, a Baptist minister.

KNOT. In the scientific sense, a knot is an endless physical line which cannot be deformed into a circle. A physical line is flexible and inextensible, and cannot be cut,—so that no lap of it can be drawn through another.

The founder of the theory of knots is undoubtedly Listing. In his "Vorstudien zur Topologie" (*Göttinger Studien*, 1847), a work in many respects of startling originality, a few pages only are devoted to the subject. He treats knots from the elementary notion of twisting one physical line (or thread) round another, and shows that from the projection of a knot on a surface we can thus obtain a notion of the relative situation of its coils. He distinguishes "reduced" from "reducible" forms, the number of crossings in the reduced knot being the smallest possible. The simplest form of reduced knot is of two species, as in figs. 1 and 2. Listing points out that these are formed, the first by right-handed, the second by left-handed twisting. In fact, if three half twists be given to a long strip of paper, and the ends be then pasted together, the two edges become one line, which is the knot in question. We may free it by slitting the paper along its middle line; and then we have the juggler's trick of putting a knot on an endless unknotted band. One of the above forms cannot be deformed into the other. The one is, in Listing's language, the "perversion" of the other, *i.e.*, its image in a plane mirror. He gives a method of symbolizing reduced knots, but shows that in this method the same knot may, in certain cases, be represented by different symbols. It is clear that the brief notice he has published contains a mere sketch of his investigations.

Fig. 1.

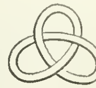

Fig. 2.

The most extensive dissertation on the properties of knots is that of Tait (*Trans. Roy. Soc. Edin.*, 1876–7). It was for the most part written in ignorance of the work of Listing, and was suggested by an inquiry concerning vortex atoms (see ATOM). Tait starts with the almost self-evident proposition that, if any plane closed curve have double points only, in passing continuously along the curve from one of these to the same again an even number of double points has been passed through. Hence the crossings may be taken alternately over and under. On this he bases a scheme for the representation of knots of every kind, and employs it to find all the distinct forms of knots which have, in their simplest projections, 3, 4, 5, 6, and 7 crossings only. Their numbers are shown to be 1, 1, 2, 4, and 8.

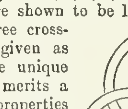

Fig. 3.

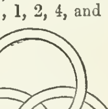

Fig. 4.

The unique knot of three crossings has been already given as drawn by Listing. The unique knot of four crossings merits a few words, because its properties lead to a very singular conclusion. It can be deformed into any of the four forms—figs. 3 and 4 and their perversions. Knots which can be deformed into their own perversion Tait calls "amphicheiral," and he has shown that there is at least one knot of this kind for every even number of crossings. He shows also that "links" (in which two endless physical lines are linked together) possess a similar property; and he then points out that there is a third mode of making a complex figure of endless physical lines, without either knotting or linking. This may be called "lacing" or "locking." Its nature is obvious from fig. 5, in which it will be seen that no one of the three lines is knotted, no

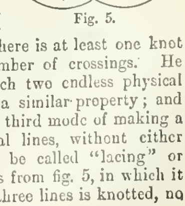

Fig. 5.

two are linked, and yet the three are inseparably fastened together.

The rest of Tait's paper deals chiefly with numerical characteristics of knots, such as their "knottiness," "beknottedness," and "knotfulness." He also shows that any knot, however complex, can be fully represented by three closed plane curves, none of which has double points, and no two of which intersect. It may be stated here that the notion of beknottedness is founded on a remark of Gauss, who in 1833 considered the problem of the number of interlinkings of two closed circuits, and expressed it by the electrodynamic measure of the work required to carry a unit magnetic pole round one of the interlinked curves, while a unit electric current is kept circulating in the other. This original suggestion has been developed at considerable length by Boeddicker (*Erweiterung der Gauss'schen Theorie der Verschlingungen*, Stuttgart, 1876). This author treats also of the connexion of knots with Riemann's surfaces.

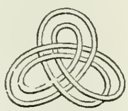

Fig. 6.

It is to be noticed that, although every knot in which the crossings are alternately over and under is irreducible, the converse is not generally true. This is obvious at once from fig. 6, which is merely the three-crossing knot with a doubled string—what Listing calls "paradromic."

Klein, in the *Mathematische Annalen*, ix. 478, has proved the remarkable proposition that knots cannot exist in space of four dimensions.

SAILORS' KNOTS.—The knots used by sailors are of many kinds. The following are the most useful:—

Overhand Knot (fig. 7).—Take the end a of the rope round the end b.

Reef Knot (figs. 8, 9).—Form an overhand knot as above. Then take the end a over the end b and through the bight. If the end a

Fig. 7.

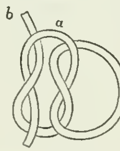

Fig. 8.

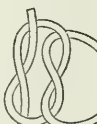

Fig. 9.

were taken under the end b a *granny* would be formed. This knot is so named from being used in tying the reef-points of a sail.

Bowline (figs. 10–12).—Lay the end a of a rope over the standing part b. Form with b a bight c over a. Take a round behind b and

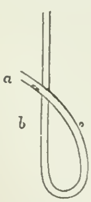

Fig. 10.

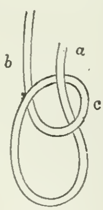

Fig. 11.

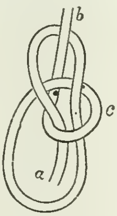

Fig. 12.

down through the bight c. This is a most useful knot employed to form a loop which will not slip.

Half Hitch (fig. 13).—Pass the end a of the rope round the standing part b and through the bight.

Clove Hitch (figs. 14, 15).—Pass the end a round a spar and cross it over b. Pass it round the spar again and put the end a through the second bight.

Blackwall Hitch (fig. 16).—Form a bight at the end of a rope, and put the hook of a tackle through the bight so that the end of the rope may be jammed between the standing part and the back of the hook.

Timber Hitch (fig. 17).—Take the end a of a rope round a spar, then round the standing part b, then several times round its own part c.

Fisherman's Bend (fig. 18).—Take two turns round a spar, then a half hitch round the standing part and between the spar and the turns, lastly a half hitch round the standing part.

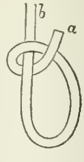

Fig. 13.

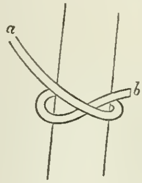

Fig. 14.

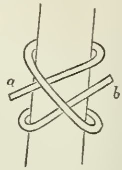

Fig. 15.

Fig. 16.

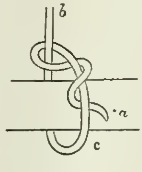

Fig. 17.

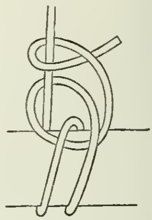

Fig. 18.

Carrick Bend (fig. 19).—Lay the end of one rope over its own standing part so as to form a bight. Put the end of the other rope through this bight, under the standing part, over the end beyond the bight, under the standing part beyond the bight, and down through the bight over its own standing part.

Sheet Bend (fig. 20).—Pass the end of one rope through the bight of another, round both parts of the other, and under its own standing part.

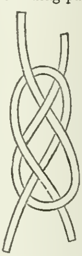

Fig. 19.

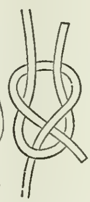

Fig. 20.

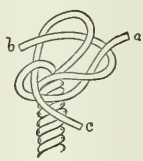

Fig. 21.

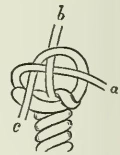

Fig. 22.

Single Wall Knot (fig. 21).—Unlay the end of a rope, and with the strand a form a bight. Take the next strand b round the end of a. Take the last strand c round the end of b and through the bight made by a. Haul the ends taut.

Single Wall Crowned (fig. 22).—Form a single wall, and lay one of the ends, a, over the knot. Lay b over a, and c over b and through the bight of a. Haul the ends taut.

Fig. 23.

Fig. 24.

Fig. 25.

Double Wall and Double Crown (fig. 23).—Form a single wall crowned; then let the ends follow their own parts round until all the parts appear double. Put the ends down through the knot.

Matthew Walker (figs. 24, 25).—Unlay the end of a rope. Take the first strand round the rope and through its own bight; the second strand round the rope, through the bight of the first, and through its own bight; the third through all three bights. Haul the ends taut.

See Nares, *Seamanship*, 4th ed., 1868; Dana, *Seaman's Manual*, 9th ed., 1863; A. H. Alston, *Seamanship*, Portsmouth, 1871; Kipping, *Masting and Rigging*, 9th ed., 1864; *Yachts and Yachting*, by "Vanderdecken" (William Cooper), 1873; *Book of Knots*, by "Tom Bowling" (J. Bonwick), 1866.

KNOT, a Limicoline bird very abundant at certain seasons on the shores of Britain and many countries of the northern hemisphere. Camden in the edition of his *Britannia* published in 1607 (p. 408) inserted a passage not found in the earlier issues of that work, connecting the name with that of King Canute, and this account of its origin has been usually received. But no other evidence in its favour is forthcoming, and Camden's statement is merely the expression of an opinion,[1] so that there is perhaps ground for believing him to have been mistaken, and that the clue afforded by Sir Thomas Browne, who (*circa* 1672) wrote the name "Gnatts or Knots," may be the true one.[2] Still the statement was so determinedly repeated by successive authors that Linnæus followed them in calling the species *Tringa canutus*, and so it remains with nearly all modern ornithologists.[3] Rather larger than a Snipe, but with a short, Plover-like bill and legs, the Knot visits the coasts of some parts of Europe, Asia, and North America at times in vast flocks; and, though in temperate climates a good many remain throughout the winter, these are nothing in proportion to those that arrive towards the end of spring, in England generally about the 15th of May, and after staying a few days pass northward to their summer quarters, while early in autumn the young of the year throng to the same places in still greater numbers, being followed a little later by their parents. In winter the plumage is ashy-grey above (save the rump, which is white) and white beneath. In summer the feathers of the back are black, broadly margined with light orange-red, mixed with white, those of the rump white, more or less tinged with red, and the lower parts are of a nearly uniform deep bay or chestnut. The birds which winter in temperate climates seldom attain the brilliancy of colour exhibited by those which arrive from the south; the luxuriance generated by the heat of a tropical sun seems needed to develop the full richness of hue. The young when they come from their birthplace are clothed in ashy-grey above, each feather banded with dull black and ochreous, while the breast is more or less deeply tinged with warm buff. Much curiosity has long existed among zoologists as to the egg of the Knot, of which not a single identified or authenticated specimen is known to exist in collections. Yet more than sixty years ago the species was found breeding abundantly on the North Georgian (now commonly called the Parry) Islands by Parry's memorable expedition, as well as soon after on Melville Peninsula by Captain Lyons, and again during the recent voyage of Sir George Nares on the northern coast of Grinnell Land and the shores of Smith Sound, where Major Feilden obtained examples of the newly-hatched young (*Ibis*, 1877, p. 407), and observed that the parents fed largely on the buds of *Saxifraga oppositifolia*. These are the only localities in which this species is known to breed, for on none of the arctic lands lying to the north of Europe or Asia has it been unquestionably observed.[4] In winter its wanderings are very extensive, as it is recorded from Surinam, Brazil, Walvisch Bay in South Africa, China, Queensland, and New Zealand. Formerly this species was extensively netted in England, and the birds fattened for the table, where they were esteemed a great delicacy, as witness the entries in the Northumberland and Le Strange Household Books; and the British Museum contains an old treatise on the subject—"The maner of kepyng of knotts, after Sir William Askew and my Lady, given to my Lord Darcy, 25 Hen. VIII." (*MSS. Sloane*, 1592, 8 *cat.* 663). (A. N.)

[1] His words are simply "*Knotts*, i. *Canuti aues*, vt opinor e Dania enim aduolare creduntur." In the margin the name is spelt "Cnotts," and he possibly thought it had to do with a well-known story of that king. Knots undoubtedly frequent the sea-shore, where Canute is said on one occasion to have taken up his station, but they generally retreat, and that nimbly, before the advancing surf, which he is said in the story not to have done.

[2] In this connexion we may compare the French *maringouin*, ordinarily a gnat or mosquito, but also, among the French Creoles of America, a small shore-bird, either a *Tringa* or an *Ægialitis*, according to Descourtilz (*Voyage*, ii. p. 249). See also Littré's *Dictionnaire*, *sub voce*.

[3] There are few of the *Limicolæ*, to which group the Knot belongs, that present greater changes of plumage according to age or season, and hence before these phases were understood the species became encumbered with many synonyms, as *Tringa cinerea*, *ferruginea*, *grisea*, *islandica*, *nævia*, and so forth. The confusion thus caused was mainly cleared away by Montagu and Temminck.

KNOWLES, JAMES SHERIDAN (1784–1862), dramatic author, was born at Cork, 21st May 1784. His father was the lexicographer James Knowles, cousin-german of Richard Brinsley Sheridan. Not long after the removal of the family to London in 1793, young Knowles began his dramatic career by composing a play which was performed by himself and his juvenile companions. At the age of fourteen he published a ballad entitled *The Welsh Harper*, which was set to music and obtained great popularity; and about the same time his precocious talents secured him the friendship of Hazlitt, through whom he also formed an intimacy with Lamb and Coleridge. Of his early career little else is known except that for some time he served in the Wilts and afterwards in the Tower Hamlets militia, and that he left the latter corps to become pupil of Dr Willan the physician, through whom he was appointed vaccinator to the Jennerian Society. Although, however, he was generously offered by Dr Willan a share in his practice, he resolved to forsake medicine for the stage, making his debut at the Crow Theatre, Dublin. At Wexford he in October 1809 married Maria Charteris, an actress from the Edinburgh Theatre. About this time he wrote *Leo*, which was played at Waterford with great success by Edmund Kean; but, although another piece, *Brian Boroihme*, which he wrote for the Belfast Theatre also drew crowded houses, his labours as an actor and author secured him so little pecuniary return that he found it advisable to become assistant to his father at the Belfast Academical Institution. In 1817 he removed from Belfast to Glasgow, where, besides conducting a flourishing school, he continued his dramatic authorship. His first important dramatic success was *Caius Gracchus*, produced at Belfast in 1815; and by *Virginius*, written for Edmund Kean, and first performed in 1820, he obtained a very high place among the dramatic authors of the century. Besides *William Tell*, in which Macready performed one of his most successful parts, the other principal plays of Knowles are *The Hunchback*, *Love*, and *The Wife*. In some of his own pieces he acted with a just appreciation of the character and with considerable vigour and fire, but he failed in the power of personation. He achieved some success, however, as a lecturer on elocution. In his later years he forsook the stage for the pulpit, and as a Baptist preacher attracted large audiences at Exeter Hall and elsewhere, while he also entered the field of polemical theology, publishing two works,—the *Rock of Rome*, and the *Idol Demolished by its own Priests*,—in both of which he combated the special doctrines of the Romish Church. Knowles was for some years in the receipt of an annual

[4] The *Tringa canutus* of Payer's expedition seems more likely to have been *T. maritima*, which species is not named among the birds of Franz Josef Land, though it can hardly fail to occur there.

pension of £200, bestowed by Sir Robert Peel. He died at Torquay, November 30, 1862

A full list of the works of Knowles and of the various notices of him will be found in his *Life*, by his son Richard Brinsley Knowles, of which twenty-five copies were printed privately.

KNOX, JOHN (1505–1572), the great Reformer of Scotland, was born at Haddington, the county town of East Lothian, in the year 1505.[1] His father was William Knox, commonly said to have been descended from the Knoxes of Ranfurly in Renfrewshire, but there is no evidence to prove what rests solely upon the authority of David Buchanan. The name of his mother was Sinclair, and some of his letters, written in seasons of danger, were signed "John Sinclair." Whatever might be their lineage, Knox's relations were in such circumstances as secured for him a liberal education in the grammar school of his native town; and, when about sixteen years of age, he was sent to pursue his studies at the university of Glasgow, where Dr John Mair or Major was principal regent, or professor of philosophy and divinity. Owing to some undiscovered cause he left the university without qualifying himself to take the degree of master of arts. It has been usual to state that from Glasgow Knox proceeded to St Andrews and there taught philosophy and theology, but no evidence can be adduced to show that he was officially connected in any way whatever with the university of that city. Not having qualified himself by taking his degree, he would be excluded from acting as a regent or professor, so that if he taught it can only have been in the way of private tuition. In truth, for some years about this time the course of life pursued by Knox is involved in obscurity. The probability is that he took orders in the Church of Rome as a secular priest about 1530, and was connected for upwards of ten years with one of the religious establishments in the neighbourhood of Haddington. In the Protocol books of that town the name of John Knox occurs among the witnesses to deeds of the years 1540, 1541, and 1542, in one deed under the style of *Schir*, that being the designation of priests who had not attained the higher academical degree of *Magister*; and as late as March 27, 1543, he pens and signs a notarial instrument as an apostolic notary, describing himself as "sacri altaris minister, Sanctiandrææ dioceseos, auctoritate appostolica notarius."

The martyrdom of Wishart in 1546 was the turning point in the spiritual life of Knox, determining him to renounce scholastic theology and to profess his adherence to the Protestant faith. As this subjected him to suspicion and trouble, he resolved to leave Scotland and visit the schools of Germany; but Douglas of Longniddrie and Cockburn of Ormiston, to whose sons Knox had for some time been acting as private tutor, prevailed on him to relinquish his design, and, along with his pupils, to enter the castle of St Andrews as a place of safety from the Romish clergy. It was there that Knox received a public call to the ministry, "whairat," to use his own graphic description of the scene in the great church, "the said Johnne abashed, byrst furth in moist abundand tearis, and withdrew him self to his chalmer."

In June of the same year (1547) the Catholics of Scotland and France joined their forces to avenge the death of Cardinal Beaton by capturing the Protestant garrison of St Andrews, the French fleet appeared in the bay, and the castle surrendered. It was stipulated that the lives of the refugees should be spared, that they should be removed to France, and that such of them as declined entering into the French service should be conveyed to any other country except Scotland. Knox, sharing the fate of his companions, was conveyed on board one of the French ships to Rouen; but the terms of the capitulation were grossly violated, and the captives were treated as prisoners of war. Knox and some others were sent on board the galleys, and, after being loaded with chains, were compelled to labour at the oar. Here they were subjected to many indignities and much suffering; but, in spite of every hardship and every threat, not one of their number renounced his faith. During the ensuing winter the galley in which he was confined lay in the Loire; and in the summer of 1548 it sailed for Scotland, and cruised off the east coast. The hardships to which he was now subjected produced a very serious effect upon his health: he was seized with a violent fever, and no hope was entertained of his recovery. He, however, regained his strength, and during his captivity had sufficient energy of mind to engage in literary work. In the winter of 1548 Henry Balnaves of Halhill, who remained a prisoner in the old palace of Rouen, had sent to Knox a treatise on the doctrine of justification by faith. With this work Knox was so much pleased that, having revised it carefully, divided the contents into chapters, and added a brief summary of the book, he sent it to Scotland for publication with an epistle addressed by "the bound Servant of Jesus Christ unto his best beloved Brethren of the Congregation of the Castle of St Andrewes, and to all Professours of Christs true Evangell" (*Works of John Knox*, vol. iii.). As the old copy of this epistle bears the title of "The Confession of Faith," this work may have been the "confession of his faith, containing the substance of what he had taught at St Andrews," which "he found means to convey to his religious acquaintances in Scotland," and which, Dr M'Crie thinks, "appears to have been lost." If so, leaving out of view the notices of his first sermon and of his disputation with Friar Arbuckle in St Leonard's Yards, contained in his *Historie*, this epistle will rank as the earliest specimen of the Reformer's composition that has been preserved.

After an imprisonment of eighteen or nineteen months Knox obtained his release from the French galleys in February or March 1549. As he probably owed his freedom to the intercession of Edward VI. or the English Government, he came to London on obtaining his liberty, and was favourably received by Archbishop Cranmer and the lords of council. Of the English section of his life, extending over five years, Knox himself disposes in few words: "The said Johne was first appointed preachar to Berwik, then to Newcastell; last he was called to London, and to the sowth partes of England, whar he remaned to the death of King Edward the Sext" (*Historie*, book i.). At Berwick, where he laboured for two years, he preached with his characteristic fervour and zeal, exposing the errors of Romanism with unsparing severity. The tendency of his zeal was not, however, calculated to recommend him to the bishop of the diocese, Dr Cuthbert Tunstall or Tonstall,

[1] Founding upon the designation "Giffordiensis" applied to him by Beza in his *Icones* of 1580, and the statement of Spottiswood in his *History* (1627) that Knox "was born in Gifford in the Lothians," later writers, beginning with David Buchanan, have given Gifford, a village a few miles to the south of Haddington, as the birthplace of Knox. On the other hand two contemporary Romanist writers—Archibald Hamilton (1577) and James Laing (1581)—assign to Haddington itself the honour in question: "Presbyter Joannes Knoxeus natus in Hadintona oppido in Laudonia"; "Joannes Knox natus prope Hadintonam, quæ est urbs in Laudonia." In 1785 the Rev. Dr Barclay of Haddington directed attention to Giffordgate, one of the suburbs of Haddington, as the locality which popular tradition has uniformly maintained to have been the spot where the Reformer was born, and which, with the grounds adjoining, is called "Knox's Walls" in a charter of 1607. Recent investigations prove that no village of the name of Gifford was in existence until the latter half of the 17th century, whereas in the Geneva Register of 1558, when Knox was admitted a burgess of Geneva, his name is thus entered: "Jehan, filz de Guillaume Cnoxe, natif de Hedington en Escosse." David Laing, who in 1846 followed M'Crie in preferring Gifford, in 1864 gives his verdict in favour of the Giffordgate, stating that a visit to the locality led him to the conclusion that the question now admits of no dispute.

who was strongly attached to the old faith. Having been accused of asserting that the sacrifice of the mass is idolatrous, the preacher was cited to appear before the bishop, and to give an account of his preaching. Accordingly, on the 4th of April 1550, Knox entered into a full defence of his opinions, and with the utmost boldness proceeded to argue that the mass is a superstitious and idolatrous substitute for the sacrament of the Lord's Supper. The bishop did not venture to pronounce any ecclesiastical censure; and the fame of the obnoxious preacher was extended by this feeble attempt to restrain the boldness of his attacks on the doctrines of Rome. The confession or vindication of his doctrine made by Knox on this occasion will be found in vol. iii. of his collected *Works*—"A Vindication of the Doctrine that the Sacrifice of the Mass is Idolatry," 1550.

Upon Knox's reforming work while a preacher at Berwick some interesting light has recently been thrown by the late Dr Lorimer's *John Knox and the Church of England*, 1875. When looking through the "Morrice" collection of manuscripts in Dr Williams's library, London, Dr Lorimer came upon four papers never before published. One of these is a letter from "Johne Knokks to the Congregatioun of Bervik," and another is "The practice of the Lord's Supper used in Berwick by John Knox, 1550." With this "practice," which is nothing more than a fragment, Dr Lorimer associates "A Summary, according to the Holy Scriptures, of the Sacrament of the Lord's Supper" to be found in the third volume of the *Works*, and to which Dr Laing has assigned the date 1550. Founding upon these documents, Dr Lorimer maintains that the very beginning of Puritan practice in the Church of England in the administration of the Lord's Supper is to be found in the order followed by Knox at Berwick, inasmuch as he not only substituted common bread for "wafer-breads," thus anticipating by several years the substitution as authorized by Edward's second Prayer-Book, published in 1552, but gave the first example of the substitution of sitting instead of kneeling in the act of communion, which has ever since continued to be a characteristic Puritan practice. At the close of 1550, or early in 1551, Knox was transferred to Newcastle-upon-Tyne, where he remained, with occasional absences in London, till the spring of 1553. In the closing month of 1551 he was appointed one of six chaplains to Edward VI., and in virtue of this appointment he was consulted in the preparation of the formularies of the Church of England. A book of forty-five articles of religion, forming the basis of the thirty-nine articles of the Anglican Church, drawn up by Cranmer, was submitted to the royal chaplains for their opinion. An original copy of these articles is preserved in H.M. State Paper Office with the autographs of the chaplains, the sixth being "Jo. Knox." Shortly after this the duke of Northumberland originated a proposal to make Knox a bishop. The letters bearing upon the proposal, not known to Dr M'Crie, were discovered by the late Mr Tytler, and published by him in his *England under the Reigns of Edward and Mary*. vol. ii. The duke's wish was that the king would "appoint Mr Knocks to the office of Rochester Bishoprick." When, however, the Scotch chaplain was informed of what was in contemplation, and was instructed to wait upon Northumberland, the latter did not find the man he thought to benefit eager to grasp at promotion, and the matter ultimately came to nothing by default of Knox himself. The last year of work in England was spent mainly in London and the southern counties. As royal chaplain Knox preached in turn before the court, and found favour with his royal hearer; but he was twice summoned before the privy council, first to answer complaints made by his would-be ducal patron, and then to vindicate his declinature of the vacant living of All Hallows in London.

Edward VI. having died in July 1553, and, the Marian persecutions having shortly afterwards broken out, Knox was persuaded to withdraw from England, and sailed for Dieppe, landing at that town in January 1554. The enforced leisure of exile gave the refugee an opportunity of completing and publishing several treatises during two sojourns in the same year at Dieppe. "An Exposition upon the Sixth Psalm of David," addressed to Mrs Bowes, "A Godly Letter of Warning or Admonition to the Faithful in London, Newcastle, and Berwick," "Two Comfortable Epistles to his afflicted Brethren in England," and "A Faithful Admonition to the Professors of God's Truth in England," all belong to the year 1554. After visiting the churches of France and Switzerland, Knox accepted an invitation to become one of the pastors of the English congregation at Frankfort-on-the-Main, and repaired thither in November of the same year. Soon after his settlement dissensions arose in the congregation in regard to the use of the surplice, the omission of the litany, the audible responses, and kneeling at the communion (see the letters and extracts from the "Brief Discourse of the Troubles at Frankfort" given by Dr Laing in vol. iv. of Knox's *Works*). A party in the congregation, clamorous for a strict adherence to the English Book of Prayer, lodged information with the magistrates that Knox, in his "Faithful Admonition," had used treasonable language in speaking of the emperor, the queen of England, and her husband Philip II. Not wishing to increase the troubles, the maligned preacher relinquished his charge on the 26th March 1555, and retired to Geneva. The closing months of that year and the opening ones of the year following form an important period in the public labours and the private life of the Reformer; for he then visited his native country, preached in Edinburgh, in West Lothian, and in Ayrshire, and dispensed the communion privately in several places. Before his visit came to a close he addressed a letter to the queen regent, in the hope that she might be persuaded to extend her protection to the Reformed preachers, or at least listen favourably to their doctrine. This letter, "augmented and explained by the author," and reprinted in 1558, "An Exposition upon Matthew iv., concerning the temptation of Christ in the wilderness," and "A letter of wholesome counsel, addressed to his Brethren in Scotland," belong to the year 1556. In visiting Scotland at that time, however, Knox was influenced by other considerations than those bearing simply on the public weal. For as far back as his Berwick ministry he had become acquainted with the family of Richard Bowes, and formed an attachment for the fifth daughter, Marjory. Dr M'Crie represents the marriage as having taken place in 1553 before Knox left England; and in support of his view it falls to be said that after that date Knox addresses Mrs Bowes as "Dearly Beloved Mother," and that he speaks of Marjory as his "wife," his "dearest spouse." But, considering the strong opposition to the union on the part of Richard Bowes and other relatives, as also the very uncertain and precarious position of the reformer at the time, there is good reason to think, with Dr Laing, that then the parties had only formally pledged themselves to one another "before witnesses," and that the actual marriage took place when Knox visited Scotland in 1555.

At the urgent solicitation of the English congregation at Geneva, consisting largely of those who had withdrawn from Frankfort, Knox left Scotland in the summer of 1556; and in the "Livre des Anglois à Genève," on the 13th September of that year, the names of "John Knox, Marjory, his wife, Elizabeth, her mother. James (*blank*), his servant, and Patrick, his puple," are entered as members of the English congregation. In Geneva the Scotch Reformer laboured with voice and pen till 1559. The literary works of that period, in addition to ten *Familiar Epistles*, include *Letters to his Brethren and the Lords professing the truth in Scotland*, three in number, 1557; *An Apology for the Protestants who are holden in prison at Paris*, 1557; *The Appellation from the Sentence pronounced by the bishops and clergy*, 1558; *A letter addressed to the Commonality of Scotland*, 1558; *An Epistle to the inhabitants in Newcastle and Berwick*, 1558; and *A brief exhortation to England for the speedy embracing of the Gospel*, 1559. Judged by the excitement it created, the most outstanding writing of this period is *The First Blast of the Trumpet against the Monstrous Regiment of Women*; and it cannot be denied that this publication was unseasonable, and might be expected to expose the author to the resentment of two queens during whose reign it was his lot to live. Indeed the sounder of the *First Blast* would seem to have realized that it was "blown out of season," for, whereas his purpose was "thrice to blow the trumpet in the same matter, if God so permit," and on the last occasion to reveal his name, the intention was never carried into effect. The resentment to which his blast against feminine government gave rise in queenly breasts did not soon subside; one immediate effect was that, when Knox resolved to return to Scotland, and applied to the English Government for permission to pass through the sister kingdom, the application was refused. Impatient of delay he sailed from Dieppe direct for Leith, and, landing at that port in safety, reached Edinburgh on 2d May 1559.

From this time to the close of his life the biography of the Reformer becomes inseparably connected with the history of Scotland. Within a few days of his arrival in Scotland, through the representations of the Romanist clergy to the queen-regent, Knox was proclaimed an outlaw and a rebel; but, undeterred by considerations of personal danger, he lost no time in joining the leaders of the Protestant party then assembled in Dundee. From Dundee he went with them to Perth, where his preaching was the antecedent though not the cause of a tumult which resulted in the altar, images, and other ornaments of the church being torn down, and the houses of the grey and black friars being laid in ruins. St Andrews is the next place of importance at which Knox joined the Protestants, at this time called the congregation, the lay leaders of the party, mostly noblemen, being known as the lords of the congregation. Here Knox announced his intention to preach in the cathedral church; and, undismayed by the threats of the archbishop, unmoved by the remonstrances of his friends, he carried his purpose into effect, preaching on four successive days, and with such signal effect that the provost, bailies, and inhabitants agreed to set up the Reformed worship in the town, stripped the church of images and pictures, and pulled down the monasteries. By the end of June Knox was again in Edinburgh, preaching in St Giles's and the abbey church; and on the 7th July he was elected minister of Edinburgh.

When the army of the queen-regent took possession of the capital, and the lords of the congregation agreed to leave it, they took their minister with them from a regard alike to the danger to which he would be exposed if left behind and the service it was in his power to render the Protestant cause. The result abundantly verified the wisdom of the step, for, set free from city labours, Knox travelled over a great part of Scotland, and visited the towns of Kelso, Jedburgh, Dumfries, Ayr, Stirling, Perth, Brechin, Montrose, Dundee, and St Andrews, with marked results in the diffusing of knowledge and the strengthening of the hands of fellow Protestants. By the end of April 1560 we find him once more in Edinburgh, having rendered important service to the Protestant leaders in their negotiations to procure aid from England, and, of necessity rather than from choice, acting the part of a politico-ecclesiastic. The most elaborate theological writing of the Scottish Reformer, although written before his final return to Scotland, was published in this year, 1560, at Geneva. It is *An Answer to the Cavillations of an Adversary respecting the doctrine of Predestination.*

The event of greatest political importance in this same year 1560 was the assembling of the Scottish parliament at Edinburgh, on 1st August. A petition having been presented by the Protestants of the country, craving the abolition of Popish doctrine, the restoration of purity of worship and discipline, and the appropriating of ecclesiastical revenues to the support of the ministry, the promotion of education, and the relief of the poor, the ministers and barons were required to lay before parliament a summary of Reformed doctrines. "Within foure dayis" this was done. The confession was read before the whole parliament, and after reasoning and voting was ratified by Act of Parliament, and the Protestant religion formally established. *The Confessioun of faith professit and belevit be the Protestants within the Realme of Scotland*, &c., in the composing of which no small share must have fallen to the minister of Edinburgh, is inserted by him at length in book iii. of his *Historie.* Between the dissolution of parliament and the first meeting of the General Assembly of the Church of Scotland on the 20th December, Knox and three other ministers were engaged in drawing up the plan of ecclesiastical government known as the *Book of Policy*, or *First Book of Discipline.* This standard document, approved by the General Assembly and subscribed by a majority of the members of privy council, is also incorporated in Knox's *Historie.*

The youthful, widowed, and fair Queen Mary, having arrived in Scotland in August 1561, lost no time in sending for Knox to the palace of Holyrood, in order that she might hold with him the first of those four or five dialogues which historians have rendered with dramatic effect not always consistent with historical accuracy. The charge brought against the Reformer of treating his sovereign with rudeness and disrespect in the course of those interviews has been thoroughly disproved by his biographer giving the details of what passed as furnished by one of the parties in his *Historie*, and is quite discredited by such a judge as Thomas Carlyle.

In the following year Knox found a more congenial sphere for the exercise of his logical and dialectic skill in a disputation with Quintine Kennedy, abbot of Crossragwell, in the neighbourhood of Maybole, Ayrshire. The abbot had set forth a number of articles respecting the mass, purgatory, praying to saints, the use of images, and other points which he declared his intention to open up more fully in his chapel at Kirkoswald. But when Knox, who happened to be in the vicinity, appeared on the Sabbath specified, the abbot deemed it prudent to absent himself, and Knox preached in his stead. This led to correspondence which resulted in arrangements for a disputation taking place. The disputants met at Maybole on the 28th September 1562 and the two following days at 8 A.M., in the house of the provost. Forty persons on each side were admitted as witnesses of the dispute, "with so many mo as the house may goodly hold, be the sight of my lord of Cassilis" (nephew of Kennedy). As usually is the case in such contentions, both sides claimed to be victorious; but, to counteract the one-sided reports circulated by the abbot and his friends, Knox published, in 1563, an account of the dispute taken from the records of the notaries present, to which he added a prologue and short marginal notes.

Queen Mary, having failed to influence the Reformer by her "many salt tears" or her flattery, endeavoured to get him into her power by moving the privy council to pronounce him guilty of treason on the ground that he had written a circular letter to leading Protestants in reference to the trial of two persons indicted for a riot in the Chapel Royal. Knox's trial took place at a special meeting of council in December 1562, at which the queen was present and acted an unseemly part as prosecutrix. To the unconcealed chagrin and intense displeasure of his sovereign, Knox was by a majority of the noblemen present absolved from all blame and commended for his judicious defence.

Before he was required to appear a second time at a privy council meeting, Knox, who had been a widower for three years, was married to his second wife Margaret Stewart, daughter of "the good" Lord Ochiltree; and in Ochiltree House, an ancient baronial residence, the room is still pointed out where, in March 1564, the marriage was celebrated. The occasion of his second appearance before the privy council was the preaching of a sermon in St Giles's about a month after the marriage of Queen Mary and Lord Darnley in July 1565. On the day the sermon was preached the young king made an imposing appearance, sitting on a throne prepared for his reception. Enraged by what he regarded as passages having a reference to himself in the discourse of the preacher, Darnley returned to the palace with the determination not to taste food till the offender had been punished. Knox was accordingly called before the council, "from my bed," as he tells us. Informed that he had offended the king, and that he must desist from preaching so long as their majesties remained in Edinburgh, Knox made reply that he had spoken nothing but according to his text (Isa. xxvi. 13–21), and, if the church should command him either to speak or abstain, he would obey, so far as the word of God would permit him. In regard to the sermon he deemed it necessary for his own exoneration to write out in full what he had spoken, and publish it with a preface dated at "Edingbrough, the 19th of September 1565." This sermon is the only specimen of Knox's pulpit discourses handed down to us. Dr M'Crie is of opinion that the prohibition was of a very temporary nature; but it does not appear that Knox resumed his usual ministrations in Edinburgh, unless at occasional intervals, till after Mary had been deprived of her authority in 1567. During this period of absence from his charge, however, the inhibited preacher was far from idle. In 1566 he drew up the most considerable portion of his *Historie of the Reformatioun*, having made a commencement in 1559 or 1560, and he wrote at the request of the Assembly various public letters. He also visited churches in the south of Scotland, and made a journey to England, in order to see his two sons, who had been there for education since the death of their mother Marjory Bowes.

On the 29th July 1567 the infant James VI. was crowned in the parish church of Stirling, and on that occasion Knox reappeared in public and preached the coronation sermon. He also preached at the opening of parliament in December of the same year, when the Confession of Faith formed and approved by parliament in 1560, with various Acts in favour of the Reformed religion, was solemnly ratified. When James Stuart, earl of Murray and regent of Scotland, was assassinated and died at Linlithgow, 23d January 1569, the event caused anguish and anxiety to the Reformer, who poured out the sorrows of his heart in the sermon and the prayers of the day on which the tidings reached the capital, and who thereafter preached the funeral sermon in the presence of three thousand persons gathered to witness the interment in the south aisle of the collegiate church of St Giles. The strain to which body and mind alike had been subjected for many years back, and the shock caused by the removal of the nobleman in whom he placed the greatest confidence, affected the Reformer's health, and in the month of October 1570 he had a stroke of apoplexy. Although he so far rallied as to have the use of speech restored to him and to resume preaching, he never entirely recovered from the debility which the stroke produced.

Resolved to take no prominent part in public affairs, and confining himself to preaching in the forenoon of the Lord's day, Knox might have spent what little of life on earth remained for him in the house assigned him by the provost and town council of Edinburgh, had he not become personally obnoxious to Kirkcaldy of Grange. This and the troubles which agitated the country induced Knox, "sore against his will, being compellit be the Brethren of the Kirk and Town," to quit the metropolis and retire to St Andrews. During his stay there of fifteen months the many infirmities of age did not prevent him engaging in his two favourite employments of preaching and writing. How he preached James Melville, then a student, afterwards minister of Anstruther, has described in an often-quoted passage of his "Diary." The latest publication of Knox in his life time was "imprentit at Sanctandrois be Robert Lekprenik, Anno Do. 1572." It is a tract in the form of an answer to a letter written by James Tyrie, a Scottish Jesuit.

By the end of July the adherents of the queen's party abandoned Edinburgh, and so enabled the banished citizens to return to their homes. One of their first acts was to send for Knox, who, travelling slowly because of weakness, reached the capital (for the last time) on the 23d August 1572. Only two more public appearances were to be made by him. The first of these was when in September tidings came to Edinburgh of the St Bartholomew massacre. Being assisted to reach the pulpit, and summoning up the remainder of his strength, he thundered out the vengeance of heaven against "that cruel murderer and false traitor, the king of France," and desired the French ambassador to tell his master that sentence was pronounced against him in Scotland, that the Divine vengeance would never depart from him nor from his house if repentance did not ensue, but that his name would remain an execration to posterity, and none proceeding from his loins should enjoy his kingdom in peace. The other occasion on which the debilitated Reformer appeared in public was the induction of Lawson, sub-principal of King's College, Aberdeen, as his successor, which took place on the 9th November. After taking a leading and solemn part in the services, he crept down the street leaning upon his staff and the arm of his attendant, and entered his house never to leave it alive.

Interesting details of his last illness and death-bed exercises are furnished in two contemporary narratives—Richard Bannatyne's "Account of Knox's Last Illness and Death" given in his *Journal of the Transactions in Scotland* 1570–1573, and the "Eximii viri Joannis Knoxii Scoticanæ Ecclesiæ instauratoris vera extremæ vitæ & obitus Historia" of Thomas Smeton, principal of the university of Glasgow, at the end of his *Responsio ad Hamiltonii Dialogum*, 1579. Both narratives are inserted by Dr Laing in his edition of the *Works*, vol. vi. part ii. Attended by his wife and friends, Knox died on Monday the 24th of November 1572, in the sixty-seventh year of his age. The funeral took place on the Wednesday following, when the body was brought from the house in the Netherbow Port by the newly-appointed regent, the earl of Morton, and other noblemen, and interred in the burying-ground connected with the church of St Giles. "When the body was laid in the grave," says Calderwood, "the earl of Morton uttered these words:—'Here lieth a man who in his life never feared the face of man; who hath been often threatened with dagge and dagger, but yet hath ended his days in peace and honour.'" If any stone ever marked the precise spot where Knox was buried—said by tradition to be in the Parliament Square, a few feet to the west of the pedestal of Charles II.'s statue—it must have been destroyed in 1633, when the burying-ground was wholly obliterated by buildings. As in the case of his illustrious contemporary and friend Calvin, no tombstone marks the place where he was interred.

Knox's family consisted of five children—two sons and three daughters. His two sons were born to him by his first wife Marjory Bowes. Nathanael and Eleazer Knox were both born in Geneva, entered as students of the university of Cambridge, and became fellows of St John's College. Both died at an early age, and by their deaths the family of the Reformer became extinct in the male line. The three daughters of Knox were Martha, Margaret, and Elizabeth. Martha was married to Alexander Fairlie of Braid, in the neighbourhood of Edinburgh, a tradition that she became the first wife of James Fleming, father of Robert Fleming, author of *The Fulfilling of the Scriptures*, having been disproved by Dr Laing (*Works*, vol. vi., part 2, lxix.); Margaret Knox married Zachary Pont, for several years minister of St Cuthbert's, Edinburgh; and Elizabeth married John Welch, or Welsh, or Welsch, minister successively of Selkirk, Kirkcudbright, and Ayr, and, when transported, of the French Protestant Church. Dr Laing considers it improbable that any lineal descendants of these daughters still exist.

Of Knox no original painting is known to exist. Several likenesses have been frequently reproduced. 1. A woodcut portrait of the Reformer occurs in Beza's *Icones*, published at Geneva in 1580, which has often been reproduced. 2. A French translation of the *Icones*, by Simon Gaulart, appeared in 1581 with a totally different portrait substituted in place of that of Knox, which is now believed to represent William Tyndale, the translator of the Bible. 3. In 1602 Verheiden, a Dutch theologian, published at the Hague his *Præstantium aliquot Theologorum Effigies*, and in that work a head engraved on copper by Hondius is given as that of Knox. There is every reason to suppose that this is merely an improved copy from Beza, and not taken from an original painting. 4. The Torphichen portrait of Knox is at Calder House. It has on the back of the canvas the inscription, in a handwriting less than a century old—"Rev. Mr John Knox. The first sacrament of the Supper given in Scotland after the Reformation was dispensed by him in this hall." It is a harsh disagreeable likeness, painted at least a century after Knox's death, with Beza's woodcut for model. 5. In 1836 the Society for the Diffusion of Useful Knowledge published an engraving of a portrait of Knox which now goes by the name of the Somerville portrait. This painting belonged to the Somerville family, and hung on the walls of their London residence till the peerage became extinct. The tradition in the family is that it was brought into their possession by James, the thirteenth baron, in the latter half of the 18th century; and the supposition of those who regard this as a veritable likeness of the reformer is that Baron Somerville had fallen in with an excellent portrait seemingly by some distinguished artist of Knox's time (presumably Francis Porbus, who painted a likeness of George Buchanan), and had a copy of it painted for his mansion of Drum, near Edinburgh. Engravings of Beza's and Verheiden's portraits will be found in Knox's *Works*, vols. i. and vi.; of the Torphichen portrait in the *Life of Knox*, 1st edition; and of all the five likenesses in *The Portraits of John Knox*, by Thomas Carlyle, whose verdict is in favour of the Somerville portrait as "the only probable likeness anywhere known to exist."

Literature.—The Works of John Knox, collected and edited by David Laing, 6 vols., Edinburgh, 1846-64, M'Crie, *The Life of John Knox*, 1st ed., 1811, 7th ed., 1855; Lorimer, *John Knox and the Church of England*, London, 1875; T. Carlyle, *An Essay on the Portraits of John Knox*, published in collected works along with *The Early Kings of Norway*, London, 1875. The life and labours, character and influence, of Knox are dealt with more generally in the following works:—Hill Burton's *History of Scotland*; J. A. Froude's *History of England*; Carlyle's *Heroes and Hero Worship*; Moncreiff, *The Influence of Knox and the Scottish Reformation on England*, London, 1860; Froude, *The Influence of the Reformation on the Scottish Character*, Edinburgh, 1865. (C. G. M'C.)

KNOXVILLE, chief city of Knox county and of East Tennessee, United States, is situated on the right bank of the Tennessee river, which is navigable up to this point, four miles below the confluence of the Holston and French Broad rivers, and about 165 miles east of Nashville. By recent statistics it is shown to be one of the six healthiest cities in the United States; the elevation is 1000 feet, mean temperature 58° Fahr., average rainfall 54·5 inches. Among its numerous handsome buildings are the United States custom-house and post-office, the university of Tennessee, and the public schools. There is a free library in the city. The university, which includes the State college of agriculture and the mechanic arts, was founded in 1807, the latter departments being added in 1869. It has a good library, and geological, mineralogical, and zoological collections. In 1881 there were 398 students. Knoxville is a busy industrial and commercial centre. Its manufactures include iron in all its forms, railway and other carriages, paper, furniture, sashes and blinds, tobacco, flour, leather and harness, pottery, &c.; and it has a brisk trade in these articles, as well as in boots and shoes, hardware, and dry-goods. Marble and coal of excellent quality are found in vast quantities near the city. Knoxville was settled in 1789, and laid out as a town in 1791, when it was named after General Henry Knox, at that time Washington's minister of war. From 1794 till 1817 it was the capital of Tennessee. During the civil war it was an important position, passing into the possession of the Union forces in 1863. The population of the city in 1880 was 9693, or, including directly connected suburbs, 15,450.

KOBELYAKI, a town of Russia, in the government of Poltava, 40 miles south-west of the government town, with a station on the railway between Kharkoff and Krementchug. The town proper is situated on the right bank of the Vorskla, but a suburb of some size, known simply as Zaryetchya or "Beyond the River," lies on the other side. Of the 13,000 inhabitants more than half are occupied exclusively with agriculture; but weaving, introduced by German colonists, is beginning to be a considerable industry in the town. Kobelyaki was founded by the Polish nobleman Nemirovitch, and is mentioned as a town in 1647. In the neighbourhood lies the village of Perevolotchna, where the Swedish forces under Charles XII. laid down their arms.

KOBRIN, a town of Russia, in the government of Grodno, 12 miles east of Brest-Litovsk and 4 miles from the Tevli station of the railway between Minsk and Brest-Litovsk. It lies in the midst of a marshy country, to the east of which are extensive forests; although situated on the Mukhavetz river, which enters into the system of canals uniting the Dnieper and Bug, it enjoys but little prosperity. Its 8000 inhabitants are chiefly engaged in agriculture; there is also some trade in grain, salt, timber, and bones. Kobrin was until the 16th century the capital of a principality of the same name.

KOCK, Charles Paul de (1794–1871), novelist, was born at Passy on the 21st of May 1794, and died at Paris on the 29th of August 1871. He was a posthumous child, his father, who was a banker of Dutch extraction, having been one of the numerous victims of the Terror, and dying on the scaffold with Hebert and Clootz, not as an extreme republican, but as "suspect" of foreign relations. The family was one of some rank in the Netherlands, and an uncle of the novelist attained to the position of minister of the interior in his native country. Paul de Kock, however, remained all his life a citizen of France. He began life as a banker's clerk, which occupation he soon quitted for literature. But his natural taste, or the memory of his father's death, kept him far apart from the republican party, and he was perhaps the most remarkable literary continuator of the *ancien régime* as far as light novels were concerned. His life was almost entirely uneventful, its chief incident being a burglary which was committed at his country house at Romainville in his later days. For the most part he resided on the Boulevard St Martin, and was one of the most inveterate of Parisians.

Paul de Kock began to write very early, and continued to produce novels almost until the end of his long life. But his period of greatest and most successful activity was the Restoration and the early days of Louis Philippe. The comparative "patavinity" of his style, and the fact of his standing aloof from the whole innovating movement in literature as in politics, made him relatively less popular in France itself than abroad, where he was considered as the special painter of life in Paris. Major Pendennis's remark that he had read nothing of the novel kind for thirty years except Paul de Kock, "who certainly made him laugh," is likely to remain one of the most durable of his testimonials, with as a companion the legendary question of a foreign sovereign to a Frenchman who was paying his respects, "Vous venez de Paris et vous devez savoir des nouvelles. Comment se porte Paul de Kock?" The disappearance of the *grisette* and of the cheap dissipation which Murger pathetically laments in more than one of his works practically made Paul de Kock obsolete, and his want of style affected him as unfavourably as it did his dramatic analogue Scribe. But to the student of manners his vivid and by all accounts truthful portraiture of low and middle class life in the first half of the 18th century at Paris will never lose its value, and, though he can hardly be said to hold a high place in literature, he is a remarkable follower of Restif de la Bretonne, and may be said to be in a sense the last of the 18th century school of novelists.

It has been said that the works of Paul de Kock are very numerous. In the fullest list that we have seen they amount to about a hundred, some of them being decidedly voluminous. With the exception of a few not very felicitous excursions into the historical romance, they are all stories of middle class Parisian life, of *guinguettes* and *cabarets* and equivocal adventures of one sort or another. The most famous of all is *Le Barbier de Paris*, which has been translated into almost every European language. Of equal literary merit, and, considering the style, of singular freedom from objectionable characteristics, is *André le Savoyard*, a remarkable story, full of narrative power, and one of the happiest examples of the working up of simple and commonplace details into an interesting whole. A certain sameness pervades most of Paul de Kock's work. It is almost untouched by the influences of the romantic movement, and has none of the strong sentiments of the school which derived from the author's contemporary Balzac. But there is a good deal of human nature in it, a good deal of accurate observation, and an almost total absence of the revolting and the preposterous. Paul de Kock was the Charles de Bernard of low life, and greater praise of its kind could hardly be given to any writer.

KODUNGALÚR, or CRANGANORE, a town in Cochin state, Southern India, 10° 13′ 50″ N. lat., 76° 14′ 50″ E. long., with a population (1876) of 9475.

Though now a place of little importance, its historical interest is considerable. Tradition assigns to it the double honour of having been the first field of St Thomas's labours (52 A.D.) in India and the seat of Cherumán Perumál's government (341). The visit of St Thomas is generally considered mythical; but it is certain that the Syrian Church was firmly established here before the 9th century (Burnell), and probably the Jews' settlement was still earlier. The latter, in fact, claim to hold grants dated 378 A.D. The cruelty of the Portuguese drove most of the Jews to Cochin. Up to 1314, when the Vypín harbour was formed, the only opening in the Cochin backwater, and outlet for the Periyár, was at Kodungalúr, which must then have been the best harbour on the coast. In 1502 the Syrian Christians invoked the protection of the Portuguese. In 1523 the latter built their first fort there, and in 1565 enlarged it. In 1661 the Dutch took the fort, the possession of which for the next forty years was contested between this nation, the Zamorin, and the rájá of Kodungalúr. In 1776 Tipú (Tippoo) seized the stronghold. The Dutch recaptured it two years later, and, having ceded it to Tipú in 1784, sold it to the Travancore rájá, and again in 1789 to Tipú, who destroyed and left it in the following year.

KOHÁT, a district in the lieutenant-governorship of the Punjab, India, is situated between 32° 47′ and 33° 53′ N. lat., and between 70° 34′ and 72° 17′ E. long., and is bounded on the N. by Pesháwar, on the E. by the Indus river, on the S. by Bannu district, and on the W. by the Kuram river and the Wazírí hills. It consists chiefly of a bare and intricate mountain region, deeply scored with river valleys and ravines, but enclosing a few scattered patches of cultivated lowland. The eastern or Khatak country especially comprises a perfect labyrinth of ranges, which fall, however, into two principal groups, to the north and south of the Teri Toi river. The Miranzái valley, in the extreme west, appears by comparison a rich and fertile tract. In its small but carefully tilled glens, the plane, palm, fig, and many orchard trees flourish luxuriantly; while a brushwood of wild olive, mimosa, and other thorny bushes clothes the rugged ravines upon the upper slopes. Occasional grassy glades upon their sides form favourite pasture grounds for the Wazírí tribes. The Teri Toi, rising on the eastern limit of Upper Miranzái, runs due eastward to the Indus, which it joins 12 miles north of Makhad, dividing the district into two main portions. The drainage from the northern half flows southward into the Teri Toi itself, and northward into the parallel stream of the Kohát Toi. That of the southern tract falls northwards also into the Teri Toi, and southwards towards the Kuram and the Indus. The frontier mountains, continuations of the Safed Koh system, attain in places a considerable elevation, the two principal peaks, Dupa Sir and Mazeo Garh, just beyond the British frontier, being 8260 and 7940 feet above the sea respectively. The Wazírí hills, on the south, extend like a wedge between the boundaries of Bannu and Kohát, with a general elevation of less than 4000 feet. The salt mines are situated in the low line of hills crossing the valley of the Teri Toi, and extending along both banks of that river. The deposit has a width of a quarter of a mile, with a thickness of 1000 feet; it sometimes forms hills 200 feet in height, almost entirely composed of solid rock-salt, and may probably rank as one of the largest veins of its kind in the world. The most extensive exposure occurs at Bahádur Khel, on the south bank of the Teri Toi. Petroleum springs exude from a rock at Panoba, 23 miles east of Kohát; and sulphur abounds in the northern range.

The census of 1868 extended over an area of 2838 square miles, and disclosed a total population of 145,419 (males, 79,323; females, 66,096). The Mohammedans numbered 136,565, as against 6544 Hindus, 1837 Síkhs, and 473 "others." The Hindus chiefly belong to the trading castes. Among the Mohammedans, 6313 rank as Sayyids; but the Patháns form by far the largest division. Only one town, Kohat, contains a population exceeding 5000 inhabitants. Since the annexation of the Punjab, cultivation has extended from 64,772 acres in 1848 to 163,015 acres in 1873-74. The agricultural staples include wheat and barley for the spring harvest, with rice, millet, Indian corn, and pulses for the autumn crops. Tobacco, mustard, and oil-seeds also cover small areas, and cotton of inferior quality is grown in favourable years. The area under wheat in 1873-74 was returned as 36,600 acres; barley, 17,070; millets, 23,705; Indian corn, 12,050; rice, 4710 acres. Cultivation has now nearly reached its utmost limit. The principal industry of the district is centred in the salt mines. Of these five are now open, from which 294,680 cwts. of salt were quarried in 1870-71. Gun barrels manufactured near Kohát town have a considerable reputation along the north-western frontier. Coloured scarfs, woollen carpets, country cloth, and pottery are also turned out at Kohát, Hangu, and Teri. The frontier military road forms the chief channel of communication, practicable throughout for wheeled conveyances and artillery. The district has altogether 249 miles of road, all unmetalled, and in many cases mere tracks, passable at best by camels, and sometimes only by bullocks or ponies. The total imperial revenue raised in the district in 1851-52 amounted to £9824, which in 1872-73 had risen to £19,443, of which the land-tax contributed £8951, and salt £8556. Education remains in a very backward stage. Four Government or aided schools and forty-three indigenous schools had a total roll of only 745 pupils in 1872-73. From its proximity to the hills, the temperature of the district is comparatively cool, except during the summer months.

KOHÁT, the chief town and cantonment of the above district, situated in 33° 35′ N. lat. and 71° 29′ 43″ E.

long., near the north bank of the Kohát Toi river, and 2 miles from the southern base of the Afridi Hills. The population in 1868, including the cantonment, was 11,274. The town is built on undulating ground, within an amphitheatre of hills, and is surrounded by a slight wall, 12 feet in height. Its principal manufacture is that of gun barrels. The cantonment and civil station lie to the east and north-east of the native city. The cantonment has accommodation for about 3000 troops.

KOHL, Johann Georg (1808–1878), traveller and author, was born at Bremen, April 28, 1808. He studied law at Göttingen, Heidelberg, and Munich, and for six years was a private tutor in Courland. In 1838, after travelling through parts of Russia, he settled at Dresden. The success of four books, which he published in 1841, describing his Russian experiences, decided his choice of literature as a profession. Travels in Europe and America supplied ample material, and book after book appeared. In 1854 he undertook to prepare an historical coast survey of the United States, in the service of Government. In 1858 he returned to Bremen, where in 1863 he was made city librarian. In that post he died, October 28, 1878.

Kohl was a prolific author, and his books, both in the original and in English translations, have enjoyed considerable popularity. His style is agreeable and lively, and not without humour; his observation was acute, and not more superficial than was inevitable from the mode in which he amassed his materials. Besides the books on Russia, Kohl published works on Austria-Hungary (1842), England, Scotland, and Ireland (1844), the Alps (1849–51), Denmark and the Northern Duchies (1846–47), south-eastern Germany (1852), the Netherlands (1850), Istria, Montenegro, &c. (1851), the Danube (1854), Canada and New England (1857), the north-west of the United States (1859), Lake Superior ("Kitchi-Gami") (1859). Among his historical, geographical, and miscellaneous writings are the following:—*Der Rhein*, 2 vols., 1851; *Aus meinen Hütten*, 3 vols., 1850; *Geschichte der Entdeckung Amerika's*, 1861; *Das Haus Seefahrt zu Bremen*, 1862; *Nordwestdeutsche Skizzen*, 1864; *History of the Discovery of Maine*, 1869; *Die Völker Europa's*, 2 vols., 1872; *Kleine Essays*, 1875.

KOLÁBA, a district of the Bombay Presidency, India, lying between 17° 52′ and 18° 50′ N. lat., and between 73° 7′ and 73° 42′ E. long. It is bounded on the N. by Bombay harbour and Tháua district, on the E. by Poona and Sátára, on the S. by Ratnágiri and Janjíra state, and on the W. by the Arabian Sea. Lying between the Sahyádri range and the sea, Kolába district abounds in hills, some being spurs of considerable regularity and height, running at right angles to the main range, whilst others are isolated peaks or lofty detached ridges. The sea frontage, of about 20 miles, is throughout the greater part of its length fringed by a belt of cocoa-nut and betel-nut palms. Behind this belt lies a stretch of flat country devoted to rice cultivation. In many places along the banks of the salt-water creeks there are extensive tracts of salt marsh land, some of them reclaimed, some still subject to tidal inundation, and others set apart for the manufacture of salt. The district is traversed by a few small streams. Tidal inlets, of which the principal are the Nágothna on the north, the Roha or Chaul in the west, and the Bánkot creek in the south, run inland for 30 or 40 miles, forming highways for a brisk trade in rice, salt, firewood, and dried fish. Near the coast especially, the district is well supplied with reservoirs. The Sahyádri range has two remarkable peaks,—Ráigarh, where Sivají built his capital, and Mirádongar. There are extensive teak and black wood forests, of which the value is increased by their proximity to Bombay. The Kolába teak has been pronounced the best grown in the Concan, and inferior only to that of Calicut. In 1875–76 the forest revenue amounted to £3634. Tigers and leopards are found all over the district, and bears on the Sahyádri range. Hyænas and jackals abound. Bison, *sámbhar*, and cheetah have been shot, but are very rare.

Kolába district, with the exception of Alíbágh subdivision, formed part of the dominions of the peshwa, annexed by the Bombay Government in 1818. Alíbágh lapsed to the paramount power in 1839.

The population in 1872 was 350,405—Hindus, 330,914; Mohammedans, 17,194; Parsis, 25; Jews, 1940; and Christians, 208. Of the Hindus the most important class are the Bráhmans, who own large gardens and palm groves along the coast. Another important class are the Bhandáras, or toddy-drawers and cocoa-nut cultivators. The Beni-Israel (see vol. xiii. p. 685) are chiefly found in the seaboard tracts. A considerable number of them enlist in the native army, and are highly esteemed as soldiers. They also monopolize the work of oil-pressing to so great an extent that they are generally known as oilmen or *telis*. The total area of Government cultivable land in 1876–77 was returned at 468,646 acres, of which upwards of 98 per cent. was taken up for cultivation. Rice forms the staple produce, and is the chief export of the district. The inferior grains are *nachni* (*Eleusine coracana*), *wari* (*Panicum miliaceum*), and *harik* (*Paspalum frumentaceum*); and these form the chief food supply of the people. The estimated value of the exports (rice, salt, timber, vegetables, and fruit) is £438,249; of the imports (grain, piece goods, oil, butter, and sugar), £170,816. The local industries are salt manufacture and silk-weaving. The total imperial, local, and municipal revenue in 1876–77 was £106,893, of which £72,462 was contributed by the land tax. There are seventy-one Government or aided schools attended by 3644 pupils. The average annual rainfall is 75 inches. The chief town of the district is Alíbágh.

KOLÁR, or Colar, a district of Mysore state, Southern India, lying between 12° 46′ and 13° 36′ N. lat., and 78° 5′ and 78° 35′ E. long. It occupies that portion of the Mysore table-land immediately bordering the Eastern Gháts. The principal watershed lies in the north-west, around the hill of Nandidrug (4810 feet), from which rivers radiate in all directions; and the whole country is broken by numerous hill ranges. The chief rivers are the Pálár, the South Pinákiní or Pennár, the North Pinákiní, and the Pápaghni, which are industriously utilized for irrigation by means of anicuts and tanks. The rocks of the district are mostly syenite or granite, with a small admixture of mica and felspar. The soil in the valleys consists of a fertile loam; and in the higher levels sand and gravel are found. The hills are covered with scrub, jungle, and brushwood. The only tract where the trees attain any size is in the neighbourhood of Nandidrug, where an area of 7 square miles has been reserved by the forest department.

The population in 1871 was 618,954, spread over an area of 2577 square miles—Hindus numbering 592,652; Mohammedans, 25,038; Jains, 651; and Christians, 613. Four towns contain upwards of 5000 inhabitants, namely, Kolár, 9924; Chikballapur, 9882; Siálghata, 7009; and Hosur, 5711. The staple agricultural products are rice, *ragi*, and *joar*. Pulses, oil-seeds, vegetables, and tobacco are also grown on limited areas. Cattle breeding has recently been fostered by the British Government, and large cattle fairs are held annually. The manufactures of the district comprise sugar, silk and cotton weaving, and oil-pressing. Iron ore is smelted in considerable quantities. The principal exports are sugar, rice, *ragi*, vegetables, cotton cloth, betel leaf, opium, and *ghi*; the imports are European piece goods and salt. The total revenue of the district in 1873–74 amounted to £119,446, of which £97,470 was derived from the land and paid by 78,247 proprietors of 678 separate estates. The Government aided and inspected schools in 1874 numbered 233, attended by 5547 pupils; in addition there were also 102 unaided schools. The district bears a good reputation for healthiness, the mean annual temperature being 76°, and the average annual rainfall 29·17 inches.

The early history of the district is enshrouded in the usual Hindu legends, chiefly localized at the village of Avani, which is still a popular place of pilgrimage, as containing a *linga* set up by Ráma himself. The earliest authentic evidence shows that Kolár in primitive times formed part of the kingdom of the Pallavas, a dynasty overthrown by the Cholás, to whom is assigned the foundation of Kolár town. After the Cholás came the Ballála kings, who in their turn gave way to the powerful monarch of Vijayanagar, in the early part of the 14th century. About this period arose the Gauda family, whose chiefs appear to have submitted successively to every conqueror until they were swept away by Hyder Ali. The first Mohammedans to invade this tract were the Bijápur kings, whose general was the Marhattá Shábjí, the father of Sivají the Great. In 1639 Shahji obtained Kolár as a fief, which he transmitted to his son Venkojí or Ekojí, the founder of the Tanjore line. Subsequently Kolár was overrun by the Mughals. In 1761 it was formally ceded by the nizám to Hyder Ali, who was a native of the state, having been born at the little village of Budikot; and after the fall of Tipú in 1799 it was incorporated in the Hindu state of Mysore. The chief historical interest of modern times centres round the hill fort of Nandidrug (Nundydroog), which was stormed by the British in 1791, after a bombardment of twenty-one days. Kolár, which with the rest of Mysore had been under British administration since 1835, was restored to its native chief in March 1881.

KÖLCSEY, Ferencz or Francis (1790–1838), a distinguished Hungarian poet, critic, and orator, was born at Szödemeter, in Transylvania, on the 8th of August 1790. His parents both died during his childhood, leaving him to the care of a trusted female servant. At an early age Kölcsey was sent to the Calvinistic school at Debreczen, where he acquired a sound knowledge of the Latin and Greek classics, as also of the leading Hungarian and German poets. In his fifteenth year he made the acquaintance of Kazinczy, and zealously adopted his linguistic reforms. In 1809 Kölcsey went to Pest with the intention of following the legal profession, and became a "notary to the royal board." The public career of a lawyer, however, proving distasteful to him, he soon left the city, and, secluding himself at Cseke in Szatmár county, devoted his time to æsthetical study, poetry, criticism, and the defence of the theories of Kazinczy. Kölcsey's early metrical pieces contributed to the *Transylvanian Museum* did not attract much attention, whilst his severe criticisms of Csokonai, Kis, and especially Berzsenyi, published in 1817, rendered him very unpopular. From 1821 to 1826 he published many separate poems of great beauty in the *Aurora*, *Hebe*, *Aspasia*, and other magazines of polite literature. Having by these means again risen in the estimation of the literary public, he was induced by Paul Szemere to join him in the production of a new periodical, styled *Élet és Literatura* ("Life and Literature"), which appeared from 1826 to 1829, in 4 vols., and gained for Kölcsey the highest reputation as a critical writer. About this time his powers as an orator began to be displayed in his capacity of upper notary to the county of Szatmár. From 1832 to 1835 he sat in the Hungarian diet, where his extreme liberal views and his singular eloquence soon rendered him famous as a parliamentary leader. In the meantime he had not been inactive as a literary savant. Elected on the 17th November 1830 a member of the Hungarian Academy of Sciences, he took part in its first grand meeting; in 1832 he delivered his famous oration on Kazinczy, and in 1836 that on his former opponent Daniel Berzsenyi. When in 1838 Baron Wesselényi was unjustly thrown into prison upon a charge of treason, Kölcsey eloquently though unsuccessfully conducted his defence; and he died about a week afterwards (24th of August) from internal inflammation. His collected works, in 6 vols., were published at Pest, 1840–48, and his journal of the diet of 1832–36 appeared in 1848. A monument erected to the memory of Kölcsey was unveiled at Szatmár-Németi on the 25th of September 1864.

See G. Steinacker, *Ungarische Lyriker*, Leipsic and Pest, 1874; F. Toldy, *Magyar Költők élete*, 2 vols., Pest, 1871; J. Ferenczy and J. Danielik, *Magyar Irók*, 2 vols., Pest, 1856–58.

KOLDING, a town in the district of Veile, Denmark, is situated on the east coast of the province of Jutland, on the Koldingfjord, an inlet of the Little Belt. It has some little shipping, but its harbour is not deep. A little to the north-west is the splendid ruin of the royal castle Koldinghuus, formerly called Oernsborg or Arensborg. It was begun by Duke Abel in 1248; in 1808 it was burned. The large square tower was built by Christian IV. (1588–1648), and was surmounted by colossal statues, of which one is still standing. The name of Kolding occurs in the 10th century; but its earliest known town-rights date from 1321. In 1644 it was the scene of a Danish victory over the Swedish, and in 1849 of a Danish defeat by the Schleswig-Holstein troops. The population in 1870 was 5400.

KOLHÁPUR, a native state in the Bombay Presidency, India, lying between 15° 58′ and 17° 11′ N. lat., and between 73° 45′ and 74° 24′ E. long.; it is bounded on the N. by Sátára district, on the E. and S. by the states of Sángli, Miráj, and Kurunchwád, and on the W. and S.W. by Sawantwári state and Ratnágiri district. The area is 3184 square miles. Kolhápur state stretches from the heart of the Sahyádri range eastwards into the plain of the Deccan. Along the spurs of the main chain of the Sahyádri hills lie wild and picturesque hill slopes and valleys, producing little but timber, and till recently covered with rich forests. The centre of the state is crossed by several lines of low hills running at right angles from the main Sahyádri range. In the east the country becomes more open, and presents the unpicturesque uniformity of a well-cultivated and treeless plain, broken only by an occasional river. Among the western hills are the ancient Marhattá strongholds of Panhála, Vishalgarh, Baura, and Rangna. The rivers, though navigable during the rains by boats of 2 tons burthen, are all fordable during the hot months. Iron ore is found in the Sahyádri range, and smelting was formerly carried on to a considerable extent; but now the Kolhápur mineral cannot compete with that imported from Europe. There are several good stone quarries. The principal agricultural products are rice, millet, sugar-cane, tobacco, cotton, safflower, and vegetables. The population of the state, including feudatories, was 802,691 in 1872, Hindus amounting to 95½ per cent., and Mohammedans to 4 per cent. Pottery, hardware, and coarse cotton and woollen cloth are the principal manufactures. The chief exports are coarse sugar, tobacco, cotton, and grain; piece goods, salt, silk, sulphur, and spices are imported.

The rájás of Kolhápur trace their descent from Rájá Rám, a younger son of Sivají the Great, the founder of the Marhattá power. The prevalence of piracy caused the British Government to send expeditions against Kolhápur in 1765 and 1792; and in the early years of this century the misgovernment of the chief compelled the British to resort to military operations, and ultimately to appoint an officer to manage the state. In 1862 a treaty was concluded with Sivají III. The revenue of the state is estimated at £304,000. The military force consists of 1618 men. Exclusive of a few missionary institutions, there are in all 104 schools, attended by 5105 pupils. The climate is on the whole temperate.

Kolhápur, the capital of the above state, is situated in 16° 42′ N. lat. and 74° 16′ E. long., 128 miles south by east of Poona. It is a picturesque, flourishing trading town, adorned with many handsome buildings. Population in 1872, 39,621.

KOLIN (Boh., *Nový Kolín*, *i.e.*, New Kolin), a town in the circle of Kaurzim, Bohemia, is situated on the Elbe, about 35 miles east of Prague, with which city as also with Brünn it is connected by the Austrian State Railway, here intersected by the north-western line, in 50° 4′ N. lat., 15° 14′ E. long. Among the many noteworthy buildings in Kolin may be specially mentioned the church of St Bartholomew (Early Gothic style), erected during the latter half of the 14th century, the castle, and the town-hall. The educational and industrial establishments comprise collegiate institutes for both sexes, a commercial school, religious houses, several sugar refineries and oil-mills, a spirit distillery, and an artificial manure factory. Population of commune 9473, of town 9199. Kolin is chiefly famous on account of the battle of Chotzemitz or Kolin, 18th June 1757, when the Prussians under Frederick the Great were defeated by the Austrians under Daun.

KOLOMEA, or Kolomyia, a town and district in the Austrian province of Galicia, lies on the right bank of the Pruth and on the railway from Czernowitz to Lemberg about 105 miles south-south-east of the latter, in 48° 31′ N. lat., 25° 1′ E. long. Kolomea is the seat of the administrative, military, and judicial authorities of the district, and has Roman Catholic churches, synagogues, a lower gymnasium, and manufactories of earthenware. More than a third of the inhabitants are Jews, who carry on the greater part both of the wholesale and retail trade. The Ruthenian or native population of the town and neighbourhood are mostly employed in agricultural pursuits, and in the pasturing of horses, oxen, and sheep. In 1881 the population amounted to 23,109.

KOLOMNA, a district town of Russia, in the government of Ryazan, situated on the railway between Moscow and Ryazan, 67 miles south-east of Moscow, at the confluence of the Moskva river with the Kolomenka. It is an old town mentioned in annals in 1177, and until the 14th century the capital of the Ryazan principality. It suffered greatly from the invasions of the Tartars, who destroyed it four times, as well as from the wars of the 17th century; but it always recovered, and never has lost its commercial importance. During this century it became a centre of manufactures of silks, cottons, and leather; there are also several smaller manufactures. The merchants of Kolomna carry on an active trade in cattle brought from southern provinces, and in grain, cattle, tallow, skins, salt, and timber purchased in the governments of Ryazan and Tula, and sent to Moscow, either by rail, or by boat down the Moskva river. Population 19,000.

KOMORN, or COMORN (Hungarian, *Rév-Komárom*), a royal free town of Hungary, and capital of the trans-Danubian county of Komárom, lies at the eastern extremity of the island of Csallóköz or Schütt, and at the confluence of the Waag with the Danube, 48 miles west-north-west from Budapest, with which city as also with Vienna it is directly connected by railway, in 47° 46′ N. lat., 18° 7′ E. long. Komorn is celebrated chiefly for its fortifications, which, owing to their favourable position and extended line of têtes-de-pont, are believed to be impregnable, and are capable of holding a force of some 30,000 defenders. The town is the seat of the county administration, and of a royal court of law, and has Roman Catholic, Greek Orthodox, Lutheran, and Calvinist churches, a Jewish synagogue, Roman Catholic and Protestant gymnasia, county and town halls, a military hospital, two savings banks, and a shipping agency. The streets are for the most part narrow, irregular, and gloomy. The commercial relations of Komorn with the chief towns on the Danube are facilitated by its important steam-packet station. The inhabitants carry on a brisk trade in grain, timber, wine, flour, and fish. The civil population at the end of 1880 amounted to 13,108, mostly Magyars and Germans by nationality.

The walls of the fortifications of Komorn were commenced from the land side in 1272. They were much strengthened and extended two hundred years later by King Matthias (Corvinus). The new fort was begun by Ferdinand I. about 1547, and received additions in 1673 under Leopold I. In 1543, 1594, 1598, and 1663 Komorn was beleaguered by the Turks. It was raised to the dignity of a royal free town in 1751. In 1767, 1768, September 1848, and April 1854 it suffered severely from fire, and in 1763, 1822, and 1851 from earthquakes. The fortifications, having been neglected during the latter half of the 18th century, were enlarged and to a great extent reconstructed between 1805 and 1809. During the revolutionary war of 1848–49 Komorn was a principal point of military operations, and was long unsuccessfully besieged by the Austrians, who on the 11th July 1849 were defeated there by General Görgei, and on the 3d August by General Klapka. On the 27th September the fortress capitulated to the Austrians upon honourable terms, and on the 3d and 4th October was evacuated by the Hungarian troops. The treasure of the Austrian national bank was removed here from Vienna in 1866, when that city was threatened by the Prussians.

KOMOTAU, a town and district of Bohemia, at the foot of the Erzgebirge, and at the junction of the Buschtiehrad, Dux-Bodenbach, and Aussig-Teplitz lines of railway, about 10 miles north-north-west of Saaz, in 50° 27′ N. lat., 13° 26′ E. long. An old but thriving town, Komotau is the seat of the military and judicial authorities of the district, as also of boards of mining and of customs. The industrial establishments comprise manufactories of woollen cloth, linen, and paper, dyeing houses, breweries, distilleries, and vinegar works, a sugar of lead manufactory, and an iron foundry. The amount of beer delivered in 1880 was 535,583 gallons. Lignite is worked in the neighbourhood. At the end of 1880 the population was 10,111.

KONGSBERG, a mining town in the district of Buskerud, Norway, is situated on the Laagen, 500 feet above the sea, and about 60 miles south-west of Christiania by rail. With the exception of the church and the town-house, the buildings are mostly of wood. The origin and whole industry of the town are connected with the Government silver-mines in the neighbourhood. Their first discovery was made by a peasant in 1623, since which time they have been worked with varying success. Over a hundred mines have been opened, but of these only three are now of any importance. The annual profit averages about £22,000. During last century Kongsberg was much more important than it now is, and contained more than double its present population. Dr Clarke in his *Travels* (1823) gives a good description of the place, and mentions a mass of native silver, nearly 600 lb in weight, found there, which is preserved in the museum at Copenhagen. Within the town of Kongsberg are situated the smelting-works, the mint, and a Government weapon factory. The population of the town in 1875 was 4311.

KÖNIGGRÄTZ (Bohemian, *Králové Hradec*), a fortified town and episcopal seat in Bohemia, at the confluence of the Adler with the upper Elbe, and at the junction of the Reichenberg-Pardubitz and North-Western lines of railway, in 50° 10′ N. lat., 15° 49′ E. long. Wax candles, gloves, shoes, woollen cloths, and musical (wind) instruments are manufactured. The population in 1880 was 6173. The place is chiefly notable from the battle of Königgrätz or Sadowa fought in its neighbourhood on 3d July 1866, when the defeat of the Austrians under Benedek decided the German supremacy of Prussia, and led to the acquisition of Venice by Italy and the constitutional independence of Hungary. See Jähns, *Die Schlacht bei Königgratz*, 1876.

KÖNIGINHOF (in Czech, *Dvur Kralové*), chief town of a department in the north-east of Bohemia, is situated on the left bank of the Elbe, about 80 miles north-east of Prague. In the tower of one of the churches Hanka discovered the Königinhof MSS. in 1817 (see vol. xi. p. 440). The Zaboj monument in the market-place commemorates the discovery. Cotton-weaving, yarn-spinning, and brewing are the leading industries. In 1421 Königinhof was stormed by the Hussites. On June 29, 1866, it was the scene of a Prussian victory over the Austrians. The population in 1869 was 6222.

KÖNIGSBERG (in Polish *Krolewiec*), chief town of a government district in the province of East Prussia, and since 1843 a fortress of the first rank, is situated on the Pregel, $4\frac{1}{2}$ miles from its mouth in the Frische Haff, 25 miles from the sea-coast, and 397 miles north-east of Berlin, in 54° 43′ N. lat. and 20° 30′ E. long. It consists of three formerly independent parts—the Altstadt (old town) to the west, Lobenicht to the east, and the island Kneiphof, together with numerous suburbs, embraced in a circuit of $9\frac{1}{2}$ miles. The Pregel, spanned by many bridges, flows through the town in two branches, which unite below the Green Bridge. Its greatest breadth within the town is from 80 to 90 yards. It is frozen from November to March. Although an old town, Königsberg does not retain many marks of antiquity. The Altstadt has long and narrow streets, but the Kneiphof quarter is roomier. Of the seven market-places only that in the Altstadt retains something of its former appearance. Among the more interesting buildings are the schloss, a long rectangle begun in 1255 and added to later, with a Gothic tower 277 feet high, and the chapel (built 1592) in which Frederick I. placed the Prussian crown on his own head in 1701; and the cathedral, begun in 1322, restored in 1856, a Gothic building with a tower 164 feet high. Behind the schloss is the parade-ground, with the statue of Frederick William III. by Kiss. To the east is the Schlossteich, a long narrow ornamental lake covering 12 acres, with beautifully laid out tree-shaded banks. The north-west side of the parade-ground is occupied by the new university buildings, completed in 1873; along with the new exchange on the south side of the Pregel, they are the finest architectural feature of the town. The university was founded in 1544 by Albert I., duke of Prussia;

it possesses a library of 200,000 volumes. Among its famous professors have been Kant (born in Königsberg in 1724), to whom a monument was erected in 1864, Herder, Herbart, Bessel, Voigt, K. E. von Baer, F. Neumann, and others. In the summer session of 1880 it had a teaching staff of 88; in the winter session 1880–81 its students numbered 808. Königsberg has also four gymnasia, two commercial schools of the first rank, an academy of painting with a public picture gallery, and a school of music, besides other educational establishments. The hospitals and benevolent institutions are numerous. The protected position of its harbour has made Königsberg one of the important trading cities of Germany. Ships of more than 1500 tons have to discharge cargo at Pillau, at the entrance to the Haff, connected with Königsberg by rail; and the grain trade with the interior is carried on by barges. The chief imports and exports of Königsberg are grain, spirits, colonial wares (especially tea), petroleum, coal, iron, herrings, flax, hemp, and wood. The exports by sea for the third quarter of 1881 amounted to 46,508 tons, and the imports from Russia alone to 12,479 tons. The number of ships that entered Königsberg and Pillau in 1879 was 1653 (278,000 tons); the number that cleared was 1656 (299,000 tons). The corresponding figures for 1880 were not so large. The manufactures of Königsberg are not very important. They include iron, machinery, beer, spirits, sail-cloth, cloth, oil, flour, leather, and its specialty "marchpane." There is also yarn-spinning, cloth-printing, dyeing, tanning, and tobacco manufacture. The population, in 1858 only 83,000, was 140,896 in 1880.

The Altstadt of Königsberg grew up around the castle built in 1255 by the Teutonic Order, to restrain the neighbouring heathens. Its first site was near the fishing village of Steindamm, but after its destruction by the Prussians in 1263 it was rebuilt in its present position. By 1327 all three parts, which were only united in 1724 by Frederick William I., had acquired city rights. In 1340 Königsberg entered the Hanseatic League; and in 1361 it was in direct alliance with England. From 1457 it was the residence of the grand master of the Teutonic Order, and from 1525 till 1618 of the dukes of Prussia. The trade of Königsberg was much hindered by the constant shifting and silting up of the channels leading to its harbour; and the great northern wars did it immense harm. By the end of the 17th century it had almost recovered; and during the 19th century the opening of the railway system in East Prussia and Russia gave its commerce a new departure, making it the principal outlet for the Russian staples—grain, seeds, flax, and hemp. It has now regular steam communication with Memel, Stettin, Kiel, Amsterdam, and Hull. The local shipping is unimportant.

KÖNIGSHÜTTE, a town in the circle of Beuthen in the government district of Oppeln, Prussia, is situated in the middle of the Upper Silesian coal and iron district, about 55 miles south-west of Oppeln. In 1869 it was incorporated with various neighbouring villages, and raised to the dignity of a town. The largest iron-work in Silesia is situated at Königshütte, and includes puddling works, rolling-mills, and zinc-works. Founded in 1797, it was formerly in the hands of Government; but it is now carried on by a company. In 1877 it employed about 3000 hands, and turned out about 54,000 tons of raw iron, 41,700 tons bar-iron, &c., 750 tons raw zinc, and 19,600 tons of steel goods for railways, &c. In the neighbourhood of the town there are coal-mines, chalk-quarries, and brick-fields. The population in 1852 was 4495; in 1875 it was 26,040.

KONITZ, or Könitz, a town of the German empire, in the Marienwerder district of the province of West Prussia, situated near the railway, about 68 miles south-west of Dantzic. It was the first fortified post established in Prussia by Balk, the grand master of the Teutonic Order, and it continued for a long time to be a place of military importance. Wool and iron are the chief objects of the local industry. The inhabitants numbered 8046 in 1875; about 3000 are Roman Catholics and 550 Jews. There is a history of the town by Uppenkamp (Konitz, 1873).

KONOTOP, a district town of Russia, in the government of Tchernigoff, 137 miles north-east of Kieff, on the railway from this town to Kursk. Its 10,000 inhabitants live by agriculture, boat-building, and trade. Situated in a district which produces a good deal of corn and is also engaged in cattle and sheep breeding, it has a brisk and rapidly increasing trade in agricultural produce. The town was founded in 1635 by the Poles, who built a strong citadel, the ruins of which still exist. In 1648 it was taken by the Cossacks of Khmelnitzky, and in 1659, during Vigovsky's insurrection, Russian troops besieged it.

KÖPENICK, or Cöpnick, a town in the circle of Teltow in the government district of Potsdam, Prussia, is situated on an island at the influx of the Dahme into the Spree, 8 miles S.E. of Berlin. Two bridges connect it with the mainland. It has a royal palace, with a ritter-saal and a chapel, and a normal school (in the palace). Silk-weaving, calico-printing, iron-rolling, and the manufacture of sugar, shoddy, glass, chemicals, gold-leaf, &c., are the chief industries. There are also steam saw-mills, and some little shipping. Köpenick was the residence of the heathen prince Jaczo, and later of the electors of Brandenburg. It was at Köpenick that Frederick the Great was tried by court martial, when crown-prince. The population in 1875 was 7113.

KOPREINITZ, an ancient royal free town of Hungary, in the province of Croatia and Slavonia and county of Körös, is situated about 16 miles north-east of the county town Körös (Kreutz), and on the Zákány-Zágráb line of the Hungarian state railway, in 46° 13′ N. lat., 16° 50′ E. long. The most interesting building is the old castle or fort, still in a good state of preservation, and now used as barracks. There are also in the town Roman Catholic and Greek Orthodox churches, a Jewish synagogue, a town-hall, and a municipal savings bank, besides the usual Government offices. Both the weekly and occasional fairs are well attended, but the trade is chiefly confined to the agricultural products of the neighbourhood. The communal lands, extending principally over a level plain, yield large quantities of grapes, fruit, beans, timber, and grain, especially maize. Population in 1880, 6049.

KOPRILI, Kiupeili, or Kjöprülü, a town in the vilayet of Prisrend, Macedonia, Turkey, is situated on both sides of the Vardar, the ancient Axius. Its Christian inhabitants call it Velesa, probably a corruption of Bylazora, described by Polybius as the chief city of Pæonia. Owing to the position of the town on sloping hills, the streets are steep; there are, however, numerous well-built houses. A wooden bridge crosses the river at this point. Mulberry trees and maize are grown in the neighbourhood. The population of Koprili, which has given its name to a celebrated family of viziers, is about 15,000.

KORAN. See Mohammed.

KORAT, a small territory, tributary to Siam, is situated to the north-east of Bangkok, on the borders of Siam and Cambodia. The approach to it from Bangkok is through an extensive malarious forest, called by the natives, on account of its fatal character, Dong Phya Phai, the forest of the king of fire. The chief mountain is named Khasjai, and from it flows the river Mahot. The productions and exports from Korat comprise stags' and panthers' skins, raw silk, manufactured silk and cotton, peacocks' tails, ivory, elephants' bones, and a small quantity of sugar. The copper-mines of Korat are said to be rich; silk of rather inferior quality is brought from Laos, Ubone, and Bassac. Elephants, buffaloes, and oxen are abundant in the province. Korat is governed by a ruler who has absolute power of life and death. It pays a tribute of gold, silver, and silk to Siam, and has to furnish a large levy of men when required. Sir John Bowring estimates the population of the whole district at 60,000. Korat, the chief town, lies about 170 miles north-east of Bangkok. It is surrounded by a wall, and stands on a stream whose banks are bordered with little plantations of betel and cocoa-nut trees. Outside the town proper is the Chinese quarter, consisting of sixty or seventy houses surrounded by a strong palisade 9 feet high. The Chinese number about 600, and are the industrious trading element in the population. The native name of Korat is Nakhon Raxa Sema, or frontier town. The population is 5000 or 6000.

KORDOFAN, a province of the Egyptian Sudan, which, though marked off from the surrounding territory by no very definite confines, may be said to lie between 12° and 16° N. lat. and between 29° 30′ and 32° 30′ E. long. On the east it does not reach the Nile, and on the west it is usually held to be separated from Darfur by a neutral strip of country. It consists for the most part of a rolling steppe in which a hill of 50 feet is a landmark for a day's journey; but towards the west there are a few isolated peaks such as Jebel Abu Senun and Jebel Kordofan, which rise to a height of 150 to 800 feet above the plain, and in the north-west there are two considerable groups, Jebel Katul and Jebel Kagga. The general elevation of the country above sea-level is given as from 1410 to 1840 feet. A granitic sand with abundance of mica and felspar forms the upper stratum throughout the greater part of the area; but an admixture of clay, which is observable in the north, becomes strongly marked in the south, where there are also stretches of black vegetable mould. Beneath there appears to unfold itself an unbroken surface of mica schist. River or stream there is really none, though a few temporary watercourses or *khôrs* exist in the rainy season; and the only permanent lakes are El Birkeh, El Rahad, and Shirkeleh, which are formed by the great Khor Abu Hable in the south. During the rainy season the water collects in myriads of little depressions, but owing partly to rapid evaporation and partly to the porous character of the soil the surface of the country is soon as dry as before. The water which has found its way through the granitic sand flows over the surface of the mica schist and settles in the hollows. Wells consequently sunk so as to reach the solid rock obtain a supply of water more or less abundant according to the spot which they happen to strike; and it is the existence of these which renders human life possible in Kordofan. It is estimated that (apart from those in a few areas of depression—Cagmar, Abu Haraze, Bara, and Mulbes—where the sand stratum is very thin and water is reached at the depth of a few feet) there are about 900 of these wells. They are narrow shafts going down from 75 to 150 or 200 feet, and supported "from the bottom to a little above the water-level" by the long roots of the mimosa, wound round so as to form a complete casing. The water is raised by rope and bucket at the cost of enormous labour, and none is available for irrigation. The very cattle are trained to go a long time without drinking. Entire villages migrate after harvest to the neighbourhood of some plentiful well; and in El Obeyd water becomes a regular article of trade soon after the close of the rains. As there is no highland area draining into Kordofan, the underground reservoirs are dependent on the local rainfall, and a large number of the wells are dry during many months. The rainy season lasts from June to September, rain falling every three or four days in brief but violent showers. The wind during that period is from the south or south-west; the air is extremely oppressive; and fevers prevail among the foreign residents. In September the north winds begin to take their turn, and from the middle of October they blow steadily throughout the winter, and produce what Europeans consider a delightful climate. With March begins the dry and sultry summer. The settled population of Kordofan is estimated at 164,740; the nomadic at 114,000. The former, who are scattered over the country in about eight hundred and sixty villages, are of very mingled blood, especially in the neighbourhood of the capital, but the Ghodiat, Gilledat, and Gowanieh appear to be the original stock. Of the nomadic tribes the most noteworthy are the Hasanieh, the Kababish, and the Bagara. The last-mentioned—who roam about the southern parts of the country—are a dark red-bronze race remarkable for their magnificent physique. The staple crop in Kordofan is the dokhn or *Penicillaria typhoides*. Eaten both uncooked and in various culinary conditions, it forms the main food of nine-tenths of the population and furnishes the raw material for the sweetish Kordofan beer or merissa. Cattle are largely bred by the Bagara, and camels by the Kababish; and horses, goats, donkeys, and sheep are kept in small numbers. Since the ostrich has been almost hunted out of the country the chief article of importance for trade is the gum yielded by the many mimosa trees, which along with the hijlij, the tamarisk, and the ṭalḥ tend to relieve the monotony of the steppe. Salt and iron ore exist within the province, but they have not become of any practical value.

Of the movements by which the present composite ethnology of Kordofan was attained little record is recoverable. In 1790 Sheikh Nasib of Sennaar subjugated the district; and under his rule the inhabitants prospered. But, piqued by his neighbour's success, Ibn Fadhl of Darfur invaded Kordofan with a powerful army numbering no less than 12,000 or 14,000 camels, and completely defeated the Sennaar governor Melek il Hashma. The Darfur supremacy continued till 1821 when Mohammed Aly undertook the conquest of Nubia and Sennaar. The defterdar, Mohammed Aly's son-in-law, subjugated Kordofan, and continued to rule it with worse than a rod of iron till he was recalled on account of his cruelties.

See the *Travels* of Sultan Teima (1821), Ruppell (1824), Holroyd (1837), Russeger (1837), Pallme (1844), Brehm (1848), Graf von Schlieffen (1853); Petherick, *Egypt, the Sudan, and Central Africa*, London, 1861; Major H. G. Prout, *General Report on Province of Kordofan*, Cairo, 1877; Marno, *Reise in der egypt. Equat. Provinz*, Vienna, 1879. The Italian travellers Matteucci and Massari traversed Kordofan in 1880, in their great journey across the continent. The geographical nomenclature is still in many cases uncertain.

KOREÁ, a petty native state in Chutiá Nágpur, Bengal, India, situated between 22° 55′ 50″ and 23° 49′ 15″ N. lat., and between 81° 58′ 15″ and 82° 48′ 15″ E. long., and having an area of 1631 square miles. The state consists of an elevated table-land of coarse sandstone, varying from 2477 to 3370 feet above sea-level. Large forest tracts of *sál* timber exist. Iron is found throughout the state, and a tribe of Kols, called Agariás from their occupation, are largely engaged in iron-smelting. The field crops consist of rice, wheat, barley, Indian corn, *maruá*, pulses, oil-seeds, cotton, &c., while the jungle produces stick lac and resin. The population in 1872 was returned at 21,127, viz., 11,093 males and 10,034 females (Hindus, 10,807; Mohammedans, 140; "others," 10,180). Of aboriginal tribes, the most numerous and influential are the Gonds (4644); next in importance are the Cheros (3009). The chief's family call themselves Chauhán Rájputs, and claim descent from a chief of that clan, who conquered Koreá six hundred years ago.

KORITSA, Goritsa, Geortcha, or Ghiorghia, a town of Albania, in the Turkish vilayet of Janina, situated in a spacious plain 45 miles east of Berat and 30 miles west of Kastoria. It is a place of about 10,000 inhabitants, containing a considerable number of well-built houses scattered among its cottages of unbaked mud. To its position on the route between the Adriatic and the Archipelago it is indebted for a flourishing trade. The metropolitan church is a large edifice richly adorned in the interior with paintings and statues.

KÖRNER, Karl Theodor (1791–1813), German patriot and poet, was born at Dresden, September 23, 1791. His father, a prosperous lawyer, made his house in Dresden a centre of literary, musical, and artistic society, and was an intimate friend of Schiller; and his mother, a daughter of the copper-plate engraver Stock of Leipsic, enjoyed Goethe's friendship through life, and in her later years claimed it for her son. Theodor Körner was at first so delicate a child that his parents made the paternal vineyard—the same in which Schiller sat and wrote *Don Carlos* a few years before—his summer schoolroom. They prescribed for lessons, gymnastics, riding, swimming, fencing, and the like, till the delicate boy grew into a young athlete, with a joyous, affectionate disposition which won the hearts of all who knew him. Partly at the Kreuzschule in Dresden, but chiefly with private tutors at home, Körner now studied languages, history, and mathematics. He was an adept at various kinds of fine wood-turning, could sketch, and play the guitar; but his happiest hours were spent over the volumes of Goethe and Schiller—the household gods; and under their influence the boy began to write verses which his parents forbore to praise, but which displayed, even then, much of the facility and grace of his later poems. At the age of seventeen he went to the school of mines in Freiberg, and worked enthusiastically for two years at mathematics, mineralogy, and chemistry. The poems he wrote during this period were collected and published under the title *Knospen*. From Freiberg Körner went to the university of Leipsic, where for some months he studied philosophy, history, and anatomy. He founded there a poetical association, and became a member of the "Macaria" and more than one student club; but he was unfortunately drawn into the hostilities then rife between two parties in the university, and, after fighting several party duels, was at last forced to leave the town to escape the results of a street fray in which he took part. From Leipsic he went to Berlin, and then to Vienna, with letters to his father's old friends, the Prussian ambassador Von Humboldt and Friedrich Schlegel. Two little pieces which he wrote for the stage, *Die Braut* and *Der grüne Domino*, were acted at the Vienna Court Theatre in July 1812 with great success; and, with the consent of his parents, he gave up all his former plans, with the hope of being able to make a living by literature alone. His other works followed with astonishing rapidity. In some fifteen months appeared some dozen dramatic pieces and the librettos of a few operas (*Das Fischermädchen*, *Der vierjährige Posten*, and *Die Bergknappen*), besides many short poems. One after the other all his plays were received at the Vienna Theatre with applause. *Zriny*, founded on an heroic incident in Hungarian history, was the favourite with the public; but Goethe praised *Die Braut*, *Der grüne Domino*, and *Die Sühne*. In January 1813, at the age of one and twenty, Körner was appointed poet to the court theatre in Vienna. With the preparation of the libretto of an opera, *Die Rückkehr des Ulysses*, for Beethoven, and with the writing, printing, and stage preparation of his plays, the young poet's hands were now full; very busy and very happy he describes himself in his letters. His betrothal to a young Viennese lady, known now only as the "Toni" of his correspondence, was another source of happiness; but this bright career came suddenly to an end. In the early spring of 1813 there was published the *Fatherland's Call to Arms in the Struggle for Liberation*, and Körner was one of the first to answer the summons. He left Vienna in March, and at Breslau joined the Prussian free-corps then forming under the command of Lützow. When the corps was solemnly consecrated in the village church at Rogau a few days later, the service was opened with a chorale, set to Körner's words, "Dem Herrn Allein die Ehre"; and almost immediately afterwards, when Petersdorf was sent on a mission to Dresden, to try to unite the Saxons in the common cause, the young poet was sent with him, and on this occasion published his spirited prose *Address to the People of Saxony*. Here Körner saw his parents and friends for the last time. In April he was made lieutenant by the vote of his comrades; and a little later, having left the infantry, he was made adjutant to Lützow himself. At Kitzen, near Leipsic, during the three weeks' armistice, he was severely wounded through the treachery of the enemy, but after several adventures escaped to Carlsbad, where he remained till he was well enough to resume his former post. Lützow's free-corps was in almost daily action when the young adjutant was welcomed back. His cheerful zeal and self-denying helpfulness had endeared him to all his comrades, and it was his wild war songs, sung by many voices to old national melodies round the camp fires at night, that helped to spread that fervour in the corps which made it peculiarly terrible to the enemy. The poems written by him at this time are published under the title *Leyer und Schwert.* They include the lines "Abschied vom Leben," which were composed during the night when he lay wounded in the wood by Kitzen. The letters written by Körner to his parents at this time are tender and thoughtful—often aflame with patriotic fervour, but with now and then a ring of intense sadness which forebodes the end. This was very near. His last poem, "Das Schwertlied," was scribbled in his pocket book at dawn on the 26th of August, when the corps was prepared for action; and he was reading it to a friend when the order to attack was given. It is the wildest of all his war-songs, a love-rhapsody to his sword,—the soldier's bride; and it was this poem that suggested the refrain of Mrs Hemans's beautiful verses to his memory. In the engagement that followed, on the high road between Gadebusch and Schwerin, Körner, as adjutant, fought at Lützow's side. The French were in great force, but were overcome and fled. Among the hottest in pursuit was Körner, who was mortally wounded, as he rode through a wood, by a shot from one of the fugitive *tirailleurs* who lay hidden there. He was buried with full military honours under an old oak on the road from Lübelow to Dreikrug, by the village of Wöbbelin, where there is now a monument to his memory.

Körner's position in the literature of his country is a peculiar one. He was not quite two and twenty when he died, and his works are necessarily but first-fruits—might all be included in the modest title *Knospen*—plentiful indeed, and full of promise of flowers to come. His earlier poems were hardly more than graceful and pleasing, and even his popular dramas scarcely entitle him to a high place in the literature of his country. It was with the war that Korner's true inspiration came. Had he lived a lifetime, he could never have excelled the productions of those few impassioned weeks; but the homage which all Germany paid, and still pays, to the young poet's memory is due, not to his lyric genius alone, but to his bright youth also, and heroic death. His works have passed through many editions. That published in one volume, with a preface by Karl Streckfuss (Berlin, 1879), includes a sketch of his life, extracts from his letters, a few English translations of his poems, and stanzas to his memory by German and English poets, of which last Felicia Hemans is the chief. There is an indifferent English translation of the life of Körner by his father, with selections from his works, by G. F. Richardson, 2 vols., 1827. (F. M.)

KOROTCHA, a district town, in the government of Kursk, Russia, 100 miles south of Kursk, on the Korotcha river. Its 7000 inhabitants live by gardening, exporting great quantities of dried cherries, by making candles and leather, and by trade; the merchants purchase cattle, grain, and salt in the south, and send them to Moscow. Founded in 1638, Korotcha formerly was a small fort erected against the invasions of Tartars.

KOROTOYAK, a town of Russia, in the government of Voronezh, on the right bank of the Don, 6 miles from the Davydovka railway station, and 47 miles south of Voronezh. It was founded in 1642 by emigrants from interior provinces of Russia, and had a small wooden fort. Owing to the proximity of Ostrogojsk, which is a trading place of some importance, its trade is insignificant, and its 9000 inhabitants live by agriculture and some trade in grain.

KOSCIUSKO, or KOSCZIUSKO, THADDEUS (1746–1817), Polish patriot, was descended from an old family of small proprietors in the province of Lithuania, and was born in 1746. From his father he inherited a taste for music, and in the other branches of education he showed such marked aptitude at the cadet school of Warsaw that along with some other youths he was sent at the expense of the state to complete his education at Versailles, Brest, and Paris. On his return to Poland he was appointed captain of artillery, but on account of the unfortunate result of his attachment to the daughter of a nobleman he in 1777 went to Paris, whence he sailed with the French fleet to aid the North American States in their war of independence. Under Washington he displayed great firmness and intrepidity in various trying circumstances, and rose to be general of a brigade. In 1786 he returned to his native country, where he lived in retirement until the reorganization of the army in 1789, when he was appointed major-general. In the war with Russia which followed the adoption of the new constitution of 1791 he conducted himself with conspicuous valour and skill, and at Dubienka, with a force of only 4000 men, held an army of 20,000 Russians at bay. All his efforts were, however, rendered fruitless by the pusillanimity of King Stanislaus, who in March 1792 agreed to a humiliating peace, upon which Kosciusko along with several other leading officers resigned his commission. A second partition of Poland was consummated in August 1793, but a spirit of resistance gradually gathered force and culminated in the insurrection of 1794, when Kosciusko was recalled to Cracow and appointed generalissimo and dictator. With an army of 5000 he marched to meet the Russians, who were advancing upon Cracow in greatly superior numbers, and after a strenuous conflict of four hours' duration completely defeated them. On receipt of the intelligence Warsaw rose against the Russian authorities, putting 7000 persons to death; and after instituting a new government Kosciusko went in pursuit of the enemy, who retired towards the Prussian frontiers. But for the interposition of Prussia the emancipation of Poland would have been accomplished. King Frederick William, however, advanced against Warsaw with an army of 40,000 men, to which Kosciusko could oppose only 15,000. He was defeated at Szezekocin, but retreated in good order upon Warsaw, which he defended with stubborn persistence, until the diversion of an insurrection in Great Poland caused them to raise the siege. Meantime an immense force of Russians was advancing against Warsaw in two divisions, the one under Suwaroff and the other under Fersen. Kosciusko resolved to attack Fersen before his junction with Suwaroff, but, as he had only 4000 men to meet the 14,000 Russians, his small army was in a few moments completely enveloped by superior numbers, and he himself fighting desperately fell pierced with several wounds. A tradition that as he fell he gave utterance to the words "Finis Poloniæ" found currency several years afterwards, but when it came to his knowledge he indignantly denied it. For two years he remained a prisoner at St Petersburg, but, gaining his liberty after the accession of Paul I., he went to England and then to America. Returning to France in 1798, he took up his residence at Fontainebleau. In 1806 he refused to allow Napoleon, whose professions he rated at their proper value, to use his name to incite a rising in Poland against Russia; and the forged address put forth by Napoleon in his name was never accepted by his countrymen as genuine, although Kosciusko was unable to disavow it until eight years after it was issued. In 1814, when the Russian army entered France on the fall of Napoleon, Kosciusko had a long interview with the emperor Alexander of Russia, who, it is said, promised to him to restore to Poland its ancient boundaries. In 1815 he settled in Switzerland, devoting himself chiefly to agricultural pursuits. His death, October 17, 1817, was the result of an accidental fall from his horse. If as a statesman Kosciusko was more ardent than sagacious, he manifested a skill and daring as a soldier which but for the overwhelming nature of his task would have gained him a place among the most renowned generals of his time, while his noble and chivalrous patriotism, untainted by any desire after self-glorification, has secured him the world's universal admiration and esteem.

See the lives by Falkenstein (1827, 2d ed. 1834), Chodzko (1837), and Paszkowski (1872), and also *Pologne et Russie, légende de Kosciusko*, by Jules Michelet (1851), reprinted in *La Pologne martyr* by the same author (1863).

KOSI, a town in Muttra (Mathura) district, North-Western Provinces, India, in 27° 47′ N. lat., 77° 28′ E. long., with a population in 1872 of 12,770.

KÖSLIN, or CÖSLIN, chief town of a circle and government district in the province of Pomerania, Prussia, is situated at the foot of the Gollenberg, 5 miles from the Baltic coast, and about 86 miles north-east of Stettin (105 by rail). It is regularly built, and is the seat of a local court. In the large market-place is the statue of Frederick William I., erected in 1824. The industries include the manufacture of soap, tobacco, iron, paper, bricks and tiles, beer, and other goods. Population in 1875, 14,814.

Köslin was built in 1188 by the Saxons, and made a town in 1266. In 1532 it embraced the Reformation. It was severely tried in the Thirty Years' War, and in the Seven Years' War. In 1720 it was burned. On the Gollenberg stands a monument to the memory of the Pomeranians who fell in the war of 1813–15. The town formerly possessed a mint of its own.

KOSLOFF, or KOZLOV, a town in the government of Tamboff, Russia, on the railway between Ryajsk and Saratoff, 45 miles west of Tamboff, on the Lesnoy Voronezh river. It had its origin in a small monastery, which was founded in the forest in 1627; nine years later, an earthwork was raised close by, for the protection of the Russian frontier against the Tartars. Situated in a very fertile country, on the highway to Astrakhan and at the head of the water communication with the Don, the town soon became a centre for the trade with these countries; as the junction of the railways leading to the Sea of Azoff, to Tsaritsin on the lower Volga, to Saratoff, and to Orel, its importance has recently been still further increased. Large transactions in grain, and also in horses and tallow, are effected in the rich agricultural district of Kosloff, as well as in those of Lipetsk and Borisoglebsk, for the Moscow market, or for western Europe, *via* Orel; manufactured wares are imported for the supply of the neighbouring districts. There are also in the town and district several tallow-melting houses, one manufactory of woollen cloth, and several distilleries. The town is built of wood, and its unpaved streets are dirty. Population, 27,000.

KOSTENDIL, GIUSTENDIL, or DJUSTENDIL, a town in the extreme south of the principality of Bulgaria, Turkey, is situated on the Strouma, the ancient Strymon. It is fortified and contains several factories. The surrounding district is fertile, and gold and silver mining is carried on. Population about 8000.

KOSTER, or COSTER, LAURENS (1370?–1440), the first Dutch printer, whose claims to be considered at least one of the inventors of the art (see PRINTING) have been recognized by many investigators. His real name was Laurens Janssoen,—Koster (*i.e.*, sacristan) being merely the title which he bore as an official of the great parish church of Haarlem. We find him mentioned several times between 1417 and 1434 as a member of the great council, as an assessor (*scabinus*), and as the city treasurer. He probably perished in the plague that visited Haarlem in 1439–40; his widow is mentioned in the latter year. His descendants through his daughter Lucia can be traced down to 1724.

See Peter Scriver, *Beschryvinge der Stad Harlem*, Haarlem, 1628; Scheltema, *Levensschets van Laurens d. Koster*, Haarlem, 1834; Van der Linde, *De Haarlemsche Costerlegende*, Hague, 1870.

KOSTROMA, a central government of Russia in Europe, surrounded by those of Vologda, Vyatka, Nijni-Novgorod, Vladimir, and Yaroslav, lies mostly on the left bank of the upper Volga, and has an estimated area of 32,700 square miles. Its surface is generally undulating, with hilly tracts on the right bank of the Volga, and extensive flat and marshy districts in its eastern parts. The rocks belong chiefly to the Permian system, a small tract being occupied by representatives of the Jurassic, and both being deeply covered with Quaternary clays. The soil in the east is for the most part sand or a sandy clay; a few patches are covered with fertile black earth. Immense forests, yielding excellent timber for shipbuilding, and in many cases still untouched, occupy no less than 70 per cent. of the surface of the government (13,230,000 acres in 1870). The export of timber is greatly facilitated by a series of navigable tributaries of the Volga, such as the Kostroma, Unzha, Neya, and Vyksa, and many others of less importance. The climate is severe; frosts of −22° Fahr. are common in January, and the mean temperature of the year is but 3°·1 (summer, 64°·5; winter, −13°·3). The population, which numbered 1,176,000 in 1870, is Russian, with some Meryas,—the indigenes of this part of Russia,—Tcheremisses, and Tartars. Agriculture is in a low state of development; only 4,000,000 acres are under crops, with a return (1,415,000 quarters of corn in 1877) unequal to the wants of the population. Flax is cultivated to some extent, and exported. Stock-breeding has steadily decreased since 1861; in 1870 there were only 394,500 horned cattle (against 420,000 in 1857), and the number has since much decreased. Bee keeping is an important branch of industry in some districts. The chief articles of commerce are timber, fuel, pitch, tar, mushrooms (yearly value upwards of £5000), and various kinds of wooden wares for building and household purposes, which are largely manufactured by the peasantry in villages, and exported to the steppe provinces of the lower Volga and Don. Boat-building for river traffic is also carried on. Some other small industries, such as the manufacture of silver and copper wares, leather wares, &c., are also prosecuted in the villages; but the trade in linen and towelling, formerly the staple, is now declining. There are now several cotton factories, spinning mills, and engineering and chemical works. The government of Kostroma is divided into twelve districts:—Kostroma, Nerekhta, Kineshma, Makarieff, Yurievets, Galitch, Tchukhloma, Soligalitch, Boui, Kologriv, Vetluga, and Varnavin.

KOSTROMA, a town of Russia, capital of the government of the same name, 230 miles north-east of Moscow and 55 miles from Yaroslav. It is situated on the left bank of the Volga, at the mouth of the navigable Kostroma river, with suburbs on the opposite side of the Volga. It is one of the oldest towns of Russia, having been founded by Youri Dolgorouky in 1152. Its fort was often the refuge of the great princes of Moscow during war, but the town was plundered more than once by Tartars. The cathedral, built in the 13th century, and situated in the *Kreml*, or former citadel, is a fine monument of old Russian architecture. Kostroma has been renowned since the 16th century for its linen, which was exported to Holland, and the manufacture of linen and linen-yarn is still carried to some extent, flax being purchased in the governments of Kostroma and of Pskoff. There are also in the town and in its province several important cotton-mills, tanneries, saw-mills, an iron-foundry, and a machine factory. Owing to its situation on the Volga, and at the mouth of a navigable river, Kostroma carries on an active trade—importing grain and exporting linen, linen-yarn, leather, and especially timber and wooden wares. Population, 30,000

KOTAH, a native state in Rájputána, India, situated between 24° 30′ and 25° 51′ N. lat., and 74° 40′ and 76° 59′ E. long. It is entirely surrounded by native territory, being bounded on the N. by Bundi, on the E. by Gwalior and Tonk, on the S. by Jhaláwár, and on the W. by Udáipur. The area is 3797 square miles, with an estimated population of 310,000. Kotah slopes gently northwards from the high table-land of Málwá, and is drained by the Chambal with its tributaries, all flowing in a northerly or north-easterly direction. The Mokandarra range, from 1200 to 1600 feet above sea-level. runs from south-east to north-west, forming the southern border of Kotah, and separating it from Jhaláwár. The Mokandarra Pass through these hills, in the neighbourhood of the highest peak (1671 feet), has been rendered memorable by the passage of Colonel Monson's army on its disastrous retreat in 1804. The defile is strikingly picturesque, and forms one of the chief outlets between the Deccan and northern India. There are extensive game preserves, chiefly covered with grass. In addition to the usual Indian grains, wheat, cotton, opium, and a little tobacco of good quality are cultivated. The manufactures are very limited. Cotton fabrics are woven, but are being rapidly superseded by the cheap products of Bombay and Manchester. Articles of wooden furniture are also constructed. The chief articles of export are opium and grain; salt, cotton, and woollen cloth are imported.

Kotah is an offshoot from Búndi state, having been bestowed upon a younger son of the Búndi rájá by the emperor Shah Jahán in return for services rendered him when the latter was in rebellion against his father Jahángir. The affairs of the state having fallen into confusion, the administration is now superintended by a British political officer. Many of the state nobility hold lands on a semi-feudal tenure. The estimated gross revenue of the state in 1876 was £253,275, of which the land yielded over £170,000. Tribute of £38,472 (including maintenance of a contingent known as the Deoli Irregular Force) is paid to the British Government, and £1439 to Jeypore. The climate is very sultry during the prevalence of the hot winds at the commencement of summer, and is considered unhealthy during the rainy season. Endemic fevers invariably appear after the close of the rains.

KÖTHEN, or Cöthen, chief town of a circle in the duchy of Anhalt, Germany, is situated on the Ziethe, at the junction of several railway lines, about 42 miles north-west of Leipsic by rail. It consists of an old and a new town with four suburbs. It has two palaces, one of which in the old town contains various scientific collections and a library of 20,000 volumes. The industries include iron-founding and the manufacture of agricultural and other machinery, malt, beet-root sugar, leather, spirits, &c.; a tolerably active trade is carried on in grain, wool, potatoes, and vegetables. In 1875 the population, including the garrison, was 14,403.

Said to have been an important Wendish city, Köthen was captured and destroyed by Henry I. in 927. In 1300 it was burned by the margrave of Meissen. In 1547 it was presented by the emperor to General Ladron, from whom it soon passed by purchase to its old possessors. Hahnemann, the founder of homœopathy, lived and worked in Köthen, and a homœopathic establishment still exists in the town. Till 1853 Köthen was the capital of the duchy of Anhalt-Köthen.

KOTRI, a town in Karáchi (Kurrachee) district, Sind, India, situated on the right bank of the Indus, in 25° 22′ N. lat. and 68° 22′ E. long. The population in 1872, including the neighbouring hamlets of Khánpur and Miáne Múltáni, was 7949—namely, 5166 Mohammedans, 2455 Hindus, 304 Christians, and 24 Parsís. Kotri is the northern terminus of the Sind Railway, which communicates with the seaport of Kurrachee (106 miles). The principal buildings, besides the Protestant and Roman Catholic churches, are the civil hospital, court-house, subordinate jail, post-office, Government and other schools, and travellers' bungalow. The Indus Steam Flotilla maintains an extensive establishment, having its offices in the old fort, with workshops for the repair of steamers and barges. There is a large transit traffic in beer, wine, and spirits, metals, railway materials, piece goods, silk, wool, cotton, grain, oil-seeds, indigo, *ghí*, oil, saltpetre, and sugar. Water from Kotri is forwarded to Kurrachee, especially for the manufacture of ice and for drinking purposes. In 1878 the Indus Valley State Railway was opened from Kotri to Sukkur, by which the importance of Kotri as a place of transshipment has been greatly diminished.

KOTTBUS, or Cottbus, chief town of a circle in the government district of Frankfort, Prussia, is situated on the Spree, about 72 miles south-east of Berlin by rail, and at the intersection of several important railway lines. It contains a mediæval castle, and is the seat of a chamber of commerce. The chief industries of the busy little town are wool-spinning and the manufacture of cloth. Cotton-spinning, and the manufacture of tobacco, machinery, beer, brandy, &c., are also carried on, while its trade is active. In 1875 the population, including the garrison, was 22,612. At one time Kottbus formed a private lordship, but in 1462 it passed by the treaty of Guben to Brandenburg.

KOTZEBUE, August Friedrich Ferdinand von (1761–1819), German dramatist, was born on the 3d of May 1761, at Weimar, where his father was a councillor of legation. Having attended the gymnasium of Weimar, he went in his sixteenth year to the university of Jena, and afterwards studied about a year in Duisburg. In 1780 he completed his legal studies, and was admitted an advocate. Through the influence of Count Görtz, Prussian ambassador at the Russian court, he became secretary at St Petersburg to the governor-general Von Baur, by whom he was recommended to the empress. In 1783 he received the appointment of assessor to the high court of appeal in Revel, where he married a daughter of lieutenant-general Von Essen. He was ennobled in 1785, and became president of the magistracy of the province of Esthonia. Before leaving Germany he had published some unimportant writings; in Revel he acquired a considerable reputation by his *Leiden der Ortenbergischen Familie* (1785), his *Kleine Gesammelte Schriften* (1787–91), and his two plays, *Menschenhass und Reue* and *Die Indianer in England* (1789). The good impression produced by these works was almost effaced by a cynical book, *Doctor Bahrdt mit der eisernen Stirn*, which appeared with the name of Knigge on the title page. After the death of his first wife Kotzebue retired from the Russian service, and resided for some time in a country house which he had built near Narva. At this time he manifested extraordinary literary activity, publishing within a few years, besides *Die jüngste Kinder meiner Laune* (in 5 volumes), upwards of twenty plays. In 1798 he accepted the office of dramatist to the court theatre of Vienna, resigning it in about two years with a pension of 1000 florins. On his way to St Petersburg, where his sons were being educated, he was arrested in April 1800, and sent to Siberia. Fortunately he had written a comedy which flattered the vanity of Paul I.; and a translation of this play so delighted the emperor that Kotzebue was brought back, received an estate from the crown lands in Livonia, and was made director of the German theatre in St Petersburg. He returned to Germany when the emperor Paul died, and in 1802 was admitted into the Academy of Sciences at Berlin. Here, in association with Merkel, he edited *Der Freimüthige*, and began his *Almanach dramatischer Spiele*, which he continued to issue until his death. He also wrote several plays in Berlin, and made some enemies by the bitterness with which he attacked Goethe. Towards the end of 1806 he was again settled in Russia, and in the security of his estate in Esthonia wrote many satirical articles against Napoleon in *Die Biene* and *Die Grille*. As councillor of state he was attached in 1816 to the department for foreign affairs in St Petersburg, and in 1817 he went to Germany as a sort of spy in the service of Russia, with a salary of 15,000 roubles. In his weekly journal (the *Literarisches Wochenblatt*) he scoffed at the pretensions of those Germans who demanded free institutions, and became an object of such general dislike that he was obliged to leave Weimar for Mannheim. He was especially detested by young enthusiasts for liberty; and one of them, Karl Ludwig Sand, a theological student, formed a deliberate resolution to kill him. On the 23d of March 1819 Sand called at Kotzebue's house in Mannheim, and stabbed him to the heart, crying, "Here, thou betrayer of the Fatherland!" The assassin was executed, and the Government of Germany made his crime an excuse for placing the universities under strict supervision. Besides his plays and the other works already mentioned, Kotzebue wrote a history of the German empire and a book on the ancient history of Prussia, neither of which has solid merit. He was also the author of *Erinnerungen aus Paris* (1804), and *Erinnerungen von einer Reise aus Livland nach Rom und Neapel* (1805). He wrote more than one hundred plays, the majority of which are now forgotten. Although destitute of poetic insight, he had remarkable facility in the invention of effective situations; and a respectable place in German literature is secured for some of his comedies by the liveliness with which their characters are portrayed, and by the sprightliness of their dialogue. There is a complete edition of his dramatic works in 28 volumes (1797–1823), another in 44 volumes (1827–29), and a third in 40 volumes (1840–41).

KOTZEBUE, OTTO VON (1787–1846), Russian navigator, son of the subject of last notice, was born at Revel on December 19, 1787. After being educated at the St Petersburg school of cadets, he accompanied Krusenstern on his voyage of 1803–6. After his promotion to lieutenant, Kotzebue was placed in command of an expedition fitted out at the expense of the imperial chancellor, Count Rumantsoff, in the brig *Rurick*. In this vessel, with only twenty-seven men, Kotzebue set out on July 30, 1815, to find a passage across the Arctic Ocean, and explore the less known parts of Oceania. Proceeding by Cape Horn, he reached on April 16, 1816, Schouten and Lemaire's Isle of Dogs. After cruising about the Pacific for some time, and discovering various islands and groups,—as the Krusenstern group, and the Kutusoff and Suwaroff Islands in the east of the Caroline archipelago,—Kotzebue made for Kamchatka, and on June 29 reached New Archangel. In the middle of July he proceeded northwards, coasting along the north-west coast of America, discovering and naming Kotzebue Gulf or Sound and Krusenstern Cape. Returning by the coast of Asia, he again sailed to the south, sojourned for three weeks at the Sandwich Islands, and on January 1, 1817, discovered New Year Island. After some further cruising in the Pacific he again proceeded north, but, a severe attack of illness compelling him to return to Europe, he reached the Neva on August 3, 1818, bringing home with him a large collection of previously unknown plants and much new ethnological information. In 1823 Kotzebue, now a captain, was entrusted with the command of a new expedition, in two ships of war, the main object of which was to take reinforcements to Kamchatka. There was, however, a staff of scientific men on board, who collected much valuable information and material in geography, ethnography, and natural history. The expedition left Cronstadt on August 23, and, proceeding by Cape Horn, visited the Radak and Society Islands, reaching Petropavlovsk in July 1824. Many positions along the coast were rectified, the Navigator Islands visited, and several discoveries made. The expedition returned by the Mariannes, Philippines, New California, and Sandwich Islands, reaching Cronstadt on July 10, 1826. There are English translations of both Kotzebue's narratives:—*A Voyage for the Purpose of Exploring a North-East Passage, undertaken in the years* 1815–18, 3 vols. (1821); and *A New Voyage Round the World in the years* 1823–26 (1830). The narrative of the second voyage is generally considered to be rather highly coloured, while in the first Kotzebue animadverts in strong terms on the conduct of the English missionaries in the Society and Sandwich Islands, who, however, were defended both by Ellis and Mr Charles Darwin. Three years after his return from his second voyage, Kotzebue retired to his estate in Esthonia, where he died February 15, 1846.

KOUSSO, Kosso, or Cusso, a drug recently introduced into English medicine as a remedy for tapeworm. It consists of the flowers of *Hagenia abyssinica*, Willd. (*Brayera anthelminthica*, Kunth.), a handsome rosaceous tree 60 feet high, growing throughout the table-land of Abyssinia, at an elevation of 3000 to 8000 feet above the sea-level. The drug as imported is in the form of cylindrical rolls, about 18 inches in length and 2 inches in diameter, and comprises the entire inflorescence or panicle kept in form by a band wound transversely round it. The flowers have a light brown hue, or in the case of the female flower a reddish tinge, for which reason the latter is sometimes distinguished as red kousso. The active principle of kousso is stated by Flückiger to be kosin, $C_{31}H_{38}O_{10}$; it is supposed to be a compound ether of isobutyric acid, since it gives off the odour of this substance when its solution in concentrated sulphuric acid is diluted with water. Kosin appears to have been first obtained as a definite crystalline substance by Merck, who prepared it in the form of tasteless yellowish rhombic needles or prisms, soluble in chloroform, ether, benzol, and bisulphide of carbon, very soluble in boiling but only sparingly so in cold alcohol. It is not decomposed by boiling dilute acids. The koussin of Bedall appears to be an impure substance containing variable quantities of crystalline kosin. Kousso yields on distillation a stearoptene-like oil having the odour of the drug, also traces of valerianic and acetic acids. The medicinal properties of kousso were first investigated in 1822 by Brayer, a French physician of Constantinople, but the drug did not come into use in Europe until 1850; in 1864 it was introduced into the British pharmacopœia. In medicine it is used in the form of an unstrained infusion of $\frac{1}{4}$ to $\frac{1}{2}$ oz. of the coarsely powdered flowers, which are swallowed with the liquid. Administered in this form it sometimes causes vomiting; hence an extract of the flowers, prepared by percolating them with castor oil to dissolve out the active principle, has been introduced. Kousso is considered to be an effectual vermifuge for both *Tænia solium* and *Bothriocephalus latus*. In its anthelminthic action it is nearly allied to male fern.

See Bruce, *Travels*, v. p. 73, 1790; Brayer, *Notice sur une nouvelle plante de la famille des Rosacées employée contre le Tænia*, 1822; *Pharmaceutical Journal*, x. p. 15; *Pharmacographia*, 2d ed., p. 256–259; *Bulletin de Thérapeutique*, 1876, p. 556.

KOVNO, a north-western province of European Russia, is bounded on the N.E. and S.E. by the provinces of Courland and Vilna, and on the S. and S.W. by Russian Poland and by Prussia, a narrow strip touching the Baltic near Memel. It has an estimated area of 23,680 square miles. The level uniformity of its surface is broken only by two low ridges which nowhere rise above 800 feet. The geological character is varied, the Silurian, the Devonian, the Jurassic, and the Tertiary systems being all represented; the Devonian is that which occurs most frequently, and all are covered with Quaternary boulder-clays. The soil is either a sandy clay or a more fertile kind of black earth. The government is well watered by the Niemen, the Windau, the Courland Aa, and the Duna, which have navigable tributaries. In the flat depressions covered with boulder-clays there are many lakes and marshes, whilst forests, now greatly reduced, still cover about 18 per cent. of the surface of the government. The climate is comparatively mild, the mean temperature at Kovno being 44° Fahr. The population (1,156,040 in 1870) is very varied, consisting of Lithuanians proper and Zhmuds, Jews, Slavs, and Germans; 82 per cent. are Catholics, 13 Jews, 3 Protestants, and 2 belong to the Greek Church. The Poles number only 3000, and the Russians (White, Little, and Great) 182,000. The chief occupation of the inhabitants is agriculture, 60 per cent. of the whole surface being under crops; both grain and potatoes are exported. The yield of corn (2,270,000 quarters prior to 1857) is now about 2,879,000 quarters per annum. Flax is also cultivated, and the linseed is exported. Stock-breeding is not carried on to any considerable extent; but, owing to the number of lakes, the fishing industry has some importance. The manufacturing industries, if distillation be left out of account, are trifling. Trade, especially the transit trade, is brisk, from the situation of the government on the Prussian frontier, the custom houses of Yurburg and Taurogen being among the most important in Russia. Kovno has seven districts:—Kovno, Novoalexandrovsk, Ponevyezh, Rossieny, Shavli, Telshi, and Vilkomir. The principal towns are Kovno (32,050 inhabitants), Shavli (15,400), Vilkomir (11,150), Rossieny (10,700), and Novoalexandrovsk (8250).

The territory which now constitutes the government of Kovno was formerly part of Lithuania. During the 13th, 14th, and 15th centuries the Livonian and Teutonic knights continually invaded and plundered it, especially the western part which was peopled with Zhmuds. In 1569 it was annexed, along with the rest of the grand principality of Lithuania, to Poland; and it suffered very much from the wars of Russia with Sweden and Poland, and from the invasion of Charles XII. in 1701. In 1795 the principality of Lithuania was annexed to Russia, and until 1872, when the government of Kovno was constituted, the territory now forming it was a part of the government of Vilna.

Kovno, the Kaune of the Lithuanians, capital of the above government, is situated on the railway between St Petersburg and Berlin, 503 miles south west from the former. It consists of two parts, the new town, built on the right bank of the Niemen, and an old town, situated on the left bank of the Vilia which here joins the Niemen. By its situation at the confluence of two navigable rivers, some few miles above the mouth of the Nevyaja, and close to a place where the Niemen sharply changes its northern direction into a western one, Kovno, which is supposed to have been built in the 11th century, soon acquired importance both as a fortified place and as a centre for trade. In its early history it often suffered from the attacks of the crusaders, and fell alternately under their dominion and under that of Lithuanians. Its citadel was destroyed in 1400, and from that time it became the centre of an active trade, being visited by German and English merchants. In the 16th, 17th, and 18th centuries it was the chief emporium for trade with Lithuania, and rivalled Königsberg. Henry of Valois said it was the best jewel of the kingdom. But continuous wars destroyed this commerce, and, when Kovno became a Russian town, in 1795, it was already a very poor place, which numbered in 1817 but two hundred houses. Owing to its advantageous situation, it has again acquired commercial importance. It has several remarkable old churches, two of which have been transferred to the Greek confession, and a beautiful old guild-hall now transformed into an imperial palace. Its population (33,050) is most varied; one half are Jews engaged in petty trades and commerce. Salt, salted fish, coal, and various manufactured wares are brought here from Prussia on vessels which return with cargoes of corn, linseed, timber, rags, bones, and wool, purchased in the governments of Vilna, Minsk, Grodno, and Tchernigoff.

KOVROFF, a town in Russia, situated in the government of Vladimir, on the railway between Moscow and Nijni Novgorod, 40 miles east-north-east of the capital of the province, on the right bank of the Klazma river. It has become, of late years, an important manufacturing centre,—cottons, machinery, and railway carriages being the principal items. It also carries on an active trade in the export of wooden wares and in the import of grain, salt, and fish, brought from the Volga provinces for the use of the government of Vladimir. Population 5000.

KOZELSK, a district town of the government of Kaluga in European Russia, situated 43 miles south-west of Kaluga, on the left bank of the river Zhizdra. The principal building is the cathedral, erected in 1700, and rebuilt by Catherine II. after the fire of 1777. In the first half of the present century sailcloth was largely manufactured in the town; but this industry has declined, and, though there are oil-mills, tanneries, rope-walks, and breweries, many of the working classes have to seek employment elsewhere Population in 1870, 13,400.

Kozelsk emerges in the middle of the 12th century. In 1238 it was utterly destroyed, and all its inhabitants put to the sword by the Tartar invaders. During the 15th century it formed a bone of contention between the Lithuanian princes and the grand-dukes of Moscow. Ivàn the Terrible surrounded it with a wooden palisade. Captured by Dolgorukoff in 1607, it withstood a heavy siege at the hands of Ismailoff.

KRAFFT, or Kraft, Adam (c. 1455–1507), sculptor of the Nuremberg school, was born, probably at Nuremberg, about the middle of the 15th century, and died, some say in the hospital, at Schwabach, about 1507. Of his life few particulars are known beyond the dates of several of his works. He seems to have emerged as sculptor about 1490, the date of the seven reliefs of scenes from the life of Christ, which, like almost every other specimen of his work, are at Nuremberg. The date of his last work, an Entombment, with fifteen life-size figures, in the Holzschuher chapel of the St John's cemetery, is 1507.

Besides these, Krafft's chief works are several monumental reliefs in the various churches of Nuremberg; the alto-rilievo Entombment outside St Sebald's church; Christ Bearing the Cross, above the altar of the same church; and various works made for public and private buildings, as the relief over the door of the Wagehaus, a St George and the Dragon, several Madonnas, and some purely decorative pieces, as coats of arms. His masterpiece is perhaps the magnificent tabernacle, 62 feet high, in the church of St Laurence, 1493–1500. See Wanderer's *Adam Kraft und seine Schule*, 1869.

KRAJOVA, or Crajova, a town in the circle of Dolschi, Roumania, is situated near the Schyl, a tributary of the Danube, about 110 miles west of Bucharest. There are prosperous salt-works situated in the town; and from its position at the junction of the Carpathian high-roads with the route from Bucharest to Widdin its trade (largely in the hands of Jews) is important. In 1873 its population was 22,764.

Krajova was the former capital of Little Wallachia. In 1397 it was the scene of a victory of the waiwode Marcea over the Turkish sultan Bajazet; and there, in October 1853, a fight between the Russians and Turks took place.

KRANTZ, or Crantz, Albert (c. 1450–1517), German historian, was a native of Hamburg. He studied law, theology, and history at Rostock and Cologne, and after travelling through western and southern Europe was appointed professor, first of philosophy and subsequently of theology, in the university of Rostock, of which he was rector in 1482. In 1492 he returned to Hamburg as theological lecturer, canon, and prebendary in the cathedral. By the senate of Hamburg he was employed on more than one diplomatic mission abroad, and in 1500 he was chosen by the king of Denmark and the duke of Holstein as arbiter in their dispute regarding the province of Dithmarschen. As dean of the cathedral chapter, to which office he was appointed in 1508, Krantz applied himself with zeal to the reform of ecclesiastical abuses, but, though opposed to various corruptions connected with church discipline, he had little sympathy with the drastic measures of Wickliffe or Huss. A deathbed utterance of his, somewhat desponding in its tone, with reference to Luther and his ninety-five theses has occasionally, but unfairly, been interpreted as a summary condemnation of that Reformer. Krantz died December 7, 1517.

Krantz was the author of a number of historical works which for the period when they were written are characterized by exceptional impartiality and research. The principal of these are *Chronicon regnorum aquilonarium Daniæ, Sveciæ, et Norvegiæ*, Strasburg, 1545; *Vandalia, sive historia de Vandalorum vera origine*, &c., Cologne, 1519; *Saxonia*, 1520; and *Metropolis sive Historia ecclesiæ in Saxonia*, 1548. See life by N. Wilckens, Hamburg, 1722.

KRASNOYARSK, a town of eastern Siberia, capital of the extensive province of Yeniseisk, which stretches as a long strip from the Chinese frontier formed by the Sayan mountains to the shores of the Arctic Ocean. It is situated on the left bank of Yenisei river, at its confluence with the Katcha, and on the highway from Moscow to Irkutsk, 662 miles west-north-west from the latter. It was founded by Cossacks in 1628, and during the early years of its existence it was more than once besieged by the Tartars and Kirghiz. It became the capital of the province in 1822, and is now the seat of the provincial administration. Its commercial importance depends entirely upon the gold-washings of the Yeniseisk district, supplies for which are sent from Krasnoyarsk. The climate is very cold, but dry, so that in the steppe which surrounds the town there is but little snow, even in mid-winter. The Yenisei river is frozen for one hundred and sixty days at Krasnoyarsk. Population, 13,000.

KREMENETZ, a district town of Russia, in the government of Volhynia, in the high valley of the Ikva, one of the tributaries of the basin of the Pripat, situated 30 miles east from Radziviloff, the great custom-house on the railway between Kieff and Lvoff. It is a poor place, the 11,800 inhabitants of which follow agriculture, raise tobacco, and excavate flint. But the Jews, who are numerous in the town, carry on a brisk trade in grain, which is stored here for export to Galicia and Odessa. The picturesque ruins of an old castle on a crag close by the town, are usually known under the name of the castle of Queen Bona; it was built, however, but in the 8th or 9th century. The hordes of Batyi vainly besieged it in 1241 and 1255. From that time Kremenetz was alternately under the dominion of Lithuania and Poland, till 1648, when it was taken by the Zaporojtzi Cossacks. During the years 1805 to 1832 its Polish lyceum was the centre of superior instruction for the western provinces of Little Russia; but after the Polish insurrection of 1831 the lyceum was transferred to Kieff, and is now the university of that town.

KREMENTCHUG, a Russian town in the government of Poltava, situated 74 miles by rail to the south-west of the government town, on the railway between Kharkoff and Nicolaieff, and on the left bank (here flat and sandy) of the Dnieper. It is supposed to have been founded in 1571; by its situation at the southern terminus of the navigable course of the Dnieper, and on the highway from Moscow to Odessa, it early acquired a great commercial importance, which it still retains; by 1655 it was a wealthy town. In 1765 it became capital of "New Russia." It now has a suburb, Kryukoff, on the right bank of the Dnieper, united with the town by a railway bridge. Nearly all commercial transactions in salt with White Russia are effected at Krementchug, the salt being deposited in large storehouses in Kryukoff, and then sent by boat to the north-west. The town is also a centre of the tallow trade with Warsaw; considerable quantities of timber, too, are floated down to this place and thence sent to the neighbouring provinces. Nearly all the trade in the brandy manufactured in the government of Kharkoff and destined for the governments of Ekaterinoslaff and Taurida is concentrated here, as also is the trade in linseed between the districts situated on the left affluents of the Dnieper and the southern ports. Other articles of commerce are rye, rye-flour, wheat, oats, and sarrasine, which are sent, partly up the Dnieper to Pinsk, partly by land to Odessa and Berislaff, but principally to Ekaterinoslaff, on light boats floated down during the spring floods. Although thus busily employed, the town does not wear the aspect of a commercial place, the linseed being mostly warehoused in the houses of the Jews who carry on this trade, and the important banking operations being also chiefly in the hands of Jews. The Dnieper is crossed at Krementchug by a remarkable tubular bridge 1081 yards long, over which passes the railway from Kharkoff to Balta; there is also a bridge of boats. The manufactures consist of carriages, agricultural machinery, and tobacco. Population, 31,000.

KREMNITZ (Hungarian, *Körmöczbánya*), a mining town in the cis-Danubian county of Bars, Hungary, lies in a deep valley, and on the Hungarian state railway, 82 miles north of Budapest, in 48° 42′ N. lat., 18° 46′ E. long. It is the seat of a board of mining control, and of the management of the mint, and has an office of woods and forests. As noteworthy buildings may be mentioned the castle, several Roman Catholic and the Lutheran churches, a Franciscan monastery (founded 1634), the town-hall, and the mint where the celebrated Kremnitz gold ducats are struck. The great bulk of the inhabitants find employment in connexion with the gold and silver mines, which, though far less productive than formerly, still yield considerable quantities of ore. By means of a tunnel 9 miles in length, constructed in 1851–52, the water is drained off from the mines into the Garam or Gran. In 1880 the population was 8552, mostly Germans.

According to tradition Kremnitz was founded in the 8th century by Saxons. In 1100 it was raised to the dignity of a royal free town. In the middle of the 12th century the population was much augmented by German colonists, and in 1328 the commune received special privileges at the hands of Charles Robert of Anjou. From 1424 to 1433 the town was frequently at the mercy of the Hussites. After the catastrophe at Mohács (1526) it suffered repeatedly from the Turks, and during the 17th century both from the forces of successive Transylvanian princes and from Ottoman hordes.

KREMSIER (in Czech, *Kromeriz*), chief town of a district in Moravia, Austria, is situated in the fertile region of Hanna on the March, about 25 miles south-west of Olmütz. It is the seat of several local courts, and is the summer residence of the bishop of Olmütz, whose palace, surrounded by a fine park and gardens, and containing a picture gallery, library, and various collections, forms the chief object of interest. Kremsier has both a German and a Slav upper-gymnasium, a higher commercial school, a convent, and a hospital. Its industries include printing, and the manufacture of sugar, malt, and pottery. In 1870 the population was 9918.

In 1131 Kremsier was the seat of a bishopric. It suffered considerably during the Hussite war; and in 1643 it was taken and burned by the Swedes. After the rising of 1848, the Austrian congress met in the palace at Kremsier from November 1848 till March 1849.

KREUTZER, CONRADIN (1782–1849), German musical composer, owes his permanent fame almost exclusively to one opera, *Das Nachtlager von Granada*, which has kept the stage for nearly half a century in spite of the changes of taste. It is written in the style of Weber, and is remarkable especially for its flow of genuine melody and depth of feeling. The same qualities are found in Kreutzer's part songs for men's voices, which at one time were extremely popular in Germany, and are still listened to with pleasure. Amongst these *Der Tag des Herrn* ("The Lord's Day") may be named as the most excellent. It is indeed a masterpiece of its kind. Kreutzer was a prolific composer, and wrote a number of operas which have disappeared from the stage and are not likely to be revived. His life also is devoid of interesting features, and may be summed up in few words. He was born November 22, 1782, at Mösskirch in Baden, and received his musical training from Albrechtsberger, the famous contrapuntist of Vienna. For the theatre of that city he composed most of his operas, including *Das Nachtlager von Granada*, produced in 1834. For a time (1812–1816) he was chapelmaster to the king of Würtemberg, and later on (1840) became conductor of the opera at Cologne. He died December 14, 1849, at Riga, where he had accompanied his daughter Cecilia Kreutzer, a singer of some renown.

KREUZNACH, or CREUZNACH, chief town of a circle in the government district of Coblentz, Prussia, is situated on the Nahe, a tributary of the Rhine, about 40 miles south-east of Coblentz. It consists of the old town on the right bank of the river, the new town on the left, and the island Badewörth, all of which are connected by a fine stone bridge. There is an iron bridge between the island and the right bank. Kreuznach is the seat of a local court, and it has a gymnasium, a business-school, and a hospital. On the Badewörth is the kurhaus, built in 1872, with baths and gardens, and also the chief spring, the Elisabethquelle, impregnated with iodine and bromine, and prescribed for scrofulous and various other affections. The climate is mild, moderately damp, and on the whole equable. The chief industries of the town are marble-polishing and the manufacture of leather and tobacco, and various knick-knacks in agate. Vines are grown on the neighbouring hills. The population in 1875 was 13,772.

The earliest mention of the springs of Kreuznach occurs in 1478; but it was only in the early half of the 19th century that Dr Prieger (whose marble statue adorns the town) brought them into prominence. Now the annual number of visitors is about seven thousand. In the 9th century Kreuzberg was known as Cruciniacum. In 1065 it was presented by Henry IV. to the bishop of Spires, from whom it passed (after becoming a town in the early part of the 13th century) to the counts of Sponheim and the Palatinate. In 1814 it became Prussian. During the 17th century Kreuznach was more than once taken and plundered; and in 1689 the French reduced the strong castle of Kauzenberg to the ruin which still surmounts the Schlossberg to the north-west of the town.

KRILOFF, KRUILOFF, or KRYLOFF, IVAN ANDREEVITCH (1768–1844), the great national fabulist of Russia, was born February 14, 1768, at Moscow, but his early years were spent at Orenburg and Tver. His father, a distinguished military officer, died in 1779; and young Kriloff was left with no richer patrimony than a chest of old books, to be brought up by the exertions of an heroic mother. In the course of a few years his mother removed to St Petersburg, in the hope of securing a Government pension; and there Kriloff obtained a post in the civil service, but he gave it up immediately after his mother's death in 1788. Already in 1783 he had sold to a bookseller a comedy of his own composition, and by this means had procured for himself the works of Molière, Racine, Boileau; and now, probably under the influence of these writers, he produced *Philomela* and *Cleopatra*, which gave him access to the dramatic circle of Knyazhin. Several attempts he made to start a literary magazine followed each other with little success; but, along with his plays, they served to make the author known to the polite society of the capital. For about four years (1797–1801) Kriloff lived at the country seats of the prince Sergius Galitzin, and when the prince was appointed military governor of Livonia he accompanied him as official secretary. About the years which follow his resignation of this post very doubtful information has been preserved, the common opinion being that he wandered from town to town under the influence of a passion for card-playing. Before long he found his place as a fabulist, the first collection of his *Fables*, twenty-three in number, appearing in 1809. From 1812 to 1841 he held a congenial appointment in the Imperial Public Library—first as assistant, and then as head of the Russian books department. His death took place November 21, 1844. His statue in the Summer Garden is one of the finest monuments in St Petersburg.

Kriloff's success as a fabulist was as rapid as it has been enduring. Honours were showered upon him while he yet lived: the Academy of Sciences admitted him a member in 1811, and bestowed upon him the same gold medal which was accorded to Karamzin for his *History of the Russian People*; in 1838 a great festival was held under imperial sanction to celebrate the jubilee of his first appearance as an author; and the emperor assigned him a handsome pension. Before his death about 77,000 copies of his *Fables* had found sale in Russia; and his wisdom and humour had become the common possession of the many. Nor is the reason far to seek. He was at once poet and sage. In spite of a superficial indifference to political matters, he observed everything with keen and collected interest. His fables for the most part struck root in some actual event, and they told at once by their grip and by their beauty. Though he began as a translator and imitator, he soon showed himself a master of invention, who found abundant material in the life of his native land. To the Russian ear his verse is of matchless quality; while word and phrase are direct, simple, and eminently idiomatic, colour and cadence vary with the theme. This perfection was the result of sustained elaboration, for, though physically indolent, Kriloff was a hard intellectual worker, and had an infinite faculty of taking pains. Of his carelessness in dress, absence of mind, and general irreverence towards etiquette, the stories told are many.

A collected edition of Kriloff's works appeared at St Petersburg, 1844. Of the numerous editions of his *Fables*, which have been often translated, may be mentioned that illustrated by Trutovski, 1872. The author's life has been written in Russian by Pletneff, by Lebanoff, and by Grot, *Liter. zhizn Kruilova*. "Materials" for his life are published in vol. vi. of the *Sbornik Statei* of the literary department of the Academy of Sciences. W. R. S. Ralston has prefixed an excellent sketch to his English prose version of the *Fables*, 1868, 2d ed. 1871.

KRISHNAGAR, town and headquarters of Nadiyá district, Bengal, India, situated on the left bank of the Jalangí river, 23° 23′ N. lat., 88° 32′ E. long. The municipal limits comprise an area of 7 square miles and a population in 1872 of 26,750 persons—Hindus, 18,114; Mohammedans, 8076; Christians, 560. Besides the usual Government offices and courts, Krishnagar is also a station of the Church Missionary Society and of a Roman Catholic mission, each body having its own church and schools. The town is a seat of considerable trade, and is noted for its manufacture of coloured clay figures, carried on by a few artists of the *kumbhar* or potter caste.

KROLEVETZ, a district town of Russia, in the government of Tchernigoff, 108 miles east of the government town. Its 14,000 inhabitants live by agriculture and gardening, by linen manufactures, and by trading in agricultural produce and salted fish imported from the province of Ekaterinoslaff, and in manufactured wares. There are two important fairs, one for horses and manufactured wares, and the other for cattle.

KROTOSCHIN (in Polish, *Krotoszyn*), chief town of a circle in the government district of Posen, Prussia, is situated about 32 miles south-west of Posen. It has a local court, three churches, a synagogue, steam saw-mills, and a steam brewery, and carries on trade in grain and seeds. The neighbouring castle of Krotoschin is the chief place of a mediatized principality of the prince of Thurn and Taxis, which was formed in 1819. The population of Krotoschin in 1875 was 8034.

KRÜDENER, BARBARA JULIANA VON WIETINGHOFF, BARONESS VON (1766–1824), authoress of the romance of *Valérie*, but better known by the religious fervour and pious mysticism of her later years, was born of noble and wealthy parents at Riga, November 21, 1766. Her education, which was an elaborate one, was received partly in her father's house and partly in Paris. While still very young she was married to the Baron von Krüdener, a Russian diplomatist twenty years her senior, whom she accompanied to Copenhagen and subsequently to Venice; the union did not prove a very happy one, and for some years the couple lived apart. It is understood that *Valérie*, published by Madame Krüdener in 1804, is to a considerable extent an autobiography of this period of her life; if this be so, it is impossible to exonerate her of all blame for the domestic misfortunes which befel her. After the death of her husband she resided for some time in Paris, mingling freely with a large and brilliant social circle, but afterwards she retired to her property in Livonia, where her sense of the vanity of earthly things gradually deepened, and religious yearnings were quickened which ultimately found satisfaction in the doctrine and worship of the Moravian community. In 1808 she saw much of Jung Stilling at Carlsruhe and of Oberlin in Steinthal; and the religious convictions now formed were held by her with such earnestness that she felt constrained to adopt the vocation of an itinerant preacher. Her obvious sincerity, her culture and refinement, her social standing, enabled her to attract considerable notice throughout Baden, in Strasburg, and in Switzerland, especially in Geneva; and at Heilbronn in 1815 she could reckon even an emperor (Alexander I. of Russia) among her attentive hearers. Her activity, however, which was hardly favourable to established church order, soon became distasteful to the authorities, and, after being invited to withdraw from more than one German state, she again retired into private life on her estate in 1818. Led by her enthusiasm of humanity to St Petersburg, she was dismissed by the emperor for having declared her sympathy for the struggling cause of Greece. Ill health now came upon her, and she was advised by her physicians to seek a warmer climate. On the southward journey she died at Karasu-Bazar on December 25, 1824. Her life has been written by Eynard (*Vie de Madame de Krüdener*, 2 vols., Paris, 1849).

KRUMEN, CROOMEN, KRUS, or CROOS, a negro people on the west coast of Africa. The name is properly Kra or Krao, though the corrupt form Crew-men has sometimes been put forward as the original. Ethnographically it ought to be confined to the tribes settled in the neighbourhood of the Sinoe in the republic of Liberia, where their chief towns are known as Settra Kru, Little Kru, and Nana Kru; but, as they were the first west African people who ventured to take service on board European vessels, it is now generally applied to about a score of tribes living along 200 miles of coast who in this respect have followed their example. In spite of the fact that the Krus have come into close connexion with Europeans for a long series of years, the information in regard to them is of the scantiest description. They are an independent as well as an enterprising people, and keep themselves very much apart from other tribes. It is said that they have never furnished even a nominal convert to Christianity. They are now mainly engaged as traders or agents; and comparatively few of the Krumen proper are to be found serving as boatmen or sailors. As soon as they have amassed a competency they return to their native country. They keep no slaves themselves, and they are never found in slavery abroad. The men are tall, strong, and well-proportioned, with bluish black complexion, woolly and abundant hair, and a greater frequency of beard than is common among negroes. They appear to be dolichocephalic and prognathic. Their women are of a lighter shade than negro women generally, and in several respects come much nearer to a European standard. Tribal or clan marks are worn on the face: the Krumen examined by Schlagintweit, for example, had a blue vertical stroke on the brow; those seen by Wittstein at Monrovia had a black stroke and an arrow directed from the ear to the eye. Dr Bleek classifies the Kru language with the Mandingo family, and in this he is followed by Latham; Dr Koelle, who published a Kru grammar (1854), considers it as distinct.

Further details will be found in Quatrefages and Hamy, *Crania Ethnica*, part ix., 1878–79, p. 363; Schlagintweit-Sakunlunski, in the *Sitzungsbericht* of the Academy at Munich, 1875; Nicolas, in *Bull. de la Soc. d'Anthrop.*, Paris, 1872.

KRUMMACHER. Three members of this family have attained some popularity as religious writers in Germany and indeed throughout Reformed Protestant Christendom.

1. FRIEDRICH ADOLF KRUMMACHER was born July 13, 1768, at Tecklenburg, Westphalia, studied theology at Lingen and Halle, and became successively rector of the grammar school at Mörs, professor of theology at Duisburg, preacher at Crefeld and afterwards at Kettwich, consistorialrath and superintendent in Bernburg, and pastor of the Ansgariuskirche in Bremen (1824), where he died on 14th April 1845. He was the author of numerous religious works, but is best known by his *Parabeln*, first published in 1805, which have gone through numerous German editions (9th ed., Essen, 1876), and have been translated into English and other European languages.

2. GOTTFRIED DANIEL KRUMMACHER, born at Tecklenburg, April 1, 1774, was pastor successively in Bärl, Wulfrath, and Elberfeld. He was the leader of the "pietists" of Wupperthal, and published several volumes of sermons, including one entitled *Israel's Wanderings*. His death occurred on January 30, 1837.

3. FRIEDRICH WILHELM KRUMMACHER, son of Friedrich Adolf, was born at Mörs, January 28, 1796, studied theology at Halle and Jena, and became pastor successively at Ruhrort (1823) and Gemarke, near Barmen (1825). In 1847 he received an appointment to the Dreifaltigkeitskirche in Berlin, and in 1853 he became court preacher at Potsdam. He died December 10, 1868. F. W. Krummacher was an influential promoter of the Evangelical Alliance. His best known works are *Elias der Thisbiter* (1828–33; 6th ed. 1874), well known to English readers, and *Elisa* (1837), also translated, but much less popular both in England and Germany than its predecessor. He published several volumes of sermons, and an *Autobiography* appeared in 1869.

KRUSENSTERN, ADAM JOHN (1770–1846), Russian navigator, hydrographer, and admiral, was born in Esthonia on November 8, 1770. In 1785 he entered the corps of naval cadets, after leaving which, in 1788, with the grade of midshipman, he served in the war against Sweden. Having been appointed to serve in the English fleet for several years (1793–99), he visited America, India, and China. Having published a paper pointing out the advantages of direct communication between Russia and China by Cape Horn and the Cape of Good Hope, he was appointed by the emperor Alexander to make a voyage to the east coast of Asia to endeavour to carry out the project. Two English ships were bought, Krusenstern commanding the one and Lisiansky the other. Leaving Cronstadt in August 1803, Krusenstern proceeded by Cape Horn and the Sandwich Islands to Kamchatka, and thence to Japan. Returning to Europe by the Cape of Good Hope, after an extended series of explorations, Krusenstern reached Kronstadt in August 1806, his being the first Russian expedition to circumnavigate the world. The emperor conferred several honours upon him, and he ultimately became admiral. As director of the Russian naval school Krusenstern did a great deal to improve the education and the position of the cadets, and in other ways the Russian navy was much indebted to his enlightened exertions. He was also a member of the scientific committee of the marine, and his contrivance for counteracting the influence the iron in vessels has on the compass was adopted in the navy. He died at Revel, August 24, 1846.

Krusenstern's *Voyage Round the World in* 1803 was published at St Petersburg in 1810–14 in 3 vols., with folio atlas of 104 plates and maps (English edition, 2 vols., 1813; French edition, 2 vols., and atlas of 30 plates, 1820). His narrative contains a good many important discoveries and rectifications, especially in the region of Japan, and the contributions made by the various savants were of much scientific importance. A work of permanent value is Krusenstern's *Atlas of the Pacific Ocean*, with its accompanying *Recueil des Mémoires Hydrographiques*, 3 vols., St Petersburg, 1824–35. See *Memoir* by his daughter Madame Bernhardi, translated by Sir John Ross, 1856.

KUBA, or KUDIAL-KALA, a town of the Caucasus, in the government of Baku, Russia, 120 miles north-west from Baku, and 25 miles west of the Caspian. Its situation at the foot of the highlands of Caucasus, on a plain watered by the numberless branches into which the Kubinka river and other smaller streams divide at their issue from the mountain valleys, makes the neighbourhood very suitable for gardening, which is the chief occupation of the 11,300 inhabitants of Kuba, mostly Mussulman Shiites. They also make carpets with very bright colours, and some silks, which are exported to Transcaucasia and Russia; whilst Jews, who are numerous, carry on an active trade in rough silk, madder, and silk and woollen goods, exported to Russia and Persia. The town, which formerly was a Persian fort, and still is protected on one side by brick walls, is badly built and dirty; it suffers very much from fever. An unsuccessful attempt was made by the military authorities in 1825 to transport the town to New Kuba, 8 miles distant; the new settlement did not increase, and the settlers returned to Kuba.

KUBAN, a Russian district and government at the north-west extremity of the Caucasus, comprising the entire basin of the river of that name. It is bounded on the N. by the lands of the Don Cossacks and the steppes of Stavropol, E. by the watershed of the river basins of the Caspian and sea of Azoff, S. and S.W. by the Caucasian Alps, and W. by the Black Sea and Straits of Kertch. Its area comprises 27,728 square miles. Ekaterinodar, the chief town (population 30,000), is the residence of the governor, who, being also ataman in chief of the Kuban Cossacks, is invested with military and civil power. Climate varies greatly, the highest temperature reaching 104° Fahr., the lowest seldom falling below 10° Fahr. The country is very healthy, except in the lowlands, where fever prevails. The soil is of extreme fertility, yielding an abundance of wheat, maize, and tobacco. Fruit, such as apples, pears, cherries, is plentiful, and the vine is cultivated with success near Temrouk and Taman. The upper valleys are richly covered with forests abounding in fir, oak, ash, beech, hornbeam, &c.; the lower parts consist of extensive pasture lands and swamps. The animals include the stag, roe-deer, bear, wild boar, wolf, fox, ibex, and chamois, also the bison (which, however, is very rare) in the virgin forests of the Teberda; numerous water-fowl, such as ducks, geese, swans, pelicans, also the pheasant, partridge, bustard, and mountain turkey. The rivers and lakes are plentifully supplied with fish, trout abounding in the mountain streams and the sturgeon at the delta of the river Kuban. The mineral wealth consists of coal, salt, petroleum, and ozokerite. The river Kuban (the ancient Hypanis, see CAUCASUS, vol. v. p. 254) is navigable in flat-bottomed boats over a distance of 100 miles between Temrouk and Ekaterinodar. The delta comprises several lakes.

It is on the upper banks of the Kuban that the Ass or Osses, and the enigmatic corner of *Asia Propria*, are believed to have been located. The history of the original settlements of the various native tribes named below, and their language and worship before the introduction of Mohammedanism, remain a blank page in the legends of the Caucasus. The peninsula of Taman, a land teeming with relics of ancient Greek colonists, has been occupied successively by the Cimmerians, Sarmatians, Khazars, Mongols, and other nations. The Genoese, who had established an extensive trade in the 13th century, were expelled by the Turks in 1484, and in 1784 Russia obtained by treaty the entire peninsula and the territory on the right bank of the Kuban,—the latter being granted by Catherine II. in 1792 to the Cossacks of the Dnieper. Then commenced the bloody struggle with the Circassians which continued for more than half a century. The mountaineers were finally subdued in 1864, and 400,000 of their number expatriated. Those, however, who elected to remain have become more prosperous than they had ever been. The population of Kuban, 862,473, embraces 510,038 Cossacks, 108,346 settlers of Russian origin, 4280 foreigners, and 95,602 natives. Cossack villages are military settlements, the men carrying arms as well as following the plough. They are exempt from the poll-tax (3 to 4 roubles) to which the others are subjected, but military service is compulsory, as is gratuitous labour in the construction and repair of roads, bridges, &c. Not only domestic but even field work is conducted mostly by women, remarkable for physical strength and endurance. Corn growing, the rearing of cattle, and fishing are the most profitable occupations. The native mountaineers, known under the general name of Circassians, but locally distinguished as the Karatchai, Abadsikh, Khakoutchy, Shapsough, have greatly altered their mode of life since the pacification of the Caucasus, still, however, maintaining Mohammedanism, speaking their vernacular, and strictly observing the customs of their ancestors. When during the late Russo-Turkish war insurrections broke out amongst the natives on the Terek, in Dagestan, and Abkhasia, these tribes remained peaceful and perfectly loyal. Their villages, especially those of the Karatchai, are striking examples of human industry, poverty being quite unknown; for the general emancipation in 1867 put an end to intestine strife, the predatory expeditions of former times, and the parasitic existence of numerous chiefs on the forced labour of serfs. The native population, as well as the Cossacks, enjoy certain rights of self-government, and are allowed to hold meetings to that end. Exports include wheat, tobacco, leather, wool, petroleum, and live cattle; imports dry goods, grocery, and hardware. Local industry is limited to a few tanneries, petroleum refineries, and spirit distilleries; but Russian and foreign capitalists have of late obtained concessions for exploring the petroleum region stretching between Khadaji and Taman, and the coal-mines of Khumarinsky in the upper valley of the Kuban.

KUBLAI KHAN (or KAAN, as the supreme ruler descended from Jenghiz was usually distinctively termed in the 13th century) (1216–1294) was the most eminent of the successors of Jenghiz (Chinghiz), and the founder of the Mongol dynasty in China. He was the second son of Tuli, youngest of the four sons of Jenghiz by his favourite wife. Jenghiz was succeeded in the khanship by his third son Okkodai, or Ogdai (1229), he by his son Kuyuk (1246), and Kuyuk by Mangku, eldest son of Tuli (1252). Kublai was born in 1216, and, young as he was, took part with his younger brother Hulaku (afterwards conqueror of the caliph and founder of the Mongol dynasty in Persia) in the last campaign of Jenghiz (1226–27). The Mongol poetical chronicler, Sanang Setzen, records a tradition that Jenghiz himself on his deathbed discerned young Kublai's promise and predicted his distinction.

Northern China, Cathay as it was called (vol. v. p. 627), had been partially conquered by Jenghiz himself, and the conquest had been followed up till the Kin or "golden" dynasty of Tartars, reigning at Kai-fung-fu on the Yellow River, were completely subjugated (1234). But China south of the Great Kiang remained many years later subject to the native dynasty of Sung, reigning at the great city of Linggan, or Kinsai (*King-sz'*, "capital"), now known as Hang-chow-fu. Operations to subdue this region had commenced in 1235, but languished till Mangku's accession. Kublai was then named his brother's lieutenant in Cathay, and operations were resumed. By what seems a vast and risky strategy, of which the motives are not quite clear, the first campaign of Kublai was directed to the subjugation of the remote western province of Yunnan. After the capture of Talifu (well known in recent years as the capital of a Mohammedan insurgent sultan) Kublai returned north, leaving the war in Yunnan to a trusted general. Some years later (1257) the khan Mangku himself entered on a campaign in west China, and died there, before Ho-chow in Sz'chuen (1259).

Kublai assumed the succession, but it was disputed by his brother Arikbugha, and by his cousin Kaidu, and wars with these retarded the prosecution of the southern conquest. Doubtless, however, this was constantly before Kublai as a great task to be accomplished, and its fulfilment was in his mind when he selected as the future capital of his empire the Chinese city that we now know as Peking. Here, in 1264, to the north-east of the old city, which under the name of Yenking had been an occasional residence of the Kin sovereigns, he founded his new capital, a great rectangular plot of 18 miles in circuit. The (so-called) "Tartar city" of modern Peking is the city of Kublai, with about one-third at the north cut off, but Kublai's walls are also on this retrenched portion still traceable.

The new city, officially termed Tai-tu ("great court"), but known among the Mongols and western people as Kaan-baligh ("city of the khan"; see vol. iv. p. 722), was finished in 1267. The next year war against the Sung empire was resumed, but was long retarded by the strenuous defence of the twin cities of Siang-yang and Fan-ching, on opposite sides of the river Han, and commanding two great lines of approach to the basin of the Great Kiang. The siege occupied nearly five years. After this Bayan, Kublai's best lieutenant, a man of high military genius and noble character, took command. It was not, however, till 1276 that the Sung capital surrendered, and Bayan rode into the city (then probably the greatest in the world) as its conqueror. The young emperor, with his mother, was sent prisoner to Kaan-baligh; but two younger princes had been despatched to the south before the fall of the city, and these successively were proclaimed emperor by the adherents of the native throne. An attempt to maintain their cause was made in Fuh-keen, and afterwards in Canton province; but in 1279 these efforts were finally extinguished, and the faithful minister who had inspired them terminated the struggle by jumping with his young lord into the sea.

Even under the degenerate Sung dynasty the conquest of southern China had occupied the Mongols during intermittent campaigns of half a century. But at last Kublai was ruler of all China, and probably the sovereign (at least nominally) of a greater population than had ever acknowledged one man's supremacy. For, though his rule was disputed by the princes of his house in Turkestan, it was acknowledged by those on the Volga, whose rule reached to the frontier of Poland, and by the family of his brother Hulaku, whose dominion extended from the Oxus to the Arabian desert. For the first time in history the name and character of an emperor of China were familiar as far west as the Black Sea, and not unknown in Europe. The Chinese seals which Kublai conferred on his kinsmen reigning at Tabriz are stamped upon their letters to the kings of France, and survive in the archives of Paris. Adventurers from Turkestan, Persia, Armenia, Byzantium, even from Venice, served him as ministers, generals, governors, envoys, astronomers, or physicians; soldiers from all Asia to the Caucasus fought his battles in the south of China. Once in his old age (1287) Kublai was compelled to take the field in person against a serious revolt, raised by Nayan, a prince of his family, who held a vast domain on the borders of Manchuria. Nayan was taken and executed. The revolt had been stirred up by Kaidu, who survived his imperial rival, and died in 1301. Kublai himself died in 1294, at the age of seventy-eight.

Though a great figure in Asiatic history, and far from deserving a niche in the long gallery of Asiatic tyrants, Kublai misses a record in the short list of the good rulers. His historical locus was a happy one, for, whilst he was the first of his race to rise above the innate barbarism of the Mongols, he retained the force and warlike character of his ancestors, which vanished utterly in the effeminacy of those who came after him. He had great intelligence and keen desire of knowledge, with apparently a good deal of natural benevolence and magnanimity. But his love of splendour, and his fruitless expeditions beyond sea, created enormous demands for money, and he shut his eyes to the character and methods of those whom he employed to raise it. A remarkable narrative of the oppressions of one of these, Ahmed of Fenáket, and of the revolt which they provoked, is given by Marco Polo, in substantial accordance with the Chinese annals.

Kublai patronized Chinese literature and culture generally. Of the great astronomical instruments which he caused to be made specimens are still preserved at Peking, which are truly splendid as works of art, and not contemptible as works of science. Though he put hardly any Chinese into the first ranks of his administration, he attached many to his confidence, and was personally popular among them. Had his endeavour to procure European priests for the instruction of his people, of which we know through Marco Polo, prospered, the Roman Catholic Church, which did gain some ground under his successors, might have taken stronger root in China. Failing this momentary effort, Kublai probably saw in the organized force of Tibetan Buddhism the readiest instrument in the civilization of his countrymen, and that system received his special countenance. An early act of his reign had been to constitute a young lama of intelligence and learning the head of the Lamaite church, and eventually also prince of Tibet, an act which may be regarded as a precursory form of the rule of the "grand lamas" of Lassa. The same ecclesiastic, Mati Dhwaja, was employed by Kublai to devise a special alphabet for use with the Mongol language. It was chiefly based on Tibetan forms of Nagari; some coins and inscriptions in it are extant; but it had no great vogue, and soon perished. Of the splendour of his court and entertainments, of his palaces, summer and winter, of his great hunting expeditions, of his revenues and extraordinary paper currency, of his elaborate system of posts and much else, an account is given in the book of Marco Polo, who passed many years in Kublai's service.

We have alluded to his foreign expeditions, which were almost all disastrous. Nearly all arose out of a hankering for the nominal extension of his empire by claiming submission and tribute. Expeditions against Japan were several times repeated; the last, in 1281, on an immense scale, met with huge discomfiture. Kublai's preparations to avenge it were abandoned owing to the intense discontent which they created. In 1278 he made a claim of submission upon Champa, an ancient state representing what we now call Cochin China. This eventually led to an attempt to invade the country through Tongking, and to a war with the latter state, in which the Mongols had much the worst of it. War with Burmah (or Mien, as the Chinese called it) was provoked in very similar fashion, but the result was more favourable to Kublai's arms. The country was overrun as far as the Irawaddy delta; the ancient capital Pagán, with its magnificent temples, destroyed, and the old royal dynasty overthrown. The last attempt of the kind was against Java, and occurred in the last year of the old khan's reign. The envoy whom he had commissioned to claim homage was sent back with ignominy. A great armament was equipped in the ports of Fuh-keen to avenge this insult; but after some temporary success the force was compelled to re-embark with a loss of 3000 men. The death of Kublai prevented further action.

Some other expeditions, in which force was not used, gratified the khan's vanity by bringing back professions of homage, with presents, and with the curious reports of foreign countries in which Kublai delighted. Such expeditions extended to the states of southern India, to eastern Africa, and even to Madagascar.

Of Kublai's twelve legitimate sons, Chingkim, the favourite and designated successor, died in 1284–85; and Teimur, the son of Chingkim, took his place. No great king arose in the dynasty after Kublai. He had in all nine successors of his house on the throne of Kaan-baligh, but the long and imbecile reign of the ninth, Toghon Teimur, ended (1368) in disgrace and expulsion, and the native dynasty of Ming reigned in their stead. (H. Y.)

KUCHÁN (a contracted form of *Kabushán*), a walled town and also a district of Persia, province Khórásán, enclosed north and south by the Hazar-Mazjíd and Ala-Dagh mountains. The town lies at the north foot of the Shah Jahan Kuh (11,000 feet), 3300 feet above the sea, in 37° 10′ N. lat., 58° 25′ E. long., about 80 miles north-west of Meshhed on the route to Shirván. It is an important place, seat of a district governor, and surrounded by extensive gardens and vineyards yielding excellent fruits and grapes from which a superior wine is made. Population 20,000.

The district forms the western section of the longitudinal valley stretching between the above-mentioned ranges from Meshhed to Shirván and communicating by the Allaho-Akbar Pass (4200 feet) northwards with the Dara-Gez country on the frontier of the new Russian Trans-Caspian Territory. It is very fertile, largely cultivated, and well watered by the upper Atrek river, which has its furthest source in an intermittent torrent just south of the pass. The whole valley is thickly dotted over with villages, while the slopes of the hills afford good pasture to the numerous flocks and herds of the warlike Zafaranlu Kurds, who guarded the frontier against the Akhal Tekke Turkomans until these marauders were reduced by the Russians in the spring of 1881. Of this region little was known until the explorations of Baker, Gill, O'Donovan, and Stewart (1874–81).

KUCH BEHAR, or COOCH BEHAR, a native state in Bengal, India, lying between 25° 57′ and 26° 32′ N. lat., and 88° 48′ and 89° 55′ E. long. It is entirely surrounded by British territory, being bounded on the N. by Jalpáigurí, on the E. by Goálpára, on the S. by Rangpur, and on the W. by Purniah districts. The state forms a level plain of triangular shape, intersected by numerous rivers. The greater portion is fertile and well cultivated, but tracts of jungle are to be seen in the north-east corner, which abuts upon Assam. The soil is uniform in character throughout, consisting of a light, friable loam, varying in depth from 6 inches to 3 feet, superimposed upon a deep bed of sand. The whole is detritus, washed down by torrents from the neighbouring Himálayas. The rivers all pass through the state from north to south, to join the main stream of the Brahmaputra. Some half dozen are navigable for small trading boats throughout the year, and are nowhere fordable; and there are about twenty minor streams which become navigable only during the rainy season. The streams have a tendency to cut new channels for themselves after every annual flood, and they communicate with one another by cross-country water-courses. There are no embankments or artificial canals, nor are any mineral products known to exist.

The population in 1872 was 532,565, distributed over an area of 1307 square miles. The Hindus numbered 127,928; the Mohammedans, 48,086. The Koch or Rájbansí tribe numbered 111,125 adult males, or 63 per cent. of the whole. This is a widely spread tribe, evidently of aboriginal descent, which is found throughout all northern Bengal, from Purniah district to the Assam valley. They are akin to the Indo-Chinese races of the north-east frontier; but they have now become largely Hinduized, especially in their own home, where the appellation "Koch" has come to be used as a term of reproach. Kuch Behar town, which contains the palace of the rájá, and has 7132 inhabitants, is the only populous place in the state. Even villages, in the ordinary sense of the word, are unknown, each well-to-do family living apart in its own homestead. Rice is grown on three-fourths of the total cultivated area. Jute and tobacco are largely grown for exportation over an increasing area year by year. The only special industries are the weaving of a strong silk from worms fed on the castor-oil plant, and of a coarse jute cloth, used for screens and bedding. The external trade is chiefly in the hands of Márwárí immigrants from Upper India. The chief exports are jute, tobacco, oil, timber; salt, sugar, and piece goods are imported. The net revenue in 1870–71 amounted to £112,093, of which £25,719 was derived from *zamíndárí* estates in British territory. The climate is damp and malarious, but not so hot as in other parts of Bengal. The average annual rainfall is 123 inches.

As in the case of many other small native states, the royal family of Kuch Behar lays claim to a divine origin in order to conceal an impure aboriginal descent. The greatest monarch of the dynasty was Nar Náráyan, the son of Visu Sinh, who began to reign about 1550. He conquered the whole of Kámrúp, built temples in Assam, of which ruins still exist bearing inscriptions with his name, and extended his power southwards over what is now part of the British districts of Rangpur and Purniah. To his reign also is attributed the introduction of the well-known Náráyaní currency, the privilege of coining which has not yet been entirely abolished. His son, Lakshmi Náráyan, who succeeded him in Kuch Behar, became tributary to the Mughal empire. In 1772 a competitor for the throne, having been driven out of the country by his rivals, applied for assistance to Warren Hastings. A detachment of sepoys was accordingly marched into the state; the Bhutiás, whose interference had led to this intervention, were expelled, and forced to sue for peace through the mediation of the lama of Tibet. By the treaty made on this occasion, April 1773, the rájá acknowledged subjection to the Company, and made over to it one half of his annual revenues. But, though the Bhutiás were driven out, the rivalry of domestic faction continued. In 1863, on the death of the rájá, leaving a son and heir only ten months old, a British commissioner was appointed to undertake the direct management of affairs during the minority of the prince, and many important reforms have thus been successfully introduced.

KUEN-LUN, or KOUEN-LUN, the name given to the mountains between western Tibet and the plains of eastern Turkestan; it is derived from the Chinese geographers, and is probably a corruption of some Turkish or Tibetan word; it appears to be unknown locally. The name having been adopted, chiefly on the initiative of Humboldt, before any correct geographical knowledge had been obtained of the region to which it was applied, it has been used with inconvenient want of precision, and this has encouraged erroneous conceptions. Little precise information is yet available on the subject, but there is no reason to doubt that, within the limits to which actual exploration has gone, the mountains designated as Kuen-lun form the northern border of the high lands of Tibet, descending to the central Asian plain, just as those commonly spoken of under the name of Himalaya constitute the broad mountainous slope which descends to the lower levels of India.

Nothing can be said with confidence of the northern border of Tibet east of 82° E. long., but from this point westward, to about the 75th meridian, it consists of a series of mountain ranges on a scale of magnitude quite analogous to that of the higher ranges of the Himalaya, and beyond the last-named meridian merges into the Thian-Shan mountains. A line of demarcation between the summit of the Tibetan plateau and its northern flank can, in the present condition of our knowledge, only be fixed in an arbitrary manner, and it may for convenience be regarded as following the watershed line from which the streams flow northward to the plain of eastern Turkestan. Using the name

Kuen-lun in the sense thus explained, the zone it includes will be seen to abut at its north-western extremity on the series of elevated plateaus known under the name of Pamir, which extend over a distance of nearly 200 miles to a little beyond 39° N. lat. Here the width of the zone is about 100 miles. To the eastward it becomes broader, and on the 79th meridian is nearly 150 miles across. In this region the chief ranges appear to be laid out, generally, in a north-west and south-east direction, like those of western Tibet, with transverse ridges at irregular intervals. The transverse direction would seem to predominate in the outer portion of the zone nearest to the plain of Turkestan, but the geographical details are too little known to permit us to say more on this point. Of the longitudinal ranges two are of conspicuous magnitude, running approximately parallel to one another about 60 or 70 miles apart; the more northern or outer may be spoken of as the main Kuen-lun; the other, which separates the waters of the Indus, which run off to the south-west, from those of the streams which pass down to the plains of Khotan, Yarkand, and Kashgar, constitutes the watershed before referred to, and has been called the Muztagh or Karakorum range from two of the best known passes across it. The latter of these great lines of elevation, from which the Kuen-lun slope of the Tibetan plateau may be said to commence, is of very considerable altitude throughout, its summits rising more than 28,000 feet above sea-level, and few of the passes falling below 18,000 or even 19,000 feet over a length of some 400 miles. Its flanks are covered with enormous glaciers, some of them being continuous for distances of 60 or 70 miles. The main Kuen-lun is not much inferior in magnitude, one of its peaks rising above 25,000 feet, while the points between that elevation and 20,000 feet are numerous. The passes lie between 18,000 feet on the east and 13,000 feet on the west. The valleys between these ranges vary in elevation from about 15,000 feet to 10,000 feet, the drainage in some cases collecting in small lakes, in others forming streams which, after flowing for some distance parallel to the separating ridges, suddenly change their direction and run off to the north-east through deep transverse lines of rupture, in a manner analogous to that observed on the border of the Himalayan mountain slope.[1]

The whole of the region is described as remarkable for its general barren character. The mountain sides are naked and the valleys for the most part narrow and steep. There is a complete absence of forest, and trees of any sort are only found at the lower levels bordering on the northern plain,—walnuts, poplars, and willows alone being mentioned, besides a few fruit trees. The vegetation is scanty and botanically poor, brushwood being found along some of the rivers, and pastures in the bottoms of the deep valleys among the higher ranges. Among the shrubs are species common in Tibet, such as tamarisk, juniper, astragalus, willow, rose, barberry, and clematis. The animal life also appears to be mainly that found in the neighbouring parts of Tibet.

Some facts of interest relating to the geological structure of these mountains may be gathered from the fragmentary reports of Dr Stoliczka, the accomplished geologist who so prematurely died from the results of exposure in these inhospitable regions. The summit of the Karakorum Pass is of Triassic age, and cretaceous beds are found in some of the ranges on the north of the Kuen-lun main range, associated with Palæozoic deposits supposed to be Carboniferous and Silurian. For the greater portion of the year the climate is very rigorous. The extremes of temperature are great, and the rainfall little.

The population is small. The fixed settlements are confined to the outer valleys; few villages or hamlets are found above 6000 feet of altitude, and hardly any over 8000 feet. The upper valleys are occupied by a nomadic population, wholly pastoral in their habits.

The tract may be regarded as appertaining politically to the sovereigns for the time being of the principalities lying in the plain below it. But from the nature of the case any recognized authority hardly extends beyond the permanently inhabited region. (R. S.)

[1] For information as to the geographical details which have been collected reference may be made to the map published in the *Royal Geog. Soc. Journal*, vol. xlviii., accompanying Captain Trotter's account of the results of Sir T. D. Forsyth's mission to Kashghar.

KUKA, or KUKAWA, the capital of the kingdom of Bornu in Central Africa, is situated in 12° 55′ N. lat. and 13° 25′ E. long., 4½ miles from the western shores of Lake Tsad or Chad,[2] in the midst of an extensive and for the most part uncultivated plain. The soil of the whole district consists of a layer of sand resting on clay, beneath which are found sand and lime. At a depth of 40 or 50 feet water is reached, usually sweet, but sometimes brackish. From a distance Kuka presents a very dead and monotonous appearance, there being no minarets or lofty buildings of any sort. The walls, built of earth, are about 20 feet in height. There are two distinct towns, separated by more than half a mile. The western town or Billa Futebe is the larger of the two, measuring from west to east about a mile and a half, and rather less from north to south. The plan is rectangular, and there is a gate in each of the four sides. From west to east runs the main thoroughfare known as the Dendal, which widens out to the west into the market place. About the middle of the Dendal stands the sheikh's secondary palace. The eastern town or Billa Gedibe is somewhat longer and narrower than the western. The Dendal continues from its western gate till closed at the east end of the town by the great palace of the sheikh, gradually widening out into a large open square. The larger dwelling-houses of Kuka are of mud or earth, with windowless walls and flat roofs; the poorer houses are mere huts of straw or reeds, varying in shape from that of a bell to that of a sugar-loaf. In almost every courtyard there is at least one large shady tree, whose branches are tenanted by storks, herons, or a variety of lesser birds; and the whole place is vocal with song. Kuka is a wealthy town. It always contains a large number of strangers—merchants, pilgrims, and adventurers—attracted even from Mecca, Medina, Morocco, Egypt, Tunis, Tripoli, by the fame of the sheikh's liberality. The town enjoys the rare advantage of being absolutely free from all taxation of trade or industry. In the Monday market, which is held outside the western gate, there are often more than 10,000 buyers and sellers. It is at once a fair for horses, cattle, camels, and other live stock, a fruit, grain, and vegetable market, a meat market, and a slave market. The currency consists mainly of Maria Theresa dollars and cowries. For the Mohammedans, not only of Bornu but of the neighbouring countries, Kuka serves as a kind of university town. In its streets are to be seen bands of mendicant students, who spend the day in collecting alms from the people, and after supper gather round the fires which they kindle in the public squares, and noisily and mechanically recite the verses of the Koran far into the night. A less cheerful feature of the street life is the unusual number of blind beggars. The population is estimated at 60,000.

Kuka was founded by Sheikh Mohammed al Amin el Kanemi. It received its name from a kuka or monkey bread tree (*Adansonia digitata*), which attracted the attention of the settlers as a rare thing in the district. In 1840 the town was laid waste by King Mohammed Sherif of Wadai; and when it was restored by Sheikh Omar he gave it the present double form. It is probably from this feature of the place that the plural *Kukawa* has become the ordinary designation of the town in Kano and throughout the Sudan; though the local inhabitants generally use the singular *Kuka*. Kuka has been visited by Denham and Clapperton, Beurmann, Vogel, Barth, Rohlfs, and Nachtigal.

For further details see Barth, *Travels in Central Africa*, London, 1858; Rohlfs, *Quer durch Afrika*, Leipsic, 1874; Nachtigal, *Saharâ und Sûdân*, Berlin, 1879, vol. i. p. 581-748. The last is the most elaborate account.

KUKU KHOTO, in Chinese KWEI-HWA-TCHENG or GUI-HUA-TCHENG, a city of the Chinese province of Shan-se, situated to the north of the Great Wall, in 40° 50′ N. lat. and 111° 45′ E. long., about 160 miles west of Kalgân. It lies in the valley of a small river which joins the Hoang-ho

[2] The fear lest the town should be submerged by the lake led the sheikh to found (1873) a new residence (Kherwa) on a range of sand hills about two hours north of Kuka.

50 miles to the south. There are two distinct walled towns in Kuku Khoto, at an interval of a mile and a half; the one is the seat of the civil governor and is surrounded by the trading town, and the other is the seat of the military governor, and stands in the open country. In the first or old town more especially there are strong traces of western Asiatic influence; the houses are not in the Chinese style, being built all round with brick or stone and having flat roofs, while a large number of the people are still Mohammedans, and, there is little doubt, descended from western settlers. The town at the same time is a great seat of Buddhism,—the lamasseries containing, it is said, no less than 20,000 persons devoted to a religious life. As the southern terminus of the routes across the desert of Gobi from Uliassutai and the Thian Shan, Kuku Khoto has a large trade, exporting flour, millet, and manufactured goods, and importing the raw products of Mongolia. A Catholic mission and a Protestant mission are maintained in the town.

Early notices of Kuku Khoto will be found in Gerbillon (1688–1698), in Du Halde (vol. ii., English edition), and in Astley's *Collection* (vol. iv.). Recent travellers who have visited it are Elias (*Journ. Roy. Geog. Soc.*, 1873) and Peftsoff.

KULDJA, the name of two towns in the valley of the Ili in Central Asia, situated about 25 miles apart.

I. Old Kuldja, the present capital of the Kuldja territory, restored to China by Russia in 1881, otherwise known as Tartar Kulja, Nin Yuan, or Kuren, lies about ½ mile to the north of the river, in 43° 58′ N. lat. and 81° 25′ E. long. The walled town is nearly square, each side being about a mile in length; and the walls are not only 30 feet high but broad enough on the top to serve as a carriage drive. Two broad streets cut the enclosed area into four nearly equal sections. Since 1870 a Russian auburb has been laid out on a wide scale. The houses of Kuldja are almost all clay-built and flat-roofed, and except in the special Chinese quarter in the eastern end of the town it is only a few public buildings that show the influence of Chinese architecture. Of these the most noteworthy are the Tarantchi and Dungan mosques, both with turned up roofs, and the latter with a pagoda-looking minaret. The population is mainly Mohammedan, and there are only two Buddhist pagodas. A small Chinese Roman Catholic church has maintained its existence through all the vicissitudes of modern times. Paper and vermicelli are manufactured with rude appliances in the town. The outskirts are richly cultivated with wheat, barley, lucerne, and poppies. Schuyler estimated the population, which includes Tarantchis, Dungans, Sarts, Chinese, Calmucks, and Russians, at 10,000 in 1873; it has since increased.

II. New Kuldja, Manchu Kuldja, or Ila, which lies lower down the valley on the same side of the stream, has been a pile of ruins whitened with bleaching bones since the terrible massacre of all its inhabitants by the insurgent Dungans in 1868. It was previously the seat of the Chinese Government for the province, with a large penal establishment and strong garrison; its population was about 70,000.

See Schuyler, *Turkistan*, London. 1876; Dilke in *Proc. Roy. Geog. Soc.*, 1874; Ujfalvy in *Tour du Monde*, 1879; E. D. Morgan in *Proc. Roy. Geog. Soc.*, 1881; and Ili, vol. xii. p. 702.

KULLU, a valley and subdivision of Kángrá district, Punjab, India, situated between 31° 20′ and 32° 26′ N. lat., and 76° 58′ and 77° 50′ E. long. It is bounded on the N. by the central Himálayan range, on the S. by the Sutlej river, on the S.W. by the Dháoladar or Outer Himálaya, Bias river, and the states of Suket and Mandi, and on the W. by Bára Bangahál hills. The Sainj, which joins the Bias at Lárgi, divides the tract into two portions, Kullu Proper and Sioráj. Kullu Proper, north of the Sainj, together with Inner Seoráj, forms a great basin or depression in the midst of the Himálayan systems, having the narrow gorge of the Bias at Sárgi as the only outlet for its waters. North and east the Bára Bangahál and Mid-Himálayan ranges rise to a mean elevation of 18,000 feet, while southward the Jalori and Dháoladhar ridges attain a height of 11,000 feet. The greater portion of Kullu must thus ever remain an utter wilderness. The higher villages stand 9000 feet above the sea; and even the cultivated tracts have probably an average elevation of 5000 feet. The houses consist of four-storied châlets in little groups, huddled closely together on the ledges or slopes of the valleys, picturesquely built with projecting eaves and carved wooden verandahs. The Bias, which, with its tributaries, drains the entire basin, rises at the crest of the Rohtang Pass, 13,326 feet above the sea, and has an average fall of 125 feet per mile. Its course presents a succession of magnificent scenery, including cataracts, gorges, precipitous cliffs, and mountains clad with forests of deodar, towering above the tiers of pine on the lower rocky ledges. Great mineral wealth exists, but the difficulty of transport and labour will probably always prevent its proper development. Hot springs occur at three localities, much resorted to as places of pilgrimage.

The census of 1872 disclosed a population of 90,313, spread over an area of 1926 square miles—Hindus numbering 90,206; Mohammedans, 100; and Christians, 7. The character of the hillmen resembles that of most other mountaineers in its mixture of simplicity, independence, and superstition. Tibetan polyandry still prevails in Seoráj, but has almost died out elsewhere. The temples are dedicated rather to local deities than to the greater gods of the Hindu pantheon. Out of a total of 799,834 acres, only 32,884 are returned as actually under cultivation. The staple spring crops include wheat, barley, poppy, tobacco, and oil-seeds; the autumn crops are maize, rice, pulses, and millets. Tea cultivation has recently been introduced into the valley. Rice, wheat, opium, tobacco, tea, and honey are exported. Manufactures are almost unknown. The climate is not healthy. Intermittent fevers and bowel complaints are endemic, while epidemics of virulent contagious fever and cholera break out from time to time. Goitre and cretinism also occur. The average annual rainfall ranges from 45 to 50 inches. The mean temperature in August is 78° Fahr., in November 55°.

KULM (in Polish, *Chelmo*), chief town of a circle in the government district of Marienwerder, Prussia, is situated on the high banks of the Vistula, about 24 miles north-west of Thorn. It is regularly built, and contains an old-fashioned town-house, a gymnasium, a high school, and a cadets' institution founded in 1775 by Frederick II It carries on trade in grain and has some shipping. The population in 1875 was 9628.

Kulm gives name to the oldest bishopric in Prussia, although the bishop resides at Pelplin. It was taken about 1220 by Duke Conrad of Masovia. Frederick II. pledged it in 1226 to the Teutonic Order, from whom it passed by the second peace of Thorn in 1466 to Poland; and it was annexed to Prussia in 1772. It joined the Hanseatic League, and used to carry on very extensive manufactures of cloth. The battle of Kulm, won August 30, 1813, over the French by the Prussians and Russians, took place at the village of Kulm in Bohemia, about 3 miles north-east of Teplitz.

KULMBACH, or Culmbach, a town in the administrative district of Upper Franconia, Bavaria, is picturesquely situated on the White Main, and on the Bamberg-Hof line of the Bavarian State Railway, about 11 miles north-west from Baireuth, in 50° 6′ N. lat., 11° 28′ E. long. The town has several linen manufactories and a large cotton spinnery, but is chiefly famed for its many extensive breweries, the latest returns showing an annual production of 4,115,637 gallons of beer, of which 3,719,478 gallons were exported. On an eminence near the town stands the former fortress of Plassenburg, which during the 15th and 16th centuries was the residence of the margraves of Brandenburg-Kulmbach. It was dismantled in 1807, and is now used as a prison. The population in November 1881 was officially estimated at 6000.

KUM, a walled city of Persia, in the province of Irak-Adjemi, in a hilly district at the western edge of the Great Salt Desert, 85 miles south of Teheran on the main route to Ispahan, and at the northern extremity of the lofty Kuru-Kuh range, which runs thence for over 600 miles south-east to the Bam highlands. It is a long, straggling, half-ruined place, with empty bazaars, and neglected streets full of holes and pitfalls. Yet it ranks second to Meshhed in sanctity, thanks to the famous shrine of Masuma Fatima, sister of the imám Riza, which also contains the remains of ten kings and four hundred and forty-four "saints," and whose gilded copper dome has been completed by the present shah. Like Kerbela, Kum is a favourite place of interment for the faithful, and is yearly visited by thousands of devout Shiah pilgrims. At one time it is said to have contained 100,000 inhabitants, and its former greatness is still attested by the surrounding ruins, of which Sir Thomas Herbert quaintly remarks that they "may gaine beliefe to the inhabitants, who say it was once comparable in pride and greatness to mightie Babylon." Even in that traveller's time it was still a flourishing place, with well-built houses "sweet and wel-furnished, her streets wide, her bazzar faire and her mosque of most honourable esteem." But the neighbourhood now presents the aspect of a vast necropolis, while not more than 4000 of its 20,000 houses are occupied. Cotton of good quality and the castor-oil plant are extensively cultivated in the district, which is watered by the Gonsir and a few other intermittent streams draining east to the great desert. Population estimated at 20,000.

KUMÁUN, a district in the North-Western Provinces of India, lying between 28° 55′ and 30° 50′ N. lat., and 78° 52′ and 80° 56′ E. long. It consists of two distinct tracts—the sub-Himalayan ranges, and the *bhábhar* or waterless forest, averaging from 10 to 15 miles in breadth, which stretches between the forests and the Tarái. See HIMALAYA, vol. xi. p. 824. Of the entire area of the highlands, only 500 square miles are returned as cultivated and 100 square miles as cultivable. The southern or *bhábhar* portion was up to 1850 an almost impenetrable forest, given up to wild animals; but since then the numerous clearings have attracted a large population from the hills, who cultivate the rich soil during the hot and cold seasons, returning to the hills in the rains. The rest of Kumáun is a maze of mountains, some of which are among the loftiest known. In fact, in a tract not more than 140 miles in length and 40 in breadth, there are over thirty peaks rising to elevations exceeding 18,000 feet (see vol. xi. p. 825). The rivers rise chiefly in the southern slope of the Tibetan watershed north of the loftiest peaks, amongst which they make their way down valleys of rapid declivity and extraordinary depth. The principal are the Káli or Gogra, and the Pindar and Káilganga, whose waters join the Alaknanda. The valuable timber of the yet uncleared forest tracts in Kumáun is now under official supervision. The chief trees are the *chír* or three-leaved Himalayan pine, the cypress, fir, alder, *sál* or iron-wood, and *saindan*. Limestone, sandstone, slate, gneiss, and granite constitute the principal geological formations of the district. Mines of iron, copper, gypsum, lead, asbestos, and coral exist: but they are not thoroughly worked.

The census of 1872 disclosed a population of 433,314, of whom 425,963 were returned as Hindus and 5569 as Mohammedans. The Kumáunis are a tolerably fair, good-looking race, active, cheerful, honest, and industrious. Polyandry is unknown, but polygamy is frequent. The 4606 villages of the district are scattered about the hillsides, the houses being built of stone laid in mud, and roofed with slates, or with planks or thatch. The only native town is Almora. There are large bazaars at the European stations of Naini Tal and Ranikhet. The area available for cultivation is small; but wherever possible the hill sides have been terraced. The soil except in some of the valleys is poor and stony, and requires much manure. On the better kinds of land rice, wheat, and tobacco are grown; on the others wheat, barley, mustard, vetches, flax, Indian corn, millets, pulses, sugar-cane, cotton, oil-seeds, &c. The staple food of the peasantry is *mandua* (*Eleusine corocana*). Potatoes are becoming common. Fruit is very plentiful, and the oranges are of excellent quality. The tea plantations form now an important and valuable feature in the district, but are almost entirely in the hands of European owners. In 1876-77 the gardens covered an area of 2222 acres, yielding 261,060 ℔ of tea. The only other manufacture is the weaving of coarse woollen clothing. The imports from Tibet include beasts of burden, salt, coarse cloths, and Chinese silk. The exports to Tibet are grain, cotton goods, broadcloth, quilts, hardware, tobacco, sugar, spices, dyes, tea, and timber. To the plains of India Kumáun sends grain, clarified butter, tea, ginger, turmeric, red pepper, drugs, spices, bark, honey, wax, a little iron and copper, timber, and wild jungle produce. The roads in the hills are for the most part only bridle-paths, more or less well laid out, but all now well bridged. Except in the *bhábhar* and deep valleys, the climate is mild. The rainfall of the outer Himalayan range, which is first struck by the monsoon, is double that of the central hills, in the average proportion of 80 inches to 40. No winter passes without snow on the higher ridges, and in some years it is universal throughout the mountain tract. Frosts, especially in the valleys, are often severe. Kumáun is occasionally visited by epidemic cholera. Leprosy is most prevalent in the east of the district. Goitre and cretinism afflict a small proportion of the inhabitants. The hill fevers at times exhibit the rapid and malignant features of plague. The *mahámari* pestilence, which was formerly confined to Garhwál, has of late years extended its ravages to Kumáun.

KUMPTA, or COOMPTAH, a town and port in North Kánara district, Bombay, India, 14° 26′ N. lat., 74° 27′ E. long., with a population in 1872 of 10,932. It is the chief commercial town in the district. The average annual value of its trade, which consists chiefly of cotton, spices, and grain, the first coming from Dhárwár district and the rest from the upland country of Kánara, is returned for the five years ending 1873–74 at £481,811 of import and £868,049 of export.

KUNCH, a town in the North-Western Provinces of India, in 25° 59′ N. lat. and 79° 12′ E. long., with a population in 1872 of 14,448 (11,956 Hindus and 2492 Mohammedans). It has markets for cotton and wheat, for molasses, rice, and tobacco, and for salt. The bazaar ways are narrow, tortuous, unmade, undrained, with poor-looking and often ruinous shops; both trade and population are declining.

KUNGUR, a district town of Russia, in the government of Perm, 58 miles south-south-east of the capital of the government, on the Sylva, a tributary of the Tchusovaya. Formerly a blockhouse erected to protect the Russian settlements against the Tartars, it has acquired commercial importance by manufacturing of boots, which are exported in great quantities to the mines of the Ural mountains and to the furthest gold-washings of western and eastern Siberia; more than 1500 men are engaged in this trade. There are also several tallow-melting houses, candle, soap, and glue works, tanneries, and a yard where steamers are made for the navigation of the Kama and its tributaries. The leather of Kungur, which is renowned for its quality, is sold in the eastern provinces of Russia, and reaches Orenburg and Irbit, whilst the tallow is sent to St Petersburg. The wharf on the Sylva is one of the most important in the basin of the Kama. Population, 10,800.

KURDISTAN, or KÚRDISTÁN,[1] is a convenient geographical designation for the lands inhabited by the Kurds, but the name is not used in the country in this general sense, nor indeed would it be technically correct, for in a very small portion only of the region in question is the population exclusively Kurdish.

Geography.—The furthest point to which the Kurds extend north-westward is the junction of the two arms of the Euphrates near Kharpút, in about 39° N. lat. and 39° E. long., while their south-eastern limit may be defined

[1] With reference to the *u* sound in this group of words it is to be observed that *Kurd* is always to be pronounced like the English *gourd*, not as in *curds* and whey.

as the frontier of Luristan, south of Kirmánsháhán, in about 34° N. lat. and 47° E. long. The whole of this space, which is roughly calculated to embrace an area of at least 60,000 square miles, is mountainous, being in fact a section of the great chain which, known in antiquity at one extremity as Taurus and at the other as Zagrus, bisects Asia Minor from west to east, and then turning to the south-east buttresses the great Persian plateau in a series of ranges rising step over step above the valley of the Tigris. Kurdistan thus defined may be divided, according to its physical features, into three separate sections. The first section, stretching from Kharpút to the Persian frontier, has been thus described by Consul Taylor, who resided for many years in the country.

"The general features," he says, "of this tract are high mountains, enclosing fertile valleys and an undulating upland, bounded on the south-west by the Tigris, and intersected at several points by numerous streams having their rise in the northern districts of the Diarbekir pashalic, and emptying themselves into that river. The scenery in the highlands yields to no other portion of Turkey for variety and romantic beauty, while the numerous rivers and streams flow through charming landscapes and thickly wooded valleys, bathing in their course the bases of castles and towns famous in profane and ecclesiastical history."

To supplement Mr Taylor's general description, it may be enough to say that there are three principal ranges running from west to east through this portion of Kurdistan:—(1) The Dújik and Mezoor Dagh (Paryadres and Abus of antiquity, and Mount Simus of Armenian history), a lofty, rugged, and inaccessible range which fills up the entire space between the two arms of the Euphrates, being connected with Anti-Taurus to the westward, and culminating far to the east in the isolated peaks of the greater and lesser Ararat; (2) The Mudikán range, south of the Murád-sú, which is a continuation of the true Taurus, and which is prolonged under the names of Nimrúd Dágh, Sipán Dágh, and Alá Dágh, till it reaches the Persian frontier to the north-east of Lake Van (in this range all the headwaters of the Tigris rise, flowing south under the names of Debeneh-sú, Ambár-sú, Batmán-sú, and the rivers of Arzen and Bohtán, and joining the main stream between Diarbekir and Jezireh); and (3) Mount Masius, or Jebel-Tur, an inferior range, south of the Tigris, which divides Kurdistan from the great Mesopotamian desert.

The second or central division of Kurdistan, which may be regarded as extending north and south from Lake Van to Sulimaníeh, is of a more exclusively mountainous character. With the exception indeed of the districts of Amadíeh, Shekelabád, and Koi-Sanják on the immediate skirts of the Tigris basin, and the open country of Azerbijáu beyond the great range to the south-west of Lake Urumíeh, where the Kurds of the mountains have overflowed into Persia, there is hardly a square mile of level land anywhere to be found. The ranges of this division, which preserve a general direction of north-north-west and south-south-east, are throughout much broken up by transverse ridges, and seem to be tossed about in inextricable disorder, a few peaks, such as the Jebel-Júdí above Amadíeh (which almost certainly represents the Ararat of the Bible) and the Gawár (or Jawár) Dágh near Julamerik in the Hakkári country, rising to a stupendous height, and thus dominating the surrounding mountains, while several large rivers, and especially the Khabúr and the Upper and Lower Záb, running in narrow and precipitous beds, burst at right angles through the gorges of the chain, and descend upon the Tigris valley in a series of cataracts amid scenery of the wildest and most impressive grandeur. The usual elevation of the hills in this part of Kurdistan is not less than 10,000 feet above the level of the sea, while some of the highest peaks reach probably to an altitude of 14,000 or even 15,000 feet.

In the third or southern division of Kurdistan, which includes the Turkish pashalic of Sulimaníeh and the Persian provinces of Ardelán and Kirmánsháhán, the mountain chain diminishes both in height and breadth. The average height of the hills is here only about 5000 or 6000 feet, and the loftiest range, that of the Bend-i-Núh, or Noah's Hill, which forms the southern barrier of the gates of Zagrus,[1] and upon which, according to the tradition of Babylonia, as opposed to the tradition of Assyria, the ark is supposed to have rested, does not exceed an elevation of 8000 feet. The pass also which traverses the range at this point, and conducts from the lowlands of Holwán to the upper plain of Kirrend, is only 10 miles in length. At the foot of the great range on the western side are the fertile plains of Shahrizor, Zoháb, and Ghilán, where rice is extensively cultivated, while on the Persian side, though rocky ridges run out to the eastward both in Ardelán and Kirmánsháhán, the general character of the country is open, and cereals are everywhere produced in extraordinary abundance.

Population.—There are no means of calculating the total Kurd population with even approximate accuracy, for neither in Turkey nor in Persia has a Government census ever been attempted, and the revenue tables which regulate taxation and conscription, and ought therefore to guide inquiry, are wilfully distorted for political purposes to such an extent as to be quite unreliable. From the materials, however, which have been recently collected by the British consular officers employed in Asia Minor, with a view of testing the relative strength of the Mohammedan and Christian populations, it seems pretty clear that the Turkish Kurds exceed one million and a half in number, while the estimates of travellers who have resided in Persian Kurdistan give about 750,000 souls for the aggregate of the tribesmen and sedentary Kurds dwelling along the mountains from Ararat to Kirmánsháhán, together with the scattered colonies of the interior. The following rough table, then, has been compiled from the above sources.

Turkey.

Pashalic of Erzeroum, including sanjaks of Erzingán, Baiburt, and Bayazíd, with Deyrsim mountains	350,000
Pashalic of Diarbekir, with sanjaks of Malatieh and Mardin and dependent tribes	320,000
Pashalic of Betlis, with sanjaks of Músh and Sa'ert, and districts of Mudikán, Sasún, Shirwán, and Northern Bohtán	130,000
Pashalic of Van, with sanjak of Hakkári and nomad tribes of the Arab and Persian frontier	170,000
Pashalic of Kharpút, with part of Deyrsim	130,000
Pashalic of Mosul, including sanjaks of Southern Bohtán, Amadíeh, Rowandiz, and Koi-Sanják, with tribes of Bilbass, Balik, &c.	250,000
Pashalic of Sulimanieh, with dependencies to Baghdad frontier	150,000
Total of Turkish Kurds	1,500,000

Persia.

Kurds of Azerbijáu, including Mikris of Sauj-Bolák, Bilbass of Lahiján, Zerzas of Ushnei, Shekáks, Hyderánli, Jelali, and frontier tribes from Ararat to Sardasht	250,000
Kurdistan Proper or Sinna-Ardelán	120,000
Province of Kirmánsháhán, including tribes of Gurán, Kalhúr, Zengeneh, &c.	230,000
Kurds of Khorásan, at Bujnurd and Kúchán, and scattered communities in Irák	150,000
Total of Persian Kurds	750,000

[1] It is this range, and not the Jebel-Júdí, as is generally supposed, that represents the Nisir of the cuneiform inscriptions, where the ark is said to have rested in the Chaldæan account of the flood; and the same tradition is to be traced in the belief which universally prevailed in Babylonia almost to modern times, that the waters of the great deluge penetrated no farther to the eastward than the "peak of Holwán." See Sachau's *Biruni*, p. 23.

Attempts have been made to classify this Kurdish population as sedentary and nomad, and in connexion with the classification to distinguish between tribal and non-tribal communities; but all such divisions are arbitrary and fallacious, and ought not to be admitted in a statistical account of the nation. No doubt the original Kurdish organization was tribal, and the prevailing habits of the tribes have always been nomadic and pastoral; but such habits are ever liable to be modified by local circumstances, and at the present day it is quite incorrect to suppose that the tribal Kurds are universally pastoral and migratory, while the non-tribal Kurds are sedentary and agricultural. In reality the distinction between living in villages as cultivators and living in tents as shepherds mainly depends on the localities where the tribes happen to be established. The Deyrsimlis, for instance, who inhabit the ranges of Dujik and Mezoor between the two arms of the Euphrates, and who number, according to Consul Taylor's estimate, above 200,000 souls, reside almost exclusively in villages, owing to the severity of their northern climate, while they follow agricultural and pastoral pursuits indifferently. But, on the other hand, the tribes to the south who have easy access to the Mesopotamian plains, prefer a nomadic life, sheltering their flocks and herds in the warm pastures beyond the Tigris during the winter, and driving them up in the summer to feed on the rich herbage of the mountain sides; and the same rule may be held to apply generally throughout Kurdistan, the tribesmen, whose natural instincts lead them to migrate between summer and winter quarters, becoming sedentary only when obstacles, either political or geographical, are placed in the way of their movements. With regard also to the distinction that is sometimes drawn between tribal and non-tribal Kurds, the hypothesis being that the latter, who live in villages and cultivate the soil, are the descendants of the aboriginal peasantry, while the former, who live in tents and support themselves with their flocks, are conquering invaders, the explanation will certainly not hold good. There is in reality no ethnic distinction between the two classes. Tribal Kurds who settle in villages very soon lose their distinctive name, and mix with the peasantry of the neighbourhood, while it constantly happens that a chief of village extraction, either by his individual character or through Government support, founds a new tribe and takes his place among the aristocracy of the nation. It may be added that in respect to the relative importance of the two classes the sedentary Kurds greatly outnumber the nomads, but that they are not so wealthy, nor so independent, nor do they stand nearly so high in popular estimation.

Character.—The Kurds generally bear a very indifferent reputation, a worse reputation, perhaps, than they really deserve. Being aliens to the Turks in language and to the Persians in religion, they are everywhere treated with mistrust, and live as it were in a state of chronic warfare with the powers that be. Such a condition is not of course favourable to the development of the better qualities of human nature. The Kurds are thus wild and lawless; they are much given to brigandage; they oppress and frequently maltreat the Christian populations with whom they are brought in contact,—these populations being the Armenians in Diarbekir, Erzeroum, and Van, the Jacobites and Syrians in the Jebel-Túr, and the Nestorians and Chaldæans in the Hakkári country,—but they are not as a general rule either fanatical or cruel. In the Hakkári country, indeed, they live under ordinary circumstances in perfect amity with the Nestorians, from whom in outward appearance they are hardly distinguishable. It must be added, too, that they are naturally brave and hospitable, and in common with many other Asiatic races possess certain rude but strict feelings of honour. Perhaps the most distinguishing characteristic of the Kurdish chief is pride of ancestry. This feeling is in many cases exaggerated, for in reality the present tribal organization does not date from any great antiquity. In the list indeed of eighteen principal tribes of the nation which was drawn up by the Arabian historian Massoudi, in the 10th century, only two or three names are to be recognized at the present day. A 14th century list, however, translated by Quatremère,[1] presents a great number of identical names, and there seems no reason to doubt that certain families both in Bohtán and Hakkári, which are extant at the present day, can really trace their descent from the Ommeyide caliphs, while the Babán chief of Sulimaníeh, representing the old Sohrans, and the Ardelán chief of Sinna,[2] who also represents an elder branch of the Gurâns, each claim an ancestry of at least five hundred years. There was up to a recent period no more picturesque or interesting scene to be witnessed in the East than the court of one of these great Kurdish chiefs, where, like another Saladin, the bey ruled in patriarchal state, surrounded by an hereditary nobility, regarded by his clansmen with reverence and affection, and attended by a bodyguard of young Kurdish warriors, clad in chain armour, with flaunting silken scarfs, and bearing javelin, lance, and sword as in the time of the crusades.

Language and Religion.—The present Kurdish language which is called Kermánjí—a title difficult to explain—is an old Persian patois, intermixed to the north with Chaldæan words and to the south with a certain Turanian element which may not improbably have come down from Babylonian times. Several peculiar dialects are spoken in secluded districts in the mountains, but the only varieties which, from their extensive use, require to be specified are the Zaza and the Gurán. The Zaza is spoken throughout the western portion of the Deyrsim country, and is said to be unintelligible to the Kermánjí-speaking Kurds. It is largely intermingled with Armenian, and may contain some trace of the old Cappadocian, but is no doubt of the same Aryan stock as the standard Kurdish. The Gurán dialect again, which is spoken throughout Ardelán and Kirmánsháhán[3] chiefly differs from the northern Kurdish in being

[1] See *Notices et Extraits des MSS.*, vol. xiii. p. 305. Of the tribes enumerated in this work of the 14th century who still retain a leading place among the Kurds, the following names may be quoted:—*Guránieh* of Dartang, modern Guráns; *Zengeneh*, in Hamadan hills, now in Kirmánsháhán: *Hasnani* of Kerkuk and Arbil, now in the Deyrsim mountains, having originally come from Khorásán according to tradition; *Sohrieh* of Shekelabad and Tel-Haftún, modern Sohrán, from whom descend the Babán of Sulimaníeh; *Zerzari* of Hinjarín mountains, modern Zerzas of Ushnei (cuneiform pillars of Kel-i-shín and Sidek noticed by author); *Julamerkieh*, modern Julamerik, said to be descended from the caliph Merwán-ibn-Hakam; *Hakkarieh*, Hakkári inhabiting *Zuzan* of Arab geography; *Bokhtieh*, modern Bohtán. The *Rowadi*, to whom Saladin belonged, are probably modern Rewendi, as they held the fortress of Arbil. Some twenty other names are mentioned, but the orthography is so doubtful that it is useless to try to identify them.

[2] The *Sheref-nameh*, a history of the Kurds dating from the 16th century, tells us that "towards the close of the reign of the Jenghizians, a man named Baba Ardilán, a descendant of the governors of Diarbekir, and related to the famous Ahmed-ibn-Merwán, after remaining for some time among the Guráns, gained possession of the country of Shahrizor"; and the Ardelán family history, with the gradual extension of their power over Persian Kurdistan, is then traced down to the Saffavean period.

[3] The Gurán are mentioned in the *Mesalik-el-Absár* as the dominant tribe in southern Kurdistan in the 14th century, occupying very much the same seats as at present, from the Hamadan frontier to Shahrizor. Their name probably signifies merely "the mountaineers," being derived from *gur* or *giri*, "a mountain," which is also found in Zagrus, *i.e.*, *za-giri*, "beyond the mountain," or *Pusht-i-koh*, as the name is translated in Persian. They are a fine, active, and hardy race, individually brave, and make excellent soldiers, though in appearance very inferior to the tribal Kurds of the northern districts. These latter indeed delight in gay colours, while the Guráns dress in the most homely costume, wearing coarse blue cotton vests, with felt caps and

entirely free from any Semitic intermixture. It is thus somewhat nearer to the Persian than the Kermánjí dialect, but is essentially the same language. It is a mistake to suppose that there is no Kurdish literature. Many of the popular Persian poets have been translated into Kurdish, and there are also books relating to the religious mysteries of the Ali-Olláhis in the hands of the Deyrsimlis to the north and of the Guráns of Kirmánsháhán to the south. European scholars too have been assiduous of late years in investigating the various Kurdish dialects. The New Testament in Kurdish was printed at Constantinople in 1857. The Rev. Samuel Rhea published a grammar and vocabulary of the Hakkári dialect in 1872. Lerch, Brugsch, Chodzko, Beresine, Blau, and many others have discussed different branches of the subject in the scientific magazines of the Continent; and quite recently (1879) there has appeared under the auspices of the Imperial Academy of St Petersburg a French-Kurdish dictionary compiled originally by Mons. Jaba, many years Russian consul at Erzeroum, but completed by Ferdinand Justi by the help of a rich assortment of Kurdish tales and ballads, collected by Messrs Socin and Pryne in Assyria. Justi's preface to the dictionary gives a good account of the present state of Kurdish studies in Europe and Asia.

The religion of the Kurds also furnishes a very curious subject of inquiry. The great body of the nation, in Persia as well as in Turkey, are Sunnis of the Shafe'í sect, but in the recesses of the Deyrsim to the north and of Zagros to the south, there are large half-pagan communities, who are called indifferently Ali-Ollahi and Kizzil-básh, and who hold tenets of some obscurity, but of considerable interest. Outwardly professing to be Shí'ahs or "followers of Ali," they observe secret ceremonies and hold esoteric doctrines which have probably descended to them from very early ages, and of which the essential condition is that there must always be upon the earth a visible manifestation of the Deity. While paying reverence to the supposed incarnations of ancient days, to Moses, David, Christ, Ali and his tutor Salmán-el-Farsi, and several of the Shí'ah imams and saints, they have thus usually some recent local celebrity at whose shrine they worship and make vows; and there is, moreover, in every community of Ali-Ollahis some living personage, not necessarily ascetic, to whom, as representing the Godhead, the superstitious tribesmen pay almost idolatrous honours. Among the Guráns of the south the shrine of Baba Yadgár, in a gorge of the hills above the old city of Holwán, is thus regarded with a supreme veneration, while in the family of a certain Syed who resides in the neighbourhood the attributes of divinity are supposed to be hereditary. Similar institutions are also found in other parts of the mountains, which may be compared with the tenets of the Druses and Ansaris in Syria and the Ismaelis in Persia.

Climate, Productions, Fauna, &c.—In a country like Kurdistan, which extends over five or six degrees of latitude, and ranges in altitude from 1500 to 15,000 feet above the sea, there is of course every variety of climate and produce. In the northern part of this region the hills are covered with pine forest, while the valleys abound with walnuts, sycamores, and planes, and all sorts of fruit trees, and in summer the hillsides and uplands are covered with a luxuriant herbage. The winters are here very rigorous, and the tribes, as far as they can, migrate at that season to the plains. In central Kurdistan the pine forests cease and give way to dwarf oak and elms, the mastic, holly, &c., while further to the south large trees almost disappear, and a rough scrub takes their place. A succinct and graphic description of Turkish Kurdistan is given by Consul Taylor in his notes of travel published in the *Geographical Journal* for 1865.

"The modern Turkish province of Kurdistan," he says, "watered by an infinity of noble streams, with a salubrious climate and rich soil, yields to no other province in the empire for the variety and richness of its vegetable and animal produce, while its numerous mountain chains abound in mineral wealth. Among its natural vegetable productions, galls, gum-tragacanth, madder-roots, and the pistachio-nut, from which the natives extract a fine oil used in making soap, are the most important,—the annual value of the export of the former alone being upwards of £35,000. Oleaginous seeds and olive oil are produced in large quantities, and the quality of the former is so superior that it finds its way to many of the northern governments. Sheep's wool was exported in 1863 to the value of £70,000; and mohair, the produce of the Angorah goats, that thrive so wonderfully in the neighbourhood of Jezireh, was eagerly sought after and bought up by native traders from Kaiseríeh and Constantinople in the same period to the amount of £20,000.

"The manufacture of native cotton cloths, shallees made from mohair, and short woollen cloaks is actively pursued; and the shallee, for texture and variety of colour and pattern, shows the extraordinary natural intelligence of the Kurdish workman. Diarbekir is famous itself for its silk piece-goods, similar to those of Aleppo and other parts of Syria, but, from its greater cheapness and durability, more in request among the poorer classes of the mountains between Diarbekir and the Black Sea. Sheep are exported in large quantities from the mountains and desert to Aleppo, Damascus, and Beyrout. and camels, purchased from the Arabs, to Kaiseríeh and other parts of Asia Minor. The uplands and hills abound in several species of polecat, martin, foxes, and wolves, whose furs add considerably in value to the sum total of the export list. A beautiful species of spotted lynx may be included among the former, although it is far more scarce than those enumerated. A rough estimate of the whole annual value of the animal and vegetable produce of the pashalic, whether consumed at home or exported (exclusive of food), will amount to more than £700,000 sterling."

This account is generally applicable to central and southern Kurdistan as well as to the pashalics of Diarbekir and Erzeroum, but it requires to be supplemented in some particulars. The rice and corn which are grown by the Kurds of the Tigris basin and the Persian plains form a very important staple of export, while the hill forests supply charcoal, wild silk, manna, and gum-mastic, in addition to the produce noticed in Consul Taylor's list, to a very large extent; and it may be further noted that along the whole range of mountains from Jezireh to Susa there is an outer ridge of low gypsum hills, which abounds throughout its whole extent with petroleum and naphtha springs. Mineral oils are not at present much appreciated by either Turks or Persians, but in the future of Kurdistan this important source of wealth cannot be left out of account.

With regard to the fauna of Kurdistan a few words must suffice. Neither lions nor tigers are ever found in the mountains, though the former frequent the banks of the Tigris and the latter are common in the Caspian forests. The wild animals of Kurdistan are the leopard and lynx, the wild cat, bear, hyæna, wild boar, wolf, jackal, and fox, the *marál* (or red deer), the roe and hog deer (and fallow deer and antelope on the skirts of the hills), the wild goat (or ibex), the wild sheep (or moufflon), together with badgers, hares, many varieties of the polecat or martin, and the ordinary smaller animals. Of game birds the most remarkable are the *Kebk-i-Derv* (or large partridge, first brought to the notice of naturalists by Consul Brandt), the grey and red-legged partridge, the *Tihoo*, quail, woodcock, and snipe, three varieties of bustard, the grey crane, and wild geese and ducks in abundance.

It has not been found possible to compute the amount of revenue which is raised from the Kurds. Consul Trotter remarks on this subject:—

"The Turkish Kurds are found in almost every possible stage, from that of thorough subjection to the Government (as in many of

coats." The Guráns have for a long period abandoned nomadic habits, and are now almost universally congregated in villages and occupied with the cultivation of the soil, so that in a great part of Kurdistan the name Gurán has become synonymous with an agricultural peasantry, as opposed to the migratory shepherds.

the Diarbekir and Erzeroum villages, where they pay all the regular taxes and are also drawn for the conscription) up to the semi-independent Kurds of Bohtán, of Mudikán, and of the Deyrsim, who never pay taxes except at the rare intervals that the Government is able to occupy their country with a military force, and who have never hitherto, except on very rare occasions, supplied soldiers to the army either regular or irregular."

And, if this uncertain liability to taxation is true of the Kurds of Erzeroum and Diarbekir, it applies equally to the districts of Hakkári and Rowandiz, and to the great tribes such as the Herki, Hartúshi, and Hyderánli, who migrate between Persia and Turkey. In Sulimaníeh, on the other hand, as well as in the Persian provinces of Azerbijan, Ardelán, and Kirmánsháhán, the revenue derived from the Kurdish population is fixed, and may be estimated at £1 per house instead of the £1, 6s. which is the usual Osmanli rate.

Antiquities.—Kurdistan abounds in antiquities of the most varied and interesting character. There is in the first place a series of rock-cut cuneiform inscriptions, extending from Malatíeh on the west to Miyandáb (in Persia) on the east, and from the banks of the Arras on the north to Rowandiz on the south, which record the glories of a Turanian dynasty, who ruled the country of Nairi during the 8th and 7th centuries B.C., contemporaneously with the lower Assyrian empire. Intermingled with these are a few genuine Assyrian inscriptions of an earlier date; and in one instance, at Van, a later tablet of Xerxes brings the record down to the period of Grecian history. The most ancient monuments of this class, however, are to be found at Holwán and in the neighbourhood, where the sculptures and inscriptions belong probably to the Guti and Luli tribes, and date from the early Babylonian period. Excavations at this spot or in the mounds along the course of the Diyáleh, which is the great river of southern Kurdistan, or more especially at Yassin Tepeh, the site of the ancient city of Shahrizor, would probably lead to the discovery of relics cognate with those which have been found in the palaces of Nineveh and Babylon.

Information has also been recently received that a cemetery full of inscribed sepulchral urns has been laid bare by a landslip in the mountains between Sulimaníeh and Kirmánsháhán, and the description is calculated to arouse the liveliest interest, though until the spot has been visited by some European scholar no definite opinion can be given as to the character and antiquity of the remains.

In the northern Kurdish districts which represent the Arzanene, Intilene, Anzitene, Zabdicene, and Moxuene of the ancients, there are also many interesting remains of Roman cities, well worth examining. Arzen, Miyafarikin (ancient Martyropolis), and Sisauronon have already been reported on by Consul Taylor, but there is still abundant room for research, and attention should be especially directed to the ruins of Dunisir near Dara, which Sachau the great Orientalist has recently identified with the Armenian capital of Tigranocerta, a city that has long been the despair of comparative geographers. Of the Macedonian and Parthian periods there are remains both sculptured and inscribed at several points in Kurdistan: at Bisitun, in a cave at Amadíeh, at the Mithraic temple of Kereftú, on the rocks at Sir Púl-i-Zohab near the ruins of Holwán, and probably in some other localities, such as the Bálik country between Lahiján and Koi-Sanják, which have never been visited by Europeans; but the most interesting site in all Kurdistán, perhaps in all western Asia, is the ruined fire temple of Pái Kúlí on the southern frontier of Sulimaníeh, a spot that has been hurriedly visited by two or three European travellers, but never thoroughly examined. Among the debris of this temple, which are scattered over a bare hillside, are to be found above one hundred slabs, inscribed with Parthian and Pehlevi characters, the fragments of a wall which formerly supported the eastern face of the edifice, and bore a bilingual legend of great length, dating from the Sassanian period. Not more than half of the inscribed slabs have as yet been copied, time and labour being required to clear out the other slabs which lie embedded in the earth on the slope of the hill down which they have rolled, and the locality, moreover, being one that cannot be easily examined or even visited, owing to its exposed position among the brigand tribes of the frontier. But it is to be earnestly hoped that, when an opportunity does offer, every fragment of inscription may be recovered, so that it may be possible to reconstruct the entire legend, which, independent of its historical interest, is of special importance as the longest and latest specimen of the lapidary Pehlevi writing. There are also remarkable Sassanian remains in other parts of Kurdistan,—at Salmús to the north, and at Kirmánsháhán and Kasr-i-Shírín on the Turkish frontier to the south; and it is probable that an active search among the hills would discover many similar objects of interest. It may indeed be asserted that there is no region of the East at the present day which deserves a more careful scrutiny and promises a richer harvest to the antiquarian explorer than the lands inhabited by the Kurds from Erzeroum to Kirmánsháhán. Dr Schultz in former times and Consul Taylor more recently have done much to illustrate northern Kurdistan between Van and Diarbekir, but the inner mountains of Bohtán, Hakkári, Rowandiz, and the Bálik country are still almost a "terra incognita," and require careful examination.

History.—With regard to the origin of the Kurds, it was formerly considered sufficient to describe them as the descendants of the Carduchi, who opposed the retreat of the Ten Thousand through the mountains, but modern research ascends far beyond the period of the Greeks. We now find that at the dawn of history the mountains overhanging Assyria were held by a people named *Gútú*, a title which signified "a warrior," and which was rendered in Assyrian by the synonym of *Gardu* or *Kardu*, the precise term quoted by Strabo to explain the name of the Cardaces (Κάρδακες). These *Gútú* were a Turanian tribe of such power as to be placed in the early cuneiform records on an equality with the other nations of western Asia, that is, with the Syrians and Hittites, the Susians, Elymæans, and Accadians of Babylonia; and during the whole period of the Assyrian empire they seem to have preserved a more or less independent political position. After the fall of Nineveh they coalesced with the Medes, and, in common with all the nations inhabiting the high plateaus of Asia Minor, Armenia, and Persia, became gradually Aryanized, owing to the immigration at this period of history of tribes in overwhelming numbers which, from whatever quarter they may have sprung, belonged certainly to the Aryan family.

The *Gútú* or Kúrdu were reduced to subjection by Cyrus before he descended upon Babylon, and furnished a contingent of fighting men to his successors, being thus mentioned under the names of Saspirians and Alarodians in the muster roll of the army of Xerxes which was preserved by Herodotus.

In later times they passed successively under the sway of the Macedonians, the Parthians, and Sassanians, being especially befriended, if we may judge from tradition as well as from the remains still existing in the country, by the Arsacian monarchs, who were probably of a cognate race. Gotarzes indeed, whose name may perhaps be translated "chief of the *Gútú*," was traditionally believed to be the founder of the Gurâns, the principal tribe of southern Kurdistan,[1] and his name and titles are still preserved in a Greek inscription at Bisitun near the Kurdish capital of Kirmánsháhán. Under the caliphs of Baghdad the Kurds were always giving trouble in one quarter or another. In 224 A.D., and again in 293, there were formidable insurrections in northern Kurdistan; and a third time, in 309, the Boide amír, Azad-ad-Dowleh, was obliged to lead the forces of the caliphate against the southern Kurds, capturing the famous fortress of Sermáj, of which the ruins are to be seen at the present day near Bisitun, and reducing the province of Shahrizor with its capital city now marked by the great mound of Yassin Teppeh. The most flourishing period of Kurdish power was probably during the 12th century of our era, when the great Saladin, who belonged to the Rewendi branch of the Hadabáni tribe, founded the Ayubite dynasty of Syria, and Kurdish chiefships were established, not only to the east and west of the Kurdistan mountains, but as far as Khorásán upon one side and Egypt and Yemen on the other. During the Mongol and Tartar domination of western Asia the Kurds in the mountains remained for the most part passive, yielding a reluctant obedience to the provincial governors of the plains, and for the last three or four centuries they have been divided in their allegiance between the Turkish and Persian crowns. After Sultan Selim in 1514 had defeated the army of Shah Ismael, the founder of the Saffavean dynasty, he employed one of his generals, Sultan Hussein Beg of Amadíeh, to recover Shahrizor and its dependencies from Persia; and from that time to the present day the political status has not been materially disturbed. The frontier line indeed bisecting Kurdistan from north to south, which was agreed upon in 1047 A.H., between Sultan Murad IV. and Shah Saffi, after the recovery of Baghdad by the former sovereign, is substantially the same line that was adopted by the Russian and British commissioners who were employed in 1840–42 to mediate between the two Asiatic powers and delimit their respective territories. But in the meantime changes of some moment have occurred in the interior organization of Kurdistan. Both in Turkey and in Persia the independent power of the Kurds has been much curtailed. In Turkey the pashas of Kharpút, Erzeroum, and Diarbekir have been invested with larger powers of control, while the authority of the sultan has been further strengthened by the establishment of Turkish

[1] "The Kalhúr tribe are traditionally descended from Gudarz-ibn-Gío, whose son Roham was sent by Bahman Keiáni to destroy Jerusalem and bring the Jews into captivity. This Roham is the individual usually called Bokht-i-nasser (Nebuchadnezzar), and he ultimately succeeded to the throne. The neighbouring country has ever since remained in the hands of his descendants, who are called Gurâns" (*Sheref-Nameh*, Persian MS.). The same popular tradition still exists in the country, and ΓΩΤΑΡΖΗΣ ΓΕΟΠΟΘΡΟΣ is found on the rock at Bisitun, showing that Gudarz-ibn-Gío was really an historic personage. See *Journ. Roy. Geog. Soc.*, vol. ix. p. 114.

governors at Bayazíd, Van, Betlís, Amadíeh, and Sulimanieh, in succession to the old hereditary Kurdish chiefs. With the tortuous policy, it is true, which is characteristic of the Osmánli race, the Porte has not unfrequently of late years encouraged the development of native strength in various parts of Kurdistan for a time and for certain special purposes; but, when the position of the local magnate has anywhere become one of political danger, the central Government has stepped in and without difficulty has reasserted its supreme authority.

In 1834, for instance, the famous Reshid Mohammed Pasha chastised the Kurds, who had everywhere broken loose from Siwas to Rowandiz, and adopted severe measures of repression, which are still remembered and dreaded. In 1843 again, Beder Khán Beg, who from his patrimonial government of Bohtán had extended his sway over the whole mountain range, and had sworn to exterminate the Nestorian Christians, was crushed immediately that the Porte put forth its strength against him; but the most notable instance of sudden Kurdish aggrandizement and collapse has occurred during the year 1881. Sheikh Obeidullah, chief of the small tribe of Oramar, who resided in a village of the mountains south of Lake Van, had acquired great local influence, owing to the sanctity of his family, but more especially from his own ascetic habits and his personal character. He seems to have really entertained the idea at one time of establishing an independent Kurdish kingdom, concentrating under his own individual authority all the scattered remnants of his race both in Persia and in Turkey. At any rate, having collected a very considerable force of Kurds in the summer of 1880, he suddenly burst in upon the plains of Persia and ravaged Azerbiján to the south of Lake Urumíeh, sweeping the country up to the walls of Maragha on one side of the lake and of Urumieh upon the other. Having been joined by the Zerzas, the Mikris, the Bilbass, and all the tribes of the Persian frontier, it is considered certain that he might have marched on and pillaged Tabriz had he taken full advantage of the panic which followed on the first invasion; but, he having faltered and thus given time for the arrival of Persian reinforcements, the movement, which was at one time most serious, collapsed, and he retired to the mountains. Now the Turkish Government had unquestionably in the first instance encouraged Sheikh Obeidullah's increasing power and aspirations, not with a view of hostility to Persia, but in the hope that the establishment of a fanatical and great independent Kurdish principality about Lake Van would paralyse any movement of the Armenian nation towards the recovery of its liberty. The Porte indeed in all probability still cherishes the idea of thus controlling the action of its Christian subjects, though it has been compelled by the pressure of the European powers, and under the threat of reprisals from Persia, to arrest Sheikh Obeidullah and keep him under surveillance at Constantinople, while measures have been taken to prevent any immediate renewal of disturbances on the frontier.

The policy of the Persian Government towards its Kurdish subjects has been not very dissimilar to the Turkish programme. Aware of the military efficiency of the tribes, the Persian crown as long ago as the time of Nadir Shah transferred a large colony of Shadillú and Zafferanlú Kurds to the Khorásán frontier, where, enjoying the rich lands of Bújnúrd and Kuchán, and strengthened by a line of fortresses, they have ever since been engaged in unceasing conflict with the Turkomans of the Attock, and from whence they afforded invaluable assistance, both in carriage and supplies, to the Russian columns in their late advance into the country of the Akhâls. Persia has also raised several regiments of regular infantry from the Kurdish Shekáks of the north, as well as from the Guráns and Kalhúrs of the south, while the shah has also placed Persian governors over the Kurdish districts south of Lake Urumíeh, and has appointed princes of the blood to administer the more distant and unruly Kurdish provinces of Ardelán and Kirmánsháhán. At present perhaps the only communities among whom a spirit of Kurdish nationality may be said to flourish free from the taint, be it for good or be it for bad, of foreign influence, are the Deyrsimlis of the upper Euphrates and the Hakkáris of central Kurdistan. (H. C. R.)

KURGAN, a district town of western Siberia, in the government of Tobolsk, 352 miles south-south-west of the capital of the province, on the left bank of the Tobol river. It has its name from a lofty tumulus (*kurgan*), close by which a wooden fort was erected in the 17th century. It is situated in a wide steppe, covered with numerous lakes, the inhabitants of which are active in agriculture, cattle-breeding, and cattle grazing, cattle being purchased in the Kirghiz steppe. It is now the chief centre of the region for trade in cattle, tallow, skins, and salt. Population, 6500.

KURILE ISLANDS, a chain of islands to the north-east of Asia, extending for about 795 miles from the southern extremity of the peninsula of Kamchatka to the northern extremity of Yezo, and forming the boundary between the Sea of Okhotsk and the outer ocean. Till 1875 the Little or Northern Kuriles belonged to Russia, and the Great or Southern Kuriles to Japan, but by the treaty of that date they were all recognized as Japanese. The principal islands, beginning at the north, are Shumshu (226 square miles), Paramushir (1135), Onekotan (244), Kharimkotan, Si Musir (161), Matua, Urup (563), Iturup (2656), and Kunashir. Like the peninsula of Kamchatka, the whole chain is of volcanic origin, and several of the islands—Yekarma, Musir, Raikoke, Matua, Iturup—are still centres of volcanic activity. Mr Milne, who cruised among the islands in 1878, counted fifty-two well-defined volcanic peaks, and at least seventeen are known to give off steam. The peak of the island of Alaid, estimated to have an altitude of at least 12,000 feet, had two great eruptions in 1770 and 1793. None of the other eminences exceed 5000 feet in height. As the slopes are for the most part exceedingly regular, the production of the volcanoes must be assigned to a comparatively recent period; and the absence of stratification seems to indicate a continuity of action. The forces at work must have been enormous if, as appears probable, the chain was built up from the bed of the sea. To the east of the islands the "Challenger" expedition found a depth of 27,930 feet. The flora of the Kuriles is poor, especially towards the north; in the southern islands it is similar to that of Yezo. In Kunashir, Urup, and Iturup there are well-wooded portions. Sea-otters, wolves, and foxes are among the wild animals hunted for their skins. Many of the islands are altogether uninhabited, and none have more than the scantiest population. In 1868–70 Knipping estimated the total at from 200 to 300 persons, and since the treaty of 1875 a large number have removed to Saghalien and other parts of Russian territory. Ethnographically the people of the Kuriles are in the main identical with the Ainos of Yezo, those of the northern islands showing the influence of intercourse with Kamchatka. They are quiet, timorous, and well-behaved, do not practise polygamy, and carefully avoid intermarriage between blood relations. The poorer people burn their dead, the wealthier embalm them. Once a year in autumn they hold a great feast. Of a supreme deity they have some indistinct idea, but they sacrifice to the sun, the moon, and the sea, and worship the bear.

The Kurile Islands were discovered in 1634 by the Dutch navigator De Vries. The Russians first learned about them from Japanese traders who visited Kamchatka in 1711; in the following year two Cossacks, Antsniphoroff and Kozuirevskii, crossed over to Shumshu; and in 1766–67 a voyage was made among the islands to collect a fur tax. In 1795 a factory of the Russian American Company was established on Urup. Captain Golovnin was taken prisoner by the Japanese on Kunashir in 1811.

See Krasheninikoff, *Kamtchatka*, Gloucester, 1764; the *Voyages* of Krusenstern and Lapérouse; and Milne's paper in *Geol. Mag.*, 1880.

KURRACHEE, or Karáchi, a district in Sind, India, lying between 23° 34′ and 26° 57′ N. lat., and between 66° 41′ 30″ and 68° 49 E. long., bounded on the N. by Shikárpur, on the E. by the Indus river and Hyderabad district, on the S. by the sea, and on the W. by Baluchistán. The area is 14,091 square miles; and the population in 1872 was 426,722. The district consists of an immense tract of land stretching from the mouth of the Indus to the Baluchi boundary. It differs in general appearance from the rest of Sind, having a rugged, mountainous tract along its western border. The country gradually slopes away to the south-east, till in the extreme south the Indus delta presents a broad expanse of low, flat, and unpicturesque alluvium. Besides the Indus and its mouths, the only river in the district is the Habb, forming the boundary between Sind and Baluchistán. The Manchhar Lake in Sehwán subdivision forms the only considerable sheet of water in Sind. The hot springs at Pír Mangho are 6 or 7 miles north of Kurrachee town.

In 1872 the population was 426,722 (males 242,516, and females 184,206)—the Hindus numbering 73,304, and the Mohammedans 348,586. Eight towns had a population exceeding 2000:—Kurrachee, 56,753; Kotri, 7949; Sehwán, 4296; Bubak, 5703; Dadu, 3357; Tatta, 7951; Mirpur Batoro, 2846; and Keti-Bandar, 2199.

In Kurrachee subdivision cultivation exists only on a few isolated spots, and depends upon wells, springs, or natural rainfall. Here the chief crops are *joár*, *bájra*, barley, and sugar-cane. In Jerruck and Sháh-bandar, where numerous canals carry the waters of the Indus through the alluvial flats, rice forms the staple crop; but wheat, sugar-cane, millets, cotton, and tobacco are also grown. In the barren hills of Kohistán, agriculture is practically unknown; and the nomad population devotes itself almost entirely to grazing cattle in the southern plains. The district trade is centred in Kurrachee town, the staple exports consisting of cotton, wool, and grain. Extensive salt deposits of the purest description occur on the Sirganda creek, a branch of the Indus. Sea fisheries form an important industry. The pearl oyster is found at several places along the coast, but the pearls are of inferior size and quality. The Indus valley line of the Sind, Punjab, and Delhi Railway runs from Kurrachee to Kotri within the district a distance of 106 miles. The administration is conducted by a collector-magistrate, assisted by several deputies. The total imperial revenue in 1873–74 amounted to £139,079, exclusive of £52,222 derived from the canals. Education in 1873–74 was afforded by forty-nine schools, attended by 3167 pupils. Kurrachee town and neighbourhood, being open to the sea-breeze, are said to possess the healthiest climate in Sind. Fevers prevail at the setting in of the cold season, and in the hot weather external inflammations, ulcers, and skin diseases are very troublesome. Cholera occasionally appears in an epidemic form. The rainfall is slight and fluctuating, the average hardly exceeding 5 inches per annum.

KURRACHEE, or KARÁCHI, the chief town of Sind, India, and a large seaport, situated at the extreme northern end of the Indus delta, in 24° 51′ N. lat. and 67° 4′ E. long. The city is almost entirely a creation of British rule, its extensive commerce, splendid harbour works, and numerous flourishing institutions having all sprung up since the introduction of settled institutions; and the architecture of the town is essentially modern and Anglo-Indian. Before 1725 no town whatever appears to have existed on its site; but about that time some little trade began to centre upon the convenient harbour, and the silting up of Sháhbandar, the ancient port of Sind, shortly afterwards drove much of its former trade and population to the rising village. Under the Kalhora princes, the khán of Khelát obtained a grant of the town, but in 1795 it was captured by the Talpur Mírs, who built the fort at Manora, at the entrance to the harbour. They also made considerable efforts to increase the trade of the port, and at the time of the British acquisition of the province the town and suburbs contained a population of 14,000.

The census of 1872 returned the inhabitants of Kurrachee, including the cantonment, at 56,753, viz., Mohammedans, 29,156; Hindus, 23,404; Christians, 3397; and "others," 796. The municipal revenue of the town in 1874 amounted to £22,596, and the expenditure to £20,142. Trade has immensely developed of late years. In 1843–44 the total value of the trade was returned at £122,160, that of the exports being only £1010. In 1873–74 the value of the trade amounted to £3,507,684, viz., imports £1,481,765 and exports £2,025,919. Up to 1851 only one English sailing ship had entered Kurrachee harbour, steamers and large vessels having to anchor outside and discharge by lighters. In 1853 the construction of the Napier Mole or causeway, 3 miles long, connecting the town with Kiamári island, and the subsequent extensive harbour improvements carried out between 1869 and 1873, at a cost of £450,000, have enabled vessels of any size to enter the harbour. In 1847–48 the number of vessels which entered the harbour was 891, all native craft, of a total burthen of 30,509 tons. In 1873–74 the vessels visiting the harbour numbered 913, of a total burthen of 161 284 tons.

KURSK, a government of European Russia conterminous with those of Tchernigoff, Orel, Voronezh, Poltava, and Kharkoff, and estimated to have an area of 17,417 square miles. The surface is irregular and even hilly, but the highest point (near the town of Tim) does not exceed 1016 feet of absolute elevation. Cretaceous and Eocene rocks prevail, and chalk, iron-stone, mill-stones, potter's clay, and tripoli are among the economic minerals. The rich black earth of the government makes it one of the best agricultural districts of the country. No fewer than four hundred streams are counted within its borders, but none of them are of any service as waterways. To the Dnieper system belong the Seim, the Vorskla, the Psel, and the Tuskor; to the Don the Northern Donets and its tributaries. Besides oats, which form the staple crop, wheat, rye, potatoes, and buckwheat are largely grown. Beeswax is sent in considerable quantities to Moscow. Horse, cattle, and sheep breeding is on the decline. The manufacturing industries—wool dressing, distillation, tanning, linen weaving—are gaining ground. Wool-spinning and the making of woollen sashes are so generally carried on by the peasant women as to be matter of commercial importance.

The government is divided into fifteen districts—Kursk, Byelgorod, Graivoron, Dmitrieff, Korotcha, Lgoff, Novuii Oskol, Oboyan, Putivl, Ruilsk, Staruii Oskol, Sudzha, Tim, Phatezh, Shtchigrui. The places with more than 5000 inhabitants are Kursk, Borisovka (30,000), Sudzha (with suburbs, 18,000), Byelgorod (16,097), Miropole (10,754), Kholka Mikhaielovka (10,000), Ruilsk (9445), Staruii Oskol (7091), Putivl (7046), Oboyan (6322), Korotoha, and Phatezh. The population of the government was 1,954,807 in 1870, chiefly Great Russians, but considerably modified by the Little Russian element. About 17 miles from the chief town, in a thickly-peopled district, is the site of the Korennaya fair, formerly the greatest of those in South Russia, and still with an annual trade valued at £900,000. It takes its name from an image of the virgin found at the root (*koren*) of a tree, and yearly carried in solemn procession from Kursk to the spot of its discovery. The Kursk district contains more than sixty old town sites; and barrows (*kurgans*) are extremely abundant. Of the latter many have been destroyed to furnish manure for the soil, but not a few have been examined by such investigators as Professor Zamokvasoff (see the publications of the Statistical Committee of Kursk).

KURSK, the chief town of the above government, is situated 333 miles south of Moscow, at the confluence of the Kur with the Tuskor, and forms the meeting place of the railways from Moscow, Kieff, and Kharkoff. The inhabitants number more than 30,000, or including the suburbs 45,000. Orchards and nursery gardens are among their chief means of subsistence, and gardeners from Kursk are numerous in the neighbouring governments. The leather works are the most extensive of the industrial establishments. Though many of the public buildings of the town are constructed on a large scale, it is enough to mention the cathedral of the Resurrection, dating from 1733, the cathedral of St Sergius (1762), and the Bogoroditskii monastery.

Kursk was already in existence in 1032. The defence of the town from an incursion of the Polovtsi is celebrated in *The Triumph of Igor*, an epic which forms one of the most valuable relics of early Russian literature. Down to the close of the 18th century the citadel, defended by the two rivers and a ditch, was a place of considerable strength; the remains are now comparatively few. The rank of government town was bestowed on Kursk in 1779.

KUSTENDJE, or KÜSTENDJIE, a seaport of Roumania on the coast of the Black Sea, 140 miles east of Bucharest, the terminus of the railway from Tchernavoda on the Danube, and the principal outlet for the produce of the Dobrudja. The harbour is well defended from the north winds, but those from the south, south-east, and south-west prove sometimes highly dangerous. Of the exports (valued at £217,828 in 1880) the chief are cereals, wool, skins, and cattle. Since the incorporation of the Dobrudja with Roumania in 1878 Kustendje gives its name to a province.

Kustendje is the Constantiana which was founded in honour of Constantia, sister of Constantine the Great. It lies at the seaward end of the Great Wall of Trajan, and has evidently been surrounded by fortifications of its own. In spite of damage done by railway contractors (see Henry C. Barkley, *Between the Danube and the Black Sea*, 1876) there are considerable remains of ancient masonry—walls, pillars, &c. A number of inscriptions have been found in the town and its vicinity which show that Tomi, the place of Ovid's banishment, must have been only a little way off.

In regard to the Kustendje inscriptions in general, see Allard, *La Bulgarie Orientale*, Paris, 1866; Desjardins in *Ann. dell' istit. di corr. arch.*, 1868; *Corpus inscript. lat.*, vol. iii.; and a paper on Weickum's collection in *Sitzungsbericht* of the Munich Academy, 1875.

KÜSTRIN, or CÜSTRIN, a town and fortress of the first rank in the circle of Königsberg-in-der-Neumark, in the government district of Frankfort, Prussia, is situated at the confluence of the Oder and Warthe, about 51 miles north-east of Berlin by rail. It consists of the town proper within the strong fortifications, a suburb on the left bank of the Oder, and one on the right bank of the Warthe. There are bridges over both rivers. Küstrin carries on several minor manufactures, and there is some shipping in the rivers. The population in 1875 (including the garrison) was 11,227.

About 1250 a town was erected on the site of Küstrin, where a fishing village originally stood. From 1535 till 1571 it was the residence of the margrave of Brandenburg-Küstrin, who died without heirs. Küstrin was the prison of Frederick the Great when crown-prince, and the scene of the execution of his friend Katte.

KUTAIAH, KUTAYA, or KIUTAHIA, the chief town of a sandjak in the vilayet of Khudavendikiar, Asia Minor, is situated on the Pursak, an affluent of the Sakaria, the ancient Sangarius. The town lies at an important point of the great road across Asia Minor from Constantinople to Aleppo. It has a busy trade, and a population variously estimated at from 40,000 to 60,000. Kutaiah has been identified with Cotiæum.

KUTAIS, a town of the Caucasus, Russia, capital of the province of same name, 60 miles east from Poti, and 4 miles from the Rion station of the railway between Poti and Tiflis. It is one of the oldest towns of the Caucasus; Procopius mentions it under the name of Kotatision. Persians, Mongolians, Turks, and Russians have again and again destroyed the town and its fortress. In 1810 it became Russian. It is situated now on both banks of the Rion river, which is spanned by an iron bridge. Its most remarkable building is the ruined cathedral, erected in the 11th century by the Bagratides, which is the most important representative of Georgian architecture. The fort Uhimerion, mentioned by Procopius, is now but a heap of ruins. During recent years Kutais has acquired some importance, and its population is rapidly increasing; it is now 12,000. The inhabitants make hats and silks, and trade in agricultural produce and wine. On the right bank of the Rion is a Government model-garden, with a model-farm for promoting the improvement of gardening, for which the warm and moist district of Imeritia is well adapted.

KUTTENBERG (in Czech, *Kutná Hora*), chief town of an official district in central Bohemia, Austria, is situated on a small stream in a fertile region, about 180 miles north-west of Vienna by rail. It consists of the town and four suburbs, and among its buildings rich in historical and architectural interest are the Gothic five-naved church of St Barbara, begun in 1368 and not yet finished, several other churches, the Wälscher Hof, formerly a royal residence and mint, the seminary, formerly a bishop's seat, and the Gothic town-house. The manufactures include starch, rape-seed oil, beer, sugar, brandy, and liqueurs; and there are various mills, and calico printing and wool-spinning establishments. The mines in the neighbourhood, discovered in 1237, used formerly to yield silver; now they give only copper and lead. The population in 1870 was 12,747.

KUTY, a municipal town in the Austrian province of Galicia, lies 20 miles south-east of Kolomea, and on the left bank of the Czeremosz, which here forms the boundary between Galicia and Bukowina, in 48° 16′ N. lat., 25° 10′ E. long. The trade, especially in prepared leather, is chiefly with Hungary and the northern or Moldavian portion of Roumania. The neighbourhood of Kuty is picturesque and mountainous, and has productive salt springs. Population 8579, mostly of Armenian, Ruthenian, Polish, and Jewish extraction. Kuty formerly belonged to the old province of Ruthenia, in the kingdom of Poland.

KUZNETSK, a district town of Russia, in the government of Samara, situated on the railway between Samara and Penza, 158 miles west of the former. In the 18th century it was but a village peopled by smiths (whence its name), and it is through this trade that it has acquired its importance. The majority of its 15,000 inhabitants are engaged in the manufacture of agricultural implements, exported to a large amount, whilst others are employed in tanneries,—the black sheep skins of Kuznetsk being widely renowned in Russia,—and in the manufacture of leather and wooden wares, which last are largely exported to the southern steppe provinces and to the Caucasus.

KYOUK-HPYÚ, a district in British Burmah, lying between 18° 55′ and 19° 22′ N. lat., and 93° 25′ and 94° E. long. It consists of, first, a strip of mainland along the Bay of Bengal, extending from the An Pass, across the main range, to the Ma-í river, and, secondly, the large islands of Ramri and Man-oung, with many others to the south, lying off the coast of Sandoway. The mainland in the north and east is highly mountainous and forest-clad, and the lower portion is cut up into numerous islands by a network of tidal creeks. Between the mainland and Ramri lies a group of islands separated by deep, narrow, salt-water inlets, forming the north-eastern shore of Kyouk-hpyú harbour, which extends for nearly 30 miles along Ramri in a south-easterly direction, and has an average breadth of 3 miles. The principal mountains are the Arakan Yomas, which send out spurs and sub-spurs almost to the sea-coast. The An Pass, an important trade route, rises to a height of 4664 feet above sea-level. The Dha-let and the An are navigable by large boats 25 and 45 miles respectively. Above these distances they are mere mountain torrents. Large forests of valuable timber cover an area of about 650 square miles. Kyouk-hpyú contains numerous "mud volcanoes," from which marsh gas is frequently discharged, with occasional issues of flame. The largest of these is situated in the centre of Cheduba Island. Earth-oil wells exist in several places in the district. The oil when brought to the surface has the appearance of a whitish-blue water, which gives out brilliant straw-coloured rays, and emits a strong pungent colour. Limestone, iron, and coal are also found.

In 1872 the population was 144,177 (males 73,056 and females 71,121):—Buddhists, 129,702; Mohammedans, 3920; Hindus, 185; Christians, 47; "others," 10,323. The largest town is Ramrí, with a population in 1877 of 4028. Kjouk-hpyu, the headquarters, situated on Ramrí Island, has 2620. Out of a total area of 4309 square miles, no less than 3740 are returned as absolutely uncultivable, and in 1876–77 only 165 square miles were under tillage. The principal crops are rice, sugar-cane, *dhaní*, and tobacco. The manufactures consist of silk and cotton cloth, indigo, salt, pottery, coarse sugar, and sesamum oil. The total imperial and provincial revenue in 1876–77 was £43,454, besides a local revenue derived from port and municipal funds, &c.

L

L represents probably the same sound in all alphabets. That sound used to be called a "liquid," in which class *m*, *n*, and *r* were included. This arrangement was unsatisfactory so far as *m* and *n* are concerned, for they have nothing common in their formation with the others. But *r* and *l* are very closely akin. They are both dentals —or more accurately front palatals—produced by raising the point of the tongue to the front part of the palate, immediately behind the gums. They differ in this: for *r* a small aperture is left over the tip of the tongue by which the air escapes; but for *l* the tongue reaches the top of the palate, but does not rest (as for *r*) against the sides of the mouth, and the voice escapes laterally by these side-apertures. The slightness of the difference in the positions of the mouth for these two sounds explains their exchangeableness. Perhaps the most remarkable variation of the *l* sound is that which is heard in Welsh and denoted by *ll*, in such words as Llanberis, Llangollen, &c. An Englishman commonly sounds this as *thl*, which is certainly not right. But the best authorities on phonetics are not agreed as to the precise nature of the sound. Mr Ellis thinks that it is produced by laying the left side of the tongue against the whole of the palate, and then forcibly ejecting the breath along the right side. But he admits that the sound thus produced differs very little from a voiceless or surd *l* (the common *l* is sonant), which stands therefore to *l* in the same relation as *f* does to *v*, or *wh* (really *hw*) to *w*. A simpler modification of the *l* sound is that heard in the Italian "gli" or in the Spanish "llano"; it is formed by raising the middle part of the tongue to the roof of the mouth, not the point against the front part of the palate, as for the ordinary *l*.

The peculiar nature of the *l* sound renders it apt to fall out before consonants with which it is inconsistent; this is specially seen in French plurals, such as "chevaux" from "cheval." It is also common, but sporadic, in English; *e.g.*, in "walk," "talk," "palm," "alms," "half," "would," &c. As is frequently the case with such vanishing sounds, it has sometimes intruded through false analogy in words with which it has nothing to do, *e.g.*, in "could" (Old English "coude"), and rather strangely in some words of Latin origin, *e.g.*, participle, principle. The form of the letter L has varied slightly, but has always consisted of two straight lines at an angle. In Greek the form was generally Λ; and this has been preserved in the Cyrillic and Russian alphabets. But in the western Greek alphabet the form was generally ∠; and this appears in old Roman inscriptions, passing by degrees into the right angle with which we are familiar.

LA BADIE, LABADISTS. Jean de la Badie, a noted Pietist leader in the 17th century, was the son of Jean Charles de la Badie, governor of Guyenne; he was born in the town of Bourg not far from Bordeaux, on the 13th of February 1610, and died in Altona, on the 13th of February 1674. He was sent along with two brothers to the Jesuit school at Bordeaux, where his talents attracted the attention of his teachers, and they secured him for their order against the wishes of his parents. In 1626 he began to study philosophy and theology, and in due time made his profession. From a study of the Bible, of Augustine, Bernard, and the mystics, he was led to hold somewhat extreme views about the efficacy of prayer and the direct influence of the Holy Spirit upon believers, and adopted Augustinian views about grace, free will, and predestination, which brought him into collision with his order. The result was that he resigned and was separated from the Jesuits on the plea of ill health. He then became a preacher to the people, and was encouraged by his bishop to devote himself to this work. The study of Calvin's *Institutes*, however, taught him that he had more in common with the Reformed than with the Roman Catholic Church, and after various adventures he joined the Reformed Church of France at Montauban in 1650. His fame had preceded him, and his accession to the ranks of the Protestants was deemed a great triumph; no such man since Calvin himself, it was said, had left the Roman Catholic Church. He was called to the pastorate of the church at Orange on the Rhone, and at once became noted for the severity of the discipline he exercised. He set his face zealously against dancing, card-playing, and worldly entertainments. The unsettled state of the country, recently annexed to France, compelled him to leave Orange. He accepted a call to the French church in London, but did not stay there long; and after various wanderings he at length settled at Middelburg, where he was called to be pastor to the French-speaking congregation. His peculiar opinions were by this time (1666) well known, and his congregation and himself at once found themselves in conflict with the ecclesiastical authorities. Various "classes" and synods met and discussed the "seditious sermons and new and erroneous doctrine which De la Badie had preached in various of our churches before he had been inducted at Middelburg," and the result was the establishment of a separate church by De la Badie and his followers. He had gathered round him some enthusiastic disciples, Peter Yvon at Montauban, Peter Dulignon, Francis Menuret, and more important than any Anna Maria v. Schürman, whose book *Eucleria* is perhaps the best exposition of the tenets of her master. At Middelburg, at the head of his separatist congregation, De la Badie developed his views for a reformation of the Reformed Churches:—the church is a communion of holy people who have been born again from sin; baptism is the sign and seal of this regeneration, and is to be administered only to believers; the Holy Spirit guides the regenerate into all truth, and the church possesses throughout all time those gifts of prophecy which it had in the ancient days; the community at Jerusalem is the continual type of every Christian congregation, therefore there should be a community of goods, the disciples should live together, eat together, dance together; marriage is a holy ordinance between two believers, and the children of the regenerate are born without original sin; marriage with an unregenerate person is not binding. The life and separatism of the community brought them into frequent collision with their neighbours and with the magistrates of Middelburg, and in 1670 they accepted the invitation of the princess Elizabeth, abbess of Herford in Westphalia, to take up their abode within her territories, and settled down in Herford to the number of about fifty. Not finding the rest they expected, however, they migrated to Altona in 1672, where they were dispersed on the death of the leaders. Small communities also existed in the Rhineland, and a missionary settlement was established in New York.

See H. van Berkum, *De Labadie en de Labadisten*, Sneek, 1851; Goebel, *Gesch. d. Christl. Lebens in der rheinisch-westphälischen Kirche*, Coblentz, 1852; Heppe, *Geschichte des Pietismus*, Leyden, 1879; Ritschl, *Geschichte des Pietismus*, vol. i., Bonn, 1880; and especially Peter Yvon, *Abrégé précis de la vie et de la conduite et des vrais sentiments de feu Mr de Labadie*, and Anna Maria v. Schürman, *Eucleria*, Altona, 1673, 1678.

LABARUM, the sacred military standard of the early Christian Roman emperors, was first adopted by Constantine the Great after his miraculous vision in 312, although, according to Gibbon, he did not exhibit it to the army till 323. The name seems to have been known before, and the banner itself was simply a Christianized form of the Roman cavalry standard. Eusebius (*Life of Const.*, i. 31) describes the first labarum minutely as consisting of a long gilded spear, crossed at the top by a bar from which hung a square purple cloth, richly jewelled. At the upper extremity of the spear was fixed a golden wreath encircling the sacred monogram, formed of the first two letters of the name of Christ. In later banners the monogram was sometimes embroidered on the cloth. A special guard of fifty soldiers was appointed to protect the sacred standard. The derivation of the word labarum is disputed; modern scholarship inclines to recognize its etymon in the Basque *labarva*, signifying standard. An illustration of a labarum is given under the heading FLAG (vol. ix. p. 278, fig. 5, A).

LABEO, MARCUS ANTISTIUS (*cir.* 50 B.C.–18 A.D.), was the son of Pacuvius Antistius Labeo, a jurist of minor note, who caused himself to be slain after the defeat of his party at Philippi. A member of the plebeian nobility, and in easy circumstances, the younger Labeo entered early upon public life, and soon rose to the prætorship; but his undisguised antipathy to the new régime, and the somewhat brusque manner in which in the senate he occasionally gave expression to his republican sympathies—what Tacitus (*Ann.* iii. 75) calls his *incorrupta libertas*—proved an obstacle to his advancement, and his rival, Ateius Capito, who had unreservedly given in his adhesion to the ruling powers, was unfairly promoted by Augustus to the consulate, when, in ordinary course, the appointment should have fallen to Labeo; the result was that, smarting under the wrong that was done him, he declined to accept the office when it was offered to him in a subsequent year (Tac., *Ann.* iii. 75; Pompon. in fr. 47, *Dig.* i. 2). From this time he seems to have abandoned politics, and devoted his whole time to jurisprudence, with which his name is much more prominently connected. His training in the science had been derived principally from Trebatius Testa, although he had also diligently attended the public audiences of most of the more eminent lawyers of the later years of the republic. To a profound knowledge of the law as he had received it from them he added a wide general culture, devoting his attention specially to dialectics, philology (*grammatica*), and antiquities, as valuable aids in the exposition, expansion, and application of legal doctrine (Gell., xiii. 10). Capito, in a letter preserved by Gellius (xiii. 12), says of him "nihil haberet nisi quod justum sanctumque esse in Romanis antiquitatibus legisset;" and this has sometimes been thought irreconcilable with the statement of Pomponius (fr. 47, *Dig.* i. 2) that in law he was an innovator. But the observations of Capito refer to what he calls Labeo's absurd craze for freedom—his horror of anything out of the old current of constitutional practice (which had led him, as Capito relates, into the ridiculous extreme of indignantly resenting, as unauthorized, the courtesy of a tribune who had ordered an officer simply to summon him to answer to a complaint, instead of apprehending him). In his jurisprudential teaching and advising there was none of this dogged indisposition to deviate from the paths of his predecessors. It was the characteristic of his rival Capito to stand as much as possible within the old lines,—"in his, quæ ei tradita fuerunt, perseverabat" (Pomp. in fr. 47, *Dig.* i. 2); that of Labeo was, with the aid of his dialectic, philology, and antiquities, to dissect a received doctrine so as to reach its innermost *ratio*, and from this to start afresh, and give the doctrine a more accurate expression and a variety of new developments. His success in this new method is attested by the position he took among his contemporaries, and the reputation in which he was held by his successors. Down to the time of Hadrian his was probably the name of greatest authority; and the fact that several of his works were abridged and annotated by later hands testifies to the estimation in which they were held by practitioners. While Capito is hardly ever referred to, the dicta of Labeo are of constant recurrence in the writings of the classical jurists, such as Gaius, Ulpian, and Paul; and no inconsiderable number of them were thought worthy of preservation in Justinian's *Digest*. Labeo gets the credit of being the founder of the Proculian sect or school, while Capito is spoken of as the founder of the rival Sabinian one (Pomponius in fr. 47, *Dig.* i. 2). It is doubtful whether this statement is quite accurate. Labeo certainly taught in some way or other; for it is recorded of him that he devoted six months of the year to giving professional advice and instructing his pupils in Rome, while the other six he spent in literary work at his country seat. But the lecturing *stationes* of which Gellius speaks (xiii. 13) had not by that time been established, and it is probable that the real founders of the two *scholæ* were Proculus and Sabinus, followers respectively of the methods of Labeo and Capito. Such conjunctions (in reference to peculiar doctrines of the schools), as "Proculus et Pegasus," "Sabinus et Cassius," are very frequent; but the name of Labeo or Capito in conjunction with another is of the rarest occurrence. There is not a single case in the texts in which the latter is credited with the introduction of a doctrine of the Sabinians, and only one or two in which Labeo is spoken of as the author of a doctrine of the other school.

Labeo's most important literary work was the *Libri Posteriorum*, so called because published only after his death. So far as can be judged, they contained a systematic exposition of the common law in at least forty books, after the order of the commentaries of Q. Mucius Scævola. They seem to have been epitomized by Javolenus, who was a leader of the Sabinian school; and numerous excerpts from them, some from the original, others from the epitome, are preserved in Justinian's *Digest*. His *Libri ad Edictum*, frequently referred to by Ulpian and Paul, as well as by earlier writers, embraced a commentary, not only on the edicts of the urban and peregrine prætors, but also on that of the curule ædiles. His *Probabilium* (πιθανῶν) *Lib. VIII.*, a collection of definitions and axiomatic legal propositions, seem to have been one of his most characteristic productions; they were abridged and annotated by Paul, and occasionally criticized by him with some severity. Amongst the writings of Labeo which we know only by report were *Commentarii de jure pontificio*, *Commentarii ad XII. Tabulas*, *Libri Epistolarum*, and *Libri Responsorum*. See Van Eck, "De vita, moribus, et studiis M. Ant. Labeonis," Franeker, 1692, in Oelrichs's *Thes. Nov.*, vol. i.; Mascovius, *De Sectis Sabinianor. et Proculianor.*, 1728; Dirksen, "Ueber die Schulen der Röm. Juristen," in his *Beiträge zur Kunde des Röm. Rechts*, 1825; Pernice, *M. Antistius Labeo,—Das Röm. Privatrecht im ersten Jahrhunderte der Kaiserzeit*, 1st and 2d vols., 1873 and 1878.

LABERIUS, DECIMUS (105–43 B.C.), a Roman knight and a prolific writer of *mimi*, or farces, was born about 105 B.C. Of his life we know little; but from the scattered notices of him in the old writers we can gather that he was a man of caustic wit, who wrote his pieces for his own pleasure, and enjoyed some consideration among his contemporaries. In 45 B.C. Julius Cæsar, promising him 500,000 sesterces, ordered him to appear in one of his own mimi in a public contest with the actor Publius or Publilius Syrus. Laberius pronounced a dignified prologue on the degradation thus thrust on his sixty years, and in the course of his acting directed several sharp allusions against the dictator. Cæsar awarded the victory to Syrus, but restored Laberius to his equestrian rank, which he had forfeited by appearing as a mimus. Laberius died at Puteoli in January 43 B.C. He was the chief of those who introduced the mimus into Latin literature towards the close of the republican period. He seems to have been a man of learning and culture, but his pieces did not escape the coarseness inherent to the class of literature to which they belonged; and Aulus Gellius (xvi. 7, 1) accuses him of extravagance in the coining of new words. The titles of forty-four of his mimi have been preserved; and what fragments remain have been collected by Ribbeck in his *Comicorum Latinorum Reliquiæ*, 1855, 2d ed. 1873.

LABIENUS, Titus, Julius Cæsar's proprætor in Gaul, first attracted his leader's favour in a civil capacity. In 63 B.C. he appeared at Cæsar's instigation as the prosecutor of Rabirius for perduellio; and in the same year, being tribune of the plebs, he carried a plebiscitum that indirectly secured for Cæsar the dignity of pontifex maximus. The military talent of Labienus was respectable, though not brilliant; but of all the officers trained under Cæsar in his Gallic campaigns he was the most trusted. His chief exploits in Gaul were the defeat of the Treviri under Indutiomarus in 54 B.C., his expedition against Lutetia (Paris) in 52 B.C., and his victory over Camulogenus and the Ædui in the same year. In 50 B.C. he was left in command of Gallia Cisalpina, while Cæsar returned to the north; but, on the outbreak next year of the civil war between Cæsar and Pompey, Labienus was one of the first to desert Cæsar. His motive is perhaps to be looked for, not so much in a deliberate calculation of chances, as in an overweening sense of his own importance, not adequately recognized by Cæsar. He was rapturously welcomed on the Pompeian side; but he brought no great strength with him. The veterans remained true to Cæsar, and even the town of Cingulum, on which Labienus had lavished much of his wealth, opened its gates to the future dictator. The ill fortune of Labienus under Pompey was as marked as his success had been under Cæsar's auspices. From the defeat at Pharsalia to which he had contributed by affecting to despise his late comrades, he fled to Africa. There, indeed, he was able by mere force of numbers to inflict a slight check upon Cæsar at Ruspina in 45 B.C.; but when the defeat at Thapsus ruined the Pompeian party in Africa, Labienus withdrew to join the younger Pompey in Spain. At Munda, on March 17, 45 B.C., he again met Cæsar, and in the ensuing defeat of his party fell sword in hand.

See the authorities referred to under CÆSAR; and Baron Carra de Vaux, *Expédition de Labienus contre Lutèce*, Paris, 1876.

LABOUR AND LABOUR LAWS. With some exceptions in the case of labour imposed as a punishment for crime or as a test or condition of aid to the poor under the poor laws, the labour here to be spoken of is labour by freemen,—that is to say, labour by persons having the primary right to choose whether they will labour or not, and to choose the terms on which they will consent to labour, if labour be their choice. Further, although voluntary labour of men is undertaken from various motives,—for their own profit, for self-preservation, for love, from public or private duty apart from the prospect of immediate gain,—the labour now treated of relates especially to that rendered to others for pecuniary reward, for money or money's worth,—in other words, for *wages*. This class of persons consists of all those who serve their employers by hand labour, whether rude or skilled, in any branch of productive industry or manufacture, including agriculture, mining, and the like, as well as the processes by which skilled artisans elaborate raw material to its final destination and use. Purely domestic service and the service of shopmen and clerks, as well as the work of contractors for the service of others, who do not work with their own hands, is excluded from specific notice here. The labourers falling within the class thus popularly described comprise upwards of a moiety of the present adult male population of the British Isles.

Although this article deals with free labour, the present position of the free labourer cannot be rightly understood without a glance at past history, and some attention to the distinction between voluntary and forced labour.

In every age and country, until times comparatively recent, compulsory personal servitude appears to have been the lot of a large, perhaps the greater, portion of mankind.[1] The slave was a man who had been captured in war or procured by purchase, or who had surrendered himself to the dominion of another as the alternative of starvation or in discharge of a debt, and it was his hands that tilled the soil, dug the mine, wove the cloth, and built the walls in ancient Greece and Italy. It has been asserted that in the early state of Rome the proportion of slaves, who were valued as property, was more considerable than that of hired servants, who could be computed only as an expense. It was thought more for the interest of the merchant or manufacturer to purchase than to hire his workmen, and in the country slaves were employed as the cheapest and most laborious instruments of agriculture. On the other hand, it has been inferred from our scanty materials that, as the Roman empire extended, the agricultural labourer and the citizen in Spain, Gaul, and Britain, in Syria and Egypt, maintained himself, as in the present day, by his own labour and that of his household, without the aid of any slave; but this is probably too favourable a picture. In the decline of the Roman empire, Roman captives were taken home by the northern conquerors. The useful craftsmen—smiths, carpenters, workmen in the metals, shoemakers, tailors, dyers, and others—employed their skill for the use or profit of their masters; while those who were destitute of art but capable of labour were condemned, without regard to their former rank, to tend the cattle and cultivate the lands of the victors. This, however, was only turning the tables on the Romans, for capture in war forms one of the principal sources of supply of slaves wherever slavery exists.

The Germans, in their primitive settlements, were accustomed to the notion of slavery, incurred, not only by captivity, but by crimes, by debt, and the wager of personal liberty in gaming. In the glimpses we get of the conditions of labour elsewhere the same essential features are discernible. In the changes of time and of geographical area of observation the harsher word slave may disappear; yet the thing not only survived the introduction of Christianity but was long regarded as not inconsistent with it, and was recognized as a national institution in civilized Europe. Whether under the name of slavery or of serfdom, or without either name, north, south, east, and west, an absolute right, apart from contract, to earnings and to the person of the labourer was accepted, if not openly vindicated. In looking at the present day at the vestiges of man's former and most permanent handiwork, it is instructive to regard them with an eye to the distinctions between periods of forced and voluntary labour. The pyramids of Egypt and the wall of China are monuments of slave labour; and the same is the case with the classic remains at Athens and Rome, so far at least as relates to the labour involved in the quarrying and hewing of stone, and the making of bricks and placing them in position. As regards Britain, our knowledge is too slight, and the conjectures as to the origin and objects of such structures as Stonehenge and Avebury are too varied, to allow of positive assertion; but it seems legitimate to conclude that the labour was forced. British and Roman camps

[1] "The simple wish to use the bodily powers of another person as a means of ministering to one's own ease or pleasure is doubtless the foundation of slavery, and as old as human nature" (Maine).

and earthworks for military purposes probably exhibit the result of organized military labour combined with the forced labour of the inhabitants of the district. In this aspect the fortresses and defences destined for use consequent on the campaigns of a Cæsar or a Napoleon, of an Alexander or a Clive, do not materially differ. The remains still to be seen of Agricola's works on the line between the Firths of Clyde and Forth, as well as of the Roman walls and roads throughout England, and the later but ruder gigantic earth work of the Mercian king between England and Wales, may be regarded as fruits of slave labour. The stupendous aqueducts of Roman brickwork in various parts of southern Europe are naturally compared with the viaducts of the present age. The comparison may well extend to the accompanying conditions of labour.

Passing over the general effect of serfdom throughout northern Europe, and of the gradual manumission of toilers, as only a minute part of a very large subject, and directing our attention to the conditions of ordinary daily labour in the earliest period of the history of the British islands, we find it necessary to classify labour in relation to its particular application.

At the present day the most obvious natural distinction to be observed in this connexion is that between the labour of the husbandman on the one hand and the labour of the mechanic and artisan on the other, a distinction to some extent parallel with a division into rural and urban labour. In an attempted division of labour in this country recorded in writing, which, although not in its present form earlier than the 15th century, and distorted by a fanciful notion of adapting everything to triads, probably gives us a knowledge of a very primitive people, the following divisions of labour are found:—(1) domestic art, with its three primary branches—husbandry or cultivation of land, pastoral cares, and weaving; and (2) mechanical arts—smith craft, carpentry, and stone-masonry (*Ancient Laws, &c., of Wales*, 1841).

The social status of these various labourers is a very difficult question. It seems clear that the heads of departments of labour, although working for the lord or chief, were freemen. The authority just cited expressly says that smiths, stone-masons, and carpenters had equal privileges, and every one following those trades was entitled, besides his maintenance and firing, to a fixed measure of land for cultivation, independently of what he might have by birthright. It is clear that there must have been subdivisions, as in the present day, between craftsmen and labourers engaged in the same trade, as between a mason and his labourer, between a ploughman and the driver of the team, and between the shepherd responsible for the flock and the cowherd who merely drove cattle to and from the pasture; a freeman might perform one branch of duty and an absolute slave or serf another on the same land, and for the same chief or head. It cannot be denied that slavery in the strictest sense was an institution among the Saxons in England, and that in the earliest English laws such slaves are found, but the true slave class was a small one, and it has been doubted whether the labour of an ordinary serf was practically more severe, or the remuneration in one form or another much less, than that of an agricultural labourer in some parts of England at this day. On the other hand, a fully qualified freeman might be a simple husbandman.

Of the main conditions of labour at an early period in English towns we have no details. With the gradual development of urban populations around the castle of the lord, it is improbable that in any great number of cases the inhabitants long continued in the condition of personal serfage. The city populations of this island had not the habit and use of slavery. Serfs and oppressed labourers from adjacent estates may have been glad to take refuge from taskmasters more than ordinarily severe, but there is no doubt that freemen gradually united with them under the lord's protection, that strangers engaged in trade sojourned among them, and that a race of artisans gradually grew up in which original class feelings were greatly modified. From these and other causes the distinctions between agricultural labourers and mechanics and artisans grew and became permanent.

Proceeding to notice the legislation of England on the subject of labour, we observe, in passing, that the provisions of Magna Charta were not in the interests of labour. The stipulations against the forced building of new bridges and embankments, and for removing all weirs in rivers, were not by way of protest against involuntary labour, but in relief of a higher class. Direct legislation on labour dates as far back as the twenty-third year of the reign of Edward III., when the first Statute of Labourers was passed. The population had been much reduced by pestilence, and the demand for labour naturally led working classes to insist on higher wages, and there were "some rather willing to beg in idleness than by labour to get their living." The statute reciting these facts, and the "lusts especially of ploughmen and such labourers," enacted that "every man and woman of our realm of England, of what condition he be, free or bond, able in body, and within the age of threescore years, not living in merchandise, nor exercising any craft, not having of his own whereof to live, nor land about whose tillage he might employ himself, nor serving any other," should be bound to serve if he is in convenient service, his estate considered, at the wages accustomed to be given in the twentieth year of that reign, or five or six years before. If he refused, he was to be committed to jail till he found surety to enter into the service. No persons were to pay more than the old wages, upon pain of forfeiting double what they paid. If the lords of the towns or manors presumed to infringe the law, they were to be sued for treble the sum paid or promised by them or their servants. Artificers and workmen were put under the same restrictions, upon pain of imprisonment for taking more. This statute is remarkable as the first in which any notice occurs of the free labourer for hire, for the necessity of a statute to force him to work at fixed wages recognizes his otherwise free state.

A statute passed two years later (25 Edward III.). reciting that the earlier ordinance was disobeyed, contained minute regulations as to wages. If labourers or artificers left their work and went into another county, process was to be issued to the sheriff to arrest and bring them back. In 1360 (34 Edward III.) the former Statute of Labourers was confirmed, except that labourers were not to be punished by fine and ransom. Instead thereof, the lords of towns (*seigneurs des villes*) might take and imprison them for fifteen days if they would not do as required by law, and then send them to the next jail, "there to abide without bail till they will do so according to the statute." The statute enacted that "all alliances and covins of masons and carpenters, and congregations, chapters, ordinances, and oaths betwixt them made, or to be made, shall from henceforth be void and wholly annulled, so that every mason and carpenter, of what condition soever he be, shall be compelled by his master to whom he serveth to do every work that to him pertaineth to do, either of free stone or of rough stone, and also every carpenter in his degree. But it shall be lawful to every lord or other to bargain and covenant for their works in gross with such labourers and artificers when it pleaseth them, so that they perform such works well and lawfully, according to the bargain and covenant with them thereof made." A workman absenting himself from his service, and going to another town or county, was to be proceeded against under the previous statute, to outlawry, to be followed by imprisonment till he did as required by law, and made satisfaction to the party; nevertheless he was to be burnt in the forehead with the letter F, "in token of the falsity," if the party aggrieved so required, and if the justices should so advise. Eight years later, in the same reign (1368, 42 Edward III.), the statute and ordinance concerning labourers was confirmed, and commissions directed to justices to hear and determine matters concerning it.

Indubitable records still exist, proving that before the passing of those statutes, and down to the 15th century, workmen of various descriptions were pressed by writs addressed to sheriffs to work for their king at wages, regardless of their will as to the terms and place of work. Diggers and hewers of stone, masons, and carpenters, as well as ordinary labourers, were so impressed, and by services thus obtained the buildings at Windsor for the Knights of the Round Table, on the institution of the order of the Garter, were erected. In this case the sheriffs were commanded to take security from the workmen not to depart from Windsor without the permission of William of Wykeham, the king's surveyor. Notwithstanding these precautions, many workmen, so impressed, secretly left, in order to work for other persons at higher wages, and writs were directed to the sheriffs of London, commanding them to make proclamation prohibiting any person from employing or retaining any of the workmen on pain of forfeiting all their goods, and, as regards the workmen, commanding their arrest and imprisonment.[1]

An Act was passed in the reign of Richard II. (1388, 12 Richard II.) by which no servant or labourer, whether man or woman, could depart out of the hundred to serve elsewhere, unless bearing a letter patent under the king's seal, expressing the cause of going and the time of return. Wages were fixed in a way that shows the classification of agricultural labour. The "bailiff for husbandry" stands first. The "master hine," the carter, and the shepherd are on an equality; the ploughman follows; after him the oxherd and cowherd, then the swineherd, the dairymaid and other women receiving equal wages, and every other labourer and servant according to his degree; no servant of artificers is to take more than the servants and labourers above named after their estate. The givers and takers forfeited the excess, or double or treble if attainted before; "and, if the taker so attainted have nothing whereof to pay the said excess, he shall have forty days imprisonment." This was followed by a remarkable clause: "also it is ordained and assented that he or she which useth to labour at the plough and cart, or other labour or service of husbandry, till they be of the age of twelve years, shall from thenceforth abide at the said labour, without being put to any trade or handicraft; and, if any covenant or bond of apprenticeship be from henceforth made to the contrary, the same shall be holden for none." By a statute of the following year (13 Richard II.), the justices were to settle and proclaim between Easter and Michaelmas what should be the wages of day labourers.

[1] These proceedings were no doubt founded on notions of the royal prerogative, of which the impressment of seamen affords a more recent illustration. This forcing men to work for the king at low wages may be contrasted with proceedings within the present reign. Workmen employed in building the Queen's Palace at Westminster (the Houses of Parliament) struck for wages in the winter of 1841, and, having nothing to do, availed themselves of vacant seats in the Court of Queen's Bench, where her Majesty was constructively present. Here they were seen from day to day enjoying the comfortable temperature, undisturbed by any fear of writs or other compulsory process to force them to return to their work.

Early in the 15th century we have a glimpse of something beyond this continued legislation interfering with freedom of labour, in a reservation in favour of children being sent to school. An Act of 7 Henry IV., putting a property qualification on apprenticeship and requiring children to be put to such labour as their fathers or mothers are of, or as their estates require, on penalty of one year's imprisonment, fine, and ransom, and of one hundred shillings for receiving such apprentices, has this sentence: "But any person may send their children to school to learn literature." Labourers and artificers are to be sworn to observe the statutes in force or be put in the stocks, and a penalty is imposed on towns neglecting to have stocks. In 1414, by a statute (2 Henry V.) reciting that the servants and labourers of the shires of the realm flee from county to county because they would not conform to the law, and because the law was not put in force in every county, the former Acts were confirmed and directed to be put in force and proclaimed by the sheriff. Justices of the peace were empowered to send writs to the sheriffs for fugitive labourers in like manner as the justices have power to send to every sheriff for the felons or thieves before they are indicted, and to examine all kinds of labourers, servants, and their masters as well as artificers, and to punish them upon confession in accordance with the statutes.

Early in the following reign (2 Henry VI., 1423) further power was given to justices to compel by process an appearance before them of masters as well as servants for examination as to the execution of the statute of Henry V., and to give offenders a month's imprisonment. Four years later (1427) the conclusion was drawn that the statutes of Richard II. were faulty,—that of 12 Richard II. because it was too hard upon the masters, that of 13 Richard II. because no penalty was attached to its breach; and, besides remedying the defects, it was enacted (6 Henry VI. c. 3) that justices should fix and make proclamation of wages. Two years earlier (1425) legislation had been directed against meetings of masons. The statute 3 Henry VI. c. 1 recites that, "by the annual congregations and confederacies made by masons in their general chapters assembled, the good courses and effect of the Statutes of Labourers are publicly violated and broken, in subversion of the law, and grievous damage of all the commonalty"; and such chapters and congregations were forbidden. It was made felony to cause them to be assembled and held, and masons attending them were to be punished by imprisonment and fine. In 1444 (23 Henry VI.) a scale of wages in agriculture and trade was fixed (including freemasons and "rough" masons, master carpenters and mesne carpenters, and master tilers and slaters), and a servant in husbandry was required before departing to give half a year's warning or else to serve his master the year following. Persons refusing to serve or labour were to be committed to jail, there to remain until they found sufficient surety to serve, and masters were entitled to a fixed fine on such.

A statute towards the close of the 15th century (1495, 11 Henry VII.) referring to previous statutes, especially to the 23 Henry VI., and complaining of their inadequacy or imperfect execution, proceeds to fix the wages of artificers and labourers with great minuteness. This Act contained a remarkable clause against unlawful conspiracy by workmen engaged in building; if such artificers or labourers "make or cause to be made any assembly to assault, harm, or hurt any person assigned to control and oversee them in their working, that he or they so offending have imprisonment for a year without letting to bail or mainprise, and further to make fine at the king's will." It is not surprising that even with so very limited knowledge of principles a short time sufficed to show how ineffectual minute legislation was to control wages. The statute was repealed in the following year, "for divers and many reasonable considerations and causes, the king's highness moving, and for the common wealth of the poor artificers, as freemasons, carpenters, and other persons necessary and convenient for the reparations and buildings, and other labourers and servants of husbandry." But what is surprising is that (although the first legislation of the 16th century was in favour of masters[1]) we find in 1514 a statute regulating wages and hours of work and even the summer day sleep of artificers and labourers, and in fact a re-enactment of the law of 1495.[2] The London workmen could not endure this restriction as to wages, and in the following year were allowed to take the previous rate when working within the city or its liberties; the king's works were, however, excepted.

At this point it is necessary to refer to the provisions made against vagrancy in the 16th century, these being closely connected with compulsory labour. The great social revolution caused by the suppression of the monasteries, and by the consequent withdrawal of the support which those institutions afforded to the indigent, and too often to the idle, had led to the dispersion over the face of the country of a multitude of beggars, many of whom were able to work but preferred idleness, often adding theft and robbery to mendicancy. Under these circumstances harsh and cruel statutes were passed in the reigns of Henry VIII., Edward VI., and Elizabeth.

In 1530 (22 Henry VIII.) any person, being whole and mighty in body and able to labour, found begging or being vagrant, and giving no satisfactory account how he lawfully obtained his living, might be arrested by a constable, and a justice might, in his discretion, cause every such idle person to be taken to the nearest town and there tied to the end of a cart naked, and to be beaten with whips throughout the town "till his body be bloody by reason of such whipping." He was then required to take an oath to return to his home "and put himself to labour as a true man ought to do." The whipping was to be repeated as often as he made default; but five years later the punishment for "rufflers, sturdy vagabonds, and valiant beggars" persisting in not working after a whipping was increased to having the upper part of the gristle of his right ear clean cut off. If still persistent he was to be tried, and executed as a felon.

On the accession of Edward VI. a law was passed by which a serving man wanting a master, or loitering or wandering, and not applying himself to honest labour, might on conviction be marked with the letter V, and adjudged to be the slave for two years of the person buying him, giving him only bread and water or small drink, and such refuse of meat as the master should think fit, and causing him to work by beating, chaining, or otherwise. If he ran away he might not only be punished by his master in the same way, but the justices, on conviction, were to have him marked on the forehead or ball of the cheek with an hot iron with the letter S, and adjudge him to be the master's slave for life. If he again ran away the offence became felony, and he was to suffer the pains of death "as other felons ought to do." Any child of a vagabond, above the age of five and under fourteen, might be adjudged the servant or apprentice of any person willing to take it until the age of twenty-four if a male and twenty if a female; if it ran away slavery followed for life. The master might put a ring of iron about the neck, arm, or leg of his slave to prevent his running away, with a penalty on any person helping him to take it off, and if the slave resisted correction he was to be executed as a felon. The slave might be sold or devised by will as other goods and chattels. This statute was repealed three years after, but it remains on the rolls of parliament, and nothing can obliterate the fact and the consequent disgrace attaching for all time to the parliament that could pass such a law, and to the country that could endure it for a day. This reintroduction of slavery in England by name, and in its worst form, is memorable, and serves to mark the alteration of opinion and feeling that has since taken place, much more than any contrast between freedom of labour and wages in the sense of the political economist.

Early in the reign of Elizabeth (5 Elizabeth, 1562) the statute commonly called "the Statute of Labourers" repealed all former statutes relating to labourers in husbandry and artificers or labourers engaged in particular trades, and consolidated and amended many former provisions. Its chief object was to provide a new rate of wages, and, in addition, to regulate in many respects the terms of employment as between the employer and the employed. This Act admits that the wages laid down by former statutes are in divers places too small in view of the general rise of prices, but approves of the principle and aims of previous legislation, the substance of which it seeks to digest into a single statute. The statute draws a main distinction between artificers and labourers in husbandry. The former may not be hired for a less term than a year, and any unemployed person brought up in a craft or who had practised it for more than three years was bound, on pain of imprisonment, to accept service if required "by any person using the art or mystery wherein he has been exercised," unless he had a farm in tillage, an estate worth 40 shillings a year, or goods to the yearly value of £10. Similar provision was made in respect of service in husbandry. Every person between the ages of twelve and sixty was in like manner bound to serve in husbandry unless possessed of property of specified amount, or employed as a fisherman or mariner, or in mining, or in any of the arts or sciences previously mentioned, or unless born a gentleman, or unless a member of a university or school. Minute regulations were made with reference to the rights and obligations both of master and servant. No person retained in husbandry or trade was to go out of the county or shire where he last served, to serve in any other, without a testimonial. No person leaving his service could be taken into another without showing such testimonial to the authorities of the place in which he was about to serve. If he broke this regulation he was to be imprisoned till he could procure a testimonial, and unless he did so within twenty-one days he was to be whipped. Every person retaining a servant without the latter showing such testimonial forfeited £5. Besides empowering justices in session to make a rate of wages, the statute fixed with great minuteness the hours of labour. In the time of harvest, justices or constables or other head officers might require artificers and persons meet for labour to serve by the day in mowing, reaping, shearing, getting, or turning of corn, grain, or hay, according to the skill and quality of the person, and upon refusal might put him in the stocks for two days and a night. Even single women between the ages of twelve and forty might be compelled to serve in such employment as the justices might direct, under pain of imprisonment. Amended provision was made towards the close of the reign for justices yearly fixing the rate of wages.

It will be seen by the preceding summary how great

[1] In 1512 (4 Hen. VIII.) the penalties for giving of wages contrary to the statute 12 Rich. II. were repealed so far and only so far as relates to the masters.

[2] Miners and workers for tin, lead, iron, or silver, colliers for sea coal, and glass makers were excepted.

were the restraints still placed by the legislature on the free action of labour. After this mass of unwholesome legislation it is instructive to notice the state of the labouring classes in England in the 16th century, as recorded by Harrison. After dividing English people into four sorts—gentlemen, citizens or burgesses, yeomen, and artificers and labourers—and describing the first three classes, he says:—

"The fourth and last sort of people in England are day labourers, poor husbandmen, and some retailers (which have no free land), copyholders, and all artificers, as tailors, shoemakers, carpenters, brickmakers, masons, &c. As for slaves and bondmen, we have none; nay, such is the privilege of our country, by the especial grace of God and bounty of our princes, that, if any come hither from other realms, so soon as they set foot on land they become so free of condition as their masters. . . . This fourth and last sort of people have neither voice nor authority in the common wealth, but are to be ruled, and not to rule others; yet they are not altogether neglected, for in cities and corporate towns, for default of yeomen, they are fain to make up their inquests of such manner of people, and in villages they are commonly made churchwardens, sidemen, ale conners, now and then constables, and many times enjoy the name of headboroughs. Unto this sort also may our great swarms of idle serving-men be referred, of whom there runneth a proverb, Young serving-men, old beggars, because service is none heritage. . . . This, furthermore, among other things I have to say of our husbandmen and artificers, that they were never so excellent in their trades as at this present. But, as the workmanship of the latter sort was never more fine and curious to the eye, so was it never less strong and substantial for continuance and benefit of the buyers. Neither is there anything that hurteth the common sort of our artificers more than haste, and a barbarous or slavish desire to turn the penny, and by ridding their work to make speedy utterance of their wares; which enforceth them to bungle up and despatch many things they care not how so they be out of their hands, whereby the buyer is often sore defrauded, and findeth to his cost that haste maketh waste, according to the proverb. Oh, how many traders and handicrafts are now in England whereof the commonwealth hath no need! How many needful commodities have we which are perfected with great cost, &c., and yet may with far more ease and less cost be provided from other countries if we could use the means! I will not speak of iron, glass, and such like, which spoil much wood, and yet are brought from other countries better cheap than we can make them here at home. I could exemplify also in many others."

Notwithstanding compulsory legislation, and the forcing of labour for the sovereign already noticed, it is evident that the condition of the labourer, even when employed on royal property, was undergoing amelioration. In a remarkable but apparently unpublished letter of Humphrey Mitchell, surveyor of the queen's works at Windsor (and for some time member of parliament for that borough), to Lord Burghley, written in 1575, he says—"At my first entry into this charge I could scarce get workmen by commission; since, with monthly 'payes,' impressing through the mayor those contumacious in work, rewarding the diligent, and thrusting out the evil where I perceive them loitering, I have brought them into such an obedience and a desire to work here that where I have one I can have twenty to serve her Majesty; and when at the first entry into the works, they had their breakfast at eight of the clock in the morning, and drinking at three in the afternoon, I have taken that idle custom from them, and have only allowed them two hours at noon, and, as necessity serveth, sometimes but one, with their contentation; and for that also I would have them they must know their duty, I bring them to the lecture at the college [Windsor] twice every week, losing no hour's work thereby, for those days they rest at twelve. I suffer not a swearer nor filthy talker in the works to my knowledge, by all which means I think her Majesty hath her work done as diligently as any other private man hath."

Light is thrown on the arrangement of hours by a clause in the above-mentioned Statute of Labourers of the fifth year of the Queen's reign. It enacted that—

"All artificers and labourers being hired for wages by the day or week shall, betwixt the midst of the months of March and September, be and continue at their work at or before five of the clock in the morning, and continue at work and not depart until betwixt seven and eight o'clock at night (except it be in the time of breakfast, dinner, or drinking), the which time at the most shall not exceed above two hours and a half in a day, that is to say, at every drinking one half hour, for his dinner one hour, and for his sleep when he is allowed to sleep, the which is from the midst of May to the midst of August, half an hour at the most, and at every breakfast one half hour; and all the said artificers and labourers betwixt the midst of September and the midst of March shall be and continue at their work from the spring of the day in the morning until the night of the same day, except it be in time afore appointed for breakfast and dinner, upon pain to lose and forfeit one penny for every hour's absence, to be deducted and *defaulked* out of his wages that shall so offend."

In the first parliament after the accession of James an attempt made towards the close of the previous reign to enforce the rating of wages and the payment of the rated amounts was renewed. The Act recites, in the same terms as were used only two years before, that the Act of 1562 "hath not, according to the true meaning thereof, been duly put in execution," and, in order to remove a doubt as to the application of the principle of assessing wages, expressly extends it "to rate wages of any labourers, weavers, spinsters, or workmen whatsoever, either working by the day, week, month, year, or taking any work at any person or persons' hand whatsoever, to be done in great or otherwise." The giving or receiving more or less than the proclaimed price was expressly declared to be an offence.

In Scotland we find complaints in the 16th century by masters of salt-pans of the great rise in wages, and early in the 17th century (1617) justices were directed to fix at quarter sessions the ordinary rate of hire and wages of workmen, labourers, and servants, and to imprison those who refused to serve for the appointed hire. At the same time, "that servants may be the more willing to obey the ordinance," power was given to the justices to compel payment of wages. This law was re-enacted in 1661. Some years previously (1606) any one hiring a collier or salter without a sufficient testimonial from his last master was compelled to deliver him up if demanded; and colliers and salters were empowered to apprehend vagabonds and sturdy beggars and force them to labour. In 1621, in consequence of "the great straits and necessities that the poor labourers of the ground" were driven to by the "fraud and malice" of servants who either refused to be hired without the promise of great wages, or else hired themselves from Martinmas to Whitsunday, then "casting them loose" on purpose to make their gain and advantage by extraordinary works, such as casting and winning peats or turfs, building fold dykes, and shearing in the harvest, hired servants were forbidden to leave unless upon proof to a justice of the peace that they were hired to another. If it was found that a servant was not so hired, his master was empowered to detain him at the previous rate of wages. Power was given to apprehend a servant "who broke loose," and to deliver him to a constable or justice, and a power to all persons to apprehend loose and masterless men and women found within their own bounds; and the justices and constables were empowered to compel them to serve for competent hire and wages. Twenty years later servants in manufactories were compelled to work at reasonable rates, and not to hire without their previous master's consent. Houses of correction were erected for disobedient servants, and in 1672 masters of correction houses were empowered to receive such servants and to force them to work, and to correct them according to their demerits. These later laws of Scotland were accompanied by others directed against vagrancy.

Passing over legislation which either affected only particular trades (although denoting the growth of manufacturing industry), or related rather to the poor laws than directly to the subject of this article, and arriving at the middle of the 18th century, we find the legislature no longer employed in compelling labourers or artisans to enter into involuntary service, but regulating the summary jurisdiction of justices in the matter of disputes between employers and employed, in relation to contracts and agreements, express or implied, presumed to have been entered into voluntarily on both sides.

The statute 20 Geo. II. c. 19 (passed in 1746) provided that all complaints, differences, and disputes arising between masters and servants in husbandry hired for one year or longer (extended by a subsequent statute of the same reign to those hired for less than a year), or arising between masters and artificers, handicraftsmen, and miners (applied in 1829 to labourers of every sort), were to be determined by one or more justices, who, upon complaint of the servant, might determine any dispute as to wages and order payment of any sum found to be due, not exceeding £10 in case of a servant in husbandry, and £5 in case of artificers and other labourers, and, in the event of non-payment, might levy the same by distress on the goods of the master. In case of complaint by the master, the authority of the justice was still larger. He had power to entertain a complaint of "any misdemeanour, miscarriage, or ill behaviour of the servant in his or her service or employment," and to hear, examine, and determine the same. If the decision was adverse to the servant, the justice might either abate some part of the wages due to such servant, or discharge him from the service, or he might punish the offender by committing him to the house of correction, "there to be corrected," which term was held to mean correction by whipping and holding to hard labour for a reasonable time, not exceeding a month.

A statute of 1823 (4 Geo. IV. c. 34), the next general statute on this subject, took a somewhat wider scope, dealing with breaches of contract on the part of the servant in not entering into the agreed service at all, as well as in quitting it before the term agreed on had expired, and subjecting these breaches as well as any misdemeanour or misconduct while in the service to the jurisdiction of the justice, who might adjudge the offender to be imprisoned in the house of correction for a term not exceeding three months (but without any power to order corporal punishment), abating a proportional part of his wages in the future, or adjudging him to lose the whole or part of his wages already earned; or, he might dismiss him from the service.

Thus stood the statute law until 1867. In consequence of considerable dissatisfaction on the part of workmen with the adjudication of justices, a select committee of the House of Commons was appointed in the previous year to inquire into the state of the law as regards contracts of service between master and servant, and as to the expediency of amending it. That committee reported—

1. That the law as it then existed was objectionable.
2. That all cases arising under the law of master and servant should be publicly tried in England and Ireland before two or more magistrates, or before a stipendiary magistrate, and in Scotland before two or more magistrates, or the sheriff.
3. That procedure should be by summons in England and Ireland, and warrant to cite in Scotland, and, failing appearance of defendant in answer to summons or citation, the court should have power to grant warrant to apprehend.
4. That punishment should be by fine, and failing payment by distress or imprisonment.
5. That the court should have power when such a course is deemed advisable to order the defendant to fulfil the contract, and also, if necessary, to compel him to find security that he will do so.
6. That in aggravated cases of breach of contract, causing injury to person or property, the magistrate or sheriff should have the power of awarding punishment by imprisonment instead of fine.
7. That the arrest of wages in Scotland in payment of fines should be abolished.

The Master and Servant Act 1867, sometimes called Lord Elcho's Act, was framed upon the report of the committee, and embodied most of the recommendations. As regards simple breaches of contract, the position of servants was considerably improved. Imprisonment, which, under the former Acts, the magistrate was authorized to impose in the first instance as a punishment for a breach of the contract, was taken away, except as auxiliary to the jurisdiction, as the consequence of disobedience to the order of the court; and wherever imprisonment might, under the former Acts, have been accompanied by hard labour, the power to order hard labour was taken away. Lord Elcho's Act did not, however, remove the dissatisfaction felt on the part of workmen, and the events of a few years rendered it desirable to reconsider the whole law, with reference not only to breaches of contract but to other special legislation of a criminal kind, and to the general law of conspiracy affecting the relation of employer and employed.

Commissioners reported in 1875 recommending, so far as relates to the scope of this article, that the proceedings should be altogether divested of a penal character and assume that of a civil proceeding for specific performance or recovery of damages, and that, to effect the main object, Lord Elcho's Act should be amended or a new Act framed in clearer language. Within a few months of the presentation of the report, Mr Cross, then secretary of state, introduced two bills, the one an "Employers and Workmen Bill," and the other a "Conspiracy and Protection of Property Bill," and these bills, after undergoing considerable discussion and alteration in their different stages, were passed and came into operation on the 1st September 1875. This article only deals with the former Act. While carrying out the recommendation of the commissioners regarding Lord Elcho's Act, and placing all provisions of a penal character in a separate Act ("Conspiracy and Protection of Property"), the legislature thought fit to go further and take away the right of enforcing performance of contracts of labour (although that is a very important branch of civil procedure in relation to various matters of contract), and make it a mere question of recovery of damages, unless both parties agree that security for performance of the contract shall be given instead of damages. Adjudication can be by courts of summary jurisdiction.[1]

Neither this Act nor its predecessor takes away the right of parties to sue in the ordinary civil tribunals of the country; but the Act puts county courts (in Scotland the ordinary sheriff court of the county, in Ireland the civil bill court) practically on the same footing with courts of summary jurisdiction,—the jurisdiction of magistrates being simply because the county courts in most places do not sit sufficiently often for the practical adjudication of these differences. The title of the Act, "to enlarge the powers of county courts in respect of disputes between employers and workmen, and to give other courts a limited civil jurisdiction in respect of such disputes," indicates its general scope, which is borne out by its provisions. It

[1] In England such courts are a police or stipendiary magistrate, or, where there is no such magistrate, two or more justices sitting at some place appointed for holding petty sessions, or, in the city of London, the lord mayor or an alderman sitting at the Mansion House or Guildhall. In Scotland the court of summary jurisdiction is the small debt court of the sheriff of the county. In Ireland the court is constituted of one or more of the divisional justices of the police district of Dublin metropolis, and elsewhere in Ireland of two or more justices of the peace in petty sessions, sitting at a place appointed for holding petty sessions. These courts are, for the purposes of the Act, civil courts.

extends to "any dispute between an employer and a workman arising out of or incidental to their relation as such." The expression "workman" does not include a domestic or menial servant, but means any person who, being a labourer, servant in husbandry, journeyman, artificer, handicraftsman, miner, or otherwise engaged in manual labour, whether under the age of twenty-one years or above that age, has entered into or works under a contract with an employer, whether the contract be made before or after the passing of the Act, be express or implied, oral or in writing, and be a contract of service or a contract personally to execute any work or labour. Payment of damages and debts under the Act, as in other cases of judgment debts, is enforceable by imprisonment for a term not exceeding six weeks, only on proof of ability and neglect to pay, whether the proceedings be in the county court or in the court of summary jurisdiction.

Two circumstances show the rapid strides made in a few years in the position of labour in relation to legislation. Lord Elcho's Act in 1867 received the title of "The Master and Servant Act." In eight years that title is silently dropped, and "Employers and Workmen" substituted. In 1867 the prime minister spoke in high terms of eulogy of Lord Elcho's Act as securing valuable rights for workmen. In 1875 the same prime minister, speaking a few weeks after the passing of the Act of that year, remarked that for the first time in the history of the country the employer and employed sat under equal laws.

Although the general tendency of colonial legislation is to follow that of the parent country, where it can be applied, that is not the case in some important British colonies in relation to the enforcement of labour contracts.

In New South Wales, servants, including artificers, journeymen, and handicraftsmen, and all agricultural labourers, as well as domestic servants, are dealt with under a colonial Act of 1857. For not fulfilling a contract, whether by deserting or not entering upon the service, or for other misconduct or ill behaviour, justices upon conviction may impose a fine not exceeding £10. In default of distress, imprisonment, not exceeding fourteen days, or forfeiture of wages then due may follow. Obtaining advances of money after entering into a contract and refusing to go to the place of service, or refusing to perform work to the extent of the advance without reasonable cause, is punishable by direct imprisonment with or without hard labour for any term not exceeding three months. Persons knowingly concealing or employing absconding or absenting servants or persuading them to violate agreements are liable to a penalty not exceeding £10, and in default imprisonment for fourteen days. On the other hand wages not exceeding £50 and full costs may be recovered by distress, and in default imprisonment for fourteen days; masters are also liable to a penalty for withholding property of their servants. Independently of these provisions, justices may hear and determine in a summary manner any complaint, difference, or dispute between a servant and his master, and the award may be enforced by cancelling an agreement or imposing a fine, and in default of distress by imprisonment not exceeding fourteen days. The power of imprisonment under the Act does not extend to women.

In South Australia, by an Act of 1878 (following in the main the tenor of Lord Elcho's Act, rather than the legislation of 1875), whenever the employer or employed neglects or refuses to fulfil any contract, or the employed neglects or refuses to enter or continue his service or absents himself, or whenever any dispute arises between the parties, the case may be summarily decided by justices, who may order an abatement of wages due, or direct the fulfilment of the contract, with a direction to the party complained against to find security by recognizance or bond with or without sureties; or the contract may be annulled and the amount of wages or compensation apportioned; or, where pecuniary compensation will not, in the opinion of the justices, meet the circumstances of the case, they may impose a fine not exceeding £20. The neglect or refusal to find security for performance of contract may be enforced by imprisonment not exceeding three months.

The Victorian statutes relating to master and servant were consolidated in 1864. Under that Act all agricultural and other labourers and workmen and artisans, as well as domestic servants, were made liable on summary conviction to imprisonment not exceeding three months, or abatement of wages, for breaches of contract or for disobedience or other misconduct or misdemeanour. The like imprisonment was provided for obtaining advances of wages and refusing to serve, and also for wilful or negligent acts involving a destruction of work or materials committed to the workman's charge, in default of payment of damages (limited to £10). Wages and amends for ill-treatment were made recoverable by order.

It is impossible within the limits of this article to follow the different provisions in various colonies affecting the relation of employer and employed. To render a summary of practical value, local peculiarities and exigencies must be borne in mind. Where native or foreign races form a material part of the industrial population, or where changes have occurred in their condition, the facts must be taken into account; for example, the legislation of Jamaica, although now constituted an ordinary British colony, must be considered in relation to the former existence of slavery and to the intermediate status of apprenticeship before its abolition. So in British Guiana, the large number of emigrants from the East Indies, many of them working on the estates under indentures, must not be lost sight of.

With regard to India, that vast area cannot be dealt with as if the industrial population consisted of Europeans, manufacturing in its cities. Although natives are increasingly sharing in the labour and ownership involved in the production of manufactures, the cultivation of the soil forms the basis of the support of two-thirds of the population. The true view of India is that as a whole it is divided into a vast number of independent self-acting organized groups, cultivating, trading, and manufacturing, governed by law made up to a great extent of local usages and customs, and where caste is often merely a name for trade or occupation,—the village communities comprising families who are hereditary weavers, potters, blacksmiths, harness makers, and so forth.

The condition of the law in European states at the present time with regard to the enforcement of labour contracts is this. In France contracts of work and service stand on the same footing as other contracts. The breach of such contracts is regarded as a private matter, as the subject of a claim for damages, but not of the application of the criminal law. The recovery of damages is regulated by the Code Napoléon. The juge de paix decides the amount when the sum claimed is under 200 francs, when above that amount the tribunal of first instance. So in Belgium there is no criminal penalty attaching to the breach of a contract of labour; such a contract entitles the aggrieved party, as a general rule, only to pecuniary damages; and the same is the case in the Netherlands, Austria Hungary, Italy, Portugal, Sweden, Norway, and Russia. In Switzerland there is no criminal liability, provided the dereliction of duty involves no consequences injurious to the public welfare or to the life or health of other persons. The performance of contracts, however, in the larger works in Switzerland is secured by the system of "décompte," or portion of wages retained as security by the employer. In Prussia, although in 1869 all the penal regulations previously existing against breaches of contract and wrongful cessation of work on the part of workmen in mills, mines, and metallurgical establishments and in underground quarries and pits were repealed, police laws are, it seems, still capable of being enforced by way of fine, and, in default, by a short imprisonment in some provinces, against agricultural labourers, and against boatmen or workmen engaged in special field or forest work.

Of the United States, the English representative wrote thus to the Foreign Office in 1869:—"There are few countries in which the working man is held in such regard as in the United States of America. The labouring classes may be said to embrace the entire American nation. Every man works for a living, follows a profession, or is engaged either in mercantile or industrial pursuits." As might be expected, it may be said that, as to both parties to a contract for labour and service, they stand upon the mere footing of contract, and such contract is not distinguished from any other contract. The matter does not belong to the province of federal legislation, but to the regulation of each particular State. There has been no legislation, however, making the breach of a contract for labour or services the subject of criminal liability. Contracts of apprenticeship are, nevertheless, enforced by statutory provisions.

We have hitherto dealt with the mode of enforcing contracts of labour. It remains to speak of the extent to which the contracts themselves are controlled.

With reference to the period of service, there is no law directly limiting it. A right even to perpetual service founded on a contract may not perhaps be illegal and void; for, if a man can contract to serve for one year, there seems to be no reason to prevent his contracting to serve for one hundred years if he should so long live,—though the courts would be inclined to consider it an improvident engagement, and would not be very strict in enforcing it (Christian). No such perpetual contracts, however, exist in actual practice, and where no time is expressly stipulated or implied the contract is generally construed to endure until determined by a reasonable notice on either side, to be construed by the general usage in relation to the particular employment. If a time is expressed or implied, the silent continuing in the service after its expiration draws with it in general a renewal of the same terms as were originally stipulated for. In agriculture the general engagement, express or implied, is for a year. In manufacture it is seldom so long, and in journeyman handicrafts it is sometimes by the hour, but the usage to calculate earnings and the time of payment by the hour or day is often of course quite distinct from the duration of the contract. Payment by measure or quantity (piece work) is very general, and so far as the calculation of earnings is concerned supersedes reference to time. Nevertheless the obligation to serve may be conditional on the employer finding a reasonable quantity of work, or may expressly or implicitly endure until a reasonable notice is given on either side. In the pottery manufacture in North Staffordshire most of the workmen in the different branches of the trade are paid by the quantity according to a price list, the engagement being by usage, from Martinmas to Martinmas; and in this and in most other manufactures where the artisan works on the material and in the manufactory or the workshop of the employer he is subject to the usual hours of work, although only paid by the quantity.

Most workmen of all classes and descriptions of labour are paid weekly, in whatever way their earnings accrue or are calculated. The contracts of infants (see INFANT) for their personal services as necessary for their maintenance are enforceable, for unless they could make such contracts they might starve. As long as these contracts were enforceable by imprisonment the courts looked closely into them, refusing to enforce them unless they were mutual, that is, capable of being enforced against the employer as well as against the servant. If there were an agreement to serve under circumstances which involved no obligation to employ, the courts would not enforce the contract, and young servants were not unfrequently discharged from custody on the ground that no obligation to serve existed by reason of the onesidedness. Contracts of APPRENTICESHIP (*q.v.*) are beyond the limits of this article.

The will of the parties is not interfered with as regards the description of labour or the adequacy of the remuneration agreed upon. In the absence of any verbal or written stipulation, the performance of labour upon an express or implied request in general involves an implied agreement to pay the value of it in the current coin of the realm; and wherever a mutuality of agreement can be implied, that is to say, where it is not onesided, it can be enforced. As the employer and employed are free, they would primarily have a right to stipulate that the remuneration for service should be for something else than money, as for articles of value, or for an exchange of labour; but the primary right of employer and employed to make their own arrangements as to the mode of remuneration is interfered with in England by legislation, especially by the so-called Truck Act, 1 and 2 Will. IV. c. 37, applying to all persons employed in the manufacture of iron from raising the stone to the completion of the making of the products of iron and steel, and the manufacture of all other hardware and cutlery, and the getting of coal, stone and slate, salt and clay, and the manufacture of pottery, and the weaving, preparation, and dyeing of woollen, worsted, cotton cloth, and silk. The object of the statute is to compel payment of wages in money. For this purpose it prohibits agreements for paying wages otherwise, and prohibits paying them in goods or money's worth. To insure obedience, it enables the artificer to repudiate a contract and payment contrary to its provisions, and, however fairly he may have been dealt with, to enforce payment in such case over again. It is obvious that such a provision is open to two most important objections:—(1) it interferes with that freedom of contract and conduct which is universally recognized as of the greatest benefit; (2) it enables an artificer who may have requested and received payment otherwise than in money, and who may have benefited thereby and been most justly and kindly treated, to commit a great dishonesty by enforcing payment again. But, grave as these objections are, the legislature has deemed it necessary to face them, in order to guard against the mischiefs of a system under which the workman may receive directly from his employer, or indirectly, as through "tommyshops" in which the employer has an interest, articles not a real equivalent of the wages; so that but for the statute an employer might engage a man to work for him with a promise of payment in goods, and cheat him by giving him goods of inferior quality or overcharged, or engaging him with a promise of money and then cheating him by a pressure to take goods, or by supplying the man with goods beyond his wages, get him into his debt, and then exercise an injurious contról over him. It is in vain to say that the master would cheat in cases where money wages were agreed for, by withholding money agreed to be paid, and that the law would redress the one wrong as readily as the other. The answer is that such a cheat is too barefaced, and would certainly be successfully resisted; while more or less of inferiority in the quality or value of goods might be endured, or, if contested, would give rise to more doubtful inquiries. Whether these mischiefs are worth the remedy, or whether the remedy is the best, is not the question to be discussed or determined in this article.

As servants in husbandry are often remunerated in part in other ways than by money, as by land or its produce, or by house room, and in a variety of ways, the Truck Act especially exempts them. Domestic servants are also specially exempted. Moreover, by express provision, the Act does not prevent any employer of any artificer or agent of such employer from supplying or contracting to supply medicine or medical attendance, or any fuel, or any materials, tools, or implements employed by the artificer in his trade or occupation if employed in mining, or any hay, corn, or other provender for horses or other beasts of burden employed by such artificer in his trade or occupation, nor from letting any tenement at a rental to any artificer, workman, or labourer within the Act, nor from supplying or contracting to supply to any artificer any victuals dressed or prepared under the roof of the employer and there to be consumed by such artificer, nor from making deductions or stoppages, or advancing money for any of these purposes, provided that only the real value is charged, and that the agreement for any such stoppage or deduction is in writing. Employers are not prevented from advancing money to an artificer for his contributions to a friendly society or to a savings bank, or for his relief in sickness, or for the education of his children, or from making deductions for such education, if the agreement for such deduction is in writing. The interpretation of the Truck Act has exercised the most subtle intellects. It has been determined by the majority of judges that the obligation to render services personally is necessary to make the Act applicable. The circumstances under which stoppages and deductions may be made, and other exceptions from the operation of the prohibitory clauses of the Act, have also been the subject of divergent opinions. A custom having prevailed among the employers of artificers in the hosiery manufactures of letting out frames and machinery to the artificers employed by them, in 1874 contracts to stop wages for frames were declared illegal, and the stoppage of wages made unlawful. By a provision of the Employers and Workmen Act 1875, forfeitures on the ground of absence or leaving work cannot, in the case of a child, young person, or woman subject to the provisions of the Factory Acts, be deducted from or set off against a claim for wages or other sum due for work done before such absence or leaving work, except to the amount of the damage (if any) which the employer sustained by reason of such absence or leaving work.

Great evils having arisen in Scotland through the arrestment of wages for debts of labourers, manufacturers, artificers, and other work people, the power to arrest wages earned there not exceeding twenty shillings a-week was in 1870 taken away, and limited in amount where the wages are above that sum. A provision of a statute of the reign of George II., "to prevent oppression of the labourers and workmen employed in any respect in or about making or manufacturing of gloves, breeches, boots, shoes, slippers, wares or goods of that sort," requires the true weight, quantity, or tale to be declared of goods and materials delivered out to be wrought up in those manufactures.

The system of the "livret" (still the law in some European states, although fallen into disuse as no longer in harmony with the direction of modern views), by which it is a condition precedent to a workman entering into a contract, or being engaged by a fresh employer, to produce a document certifying that he has fulfilled his previous engagements, is unknown now in England. The former system of rules stood much on the same footing, and there is something closely resembling it introduced into the rules regulating the employment of drivers of public vehicles in the metropolis. It is only in relation to domestic service that a new employer concerns himself with the antecedents of a servant or with anything beyond the capacity to work; and the former employer in whose interests "livrets" were imposed does not in general deem it worth while, with the present abundance of labour in every field of work, to impose any restraint on the departure of a dissatisfied workman. The practical ground of complaint is not so much a workman exchanging employers, as a neglect of work while remaining in service.

The legal remedies at present in existence for breaches of contract have been necessarily stated in the outline of the last statute on the subject of employer and employed. The weak point is the absence in England of any mode by which the performance of contracts of labour can be enforced, as contracts of other kinds can be where damages do not afford a remedy. Lord Elcho's Act of 1867 purposely gave a remedy in the nature of specific performance, and where carefully applied was found to work very well. The commission of 1875 expressly recommended the retention of this power as quite distinct from criminal punishment. Provision for compelling the performance of a contract exists in many countries where any application of criminal law is repudiated. Nevertheless, not so much from any objection on the part of the framers to compulsory performance as from fear of its abuse by the heavy hand (the bane of administrative legislature as of inventive genius), the power is gone. The result is undoubted hardship to employers, particularly to those (and there are many of them) who are themselves workers and entirely dependent on the due performance of contracts by their fellow-workers. That home legislation is defective in this respect may be inferred from the fact that subsequent colonial legislation has given the means of getting labour contracts performed without trenching on the domain of criminal law. As, however, there is little probability of an amendment of home law in the direction indicated, it is to be hoped that compensation for diminished legal remedy will be found in an increased sense of moral responsibility.

Arbitration is frequently employed to settle differences between masters and workmen.

The institution of "conseils de prud'hommes" is known by name as in force in most of the manufacturing districts of France and Belgium and other Continental countries. The council is a recognized tribunal consisting of equal numbers of employers and employed. All disputes between master and workmen, whether as to quality of work or rate of wages, are first submitted to a committee, which sits privately, to endeavour to settle the question amicably and at a nominal expense; failing this, the case is referred to the council, which sits in public once a month, or oftener if required. Though the right of appeal to the regular courts exists, it is seldom resorted to.

In Austria a law of 1869 instituted arbitration courts of this description in every important manufacturing town and district, to settle all disputes respecting wages, continuance of work, fulfilment of contracts, and claims on benefit clubs and relief funds and matters of that kind. Each court of arbitration must be composed of at least twelve and at most twenty-four members,—one half of them employers elected by employers, and the other half workmen elected by workmen, each class voting separately. Workmen sitting on cases judged by these courts are paid by the commune for every day's sitting. In the case of the minor trades, which cannot maintain regular arbitration courts, the trade laws assign the adjudication of all disputes between masters and men in the first instance to the representatives of the trade in which such disputes arise, and, in places where the necessary quorum for that purpose cannot be made up by the local representatives of any particular trade, the deficiency is supplied by a certain number of workmen temporarily appointed by the municipal authorities from amongst the most respectable and intelligent members of their class to act as arbitrators in such cases. Disputes which cannot be settled in this way must be decided by the common law courts; and it is only a court of law which can take cognizance of a claim raised thirty days after the expiration of a contract to which it refers.

In England no such compulsory legislation exists. The old guilds acted as arbitration courts, and, although their decision was practically binding, the guilds were only adapted to deal with small craftsmen acting singly. In modern times the law has been very reluctant to give effect even to voluntary agreements for referring disputes to arbitration, on a notion that to take away the jurisdiction of the ordinary tribunals and to set up another was contrary to settled principles. There are now several statutes, however, for giving legal effect to the awards of arbitrators in trade disputes voluntarily referred to arbitration and sitting in the way pointed out. The most successful arbitrations between employers and employed appear to be under voluntary submissions, in accordance with rules previously agreed to by employers and employed, in particular manufactures, the decisions being acted upon independently of any legislative aid.

Applied to the one pre-eminently important—probably the only great—question, the rate of wages, reference to arbitration is full of difficulties. The difference relates to the future, not to the past. It is an erroneous notion that strikes and lock-outs involve any breach of contract. In former days it may have been that employer and employed refused to carry out a contract on the ground that the other side had first failed in the performance of some condition precedent to the right to call on the other to perform work or to pay for it, as the case might be; but in the present day the disturbance of the previous relationship of employer and employed generally occurs without any such allegation on one side or the other. Thus, in a strike terminated while this article is in the press, the contracts between employers and employed in the pottery trade of North Staffordshire were previously at an end by lapse of time. The question in such cases is on what terms the parties will agree for the future relationship of employer and employed, there being no such relationship when the strike began, and of course none while it is pending. This goes to the root of the whole matter, although it may seem a technical mode of looking at it. But if no such obstacle existed, there are difficulties of another kind. In such cases a board of conciliation is inevitably equally divided, and reference to an umpire becomes necessary. To give confidence, he must not be an employer or employed in the trade. In general, therefore, he must know nothing previously of the subject he has undertaken to settle. He must deal with it on such imperfect knowledge as he can acquire in the arbitration, and apply such general principles as may occur to him. Nevertheless much good has been done by a good-tempered calm inquiry in which both sides learn perhaps for the first time the grounds on which the demand is made or resisted.

A recent important Act of Parliament, the Employers' Liability Act 1880, must be noticed. To render its provisions intelligible, it is necessary to state the general law on the subject of civil liability for negligence. A person who causes injury to the person or property of another is liable in damages to that person, and if the injury has resulted in death the right of action is extended to the representatives, on behalf of the widow or children, independently of any criminal liability incurred by the negligence. If the person who committed the negligent act is in the service of another, and the negligent act was committed in the course of the discharge of his duty, the civil liability extends to the master. This liability of the master is important to the injured person, because the servant is in most cases a much poorer person than the master. If they were equally able to pay damages, nothing would be gained by resorting to the master. But the liability of the latter was not, before 1880, extended to make the master responsible in damages if the person injured and the negligent servant were both in his service and both were performing the same kind of duty, a "common employment" as it has been termed, and if the master, so far from being guilty of any actual negligence himself, had employed a generally competent person, and had provided him with the means of properly performing his duty. No vindication of the then law seems necessary, for, whether the liability of an employer to strangers is just or not, there is an obvious distinction between such a liability and responsibility where all parties are "rowing in the same boat," to adopt an expression used in one case, whether the injured person be a servant or guest of the master. Both are volunteers, and both know that the master will not personally intervene. There does not appear to be any injustice in such a case in confining the liability to that of the servant personally guilty of the negligence, although a poor man. However, some apparently hard cases, especially arising out of accidents on railways, where, while a passenger could sue the company for negligence, an engine-driver or a guard's remedy was limited to the person actually guilty of the negligence, led to the attention of parliament being called to the subject. In 1877 a committee of the House of Commons, pointing out that the development of modern industry has created large numbers of employing bodies, such as corporations and public companies, to whom it is not possible to bring home personal default, and that there are other cases in which masters leave the whole conduct of their business to agents and managers, themselves taking no personal part whatever either in the supply of materials or in the choice of subordinate servants, reported thus:—

"Your committee are of opinion that in cases such as these, that is, where the actual employers cannot personally discharge the duties of masters, or where they deliberately abdicate their functions and delegate them to agents, the acts or defaults of the agents who thus discharge the duties and fulfil the functions of masters should be considered as the personal acts or defaults of the principals and employers, and should impose the same liability on such principals and employers as they would have been subject to had they been acting personally in the conduct of their business, notwithstanding that such agents are technically in the employment of the principals. The fact of such a delegation of authority would have to be established in each case, but this would not be a matter of difficulty. Your committee are further of opinion that the doctrine of common employment has been carried too far when workmen employed by a contractor and workmen employed by a person or company who has employed such contractor are considered as being in the same common employment."

Three years afterwards the Act in question was passed. By sect. 1, where personal injury is caused to a workman—

"(1) By reason of any defect in the condition of the ways, works, machinery, or plant connected with or used in the business of the employer; or (2) by reason of the negligence of any person in the service of the employer, who has any superintendence entrusted to him, whilst in the exercise of such superintendence; or (3) by reason of the negligence of any person in the service of the employer to whose orders or directions the workmen at the time of the injury was bound to conform and did conform, where such injury resulted from his having so conformed; or (4) by reason of the act or omission of any person in the service of the employer done or made in obedience to the rules or bye-laws of the employer, or in obedience to particular instructions given by any person delegated with the authority of the employer in that behalf; or (5) by reason of the negligence of any person in the service of the employer who has the charge or control of any signal, points, locomotive engine, or train upon a railway,—the workman, or in case the injury results in death the legal personal representatives of the workman, and any persons entitled in case of death, shall have the same right of compensation and remedies against the employer as if the workman had not been a workman of nor in the service of the employer, nor engaged in his work."

Section 2 provides that a workman shall not be entitled under the Act to any right of compensation or remedy against the employer in any of the following cases:—

(1) Under subsection 1 of section 1, unless the defect therein mentioned arose from, or had not been discovered or remedied owing to, the negligence of the employer, or of some person in the service of the employer, and entrusted by him with the duty of seeing that the ways, works, machinery, or plant were in proper condition; (2) under subsection 4 of section 1, unless the injury resulted from some impropriety or defects in the rules, bye-laws, or instructions therein mentioned; provided that, when a rule or bye-law has been approved or has been accepted as a proper rule or bye-law by one of her Majesty's principal secretaries of state, or by the Board of Trade, or any other department of the Government, under or by virtue of any Act of Parliament, it shall not be deemed for the purposes of this Act to be an improper or defective rule or bye-law; (3) in any case where the workman knew of the defect or negligence which caused his injury and failed within a reasonable time to give, or cause to be given, information thereof to the employer or some person superior to himself in the service of the employer, unless he was aware that the employer or such superior knew of the said defect or negligence."

Compensation under this Act (which extends to a railway servant and any person to whom the Employers and Workmen Act 1875, already noticed, applies) is enforced by action in the county court (in Scotland the sheriff's court, in Ireland the civil bill court) after notice within six weeks of the nature and particulars of the claim (unless there was reasonable excuse for the want of notice in the case of death). The compensation is limited to three years' earnings, and the action must be commenced within six months from the occurrence of the accident, or in case of death within twelve months from the time of death.

Neither in the United Kingdom nor abroad does the right to damages for breach of contracts override the general law as to offences, so that, if any of the parties do anything amounting to a criminal offence, a prosecution may follow although a breach of contract is involved for which breach damages may be recovered. There are moreover a variety of Acts of Parliament from the reign of Anne still in force for securing employers from the frauds of workmen employed in various trades in working up materials, not only as regards the misappropriation of property entrusted to them, but also in relation to fraudulent contrivances for misrepresenting the amount of work done. For such offences fine or imprisonment may be inflicted.

Apart from the legislation already mentioned, there are a great number of Acts of parliament directly or indirectly affecting labour. The general direction of all such legislation is to ameliorate the condition of workmen.

The legislation regulating the hours of labour of young persons, originating in the benevolent exertions of the earl of Shaftesbury, and extended by Lord Aberdare as secretary of state for the home department and others, is most important (see FACTORY ACTS). The indirect effects of those provisions in causing better order in the conduct of manufacturing industries cannot be overlooked. The Agricultural Gangs Act 1867, arising out of the practice in the east of England of persons known as gang masters hiring children, young persons, and women, with a view to contracting with farmers and others for agricultural work is a recent illustration of the direct objects of such legislation. The fencing of machinery, the careful working of coal and metalliferous mines, and the like, have been the subject of minute legislative provisions, which, as well as the Explosives Act 1875, intimately affect the wellbeing of the labouring community and the general safety.

The wants of servants are considered in the preference shown to claims for wages in the case of death and bankruptcy, and the general need of all classes of workmen is kept in view in the provisions relating to workmen's dwellings, and the obligation of railway companies to afford facilities for their conveyance at a low rate. Less directly they are considered in the legislation relating to friendly and provident societies; of equivocal effect was the legislation respecting small loans, intended to facilitate the purchase of tools, but taken advantage of to form loan societies of doubtful general benefit to the community. We cannot notice here the effect of the laws regulating the land and sea forces on contracts relating to labour by persons entering the army or navy. (J. E. D.)

LABRADOR, in the widest acceptation of the word, is the peninsular portion of North America bounded on three sides by the Gulf of St Lawrence, the North Atlantic, Hudson's Straits, and Hudson's Bay, and vaguely defined towards the south-west by Rupert's river, the Mistassini river, and the Bersiamits river. It extends from about 49° to 63° N. lat., and from the 55th to the 79th meridian. Its greatest length from the Straits of Belle Isle, which separate it from Newfoundland, to Cape Wolstenholme, its most northern extremity, is 1100 miles; its greatest breadth is about 700 miles. The area is approximately 420,000 square miles, equal to the united areas of the British Isles, France, and Prussia. As a permanent abode of civilized man, Labrador is on the whole one of the most uninviting regions on the face of the earth. The Atlantic coast is the edge of a vast solitude of rocky hills, split and blasted by frosts and beaten by the waves. A vast table-land, in one region 2240 feet above the sea-level, occupies much of the interior. This plateau, says Professor Hind, "is pre-eminently sterile, and, where the country is not burned, caribou moss covers the rocks, with stunted spruce, birch, and aspen in the hollows and deep ravines. The whole of the table-land is strewed with an infinite number of boulders, sometimes three and four deep; these singular erratics are perched on the summit of every mountain and hill, often on the edges of cliffs, and they vary in size from 1 foot to 20 feet in diameter. Language fails to paint the awful desolation of the table-land of the Labrador peninsula."

The interior of Labrador has been but very partially explored, and even the course of the main rivers is largely matter of conjecture. The largest is probably the Ashwanipi or Hamilton river, which rises in the rear of the Seven Islands, drains a portion of the vast table-land, and falls into Hamilton Inlet, on the Atlantic coast. At its mouth it is nearly a mile and a half in width. One hundred miles from its mouth are the great falls and rapids which extend over 20 miles, and involve fifteen portages. The valley of this river is well wooded, some of the trees, which are chiefly spruce, white birch, and poplar, being of considerable size, and tracts of loamy soil being found at intervals along its banks. The Kenamou and the Nasquapee or North-West river also fall into Hamilton Inlet. The Eagle river, the West and East rivers, all famous for salmon and trout, discharge their waters into Sandwich Bay. Of the rivers falling into Ungava Bay the largest is Koksoak or South river, which is 3 miles wide at its mouth, and has its source in Lake Kaniapuscaw, 70 miles long and 20 broad, which occupies the very centre of the peninsula, being equidistant from the St Lawrence, Ungava, and Hamilton Inlet, and 350 miles from each. George's river and Whale river also fall into Ungava Bay. The aspect of the country drained by these rivers is forbidding in the extreme, bleak and barren rocks, with a few stunted trees at the mouths of the rivers or around the lakes, being the most marked features. In a few sheltered spots, however, on the margins of the rivers, timber of fair size is to be found. The rivers discharging into Hudson's Bay are Rupert's river, East Main, and Great and Little Whale rivers. The Moisie river, 250 miles in length, the Mingan, and the Ounaneme fall into the Gulf of St Lawrence. The St Augustine falls into a fine bay of the same name, and has its source in the lakes and marshes of the table-land. The country through which these rivers flow is rugged and mountainous, swamps and innumerable lakes occupying the lower grounds.

By far the most important portion of Labrador is the Atlantic seaboard. The coast itself is rugged, but is deeply indented with bays and inlets, and has many fine harbours. The scenery is grand and impressive. Dark and yellow headlands towering over the waters are ever in sight, some grim and naked, others clad in the pale green of mosses and dwarf shrubbery. With miles on miles of rocky precipices alternate lengthened sea slopes, tame and monotonous, or fantastic and picturesque in form, with stony vales winding alway among the blue hills of the interior. Battle Harbour at the northern extremity of the straits of Belle Isle, is a busy fishing settlement with a narrow sheltered roadstead about half a mile in length between Battle Islands and Great Caribou Island. The water is of great depth in this neighbourhood, and is noted for its wonderful ground swell, which at times rolls in without wind from the eastward into St Lewis Sound, "bursting," as Admiral Bayfield describes it, "with fury over islets 30 feet high, or sending sheets of foam and spray sparkling in the sunbeams 50 feet up the sides of precipices." By far the greatest of the numerous inlets which indent the coast is Eskimo Bay or Ivuktoke or Hamilton Inlet, 250 miles north of the straits of Belle Isle. This inlet is 30 miles wide at the entrance, but at Port Rigolette, 50 miles from the sea, it narrows to a mile. On both sides of these narrows hills tower to the height of 1000 feet, wooded with spruce from base to summit. At the termination of this gorge the inlet again expands and forms Lake Melville, 30 miles in length and 20 in breadth. After narrowing again it forms another lake (Goose Bay) 7 miles wide and 20 long, and at its extremity the head of the great inlet is reached, 150 miles from the sea. The scenery along the shores of Hamilton Inlet is wild and rugged, and above Rigolette becomes very grand. Along the south shore of Melville lake are the volcanic peaks of the Mealy Mountains, 1500 feet in height. This range commences 100 miles to the south of Hamilton Inlet, running nearly parallel to the coast; and after skirting Lake Melville it strikes westerly and is lost in the hilly regions of the interior.

Northern Labrador, from Cape Webeck to Cape Chudleigh, is the proper home of the Eskimo of this region, who are now about 1400 in number.[1] By the labours of the Moravian Brethren, commenced in 1770, nearly the whole of them have been brought under Christian training. The Brethren have four stations—Hopedale, (55° 25′ N. lat.), Nain (56° 25′), Okkak (57° 33′), and Hebron, (58° 50′). Each station has a church, store, dwelling-house for the missionaries, and workshops for the native tradesmen. The missionaries number about twenty.

The white inhabitants of the St Lawrence coast of Labrador are chiefly of Acadian or Canadian origin, with a few settled fishermen from France. On the Atlantic coast of Labrador many of the white inhabitants are British sailors and their descendants. Salmon and cod fishing are their main occupations; and the products of their industries are exchanged with traders on the spot for such commodities as they require. The winter is passed in trapping fur-bearing animals. There are nine places of worship—four of the Church of England, three of the Church of Rome, and two Wesleyan. During the fishing season a steamer carrying mails and passengers plies fortnightly on the coast, connecting with the Newfoundland coastal steamer at Battle Harbour.

The Indians inhabiting the interior of Labrador are now greatly reduced in numbers. The returns of the Hudson's Bay Company show that about four thousand of these Indians frequent the company's posts throughout the whole of Labrador; and this account probably includes nearly their whole strength. Nineteen-twentieths of them are nominally Roman Catholics. The early Jesuit missions in Canada extended to Labrador; and of late years Roman Catholic missions have been resumed and are now systematically carried on. Game of all kinds is every year becoming scarcer, and in many parts has almost disappeared. Fires have destroyed the forests, berry-bearing shrubs, mosses, and lichens, and converted whole districts into hopeless deserts. The savage tribes wander over a vast extent of country, and have established routes along certain rivers and lakes, by which periodically they make their way to the sea-coast, to exchange the products of the chase for firearms, clothing, and other necessaries.

It is only in the interior valleys of the rivers, at some distance from the coast, that any extent of forest appears; but there sufficient timber for fuel and building purposes can almost always be found. The trees are chiefly larch, birch, aspen, silver fir, black, white, and red spruce, willow, cherry, and mountain ash. Among the wild animals may be enumerated reindeer, black and white bears, wolves, foxes, martens, lynxes, otters, minks, beavers, musk-rats, hares, rabbits, moles. The birds are represented by the hawk, falcon, eagle, owl, raven, ptarmigan, spruce partridge, curlew, grey plover, sandpipers and other waders, geese, ducks, gulls, divers, swallows, martins, snipe, pigeons. Berry-bearing plants abound in many regions—whortleberries, raspberries, cranberries, partridge berries, bake appleberries, wild currants, and wild gooseberries. In summer, where there are sheltered spots, mosses of every hue, wild flowers of the most delicate colours, ferns, and tall grasses diversify the scene.

Though Labrador is detached from Arctic lands, and though much of it lies between the same parallels of latitude as Great Britain, the climate is rigorous in the extreme, owing mainly to the ice-laden Arctic current which washes its shores. Snow lies from September or October till June. In winter the whole coast is blockaded by ice-fields drifting from Baffin's Bay and other outlets of the Arctic Ocean; while in summer icebergs, stranded or floating, impart a stern grandeur to the frowning shores. At Nain the mean annual temperature is 22·52° Fahr., at Okkak, 27·86°, and at Hopedale, 27·82°. In summer the thermometer sometimes reaches 75°; spirits freeze in the intense cold of winter, and 30° below zero is not uncommon; but, owing to the dryness of the air and the absence of high winds, such a temperature is not felt as uncomfortable. The winter is one continued stretch of cold dry frosty weather, and is felt to be bracing by those accustomed to it. Travelling is performed by sledges drawn by dogs, sometimes at the rate of 100 miles a day, over the frozen snow.

The total permanent population of Labrador is about 12,500, and is distributed as follows:—

On the St Lawrence coast from Port Neuf to Blanc Sablon	4,411
On the Atlantic coast—white populatinn	2 416
,, ,, Eskimo	1,700
Indians of the interior	4,000
Total	12,527

Tourists in search of the picturesque, invalids, sportsmen, and anglers are finding their way, of late years, in increasing numbers to Labrador during its brief but lovely summer; and in the fishing season from the end of June to the first or second week of October the migratory population from Newfoundland, Nova Scotia, Canada, and the United States numbers between 20,000 and 25,000.

But little is known of the geology of Labrador. It has been ascertained, however, that the Laurentian formation constitutes the great framework of the peninsula, and that Lower Silurian beds, principally Potsdam, rest on the Laurentian at various points along the coast. On the north side of the Straits of Belle Isle there is a large development of Lower Silurian rocks, corresponding to those on the Newfoundland side opposite. The Potsdam rocks here are grey and reddish sandstones, 230 feet in thickness, overlaid by 140 feet of limestone, with some shale. These limestones and sandstones extend about 80 miles along the coast, and about 10 miles back from the shore. All over the country gneiss ranges of mountains and hills and gneiss boulders in countless multitudes are everywhere met with. "The rocks of this formation," says Sir William Logan, "are the most ancient known on the American continent, and correspond probably to the oldest gneiss of Finland and Scandinavia, and to some similar rocks in the north of Scotland." The system is made up of crystallized rocks, and may be considered as an alternation of crystalline schists, quartzites, limestones, and serpentines. Copper ore has been discovered at various points along the coast; also silver, lead, and mica, as well as gold.

The southern portion of the Labrador coast, as far north as Sandwich Bay, has been frequented as a fishing ground for more than a century. Since about 1850 large numbers of fishermen have extended their operations as far north as Cape Harrison or Webeck. From about 1870 Newfoundland cod-fishers have ventured as far north as Cape Mugford; and the probability is that they will soon be attracted still farther, to Cape Chudleigh, at the entrance of Hudson's Straits, by the reports of the amazing quantity of fish. From Cape Harrison to Cape Mugford the coast, like that of Norway, is deeply serrated by a succession of narrow fiords stretching from 30 to 50 miles into the interior. As far as Freestone Point, 120 miles north of Cape Harrison, the heads of many of these fiords contain timber fit for the construction of fishing craft and all ordinary building purposes. The climate and soil of these sheltered spots also permit the cultivation of potatoes and garden vegetables. According to Professor Hind, "it is fringed with a vast multitude of islands forming a continuous archipelago from Cape Aillik to Cape Mugford, averaging 20 miles in depth seawards. Outside these islands, and about 15 miles seawards from them, are numerous banks and shoals which form the summer feeding ground of large cod, and a second range of banks, outside the shoals, which are probably their winter feeding grounds." This island-studded area, exclusive of the banks and shoals, from Cape Harrison to Cape Mugford, he estimates at 5200 square miles, furnishing a boat fishing ground for cod (which as yet has hardly been touched) nearly as large as the combined areas of the English and French boat fishing ground on the coasts of Newfoundland. The Arctic current which washes the coast of Labrador exerts a most important influence on the fish life of those regions, as well as on that of the seas around Newfoundland, Canada, and the United States, forming, in many places, "a living mass, a vast ocean of living slime;" and this slime "accumulates on the banks of northern Labrador, and renders the existence possible of all those forms of marine life which contribute to the support of the great shoals of cod which also find their home there" (Hind). The same current which brings the slime and multitudes of minute crustaceans also carries on its bosom innumerable cod ova, and distributes them far and wide.

The principal fisheries are those of cod, herrings, salmon, and seals. The following table is compiled from the Newfoundland customs returns for the year ending July 31, 1880:—

Exported by Newfoundland Houses from Labrador direct.

393,436	quintals dried codfish	$1,180,308
144	do. green do.	144
1,096	seal skins	1,096
50	tuns seal oil	0,400
76	do. cod oil	10,032
1	do. other oils	108
17	do. blubber	236
592	tierces pickled salmon	8,288
16,970	barrels pickled herrings	50,910
14	do. do. trout	98
459	do. do. mackerel	1,376
58	do. dried capelin	29
		1,259,025

Exported by Houses not connected with Newfoundland.

14,000	quintals dried codfish	$42,000
110	seal skins	110
14	tuns seal oil	1,792
55	do. cod oil	7,260
2	do. refuse	28
15	do. blubber	210
400	tierces pickled salmon	5,600
30,000	lb salmon in tins	3,000
700	barrels pickled herrings	2,100
40	do. do. trout	280
200	do. do. mackerel	600
180	do. dried capelin	80
		63,060

The estimated value of exports by traders being 19,950, this gives for the total exports $1,342,035, or £279,590 sterling.

To these direct exportations must be added the fish of various kinds taken at Labrador and sent to Newfoundland for shipment, amounting to about a third of the whole; also the quantities

[1] The dialect of the Labrador Eskimo is treated of in Kleinschmidt, *Gram. d. grönland. Sprache*, Berlin, 1851.

taken by American and Canadian fishermen of which no returns can be obtained, but which are estimated to be about an eighth of the quantities taken by Newfoundland fishermen. These last can work the fisheries more successfully than those coming from a distance, and are gradually absorbing the trade. The total catch by Newfoundlanders, Canadians, Americans, and Eskimo on the Atlantic and St Lawrence coasts of Labrador may be valued at £1,000,000 sterling per annum, and is increasing steadily. The number of vessels employed annually is estimated at from 1100 to 1200.

Labrador as well as Newfoundland was discovered by John Cabot in 1497; the recent discovery of a map made by or under the direction of Sebastian Cabot proves that it must surrender the honour of being his "Prima tierra vista" to the present island of Cape Breton. Cabot does not appear to have given any name to Labrador; tradition has it that a Basque whaler, called "Labrador," penetrated as far as Labrador Bay (now Bradore Bay), and that, as this bay was in process of time much frequented by Basque fishermen, the name was extended to the whole coast. The Basques were the successors of the Norsemen. After them, about the year 1520, came the Bretons, who founded the town of Brest in Bradore Bay, about 3 miles from Blanc Sablon Harbour, which at one time contained upwards of one thousand permanent residents. The ruins and terraces of this old town are still visible. For a lengthened period extensive fisheries (to which they attached the greatest importance) were carried on by the French on the Labrador coast, near the Straits of Belle Isle. After the British conquest of Canada the whole fisheries along the southern and eastern shores of Labrador were placed under the government of Quebec, and they continued so till 1763, when the Atlantic coast was annexed to the government of Newfoundland, the boundary between the two jurisdictions being fixed at Blanc Sablon. In 1773, owing to difficulties arising out of grants made to a few persons, under French rule, the eastern coast was restored to the government of Quebec; but since 1809 it has been again attached to Newfoundland. In 1824 the governor of Newfoundland was empowered to institute a court of civil jurisdiction on the coast of Labrador. At present the civil and criminal court of Labrador is presided over by one judge appointed by the governor in council. All goods landed are subjected to the duties imposed on like goods in any part of the island of Newfoundland. The extent of the jurisdiction of the government of Newfoundland in Labrador is thus defined (Letters-Patent, 28th March 1876); "all the coast of Labrador from the entrance of Hudson's Straits to a line to be drawn due north and south from Anse Sablon on the said coast to the fifty-second degree of north latitude, and all the islands adjacent to that part of the said coast of Labrador." The north-western portion, or that which drains into Hudson's Bay and Hudson's Straits, now forms the North-East Territory of the Dominion of Canada, and the southern portion, draining into the Gulf of St Lawrence, is incorporated with the province of Quebec. An undefined area of what is now the North-East Territory was formerly known as East Main.

See Cartwright, *Sixteen Years on the Coast of Labrador*, Newark, 1792; Hind, *Explorations of the Labrador Peninsula*, 1863; Chimmo, in *Journ. Roy. Geog. Soc.*, 1868; Bell, in *Report of the Geol. Survey of Canada*, 1879. (M. H.)

LA BRUYÈRE, Jean de (1645-1696), essayist and moralist, was born at Paris in August 1645, and not, as has more commonly been asserted, at Dourdan (Seine-et-Oise) in 1639. His family was of the middle class, and his reference to a certain Geoffroy de la Bruyère, a crusader, is only a satirical illustration of a method of self-ennoblement common in France as in some other countries. Indeed he himself always signed the name Delabruyère in one word, thus avowing his *roture*. His progenitors, however, were of respectable position, and he could trace them back at least as far as his great-grandfather, who had been a strong Leaguer. La Bruyère's own father held a municipal appointment in the capital, and seems as well as his son to have been in easy circumstances. The son was educated by the Oratorians, and at the university of Orleans; he was called to the bar, and in 1673 bought a post in the revenue department at Caen, which gave the status of noblesse and a certain income. He afterwards in 1687 sold this office. His predecessor in it was a relation of Bossuet, and it is thought that the transaction was the cause of La Bruyère's introduction to the great orator. Bossuet, who from the date of his own preceptorship of the dauphin, was a kind of agent-general for tutorships in the royal family, introduced him in 1683 or 1684 to the household of the great Condé, whose grandson Henri Jules de Bourbon he was charged to educate. The rest of his life was passed in the household of the prince or else at court, and he seems to have profited by the inclination which all the Condé family had for the society of men of letters without suffering from the capricious and tyrannical temper which was also one of the characteristics of the house. Very little is known of the events of this part or indeed of any part of his life. Although he certainly mixed freely in society at a time when more gossip was committed to paper than at almost any other, the notices of him are very few, though they are almost always favourable. The impression derived from them is of a silent observant but somewhat awkward man, resembling in manners our own Addison, whose master in literature La Bruyère undoubtedly was. Yet despite the numerous enemies which his book raised up for him, most of the few personal notices we have are, as has been said, favourable—notably that of St Simon, an acute judge and one bitterly prejudiced against roturiers generally. There is a curious passage in a letter from Boileau to Racine in which he regrets that "nature has not made La Bruyère as agreeable as he would like to be," which, as he at the same time calls him a "fort honnête homme," and says that he would lack nothing were it not for the conduct of nature in this respect, can only refer to the want of manner just noticed. His *Caractères* appeared in 1688, and at once, as Malezieu had predicted, brought him "bien des lecteurs et bien des ennemis." At the head of these were Thomas Corneille, Fontenelle, and Benserade, who were pretty clearly aimed at in the book, as well as innumerable other persons, men and women of letters as well as of society, on whom the cap of La Bruyère's fancy-portraits was fitted by manuscript "keys" which were at once compiled by the scribblers of the day. The friendship of Bossuet and still more the protection of the Condés defended the author quite sufficiently, and he continued to insert fresh portraits of his contemporaries in each new edition of his book. Those, however, whom he had attacked were powerful in the Academy, and numerous defeats awaited La Bruyère before he could make his way into that guarded hold. He was defeated thrice in 1691, and on one memorable occasion he had but seven votes, five of which were those of Bossuet, Boileau, Racine, Pelisson, and Bussy-Rabutin. It was not till 1695 that he was elected, and even then an epigram, which, considering his admitted insignificance in conversation, was not of the worst, *hæsit lateri*:—

> "Quand la Bruyère se présente
> Pourquoi faut il crier haro ?
> Pour faire un nombre de quarante
> Ne falloit il pas un zéro ?"

His unpopularity was, however, chiefly confined to the subjects of his sarcastic portraiture, and to the hack writers of the time, of whom he was wont to speak with a disdain only surpassed by that of Pope. His description of the leading newspaper of the day as "immédiatement au dessous du rien" is the best remembered specimen of these unwise attacks which, both in France and England, retarded the establishment of an independent profession of letters for many years. La Bruyère's discourse of admission at the Academy was, like his admission itself, severely criticized, yet it is certainly one of the best of its kind. With the *Caractères*, the translation of Theophrastus, and a few letters, it completes the list of his literary work, with the exception of a curious and much-disputed posthumous treatise. La Bruyère died very suddenly, and not long after his admission to the Academy. He is said to have become suddenly deaf in an assembly of his friends, and, being carried home to the Hôtel de Condé, to have expired of apoplexy a day or two afterwards. It is not surprising that, considering the recent panic about poisoning, the bitter personal enmities which he had excited, and the peculiar circumstances of his death, suspicions of foul play should have been entertained, but there seems to be no foundation for them. Two years after his death appeared certain *Dialogues sur le Quiétisme*, alleged to have been found among his papers incomplete, and to have been completed by the editor. As these dialogues are far inferior in literary merit to La Bruyère's other works, their genuineness has been denied. But the straightforward and circumstantial account of their appearance given by their editor, the Abbé Dupin, a man of acknowledged probity, the intimacy of La Bruyère with Bossuet, whose views in his contest with Fénelon these dialogues are designed to further, and the entire absence at so short a time after the alleged author's death of the least protest on the part of his friends and representatives, seem to be decisive in their favour.

Although for reasons to be given shortly it is permissible to doubt whether the value of the *Caractères* has not been somewhat exaggerated by traditional French criticism, they deserve beyond all question a high place among the great works of French literature. The plan of the book is thoroughly original, if that term may be accorded to a novel and skilful combination of existing elements. That the little treatise of Theophrastus may have furnished the first idea of it is doubtless true, but only a very small part of the Frenchman's work is due to the Greek. With the ethical generalizations and social Dutch painting of Theophrastus La Bruyère combined the peculiarities of the Montaigne essay, of the *Pensées* and *Maximes* of which Pascal and La Rochefoucauld are the masters respectively, and lastly of that peculiar 17th century product, the portrait or elaborate literary picture of the personal and mental characteristics of an individual. The result was quite unlike anything that had been before seen, and it has not been exactly reproduced since, though the essay of Addison and Steele resembles it very closely, especially in the introduction of fancy portraits. In the titles of his work and in its extreme desultoriness La Bruyère reminds the reader of Montaigne, but he aimed too much at sententiousness to attempt even the apparent continuity of the great essayist. The short paragraphs of which his chapters consist are made up of maxims proper, of criticisms literary and ethical, and above all of the celebrated sketches of individuals baptized with names taken from the plays and romances of the time. These last are undoubtedly the great feature of the work, and that which gave it its immediate if not its enduring popularity. They are wonderfully piquant, extraordinarily life-like in a certain sense, and must have given great pleasure or more frequently exquisite pain to the originals, who were in many cases unmistakable and in most recognizable by a society which held to the full Madame de Sévigné's views of the usefulness of "le prochain" as a butt for satirical observation. But there is something wanting in them. The criticism of Charpentier, who received La Bruyère at the Academy, and who was of the opposite faction, has usually been dismissed as one-sided, but it is in fact fully justified as far as it goes. La Bruyère literally "est [trop] descendu dans le particulier." He has neither like Molière embodied abstract peculiarities in a single life-like type, nor has he like Shakespeare made the individual pass *sub speciem æternitatis*, and serve as a type while retaining his individuality. He is a photographer rather than an artist in his portraiture. So too his maxims, admirably as they are expressed, and exact as their truth often is, are on a lower level than those of La Rochefoucauld, which, rather unwisely, they sometimes follow very closely. Beside the sculpturesque precision, the Roman brevity, the profoundness of ethical intuition "piercing to the accepted hells beneath," of the great Frondeur, La Bruyère has the air of a literary *petit-maître* dressing up superficial observation in the finery of *esprit*. It is indeed only by comparison that he loses, but then it is by comparison that he is usually praised. There is no doubt that his abundant wit and his personal "malice" have done much to give him his rank in French literature, but much must also be allowed to his purely literary merits. With Racine and Massillon he is probably the very best writer of what is somewhat arbitrarily styled classical French. He is hardly ever incorrect—the highest merit in the eyes of a French academic critic. He is always well-bred, never obscure, rarely though sometimes "precious" in the turns and niceties of language in which he delights to indulge, in his avowed design of attracting readers by form now that in point of matter "tout est dit." It ought to be added to his credit that he was sensible of the folly of impoverishing French by ejecting old words. His chapter on "Les ouvrages de l'esprit" contains much good criticism, though it shows that, like most of his contemporaries except Fénelon, he was lamentably ignorant of the literature of his own tongue.

The editions of La Bruyère, both partial and complete, have been extremely numerous. *Les Caractères de Théophraste traduits du Grec, avec les Caractères et les Mœurs de ce Siècle*, appeared for the first time in 1688, being published by Michallet, to whose little daughter, according to tradition, La Bruyère gave the profits of the book. Two other editions, little altered, were published in the same year. In the following year, and in each year until 1694, with the exception of 1693, a fresh edition appeared, and, in all these five, additions, omissions, and alterations were largely made. A ninth edition, not much altered, was put forth in the year of the author's death. The Academy speech appeared in the eighth edition. The Quietist dialogues were published in 1698; most of the letters, including those addressed to Condé, not till 1867. In the last thirty or forty years numerous editions of the complete works have appeared, notably those of Walckenaer (1845), Servois (1867), Asselineau (a scholarly reprint of the last original edition, 1872), and finally Chassang (1876); the last is one of the most generally useful, as the editor has collected almost everything of value in his predecessors. The literature of "keys" to La Bruyère is extensive and apocryphal. Almost everything that can be done in this direction and in that of general illustration was done by the late M. Edouard Fournier in his learned and amusing *Comédie de La Bruyère*. (G. SA.)

LABUAN, or LABUHAN, an island of the East Indian Archipelago, which has been a British possession since 1846. It lies about 6 miles off the north-west coast of Borneo, opposite the northern end of the great bay of Brunei. Rudely triangular in shape, it measures about 7 miles across the base, and has a length of 11 miles from north to south. The general flatness of the surface is broken by a number of undulating hills, none of which, however, exceed 90 feet in height. At the time of the first settlement most of the ground was occupied by virgin forest, in which camphor trees of noble proportions were conspicuous; but nearly the whole of this has been destroyed either by human effort or by jungle fires. The soil is very poor, except in the valleys of the larger streams. Of the total area, estimated at over 45 square miles, or 29,350 acres, 21,000 acres are supposed to be capable of cultivation; but of this not more than 1500 acres are sown with rice, the only crop attempted on a large scale in the island. The cocoa-nut flourishes to no small profit on the little island of Daat; and the African oil palm promises well. At the time of its occupation a brilliant future was prophesied for Labuan: its harbour was to make it a second Singapore, and its coal beds were to prove an unfailing source of wealth. Such anticipations are far from having been realized. Though the workable coal in the island has been estimated at no less than 400,000,000 tons, the mines have commercially proved an utter failure. The Scottish Oriental Coal Company—the fourth of its kind—came to an untimely end in 1880; from 1868 it had raised 53,741 tons of clean coal, each tion costing about 72s. and selling for not more than 25s. or 30s. The want of machinery strong enough to keep the workings dry is assigned as one of the chief reasons of the collapse. The coal, which appears to be of Tertiary formation, is of good quality; the mines are on the north end of the island near the village of Lubok Tamiang. The general trade of Labuan consists mainly of the importation and re-exportation of Bornean produce; and most of the Labuan merchants are from Singapore houses. There are several factories for the preparation of sago flour. The total burden of the vessels entering the port in 1879 was only 10,787 tons, of which 8516 was due to steam ships. The population, which in 1861 was 2373 (1627 males, 701 females), was 5731 (3414 males, 2317 females) in 1881. It includes Chinese, Klings, chiefly from Karikal in French India, Malay fishermen, and Kudayans and Tutongs from Borneo. Port Victoria, the principal settlement, has no municipal government.

The colony is now self-supporting. The Chinese have schools for their own children; and Sir Henry Bulwer established in 1873 a school for the teaching of Malay and English. The temporary diocese of Labuan includes, not only Sarawak in Borneo, but also Singapore (which is 770 miles distant); and the church of St Andrews in that city is the cathedral of the see. Convicts have been sent to Labuan from the Straits settlements since 1866.

See Keppel, *Visit to Indian Archipelago*, London, 1853; Mundy, *Narrative of Events in Borneo*, London, 1848; Burbidge. *Gardens of the Sun*, London, 1880.

LABURNUM is the specific name of a familiar tree of the genus *Cytisus*, Dec., of the pea family or *Leguminosæ*. It is a native of the mountains of France, Switzerland, southern Germany, northern Italy, &c., has long been cultivated as an ornamental tree throughout Europe, and was introduced into north-east America by the European colonists. Gerard records it as growing in his garden in 1596 under the names of anagyris, laburnum, or beane trefoyle (*Historie of Plants*, p. 1239), but the date of its introduction into England appears to be unknown. In France it is called l'aubour—a corruption from laburnum according to Du Hamel—as also arbois, *i.e.*, arc-bois, "the wood having been used by the ancient Gauls for bows. It is still so employed in some parts of the Mâconnois, where the bows are found to preserve their strength and elasticity for half a century" (Loudon, *Arboretum*, ii. p. 590).

Several varieties of this well-known tree are cultivated, differing in the size of the flowers, in the form of the foliage, &c., such as the "oak-leafed" (*quercifolium*), *pendulum*, *crispum*, &c. One of the most remarkable forms is *C. Adami*, Poir. (*C. purpurascens*, Hort.), which bears three kinds of blossoms, viz., racemes of pure yellow flowers, others of a purple colour, and others of an intermediate brick-red tint—all three kinds being borne by one and the same tree. The last are hybrid blossoms, and are sterile, with malformed ovules, though, curiously enough, the pollen appears to be good. The yellow and purple "reversions" are fertile. It originated in Paris in 1828 by M. Adam, who inserted a "shield" of the bark of *C. purpureus*, Scop., into a stock of *C. Laburnum*, L. A vigorous shoot from this bud was subsequently propagated. Hence it would appear that the two distinct species mentioned above became united by their cambium layers, and the trees propagated therefrom subsequently reverted to their respective parentages in bearing both yellow and purple flowers, but produce as well blossoms of an intermediate or hybrid character. Such a result, Mr Darwin observes, may be called a "graft-hybrid." For full details see Darwin's *Animals and Plants under Domestication*.

The laburnum has highly poisonous properties. A case is recorded of nearly fatal results to several boys who masticated the roots on finding they tasted like liquorice, which is a member of the same family as the laburnum. It has proved fatal to cattle, though hares and rabbits eat the bark of it with avidity (*Gardener's Chronicle*, 1881, vol. xvi. p. 666). The seeds also are highly poisonous, possessing emetic as well as narcotico-acrid principles, especially in a green state. Gerard (*loc. cit.*) alludes to the powerful effect produced on the system by taking the bruised leaves medicinally. Pliny records that bees will not visit the flowers (*N. H.*, xvi. 31), but this may be an error, for Mr Darwin found by experiment that insects play an important part in the fertilization of the laburnum.

The heart wood of the laburnum is of a dark reddish-brown colour, hard and durable, and takes a good polish. Hence it is much prized by turners, and used with other coloured woods for inlaying purposes. The laburnum has been called false ebony from this character of its wood.

The roots are subject to a peculiar disease, not at all uncommon in other members of the *Leguminosæ*, the fine rootlets swelling into minute club-shaped processes called exostoses, resembling coral-branches in shape. Large masses of such, one or two inches in diameter, may be found at the extremities of the roots of old laburnum trees. They are apparently caused by a fungus which appears to be ubiquitous, as the disease is rarely, if ever, known to be absent, though it does not seem to cause much if any injury to the health of the plants it attacks. See *Studier öfver Leguminosernas rotknolär*, 1874, by Dr Jacob Erikssen; also *Gardener's Chronicle*, 1879, xi. p. 209, and xii. p. 112.

LABYRINTH. I. The legendary labyrinth is one of the clearest examples of the close relation between mythology and the early stages of the industrial arts. The word λαβύρινθος is derived from the λαύραι or passages of a mine; the digamma before the ρ has become in the latter a vowel, while in the former it retains its consonantal value. The mines of Greece, like those of Thrace and the Ægean Islands, were probably first worked by the Phœnician traders; and the simple-minded natives regarded the strange holes in the ground with wonder and awe. To the natural fear of darkness was added the invariable tendency of the uneducated to regard as supernatural the power conferred by superior knowledge; moreover, the god of the riches of the lower world was also the god of death and the dead. Their fear expressed itself in tales of the extraordinary ramifications of the dark passages and of the danger to which any heedless intruder into them was exposed. The maze of passages was called a labyrinth; the word became a proper name and gained a life and meaning of its own in legend, quite unconnected with its original application. It retained a more antique form, as proper names frequently do, whereas the mining term λαύρα lost the older character of the digamma. It must have been comparatively late before the word labyrinth acquired this new independence and connotation. The best-known instance of its mythic character is found in the legends of Crete. It was interwoven with the tales, partly founded on historical events and partly derived from ancient religion, which clustered round the name of Minos. The skilful workman, Dædalus, who sums up all the legendary conceptions of skill in handicraft, made for King Minos a labyrinth, in the centre of which the Minotaur was placed. No one who entered this labyrinth could find his way out again; he became the prey of the monster. The seven youths and seven maidens sent regularly by the Athenians as tribute were thus devoured, until Theseus slew the Minotaur, and escaped out of the labyrinth by the help of the clue which Ariadne had given him.

Pliny says that there had been in Crete a building called the labyrinth, of which no remains existed in his time; but Hoek has proved quite certainly from the discrepancies and contradictions in accounts and in representations on coins that it had never a real existence. The rocks of Crete are full of winding caves, and these gave the first hint of the legendary labyrinth. This labyrinth is, by the older writers, placed beside Cnossus, and is figured on coins of that city. Late writers, such as Claudian, represent it as being beside Gortyna, and there is a wonderful set of winding passages and chambers in the rocks near that place, which is still pointed out as the labyrinth. When the name had once acquired this meaning, it was applied to several real buildings, of which the following are the most famous. 1. The Egyptian labyrinth, beside the town of Arsinoe or Crocodilopolis, was in two stories, one of them underground, and contained three thousand rooms. Strabo thinks it was built as a common place of meeting for the people of the various nomes; Herodotus and Diodorus say that it was the burial place of the twelve kings who ruled Egypt about 700 B.C. Müller (*Hist. Greek Art*, § 50-2) also thinks the object of such buildings must have been sepulchral. 2. The Samian labyrinth was built by Theodorus, one of the Samian school of sculptors, for the tyrant Polycrates. It had a hundred and fifty columns, and Pliny says that some scanty remains of it existed in his time. 3. The Lemnian labyrinth, mentioned by Pliny, seems to be a confusion with the Samian (*cf.* Pliny, xxxvi. 19, 3 with 83). 4. The Italian labyrinth was a series of chambers in the lower part of the grave of Porsenna at Clusium. Some maintain that this tomb has been found in the mound named Poggio Gajella near Chiusi.

See Herod. ii. 148; Str. p. 811; Plin. xxxvi. 13 and 19; Müller, *Etrusker*; Dennis, *Cities and Cemeteries of Etruria*; Hoek, *Kreta*. Cockerell (*Travels*), and Prokesch (*Denkwürdigkeiten*) describe the so-called labyrinth of Gortyna.

II. In gardening, a labyrinth or maze means an intricate network of pathways enclosed by hedges or plantations, so that those who enter become bewildered in their efforts to find the centre or make their exit. It is a remnant of the old geometrical style of gardening, but is yet occasionally introduced into pleasure grounds. There are two methods of forming it. That which is perhaps the more common consists of walks, or alleys as they were formerly called, laid out and kept to an equal width or nearly so by parallel hedges, which should be kept so close and thick that the eye cannot readily penetrate through them. The task is to get to the centre, which is often raised, and generally contains a covered seat, a fountain, a statue, or even a small group of trees. After reaching this point the next thing is to return to the entrance, when it is found that egress is as difficult as ingress. To every design of this sort there should be a key, but even those who know the key are apt to be perplexed. Sometimes the design consists of alleys only, as in fig. 1, published in 1706 by

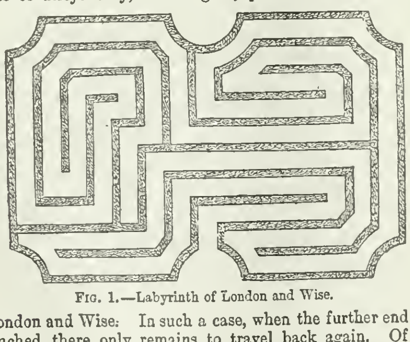

FIG. 1.—Labyrinth of London and Wise.

London and Wise. In such a case, when the further end is reached, there only remains to travel back again. Of a more pretentious character was a design published by Switzer in 1742. This is of octagonal form, with very numerous parallel hedges and paths, and "six different entrances, whereof there is but one that leads to the centre, and that is attended with some difficulties and a great many stops." Some of the older designs for labyrinths, on the other hand, avoid this close parallelism of the alleys, which, though equally involved and intricate in their

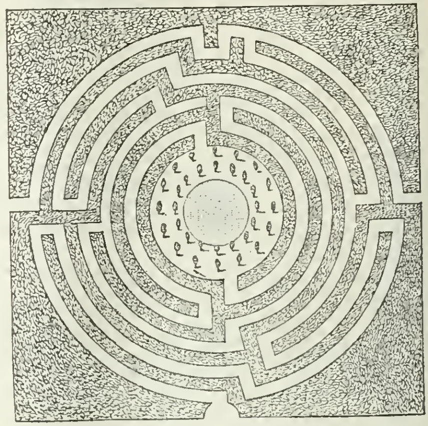

FIG. 2.—Labyrinth of Batty Langley.

windings, are carried through blocks of thick planting, as shown in fig. 2, from a design published in 1728 by Batty Langley. These blocks of shrubbery have been called

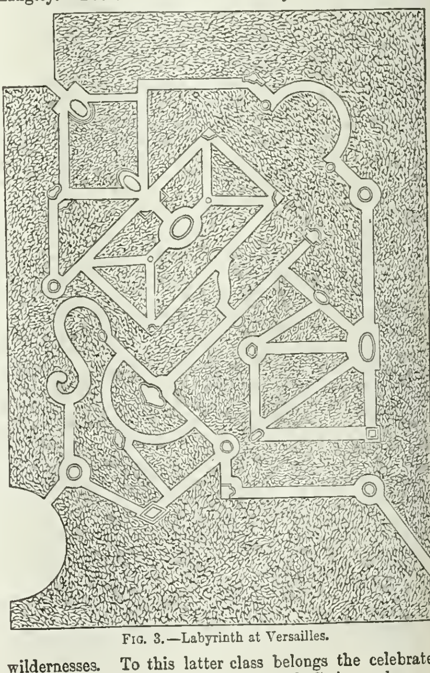

FIG. 3.—Labyrinth at Versailles.

wildernesses. To this latter class belongs the celebrated labyrinth at Versailles (fig. 3), of which Switzer observes, that it "is allowed by all to be the noblest of its kind in the world."

Whatever style be adopted, it is essential that there should be a thick healthy growth of the hedges or shrubberies that confine the wanderer. The trees used should be impenetrable to the eye, and so tall that no one can look over them; and the paths should be of gravel and well kept. The trees chiefly used for the hedges, and the best for the purpose, are the hornbeam among deciduous trees, or the yew among evergreens. The beech might be used instead of the hornbeam on suitable soil. The green holly might be planted

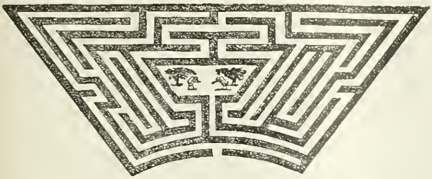

Fig. 4.—Maze at Hampton Court.

as an evergreen with very good results, and so might the American arbor vitæ if the natural soil presented no obstacle. The ground must be well prepared, so as to give the trees a good start, and a mulching of manure during the early years of their growth would be of much advantage to them. They must be kept trimmed in or clipped, especially in their earlier stages; trimming with the knife is much to be preferred to clipping with shears. It is not advisable to allow the hedge to run up too quickly or irregularly, so that any plants getting much in advance of the rest should be topped, and the whole kept to some 4 feet or 5 feet in height until the lower parts are well thickened, when it may be allowed to acquire the allotted height by moderate annual increments. In cutting, the hedge (as indeed all hedges) should be kept broadest at the base and narrowed upwards, which prevents it from getting thin and bare below by the stronger growth being drawn to the tops.

The maze in the gardens at Hampton Court Palace (fig. 4) is considered to be one of the finest examples in England. It was planted in the early part of the reign of William III., though it has been supposed that a maze had existed there since the time of Henry VIII. It is constructed on the hedge and alley system, and was, we believe, originally planted with hornbeam, but many of the plants have died out, and been replaced by hollies, yews, &c., so that the vegetation is mixed. The walks are about half a mile in length, and the extent of ground occupied is a little over a quarter of an acre. The centre contains two large trees, with a seat beneath each. The key to reach this resting place is to keep the right hand continuously in contact with the hedge from first to last, going round all the stops.

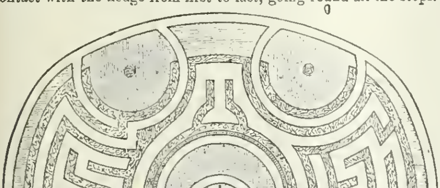

Fig. 5.

The maze in the gardens at Somerleyton Hall, near Lowestoft (fig. 5), was designed by Mr John Thomas. The hedges are of English yew, and are in very fine condition, without a break or flaw. They are about 6½ feet high, and have been planted a little over thirty years. In the centre is a grass mound, which is raised to the height of the hedges, and on this mound is erected a pagoda, which is approached by a curved grass path. At the two corners on the western side are banks of laurels some 15 or 16 feet high, which are kept trimmed with the knife. On each side of the hedges throughout the labyrinth is a small strip of grass.

There was also a labyrinth at Theobald's Park, near Cheshunt, when this place passed from the earl of Salisbury into the possession of James I. Another is said to have existed at Wimbledon House, the seat of Earl Spencer, which was probably laid out by Brown in the last century. There is an interesting labyrinth, somewhat after the plan of fig. 2, at Mistley Place, Manningtree, the seat of the Rev. C. F. Norman.

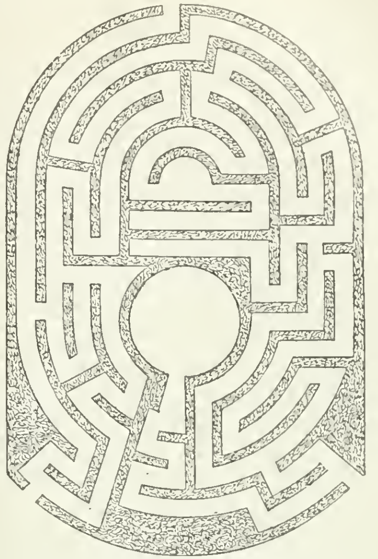

Fig. 6.—Labyrinth in Horticultural Society's Garden.

When the gardens of the Royal Horticultural Society at South Kensington were being planned, the Prince Consort, the president of the society, especially desired that there should be a maze formed in the ante-garden, which was made in the form shown in fig. 6. This labyrinth, which was designed by the late Lieut. W. A. Nesfield, was for many years the chief point of attraction to the younger class of visitors to the gardens; but at last it was allowed to go to ruin, and had to be destroyed. (T. MO.)

LAC is a compound resinous and tinctorial incrustation formed on the twigs and young branches of various trees by an insect, *Coccus lacca* (*Carteria lacca* of Signoret), which infests them. The species of trees upon which it is principally obtained include *Urostigma religiosa*, *U. indica*, *Croton laccifera*, *C. sanguifera*, *Aleurites laccifera*, *Carissa spinarum*, *Mimosa cinerea*, *Erythrina indica*, *Inga dulcis*, *Butea frondosa*, *Zizyphus Jujuba*, *Vismia laccifera*, *Feronia elephantum*, and *Vatica laccifera*. Lac is a product of the East Indies, coming especially from Bengal, Pegu, Siam, and Assam. The insect which yields it is closely allied to the cochineal insect, *Coccus cacti*, kermes, *C. ilicis*, and Polish grains, *C. polonicus*, all of which, like the lac insect, yield a red dye colour. The term lac (*Laksha*, Sanskrit; *Lakh*, Hindi) is the same as the numeral lakh—a hundred thousand—and is indicative of the countless hosts of insects which make their appearance with every successive generation. Two evolutions of the young of the lac coccus make their appearance annually, one about the beginning of July and the other early in December. As soon as the minute larval insects make their appearance they fasten in myriads on the young shoots, and, inserting their long proboscides into the bark, draw their nutriment from the sap of the plant. The insects begin at once to exude the resinous secretion over their entire bodies, which forms in effect a cocoon, and, the separate exudations coalescing, a continuous hard resinous layer regularly honeycombed with small cavities is deposited over and around the twig. From this living tomb the female insects, which form the great bulk of the whole, never escape. After their impregnation, which takes place on the liberation of the males, about three months from their first appearance, the females develop into a singularly amorphous-like organism consisting in its main features of a large smooth shining crimson-coloured sac—the ovary—with a beak stuck into the bark, and a few papillary processes projected above the resinous surface. The red fluid in the ovary is the substance which forms the lac dye of commerce, and, when the young are allowed to hatch out, the greater part of this colouring matter is lost, and only a dead resinous substance remains on the twig. To obtain the largest amount of both resin and dye-stuff therefore it is necessary to gather the twigs with their living inhabitants in or near June and November. Lac encrusting the twigs as gathered is known in commerce as "stick lac"; the resin crushed to small fragments and washed free from colouring matter constitutes "seed lac"; when melted, strained through thick canvas, and spread out into thin layers, this is known as "shell lac," and it is in this last form that the resin is usually brought to European markets. Shell lac, which varies in colour from a dark amber to an almost pure black appearance, may be bleached by dissolving in a boiling lye of caustic potash and passing chlorine through the solution till all the resin is precipitated. Bleached lac takes light delicate shades of colour, and dyed a golden yellow it is much used in the East Indies for working into chain ornaments for the head and for other personal adornments. Lac is a principal ingredient in sealing wax, and forms the basis of some of the most valuable varnishes, besides being useful in various cements, &c. (see LACQUER). Average stick lac contains about 68 per cent. of resin, 10 of lac dye, and 6 of a waxy substance. The resin of lac is a composite body, whose constituents behave differently in presence of chemical reagents.

Lac dye, which is separated by washing stick lac in hot or cold water or in a weak alkaline solution, and dried either by exposure over a fire or in the sun, comes into commerce in the form of small square cakes. It is in many respects similar to, although not identical with, cochineal, and will dye less brilliant shades than that colour. It contains about 50 per cent. of colouring matter, with 25 per cent. of resin and 22 per cent. of earthy admixture, &c. It is used for dyeing silk and wool, for which purposes it is dissolved in dilute sulphuric acid or somewhat stronger hydrochloric acid; and the substance to be dyed is prepared with a mordant of strong lac spirit, which consists of a solution of stannous chloride. Lac dye has been used from time immemorial in the East, but the knowledge of the substance in the West is comparatively recent. It was first brought to Europe by the East India Company as a substitute for cochineal. The best lac dye comes from Calcutta. Lac lake is an alumina lake containing about 50 per cent. of colouring matter, 40 per cent. of resin, and 9 or 10 per cent. of alumina.

LACAILLE, NICOLAS LOUIS DE (1713–1762), a zealous and successful astronomer, was born at Rumigny, near Rheims, March 15, 1713. Left destitute by the death of his father, who held a post in the household of the duchess of Vendôme, his theological studies at the Collége de Lisieux in Paris were prosecuted at the expense of the duke of Bourbon. After he had taken deacon's orders, however, he devoted himself exclusively to science, and, through the patronage of Cassini, obtained employment, first in surveying the coast from Nantes to Bayonne, then, in 1739, in remeasuring the French arc of the meridian. The success of this difficult operation, which occupied two years, and achieved the correction of the anomalous result obtained by the elder Cassini in 1684, was mainly due to Lacaille's industry and skill. He was rewarded by admission to the Academy, and the appointment of mathematical professor in Mazarin college, where he worked diligently for some years in a small observatory fitted up for his use. His desire to observe the southern heavens led him to propose, in 1750, an astronomical expedition to the Cape of Good Hope, which was officially sanctioned, and fortunately executed (see ASTRONOMY, vol. ii. p. 757). On his return in 1754 he was distressed to find himself an object of public attention, and withdrew to his former retreat in Mazarin college, where he died, March 21, 1762, of an attack of gout aggravated by unremitting toil. Lalande said of him that, during a comparatively short life, he had made more observations and calculations than all the astronomers of his time put together. And, his carefulness equalling his rapidity, the quality of his work rivalled its quantity. The rectitude of his moral character earned him universal respect, and his career ranks, if not amongst the most brilliant, amongst the most useful and honourable in the annals of science.

His principal works are—*Astronomiæ Fundamenta*, 1757; *Tabulæ Solares*, 1758, giving, for the first time, corrections for planetary perturbations; *Cœlum australe stelliferum*, 1763, a catalogue of 10,035 southern stars; *Observations sur 515 étoiles du Zodiaque*, 1763; *Leçons élémentaires de Mathématiques*, 1741, frequently reprinted; ditto *de Mécanique*, 1743, &c.; ditto *d'Astronomie*, 1746, 4th edition augmented by Lalande, 1779; ditto *d'Optique*, 1750, &c. Calculations by him of eclipses for eighteen hundred years were inserted in *L'art de vérifier les dates*, 1750; he communicated to the Academy in 1755 a classed catalogue of forty-two southern nebulæ, and gave in vol. ii. of his *Éphémérides*, 1754, practical rules for the employment of the lunar method of longitudes, proposing in his additions to Bouguer's *Traité de Navigation*, 1760, the model of a nautical almanac.

LA CALLE, or LA CALA, a seaport town of Algeria, in the province of Constantine, the centre of the Algerian and Tunisian coral fisheries. It lies 40 miles east of Bone and 10 miles from the Tunisian frontiers. The harbour is small and inconvenient, but it is proposed to construct a military port and harbour of refuge a little to the west. La Calle proper, or the old fortified town, is built on a ridge of rocks about 400 yards long, connected with the mainland by a bank of sand; but a new town has grown up along the coast. Besides the coral fisheries the curing of sardines is largely carried on. The population, without the garrison, was 3308 in 1871.

La Calle is mentioned as Mersa el Kharez by El Bekri (see *Journ. Asiat.*, 1859), and was even then the residence of coral merchants. In the early part of the 18th century it was the seat of an English trading factory, but on the failure of the company the French-African Company moved their factory from Bastion de la France to La Calle. The company was suppressed in 1794. In 1806 Mr Blanckley, British consul-general at Algiers, obtained the right of occupying Bone and La Calle for an annual rent of £11,000; but though the money was paid for several years no practical effect was given to the agreement. The French regained possession in 1817, were expelled during the wars of 1827, but returned and rebuilt the place in 1836.

See Abbé Poiret, *Voyage en Barbarie*, Paris, 1787; Broughton, *Six Years in Algeria*; and Playfair, *Travels in the Footsteps of Bruce*.

LACCADIVES, a group of coral reefs and islands in the Indian Ocean, lying between 10° and 12° 20′ N. lat. and 71° 40′ and 74° E. long. The name Laccadives (*laksha dwipa*, the "hundred thousand isles") is that given by the people of the continent, and was probably meant to include the myriad Maldives; they are called by the natives simply *Divi*, "islands," or *Amendivi*, from the chief island. There are about nineteen separate reefs, containing, however, only thirteen islands, and of these only eight are inhabited. The islands have in nearly all cases emerged from the eastern and protected side of the reef, and have gradually extended towards the west over the shallow lagoon of which the rest of the space within the barrier-reef consists. The islands are small, none exceeding a mile in breadth, and lie so low that they would be hardly discernible but for the cocoa-nut groves with which they are thickly covered. The soil is light coral sand, beneath which, a few feet down, lies a stratum of coral stretching over the whole of the island. This coral, which is generally a foot to a foot and a half in thickness, has been in the principal islands wholly excavated, whereby the underlying damp sand is rendered available for cereals. These excavations—a work of vast labour—were made at a remote period, and according to the native tradition by giants. In these spaces [*totam* = "garden"] are cultivated coarse grain, pulse, bananas, and vegetables; cocoa-nuts grow abundantly everywhere, and for rice the natives depend upon the mainland.

Population and Trade.—Of the eight Laccadive islands, four are directly under British rule and form part of the South Kanara collectorate in the Madras presidency. The other four (together with Minicoy, noticed below) form part of the estate of the bibi of Cannanore. The following are the names of the islands, with population in 1881:—

British Islands.		*Cannanore Islands.*	
Amini	2060	Agathi	1376
Chetlat	577	Kawrati	2127
Kadamat	245	Androt	2896
Kiltan	790	Kalpéni	1216
Total	3672	Total	7615

making a total for all the islands of 11,287, a dense population for so small an area. Amini, Kalpeni, Androt, and Kawrati are the principal or *tarwat* islands, and in them only do the high caste natives reside. The others are called *melacheri*, or low caste islands. The people are Moplas, *i.e.*, of mixed Hindu and Arab descent, and are Mohammedans. Their manners and customs are similar to those of the coast Moplas; but they maintain their own ancient caste distinctions. The language spoken is Malayala, but it is written in the Arabic character. Reading and writing are common accomplishments among the men. The chief industries are the manufactures of coir and jaggery, the Laccadive coir being esteemed the best in India; the various processes are entrusted to the women. The men employ themselves with boat-building and in conveying the island produce to the coast—in the case of the English islands to Mangalore, and in that of the bibi's islands to Cannanore. In each case the coir is taken by the ruling Government at lower than market rates, and the natives are not subject to any other taxation. At Mangalore they are paid partly in money and partly in rice, and the rates are not altered for many years. On the other hand the varying and oppressive tariff imposed upon the Cannanore islands has led to a diminished and inferior manufacture of coir, and to frequent complaints. This monopoly system, however fairly worked by the British Government, interferes with the trading capabilities of the natives, and puts them at considerable disadvantage with their rivals of Minicoy and the Maldives. The exports from the Laccadives are of the annual value of £17,000.

History and Government.—No data exist for determining at what period the Laccadives were first colonized. The earliest mention of them as distinguished from the Maldives seems to be by Albírúní (*circ.* 1030), who divides the whole archipelago (Dibaját) into the *Dívah Kúzah* or Cowrie Islands (the Maldives), and the *Dívah Kanbar* or Coir Islands (the Laccadives). See *Journ. Asiat.*, September 1844, p. 265. According to native tradition, the islands were first occupied about a thousand years ago. The early polity, according to Mr Robinson, was patriarchal, conducted by a *modalal*, or chief inhabitant, and the heads of the principal families. Each island was independent. This kind of internal economy seems to have lasted until the advent of the Portuguese. During their independence the islanders were converted to Islam by an Arab apostle named Mumba Mulyaka, whose grave at Androt still imparts a peculiar sanctity to that island. The kazee of Androt was in 1847 still a member of his family, and was said to be the twenty-second who had held the office in direct line from the saint. This gives colour to the tradition that the conversion took place about 1250. It is also further corroborated by the story given by Ibn Batuta of the conversion of the Maldives, which occurred, as he heard, four generations (say one hundred and twenty years) before his visit to these islands in 1342. The Portuguese discovered the Laccadives in 1499, and built forts upon them, but about 1545 the natives rose upon their oppressors, and with the aid of the raja of Cherical exterminated them. For this aid the raja obtained the suzerainty of the group, but he afterwards conferred them upon the head of the Cannanore moplas for an annual tribute. The Cannanore raja ceased to pay this tribute about the middle of the 18th century. In 1784 the Amini islands threw off the yoke, and put themselves under the protection of Tippoo, from whom, at the fall of Seringapatam in 1799, they passed to the East India Company. The remaining islands had already in 1791 fallen into the power of the Company by the storming of Cannanore, but by the peace of Seringapatam (1792) were permitted to remain under the management of the bibi at a yearly tribute. This has been often in arrear, and on this account these islands have been sequestrated by the British Government since 1877, to the general satisfaction of the inhabitants. See Mr Robinson's *Report*, Madras, 1874; Mr Hume in *Stray Feathers*, vol. iv., 1876, Calcutta.

Minicoy (called *Máliku* by the natives), a small island 5 miles in length, 108 miles south of Kalpéni and 68 miles north of the Maldives, belongs politically to the Laccadives in so far as it forms part of the estate of the bibi of Cannanore. The natives, however, are of the same race and speak the same language as the Maldivians. The population in 1881 was 3915. The people are well behaved, but of a very independent character; they are active and enterprising sailors, and lazy cultivators. They are divided into four classes, viz., *málikans*, the aristocracy, *malumnics*, the pilots and mates of vessels, *klasics*, smaller landed proprietors and sailors, and *melacheries*, toddy drawers. Minicoy anciently formed part of the Maldive realm, but, probably in the 16th century, was given by a Maldive sultan to his brother. In 1607, when it was visited by Pyrard, it was governed by a lady who for greater security held it of the raja of Cannanore (Pyrard's *Voyage*, chap. xxiii.). The island has never been restored to the Maldive kings.

LACE[1] is the name applied to an ornamental open work of threads of flax, cotton, silk, gold, or silver, and occasionally of mohair or aloe fibre. Such threads may be either looped or plaited or twisted together in one of three ways:—(1) with a needle, when the work is distinctively known as "needlepoint lace"; (2) with bobbins, pins, and a pillow or cushion, when the work is known as "pillow lace"; and (3) by machinery, when imitations of both needlepoint and pillow lace patterns are produced.

History.—Special patterns for needlepoint and pillow laces date from the beginning of the 16th century. Before that period such works as might now be classified as laces consisted of small cords of plaited and twisted threads fastened in loops (or "purls") along the edges of costumes, of darning work done upon a net ground, and of drawn and cut embroidery. From these classes of earlier work lace is descended. Pillow lace can be distinctly traced up to the "merletti a piombini" of the 16th century. At a very early period embroidery of geometrical patterns in coloured silk, &c., on a network of small square meshes was known and made throughout Europe. This in the 13th and 14th centuries was known in ecclesiastical circles as "opus filatorium" or "opus araneum" (spider work), and examples dating from the 13th century still exist in public collections. The productions of this art, which has some analogy to weaving, in the early part of the 16th century came to be known as "punto a maglia quadra" in Italy and as "lacis" in France—the patterns, stiff and geometrical, being sometimes cut out of linen or separately sewed and applied to the meshed surface; but more frequently they were darned in, the stitches being counted as in tapestry, and hence it was known as "point compté" or darned netting. With the development of the renaissance of art, free flowing patterns and figure subjects were introduced and worked in lacis.

Drawn and cut works were ancient forms of embroidery

[1] Italian, *merletto*, *trina*; Genoese, *pizzo*; German, *Spitzen*; French, *dentelle*; Dutch, *kanten*; Spanish, *encaje*. The English word is the Fr. *lassis* or *lacis*, connected with the Latin *laqueus*. Early French laces were also called *passements* ("insertions")

which directly developed into point lace. The methods of producing them were various. A common way was to fasten on a light frame a reticulation of threads, under which was fastened, by gum or otherwise, a piece of fine lawn. Then along these threads the pattern to be formed was stitched to the lawn background in button-hole stitching, and the superfluous parts of the lawn were afterwards drawn or cut away,—whence the names "punto a reticella" and "punto tagliato." In other cases no cloth at all was used, and the pattern, consisting of an interlacing framework of threads, was simply sewed over with button-hole stitches. This was "punto in aria." The early geometrical patterns of the "punto a reticella" or "punto tagliato" and "punto in aria" were probably derived from the Ionian Islands and Greece, and the cut-work itself was indeed also known as Greek lace. The close connexion of the proud and powerful Venetian republic with Greece and the eastern islands, and its commercial relations with the East, sufficiently explain the early transplanting of these arts into Venice. Once fairly established, they quickly grew in beauty and variety of pattern, complexity of stitch, and delicacy of execution, until Venetian lace attained an artistic grace and perfection which baffle all description. The making of the principal and most important variety of Venetian needlepoint lace, the "punto in aria," began to be practised in the middle of the 16th century.[1]

It is a noteworthy circumstance that the two widely distant regions of Europe where pictorial art first flourished and attained a high perfection, North Italy and Flanders, were precisely the localities where lace-making first took root, and became an industry of importance both from an artistic and from a commercial point of view. The invention of pillow lace is generally credited to the Flemings; but there is no distinct trace of the time or the locality. In a picture said to exist in the church of St Gammar at Lierre, and sometimes attributed to Quentin Matsys (1495), is introduced a girl working lace with pillow, bobbins, &c., which are somewhat similar to the implements in use in more recent times.[2] From the very infancy of Flemish art an active intercourse was maintained between the Low Countries and the great centres of Italian art; and it is therefore only what might be expected that the wonderful examples of the art and handiwork of Venice in lace-making should soon have come to be known to and rivalled among the equally industrious, thriving, and artistic Flemings. And so we find that, at the end of the 16th century, lacis and needlepoint lace were also known and made in Flanders, and pattern-books were issued having the same general character as those published for the instruction of the Venetians and other Italians. In Italy, under the name of "merletti a piombini," the art of twisting and plaiting threads by means of bobbins or *fuxii* was early practised; and in later times fine scrolls in great widths for altar frontals were made in Italy on the pillow.

France and England were not far behind Venice and Flanders in adopting lace. Henry III. of France (1574–1589) appointed a Venetian, Frederic Vinciolo, to be pattern maker for varieties of linen needle works and laces to his court. Through the influence of this fertile designer the seeds of a taste for lace in France were principally sown. But the event which *par excellence* would seem to have fostered the art of lace making there was the aid and patronage officially given it in the following century by Louis XIV., acting on the advice of his minister Colbert. Intrigue and diplomacy were put into action to secure the services of Venetian lace-workers; and by an edict dated 1665 lace-making centres were founded at Alençon, Quesnoy, Arras, Rheims, Sedan, Château Thierry, Loudun, and elsewhere. The state made a contribution of 36,000 francs in aid of a company to carry out the organization of these establishments; and at the same time the importation of Venetian, Flemish, and other laces was strictly forbidden.[3] The edict contained instructions that the lace-makers should produce all sorts of thread work, such as those done on a pillow or cushion and with the needle, in the style of the laces made at Venice, Genoa, Ragusa, and other places; these French imitations were to be called "points de France." By 1671 the Italian ambassador at Paris writes, "Gallantly is the minister Colbert on his way to bring the 'lavori d'aria' to perfection." Six years later an Italian, Domenigo Contarini, alludes to the "punto in aria," "which the French can now do to admiration." The styles of design which emanated from the chief of the French lace centres, Alençon, were more fanciful and floral than the Venetian, and it is quite evident that the Flemish lace-makers adopted many of these French patterns for their own use. The importance of the French designs, which owe so much to the state patronage they enjoyed, was noticed early in the 18th century by Bishop Berkeley. "How," he asks, "could France and Flanders have drawn so much money from other countries for figured silk, lace, and tapestry, if they had not had their academies of design?"

The humble endeavours of peasantry in England (which could boast of no schools of design), Germany, Sweden, Russia, and Spain could not result in work of high artistic pretension. Lace making is said to have been promoted in Russia through the patronage of the court there, after the visit of Peter the Great to Paris in the early days of the 18th century. In Germany, Barbara Uttmann, a native of Nuremberg, instructed peasants of the Harz mountains to twist and plait threads in 1561. She was assisted in this by certain refugees from Flanders. A sort of "purling" or imitation of the Italian "merletti a piombini" was the style of work produced here. It did not develop in any important way, nor have German laces acquired great artistic reputation. Spain has been considered to have been a lace-making country, and no doubt a good deal of lace, having, however, no distinctive character, was made in Spanish conventual establishments. The "point d'Espagne," however, appears to have been a commercial name given by French manufacturers of a class of lace greatly esteemed by Spaniards in the 17th century. No lace pattern books have been found to have been published in Spain. The point laces which came out of Spanish monasteries in 1830, when these institutions were dissolved, were not distinguishable from similar Venetian needle-made laces. The lace vestments preserved at the cathedral at Granada hitherto presumed to

[1] The prevalence of fashion in the above-mentioned sorts of embroidery during the 16th century is marked by the number of pattern-books then published. In Venice an early work of this class was issued by Alessandro Paganino in 1527; another of a similar nature, printed by Pierre Quinty, appeared in the same year at Cologne; and *La fleur de la science de pourtraicture et patrons de broderie, façon arabicque et ytalique*, was published at Paris in 1530. From these early dates until the beginning of the 17th century pattern-books for embroidery in Italy, France, Germany, and England were produced and published in great abundance. The designs contained in many of those dating from the early 16th century were to be worked for costumes and hangings, and consisted of scrolls, arabesques, birds, animals, flowers, foliage, herbs, and grasses. So far, however, as their reproduction as laces might be concerned, the execution of complicated work was involved which none but practised lace-workers, such as those who arose a century later, could be expected to overcome.

[2] The picture, however, as Seguin has pointed out, was probably painted some thirty years later, and by Jean Matsys.

[3] See the poetical skit *Revolte des Passements et Broderies*, written by Mademoselle de la Tousse, cousin of Madame de Sévigné, in the middle of the 17th century, which marks the favour which foreign laces at that time commanded amongst the leaders of French fashion. It is fairly evident too that the French laces themselves, known as "bisette," "gueuse," "campane," and "mignonette," were small and comparatively insignificant works, without pretence to design.

be of Spanish work are Flemish of the 17th century. The industry is not alluded to in Spanish ordinances of the 15th, 16th, or 17th centuries. Much Flemish lace was imported into Spain from Spanish Flanders. The black and white silk pillow laces, or "blondes," date from the 18th century. They were made in considerable quantity in the neighbourhood of Chantilly, and imported by Spain for mantillas. Although after the 18th century the making of silk laces has more or less ceased at Chantilly and the neighbourhood, the craft is now carried on in Normandy—at Bayeux and Caen—as well as in Auvergne. Silk pillow lace making is carried on in Spain, especially at Barcelona. The patterns are almost entirely imitations from the French. Malta is noted for producing a thick pillow lace of black, white, and red threads, chiefly of geometric pattern, in which circles, wheels, and radiations of shapes resembling grains of wheat are a principal feature. This characteristic of design, appearing in laces of similar make which have been identified as Genoese pillow laces of the early 17th century, reappears in Spanish and Paraguayan work. Pillow lace in imitation of Maltese, Buckinghamshire, and Devonshire laces is made in Ceylon, and in different parts of India where attempts have been made to introduce European arts to native labour.

At present the chief sources of hand-made lace are Belgium, England, and France, but a successful effort has also been made to re-establish the industry in the island of Burano near Venice, and much fine work of good design is now (1882) made there. Russian peasants in the districts of Vologda, Balakhua (Nijni-Novgorod), Bieleff (Tula), and Mzensk (Orel) make pillow laces of simple patterns. But by far the greatest amount of lace now made is that which issues from machines in England and France.[1] The total number of persons employed in the lace industry in England in 1871 was 49,370; and according to official returns of the year 1873, 240,000 women were similarly employed in France.

The early history of the lace-making machine coincides with that of the stocking-frame, that machine having been adapted about the year 1768 for producing open-looped stitches, which had a net-like appearance. In the years 1808 and 1809 John Heathcoat of Nottingham obtained patents for machines for making bobbin net, which form the real foundation of machine making of lace. These machines were improved on in 1813 by John Leavers, whose lace-making machines are in use at the present time. The application of the celebrated Jacquard apparatus to these net machines has enabled manufacturers to produce all sorts of patterns in thread work in imitation of the patterns for hand-made lace. The latest improvement in machinery for lace making has resulted in a French machine called the "dentellière" (see *La Nature* for 3d March 1881). The work produced by this machine is plaited. That produced by the English and by other French machines is of twisted threads. At present, however, the expense attending the production of plaited lace by the "dentellière" is as great as that of pillow lace made by the hand.

Before considering technical details in processes of making lace, the principal parts of a piece of lace may be named. A prominent feature is the ornament or pattern. This may be so designed that the different parts may touch one another, and so be fastened together, no ground-work of any sort being required. Ground works are useful to set off the pattern, and either consist of links or tyes, which give an open effect to the pattern, or else of a series of meshes like net. Sometimes the pattern is outlined with a thread or cord line, or more strongly marked by means of a raised edge of button-hole stitched or plaited work. Fanciful devices are sometimes inserted into various portions of the pattern. In some of the heavy laces, which resemble delicate carving in ivory, little clusters of small loops are distributed about the pattern. French terms are frequently used in speaking of details in laces. Thus the pattern is called the *toilé* or gimp, the links or tyes are called *brides*, the meshed grounds are called *réseaux* (retiola), the outline to the edges of a pattern is called *cordonnet*, the insertions of fanciful devices *modes*, the little loops *picots*. These terms are applicable to the various portions of all laces made with the needle, on the pillow, or by the machine.

The history of patterns in lace is roughly as follows. From about 1540 to 1590 the forms were geometric, chiefly common, without *brides* or *réseaux*. From 1590 to 1630 may be dated the introduction of floral and human forms and slender scrolls held together by *brides*. At this time lace makers enriched their works with insertions of *modes*. To the period extending from 1620 to 1670 belongs the development of scrolls and elaboration of details like the *cordonnet* with massings of *picots*. Much heavy raised lace enriched with fillings in of *modes* was made at this time. About 1660 *réseaux* came into use. From 1650 to 1720 the scroll patterns gave way to arrangements of detached ornamental details which were frequently filled in with elaborate *modes*. A closer imitation of all sorts of subjects was attempted in lace patterns. Pictorial representations of figures, incidents, persons, arose. The purely conventional scrolls were succeeded by naturalistic renderings of garlands, flowers, birds, and such like. The use of meshed grounds extended, and grounds composed entirely of varieties of *modes* were made. From 1720 to 1780 small details of bouquets, sprays of flowers, single flowers, leaves, buds, spots, and such like were adopted, and sprinkled over meshed grounds. Since that time down to the present day all these styles of pattern have been used as fashion has required.

Needlepoint Lace.—The way in which the early Venetian "punto in aria," as already described, was made appears to correspond precisely with the elementary principles upon which needlepoint lace is now worked. The pattern is first drawn upon a piece of parchment. The parchment is then stitched to a stout bit of linen. Upon the leading lines drawn on the parchment threads are laid, which are here and there fastened through to the parchment and linen by means of stitches. When the skeleton thread pattern is completed, a compact covering of thread in button-hole stitches is cast upon it (fig. 1). The portions which may be required to be represented as close linen work or *toilé* are worked as indicated in the enlarged diagram (fig. 2). Between the leading lines of the pattern may be inserted tyes (links) or meshes, so that the pattern is held together. When all is finished, a knife is passed between the parchment and the stout linen, cutting the stitches which have passed through the parchment and linen, and so releasing the lace itself from its pattern parchment. For about sixty years the laces thus made were chiefly geometric in pattern (fig. 3). They were used both for insertions between seams and for borders. Following closely upon these geometric laces

[1] See Felkin's *Machine-wrought Hosiery and Lace Manufactures.*

came laces of a freer style of design, and towards the end of the 16th century, designs for scrolls with the introduction of all kinds of odd figures and leaves and blossoms were produced (fig. 4). Links or tyes—*brides*—came to be inter-

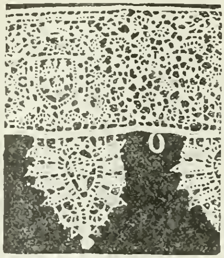

Fig. 5.—Needlepoint Lace, showing use of tyes or "brides."

spersed between the various details of the patterns (fig. 5). The work was of a flat character. Some large and elaborate specimens of this flat point lace were made at this time. The lace workers occasionally used gold thread with the white thread. The nomenclature of these earlier needle-made laces is somewhat modern. At the present time the different sorts of early Venetian point laces are called "flat Venetian point," "rose (raised) point," "caterpillar point," "bone point," &c.; and works of bold design done in relief are called "gros point de Venise." Lace of this latter class (figs. 6, 7) was used for altar cloths, flounces, and heavily trimmed *jabots* or neckcloths which hung beneath the chin over the breast. *Tabliers* and ladies' aprons were also made of such lace. The laces which have hitherto been referred to are laces in which no regular ground was used. All sorts of minute embellishments, like little knots, stars, and loops or *picots*, were worked on to the irregularly arranged *brides* or tyes holding the main patterns together, and these devices as a rule gave a rich effect to the lace work. Following this style of treatment came laces with groundworks; and grounds of *brides* or tyes arranged in a honeycomb pattern were, it appears, first used early in the 17th century (fig. 8). To them succeeded a lighter sort of lace, one in which the rich and compact relief gave place to much flatter work with a ground of meshes. The needle-made meshes were sometimes of single and sometimes of double threads. A diagram is given of an ordinary method of making such meshes (fig. 9). The delicate Venetian point lace made with a

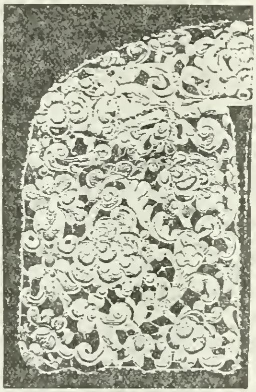

Fig. 6.—Venetian Needlepoint Lace.

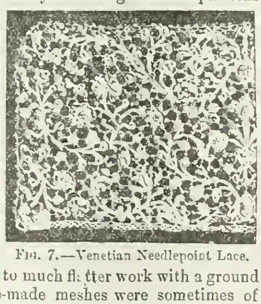

Fig. 7.—Venetian Needlepoint Lace.

ground of meshes is usually known as "point de Venise à réseau." It was contemporary with the famed needle-made French laces of Alençon and Argentan. "Point d'Argentan" has been thought to be especially distinguished on account of its ground of hexagonally arranged *brides*. But this has been noticed as a peculiarity in certain Venetian point laces of earlier date.[1] Often intermixed with this stiff hexagonal *brides* ground is the fine-meshed ground or *réseau*, which has been held to be distinctive of "point d'Alençon" (fig. 10). But, apart from the assumedly distinctive grounds, the styles of patterns and the methods of working them, with rich variety of insertions or *modes*, with raised button-hole-stitched edgings or *cordonnets*, are precisely alike in the two classes of Argentan and Alençon needle-made laces. Besides the hexagonal *brides* ground and the ground of meshes there was another variety of grounding used in the Alençon laces, which was extensively used and forms a third class. This ground consisted of button-hole-stitched skeleton hexagons within each of which was worked a small solid hexagon connected with the outer surrounding hexagon by means of six little tyes or *brides* (see fig. 11). Lace, with this particular ground has been called "Argentella," and some writers on lace have thought that it was a specialty of Genoese or Venetian work. The character of the work and the style of the floral patterns worked upon such grounds are those of Alençon laces, and specimens of this "Argentella" often contain insertions of the Argentan *brides* and the Alençon fine meshes.

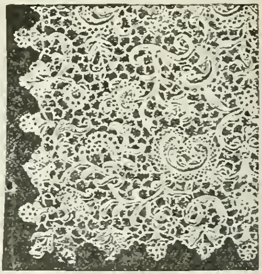

Fig. 8.—Venetian Needlepoint Lace.

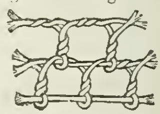

Fig. 9.

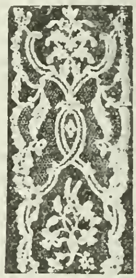

Fig. 10.—French Needlepoint Lace.

There are very slight indications respecting the establishment of a lace manufactory at Argentan, whereas those regarding Alençon are numerous. A family of thread and linen dealers, inhabitants of Alençon, by name Monthuley, are credited with the establishment of a branch manufactory or *succursale* for lace at Argentan. In the course of business, the Monthuleys assisted the interchange of lace patterns between Argentan and Alençon, which are distant one from another about 10 miles. Thus if a piece of lace was produced at Alençon it was called "point d'Alençon," and if at Argentan "point d'Argentan," though both works might have been made

Fig. 11.

[1] The lace workers at Alençon and its neighbourhood produced work of a daintier kind than that chiefly made by the Venetians. As a rule the hexagonal *bride* grounds of Alençon laces are smaller than similar details in Venetian laces. The average size of a diagonal taken from angle to angle in an Alençon (or so-called Argentan) hexagon was about one-sixth of an inch, and each side of the hexagon was about one-tenth of an inch. An idea of the minuteness of the work can be formed from the fact that a side of a hexagon would be overcast with some nine or ten button-hole stitches.

from one design. From about 1670 to 1780 a great deal of point lace was made at Alençon and in the neighbouring villages. The styles of patterns varied, as has been stated. Point d'Alençon is still made.

In Belgium, Brussels has acquired some celebrity for needle-made laces. These, however, are chiefly in imitation of those made at Alençon. Brussels needlepoint lace is often worked into meshed grounds made on a pillow. The Brussels needle-lace workers used a plain thread as a *cordonnet* for their patterns instead of a thread overcast with button-hole stitches as in the Venetian and French needlepoint laces.

This kind of lace has also been produced in England. Whilst the character of English design in needlepoint laces of the early 17th century (fig. 12) is simpler than that of

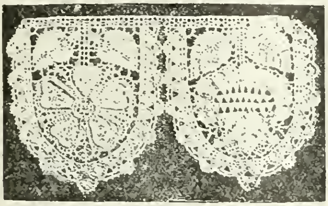

Fig. 12.—English Point Lace.

the contemporary Italian, the method of workmanship is virtually the same. Specimens of needle-made work done by English school children may be met with in samplers of the 17th and 18th centuries. Point lace is successfully made in Irish convents. In all great towns like London, Paris, Brussels, Vienna, lace dealers undertake to supply demands for finely executed modern imitations of old needle-made lace. At Burano the lace-making school lately established there produces hand-made laces which are, to a great extent, careful reproductions of the more celebrated classes of point laces, such as "punto in aria," "rose point de Venise," "point de Venise à réseau," "point d'Alençon," "point d'Argentan," and others. A weaving of threads with a needle into a foundation of net—very distinctive, and different from the "punto a maglia" or "lacis"—has been done for a long time in Spain. Its leading characteristic is the pattern of repeated squares, filled up with star figures. When fine thread is used the effect of heavy cobwebs is produced. Work of this description has been made in Paraguay, where a coarse "torchon" pillow lace is also produced.

Pillow-made Lace.—Pillow-made lace is built upon no substructure, like a skeleton thread pattern, such as is used for needlepoint lace. It is the representation of a pattern obtained by twisting and plaiting threads. The only pre-existing analogue of pillow laces is to be found in the primitive twistings and plaitings of fibres and threads. The English word "lace" in the 15th century was employed to describe fine cords and braids. In a Harleian MS. of the time of Henry VI. and Edward IV., about 1471, directions are given for the making of "lace Bascon, lace indented, lace bordered, lace covert, a brode lace, a round lace, a thynne lace, an open lace, lace for hattys," &c. The MS. opens with an illuminated capital letter, in which is the figure of a woman making these articles. Her implements are not those with which pillow lace of ornamental quality from the middle of the 16th century and onwards has been made. The MS. supplies a clear description how threads in combinations of twos, threes, fours, fives, to tens and fifteens, were to be twisted and plaited together. Instead of the pillow, bobbins, and pins with which pillow lace is made, the hands were used. Each finger of a hand served as a peg. The writer of the MS. says that it shall be understood that the first finger next the thumb shall be called A, the next B, and so on. According to the sort of twisted cord or braid which had to be made, so each of the four fingers A, B, C, D might be called upon to act like a reel, and to hold a "bowys" or "bow," or little ball of thread. Each ball might be of different colour from the other. A "thynne lace" might be made with three threads, and then only fingers A, B, C would be required. A "round" lace, stouter than the "thynne" lace, might require the service of four or more fingers. By occasionally dropping the use of threads from certain fingers a sort of indented lace or braid might be made. But when laces of more importance were wanted, such as a broad lace for "hattys," the hands of assistants were required.

Pillow lace making was never so strictly confined to geometric patterns as point lace making. Curved forms, almost at its outset, seem to have been found easy of execu-

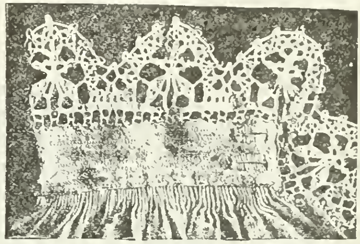

Fig. 13.—Cuff trimmed with Plaited and Twisted Thread Work in Points, or Scallops. Late 16th century.

tion (fig. 13). One reason for this no doubt is that the twisted and plaited work was not constrained by a foundation of any sort. The plaitings and twistings gave the workers a greater freedom in reproducing designs. At the same time, little speciality of pattern seems to have been produced for the pillow lace workers, and so laces worked on the pillow, particularly those of higher pretence to artistic design, were similar in pattern to those worked with the needle. The early wiry-looking twisted and plaited thread laces were soon succeeded by laces in which flattened and broader lines occupy a prominent position (fig. 14). Tape was also sometimes used for the broad lines. The weaving of tape appears to have been begun in Flanders about the end of the 16th or the beginning of the 17th century. In England it dates no farther back than 1747, when two Dutchmen of the name of Lanfort were invited by an English firm to set up tape looms in Manchester and give instructions in the method of weaving tape.

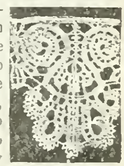

Fig. 14.—Plaited and Twisted Thread Work known as "Merletti a Piombini." About 1560.

The process by which lace has been made on the pillow from about the middle of the 17th century is very roughly and briefly as follows. A pattern is first drawn upon a piece of paper or parchment. It is then pricked with holes by a skilled "pattern pricker," who determines where the principal pins shall be stuck for guiding the threads. This pricked pattern is then fastened to the

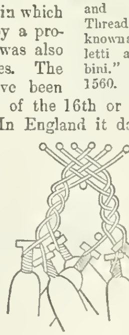

Fig. 15.—Diagram showing six Bobbins in use.

pillow. The pillow or cushion varies in shape in different countries. Some lace makers use a circular pad, backed with a flat board, in order that it may be placed upon a table and easily moved as the worker may wish. Other lace workers use a well-stuffed round pillow or short bolster, flattened at the two ends, so that they may hold it between their knees. On the upper part of the pattern are fastened the ends of the threads from the bobbins. The bobbins thus hang across the pattern. Fig. 15 shows the commencement of a double set of three-thread plaitings. The compact portion in a pillow lace has a woven appearance (fig. 16).

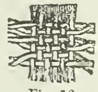

Fig 16.

In the 17th century pillow lace in imitation of the scroll patterns of point lace was made. This sort of work, produced chiefly in Flanders, went under the name of "point d'Angleterre" (fig. 17). Into Spain and France much lace from Venice and Flanders was imported as well as into England, where from the 16th century the manufacture of "bone lace" by peasants in the midland and southern counties was carried on. This bone lace consisted chiefly of borders done in imitation of the Venetian "merletti a piombini." In Charles II.'s time its manufacture was of sufficient importance to demand parliamentary attention. The trade was threatened with extinction by the more artistic and finer Flemish laces. The importation of the latter was prohibited. Flemish lace workers sought to evade the prohibitions by calling certain of their laces "point d'Angleterre." But the difficulties which attended the smuggling into England of these "points d'Angleterre" appear to have stimulated English dealers in lace anxious to supply the demands of fashion to obtain the services of Flemish lace makers and to induce them to settle in England. It is from some such cause that English pillow lace closely resembles in character of design pillow laces of Brussels, Mechlin, and Valenciennes.

Fig. 17.—Pillow-made Lace "à brides." Flemish. 17th century. Sometimes called "Point d'Angleterre."

Fig. 18 gives three sorts of Buckinghamshire pillow laces, the patterns of which have been in use since the middle of the 18th century. In (*a*) is a variety of fillings-in, which give the name of "trolly" to such specimens. It is an adaptation of Mechlin "trolle kant" or sampler lace, sent round to dealers and purchasers to show the variety of patterns which the lace makers happened to be at work upon. Specimens (*b*) and (*c*) are both in the style of certain 18th century Mechlin laces, (*c*) being also like laces made at Lille and Arras.

As skill in making lace developed, patterns and particular plaitings came to be identified with certain localities. Mechlin enjoyed a high reputation for her production, which was in the 17th century poetically styled the "queen of laces." The chief features of this pillow lace are the plaiting of the meshes, and the outlining of the pattern or *toilé* with a thread. The ordinary Mechlin mesh is hexagonal in shape. Four of the sides are of double twisted threads, two are of four threads plaited three times (fig. 19). The mesh of Brussels pillow lace is also hexagonal. Four of the sides are of double-twisted threads, two are of four threads plaited four times (fig. 20). The finer specimens of Brussels lace are remarkable for the fidelity and grace with which floral compositions are rendered. Many of these compositions are either reproductions or adaptations of designs for point d'Alençon, and in such patterns the soft quality of fine pillow-made lace contrasts with the harder and more crisp appearance of needlepoint lace. In

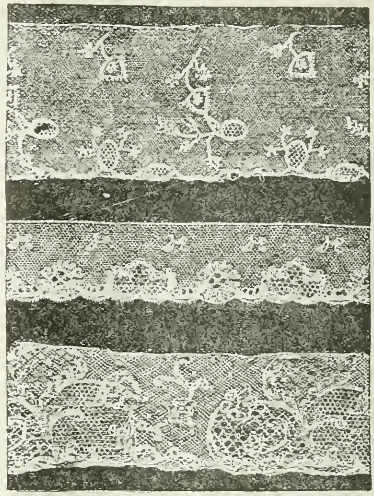

Fig. 18.—English Pillow Laces. 18th century.

the Brussels pillow lace (fig. 21) much realistic effect is obtained by the delicate modelling imparted to the flowers by means of a bone instrument used to give concave shapes to petals and leaves, the edges of which are often marked

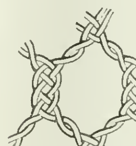

Fig. 19.—Mechlin Mesh.

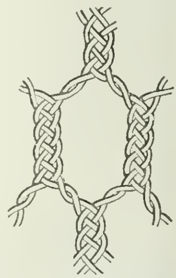

Fig. 20.—Enlargement of Mesh of Brussels ground, showing the four-twisted and two-plaited sides in each mesh.

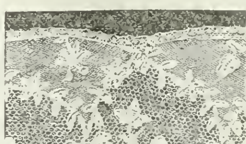

Fig. 21.—Pillow Lace. Brussels. 18th century.

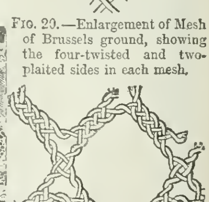

Fig. 22.

by a flattened and slightly raised *cordonnet* of plaited work. Honiton pillow lace resembles Brussels lace. As a rule it is made with a coarser thread, and the designs lack the careful drawing and composition which may be seen in Brussels pillow laces. In Valenciennes lace there are no twisted sides to the mesh; all are closely plaited (fig. 22), and as a rule the shape of the mesh is diamond. No outline or

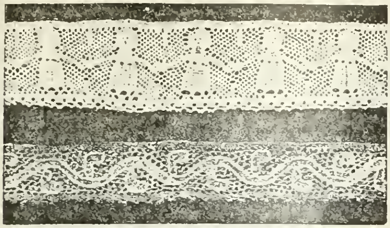

Fig. 23.—Peasant Lace from Crete.

cordonnet is used in Valenciennes lace. Besides these distinctive classes of pillow-like laces, there are others in which

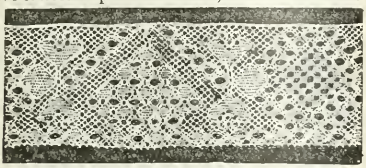

Fig. 24.—German Pillow-made Lace. 18th century.

equal ingenuity is displayed, though the character of the design remains primitive, as for instance in peasant laces from Crete (fig. 23), Russia, and Germany. Pillow lace making in Crete would seem to have arisen in consequence of Venetian intercourse with the island. The art is now said to be extinct. The laces were chiefly made of silk. The patterns in many specimens are outlined with one, two, or three bright-coloured silken threads. As a rule the motives of the Cretan lace patterns are traceable to orderly arrangement and balance of simple symmetrical and geometrical details, such as diamonds, triangles, and odd polygonal figures. Uniformity in character of design may be observed in many of the German and Russian laces, especially in respect of patterns like that shown in fig. 24 and fig. 25 *a*. This sort of pattern is used in peasant laces of Sweden, in common French "torchon" laces, and in a lace made at Ripon in Yorkshire. The meshed grounds (*réseaux*) of the Chantilly silk laces were generally simple in character, as shown in fig. 26.

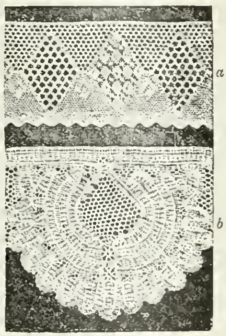

Fig. 25.—Russian Pillow Laces. 19th century.

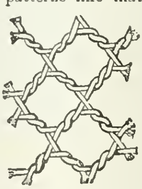

Fig. 26.

Guipure.—This name, often applied to needlepoint and pillow laces, properly designates a kind of lace or "passement" made with "cartisane" and twisted silk. "Cartisane" is a little strip of thin parchment or vellum, which was covered with silk, gold, or silver thread. Guipure is also made with fine wires whipped round with silk, and with cotton thread similarly treated. These stiff threads, formed into a pattern, were held together by stitches worked with the needle. Such work, which is very much dependent upon the ductile characteristics of the materials employed, is now called gimp work. Gold and silver thread laces were usually made on the pillow.

Machine-made Lace.—We have already seen that a technical peculiarity in making needlepoint lace is that a single thread and needle are alone used to form the pattern, and that the button-hole stitch and other loopings which can be worked by means of a needle and thread mark a distinction between lace made in this manner and lace made on the pillow. For the process of pillow lace making a series of threads are in constant employment, plaited and twisted the one with another. A button-hole stitch is not producible by it. The machine does not attempt to make either a button-hole stitch or a regular plait. Up to the present, however ingenious may be the counterfeits of design of all sorts of lace produced by the machine, an essential principle of the machine-made work is that the threads are merely twisted together. The only exception which could be made to this statement would be as regards the plaited lace made by the "dentellière" already mentioned. The Leavers lace machine is that which is generally in use at Nottingham and Calais. French ingenuity has developed improvements in this machine whereby laces of delicate thread are made; but as fast as France makes an improvement England follows with another, and both countries virtually maintain an equal position in this branch of industry. The number of threads brought into operation in a Leavers machine is regulated by the pattern to be produced, the threads being of two sorts, beam or warp threads and bobbin or weft threads. Upwards of 8880 are sometimes used, sixty pieces of lace being made simultaneously, each piece requiring 148 threads—100 beam threads and 48 bobbin threads. The ends of both sets of threads are fixed to a cylinder upon which as the manufacture proceeds the lace becomes wound. The supply of the beam or warp threads is held upon reels, and that of the bobbins or weft threads is held in bobbins. The beam or warp thread reels are arranged in frames or trays beneath the stage, above which and between it and the cylinder the twisting of the bobbin or weft with beam or warp threads takes place. The bobbins containing the bobbin or weft threads are flattened in shape so as to pass conveniently between the stretched beam or warp threads. Each bobbin can contain about 120 yards of thread. By most ingenious mechanism varying degrees of tension can be imparted to warp and weft threads as required. The bobbins of the weft threads as they pass like pendulums between the warp threads are made to oscillate, and through this oscillation the threads twist themselves or become twisted with the warp threads. As the twistings take place, combs passing through both warp and weft threads compress the twistings. Thus the usual machine-made lace may generally be detected by its compressed twisted threads. Figs. 27 and 28 are intended

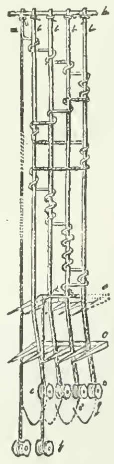

Fig. 27.

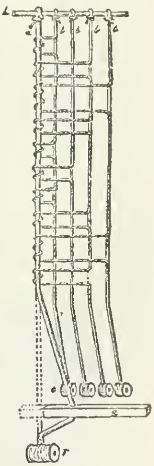

Fig. 28.

to show effects obtained by varying the tensions of weft and warp threads. For instance, if the weft, as threads *b, b, b, b* in fig. 27, be tight and the warp thread slack, the

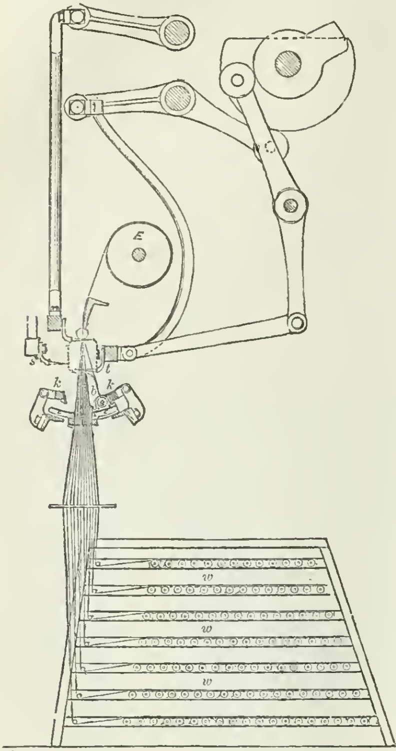

Fig. 29.—Section of Lace Machine.

warp thread *a* will be twisted upon the weft threads. But if the warp thread *a* be tight and the weft threads *b, b, b, b* be slack, as in fig. 28, then the weft threads will

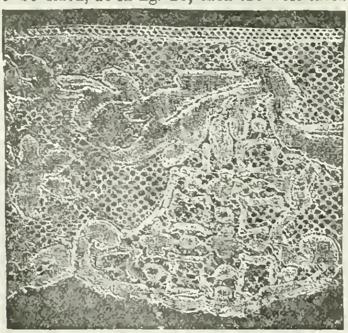

Fig. 30.—Pillow-made Lace. Mechlin. Early 18th century.

be twisted on the warp thread. At the same time the twisting in both these cases arises from the conjunction of movements given to the two sets of threads, namely, a movement from side to side of the beam or warp threads, and the swinging or pendulum-like oscillations of the bobbin or weft threads between the warp threads. Fig. 29 represents a section of part of a lace machine. E is the cylinder or beam upon which the lace is rolled as made, and upon which the ends of both warp and weft threads are fastened at starting. Beneath are *w, w, w,* a series of trays or beams, one above the other, containing the reels of the supplies of warp threads; *c, c* represent the slide bars for the passage of the bobbin *b* with its

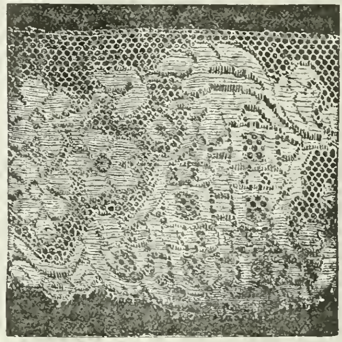

Fig. 31.—Machine-made Imitation of Mechlin Pillow Lace.

thread from *k* to *k*, the landing bars, one on each side of the rank of warp threads; *s, t* are the combs which take it in turns to press together the twistings as they are made. The combs are so regulated that they come away clear from the threads as soon as they have pressed them together and fall into positions ready to perform their pressing operations again. The contrivances for giving each thread a particular tension and movement at a certain time are connected with an adaptation of the Jacquard

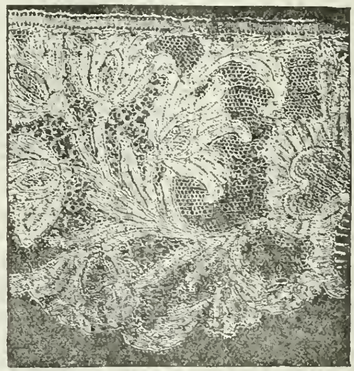

Fig. 32.—Venetian Point Lace, à réseau. 17th century.

system of pierced cards. The machine lace pattern drafter has to calculate how many holes shall be punched in a card and to determine the position of such holes. Each hole regulates the mechanism for giving movement to a thread. Fig. 30 is a specimen of a Flemish pillow lace of the early 18th century. The meshes of the ground are variegated in appearance. A thread outlines the pattern. In fig. 31 it will be seen that the manufacturer has merely attempted to reproduce the pattern of the foregoing. His meshes are regular. No outlining thread marks the pattern, which, instead of being filmy, like cambric, is ribbed. This specimen, recently made at Calais with a Leavers machine, is produced at a cost of 1s. 2d. a yard, whilst the value of the original hand-made pillow lace is at least £1, 5s. a yard. Fig. 32 is taken from a piece of fine needle-made lace (point de Venise à réseau). The flat and even appearance in the close portions (the *toilé*) of the pattern, the slight thread (*cordonnet*) outlining the pattern, and the delicate fillings-in or *modes* of tracery work may be noted for comparison

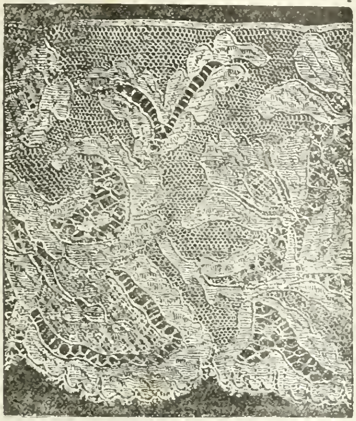

Fig. 33.—Machine-made Imitation of Venetian Point Lace, à réseau.

with corresponding details in the machine-made imitation (fig. 33). In this the close portions are ribbed, the *cordonnet* is stouter and stands in relief, and the tracery *modes* are simpler in composition.

Literature.—The literature of the art of lace making is considerable. The series of 16th and 17th century lace pattern-books, of which the more important are perhaps those by F. Vinciolo (Paris, 1587), Cesare Vecellio (Venice, 1592), and Isabetta Catanea Parasole (Venice, 1600), not to mention several kindred works of earlier and later date published in Germany and the Netherlands, supplies a large field for exploration. Recently Signor Ongania of Venice has published a limited number of facsimiles of the majority of such works. M. Alvin of Brussels issued a brochure in 1863 upon these patterns, and in the same year the Marquis Girolamo d'Adda contributed two bibliographical essays upon the same subject to the *Gazette des Beaux Arts* (vol. xv. p. 342 *sq.*, and vol. xvii. p. 421 *sq.*). In 1864 Cavaliere A. Merli wrote a pamphlet (with illustrations) entitled *Origine ed uso delle Trine a filo di refe*; Mons F. de Fertiault compiled a brief and rather fanciful *Histoire de la Dentelle* in 1843, in which he reproduced statements to be found in Diderot's *Encyclopédie*, subsequently quoted by Roland de la Platière. The first *Report of the Department of Practical Art*, 1853, contains a "Report on Cotton Print Works and Lace Making" by Octavius Hudson, and in the first *Report of the Department of Science and Art* are some "Observations on Lace," with magnified representations of details showing stitches and plaits used in various laces. Mr Hudson delivered two lectures "On Lace made by Hand" in 1858. Reports upon the International Exhibitions of 1851 (London) and 1867 (Paris), by M. Aubry, Mrs Palliser, and others, contain information concerning lace making. But the most important work first issued upon the history of lace making is that by the late Mrs Bury Palliser (*History of Lace*, 1869; latest edition, 1875). In this work the history is treated rather from an antiquarian than a technical point of view; and wardrobe accounts, inventories, state papers, fashionable journals, diaries, plays, poems, have been laid under contribution with surprising diligence. *The Queen Lace Book*, an historical and descriptive account of the hand-made laces of all countries, published in London in 1874, relies for much of its data upon Mrs Palliser's book, and contains some illustrations of excellent specimens of work. In 1875 the Arundel Society brought out a folio volume of permanently printed photographs taken from some of the finest specimens of ancient lace which were collected for the International Exhibition of 1874. These were accompanied by a brief history of lace, written from the technical aspect of the art, by Mr Alan S. Cole. At the same time appeared a bulky imperial 4to volume by M. Seguin, entitled *La Dentelle*, which is illustrated with woodcuts and fifty photo-typographical plates. M. Seguin divides his work into four sections. The first of these is devoted to a sketch of the origin of lace; the second deals with pillow laces, bibliography of lace, and a review of sumptuary edicts; the third relates to needle-made lace; and the fourth contains an account of places where lace has been and is made, remarks upon commerce in lace, and upon the industry of lace makers. This method of treating the subject entails the repetition of numerous facts and observations. Without sufficient conclusive evidence M. Seguin accords to France the palm for having excelled in producing the richer sorts of laces, which both before and since the publication of his otherwise valuable work have been identified as being Italian in origin. Descriptive catalogues are issued of the lace collections at South Kensington Museum, at the Science and Art Museum, Dublin, and at the Industrial Museum, Nuremberg. In 1881 a series of four Cantor Lectures on the art of lace making were delivered before the Society of Arts by Mr Alan S. Cole, and have since been extracted from the journal of the society, and published in a pamphlet form, with illustrations. The latest work on the subject is a *Technical History of the Manufacture of Venetian Laces*, by G. M. Urbani de Gheltof, with plates, translated by Lady Layard, and published at Venice by Signor Ongania. The *History of Machine-wrought Hosiery and Lace Manufacture* (London, 1867), by Felkin, has already been referred to. There is also a technological essay upon lace made by machinery, with diagrams of lace stitches and patterns (*Technologische Studien im Sächsischen Erzgebirge*, Leipsic, 1878), by Hugo Fischer. (A. S. C.)

LACEDÆMON. See Laconia and Sparta.

LACÉPÈDE, Bernard Germain Étienne de la Ville, Comte de (1756–1825), French naturalist, was born at Agen in Guyenne, December 26, 1756. His education was carefully conducted by his father, and the early perusal of Buffon's *Natural History* awakened an interest in that branch of study, which for the remainder of his life absorbed his chief attention. His leisure he devoted to music, in which, besides becoming a good performer on the piano and organ, he acquired considerable mastery of composition, two of his operas, which, however, were never published, meeting with the high approval of Gluck; and in 1781–85 he also brought out in two volumes his *Poétique de la Musique.* Meantime he wrote two treatises, *Essai sur l'Électricité* (1781) and *Physique générale et particulière* (1782–84), which gained him the friendship of Buffon, who in 1785 appointed him sub-demonstrator in the Jardin du Roi, and proposed to him to become the continuator of his *Histoire Naturelle.* This continuation was published under the titles *Histoire des Quadrupèdes ovipares et des Serpents* (2 vols., 1788–89) and *Histoire Naturelle des Reptiles* (1789). After the Revolution Lacépède became a member of the legislative assembly, but during the Reign of Terror he deemed it advisable to leave Paris, his life having become endangered by his disapproval of the massacres. When the Jardin du Roi was reorganized as the Jardin des Plantes Lacépède was appointed to the chair set apart to the history of reptiles and fishes, which he conducted with such success that in 1796 he was chosen a member of the Institute. Two years afterwards he published the first volume of *Histoire Naturelle des Poissons*, the 5th volume appearing in 1803; and in 1804 appeared *Histoire des Cétacés.* From this period till his death the part he took in politics prevented him from making any further contribution of importance to science. In 1799 he became a senator, in 1801 president of the senate, in 1803 grand chancellor of the legion of honour, in 1804 minister of state, and at the Restoration in 1819 he was created a peer of France. He died at Épinay, October 6, 1825. During the latter period of his life he wrote *Histoire générale physique et civile de l'Europe*, which was published posthumously in 18 vols., 1826. A collected edition of his works on natural history was published in the same year, and has been frequently reprinted. See Ichthyology. vol. xii. p. 633.

LA CHALOTAIS, Louis René de Caradeuc de (1701–1785), representative of the French provincial parliaments in their struggles with Louis XV., was born at Rennes in Brittany, March 6, 1701. He entered with keen vigour into the question of the suppression of the Jesuits, which began to be most openly mooted after the affair of Martinique; and as procureur général of the parliament of Brittany he submitted to the parliament in 1761 and 1762—the very heat of the conflict—two *Comptes Rendus des Constitutions des Jésuites*, which dealt the society some of the most powerful blows it had received since Pascal, and undoubtedly contributed largely to secure the edict of suppression in 1764. In the friends of the Jesuits La Chalotais had thus prepared for himself bitter enemies, and he was to feel their power in the events of the quarrel between the court and the parliaments. The breach between the estates of Brittany and the king, in which La Chalotais was more immediately concerned, originated in an order passed by Government that the voices of two of the three estates should bind the other, that is, that the clergy and citizens should control the landed proprietors. To this order, designed to secure the registration of certain fiscal edicts in spite of the proprietors, who formed a majority in the estates, and upon whom the taxes would fall most heavily, the opposition was marked by all the obstinacy of the Breton character. La Chalotais endeavoured to carry through a compromise, but at the same time animadverted somewhat acrimoniously upon the coercive efforts of the Duc d'Aiguillon, governor of Brittany, who already, as a supporter of the Jesuits, regarded the procureur with animosity. When the estates, therefore, absolutely refused to register the edicts, the court chose to regard La Chalotais as the moving spirit in the opposition; and in November 1765 he was arrested on a charge of having written certain anonymous and seditious letters to the king. No attention was paid to his protestations of innocence; and, when the parliament of Rennes tried to force matters to a crisis by resigning in a body, Louis merely appointed commissioners to sit as a new parliament and to try La Chalotais, with his son and some other magistrates who had been arrested at the same time. But the question had spread beyond Brittany; other provincial parliaments, and even the parliament of Paris, took it up; and the strife began to assume the ominous significance of one between the people and the crown. No lower tribunal ventured to pass sentence upon La Chalotais, and in 1769 the king, calling the case before himself in council, attempted to settle it in his own autocratic way: silence was imposed as to the future, oblivion as to the past; the innocence of the accused was acknowledged, but they were exiled from their province. Such a decision was no settlement. The parliament, now restored, accused the Duc d'Aiguillon of having suborned witnesses against La Chalotais, and, when he published memoirs retorting the charge, caused them to be burned by the hand of the common hangman. Maupeou, minister of the king, after vainly endeavouring to enforce the royal edict of silence, summoned the case before the parliament of Paris in 1770. That body, however, gave such unequivocal signs of favour to La Chalotais, that the king interfered and quashed the whole proceedings by a "bed of justice." The entire matter thus lay over so far as it affected the procureur, till the death of the king in 1774 allowed him to return to his official duties. La Chalotais died at Rennes, July 12, 1785.

Besides the *Comptes Rendus* and the *Exposé Justificatif* (three parts, 1766–67), written in prison, La Chalotais was the author of an *Essai d'Éducation Nationale* (1763), a work extravagantly praised by Voltaire. It was written in view of the disorganization in matters educational that would follow the expected expulsion of the Jesuits from France.

LACHISH (לָכִישׁ), a town in the low country of Judah (Josh. xv. 39), and one of the strong fortresses that offered an obstinate resistance to Nebuchadnezzar (Jer. xxxiv. 7). It was to Lachish that Amaziah fled from the conspiracy raised against him at Jerusalem, and there he was killed (2 Kings xiv. 19). From an obscure allusion in Micah i. 13 it would appear that the place was a chariot city. For this it was doubtless recommended by its position in the rich low country, and the same reason, together with the fact that it commanded the line of advance from Egypt, is sufficient to explain why it was the headquarters of Sennacherib during part of his Judæan campaign (2 Kings xviii. 14; Isa. xxxvii. 8). The name of Lachish occurs on the monuments of Sennacherib, and a bas-relief now in the British Museum, representing the king receiving its spoils, is given in G. Smith's *History of Sennacherib* (1878). Lachish was reoccupied by the Jews after the captivity (Neh. xi. 30), and the *Onomastica* place it 7 miles from Eleutheropolis on the southern road. The site has not been identified. Umm Lákis does not agree with the statement of the *Onomastica*, and the name ("Mother of Itch") has no connexion with the Hebrew, while El Hasy, suggested by Conder, has still less to recommend it. As the cities in this district were built of brick. the ruins may probably have all but disappeared.

LACHMANN, KARL KONRAD FRIEDRICH WILHELM (1793–1851), a highly distinguished philologist and critic, was born March 4, 1793, at Brunswick, where his father held an appointment as preacher in the Andreas Kirche. In his eighth year he entered the Katharineum of his native town, where the strong bent of his vigorous mind towards philology and literature soon made itself unmistakably evident. In 1809 he passed to the university of Leipsic as a student of philology and theology; in the same year he transferred himself to Göttingen, where, under the influence of Heyne, his enthusiasm for philological pursuits almost completely extinguished his interest in theology; the pagan classics and particularly the Roman poets became his absorbing study. Stronger even than that of Heyne was the influence of Dissen over the young and rising scholar, who found additional intellectual stimulus in the companionship of such fellow students as C. K. J. Bunsen, Ernst Schulze, and C. A. Brandis. Under G. F. Benecke he also devoted himself to Italian and English, and ultimately to Old German. In 1815 he was led by the stirring political events of the day to interrupt his studious life and join the Prussian army as a volunteer chasseur; in this capacity he accompanied his detachment to Paris, but to his great regret never encountered the enemy. The regiment being disbanded he went to Berlin, where he became an assistant master in the Friedrich Werder gymnasium, and in the spring of 1816 he "habilitated" at the university. His thesis was published immediately afterwards, the subject being "The original form of the *Nibelungennoth*." Almost simultaneously appeared his edition of Propertius. The same summer he became one of the principal masters in the Fridericianum of Königsberg, where he assisted his colleague Karl Köpke with his edition of Rudolf von Monfort's *Barlaam und Josaphat* (1818), and also took part in the researches of his friend towards an edition of the works of Walther von der Vogelweide. In January 1818 he became professor extraordinarius of classical philology in the university of Königsberg, where Lobeck also was; he at the same time began to lecture on Old German grammar and the Middle High German poets. In connexion with this task he devoted himself during the following seven years to an extraordinarily minute study of all that could be found, whether in print or in manuscript, relating to these subjects, and in the summer of 1824 he obtained leave of absence in order that he might search the libraries of Middle and South Germany for further materials. In February 1825 Lachmann was nominated extraordinary professor of classical and German philology in the university of Berlin;

in June 1827 he was promoted to the ordinary professorship in the same department; and in 1830 he was admitted a member of the Academy of Sciences. The remainder of his laborious and fruitful life as an author and a teacher presents no episode requiring special record. In January 1851 he was seized with an inflammatory affection of the left foot, to which he ultimately succumbed on March 13, 1851. See Hertz, *Karl Lachmann, eine Biographie* (Berlin, 1851).

Lachmann, who was the translator of the first volume of P. E. Müller's *Sagaenbibliothek des Skandinavischen Alterthums*, published at Berlin in 1816, is a figure of considerable importance in the history of German philology (see Rudolf von Raumer, *Gesch. d. germanischen Philologie*, 1870). In his "habilitationsschrift" on the *Nibelungennoth*, and still more in his review of Hagen's *Nibelungen* and Benecke's *Bonerius*, contributed in 1817 to the *Jenaische Literaturzeitung*, he had already laid down the rules of text criticism and elucidated the phonetic and metrical principles of Middle High German in a manner which marked a very distinct advance in that branch of learned investigation. The rigidly scientific character of his method becomes increasingly apparent in the *Auswahl aus den Hochdeutschen Dichtern des dreizehnten Jahrhunderts* (dedicated to Benecke, 1820), in the edition of Hartmann's *Iwein* (the text being Lachmann's special care, while the explanatory notes are by Benecke, 1827), in those of Walther von der Vogelweide (1827) and Wolfram von Eschenbach (1833), in the papers "Ueber das Hildebrandslied," "Ueber althochdeutsche Betonung und Verskunst," "Ueber den Eingang des Parzivals," and "Ueber drei Bruchstücke niederrheinischer Gedichte" published in the *Abhandlungen* of the Berlin Academy, and in *Der Nibelungen Not mit der Klage in der ältesten Gestalt mit den Abweichungen der gemeinen Lesart* (1826), which was followed by a critical commentary in 1836. Lachmann's "Betrachtungen über die Ilias," first published in the *Abhandlungen* of the Berlin Academy in 1837 and 1841, in which he sought to show that the *Iliad* consists of sixteen independent "lays" variously enlarged and interpolated, have had considerable influence on modern Homeric criticism. See HOMER. His smaller edition of the New Testament appeared in 1831, 3d ed. 1846; the larger, in two volumes, in 1842–50 (*Novum Testamentum Græce et Latine: Carolus Lachmannus recensuit, Philippus Buttmannus Græcæ lectionis auctoritates apposuit*). The plan of Lachmann's edition, which has been explained by himself in the *Stud. u. Krit.* of 1830, is a modification of the unaccomplished project of Bentley. It seeks to restore the most ancient reading current in Eastern MSS., using the consent of the Latin authorities (Old Latin and Greek Western Uncials) as the main proof of antiquity of a reading where the oldest Eastern authorities differ. Besides Propertius, Lachmann edited Catullus, 1829; Tibullus, 1829; Genesius, 1834; Terentianus Maurus, 1836; Babrius, 1845; Avianus, 1845; Gaius, 1841–42; the Agrimensores Romani, 1848–52; and Lucretius, 1850. The last, which was the main occupation of the closing years of his life, from 1845, was perhaps his greatest achievement, and has been characterized by Monro as "a work which will be a landmark for scholars as long as the Latin language continues to be studied."

LA CONDAMINE, CHARLES MARIE DE (1701–1774), French geographer and mathematician, born at Paris, January 28, 1701, was trained for the military profession, but turned his attention to science and geographical exploration. He was a member with Godin and Bouguer of the expedition sent to Peru in 1735 to determine the length of a degree of the meridian in the neighbourhood of the equator (see vol. vii. 598), and on his homeward route made the first scientific exploration of the river Amazon. He returned to Paris in 1745, and published the results of his measurements and travels with a map of the Amazon in *Mém. de l'Académie des Sciences*, 1745 (English translation 1745–47). La Condamine continued to interest himself in metrical problems, and on a visit to Rome made careful measurements of the ancient buildings with a view to a precise determination of the length of the Roman foot. The journal of his voyage to the equator was published at Paris in 1751. He also wrote in favour of inoculation. He died February 4, 1774.

LACONIA, the Greek Λακωνική, is the name generally applied in modern times to the country which occupied the south-eastern corner of the Peloponnesus, often called Lacedæmon, Λακεδαίμων, which is the only name used in Homer. The history of the district has already been given (see GREECE), and it only remains to give a slight sketch of its physical features. These are very peculiar, and had great influence in producing the marked and distinctive character of the section of the Dorian race which occupied Laconia throughout the historical period. The country is a deep valley almost completely surrounded by mountains, and it is the general opinion that both names, Laconia and Lacedæmon, refer to this hollow sunken character, being connected with *lacus*, λάκκος, &c. The mountains of Arcadia shut in this valley on the north, and from them two parallel chains of mountains stretch due south bounding the valley on the east and on the west. The eastern chain bore in ancient times the name Taygetus, the western, Parnon; both ridges stretched far out into the sea, forming respectively the promontories of Taenarus and Malea. Taygetus, now called Pentedaktylon, is a splendid unbroken chain of lofty peaks, well deserving its Homeric epithet περιμήκετος; the highest point is the ancient Taleton, now St Elias, 7900 feet high. Mount Parnon is not such a fine ridge, but still forms a strong barrier along the sea-coast. Through the whole length of the valley from north to south flows the river Eurotas, which has only one tributary of any consequence, the Oenus. The soil was not remarkably fertile, except in the low ground towards the sea; but the sides of Taygetus were covered with dense forests which afforded excellent sport to the inhabitants of the plain. The people were thus inured to the hardy life of mountaineers; they were so securely defended by nature against invasion that the victorious Epaminondas hesitated to attack the country; while with command of the passes they could at any time invade the neighbouring countries. Over Mount Taygetus there was hardly any pass practicable for an army; from Arcadia there were only two entrances, both easily defended, one by the course of the Oenus, the other by the Eurotas. Mount Parnon stretched along the east coast, which offered no harbour, hardly even a landing place, for foreign ships. While adding to the security of the country, the same causes isolated it greatly from intercourse with other peoples, tended to keep the inhabitants backward and to prevent education, and led to that jealous and exclusive character which distinguished the Lacedæmonians.

LACORDAIRE, JEAN BAPTISTE HENRI (1802–1861), French orator, was born at Recey-sur Ource, Côte d'Or, 12th March 1802. He was the second of a family of four, the eldest of whom travelled a great deal in his youth, and subsequently occupied the chair of comparative anatomy at Liége, from which he contributed some valuable treatises on entomology. For several years Lacordaire studied at Dijon, showing a marked talent for rhetoric; this naturally led him to the pursuit of law, and in the local debates of the advocates he attained a high celebrity. At Paris he for a time thought of going on the stage, but was induced to finish the course, and, having done so with credit, applied himself for eighteen months with much success to the consideration of briefs. Meanwhile a great change was passing over his convictions. Lamennais had published his *Essai sur l'Indifférence*,—a passionate vindication of belief as against the tolerant contempt of a generation which regarded truth and falsehood in every department of life with equal complaisance, a demonstration of the weakness of individual reason and an assertion of the rightful supremacy of a central religious authority. Lacordaire read and was convinced. His ardent and believing nature was weary of the theological negations of the Encyclopedists. He was impelled towards a deistical explanation of the universe, from which in turn he went on to Catholicism as the only faith calculated to keep society from disintegration. In 1823 he became a theological student at the seminary of Saint Sulpice; four years later he was ordained and became almoner of the college of Henry IV. He was called from it to co-operate with Lamennais in the editorship of *L'Avenir*, a journal established for the purpose of advocating the union of the democratic principle with ultramontanism. To be a Catholic was to be a royalist in the popular definition; Lacordaire strove to show that Catholicism was not bound up with the idea of dynasty, and definitely allied it with a well-defined liberty, equality, and fraternity. But the new propagandism was denounced from Rome in an encyclical. In the meantime Lacordaire and Montalembert, believing that, under the charter of 1830, they were entitled to liberty of instruction, opened an independent free school and began to teach in it. It was closed in two days, and the teachers fined before the court of peers. These reverses Lacordaire accepted with quiet dignity; but they brought his relationship with Lamennais to a close. He now began the course of Christian *conférences* at the Collége Stanislas, which attracted the art and intellect of Paris; thence he went to Notre Dame, and for two years his sermons were the delight of the capital. His presence was dignified, his voice capable of indefinite modulation, and his gestures animated and attractive. He still preached the gospel of the people's sovereignty in civil life and the pope's supremacy in religion, but brought to his propagandism the full resources of a mind familiar with philosophy, history, and literature, and indeed led the reaction against Voltairean scepticism. He was asked to edit the *Univers*, to take a chair in the university of Louvain, but declined both appointments, and in 1836 set out for Rome, revolving a great scheme for Christianizing France by restoring the old order of St Dominic. At Rome he prepared himself for the life of the new brotherhood, donning the habit of the preaching friar and joining the monastery of Minerva. His *Mémoire pour le rétablissement en France de l'ordre des frères prêcheurs* was then prepared and dedicated to his country; at the same time he collected the materials for the life of his avowed master, St Dominic. But he did not return to France until 1841, when he resumed his preaching at Notre Dame, and was successful in re-establishing the order of which he ever afterwards called himself monk. His funeral orations are the most notable in their kind of any delivered during his time, those devoted to the death of Drouot and O'Connell being especially predominant in the qualities of point and clearness. He next thought that his presence in the Assembly would be of use to his cause; but he remained there only a short while, finding the true field of his influence to be the pulpit. Many popular movements he advocated with the fervour of high conviction. In 1850 he went back to Rome and was made provincial of the order, and for four years laboured to make the Dominicans a religious power. In 1854 he retired to Serèze to become director of a private lyceum, and remained there in self-chosen obscurity until he died, 22d November 1861.

LACQUER, or LACKER, in general terms may be said to be coloured and frequently opaque varnishes applied to certain metallic objects and to wood. The term is derived from the resin lac, which substance is the basis of lacquers properly so called. Technically, among Western nations, lacquering is restricted to the coating of polished metals or metallic surfaces, such as brass, pewter, and tin, with prepared varnishes which will give them a golden, bronze-like, or other lustre as desired. Of the numerous recipes for the preparation of the various lacquers, the following for a gold lacquer for brass work may be taken as a sample:—shell-lac 8 oz., sandarach 2 oz., turmeric 8 oz., arnotto 2 oz., dragon's blood $\frac{1}{4}$ oz., dissolved in 1 gallon of rectified spirit. Throughout the East Indies the lacquering of wooden surfaces is universally practised, large articles of household furniture, as well as small boxes, trays, toys, and papier mâché objects, being decorated with bright-coloured and variegated lacquer. The lacquer used in the East is, in general, variously coloured sealing-wax, applied, smoothed, and polished in a heated condition; and by various devices intricate marbled, streaked, and mottled designs are produced. Quite distinct from these, and from all other forms of lacquer, is the lacquer work of Japan. The source and nature of the raw material of Japanese lacquer has been referred to under JAPANNING, and there also will be found some allusion to its extraordinary durability and resistance to all ordinary solvents. Not less extraordinary is the manipulative skill shown by the Japanese in this kind of work, and the variety and exquisite perfection of its decorative treatment, which all go to place Japanese lacquer of high quality among the rarest and most prized treasures of decorative art. In the preparation of Japanese lacquer work the wooden object to be treated is first coated with several layers of raw lacquer mixed with brick dust, &c., which, when hardened, are smoothed with gritty stone. A few layers of common or inferior varnish of the colour desired in the finished object are then successively added. After each coating the objects are placed to dry in an enclosed box, the sides of which are kept moist with water, so that hardening takes place in a dark damp atmosphere. The final coating is composed of the best quality of lacquer, and it is smoothed with great care and polished with powdered deer horn. The brilliant smooth polish of plain black lacquer is brought up by repeated thin rubbings over with uncoloured lacquer and polishings with deer horn. Such are the elaborate processes used for entirely unornamented lacquer; but most Japanese work is enriched with decorations which introduce an endless variety of treatment and much more complex, tedious, and costly processes of operation. Flat work, variously coloured and speckled, ornamented with gilt patterns, is among the simplest of the artistic lacquer productions of Japan. Relief or raised lacquer work, on the other hand, is a most elaborate and costly production, the labour of months and even years being expended on the preparation of fine high-relief examples. The raised designs are produced with a mixture of red oxide of iron and lacquer repeatedly applied till the desired elevation is attained, the form of the raised surface being carefully modelled and controlled between successive applications by rubbing and grinding with charcoal powder. Metallic powders—gold, silver, bronze, &c.—are applied with the final coat while the work is still in a viscous condition, and these sinking into the lacquer produce a strongly adherent surface with a fine subdued metallic lustre. Other methods of ornamental treatment consist of inlaying and incrusting the lacquer with mother of pearl, ivory, gold, bronze, or tinfoil. A great variety of decorative effect may be thus produced, but lacquers so treated are not held in the same high esteem as the raised or even the flat varieties. Thin sections of the substance to be inlaid are placed on the surface of a freshly coated and yet "tacky" object, and imbedded by the repeated applications of additional coatings; the surface is then rubbed and reduced till the inlay and lacquer form one smooth continuous surface. Relief incrustations are managed in an analogous manner, the lacquer being smoothed and polished around the incrusted object or pattern. Lacquer is also ornamented by carving, a style mostly applied to red lacquer, although it is also occasionally done in black and other dark colours. This method of treatment has been introduced from China, where red carved lac or Peking lac is a characteristic ornamental substance.

LACRETELLE, CHARLES DE (1766–1855), historian and journalist, was born at Metz. Shortly before the

Revolution he was introduced to some of the constitutionalist leaders, and soon joined the staff of the *Moniteur* and the *Débats*; then he became secretary to the Duc de la Rochefoucauld-Liancourt. He returned to journalism and joined Chénier and Roucher on the *Journal de Paris*. The triumph of the Jacobins was not without danger for him, and to avoid it he enlisted in the army, but after Thermidor returned once more to Paris and to newspaper work. The 13th Vendémiaire again drove him from both, and he took to serious composition. He had more than one fluctuation of fortune of the same kind still to undergo, and was actually imprisoned for a considerable time, but continued his historical work, to which after the establishment of Napoleon's power he wholly devoted himself. He became a member of the Academy in 1811, and professor of history in the Parisian faculty of literature next year. The Restoration pleased him from the constitutional point of view, and after it the July monarchy. In 1848 he retired to Mâcon, where he died seven years later. Lacretelle's chief work is a series of histories of the 18th century, the Revolution, and its sequel (*Eighteenth Century*, 1808; *Revolution*, 1821–26; *Consulate and Empire*, 1840; *Restoration*, 1846). He had previously given a *Précis Historique* of the Revolution (1801–6). Mr Carlyle's sarcastic remark on Lacretelle's *History of the Revolution* that it "exists but does not profit much" is partly true of all his books. The author was a moderate and fair-minded man, but possessed neither great powers of style, nor striking historical insight, nor the special historian's power of uniting minute accuracy of detail with breadth of view. If his history of the 18th century deserves to be singled out from his other books, it is chiefly because no exact successor to it has appeared. Besides the works mentioned, he also wrote a *History of the Religious Wars*, some sketches of his personal adventures in the Revolution, &c. As a journalist, if not as an historian, Lacretelle was not scrupulous about absolute accuracy. The legend of the Abbé Edgeworth's last words to Louis XVI. has been traced to him.

LACROSSE is the national ball game of Canada, as cricket is of England and base ball of the United States of America. The aborigines had the game before the discovery of the New World, and different Indian tribes played it in different manners, generally with much roughness and violence. The present name was given it by French Canadians, owing to the resemblance of the curved netted stick, the chief implement used in the pastime, to a bishop's crozier or *crosse*. As white men gradually took up the game it became more refined. In 1867 the National Lacrosse Association of Canada was formed, and drew up a recognized code of rules. Lacrosse cannot be aptly compared to hockey or football, since striking or even touching the ball with the hands or feet is inadmissible. The crosse somewhat resembles a racket bat. It is a stick with one end curved, and the hook so formed is fitted with network, which must not bag. The ball is of indiarubber, from 8 to 9 inches in circumference. The other requisites are a level piece of turf, about 200 by 100 yards, and the goals. These may be any distance apart, according to agreement and the space available. Each goal is composed of two flag posts, 6 feet high and a like distance apart. The usual number of players is twelve on each side, and the captains station them somewhat as in football. A game is scored by one side driving the ball between their opponents' goal posts, and a match is three games out of five. There is no "off side" as in football, and the chief feat of the player is to catch the ball on the network of the crosse, dodge his opponents by running as far as practicable, and then throw the ball to one of his own side who is nearer the enemy's goal. A game is commenced by the ball being placed on the ground midway between the two goals and a player from each side "facing" for it with the crosse till one of them succeeds in sending it on the way to the opposite goal. After each game goals are changed. During winter the game is played by skaters on the ice, or on the snow with the aid of snow shoes. A native Indian team introduced the pastime into England in 1867; several amateur clubs were formed; and a set of rules was drawn up by an English Lacrosse Association on February 12, 1868. They differ somewhat from the Canadian regulations,—the goal posts being 7 feet apart with a tape across the top, and a match being decided by the number of goals won during a specified time. The pastime, however, never took deep root in England, so many other old established games of ball being more popular, and is now but little practised.

LA CROSSE, chief city of La Crosse county, Wisconsin, United States, is situated on the east bank of the Mississippi, at the confluence of the Black and La Crosse rivers, 196 miles by rail west-north-west of Milwaukee. La Crosse is the second commercial city and the fourth in the scale of population in the State. An extensive lumbering trade is carried on by means of the Black river. The city contains foundries, machine-shops, saw-mills, flour-mills, shipbuilding yards, and manufactories of agricultural implements, beer, and leather. It has 3 English dailies and 5 weekly newspapers (2 English, 2 Norwegian, 1 German), 20 churches, and a public library containing 3300 volumes. La Crosse became a city in 1856. The population in 1880 was 14,505.

LACRYMATORY, a modern word employed to describe a class of small vessels of terra-cotta, or, more frequently, of glass, found in Roman and late Greek tombs, and fancifully supposed to have been bottles into which mourners dropped their tears. They were used to contain unguents, and it is to the need of unguents at funeral ceremonies that the finding of so many of these vessels in tombs is due. They are shaped like a spindle, or a flask with a long small neck and a body in the form of a bulb.

LACTANTIUS FIRMIANUS, also called Lucius Cæcilius or Lucius Cælius Lactantius Firmianus, was a Christian writer who from the beauty of his style has been called the "Christian Cicero." His history is very obscure. His very name is doubtful; his birthplace, whether in Italy or in Africa, is uncertain; it is impossible to say with any accuracy when his writings were published; and the date of his death is unknown. His parents were heathens; he was a pupil of Arnobius in Sicca in Africa; he went to Nicomedia in Bithynia while Diocletian was emperor to teach rhetoric, but found little work to do in that Greek-speaking city; he became a convert to Christianity, probably late in life; and about ten or twelve years before his death (312–318) he went to Gaul on the invitation of Constantine the Great, and became tutor to his eldest son Crispus. These facts, with his writings, are all that is known about Lactantius. His chief work *Divinarum Institutionum Libri Septem* is a long introduction to Christianity, written in exquisite Latin, but displaying such ignorance as to have incurred the charge of favouring the Arian and Manichæan heresies. The date of publication has been variously given from 302 to 323 A.D. One sentence seems to say that a persecution, which can scarcely be any other than the Diocletian, was raging while the book was being written (v. 17, 5); whilst in the first, second, fourth, and fifths books Constantine is addressed as emperor. Those who assert the earlier date of publication point out that the references to Constantine are omitted in several MSS. Others adopt the conjecture of Baluze that an early edition was published in Nicomedia and a later twenty years afterwards (*cf.* Ebert, *Ueber den Verfasser des Buches De Mort. Persecut.*, p. 129 *sq.*). The seven books of the Institutions have separate titles given to them either by the author or by a later editor. The first, *De Falsa Religione*, and the second, *De Origine Erroris*, attack the polytheism of heathendom, show the unity of the God of creation and providence, and try to explain how men have wandered from truth into polytheistic error. The third book, *De Falsa Sapientia*, describes and criticizes the various systems of prevalent philosophy, showing how baseless and contradictory they are. The fourth book, *De Vera Sapientia et Religione*, insists upon the inseparable union of true wisdom and true religion, and maintains that this union is made real in the person of Christ. The fifth book, *De Justitia*, maintains that true righteousness is not to be found apart from Christianity, and that it springs from piety which consists in the knowledge of God. The sixth book, *De Vero Cultu*, describes the true worship of God, which is righteousness, and consists chiefly in the exercise of Christian love towards God and man. The seventh book, *De Vita Beata*, discusses, among a variety of subjects, the chief good, immortality, the second advent, and the resurrection. Jerome tells us that Lactantius wrote an epitome of these *Institutions*, and such a work was discovered in the royal library at Turin in 1712 by C. M. Pfaff; it is doubtful, however, whether this MS. is the epitome of Lactantius. Besides the *Institutions*, Lactantius wrote a treatise, *De Ira Dei*, addressed to one Donatus and directed against the Epicurean philosophy; an argument for the wisdom and goodness of God as exhibited in the creation and preservation of the world, *De Opificio Dei sive de Formatione Hominis*; and a very celebrated treatise *De Mortibus Persecutorum*, which describes God's judgments on the persecutors of his church from Nero to Diocletian, and has served as a model for numberless subsequent writings of a like nature. *De Mort. Persecut.* is not included in the earlier editions of Lactantius; it was discovered and printed by Baluze in 1679. Many critics do not believe it to be the work of our author, and ascribe it to an unknown Lucius Cæcilius (see the work of Ebert above quoted). Jerome speaks of Lactantius as a poet, and several poems have been attributed to him:—*De Phenice*, *Symposium*, *De Pascha ad Felicem Episcopum*, and *De Passione Domini*. It is extremely probable that all these are the productions of a much later age.

MSS. of Lactantius are very numerous; a very complete catalogue of these and of the earlier printed editions will be found in Le Brun and Lenglet Dufresnoy's edition, 2 vols. Paris, 1748. The best editions besides Dufresnoy's are those of Walch, Leipsic, 1715; of Bünemann, Leipsic, 1739; and in Migne's *Patrologia Latina*, vols. vi. and vii. A new edition is promised in the Vienna *Corpus Script. Eccles. Latin.*

LACTIC ACID, a chemical term, which, though originally invented to designate the particular acid contained in sour milk, has now, through the discovery of other acids isomeric with and very similar to that acid, acquired a generic, in addition to its original specific, meaning.

1. *Lactic Acid properly so called, Fermentation Lactic Acid, Ethylidene Lactic Acid.*—Scheele (*Transactions of Stockholm Acad.*, 1780) was the first to isolate this acid (from sour milk) and establish its individuality. About twenty-four years later Bouillon Lagrange, and, independently of him, also Fourcroy and Vauquelin maintained that Scheele's new acid was nothing but impure acetic. But this notion was combated by Berzelius, and finally refuted (in 1832) by Liebig and Mitscherlich, who by the elementary analyses of lactates proved the existence of this as a distinct acid.

In the article FERMENTATION (vol. ix. p. 97) it is explained how lactic acid is produced from milk-sugar and from ordinary glucose by "lactic fermentation." The most convenient process for the preparation of the acid is Bensch's. A solution of "invert-sugar" (see vol. ix. p. 96) is produced by dissolving 6 parts of cane-sugar and $\frac{1}{100}$th part of tartaric acid in 35 parts of boiling water and allowing to stand for two days. There is then added $\frac{1}{14}$th part of foul cheese, 8 parts of sour milk, and $2\frac{1}{2}$ parts of carbonate of zinc, and the mixture kept at 40° to 45° C. for eight to ten days. The sugar, $C_6H_{12}O_6$, ferments into lactic acid, $C_3H_6O_3$, which, by the carbonate present, is converted into lactate of zinc. But part of the lactate is invariably lost through "butyric fermentation" with evolution of hydrogen, which latter converts part of the sugar into mannite, $C_6H_{14}O_6$. The fermented liquid is heated to boiling, strained clear, and allowed to cool, when the lactate of zinc separates out in crystalline crusts, which are purified by recrystallization from hot water. The free acid is obtained by decomposing the hot aqueous solution of the salt with sulphuretted hydrogen and filtering off the sulphide of zinc. The filtrate is evaporated on a water bath to a syrup, which is treated with ether. Mannite and other impurities remain, and the acid passes into the filtrate, from which the ether is easily expelled by distillation, and subsequent evaporation in an open basin. What ultimately remains is a thick colourless syrup, which, in ordinary chemical parlance, goes as *lactic acid*, although it is at best only an approximation to the hydrate, $C_3H_6O_3.H_2O$. The extra H_2O is easily enough removed by continued evaporation, but no portion of it can be thus got rid of without the acid $C_3H_6O_3$ itself suffering dehydration into *lactic anhydride*, $C_6H_{10}O_5$, and *lactide*, $C_6H_8O_4$, by successive subtractions of H_2O from $2C_3H_6O_3$.

The behaviour of lactic acid solution to basic reagents and of the acid itself to alcohols (in the presence of dehydrators) is strictly that of a monobasic acid $C_3H_6O_3$; *i.e.*, so much lactic is strictly equivalent to one molecule of acetic acid, and as the latter is proved to be $CH_3.COOH$, lactic acid must be assumed to be (C_2H_5O) COOH. But the radicle C_2H_5O (unlike the CH_3 of acetic acid) still contains one hydrogen atom, which, although not replaceable by metals, can be replaced by acid radicles such as acetyl C_2H_3O or, conjointly with the oxygen atom, by Cl, Br, I. Thus, for instance, lactic ether, $(C_2H_5O)COOC_2H_5$, when treated with chloride of acetyl, $C_2H_3O.Cl$, gets converted into acetyl-lactic ether, $[C_2H_4(C_2H_3O)O]COO(C_2H_5)$, with formation of hydrochloric acid. By the action of hydriodic acid the same H conjointly with the O of the radicle is replaced by iodine with formation of water. In a word, lactic acid, besides being an acid analogous to, for instance, acetic acid, CH_3COOH, is at the same time an alcohol analogous to ordinary spirit of wine, $C_2H_5.OH$, as shown by the formula $HO—C_2H_4—COOH$. This two-fold character of our substance explains the readiness with which it passes into anhydrides. Lactic acid the acid acts upon lactic acid the alcohol; the replaceable H in the former unites with the OH of the latter, and the two rests combine into an ether which is lactic anhydride. Thus:—

$(C_2H_4OH)—COO$	H
(C_2H_4COOH)	OH
Lactic anhydride.	Water.

The slanting lines show the mode of combination after the reaction. The anhydride, as we see, still contains an OH and COOH, and a repetition of the group within its molecule leads to lactide, $C_6H_8O_4$. This latter body could be presumed to be formed from one molecule of lactic acid:

$$HO(C_2H_4)COOH = (C_2H_4)COO + H.OH;$$

but the vapour density determination proves the molecular weight to be in accordance with the larger formula $C_6H_8O_4$.

Admitting, as well we may, that lactic acid is a compound of COOH and OH with C_2H_4, what is this C_2H_4 itself? This question has been satisfactorily answered. When lactic acid is distilled rapidly, it breaks up into formic acid, H.COOH, and aldehyde, $(CH_3)(CO)H$. Conversely when aldehyde is treated with hydrocyanic acid and muriatic acid it is converted into lactic acid, in two steps, thus: (1) the C=O in the aldehyde combines with the (NC)H, the H going to the O and the (NC) by its C to the C, to form the group (NC)—C—O—H; and (2) the NC of this group, by the action of the water, gets converted into a COOH, with formation of NH_3, which combines with the muriatic acid. $NC + 2H_2O = NH_3 + COOH$. The (CH_3) and H in the original aldehyde retain their places, so that what we obtain ultimately must be

$$(CH_3)—(CH)<^{OH}_{COOH}$$

and this consequently is the structure of lactic acid. The radicle

$(CH_3)(CH)$ is called ethylidene, to distinguish it from "ethylene," which is $(CH_2)(CH_2)$.

2. *Paralactic or Sarcolactic Acid.*—This acid was discovered by Berzelius in the juices of flesh. It is almost identical with ordinary lactic, but differs from it in this that it (and its salts) turn the plane of polarized light, and also in this that the sarcolactates in general are more readily soluble than ordinary lactates, and contain different proportions of crystal water from these. Thus, for instance, we have for the zinc salts

Ordinary.	*Sarco-.*
$Zn(C_3H_5O_3)_2 \cdot 3H_2O$.	$Zn(C_3H_5O_3) \cdot 2H_2O$.
Soluble in 60 parts of cold and in 6 parts of boiling water.	Soluble in 17 parts of cold water.

The isomerism of the two acids used to be explained by assuming that the sarco-acid contained ethylene in lieu of the ethylidene of the ordinary acid, thus:

$$(OH)—(CH_2)—(CH_2)—COOH,$$

i.e., that the OH and COOH were attached to different carbon atoms. But this has been proved by Erlenmeyer to be a mistake. The sarco-acid has precisely the same structure as ordinary lactic acid. It is a case of absolute (*i.e.*, of unexplained) isomerism.

3. *Hydracrylic Acid.*—From glyceric acid by the action of hydriodic acid we obtain β-iodopropionic, which, when treated with water and oxide of silver, exchanges its iodine for OH:

$$I \cdot H_2C—CH_2—COOH$$

gives

$$(OH) \cdot H_2C—CH_2—COOH,$$

which is hydracrylic, an ethylene-lactic acid. That this really is so was proved by Erlenmeyer, who obtained it by the action of water (+HCl) on undoubted ethylene-cyanhydrine $(OH)—(C_2H_4)—(CN)$. As suggested by the formula, it differs markedly in its reactions from the two more properly so-called lactic acids.

All lactic acids, when heated with hydriodic acid in sealed-up tubes, pass ultimately into (the same) propionic acid, $(CH_3)—(CH_2)—COOH$. (W. D.)

LADAK AND BALTI. The name Ladák (pronounced in Tibetan Lata) belongs primarily to the broad valley of the upper Indus in West Tibet, but includes several surrounding districts in political connexion with it; the present limits are between 75° 40′ and 80° 30′ E. long., and between 32° 25′ and 36° N. lat. It is bounded N. by the Kuen-lun range and the slopes of the Karakorum, N.W. and W. by the Mussulman state of Balti or Little Tibet, S.W. by Kashmir, S. by British Himalayan territory, and E. by the Chinese Tibetan provinces of Ngari and Rudók.[1] The whole region lies very high, the valleys of Rukshu in the south-east being 15,000 feet, and the Indus near Lé 11,000 feet, while the average height of the surrounding ranges is 19,000 feet. The proportion of arable and even possible pasture land to barren rock and gravel is very small.

The natural features of the country may be best explained by reference to two native terms, under one or other of which every part is included, viz., *changtang*, *i.e.*, "northern, or high plain," where the amount of level ground is considerable, and the hills proportionally further apart; and *rong*, *i.e.*, "deep valley," where the contrary condition prevails. The former predominates in the east, diminishing gradually westwards. There, although the vast alluvial deposits which once filled the valley to a remarkably uniform height of about 15,000 feet have left their traces on the mountain sides, they have undergone immense denudation, and their débris now forms secondary deposits, flat bottoms, or shelving slopes, the only spots available for cultivation or pasture. These masses of alluvium are often found either metamorphosed to a sub-crystalline rock still showing the composition of the strata, or simply consolidated by lime.

Grand scenery is exceptional, for the valleys are confined, and from the higher points the view is generally of a confused mass of brown or yellow absolutely barren hills, of no great apparent height. The parallelism characteristic of the Himalayan ranges continues here, the direction being north-west and south-east. A central range divides the Indus valley, here 4 to 8 miles wide, from that of its north branch the Shayok, which with its fertile tributary valley of Nubra is again bounded on the north by the Karakorum. This central ridge is mostly syenitic gneiss, and north-east from it are found, successively, Silurian slates, Carboniferous shales, and Triassic limestones, the gneiss recurring at the Turkestan frontier. The Indus lies along the line which separates the crystalline rocks from the Eocene sandstones and shales of the lower range of hills on the left bank, the lofty mountains behind them consisting of parallel bands of rocks from Silurian to Cretaceous.[2]

There are several lakes in the east districts at about 14,000 feet. They have evidently been of much greater extent, and connected with the river systems of the country, but they are now mostly without outlet, saline, and in process of desiccation.

The climate is intensely dry, practically rainless, the little snow which falls soon disappearing;[3] above a certain height no dew is deposited. The alternations of temperature are great; the sun's direct rays are hotter than in the Indian plains,[4] while the afternoon winds are piercingly cold; except in summer it freezes every night, even in the lower districts, and nightly throughout the year at 15,000 feet.

Vegetation therefore is confined to valleys and sheltered spots, where a stunted growth of tamarisk and *Myricaria*, *Hippophae* and *Elæagnus*, furze, and the roots of *burtsi*, a salsolaceous plant, supply the traveller with much-needed firewood. The trees are the pencil cedar (*Juniperus excelsa*), the poplar and willow (both extensively planted, the latter sometimes wild), apple, mulberry, apricot, and walnut. Agriculture depends on irrigation, which is skilfully managed, the principal products being wheat, common and naked barley (from which the returns are usually small), millet, buckwheat, pease, beans, and turnips. Lucerne and prangos (an umbelliferous plant) are used as fodder.

Among domestic animals are the famous shawl goat, two kinds of sheep, of which the larger (*huniya*) is used for carrying burthens, and is a principal source of wealth, the yak, and the dso, a valuable hybrid between the yak and common cow. Among wild animals are the kyang or wild ass, ibex, markhor, antelope, *Ovis Poli*, marmot, hare, and other Tibetan fauna.

The capital, Lé (population 4000), lies 4 miles from the river on the right bank, 11,540 feet above the sea, at the southern base of a spur from the central range,—a terraced slope, with scattered hamlets, extending thence to the Indus. It contains the palace of the old gyalpos, an imposing structure seven stories high, and a wide bazaar where polo is played. It is surrounded by poplar plantations, with manis[5] and ch'hordtens[6] beyond. The houses

[1] Geographically the east boundary is a mountain ridge some way within Chinese territory, which, running north, is the watershed between East and West Tibet, and from the north part of which the Indus, from the south the Sutlej, take their rise.

[2] Here, in the Zanskar, as the name implies, copper is found.

[3] The average height of the snow-line is about 19,000 feet.

[4] Gerard records 158° in Rupshu, *i.e.*, only 27° below boiling point at that altitude.

[5] "Mani," a long stone wall, several feet wide, running along the roadside, covered with loose stones deposited by the passers-by, inscribed with the prayer or ejaculation, "Om mani padme hom."

[6] "Ch'hordten," the monumental tomb of a lama.

are usually two-storied, with flat roofs and balconies to the south or west, the doors and shutters striped red and white.

The numerous monasteries are built (as the houses used to be, for defence) in lofty and picturesque situations, and would be strategically strong but for the absence of water. They are supported partly by their own lands, but chiefly by liberal gifts from the peasantry, with whose interests the lamas identify themselves. The latter are hospitable, and their superiors often refined, intelligent, and genial.

The religion is Buddhist, chiefly of the Dukpa or Red Sect, but traces of an older faith linger, to which the masked dances of the monks may possibly be referred. Mohammedanism, previously on the increase, is discouraged by the Kashmir Government, its Hindu influence tending, as Hinduism has done in Nepal, to introduce caste ideas.

Polyandry is general, except among the rich.

The home trade is worth little over £4000; the chief exports are wool, dried fruits, salt, and small quantities of gold, borax, and sulphur; the chief imports, provisions, hardware, and tea; but the transit trade is relatively very important, the chief routes from the Punjab, Afghanistan, and Kashmir into Eastern Turkestan and Chinese Tibet all passing through Lé.[1] It is carried by coolies, or on ponies, sheep, or yaks, over difficult passes often 18,000 feet high, and is further hampered by the exclusive policy of China and Russia. The mechanical and political obstacles have long engaged the attention of the Indian Government.

History.—The earliest notice of Ladák is by the Chinese pilgrim Fa-hian, 400 A.D., who, travelling in search of a purer faith, found Buddhism flourishing there, the only novelty to him being the prayer-cylinder, the efficacy of which he declares is incredible. Ladák formed part of the Tibetan empire until its disruption in the 10th century, and since then has continued ecclesiastically subject, and sometimes tributary, to Lhasa. Its inaccessibility saved it from any Mussulman invasion until 1531, when Sultan Said of Kashgar marched an army across the Karakorum, one division fighting its way into Kashmir and wintering there. Next year they invaded eastern Tibet, where nearly all perished from the effects of the climate.

Early in the 17th century Ladák was invaded by its Mohammedan neighbours of Balti, who plundered and destroyed the temples and monasteries; and again, in 1685–88, by the Sokpa or Calmucks, who were expelled only by the aid of the lieutenant of Aurangzeb in Kashmir, Ladák thereafter becoming tributary. The gyalpo or king then made a nominal profession of Islam, and allowed a mosque to be founded at Lé, and the Kashmiris have ever since addressed his successors by a Mohammedan title. When the Sikhs took Kashmir, Ladák, dreading their approach, offered allegiance to Great Britain. It was, however, conquered and annexed in 1834–41 by Ghulab Singh of Jamn—the unwarlike Ladákis, even with nature fighting on their side, and against indifferent generalship, being no match for the Dogra troops. These next turned their arms successfully against the Baltis (who in the 18th century were subject to the Mogul), and were then tempted to revive the claims of Ladák to the Chinese provinces of Rudók and Ngari. This, however, brought down an army from Lhasa, and after a three days' fight the Indian force was almost annihilated—chiefly indeed by frostbite and other sufferings, for the battle was fought in mid-winter, 15,000 feet above the sea. The Chinese then marched on Lé, but were soon driven out again, and peace was finally made on the basis of the old frontier. The widespread prestige of China is curiously illustrated by the fact that tribute, though disguised as a present, is paid to her, for Ladák, by the maharaja of Kashmir.

The adjoining territory of Balti—possibly the Byltæ of Ptolemy—forms the west extremity of the vast region known as Tibet, whose natural limits here are the Indus from its abrupt southward bend in 74° 45′ E. long., and the mountains to the north and west, separating a comparatively peaceful Tibetan population from the fiercer Aryan tribes beyond. Mohammedan writers about the 16th century speak of Balti as "Little Tibet," and of Ladák as "Great Tibet," thus ignoring the really Great Tibet altogether. The Balti people call Gilghit "a Tibet," and Dr Leitner says that the Chilasi, a Dard people west of the Indus, call themselves Boté, or Tibetans;[2] but, although these districts may have been, like Kashmir, overrun by the Tibetans, or have received rulers of that race, the ethnological frontier coincides with the geographical one here given. Balti is a mass of lofty mountains, the prevailing formation being gneiss. In the north is the Baltoro glacier, the largest out of the arctic regions, 35 miles long, contained between two ridges whose highest peaks to the south are 25,000 and to the north 28,265 feet. The Indus, as in Lower Ladák, runs in a narrow gorge, widening for nearly 20 miles after receiving the Shayok. The capital, Skardo, a scattered collection of houses, stands here, perched on a rock 7740 feet above the sea. The house-roofs are flat, occupied only in part by a second story, the remaining space being devoted to drying apricots, the chief staple of the main valley, which supports little cultivation. But the rapid slope westwards is seen generally in the vegetation. Birch, plane, spruce, and *Pinus excelsa* appear; the fruits are finer, including pomegranate, pear, peach, vine, and melon, and where irrigation is available, as in the North Shigar, and at the deltas of the tributary valleys, the crops are more luxuriant and varied.

Population.—The Ladákis, numbering about 21,000, are Tibetan, with a slight Caucasian admixture, and there are numerous Baltis and Dards (the latter superficially Buddhist) in the western districts. The Changpa, *i.e.*, "mountaineers," in the east are also Tibetan. They are singularly hardy, good-humoured, not stupid though simple and clumsy, dirty (washing, it is said, once a year, but not regularly), fond of social gatherings. The national drink, chang, is a sort of beer made from barley. The Balti type contains a much larger Aryan element, the isolated Dard (or Shin) communities being probably relics of an early Aryan population, subsequently overlaid by a Tibetan. The cross is a good one, the Baltis being more intelligent, if less genial, than the Ladákis, and equally industrious. They are taller, less beardless, and their noses less flat. They eschew pigtails. Polo is played more generally, and with more spirit, than in Ladák. The two languages are mutually intelligible. Like many Tajik and other mountain tribes westwards, the Baltis are Shiah Mohammedans. The women are thus more secluded than in Ladák, where they are particularly independent. They have abandoned polyandry, and (possibly in consequence) their numbers—some 58,000 in Balti and western Ladák—are larger than the country can support. Many emigrate to Kashmir and to British territory, where they do well. In the west the Dards are numerous, and a Dard element is especially observable in the families of the chiefs, some of whom, as in Ladák, were semi-independent before the annexation.

The principal works consulted have been Mr F. Drew's excellent book on *The Jummoo and Kashmir Territories*; a valuable paper by General H. Strachey "On the Physical Geography of Western Tibet," in the *Roy. Geog. Soc. Journ.*, vol. xxiii.; Cunningham's *Ladak*; *The Tribes of the Hindoo Koosh*, by Major J. Biddulph; the travels of Vigne, and of Moorcroft and Trebeck; papers by R. Lydekker, in *Records of the Geological Survey of India*, vols. xiii. and xiv., and by Dr F. Stoliczka, in *Report* of Sir T. D. Forsyth's mission to Yarkand. (C. T.)

LA DIXMERIE, NICOLAS BRICAIRE DE (1730-1791), French man of letters, was a native of Champagne, and was born about 1730. While still young he removed to Paris, where the rest of his life was spent in considerable

[1] The trade registered at Lé, chiefly between India and Eastern Turkestan, averages £134,000, the principal exports from India being cotton goods, value £29,200; silk ditto, £6000; skins, £3600; and tea, £3500; and from Eastern Turkestan—raw silk, £14,100; silver, £29,700; gold, £7000; charas, £6400; horses, £3200.

[2] This, however, it has been said, is only taken from the name of a former ruling family.

literary activity. He died suddenly on November 26, 1791. His numerous works include *Contes Philosophiques et Moraux* (1765), characterized by Sabatier as "less agreeable than those of Marmontel, but more moral, more varied, and showing a keener sensibility;" *Les deux âges du Goût et du Génie sous Louis XIV. et sous Louis XV.*, a parallel and contrast, in which the decision is given in favour of the latter; *L'Espagne littéraire* (1774); *Éloge de Voltaire* (1779) and *Éloge de Montaigne* (1781).

LADOGA, formerly NEVO, a lake of northern Russia, situated between 59° 56′ and 61° 46′ N. lat., and 29° 53′ and 32° 50′ E. long., surrounded by the governments of St Petersburg, Olonetz, and Wiborg. It has the form of a quadrilateral, elongated from north-west to south-east. Its eastern and southern shores are flat and marshy, whilst the north-western margin is craggy and fringed by numerous small rocky islands, the largest of which are Valaam and Konevetz, and which occupy altogether an area of 223 square miles. Lake Ladoga is 7000 square miles in area, that is, thirty-one times as large as the Lake of Geneva; but, its depth being less, it contains only nineteen times as much water as the great lake of Switzerland. The greatest depth, 244 yards, is in a cavity situated in the north-western part of the lake, the average depth not exceeding 100 yards. The level of Lake Ladoga is 55 feet above the Gulf of Finland, but it rises and falls about 7 feet according to atmospherical conditions. The western and eastern shores consist of boulder clay, as well as a narrow strip on the southern shore, south of which runs a ridge of crags of Silurian sandstones; the hills of the north-western shore afford a variety of granites and crystalline slates of the Laurentian system, whilst the Valaam island is made up of a rock which Russian geologists describe as orthoclastic hypersthenite. The granite and marble of Serdobol, and the sandstone of Poutilovo, are much used for buildings at St Petersburg; copper and tin from the Pitkaranda mine are exported. No less than sixty rivers enter Lake Ladoga, pouring into it the waters of numberless smaller lakes which lie at higher levels around it. The Volkhov, which conveys the waters of Lake Ilmen, is the largest; Lake Onega discharges its waters by the Svir; and the Saima system of lakes of eastern Finland contributes the Wuoxen and Taipala rivers; the Syass brings the waters from the smaller lakes and marshes of the Valdai plateau. Lake Ladoga discharges its surplus water by means of the Neva, which flows from its south-western corner into the Gulf of Finland, rolling down its broad channel 104,000 cubic feet of water per second. The water of Lake Ladoga is very pure and cold; in May its temperature on the surface does not exceed 36° Fahr., and even in August it reaches only 50° and 53°, the average yearly temperature of the air at Valaam being 36°·8. The lake begins to freeze in October, but it is only about the end of December that it is frozen in its deeper parts; and it remains under the ice covering until the end of March, whilst wide icefields continue to float in the middle of the lake until they are broken up by gales and scattered on the shores. Only a small part of the Ladoga ice is discharged by the Neva; but it is enough to produce in the middle of June a return of cold in the northern capital. The thickness of the ice does not exceed 3 or 4 feet; but during the alternations of cold and warm weather, with strong gales, in winter, heaps of ice, 70 and 80 feet high, are raised on the banks and on the icefields. The water of the lake is in continuous rotatory motion, being carried along the western shore from north to south, and along the eastern from south to north. The vegetation on the shores is poor; immense forests, which formerly covered them, are now mostly destroyed; but the fauna of the lake is somewhat rich; a species of seal which inhabits its waters, as well as several arctic species of crustaceans, recall its former connexion with the Arctic Ocean The great variety of sweet water *Diatomaceæ* which are found in the ooze of the deepest parts of the lake has also an arctic character. Fishing is very extensively carried on. Navigation on the lake, which is practicable for only one hundred and eighty days in the year, is rather difficult owing to fogs and gales, which are often accompanied, even in April and September, with snow storms. The prevailing winds are north-west and south-west; north-east winds cause the water to rise in the south-western part of the lake, sometimes from 3 to 5 feet. A phenomenon very similar to the *seiches* of the Lake of Geneva is observed in connexion with the rise and fall of the barometer. Steamers ply regularly in two directions from St Petersburg—to the monasteries of Konevetz and Valaam, and to the mouth of the Svir, whence they go up that river to Lake Onega and Petrozavodsk; and no less than from 600 to 800 small vessels transport timber, firewood, planks, iron, kaolin, granite, marble, fish, hay, and various small wares from the northern shore to Schlüsselburg, and thence to St Petersburg. The rivers Volkhov, Syass, and Svir being parts of the three great systems of canals which unite the upper Volga with the Gulf of Finland, and the navigation on Lake Ladoga being too dangerous for small craft, three canals with an aggregate length of 70 miles were dug along the southern shore of Lake Ladoga, uniting the mouths of these three rivers with the Neva at Schlüsselburg; thousands of vessels pass yearly along them on their way to St Petersburg. The population on the shores of the lake is sparse, and the towns Schlüsselburg, with 6000 inhabitants, New Ladoga (4500), Kexholm (1000), and Serdobol (800) are poor; many small villages are situated on the southern, north-eastern, and western shores, but the total population of the shores of Lake Ladoga does not exceed 35,000. The monasteries of Valaam, founded in 960, on the island of same name, and Konevskiy, on the Konevetz island, founded in 1393, are highly venerated, and are visited every year by many thousands of pilgrims.

LADRONE OR MARIANA ISLANDS, a chain of fifteen islands in the North Pacific Ocean, situated to the north of the Carolines, and between 13° and 21° N. lat., and 144° and 146° E. long. The name Islas de los Ladrones, or "Islands of the Thieves," was given them by the ship's crew of Magellan on account of the thieving propensity of the inhabitants. Magellan himself styled them Islas de las Velas Latinas, or "Islands of the Lateen Sails." San Lazarus archipelago, Jardines, and Prazeres are among the names applied to them by later navigators. They received their present recognized official appellation "Las Marianas" in 1668 in honour of Maria Anna of Austria, widow of king Philip IV. of Spain, and they still form a Spanish colony under the general government of the Philippines. A broad channel divides the Ladrones into two groups, containing a total area of about 417 square miles. The northern group (Gani) consists of ten islands, now uninhabited; five islands, of which four are inhabited, form the southern group, viz., Guahan (Guam, Spanish Guajan, the San Juan of old Spanish charts), Rota, Aguigan, Tinian, and Saypan. On Guahan, the largest and southernmost of the group, is the only town in the colony, San Ignacio de Agaña, and the fortified harbour of Umata.

The general surface of the southern islands is far inferior in elevation to that of the northern group, which is mountainous, though the altitudes do not exceed 2600 to 2700 feet. The predominant rock in the southern group is madreporic limestone, but in some instances, and especially at Guahan, volcanic formations occur. The northern islands are entirely of igneous origin, and on Pagan and Uraccas are smoking craters. The coasts of the southern islands are in many instances surrounded by reefs. All the islands except Farallon de Medinilla and Mangs (in the northern group) are more or less densely wooded, and the vegetation is luxuriant, much resembling that of the Philippines, whence many species of plants have been introduced. Owing to the humidity of the soil cryptogams are very numerous, as also most kinds of grasses. Among the useful vegetable products may be mentioned areca and cocoa-nut palms, rice, maize, sugar, tobacco, cotton, indigo, breadfruit, bananas, and castor oil. In consequence of the laziness of the native population, agriculture is almost entirely neglected, in spite of the exceptional advantages offered by the climate and soil. On most of the islands there is a plentiful supply of water; at Guahan, however, the partial clearing away of the woods has caused several full streams to dwindle to mere brooks.

The fauna of the Ladrones, though inferior in number and variety, is similar in character to that of the Carolines, and certain species are indigenous to both colonies. Swine and oxen are allowed to run wild, and are hunted when required: the former were known to the earlier inhabitants; the latter with most other domestic animals were introduced by the Spaniards. The roe was imported from the Philippines.

The climate of the Ladrones, though humid, is salubrious, whilst the heat, being tempered by the trade winds, is milder than that of the Philippines. The yearly mean temperature at Guahan is about 81° Fahr. August and September are the warmest months, but the variations of temperature are not great. The year may be divided into a wet and dry season, though even in the latter rain often falls. From October to May the general winds are north-easterly; during the other four months they are often north-westerly and south-westerly, the latter being accompanied by much rain.

The present population of the Ladrones consists of descendants from the original inhabitants, called by the Spaniards Chamorros, of Tagal settlers from the Philippines, and of a mixed race formed by the union of Spaniards and Chamorros. On the island of Saypan there is a colony from the Carolines. With the exception of the last-mentioned settlers, who are very active, and have founded the village of Garapan, the inhabitants are generally wanting in energy, of indifferent moral character, and miserably poor. Little has yet been done for the improvement of their intellectual and social condition, with the exception of the establishment of a few schools, now mostly fallen into decay. The number of the original inhabitants previous to the subjection of the islands by the Spaniards in 1668 has been variously estimated at from 40,000 to 60,000. The Spanish conquest and the forcible suppression of the protracted opposition of the natives reduced their numbers to such an extent that in 1741 the population was only 1816. From that date, however, owing to the introduction of new colonists from the Philippines, the population began to increase, and in 1856 was 9500. In the last year a severe epidemic carried off more than a third of the inhabitants. Since 1871 the total population of the Ladrones has been roughly estimated at 8000. All the inhabitants understand and are able to speak Spanish, which is gradually supplanting the native language, a Micronesian dialect nearly allied to that used by the Tagals of the Philippines. The residence of the governor is at Agaña in Guahan. Spain gains no revenue by the possession of these islands.

The honour of the discovery of this archipelago, the first found by Europeans in the Pacific, is due to Magellan, who upon the 6th of March 1521 observed the two southernmost islands, and sailed between them (O. Peschel, *Geschichte des Zeitalters der Entdeckungen*, Stuttgart, 1877, p. 500). Modern research in the archipelago began with the visit of Commodore Anson, who in August 1742 landed upon the island of Tinian, where he found extensive ruins (Anson's *Voyage*, bk. iii.). The Ladrones were visited by Byron in 1765, Wallis in 1767, and Crozet in 1772. Great additions to our knowledge of the islands were made in the present century by Freycinet, in 1829 (*Voyage autour du monde*, part histor. ii.), and the Spanish captain Sanchez y Zayas, in 1865.

Besides works above mentioned, see especially C. E. Meinicke, *Die Inseln des Stillen Oceans*, Leipsic, 1875-76, part ii.; "The Mariannas Islands," in the *Nautical Magazine*, vols. xxxiv., xxxv., London, 1865, 1866; and P. A. Lesson, *Les Polynésiens, leur origine*, &c., Paris, 1880. (E. D. B.)

LADY DAY, the Feast of the Annunciation of the Virgin Mary. See ANNUNCIATION.

LAENNEC, RENÉ THÉODORE HYACINTHE (1781-1826), inventor of the stethoscope, was born at Quimper in Britanny, February 17, 1781. Early trained to medicine under his uncle at Nantes, he completed his medical studies at Paris, where he received the degree of doctor in 1804. He specially distinguished himself by his researches in pathological anatomy, and was regarded as one of the first practitioners of the capital when in 1816 he was appointed physician at the Necker hospital. There he continued those researches which resulted in the discovery of the stethoscope in the manner already fully described under AUSCULTATION (vol. iii. p. 100). Laennec himself fell a victim to phthisis, the disease which, of all others, he had specially studied. For a few years he was able to occupy a medical chair in the Collége de France; but he died on August 13, 1826.

Laennec's chief work is the *Traité de l'Auscultation médiate*, 1819, in which he announced his discovery. It has been translated into various languages. He was the author also of *Propositions sur la doctrine médicale d'Hippocrate*, 1804; of *Mémoires sur les vers vésiculaires*, 1804; and of articles in the *Dict. des Sciences Médicales*, and other publications.

LAER, or LAAR, PIETER VAN (1613-1675), painter, was born at Laaren in Holland in 1613. The influence of a long stay in Rome begun at an early age is to be traced in his landscape and backgrounds, but in his subjects he remained true to the Dutch tradition, choosing generally lively scenes from peasant life, as markets, feasts, bowling scenes, farriers' shops, robbers, hunting scenes, peasants with cattle, and the like. From this taste, or from his personal deformity, he was nicknamed Bamboccio by the Italians. On his return to Holland about 1639, he lived chiefly at Amsterdam and Haarlem, in which latter city he died in 1674 or 1675. Pieter van Laer's pictures are marked by skilful composition and good drawing; he was especially careful in perspective. His colouring, according to Crowe, is "generally of a warm brownish tone, sometimes very clear, but oftener heavy, and his execution broad and spirited." Certain etched plates are also attributed to him.

LÆSTRYGONES, a mythic race of giants, mentioned in the *Odyssey*. After leaving the island of Æolus, Ulysses reached in six days the coast of the Læstrygonians and the city of Lamus, where the paths of day and night approach so close that a sleepless man might make double wages by herding continuously, watching one flock while the other rested. This feature of the tale obviously contains some hint of the long nightless summer in the Arctic regions, which perhaps penetrated to the Greeks with the merchants who fetched amber from the Baltic coasts. The Læstrygonians were cannibals; and, when three sailors sent as scouts incautiously entered the city, the king Antiphates ate one and the people pursued the others to the ships. As the vessels tried to escape from the harbour, the giants pelted them with masses of rock, and sunk all except the one in which Ulysses was. The Læstrygonians must be a mythic multiplication of the one ultimate demonic being who is called their king, just as the kindred race of the Cyclopes is a multiplication of the single one-eyed sun god Polyphemus, the Cyclops *par excellence*. The name Antiphates is a fanciful one, but the other name Lamus takes us into a religious world where we can trace the origin of the legend, and observe the god of an older religion becoming the subject of fairy tales in a later period (see LAMIA). Among the Greeks it was usual to place the country of the Læstrygones in Sicily, either beside Etna or towards the northwest promontory of the island; but on the other hand, Horace and other Latin authors speak of them as living in southern Latium, near Formiæ.

LA FARINA, GIUSEPPE (1815–1863), Italian author and politician, was born at Messina in 1815. On account of the part taken by him in the insurrection of 1837 he found it necessary to quit Sicily, but returning in 1839 he conducted various newspapers of liberal tendencies, until his efforts were completely interdicted, when he removed to Florence. In 1840 he had published *Messina ed i suoi Monumenti*, and after his removal to Florence he brought out *La Germania coi suoi Monumenti*, 1842; *L'Italia coi suoi Monumenti*, 1842; *La Svizzera Storica ed Artistica*, 1842–43; *La China*, 4 vols., 1843–47; and *Storia d'Italia*, 7 vols., 1846–54. He also in 1847 established a democratic journal *L'Alba* in the interests of Italian freedom and unity, but on the outbreak of the revolution in Sicily in 1848 he returned thither and was elected one of the committee of war. In the following year he was chosen to represent Messina in parliament, where he moved the deposition of King Ferdinand and the adoption of a new constitution. In April 1849 the provisional government, in which La Farina was minister successively of public instruction, of public works, and of the interior, resolved, notwithstanding his strong advocacy of resistance, to submit to the royal authority, and he removed to France. In 1850 he published *Istoria della Rivoluzione Siciliana*, and in 1851–52, in 6 vols., *Storia d'Italia dal* 1815 *al* 1850. He also began in 1851 *Rivista Enciclopedica Italiana*, and in 1856 *Piccolo Corriere d'Italia*, an organ which had great influence in propagating the political sentiments of the Societa Nazionale Italiana, of which he ultimately was chosen president. During the remainder of his life he was a devoted supporter of Victor Emmanuel, and in 1860 he was chosen a member of the first Italian parliament. He died Sept. 5, 1863. See Franchi's *Epistolario de Giuseppe La Farina*, 2 vols., 1869.

LA FAYETTE, the capital of Tippecanoe county, Indiana, U. S., is situated at the head of navigation on the Wabash river, and near the battle-ground of Tippecanoe, where, in 1811, General Harrison, afterwards president, defeated a large force of Indians. The city—which is much the largest of the twenty-four towns in the United States named in honor of General La Fayette—is beautifully situated in the center of a rich agricultural region and amid an amphitheater of hills, which are covered with suburban homes. La Fayette has eight lines of railway communication and ten graded turnpikes extending in various directions. The La Fayette car-works employ eight hundred men. There are four national banks, three daily and nine weekly newspapers, five large boot and shoe manufactories, four breweries, one distillery, four large cooperage establishments, a paper mill, porkhouses for summer and winter curing, a homing mill, iron-works, together with numerous foundries and smaller manufacturing enterprises. The city is supplied with gas and waterworks, and sulphur water, valuable for drinking and bathing purposes, flows from an artesian well in the public square. It is the seat of Purdue university, an agricultural college, richly endowed by a congressional land grant, and named in honor of John Purdue, who gave it $150,000. Population in 1880, 14,860.

LA FAYETTE.

MARIE JEAN PAUL ROCH YVES GILBERT MOTIER, MARQUIS DE LA FAYETTE was born in the romantic district of the Auvergne, France, about two hundred miles south of Paris, September 6, 1757. When he was but two years old, he lost his father, a gallant soldier, killed in the battle of Minden, which yielded so great a victory to the allied English and Prussians over the French. At thirteen years La Fayette was left, by his mother's death, sole heir to a great fortune. At sixteen years he married the daughter of Duc d'Ayen, thus uniting himself with one of the most ancient and important families in all France. Being himself also of a noble and titled stock, sentiment and custom compelled him to become either a courtier or a soldier. With his intense love of action he chose the camp, and joined the Guards, an organization composed chiefly of aristocratic youth, and peculiarly devoted to the king. At nineteen he was a captain of dragoons, skilled for fight on horseback or afoot. The stirring news of the Declaration of American Independence reached Paris, and aroused the ardor of all generous youth throughout France. La Fayette took fire at once. He declared many years afterward: "At the first news of this quarrel my heart was enrolled in it." He desired to go immediately to aid in the struggle of the Americans. He consulted an old friend of his family, the Count de Broglie, who tried to dissuade him from a purpose seemingly so rash. He recalled the bloody deaths of La Fayette's father and uncle in the recent wars, and urged the lad not to risk the ruin of the family by exposing its only remaining representative to the hazards of battle. Unshaken in his design, La Fayette procured an introduction to Baron de Kalb, who was about setting out to America, and through him to Silas Deane, of Connecticut, then at Paris, and acting as agent of the colonies in securing French coöperation. In December, 1776, it was arranged with Deane that La Fayette should enter the service sought, as a major-general. Just then came news of disaster to the American arms. New York had fallen into the hands of the British, and the ruin of Washington's army was reported. Silas Deane was relieved by Franklin and Lee, both of whom were unwilling to encourage the young soldier in his plans, nor did they feel themselves entitled to confirm Deane's pledge of a high military position, while the French king bade him remain at home. But La Fayette bought a ship, nothing daunted, and asked certain friends to sail with him. The British ambassador protested, whereupon orders went out from court to seize the ship and arrest La Fayette. But the ship was covertly sailed from Bordeaux to the port of Pasajes, Spain, and La Fayette slipped through the guard line in disguise, and before he could be caught was well at sea, with eleven picked companions. Two English war sloops chased him, but missed their aim, and the gallant fugitive landed near Georgetown, S. C., after a stormy voyage of two months. Warmly welcomed by the patriots, he rested for a few days, before his journey to the Congress at Philadelphia.

But nineteen years old, able to speak the English language only in a very broken manner, and expecting the high rank of major-general, he was at first received somewhat coldly by members of Congress. Deane, in his zeal, had promised more than could be fulfilled. La Fayette, on learning the situation, instantly asked the privilege of joining the American army on two conditions: First, that he might serve as a volunteer without command; second, that he should receive no pay for his services. This generosity, coupled with the great sacrifices the young marquis had already made, completely won the hearts of the Congress. A resolution was passed July 31, 1777, accepting his service and declaring that, in consideration of his zeal, illustrious family and connections, he should have the rank and commission of a major-general of the United States.

The very next day he was introduced to Washington, who was immediately won by the young man's engaging character. The general received the youth without delay into his own military family, to the great joy of the guest, and thus began a friendship notable in the history of great men, and which continued with singular devotion till the farewell of death.

It was impracticable to place La Fayette immediately at the head of a fighting force. It would have been unjust to the American officers, who had nobly led their men during the two years of hardship already endured. But at the battle of Brandywine, near Philadelphia, September 11, 1777, he so distinguished himself by gallant fighting as to win unusual praise. He was also severely wounded in the leg as he was fearlessly trying to rally some retreating soldiers. Washington promptly reported the splendid conduct of his friend to the Congress, and in a warm and dignified appeal set forth the advantages to the service of placing so worthy and earnest a friend of the patriot cause in immediate leadership of its soldiery, and closed by a recommendation that his commission as general be made more than honorary alone. Congress immediately responded, by giving the marquis the command of a division of troops, making him thereby the happiest man in America, and with good reason. Just twenty years old, an enthusiastic friend of popular liberty in whose battles he had just poured out his own blood, eager for honorable fame, the acknowledged favorite and friend of the greatest of patriot generals on earth, he was already honored with rank and authority of the foremost worth. He had won a place among the world's immortals, and yet a boy in years. What his friends had counted folly, and the state disloyalty, he had justified as valor, and glorified with fame.

Circumstances did not favor La Fayette with remarkable occasions for military renown during the American Revolution, but whatever responsibilities he did assume were ably sustained. He proved a discreet and efficient commander on every field where he fought. His conduct at the battle of Monmouth in 1778 was so heroic that Congress by special vote acknowledged it with gratitude. The masterly withdrawal of his little army at Barren Hill, when almost surrounded by a hostile force several times as large as his own, called out the unqualified praise of Washington, who was a witness to the gallant transaction. He was equally valuable as a wise arbitrator of the jealousies that occasionally threatened the good relations between French and American officers in the field. When at last France entered into an actual alliance with the American Colonies, both for purposes of commerce and war, and on February 7, 1778, war against England was declared, La Fayette felt it wise to return to his native land for consultation with the king; Washington heartily approved, realizing the great value to the American cause of an advocacy at court from one so devoted to its success, so fully informed as to its merits and prospects and so esteemed among the influential classes of the nation. The young ambassador, for such he really proved, was occupied with his mission about six months; he was immensely active and did much to create enthusiasm for the American cause and to persuade the government to an unqualified support of the war. He was met with universal affection and became the popular hero. Franklin wrote to Congress, in March, 1779: "The Marquis de La Fayette, who, during his stay in France, has been extremely zealous on all occasions, returns again to fight for us. He is infinitely esteemed and beloved here, and I am persuaded will do everything in his power to merit a continuance of the same affection from America."

When La Fayette came back, Congress passed a special resolution of welcome. He was immediately placed in charge of the defense of Virginia. He retained this important command till October, 1781, performing its difficult duties with consummate skill, doing all it was possible to do with the means at his command on the witness of no less a personage than Washington himself. He shared in the perils and honors of the siege of Yorktown, contributing an important part to this, the crowning success of the Revolutionary War. The independence of the United States assured, this friend of liberty sought leave to return to France, where he saw the signs of the coming struggle for popular rights which was to unfold into the great drama of the French Revolution. Active preparations were in progress for a combined French and Spanish naval expedition against some of the British islands in the West Indies; he was appointed chief of staff, and had repaired to Cadiz, where a powerful fleet had rendezvoused, when on November 30, 1782, the war was ended by treaty. La Fayette was permitted to officially make the important announcement to the American Congress, thus being the first to inform the American people, that the liberty he and they had so bravely fought to win, was forever assured.

His return to his native land had been signalized by a joyful welcome from his countrymen, who regarded him as one of the noblest heroes of humanity; he came honored with the distinguished consideration of the great Washington and the hearty commendation of the government of the new nation he had aided to establish. The French minister of war announced to him that he should hold the same rank in the French army as had been allotted him in America, his commission to date from the surrender of Cornwallis at Yorktown.

In 1784 he visited the United States to enjoy the spectacle of national well-being to which he had so gloriously contributed and to refresh his affections with the renewal of precious friendships. He was received with the acclamations of a grateful people; in public and private, honors were rendered him with a ceaseless love. For five months he remained in this, his second home, having made meantime the notable visit to Washington at quiet Mt. Vernon.

After his return to France he continued in private life for about five years, emerging to the view of the world as a member of the Assembly of Notables in 1787, and for the next five years he remained one of the most conspicuous actors, as he was the wisest and most generous, in the tremendous career of the French Revolution. No man of all who took part in the procedure of that fierce era preserved so perfect a poise of judgment, so calm a courage and so kind a heart as this true friend and brother of man.

He was the only man in France in whom all—king, courtiers and people—had perfect faith. He was known to be absolutely incorruptible, a patriot whom neither fear nor favor could move from his simple duty, and always the sincere and discreet friend of national liberty. He necessarily came to the front in those agitating days, when the throne was trembling to its fall. The call of a nation brought the States-General together to legislate a new order of government into being. This was in May, 1789. The kingdom had actually passed away, though there still sat on the throne a living image of royalty in the mild and incapable Louis XVI. The people already held the power of life and death over the public and the private citizen in their own keeping. Quickly the States-General, with its ancient division into noble, priest and commoner, was transformed into the National Assembly, where the citizen alone was recognized as the fountain and head of all national authority, and simple manhood was named diviner than the right of kings. Here La Fayette, on July 11, 1789, brought forward a declaration of the rights of man, modeled closely after the American Declaration of Independence. It was adopted with enthusiasm. The king was put under guard by the people whose ruler he had hitherto supposed himself to be.

A national guard was organized, consisting of 300,000 citizens; La Fayette was appointed its commander-in-chief by the common voice. For three years this noblest of patriots held the difficult and dangerous post of public duty through a storm of popular frenzy, in which well nigh all but he seemed bereft of reason, conscience and humanity. He went straight forward on the path of duty, through constant peril to his own life, weighted with a thousand cares and face to face with titanic difficulties. He bravely resisted the maddened populace when they sought to murder the king he had sworn to protect; he saved the queen from most brutal murder in October, 1789, and stood between the raging mob and trembling men and women, whose blood the populace clamored to drink. He repeatedly risked his own life to rescue others. Finally, unable to prevent the crimes he abhorred, he resigned his command. No man could be found to fill his place, and the people plead for his return, and he reluctantly resumed the office. He made his voice heard in the Assembly on every possible occasion in behalf of wise laws. He advocated the principles of a true republic — religious toleration, trial by jury, freedom of the press, abolition of titles of nobility and the destruction of all special privileges to any class.

Owing to the intrigues of escaped royalists, who were bent on seeing foreign armies thrust upon France in order to restore the power of the king, war was declared against Austria and her allies; three armies, each 50,000 strong, were raised, the command of one being committed to La Fayette. On the way to camp he passed through Paris amid the acclamations of the people. The president of the Assembly received him with distinction, declaring before the full house of deputies that "the nation would oppose to its enemies the constitution and La Fayette."

But passion and ferocity had now seized the places of power, and there was to be for a time no place in the public service for the noblest of citizens. The reign of terror was at hand. Cruelty and fury joined hands to war upon order and moderation. La Fayette, the steadfast friend of good order and constitutional government, denounced the Jacobin Club and its bloody tyranny, and demanded that the Assembly suppress it and bring its murderous leaders to deserved punishment. The fury of the Club now turned upon him. August 8th a motion was made in the Assembly for his arrest and trial as an enemy of his country. It failed by a vote of 224 against 446. Two days later the king and queen were hurried to prison by the frantic mob, to emerge only for the march to the scaffold.

There was nothing left for La Fayette but to save his own imperiled life by flight. He would gladly have led his army to Paris for the suppression of the bloody faction that was outraging all the rights of man in the sacred name of liberty, but his own soldiers were widely infected with the same fanaticism that was desolating the capital with indiscriminate murder. He was not safe for a day after he had been publicly denounced by the fierce men who now wielded all the power of the state. He quietly took refuge in the neutral territory of Liège, a province of Belgium, where, contrary to the law of nations, he was almost immediately made a prisoner by the Austrians. For five years he was kept in unwholesome prisons, first in Prussia, later at Olmutz, in eastern Austria. The affecting pleadings of his heroic wife, who voluntarily shared his hard fate, the protests of the English Parliament, the noble intercessions of Washington and the honorable appeal of the Congress of the United States produced no effect on the stubborn Emperor of Austria, who kept his illustrious captive closely confined without a pretense of justice. In 1797 Napoleon brought about his release, though he had no better title for the patriot he had delivered than "noodle." The "Directory," still under the spell of the revolutionary absolutism, at first refused him permission to return to France. He came back after Napoleon's power was established and the Directory made useless. But nothing could weaken his sturdy republicanism. In 1803 he voted against the life consulate of the great soldier and later against making him emperor. For ten years thereafter he lived quietly at his castle of La Grange.

Just before the battle of Waterloo he was made vice-president of the National Assembly, and during the years following, as a member for the city Meaux, he frequently made his influence felt on the legislation of the country.

In 1824 he visited the United States, where his reception was the grandest ovation ever given by a free people. Congress voted him a gift of $200,000 and a township of land.

In 1830 he again became prominent in the public affairs of his native land, taking command of the National Guard during the brief revolution that unseated Charles X. and introduced a constitutional monarchy. He continued active in affairs to the end of his long life, making a public speech on political refugees a few weeks before his death, which occurred at Paris, May 20, 1834.

La Fayette, in some sense, was the product of happy fortunes —born of distinguished parentage, heir to an affluent estate and an early favorite among the most important people of his country. But he owed his high place in the esteem of men chiefly to his own worthy achievement. He was a man of the purest ideals, living always for some principle that appealed to his noblest self. He was from first to last a lover of his fellow men, an earnest laborer for the renovation of society, a statesman whose motives no one in a time of unusual distrust suspected, a citizen who did his duty without hesitation or fear, chivalrous to his enemies, unwavering in friendship and possessed of a humanity that embraced the whole world in its sympathy. He stood next to Washington in the affection of the American people, and he retained the respect and confidence of the people of his native France longer than any other citizen of that nation of great enthusiasms. He loved the favor of the people, but he loved more the virtues that made him worthy of it. No man on earth was braver than he, and no one was oftener put to the test; but he never failed. He was the loyal knight of duty, the gentle friend of the needy, the steadfast soldier of progress and foremost among the laureled leaders of the liberty of man. (M. L. W.)

LA FLÈCHE, chief town of an arrondissement in the department of Sarthe, France, is situated on the right bank of the Loir, about 24 miles south-west of Le Mans. The chief buildings are the military academy (Prytanée), originally a college founded in 1607 by Henry IV., the church of St. Thomas, the prison, and the hospital. Near the bridge are the ruins of an ancient castle. La Flèche carries on manufactures of cloth, gloves, hosiery, candles, and glue, besides wax bleaching, tanning, and paper-making. It has the usual country trade, managed mainly by means of fairs. The population in 1876 was 7468.

LA FONTAINE, Jean de (1621–1695), one of the most popular and original of French poets, was born at Château Thierry in Champagne, probably on the 8th of July, 1621, and died at Paris on the 13th of April, 1695. His father was Charles de La Fontaine, "maître des eaux et forêts" — a kind of deputy-ranger — of the duchy of Château Thierry; his mother was Françoise Pidoux. On both sides his family was of the highest provincial middle class, but was not noble; his father was also fairly wealthy. Jean, who was the eldest child of his parents, was educated at the *collége* (grammar-school) of his native town, and at the end of his school days he had, singularly enough, an idea of taking orders. He entered the Oratory in May 1641, and the seminary of St Magloire in October of the same year; but a very short sojourn proved to him that he had mistaken his vocation. He then apparently studied law, and is said to have been admitted as *avocat*, though there does not seem to be actual proof of this. He was, however, settled in life, or at least might have been so, somewhat early. In 1647 his father resigned his rangership in his favour, and arranged a marriage for him with Marie Héricart, a young girl of sixteen, who brought him twenty thousand livres, and expectations. She seems to have been both handsome and intelligent, but the two did not get on well together. There appears to be absolutely no ground for the vague scandal as to her conduct, which was, for the most part long afterwards, raised by gossips or personal enemies of La Fontaine. All that is positively said against her is that she was a negligent housewife and an inveterate novel reader; La Fontaine on the other hand was constantly away from home, was certainly not strict in point of conjugal fidelity, and was so bad a man of business that his affairs became involved in hopeless difficulty, and a *séparation de biens* had to take place in 1658. This was for the benefit of the family, and was a perfectly amicable transaction; by degrees, however, the pair, still without any actual quarrel, ceased to live together, and for the greater part of the last forty years of La Fontaine's life he himself lived in Paris while his wife dwelt at Château Thierry, which, however, he frequently visited. One son was born to them in 1653, and was educated and taken care of wholly by his mother.

Even in the earlier years of his marriage La Fontaine seems to have been much at Paris, but it was not till about 1656 that he became a regular visitor to the capital. The duties of his office, which were only occasional, were compatible with this non-residence, and he continued to hold it till 1672. It was not till he was past thirty that his literary career began, for he was by no means a precocious writer. The reading of Malherbe, it is said, first awoke poetical fancies in him, but for some time he attempted nothing but trifles in the fashion of the time—epigrams, ballades, rondeaux, &c. His first serious work was a translation or adaptation of the *Eunuchus* of Terence (1654). At this time the Mæcenas of French letters was the superintendant Fouquet, to whom La Fontaine was introduced by Jacques Jannart, a connexion of his wife's. Few people who had paid their court to Fouquet went away empty-handed, and La Fontaine soon received a pension of 1000 livres (1659), in repayment possibly of the poem of *Adonis* which in 1658 he had, in manuscript, dedicated to the financier. He began too a medley of prose and poetry, entitled *Le Songe de Vaux*, on Fouquet's famous country house. It was about this time, as has been said, that his wife's property had to be separately secured to her, and he seems by degrees to have had to sell everything of his own; but, as he never lacked powerful and generous patrons, this was of small importance to him, especially as he had no establishment to maintain. In the same year he wrote a ballet, *Les Rieurs du Beau-Richard*, and this was followed by many small pieces of occasional poetry addressed to various personages great and small, from the king downwards. Fouquet soon incurred the royal displeasure, but La Fontaine, like most of his literary protégés, was not unfaithful to him, the well-known elegy *Pleurez, Nymphes de Vaux*, being by no means the only proof of his devotion. Indeed it is thought not improbable that a journey to Limoges which he took in 1663 in company with Jannart, and of which we have an account written to his wife, was not wholly spontaneous, as it certainly was not on Jannart's part. Just at this time his affairs did not look promising. His father and himself had assumed the title of esquire, to which they were not strictly entitled, and, some old edicts on the subject having been put in force by the king, an informer procured a sentence against the poet fining him 2000 livres, which from what is known of the state of his private affairs it was probably impossible for him to pay. He found, however, a new protector in the duke and still more in the duchess of Bouillon, his feudal superiors at Château Thierry, and nothing more is heard of the fine. Some of La Fontaine's liveliest verses are addressed to the duchess, Anne Mancini, the youngest of Mazarin's nieces, and it is even probable that the taste of the duke and duchess for Ariosto had something to do with the writing of his first work of real importance, the first book of the *Contes*, which appeared in 1664. He was then, let it be remembered, forty-three years old, and his previous printed productions had been comparatively trivial, though, as was the habit of the time, much of his work was handed about in manuscript long before it was regularly published. It was about this time that the quartette of the Rue du Vieux Colombier, so famous in French literary history, was formed. It consisted of La Fontaine, Racine, Boileau, and Molière, the last of whom was almost of the same age as La Fontaine, the other two considerably younger. Chapelle was also a kind of outsider in the coterie. There are many anecdotes, some of which are pretty obviously apocryphal, about these meetings. The most characteristic of these is perhaps that which asserts that a copy of Chapelain's unlucky *Pucelle* always lay on the table, a certain number of lines of which was the appointed punishment for offences against the company. The coterie furnished under feigned names the personages of La Fontaine's version of the Cupid and Psyche story, which, however, with *Adonis*, was not printed till 1669. Meanwhile the poet continued to find friends. In 1664 he was regularly commissioned and sworn in as gentleman to the duchess dowager of Orleans, and was installed in the Luxembourg. He still retained his rangership, and in 1666 we have something like a reprimand from Colbert suggesting that he should look into some malpractices at Château Thierry. In the same year appeared the second book of the *Contes*, and in 1668 the first six books of the *Fables*, with more of both kinds in 1671. In this latter year a curious instance of the docility with which the poet lent himself to any influence was afforded by his officiating at the instance of the Port-Royalists as editor of a volume of sacred poetry dedicated to the Prince de Conti. A year afterwards his situation, which had for some time been decidedly flourishing, showed signs of changing very much for the worse. The duchess of Orleans died, and he apparently had to give up his rangership, probably selling it to pay debts. But there was always a providence for La Fontaine. Madame de la Sablière, a woman of great beauty, of considerable intellectual power, and of high character, invited him to make his home in her house, where he lived for some twenty years. He seems to have had no trouble whatever about his affairs thenceforward; he was free to amuse himself or to work as he liked, and as a matter of fact he worked steadily at his two different lines of poetry. Besides these he ventured on a third, in which he met and indeed deserved much less success,—that of theatrical composition.

The next event of importance in La Fontaine's life, apart from the publication of his works, did not occur till after nearly ten years. In 1682 he was a man of more than sixty years old, recognized as one of the first men of letters of France. Madame de Sévigné, one of the soundest literary critics of the time, and by no means given to praise mere novelties, had spoken of his second collection of *Fables* published in the winter of 1678 as divine; and it is pretty certain that this was the general opinion. It was not unreasonable therefore that he should present himself to the Academy, and, though the subjects of his *Contes* were scarcely calculated to propitiate that decorous assembly, while his attachment to Fouquet and to more than one representative of the old Frondeur party made him suspect to Colbert and the king, most of the members were his personal friends. He was first proposed in 1682, but was rejected for Dangeau. The next year Colbert died and La Fontaine was again nominated. Boileau was also a candidate, but the first ballot gave the fabulist sixteen votes against seven only for the critic. The king, whose assent was necessary, not merely for election but for a second ballot in case of the failure of an absolute majority, was ill-pleased, and the election was left pending. Another vacancy occurred, however, some months later, and to this Boileau was elected. The king hastened to approve the choice effusively, adding, "Vous pouvez incessamment recevoir La Fontaine, il a promis d'être sage." His admission was indirectly the cause of the only serious literary quarrel of his life. A dispute, into the particulars of which there is no need to enter here, took place between the Academy and one of its members, Furetière, on the subject of the latter's French dictionary, which was decided to be a breach of the Academy's corporate privileges. Furetière, a man of no small ability, bitterly assailed those whom he considered to be his enemies, and among them La Fontaine, whose fault probably was not so much that he was a principal offender as that the unlucky *Contes* made him peculiarly vulnerable. His second collection of these tales had been actually the subject of a police condemnation, of which, as may be supposed, Furetière did not fail to make the most. The death of the author of the *Roman Bourgeois*, however, put an end to this quarrel. Shortly afterwards La Fontaine had a share in a still more famous affair, the celebrated ancient-and-modern squabble in which Boileau and Perrault were the chiefs, and in which La Fontaine (though he had been specially singled out by Perrault for favourable comparison with Æsop and Phædrus) took the ancient side. About the same time (1685–87) he made the acquaintance of the last of his many hosts and protectors, Monsieur and Madame d'Hervart, and fell in love with a certain Madame Ulrich, a lady of some position but of doubtful character. This acquaintance was accompanied by a great familiarity with Vendôme, Chaulieu, and the rest of the libertine coterie of the Temple; but, though Madame de la Sablière had long given herself up almost entirely to good works and religious exercises, La Fontaine continued an inmate of her house until her death in 1693. What followed is told in one of the best known of the many stories bearing on his childlike nature. Hervart on hearing of the death, had set out at once to find La Fontaine. He met him in the street in great sorrow, and begged him to make his home at his house. "J' y allais" was La Fontaine's answer. He had already undergone the process of conversion during a severe illness which befell him the year before. An energetic young priest, M. Poucet, had brought him, not indeed to understand, but to acknowledge the impropriety of the *Contes*, and it is said that the destruction of a new play of some merit was demanded and submitted to as a proof of repentance. A pleasant story is told of the young duke of Burgundy, Fénelon's pupil, who was then only eleven years old, sending 50 louis to La Fontaine as a present of his own motion. But though La Fontaine recovered for the time he was quite broken by age and infirmity, and his new hosts had to nurse rather than to entertain him, which they did very carefully and kindly. He did a little more work, completing his *Fables* among other things; but he did not survive Madame de la Sablière much more than two years, dying on the 13th of April 1695, at the age of seventy-three. He was buried in the cemetery of the Holy Innocents. His wife survived him nearly fifteen years, and his posterity lasted until the present century.

The curious personal character of La Fontaine, like that of some other men of letters, has been enshrined in a kind of myth or legend by literary tradition. At an early age his absence of mind and indifference to business gave a subject to Tallemant des Réaux, the most indefatigable and least scrupulous (at best the least critical) of gossips. His later contemporaries helped to swell the tale, and the 18th century finally accepted it. We have neither space nor desire to recount the anecdotes of his meeting his son, being told who he was, and remarking, "Ah, yes, I thought I had seen him somewhere!" of his insisting on fighting a duel with a supposed admirer of his wife, and then imploring him to visit at his house just as before; of his going into company with his stockings wrong side out, &c. It may be taken for granted that much of this is apocryphal, and the companion anecdotes of his awkwardness and silence, if not positive rudeness, in company are still more doubtful. It ought to be remembered, as a comment on the unfavourable description which La Bruyère gives or is supposed to give of his social abilities, that La Fontaine was a special friend and ally of Benserade, La Bruyère's chief literary enemy, who long prevented the author of the *Caractères* from entering the Academy. But after all deductions much will remain, especially when it is remembered that one of the chief authorities for such anecdotes is Louis Racine, a man who possessed intelligence and moral worth, and who received them from his father, La Fontaine's attached friend for more than thirty years. Perhaps the best worth recording of all these stories is one of the Vieux Colombier quartette, which tells how Molière, while Racine and Boileau were exercising their wits upon "le bonhomme" or "le bon" (by both which titles La Fontaine was familarly known), remarked to a bystander "nos beaux esprits ont beau faire, ils n'effaceront pas le bonhomme." They have not effaced him and will not do so, and the half contemptuous term "nos beaux esprits" marks well enough the sound judgment of the greatest of the four as to the merits of his companions.

The works of La Fontaine, the total bulk of which is considerable, fall no less naturally than traditionally into three divisions, the *Fables*, the *Contes*, and the miscellaneous works. Of these the first may be said to be known universally, the second to be known to all lovers of French literature, the third to be with a few exceptions practically forgotten. This distribution of the judgment of posterity is as usual just in the main, but not wholly. There are excellent things in the *Œuvres Diverses*, but their excellence is only occasional, and it is not at the best equal to that of the *Fables* or the *Contes*. It was thought by contemporary judges who were both competent and friendly that La Fontaine attempted too many styles, and there is something in the criticism. His dramatic efforts are especially weak, and indeed it is evident that his forte lay neither in the dramatic delineation of character nor in the arrangement of dramatic action. The best pieces usually published under his name—*Ragotin*, *Le Florentin*, *La Coupe Enchantée*, were not originally fathered by him but by Champmeslé, the husband of the famous actress who captivated Racine and Charles de Sévigné. His avowed work was chiefly in the form of opera, a form of no great value at its best. *Psyche* has all the advantages of its charming story and of La Fontaine's style, but it is perhaps principally interesting nowadays because of the framework of personal conversation already alluded to. The mingled prose and verse of the *Songe de Vaux* is not uninteresting, but its best things, such as the description of night—

"Laissant tomber les fleurs et ne les semant pas,"

which has enchanted French critics, are little more than conceits, though as in this case sometimes very beautiful conceits. The elegies, the epistles, the epigrams, the ballades, contain many things which would be very creditable to a minor poet or a writer of vers de société, but even if they be taken according to the wise rule of modern criticism, each in its kind, and judged simply according to their rank in that kind, they fall far below the merits of the two great collections of verse narratives which have assured La Fontaine's immortality.

Between the actual literary merits of the two there is not much to choose, but the change of manners and the altered standard of literary decency has thrown the *Contes* into the shade. These tales are identical in general character with those which amused Europe from the days of the early *fabliau* writers through the period of the great Italian *novellieri* to that of the second great group of French tale-tellers ranging from Antoine de la Salle to Béroalde de Verville. Light love, the misfortunes of husbands, the cunning of wives, the breach of their vows by ecclesiastics, constitute the staple of their subject. In some respects La Fontaine is the best of such tale-tellers, while he is certainly the latest who deserves such excuse as may be claimed by a writer who does not choose indecent subjects from a deliberate knowledge that they are considered indecent and with a deliberate desire to pander to a vicious taste. No one who followed him in the style can claim this excuse ; he can, and the way in which contemporaries of stainless virtue such as Madame de Sévigné speak of his work shows that though the new public opinion was growing up it was not finally accepted. In the *Contes* La Fontaine for the most part attempts little originality of theme. He takes his stories (varying them it is true in detail not a little) from Boccaccio, from Marguerite, from the *Cent Nouvelles Nouvelles*, &c. He applies to them his marvellous power of easy sparkling narration, and his hardly less marvellous faculty of saying more or less outrageous things in the most polite and gentlemanly manner. These *Contes* have indeed certain drawbacks. They are not penetrated by the half pagan ardour for physical beauty and the delights of sense which animates and excuses the early Italian Renaissance. They have not the subtle mixture of passion and sensuality, of poetry and appetite, which distinguishes the work of Marguerite and of the Pléiade. They are emphatically *contes pour rire*, a genuine expression of the *esprit gaulois* of the fabliau writers and of Rabelais, destitute of the grossness of envelope which had formerly covered that spirit. A comparison of "La Fiancée du Roi de Garbe" with its original in Boccaccio (especially if the reader takes M. Émile Montégut's admirable essay as a commentary) will illustrate better than anything else what they have and what they have not. Some writers have pleaded hard for the admission of actual passion of the poetical sort in such pieces as "La Courtisane Amoureuse," but as a whole it must be admitted to be absent.

The *Fables*, with hardly less animation and narrative art than the *Contes*, are free from disadvantages (according to modern notions) of subject, and exhibit the versatility and fecundity of the author's talent perhaps even more fully. La Fontaine had of course many predecessors in the fable and especially in the beast fable. In his first issue, comprising what are now called the first six books, he adhered to the path of these predecessors with some closeness ; but in the later collections he allowed himself far more liberty, and it is in these parts that his genius is most fully manifested. The boldness of the politics is as much to be considered as the ingenuity of the moralizing, as the intimate knowledge of human nature displayed in the substance of the narratives, or as the artistic mastery shown in their form. It has sometimes been objected that the view of human character which La Fontaine expresses is unduly dark, and resembles too much that of La Rochefoucauld, for whom the poet had certainly a profound admiration. The discussion of this point would lead us too far here. It may only be said that satire (and La Fontaine is eminently a satirist) necessarily concerns itself with the dark rather more than with the lighter shades. Indeed the objection has become pretty nearly obsolete with the obsolescence of what may be called the sentimental-ethical school of criticism. Its last overt expression was made some thirty years ago, in a curious outburst of Lamartine's, excellently answered by Sainte-Beuve. Exception has also been taken to the *Fables* on more purely literary grounds by Lessing, but, as this exception depends on differences inevitable between those who would shape all literature on rules derived from the study of Greek models and those who with the highest respect for those models rank them only among and not above others, it is equally needless to enter into it. Perhaps the best criticism ever passed upon La Fontaine's *Fables* is that of Silvestre de Sacy, to the effect that they supply three several delights to three several ages : the child rejoices in the freshness and vividness of the story, the eager student of literature in the consummate art with which it is told, the experienced man of the world in the subtle reflexions on character and life which it conveys. Nor has any one, with the exception of a few paradoxers like Rousseau and a few sentimentalists like Lamartine, denied that the moral tone of the whole is as fresh and healthy as its literary interest is vivid. The book has therefore naturally become the standard reading book of French both at home and abroad, a position which it shares in verse with the *Télémaque* of Fénelon in prose. It is no small testimony to its merit that not even this use or misuse has interfered with its popularity among French men of letters, who, with hardly an exception, speak as affectionately of it as if they had never been kept in on a summer's day to learn *La Cigale et la Fourmi*.

The general literary character of La Fontaine is, with allowance made for the difference of subject, visible equally in the *Fables* and in the *Contes*, and it is necessary to say a few words as to the nature of this character. Perhaps one of the hardest sayings in French literature for an English student is the dictum of Joubert to the effect that "Il y a dans La Fontaine une plénitude de poésie qu'on ne trouve nulle part dans les autres auteurs Français." Most English critics would probably admit at once La Fontaine's claim to a position in the first class of writers, but would demur to his admission to the first class of poets. The difference arises from the ambiguity of the terms. In Joubert's time, and perhaps a good deal later, inventiveness of fancy and diligent observation of the rules of art were held to complete the poetical differentia, and in both these La Fontaine deserves if not the first almost the first place among French poets. As to the first point there is hardly any dispute ; few writers either in French or any other language have ever equalled him in this respect. In his hands the oldest story becomes novel, the most hackneyed moral piquant, the most commonplace details fresh and appropriate. As to the second point there has not been such unanimous agreement. It used to be considered that La Fontaine's ceaseless diversity of metre, his archaisms, his licences in rhyme and orthography, were merely ingenious devices for the sake of easy writing, intended to evade the trammels of the stately couplet and *rimes difficiles* enjoined by Boileau. Lamartine in the attack already mentioned affects contempt of the "vers boiteux, disloqués, inégaux, sans symmétrie ni dans l'oreille ni sur la page." This opinion may be said to have been finally exploded by the most accurate metrical critic and one of the most skilful metrical practitioners that France has ever had, M. Théodore de Banville; and it is only surprising that it should ever have been entertained by any professional maker of verse. There can be little doubt that La Fontaine saw the drawbacks of the "Alexandrine prison," as it has been called, but in freeing himself from it he by no means took refuge in merely pedestrian verse. His irregularities are strictly regulated, his cadences carefully arranged, and the whole effect may be said to be (though of course in a light and tripping measure instead of a stately one) similar to that of the stanzas of the English pindaric ode in the hands of Dryden or Collins. There is therefore nothing against La Fontaine on the score of invention and nothing on the score of art. But something more, at least according to English standards, is wanted to make up a "plenitude of poesy," and this something more La Fontaine seldom or never exhibits. In words used by Joubert himself elsewhere, he never "transports." The faculty of transporting is of course possessed and used in very different manners by different poets. In some it takes the form of passion, in some of half mystical enthusiasm for nature, in some of commanding eloquence, in some of moral fervour. La Fontaine has none of these things: he is always amusing, always sensible, always clever, sometimes even affecting, but at the same time always more or less prosaic, were it not for his admirable versification. The few passages which may be cited to the contrary are doubtfully admissible, and cannot in any case suffice to leaven so great a mass of other work. It is needless to say that this is no discredit to him. A man can but be the very best in his own special line, and that very best La Fontaine assuredly is. He is not a great poet, and a deficiency very similar to that which deprives him of this name deprives him of the name of a great humorist; but he is the most admirable teller of light tales in verse that has ever existed in any time or country ; and he has established in his verse-tale a model which is never likely to be surpassed, and which has enriched literature with much delightful work.

La Fontaine did not during his life issue any complete edition of his works, nor even of the two greatest and most important divisions of them. The most remarkable of his separate publications have already been noticed. Others were the *Poëme de la Captivité de St Malc* (1673), one of the pieces inspired by the Port-Royalists, the *Poëme du Quinquina* (1602), a piece of task work also, though of a very different kind, and a number of pieces published either in small pamphlets or with the works of other men. Among the latter may be singled out the pieces published by the poet with the works of his friend Maucroix (1685). The year after his death some posthumous works appeared, and some years after his son's death the scattered poems, letters, &c., with the addition of some unpublished work bought from the family in manuscript, were carefully edited and published as *Œuvres Diverses* (1729). During the 18th century two of the most magnificent illustrated editions ever published of any poet reproduced the two chief works of La Fontaine. The *Fables* were illustrated by Oudry (1755–59), the *Contes* by Eisen (1762). This latter under the title of "Édition des Fermiers-Généraux" fetches a high price. During the first thirty years of the present century Walckenaer, a great student of French 17th century classics, published for the house of Didot three successive editions of La Fontaine, the last (1826–27) being perhaps entitled to the rank of the standard edition. More recently the editions of M. Marty-Laveaux in the *Bibliothèque Elzévirenne*, A. Pauly in the

Collection des Classiques Françaises of M. Lemerre, and L. Moland in that of M. Garnier supply in different forms all that can be wished. The second is the handsomest, the third, which is complete, perhaps the most generally useful. Editions, selections, translations, &c., of the *Fables*, especially for school use, are innumerable; but an illustrated edition published by the *Librairie des Bibliophiles* (1874) deserves to be mentioned as not unworthy of its 18th century predecessors. (G. SA.)

LAFOSSE, CHARLES DE, (1640–1716), French painter, was one of the most noted and least servile pupils of Lebrun, under whose direction he shared in the chief of the great decorative works undertaken in the reign of Louis XIV. He was born at Paris in 1640, and left France for Italy in 1662. He then spent two years in Rome and three in Venice, and the influence of his prolonged studies of Veronese is evident in his Finding of Moses (Louvre), and in his Rape of Proserpine (Louvre), which he presented to the Academy as his diploma picture in 1673. He was at once named assistant professor, and in 1674 the full responsibilities of the office devolved on him, but his engagements did not prevent his accepting in 1689 the invitation of Lord Montagu to decorate Montagu House. He visited London twice, remaining on the second occasion—together with Rousseau and Monnoyer—more than two years. William III. vainly strove to detain him in England by the proposal that he should decorate Hampton Court, for Lebrun was dead, and Mansart pressed Lafosse to return to Paris to take in hand the cupola of the Invalides. The decorations of Montagu House are destroyed, those of Versailles are restored, and the dome of the Invalides (engraved, Picart and Cochin)—for to his vexation the rest of the surface fell into other hands—is now the only work existing which gives a full measure of his talent. During his latter years Lafosse executed many other important decorations in public buildings and private houses, notably in that of Crozat, under whose roof he died on 13th December 1716.

LAGO MAGGIORE. See MAGGIORE.

LAGOS, a town in the district of Faro, which is coextensive with the province of Algarve, in Portugal, is situated on the south coast of the kingdom, on a bay which forms its harbour. The town is fairly well built; but beyond one or two churches, the batteries that defend the port, and an aqueduct 800 yards long, it has no special features of interest. It holds the formal rank of city, and enjoys a respectable historical position from its connexion with Prince Henry the Navigator, whose caravels generally sailed from its harbour. The material prosperity of the town was injured by an earthquake that laid it in ruins in 1755. The inhabitants are engaged in the tunny fishery and in vine raising. The population in 1878 was 7881. Lagos is held to be situated on or near the site of the Roman colony Lacobriga.

LAGOS, a British settlement on the west coast of Africa, united since 1876 with the Gold Coast colony, and by the terms of the charter comprising all British possessions between the second and fifth degrees of east longitude. The actual settlement is situated on a low island within the mouth of the so-called Lagoa river, which is really a lagoon of considerable extent, into which the Ogun and several other rivers discharge. The seaward entrance is about 3 miles wide, but it requires skilful pilotage to take a vessel across the bar into the smooth and deep water. Lagos was formerly the chief seat of the slave trade in the Bight of Benin. In 1851 it was captured by the British, and in 1861 the "king" Docemo was practically constrained to give up his territorial jurisdiction, and accept a pension of 1200 bags of cowries, or about £1030. There is now a flourishing settlement. The mangrove swamp has been cleared away from a large part of the island; a well-kept road runs for a mile along the shore in front of the European quarter; wooden wharves have been built; marshy spots have been turned into gardens, and among the houses are a number of bright stucco-fronted villas.

Immediately after the proclamation of the British annexation, a steady current of immigration from the mainland set in, and in 1871 the population of Lagos proper was 13,520 males and 14,998 females. Within the Lagos district are Badagry (1148 males, 1343 females), Palma (814), and Leke (165), making a total for the settlement of 31,998. Besides the local tribes the population contains Sierra-Leonians, Krumen, and Fanti, as well as from 4000 to 6000 Brazilian *emancipados*. The trade of Lagos consists mainly in the exportation of palm oil and palm kernels, and the importation of liquors, tobacco, and cotton goods. Most of the business is in the hands of German and French houses. The average value of imports for 1875–1879 was £512,857, and of exports £620,644. In 1879 the Church of England had 13 churches in the settlement, the Wesleyans 7, the Roman Catholics (who are largely recruited by the Brazilian immigrants) 2, and the Baptists 1. The schools numbered 28, several being subsidized by the Government. The 8000 Mohammedans have 27 mosques and about 37 small Koran schools. During the five years from 1875 to 1879 the aggregate revenue of the settlement was £253,445, the aggregate expenditure £227,523.

LAGRANGE, JOSEPH LOUIS (1736–1813), a mathematician of the highest rank, was born at Turin, January 25, 1736. He was of French extraction, his great grandfather, a cavalry captain, having passed from the service of France to that of Sardinia, and settled in Turin under Emmanuel II. His father, Joseph Louis Lagrange, married Maria Theresa Gros, only daughter of a rich physician at Cambiano, and had by her eleven children, of whom only the eldest (the subject of this notice) and the youngest survived infancy. From his post as treasurer at war, as well as through his wife, he derived ample means, which he, however, lost by rash speculations, a circumstance regarded by his son as the prelude to his own good fortune; for had he been rich, he used to say, he might never have known mathematics.

The genius of Lagrange did not at once take its true bent. His earliest tastes were literary rather than scientific, and he learned the rudiments of geometry during his first year at the college of Turin, without difficulty, but without distinction. The perusal of a tract by Halley (*Phil. Trans.*, vol. xviii. p. 960) roused his enthusiasm for the analytical method, of which he was destined to develop the utmost capabilities. He now entered, without aid or guidance save those afforded by his own unerring tact and vivid apprehension, upon a course of study which, in two years, placed him on a level with the greatest of his contemporaries. At the age of nineteen he communicated to the celebrated Euler his idea of a general method of dealing with "isoperimetrical" problems, known later as the Calculus of Variations. It was eagerly welcomed by the Berlin mathematician, who had the generosity to withhold from publication his own further researches on the subject, until his youthful correspondent should have had time to complete and opportunity to claim the invention. This prosperous opening gave the key-note to Lagrange's career. Appointed, in 1754, professor of geometry in the royal school of artillery, he formed with some of his pupils—for the most part his seniors—friendships based on community of scientific ardour. With the aid of the Marquis de Saluces and the eminent anatomist Cigna, he founded in 1758 a society which rose later to the dignity of the Turin Academy of Sciences. The first volume of its memoirs, published in the following year, contained a paper by Lagrange entitled *Recherches sur la nature et la propagation du son*, in which the power of his analysis and his address in its application were equally conspicuous. Without assumption, but without hesitation, he made his first appearance in public as the critic of Newton, and the arbiter between D'Alembert and Euler. By considering only the particles of air found in a right line, he reduced the problem of the propagation of sound to the solution of the same partial differential equations that include the motions of vibrating strings, and demonstrated the insufficiency of the methods employed by both his great contemporaries in dealing with the latter subject. He further treated in a masterly manner of echoes and the mixture of sounds, and explained the phenomenon of grave harmonics as due to the occurrence of beats so rapid as to generate a musical note. This was followed, in the second volume of the *Miscellanea Taurinensia* (1762) by his "Essai d'une nouvelle méthode pour déterminer les maxima et les minima des formules intégrales indéfinies," together with the application of this important development of analysis to the solution of several dynamical problems, as well as to the demonstration of the mechanical principle of "least action." The essential point in his advance on Euler's mode of investigating curves of maximum or minimum consisted in his purely analytical conception of the subject. He not only freed it from all trammels of geometrical construction, but by the introduction of the symbol δ gave it the efficacy of a new calculus. He is thus justly regarded as the inventor of the "method of variations"—a name supplied by Euler in 1766.

By these performances Lagrange found himself, at the age of twenty-six, on the summit of European fame. But such a height had not been reached without cost. Intense application during early youth had checked his growth, and weakened a constitution never robust. Accesses of feverish exaltation culminated, in the spring of 1761, in an attack of bilious hypochondria, which permanently lowered the tone of his nervous system, and rendered him liable, throughout his life, to recurrences of the same complaint at the same time of year. Rest and exercise, however, temporarily restored his health, and he gave proof of the undiminished vigour of his powers by carrying off, in 1764, the prize offered by the Paris Academy of Sciences for the best essay on the libration of the moon. His treatise was remarkable, not only as offering a satisfactory explanation of the coincidence between the lunar periods of rotation and revolution, but as containing the first employment of his radical formula of mechanics, obtained by combining with the principle of D'Alembert that of virtual velocities. His success encouraged the Academy to propose, in 1766, as a theme for competition, the hitherto unattempted theory of the Jovian system. The prize was again awarded to Lagrange; and he subsequently earned the same distinction with essays on the problem of three bodies in 1772, on the secular equation of the moon in 1774, and in 1778 on the theory of cometary perturbations.

He had in the meantime gratified a long felt desire by a visit to Paris, where he enjoyed the keen and stimulating delight of conversing with such mathematicians as Clairaut, D'Alembert, Condorcet, and the Abbé Marie. An attack of illness frustrated his design of extending his journey to London, and he returned, though not for long, to the comparative isolation of the Piedmontese capital. The post of director of the mathematical department of the Berlin Academy (of which he had been a member since 1759) becoming vacant by the removal of Euler to St Petersburg, both he and D'Alembert united, by unpremeditated concert, to recommend Lagrange as his successor. Euler's eulogium was enhanced by his desire to quit Berlin, D'Alembert's by his dread of a royal command to repair thither; and the result was that an invitation, conveying the wish of the "greatest king in Europe" to have the "greatest mathematician" at his court, was sent to Turin. On November 6, 1766, Lagrange was installed in his new position, with a salary of 6000 francs, ample leisure for scientific research, and an amount of royal favour sufficient to secure him respect without exciting envy. The national jealousy of foreigners, it is true, was at first a source of annoyance to him; but such prejudices were gradually disarmed by the mild inoffensiveness of his demeanour, and by his strict adherence to a policy of non-intervention outside his own immediate domain. We are told that the universal example of his colleagues, rather than any desire for female society, impelled him to matrimony; an excess of home-sickness, however, probably directed his choice towards a lady of the Conti family (related to his own by a previous alliance), who, by his request, joined him at Berlin. The experiment was cut short by a lingering illness, during which he devoted all his time, and a considerable store of medical knowledge, to the care of the dying woman.

The long series of memoirs—some of them complete treatises of great moment in the history of science—communicated by Lagrange to the Berlin Academy between the years 1767 and 1787 were not the only fruits of his exile on the banks of the Spree. His *Mécanique Analytique*, the production in which his genius most fully and characteristically displayed itself, was due to the same period. This great work was the perfect realization of a design present to the mind of its author almost from boyhood, and of which he had given a clear though concise sketch in his first published essay.[1] Its scope may be briefly described as the reduction of the theory of mechanics to certain general formulæ, from the simple development of which should be derived the equations necessary for the solution of each separate problem.[2] From the fundamental principle of virtual velocities, which thus acquired a new significance, Lagrange deduced, with the aid of the calculus of variations, the whole system of mechanical truths, by processes so elegant, lucid, and harmonious as to constitute, in Sir William Hamilton's words, "a kind of scientific poem." This unification of method was one of matter also. By his mode of regarding a liquid as a material system characterized by the unshackled mobility of its minutest parts, the separation between the mechanics of matter in different forms of aggregation finally disappeared, and the fundamental equation of forces was for the first time extended to hydrostatics and hydrodynamics.[3] Thus a universal science of matter and motion was derived, by an unbroken sequence of deduction, from one radical principle; and analytical mechanics assumed the clear and complete form of logical perfection which it now wears.

A publisher having with some difficulty been found, the book appeared in Paris, under the supervision of Legendre, in 1788. But before that time Lagrange himself was on the spot. After the death of Frederick the Great, his presence was competed for by the courts of France, Spain, and Naples, and a residence in Berlin having ceased to possess any attraction for him, he removed to Paris in 1787. His reception was most flattering. Marie Antoinette warmly patronized him. He was lodged in the Louvre, received the grant of an income equal to that hitherto enjoyed by him, and, with the title of "veteran pensioner" in lieu of that of "foreign associate" (conferred in 1772), the right of voting at the deliberations of the Academy. In the midst of these distinctions, a profound melancholy seized upon him. His mathematical enthusiasm, hitherto the happiness of his life, was for the time completely quenched, and during two years the printed volume of his *Mécanique*, which he had seen only in manuscript, lay unopened beside him. He relieved his dejection with miscellaneous studies, especially with that of chemistry, which, in the new form given to it by Lavoisier, he found "aisée comme l'algèbre." The dis-

astrous crisis of the Revolution roused him once more to activity and cheerfulness. Curiosity impelled him to remain and watch the progress of such a novel phenomenon; but curiosity was changed into dismay as the terrific character of the phenomenon unfolded itself. He now bitterly regretted his temerity in braving the danger. "Tu l'as voulu" he would repeat self-reproachfully. Even from revolutionary tribunals, however, the name of Lagrange uniformly commanded respect. His pension was continued by the National Assembly, and he was partially indemnified for the depreciation of the currency by remunerative appointments. Nominated president of the Academical commission for the reform of weights and measures, his services were retained when its "purification" by the Jacobins removed his most distinguished colleagues. He again sat on the commission of 1799 for the actual construction of the metrical system, and by his zealous advocacy of the decimal principle of subdivision largely contributed to its adoption.

The interval had, however, been marked by some of the most considerable events in the placid life of our mathematician. On the 31st of May 1792 he married Mademoiselle Lemonnier, daughter of the astronomer of that name, a young and beautiful girl, whose devotion ignored disparity of years, and formed the one tie with life which Lagrange found it hard to break. He had no children by either marriage, and never regretted their absence. Although specially exempted from the operation of the decree of October 1793, imposing banishment on foreign residents, he took alarm at the fate of Bailly and Lavoisier, and prepared to resume his former situation in Berlin. His design was frustrated by the establishment of and his official connexion with the École Normale, and then the École Polytechnique. The former institution had an ephemeral existence, and his lectures there were consequently few and elementary; but amongst the benefits derived from the foundation of the École Polytechnique one of the greatest, it has been observed,[1] was the restoration of Lagrange to mathematics. The remembrance of his teachings was long treasured by such of his auditors—amongst whom were Delambre and Lacroix—as were capable of appreciating them. In expounding the principles of the differential calculus, he started, as it were, from the level of his pupils, and ascended with them by almost insensible gradations from elementary to abstruse conceptions. He seemed, not a professor amongst students, but a learner amongst learners; pauses for thought alternated with luminous exposition; invention accompanied demonstration; and thus originated his *Théorie des fonctions analytiques* (Paris, 1797). The leading idea of this remarkable work was contained in a paper published in the *Berlin Memoirs* for 1772.[2] Its object was the elimination of the to some minds unsatisfactory conception of the infinite from the metaphysics of the higher mathematics, and the substitution for the differential and integral calculus of an analogous method depending wholly on the serial development of algebraical functions. By means of this "calculus of derived functions" Lagrange hoped to give to the solution of all analytical problems the utmost "rigour of the demonstrations of the ancients";[3] but it cannot be said that the attempt was successful. The validity of his fundamental position was impaired by the absence of a well-constituted theory of series; the notation employed was inconvenient, and was abandoned by its inventor in the second edition of his *Mécanique*; while his scruples as to the admission into analytical investigations of the idea of limits or vanishing ratios have long since been laid aside as idle. Nowhere, however, were the keenness and clearness of his intellect more conspicuous than in this brilliant effort, which, if it failed in its immediate object, was highly effective in secondary results. His purely abstract mode of regarding functions, apart from any mechanical or geometrical considerations, led the way to a new and sharply characterized development of the higher analysis in the hands of Cauchy, Jacobi, and others.[4] The *Théorie des Fonctions* is divided into three parts, of which the first explains the general doctrine of functions, the second deals with its application to geometry, and the third with its bearings on mechanics.

On the establishment of the Institute, Lagrange was placed at the head of the section of geometry; he was one of the first members of the Bureau des Longitudes; and his name appeared in 1791 on the list of foreign members of the Royal Society. On the annexation of Piedmont to France in 1796, a touching compliment was paid to him in the person of his aged father. By direction of Talleyrand, then minister for foreign affairs, the French commissary repaired in state to the old man's residence in Turin, to congratulate him on the merits of his son, whom they declared "to have done honour to mankind by his genius, and whom Piedmont was proud to have produced, and France to possess." Bonaparte, who styled him "la haute pyramide des sciences mathématiques," loaded him with personal favours and official distinctions. He became a senator, a count of the empire, a grand officer of the legion of honour, and just before his death received the grand cross of the order of reunion.

The preparation of a new edition of his *Mécanique*, to which he devoted himself with extraordinary zeal, exhausted his already failing powers. Frequent fainting fits gave presage of a speedy end, and on the 8th of April 1813 he had a final interview with his friends Lacépède, Monge, and Chaptal. He spoke with the utmost calm of his approaching death; "c'est une dernière fonction," he said, "qui n'est ni pénible ni désagréable." He, however, looked forward to a future meeting, when he promised to complete the autobiographical details which weakness obliged him to interrupt. They remained untold, for he died two days later, April 10, at the age of seventy-seven, and was buried in the Pantheon, the funeral oration being pronounced by Laplace and Lacépède.

Lagrange would never allow his portrait to be painted, holding that a man's works, not his features, deserve remembrance. From a sketch, however, obtained by stealth at a meeting of the Institute, coupled with the descriptions of those who knew him, we can, in some sort, construct an image of his mild and venerable aspect. He was of the middle height, with a slight, well-proportioned figure. His head was finely formed, though not massive; his features strongly marked, with a stamp of grave and noble beauty; eyes ashy blue, habitually cast down in meditation, but when raised, clear and penetrating; complexion pale and faded. The whole physiognomy was more expressive of benignity than of strength, and his social attitude was one of deprecation rather than of self-assertion. He was timid and affable in conversation, slow to give his opinion, though frequently betraying, by his remarks even on subjects alien to his habitual studies, unexpected stores of information and depths of thought. The phrase "Je ne sais pas" became habitual with him, serving to express his sense of failure in the search for words to fit accurately with ideas always precise. Of music he used to say "Je l'aime, parce qu'elle m' isole"; and his most abstruse reasonings were frequently pursued under its soothing influence. The sight of suffering was intolerable to him; he abhorred controversy, tolerated—

perhaps unduly—what he could not approve, and was emphatically, in his own phrase, "philosophe sans crier."

The delicacy of his health demanded precautions exaggerated, under the influence of nervous anxiety, into minute watchfulness. He observed a scrupulous regimen, living mainly on fruit and vegetables, and his temperance doubtless helped to keep his faculties unimpaired to the last. By self-imposed rules of study, he regulated his vast capability of work as strictly as if it had been a machine entrusted to his care. It was one of his maxims that the mind gains full command over its powers only by exercise and discipline. He had learned from Frederick the Great always to do the same things at the same hours, assigning the most difficult to the morning. Each day he set himself a task for the next, and from the first aimed at mastering certain points of his subject, with a view to inventing improvements. He always read with a pen in his hand, developing the methods of his author as he proceeded; and his own works were so profoundly meditated that they were usually written without erasures.

Amongst the brilliant group of mathematicians whose magnanimous rivalry contributed to accomplish the task of generalization and deduction reserved for the 18th century Lagrange occupies an eminent place. It is, however, by no means easy to distinguish and apportion the respective merits of the competitors. This is especially the case between Lagrange and Euler on the one side, and between Lagrange and Laplace on the other. The calculus of variations lay undeveloped in Euler's mode of treating isoperimetrical problems. The fruitful method, again, of the variation of elements was introduced by Euler, but adopted and perfected by Lagrange, who first recognized its supreme importance to the analytical investigation of the planetary movements. Finally, of the grand series of researches by which the stability of the solar system was ascertained the glory must be almost equally divided between Lagrange and Laplace. In analytical invention, and mastery over the calculus, the Turin mathematician was admittedly unrivalled. Laplace owned that he had despaired of effecting the integration of the differential equations relative to secular inequalities until Lagrange showed him the way. On the other hand, Laplace unquestionably surpassed his rival in practical sagacity, and the intuition of physical truth. Lagrange saw in the problems of nature so many occasions for analytical triumphs; Laplace regarded analytical triumphs as the means of solving the problems of nature. One mind seemed, as it were, the complement of the other; and both united in honourable rivalry formed an instrument of unexampled perfection for the investigation of the celestial machinery. What may be called Lagrange's first period of research into planetary perturbations extended from 1774 to 1784 (see ASTRONOMY, vol. ii. p. 761). The remarkable group of treatises communicated, 1781–84, to the Berlin Academy was designed, but did not prove, to be his final contribution to the theory of the planets. After an interval of twenty-four years the subject, having been reopened by Poisson in a paper read June 20, 1808, was once more attacked by Lagrange with all his pristine vigour and fertility of invention. Resuming the inquiry into the invariability of mean motions, Poisson carried the approximation, with Lagrange's formulæ, as far as the squares of the disturbing forces, hitherto neglected, with the same result as to the stability of the system. He had not, however, attempted to include in his calculations the orbital variations of the disturbing bodies; but Lagrange, by the happy artifice of transferring the origin of coordinates from the centre of the sun to the centre of gravity of the sun and planets, obtained a simplification of the formulæ, by which the same analysis was rendered equally applicable to each of the planets severally. It deserves to be recorded as one of the numerous coincidences of discovery that Laplace, on being made acquainted by Lagrange with his new method, produced analogous expressions, to which his independent researches had led him. The final achievement of Lagrange in this direction was the extension of the method of the variation of arbitrary constants, successfully used by him in the investigation of periodical as well as of secular inequalities, to any system whatever of mutually interacting bodies.[1] "Not without astonishment," even to himself, regard being had to the great generality of the differential equations, he reached a result so wide as to include, as a particular case, the solution of the planetary problem recently obtained by him. He proposed to apply the same principles to the calculation of the disturbances produced in the rotation of the planets by external action on their equatorial protuberances, but was anticipated by Poisson, who gave formulæ for the variation of the elements of rotation strictly corresponding with those found by Lagrange for the variation of the elements of revolution. The revision of the *Mécanique Analytique* was undertaken mainly for the purpose of embodying in it these new methods and final results, but was interrupted, when two-thirds completed, by the death of its author.

In the advancement of almost every branch of pure mathematics Lagrange took a conspicuous part. The calculus of variations is indissolubly associated with his name. In the theory of numbers he furnished solutions of many of Fermat's theorems, and added some of his own. In algebra he discovered the method of approximating to the real roots of an equation by means of continued fractions, and imagined a general process of solving algebraical equations of every degree. The method indeed fails for equations of an order above the fourth, because it then involves the solution of an equation of higher dimensions than the proposed. It possesses, however, the great and characteristic merit of generalizing the solutions of his predecessors, exhibiting them all as modifications of one principle. To Lagrange, perhaps more than to any other, the theory of differential equations is indebted for its position as a science, rather than a collection of ingenious artifices for the solution of particular problems. To the calculus of finite differences he contributed the beautiful formula of interpolation which bears his name; although substantially the same result seemed to have been previously obtained by Euler. But it was in the application to mechanical questions of the instrument which he thus helped to form that his singular merit lay. It was his just boast to have transformed mechanics (defined by him as a "geometry of four dimensions") into a branch of analysis, and to have exhibited the so-called mechanical "principles" as simple results of the calculus. The method of "generalized coordinates," as it is now called,[2] by which he attained this result, is the most brilliant achievement of the analytical method. Instead of following the motion of each individual part of a material system, he showed that, if we determine its configuration by a sufficient number of variables, whose number is that of the degrees of freedom to move (there being as many equations as the system has degrees of freedom), the kinetic and potential energies of the system can be expressed in terms of these, and the differential equations of motion thence deduced by simple differentiation. Besides this most important contribution to the general fabric of dynamical science, we owe to Lagrange several minor theorems of great elegance—among which may be mentioned his theorem that the kinetic energy imparted by given impulses to a material system under given constraints is a maximum. To this entire branch of knowledge, in short, he successfully imparted that character of generality and completeness towards which his labours invariably tended.

His share in the gigantic task of verifying the Newtonian theory would alone suffice to immortalize his name. His co-operation was indeed more indispensable than at first sight appears. Much as was done *by* him, what was done *through* him was still more important. Some of his brilliant rival's most conspicuous discoveries were implicitly contained in his writings, and wanted but one step for completion. But that one step, from the abstract to the concrete, was precisely that which the character of Lagrange's mind indisposed him to make. As notable instances may be mentioned Laplace's discoveries relating to the velocity of sound and the secular acceleration of the moon, both of which were led close up to by Lagrange's analytical demonstrations. In the *Berlin Memoirs* for 1778 and 1783 Lagrange gave the first direct and theoretically perfect method of determining cometary orbits. It has not indeed proved practically available; but his system of calculating cometary perturbations by means of "mechanical quadratures" has formed the starting-point of all subsequent researches on the subject. His determination[3] of maximum and minimum values for the slowly varying planetary eccentricities was the earliest attempt to deal with the problem. Without a more accurate knowledge of the masses of the planets than was then possessed a satisfactory solution was indeed impossible; but the upper limits assigned by him agreed closely with those obtained later by Leverrier.[4] As a mathematical writer Lagrange has perhaps never been surpassed. His treatises are not only storehouses of ingenious methods, but models of symmetrical form. The clearness, elegance, and originality of his mode of presentation give lucidity to what is obscure, novelty to what is familiar, and simplicity to what is abstruse. His genius was one of generalization and abstraction; and the aspirations of the time towards unity and perfection received, by his serene labours, an embodiment denied to them in the troubled world of politics.

Lagrange's numerous scattered memoirs have been collected and published in seven handsome 4to volumes, under the title *Œuvres de Lagrange, publiées sous les soins de M. J. A. Serret*, Paris, 1867–77. The first, second, and third sections of this important publication comprise respectively the papers communicated by him to the Academies of Sciences of Turin, Berlin, and Paris; the fourth includes his miscellaneous contributions to other scientific collections, together with his additions to Euler's *Algebra*, and his *Leçons Elémentaires* at the Ecole Normale in 1795. Delambre's notice of his life, extracted from the *Mém. de*

l'Institut, 1812, is prefixed to the first volume. Besides the separate works already named are *Résolotion des Équations Numériques*, 1798 (2d ed. 1808, 3d ed. 1826), and *Leçons sur le Calcul des Fonctions*, 1805 (2d ed. 1806), designed as a commentary and supplement to the first part of the *Théorie des Fonctions*. The first volume of the enlarged edition of the *Mécanique* appeared in 1811, the second, of which the revision was completed by MM. Prony and Binet, in 1815. A third edition, in 2 vols. 4to, was issued in 1853–55, and a second of the *Théorie des Fonctions* in 1813. Wiss.*, 1873; Dühring, *Kritische Gesch. der allgemeinen Principien der Mechanik*, 1877 (2d ed.); Gantier, *Essai Historique sur le Problème des trois Corps*, 1817; Grant, *History of Physical Astronomy*, &c. (A. M. C.)

LAGRENÉE, Louis Jean François (1724–1805), French painter, was a pupil of Carle Vanloo. Born at Paris 30th December 1724, in 1755 he became a member of the Academy, presenting as his diploma picture the Rape of Deianira (Louvre). He visited St Petersburg at the call of the empress Elizabeth, and on his return was named in 1781 director of the French Academy at Rome; he there painted the Indian Widow, one of his best-known works. His pictures, which have nearly all been engraved, are frequently to be met with out of France. In 1804 Napoleon conferred on him the cross of the legion of honour, and on 19th June 1805 he died in the Louvre, of which he was honorary keeper.

LAHIRE, Laurent de (1606–1656), French painter, was born at Paris on 27th February 1606. He became a pupil of Lallemand, studied the works of Primaticcio at Fontainebleau, but never visited Italy, and belongs wholly to that transition period which preceded the school of Simon Vouet. His picture of Nicolas V. opening the crypt in which he discovers the corpse of St Francis of Assisi standing (Louvre) was executed in 1630 for the Capuchins of the Marais; it shows a gravity and sobriety of character which marked Lahire's best work, and seems not to have been without influence on Le Sueur. The Louvre contains eight other works, and paintings by Lahire may also be found in the museums of Strasburg, Rouen and Mans. His drawings, of which the British Museum possesses a fine example, Presentation of the Virgin in the Temple, are treated as seriously as his paintings, and sometimes show simplicity and dignity of effect. The example of the Capuchins, for whom he executed several other works in Paris, Rouen, and Fécamp, was followed by the goldsmiths' company, for whom he produced in 1635 St Peter healing the Sick (Louvre) and the Conversion of St Paul in 1637. In 1646 he shared with eleven other artists the honour of founding the French Royal Academy of Painting and Sculpture. Richelieu called Lahire to the Palais Royal; Chancellor Séguier, Tallemant de Réaux, and many others entrusted him with important works of decoration; for the Gobelins he designed a series of large compositions. Lahire painted also a great number of portraits, and in 1654 united in one work for the town-hall of Paris those of the principal dignitaries of the municipality. Two years later, 28th December 1656, he died. His works have been frequently engraved by his own pupil Chauveau, and by Lasne, Boulanger, De la Court, Rousselet, and Faithorne.

LAHORE, or Lahór, capital of the Punjab, India, gives its name to a civil division of the British territory in that province, and to the headquarters district of the division.

Lahore Division.—This division, the most central of the ten into which British Panjáb is divided, is fourth in order of size, 8961 square miles, and fifth in respect of population, 1,889,495 (by the census of 1868), averaging 211 to the square mile. The Lahore division has three districts—Lahore, Firózpúr, Gujránwála. The whole area is alluvial plain, for the most part devoid of trees, except such as have been planted since British occupation. It is intersected by the rivers Rávi and Sutlej, and the Bári Doáb canal drawn from the Rávi at the foot of the hills; also by the old bed of the Biás river deserted about the middle of last century. The Chenáb river is the boundary on the north-west, between the Lahore and the Ráwal Pindi divisions. Of the towns in the division there are five which have over 10,000 inhabitants, namely, Lahore, Kasúr, Gujránwála, Wazirábád, Firózpúr. The common language of the rural population and of artisans is Punjabi. Urdu (Hindustani) is the language of the better educated classes, and is everywhere becoming more generally understood and used. In Government schools Punjabi is not taught.

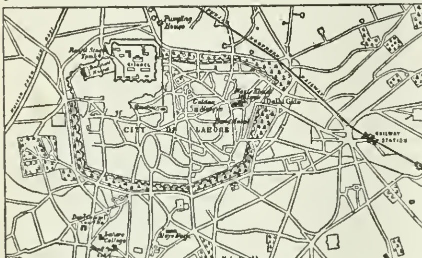
So far from the seaboard, the range between extremes of winter and summer temperature is great. The mean temperature in the shade in June is about 92°, in January about 50°. In midsummer the thermometer sometimes rises to 115° in the shade, and remains (on rare occasions) as high as 105° throughout the night. In winter the morning temperature has sometimes been as low as 20°. The rainfall is uncertain as well as scanty: the annual average is about 15 inches; it is sometimes as low as 8°; a total of 25° is exceptionally high. The harvests are greatly dependent on irrigation. The prevailing winds are westerly (N.W. and S.W.) in the hot weather, and easterly (E. and N.E.) in the cold season. The Lahore division became British territory in March 1849, on the annexation of the part of the Punjab west of the Biás river, at the close of the second Sikh war.

Lahore District has an area of 3648 square miles, with a population of 789,666 (438,335 males and 351,331 females;—Sikhs, 119,268; Hindus, 116,287; Mohammedans, 470,216; others, 83,895). Of this number about 3000 are Europeans and Eurasians, residing chiefly at Lahore and its cantonment of Mián Mír. The district contains 1455 villages, with an agricultural population of 354,012. The gross revenue is £110,518—£74,353 being derived from the land. Of the area 1,165,440 acres are under cultivation, 811,520 uncultivated, and 357,760 uncultivable. Of the uncultivated area nearly 237,000 acres are unappropriated cultivable waste land, the property of the Government. Irrigation is supplied to upwards of 180,000 acres by the Bári Doáb canal and three inundation canals from the Sutlej (filled for a certain time each year by the rise of the river), which are Government works, and about 267,000 acres are watered by private wells.

The chief crops are—wheat, about 436,000 acres; *gram* (chick-pea, for cattle), 230,000; barley, 58,000; maize, 25,000; rice, 18,000; various food grains, 85,000; sugar cane, 2500; vegetables, 7000; capsicum, 1500; tobacco, 5000; poppy, 1000; cotton, 40,000; oil seeds, 15,000. Indigo, now only grown on a small scale in this part of India, was formerly one of the important products of the country round Lahore, which had the reputation of great fertility. The traders on the part of the East India Company in the 17th century paid much attention to the indigo of Lahore. The court minutes of the Company, July 19, 1614, notice the proposal of Captain Newport at Surat for "a voyage to the river Syndus, whence the Lahore indigo comes." Captain Downton, writing to the Company in November of the same year regarding the opposition which the English merchants met with at Surat, expresses a wish that they had some hope of being able "to transport their goods by that fair river of Sinde to and from that goodly country round Lahore." And another trader speaks in 1615 of the great store of indigo to be had both at Ahmadabad and at Lahore. No doubt what was reckoned Lahore indigo may have been in great part indigo from elsewhere, passing through Lahore as the trade centre of that part of India,—just as, at the present day, the rock salt of the Punjab is in other provinces commonly called *Lahori*, though it comes from the salt hills west of the Jhelum. The importance of Lahore as a centre of trade at the time above referred to, is shown also in some of Sir T. Roe's letters. Lahore now receives indigo from Bengal. The rent per acre of good wheat land in the Lahore district is about 5 rupees. The selling price of wheat in ordinary years is about 26 *seers* (52 lb) for a rupee. The water-level in the neighbourhood of Lahore is at a depth of 30 to 36 feet from the surface of the ground. In the tract between the Rávi and the Chenáb it is from 15 to 30 feet. In the south and south-west parts of the district, between the Rávi and the Sutlej, the depth is from 40 to 70 feet, except in some strips of low land.

After the opening of the Bari Doab canal, the water-level in wells of village lands on both sides of the canal was permanently raised, in some cases as much as 12 feet. The Lahore district has 107 miles of metalled roads and 688 miles unmetalled, 97 miles of railway, and 104 miles of navigable rivers.

LAHORE CITY lies in 31° 34′ N. lat. and 74° 21′ E. long., on the left bank of the river Rávi, about 900 feet above the sea-level. It is a walled town, about $1\frac{1}{4}$ miles in length from west to east, and about $\frac{3}{4}$ mile in breadth from north to south. The intramural population is 98,924; with the suburbs Anarkali, Muzang, and Ichra, the number is 128,441. The city walls, rebuilt in the time of Akbar, towards the end of the 16th century, were of great height, in some parts upwards of 36 feet, and higher at the gateways and parts adjoining. Ranjít Singh added a deep ditch, with a broad faussebraie (*rauní*) between the ditch and the walls, and large outworks, shielding with a massive defence each of the city gates. The fort or citadel, in which was the palace, is on high ground on the north face of the city, and has three gates, one direct to the open plain on the north, and one on each side, east and west, into the city. Only the north gate of the fort is now open. The city gate next the fort on the west, called the



Plan of Lahore.

Roshnái or bright gate, leads into the small enclosure, called the Huzúri Bagh or Court Garden, from which on the one side rises the great flight of steps to the terrace of the imperial mosque, and on the other the ascent through a fine gateway (now closed) to the palace in the fort. The fort and palace, with the conspicuous *Saman Burj* (properly *musamman*, octagonal tower; it is a half octagon), present a striking appearance viewed from the open plain on the north.

The site of the present city has been occupied from early times, and much of it stands high above the level of the country outside, raised on the remains of many successive series of former habitations. Some of the old buildings, which have been preserved when changes were going on around, stand now below the surface of the ground about them. This is well seen in the mosque now called Masjid *Níwín* (or sunken), built 1560, the mosque of Mullah Rahmat, 7 feet below, and the *Shivála* (Hindu temple), a very old building near the revenue office, about 12 feet below the surrounding ground. The houses are of brick, irregular in construction, three and more stories in height, many of them with projecting balconies and lattice windows ornamented with varieties of carved woodwork. The streets, narrow and winding, were, under the Sikh Government, and at the time of the first British occupation of the city in 1846, extremely unregulated and dirty. The water supply, from numerous wells throughout the city, was for the most part exceedingly impure. A cleansing and draining of the streets had to be taken in hand at once, when the city was held by British troops. The governor-general of India, Lord Hardinge, having, after the defeat of the Sikh army at Sabráon, advanced to Lahore and concluded a treaty with the Sikh Government, a British force was left, to hold Lahore for that year (1846), the fort being reserved for the maharaja. But the occupation of Lahore was prolonged. A British resident was appointed, and barracks were built for the troops in the Anarkali suburb. After the annexation of the Panjáb in 1849 the government of the country was placed in the hands of a board of administration. The fort was held by the British troops, the rest of the force assigned to Lahore being quartered outside the city in the cantonment of Anarkali. Subsequently a site for a permanent cantonment was selected at Mián Mír, about five miles south-east of the city; and all the troops, British and native, are now quartered there, except the small garrison of the fort.

In 1852 the lofty walls, which greatly impeded the free airing of the interior of the city, were reduced to a height of from 14 to 20 feet, and the whole of the massive outworks were removed. In 1863 the ditch was filled in and the faussebraie levelled; and on this broad strip of new land immediately outside the city walls public gardens were laid out, and supplied with a watercourse from the Bári Doáb canal. This work of improvement was carried out under the immediate direction of the native gentlemen of the Lahore municipal committee.

The municipality now includes within its limits the greater part of the civil station of Lahore, which covers, in addition to the ground occupied by the old Anarkali cantonment, a large area south and south-east of the city. All new public buildings have been erected in this civil station outside the walls. The principal of these are the deputy commissioner's court-house, the Government college, the Mayo hospital, the senate hall of the Punjab University College (the gift of the nawáb of Bahawalpúr). The Lahore Industrial and Antiquarian Museum is in the building erected for the "Punjab Exhibition" of 1864. A building for the school of art in connexion with the museum is in progress. The medical school, at first held in a disused barrack of the Anarkali cantonment, and then in hired houses, is now about to be provided with a suitable building at the Mayo hospital. The block of buildings erected for the British residency and offices, and used for this purpose up to the time of annexation, is now occupied by the chief court, the Government secretariat offices, civil and military, and the offices of the financial commissioner of the Punjab, and of the commissioner of the Lahore division. A new building for the chief court is about to be erected. A large building for the Government telegraph department has lately been finished. The post-office occupies one of the barracks of the old cantonment, and others of them continue to be occupied by the offices of various Government departments—public works, public instruction, prisons, &c. The central jail stands on the site of the British camp of 1846; and in the large public grounds which contain the botanical and zoological gardens stand the John Lawrence Hall and the Montgomery Hall, erected in honour of the first two lieutenant-governors of the Punjab. Of native buildings applied to new purposes there are, in the palace (1630–1640) the Diwán-i-ám (or hall of audience), serving as a barrack for the fort garrison; the two buildings called *Khwáb-gah* (or sleeping apartments), used as the Protestant and Roman Catholic places of worship for the troops in the fort; the vaults of the *Kála Burj* and *Lal Burj* (black and red towers) used as commissariat store-rooms; the *Móti Masjid* (pearl mosque), which Ranjit Singh made his treasury, still used for the same purpose. The armoury, in an adjoining building, contains an interesting collection of arms and armour of the Mughal and Sikh times.

In the city, the mansion of Raja Dhyan Singh, Ranjit's prime minister (which was the British artillery mess house in 1846), contains the Government district school, the Oriental college, and the hall of the *Anjuman-i-Panjab*, an active literary and educational society. The quadrangle of the *Huzúri Bagh* (or royal garden) contains the Government normal school. In the *Rang Mahal* is the large high school of the American Presbyterian mission.

Outside the city, half way between the civil and military stations, is Government House, the official residence of the lieutenant-governor of the Punjab, formerly the house of the Jamadar Khush-hál Singh, a Brahman who, with varied fortunes, held high offices under Ranjit Singh. The original building round which the present large house was erected was the tomb of Sayid Nur-ud-din, called also Nur-ul-Alam, of Bokhara (1616), which is the lofty square apartment in the middle of the present building. The tomb of Nádirah Begam was fitted up in the early days of British rule as the station church, and continues to be used for this purpose. (A large new church has been commenced, which will now be the cathedral of the lately constituted diocese of Lahore.) The tomb of Shah Chirágh (1660 A.D.) is, with large additions made from time to time, the office of the accountant-general of the province. The *báradari* or summer house (commonly called *chau-burji*, the building with four turrets) of Nawab Wazir Khan (1631), long occupied by the museum, is now the station library and reading room.

Educational and other Institutions.—The Punjab University College, established in 1869 to give special encouragement to the cultivation of Oriental learning, and instruction in European science through the vernacular languages, is supported with much zeal by the chiefs and native gentlemen of the Punjab. It is now about to be raised to the status of a university, with power to confer degrees. The other educational institutions of Lahore are the Government college, the normal school, the Oriental college, the district Anglo-vernacular school, the high school for boys of European parentage, the Anarkali school for girls, another girls' school of the same class near the railway station, chiefly for the children of the railway employés, St James's orphanage and free school, for poorer children, European and Eurasian. The large and prosperous school of the American Presbyterian mission in the city has been mentioned above. The medical school, established in 1860, gives a five years' course, in the English language, qualifying for a diploma as licentiate in medicine, and for employment in the Government service in the grade of assistant-surgeon. A three years' course, in the Urdu language, trains a lower class of students for the grade of hospital assistant or native doctor. The number of students in the upper class is between fifty and sixty, in the lower from eighty to one hundred. The Mayo school of industrial art has in view mainly the cultivation of Oriental art as applied to decoration and manufactures, and, in aid of this purpose, instruction in drawing, modelling, &c. Among other works on which the trained pupils have been employed is the production of plaster casts of the Buddhist sculptures in the museum, obtained from explorations in the north-west districts of the Punjab. St John's Divinity College (Church Missionary Society) gives theological instruction, in the Urdu language, to native Christian students, ten of whom are now pastors of native congregations in different parts of northern India.

There is a Government book depot for the sale of educational and other books; and from the depository of the Punjab Religious Book Society there is a large and increasing sale of books of religious and general literature in English and in the vernacular languages. A large number of books in the native languages are issued annually from the local presses. Nine newspapers in Indian languages are published at Lahore—seven in Urdu, one in Hindi, and one in Arabic. One of the Lahore Urdu papers has the largest circulation of any native paper published out of Bengal. There is one daily English paper, and one under native editorship and management in the English language.

In the Lahore central jail, which is capable of receiving 2000 inmates, many useful manufactures are carried on by the prisoners. For the carpets made in this jail there is a large demand in the English market. Besides the two smaller jails, the district jail and the female jail, there is a *Thaggi* jail and school of industry, in which the few remaining *Thags* (or Thugs—highway stranglers and robbers) are taught useful work, chiefly tent making. A large lunatic asylum occupies the enclosed buildings of one of the old Sikh cantonments.

Trade.—The Lahore municipality has an annual income of nearly 170,000 rupees, the chief source of which is the octroi. Lahore imports from other parts of the Punjab, and the hill countries beyond, tobacco, dyes, bamboos, hides, Kashmir paper, felts, and silk fabrics; from Bengal and the southern provinces, indigo, spices, English piece goods, and other foreign products and manufactures; from Bombay, metals and metal work, cutlery, &c., and drugs. The chief manufactures of Lahore—but they are none of them on a great scale—are woollen and silk fabrics for clothing, carpets (cotton and woollen), embroidery on leather, ivory carving, toys, pottery, turnery, metal work of various kinds, arms, jewellery, &c. Lahore has long been noted for its carpets. One of the travelling agents of the East India Company in 1617, writing from Agra, reports the purchase of various articles, including thirty Lahore carpets. Soon after he writes from the same place, "It requires a long time to get well chosen carpets. True Lahore carpets are not suddenly to be gotten." Two years later, December 1619, another, writing from Sirhind about carpets, says, "Lahore is the chief place for that commodity." A little later in the same century it is observed that from Lahore were obtained fine muslins, flowered and embroidered silks, woollen drapery, and all sorts of carpets.

Health.—The general health of Lahore is good, but the city and civil station, as well as the cantonment of Mián Mír, have suffered from occasional severe visitations of cholera and fever, as well as of small-pox. A large amount of rain within a short space of time, though the total of the year may be under the average, is usually followed by malarious fever, while a larger rainfall, more distributed, is healthy. Of much importance to the health of Lahore is the large work which the municipality has executed for the supply of water to the city and suburbs. The water is pumped from wells in the bed of the river Rávi to a covered reservoir in a high part of the city, from which it is distributed. A scheme of drainage and sewerage works, dependent on this supply of water, is about to be carried out. For the military station of Mián Mír water has been brought in by a cut from the Bári Doáb canal.

Communication.—Lahore is in railway communication with the most important places in the Punjab, and with the other provinces of India. Its distance from Delhi is 323 miles (Sind, Punjab, and Delhi Railway); from Calcutta, 1277 miles (East India Railway); from Bombay by Delhi and Allahabad (East India Railway and Great Indian Peninsular), 1558 miles; from Bombay by Delhi and Ajmír (Rajputana State Railway), 1280; from Multan (Sind, Punjab, and Delhi Railway), 207; from Kurrachee, the nearest point on the sea-coast (Sind, Punjab, and Delhi Railway and Indus Valley State Railway), 814; and from the Afghan frontier at Peshawar (Punjab Northern State Railway), 271 miles. This last line still wants, to complete it, the great bridge across the Indus at Attok, now in course of construction. A narrow-gauge branch, from this line, for the salt traffic, is open to the bank of the Jhelum river, opposite Pind Dadan Khan. At Lahore there is one central railway station for all the lines, a short distance east of the Delhi gate.

History and Antiquities.—To this account of Lahore under British rule will now be added a short sketch of its previous history, and the works of former days which still remain.

Lahore is said to have been founded by *Láva* or *Loh*, one of the sons of Ráma; and it has borne the names Lavapúr, Loh-púr, Loh-kót, Lohâwar, Lâhawar. The city of Lava is probably the *Laulaha* of the *Raja Tarangini*, or history of the kings of Kashmir. To Kashmir belonged for a long time the country (Lavana or Lavanya) as far south as Lahore, and beyond. Lavana, which also means salt, may have taken its name from the salt region west of Jhelum. Captain Wilford (*As. Res.*, ix. 53) recognized Lahore in the Λάβακα and Λάβοκλα of Ptolemy. Labaka is placed in the country of the Pandús about the Jhelum, and Labokla in Kashmir territory, which in reality embraced the other. Cunningham (*Ancient Geography of India*) suggests that Labokla should be read Labolka = Láva-laha or Láva-lók. There appears to be no mention of Lahore by the historians of Alexander; it used to be supposed that it was *Sangala* or *Sagala*, in the country of the Cathæ, but this place is better represented by the hill still called Sangala, to the west of Lahore, between the Rávi and the Chenáb.

At the time of the first Mohammedan invasion of India, in the 7th century, Lahore was in the possession of a Chauhán Rajpút prince of Ajmir. Towards the end of the 10th century Raja Jaipal, the ruler of the Lahore territory, was driven back after an encounter, on the frontier (978), with Sabaktagín, who had just risen to the throne of Ghazni. In 1001 Jaipál had to meet the first incursion of Sabaktagín's son Mahmúd. In his third invasion of the Punjab Mahmúd advanced as far as Bhera on the Jhelum, which used to be the raja's place of residence alternately with Lahore, and which had been for a time the Hindu capital. The sixth time Mahmúd came (1008), a great battle was fought near the Indus with the raja of Lahore, Anangpál, the successor of Jaipál. At length, on his fourteenth invasion of India (1023), Mahmúd took possession of Lahore, and appointed a governor, the raja, Jaipál II., having fled to Ajmir.

Under Mahmúd and seven successors Lahore continued to be ruled by governors appointed by them. When the kings of Ghazni were fully occupied in war with the Seljúks, their Indian subjects were roused to revolt, and, with the aid of the raja of Delhi, attacked Lahore. But the city was successfully held against them, and in the reign of Masaúd II., the eighth from Mahmúd, it was for a time made the seat of the government (1110). His successor Bahram went back to Ghazni; but his son, Khusrú Shah, after repeated defeats by the prince of Ghor, was driven to take refuge in the Punjab, and again made Lahore the capital. When Ghaiás-ud-dín and Shaháb-ud-dín of Ghor were ruling jointly at Ghazni, the latter proceeded to follow up the defeat of their Ghaznavi predecessors by an invasion of the Punjab, and, capturing Khusrú Malik, son of Khusrú Shah, took possession of Lahore (1186). It was next seized by the *Gakkars*, an ancient tribe of the hill country in the north-west of the Punjab. Shaháb-ud-dín succeeded in expelling them, but they murdered him on his way back to Ghazni, in 1206. Kutb-ud-dín, a Turki slave originally, who had held the chief command in India during these troubled times of his late master's reign, succeeded to the sovereignty of the

Indian provinces, which ceased from this time to be dependent on Ghazni. He had to fight for the possession of Lahore, which had been seized by a rival, and the seat of government was then transferred from Lahore to Delhi.

The buildings at Lahore of the Hindu times, and of this first Mohammedan period, are few in number. To the former probably belongs the Shivala or temple of Shiva in the middle of the city, now surrounded by more modern additions. It is ascribed to the time of Loh, the founder of the city. The temple of Bhairava (a form of Shiva), about a mile south of Lahore, is generally ascribed to a later period, but Lahore is said by the author of the *Raja Tarangini* to have been addicted in early times to the worship of Bhairava. To the Ghaznavi times belongs the tomb of Malik Ayáz, governor of Lahore. It is in the heart of the city, and was built about 1046. Hazrat Ganj Bakhsh, who also came with Mahmúd to Lahore, is buried outside the Bhati gate, and at his tomb (built 1073) a weekly fair is now held, resorted to by Hindus as well as Mohammedans. About the same time were built the tomb of Pír Ali Makhdúm of Baghdad, and the tomb of Saiad Isháк, near Wazír Khan's mosque in the city.

The Mughal army sent into India by Jenghiz Khan in 1224 and subsequent years swept over the middle of the Punjab and in 1241 captured the old capital, Bhera, and laid waste Lahore and Multan. In 1269 the king of Delhi, Ghaiás-ud-dín Balban, visited Lahore, and rebuilt the fort which the Mughal invaders had destroyed. His eldest son Muhammad Sultan, the khan of Multan, came to Lahore in 1285, to oppose another invasion under Samar, one of the Mughal generals. The fight in which the young prince fell at Lahore is further memorable from the capture of his friend Amír Khusrú, the Persian poet.

After more than a hundred years, during which the history of Lahore is comparatively unimportant, though it was not untroubled, it suffered like other wealthy places in North India from Timúr's invasion in the end of the 14th century. On his return from the sack of Delhi, Timúr sent a force to Lahore, with instructions to raise a large contribution there, to which was afterwards added an order for the plunder of the city and the country around. And then Lahore had a time of repose. In 1450, when Bahlól, the first of the Lódi dynasty, had been raised to the sovereignty at Delhi, and the charge of the several divisions of his territory was assigned to different officers, Lahore was reserved for himself.

The 14th and 15th centuries have left no known buildings at Lahore, though some of the following century are marked by the Pathan style belonging to the earlier period.

The next change in the fortunes of Lahore was a great and important one. In 1522 it passed into the hands of Timúr's descendant Baber (Bábar), the first of a line of new masters who were to give it new life, though it gained little under Baber himself. Invited by the governor of Lahore, who had become disaffected to the Lodi king, Baber came on with an army, and, having defeated the Lodi forces, he gave up the city to plunder. On his departure for Cabul in 1524 he left Lahore in charge of his relative Abd'ul Azíz. Baber lived occasionally at Lahore, but his reign of frequent contests gave him little rest at any permanent seat of government. Humáyún, who succeeded his father Baber in 1530, did not long retain Lahore undisturbed. His brother Kámrán, governor of Kandahar and Cabul, who laid claim to the Indian sovereignty, came to Lahore, and by artifice succeeded in gaining the city without bloodshed. Five years later Kámrán had to march to the relief of Kandahar, and during his absence an attempt was made upon Lahore, which was defeated by his rapid return. In 1540 the Afghans made another endeavour to recover power in India under Shír Shah Súr, who took possession of Lahore and of Bhéra, the other old capital, which still retained some importance.

Kámrán lived long enough at Lahore to make his mark there in three pieces of work of which there are still remains, but altered and added to by others since, so that of his part there is not much to be seen. One of these was the *báradari* or summer house of the Dil-Kusha garden on the bank of the Rávi opposite Lahore, on which now stands the house built over it by Ranjit Singh. Kámrán's garden of Shalamár was the beginning of the grander work completed by Shah Jahán. Of his palace at Naulakka, east of the city, only the gateway now remains. Other buildings at Lahore of this earliest Mughal period are the tomb of Khojah Salár Khan and the Khojah Masjid, the mosque now called *Niwin*, and the *Shiranwali* Masjid.

In the time of Humayún's son and successor, Akbar (1556–1605), Lahore rose to a condition of prosperity unknown at any previous time. To his reign belongs the commencement of its architectural greatness, which increased in the two following reigns. He made the city the royal residence, rebuilt the fort, and began the palace buildings. He rebuilt also the walls which, altered and added to by his successors and now reduced, still surround the city. To this time belong many of the well-known buildings now to be seen at Lahore. The mosque near the Masti gate (opposite the Poor House of the present day) is said to have been built by the emperor's mother. Of the same date are the tombs of Abd'ul Isháк at Muzang, of Kasim Khan, of Mauj Darya (a saint whose prayers procured Akbar's success in his attack on Chitór), and of Shah Músa. This last, called *Sabz Gumbaz*, is the earliest of the Lahore buildings coloured with the glazed tile-work commonly called *káshi*. The tomb of Nádirah Bégam, called also Sharíf-un-nissa, a slave of Akbar's, whom he named Anarkali, was built about the end of his reign; it is the building now used as the station church. To this period belongs also the mosque of Mullah Rahmat as well as the earliest work of the Sikhs in the city. The *báoli* or masonry tank in the middle of the city was built in 1584 by Rám Dás, the *gurú* or spiritual leader of the Sikhs, fourth in order from Nának the founder of the sect.

A curious and special interest attaches to Lahore in the time of Akbar, in connexion with the first teaching of Christianity in northern India by the Jesuit missionaries whom the emperor had invited to Lahore from Goa, after receiving the visit of Antony Capral at Agra in 1578. They were first Rodolph Aquaviva, Antony Manserrat, and Francis Henric. Afterwards came Edward Leighton and Christopher Vega in 1589. When they, like the others, had gone away disappointed, and the emperor's invitation was repeated, two others were sent,—Jerome Xavier (nephew of Francis) and Emanuel Pinnero. Akbar built a church for them in Lahore. He then for a time shut up the Lahore mosques. The church of the Jesuits was thronged with Mohammedans. On the day of Pentecost 1599 a number of converts walked in procession through the streets of Lahore to the church, and were publicly baptized by Pinnero. Benedict Goes passed through Lahore in 1603, on his journey to solve the question of the identity of China and Cathay, and was kindly received and helped by Akbar. Lastly, a new missionary, Father D'Acosta, came to Lahore soon after the beginning of Jahángir's reign. The marks of Christian work and success at Lahore at this period remained on some of the buildings there when the men who had been brought under its influence passed away and no traces remained with their children. De Laet says that in 1630 (three years after Jahángir's death) he saw over one of the palace gates at Lahore figures of our Saviour and of the Virgin. They are described also by Thevenot, who visited Lahore in 1666; he says they had been put up by Jahángir to please the Portuguese. Remains of the Jesuit church also were to be seen when Thevenot was at Lahore. Some traces of Christian art are still to be seen, which may be referred to the same period,—the winged heads on the principal gate of the fort and of the Gola sarái (1622).

When Jahángir succeeded to the throne of Akbar, Lahore was immediately the scene of one of those family contests which so often marked the Mughal reigns. His son Khusrú aimed at power, and attempted, unsuccessfully, to obtain possession of the city. Among those on whom the emperor's displeasure fell was the Sikh leader, Arjun Mal, fifth *guru*, compiler of the *Adi Granth*, who had succeeded his father Rám Dás in 1581. Having offered up prayers for Khusrú he was imprisoned by Jahángir, and died the same year, 1606. His little tomb stands just outside the fort.

The buildings at Lahore of Jahángir's time are numerous. The most important and the best preserved are—the *Saman Burj*, and some other parts of the palace in the fort, built during several successive years (1606, &c.); the sarái at Shahdara (1612); the tomb of Saiad Nur-ud-dín, Nur ul Alam, Bukhári (1616), now Government House; the tomb of Shah Abu'l Maali, and the mosque beside it (1616); the masjid of Dái Sádhu-wali (1621); the tomb, near Shalamar, of Madhu Lál Hussein, a converted Hindu (1621); the little tomb, covered with many coloured *káshi*, of Faríd Pakkiwala, a pupil of Mauj Darya (1621); and the Gola sarái (1622), which retains some fine specimens of the same kind of ornamentation.

Shah Jahan's reign was, at Lahore as elsewhere, the greatest and most vigorous period of Mughal architecture. Lahore as well as Delhi testifies, though in a minor degree, to the power and taste which seem to have inspired others besides the emperor to raise the many monuments that still remain of the grandeur of his time. The first place is due to the splendid tomb of Jahángir, erected by his widow Nur Jahán, at Shahdara, on the bank of the Rávi opposite Lahore (1630), near which was afterwards built (1632) the tomb of her brother Asaf Khan, Jahángir's commander-in-chief, and then (1650) that of the widowed queen herself. Before these, in order of time, were the gate and ascent called *háthi páon* to the fort (1629), and then, in 1630 and following years, the series of fine palace buildings within the fort, which have since been altered and added to by the emperor's Mughal successors and by Ranjít Singh.

Two of Shah Jahán's principal officers of state were his chief supporters and followers in the construction of the great works of his time at Lahore. One of these was Ali Mardan Khan, a Persian, formerly governor of Kandahar, then successively governor of Kashmir and of the Punjab, who was also an eminent engineer and architect. The other was the court physician and afterwards prime minister, Hakím Alam-ud-dín, better known as the Nawáb Wazír Khan. Ali Mardan Khan built, under Shah Jahan's orders, the finest of the great saráis for travellers on the imperial road from Delhi to Lahore and Lahore to Kashmir. He proposed and carried out (1639) the canal from the Rávi at the foot of the hills, which was called the Lahore canal. Other canals of the same kind he executed elsewhere. His chief work at Lahore is the tomb of his mother (1627), where he himself also was buried (1657), and which is known as the tomb of Ali Mardan Khan. Wazír Khan's chief works at Lahore are his own *baradari* or summer house (1631), the sarái and *hammám* (baths) in the street now called Hira Mandi (1635), the *Rang Mahal* or painted palace (1635), and the *Pari Mahal* or fairy palace (1638). Prince Dára Shiko, the emperor's son, who made Lahore his place of residence, built (1640) the tomb of Mián Mír, his religious teacher. Of the other works at Lahore of Shah Jahan's time the principal are the tombs of Nawáb Jáfar Khan (1631), of Shah Biláwal (1636), of Abu'l Hassan Khan (1641), of Shah Jamál (1651), and of the emperor's son, Prince Parvíz (1651),—also the tombs of two notable literary men, Muhammad Sálah, author of *Bahár Dánish*, and Sheikh Ináyat-Ullah, author of the historical work called *Shah-jahán-námah.* The mosque in the city called Wazír Khan's was built (1641) by the emperor in honour of his faithful servant whose name it bears. It is faced with beautiful *káshi* work of various colours, a kind of ornamentation largely used in the buildings of this time at Lahore. Decorated in the same manner is the gateway of the *Gulábi Bagh* made by Sultan Beg, the emperor's son-in-law. The Shalamar garden, restored and largely extended by Shah Jahan (1640), is one of the finest works at Lahore of his time. During Shah Jahan's reign Lahore was visited (1626) by two English travellers Mr Crowther and Mr Still; in 1638 by Mandelslo, a member of the Holstein embassy to Persia; and three years later by Manriquez, a Spaniard.

Aurangzíb (1658–1707), though he lived little at Lahore, contributed to it one of the largest and most important of the existing buildings, the *Bádsháhi Masjid*, or imperial mosque, built 1673–80. Two buildings at Lahore are connected with the name of Aurangzíb's daughter, Zíb-un-nissa, authoress of a book of poems called the *Diwán-i-Makhfi.* One is the gateway of her garden (1665) called *Chau-burji* (four towered) and now *Si-burji* (three towered), one of the corner minarets having been cut away by the water of a neighbouring nullah. The other is her tomb, built 1670. The tombs of Shah Chirágh (1658), of Sultana Begam, daughter of Shah Jahán, wife of Sultan Beg (1660), and of Abd'ur Rizák, Makki (1673), which is known as the *lila gumbaz*, or blue dome,—are the best of the other remains at Lahore of the work of Aurangzíb's reign.

From the reign of Aurangzíb's successor, Bahadur Shah (Shah Alam I.), Lahore has little to show except two small buildings of 1710, one Hindu and one Mohammedan—the Chaubara, or hall, of Chajjú Bhagat, and the tomb of Pír Ain-ul-Kamál. One of the city gates bears the name of Shah Alam. In the reign of Mohammed Shah, the third from Shah Alam (1719–48), Lahore came in the path of another of the ruthless invaders from the west, Nádir Kuli Khan, better known as Nadir Shah (1737), who rapidly swept over the plains of the Punjab to the chief city. He was met but not actively resisted by the governor of Lahore, and Nadir's army encamped for a time at Shálamár. Again, in the repeated invasions of Ahmad Shah Abdáli (1748–1767), in the reigns of his namesake Ahmad Shah and of Alamgir II., Lahore had to take its part, with varied fortunes, but with no important permanent result. To the reign of Ahmad Shah (1748–54) belongs one little building which makes some show in the city, the Masjid *Tildi*, or golden (now commonly called *Sunahri* which has the same meaning), having its domes covered with gilt plates of copper (1750). This is the latest work of the kind at Lahore before the Mohammedan power in the Punjab was subverted by the Sikhs, who obtained temporary possession of the city eight years later, and, with rapidly growing influence as well as numbers, soon became a formidable enemy of the nominal rulers, till, finally, they became masters of Lahore, under Ranjít Singh. Lahore was conferred upon Ranjit in the end of last century by the last of the invaders of India from the west, Zamán Shah, when the last of the reigning Mughals, Shah Alam II., had lost all real hold of this northern part of his empire. The long, vigorous, and expansive rule of Ranjit Singh brings Lahore within the general history of the Sikhs and of the Punjab, and connects the Punjab directly with the history of British India.

Except the additions which Ranjít Singh made to the defences of the city little work of usefulness or adornment was done in his days at Lahore which did not owe something very directly to works of earlier times. Ranjít built a large summer house, which he called *Tar-ghar*, on the remains of prince Kámrán's *Dil-kusha*, or country palace, on the bank of the Rávi opposite Lahore. The fine marble *báradari* which he set up in the middle of the Huzúri Bagh was taken from Jahángir's tomb at Shahdara.

Lahore in the time of Ranjit Singh has been the subject of many descriptions and narratives from many pens. Very interesting are the accounts in Victor Jacquemont's *Letters* and Sir Henry Lawrence's *Adventurer in the Punjab.* The pictures of Ranjit's court at Lahore introduce also the figures of men whose names became very familiar to English ears in the later days of Ranjit's reign: the Hindu brothers Dhyán Singh and Ghuláb Singh, the men of action and intrigue; the Mussulman brothers Aziz-ud-dín and Nur-ud-dín (of the *Fakír* family as it is called), the men of business; the sagacious counsellor Dína Nath; the French military officers Allard, Ventura, Court; and others. But the great figure always in these Lahore pictures is the small, one-eyed maharaja himself. Uneducated, but full of knowledge, which was power,—of a feeble frame worse enfeebled by himself, but of astonishing energy and indomitable will,—he made the whole Punjab his own, and created for his own use an army the most powerful and best organized that Britain has ever encountered in India. Ranjit Singh died in 1839, leaving to his successors this dangerous legacy, consisting of sixty regiments of regular infantry and a larger force of irregulars, numbering in all 92,000; cavalry, 31,800; artillery, 171 garrison guns and 384 field pieces.

Immediately after the close of his life began the wild anarchy and bloodshed of which Lahore was the constant scene for years following. Within four months Ranjit's son and successor Kharak Singh was removed by death, in what way is not clearly known. The reign of Nan Nihál Singh, who came after him, lasted a few days only. A longer time of power was enjoyed by Shír Singh, who at length was murdered in 1843. After a time of worse confusion, constant fighting, and more murders, Dhalíp Singh, a young son of Ranjít, became maharaja,—the government, such as it was, being in the hands of his mother, and of the vizier Lál Singh. Seven years after Ranjit Singh's death a great part of his great army, which had come to feel its strength and make it felt, when no longer held in the iron grasp of its only master, crossed the Sutlej into British territory, and took thus the first step towards its own destruction. The result, after four great conflicts, one of them a conflict of unexampled peril to the British power in India, was the first occupation of Lahore by English troops in March 1846. Of Lahore in British hands an account has been given above.

The tomb of Ranjit Singh, a building of no great architectural merit, which stands just outside the Roshnai gate, was in progress when the city was taken possession of in 1846, and was completed after the annexation of the Punjab in 1849.

LAHR, chief town of an official district in the circle of Offenburg, Baden, is situated on the Schutter, about 9 miles south of Offenburg. As one of the busiest towns in Baden, it carries on manufactures of tobacco and cigars, woollen goods, chicory, leather, pasteboard, hats, and numerous other articles, and has besides considerable trade. The population in 1875 was 8491.

LAIBACH, or LAYBACH (Slovenian, *Ljubljana*), capital of the duchy of Carniola, Austria, is situated on the Laibach near its influx into the Save, and on the Crown Prince Rudolph and Austrian Southern Railways, 45 miles north-east of Trieste, in 46° 3′ N. lat., 14° 31′ E. long. It consists of the town proper and eight suburbs, and possesses a cathedral in the Italian style, ten churches, the palaces of the prince and count of Auersperg, an ancient castle on the Schlossberg now used as a military depot and prison; besides the usual public buildings and educational establishments of a provincial capital and episcopal see. There are manufactories of earthenware, linen and woollen cloth, silk, fire-hose, and cigars; oil, paper, and chicory mills; a sugar refinery, and a bell-foundry. On the 31st December 1880 the civil population was 24,618 (11,185 males, 13,433 females); together with the military it was 26,284. The native language is Slovenian, but the educated classes speak German or Italian.

Laibach occupies the site of the ancient Emona or Æmona. In 388 A.D. Emona was visited by the emperor Theodosius; in 400 it was besieged by Alaric; and in 451 it was desolated by the Huns. In 900 Laibach suffered much from the Magyars, who were, however, defeated there in 914. In the 12th century the town passed into the hands of the dukes of Carinthia; in 1270 it was taken by Ottocar of Bohemia; and in 1277 it came under the sway of the Hapsburgs. In the early part of the 15th century the town was several times besieged by the Turks. The bishopric was founded in 1461. On the 17th March 1797 and again 3d June 1809 Laibach was taken by the French, and from 1809 to 1813 it became the seat of their general government of the Illyrian provinces. From 1816 to 1849 Laibach was the capital of the kingdom of Illyria. For the congress of Laibach (January to May 1821) see vol. xiii p. 485.

LAING, ALEXANDER GORDON (1793–1826), an African explorer, was born at Edinburgh 27th December 1793. At first it seemed that he would follow his father's profession, that of a teacher of the classics; but, his fancy being fired with the military ardour of the time, he set out for Barbados, where his maternal uncle Colonel Gordon was then stationed. Here he met with Sir George Beckwith, who procured him a commission in the York light infantry. His career as a traveller began in 1822, when he was sent on a mission to the country of the Sulimas and advanced as far as the sources of the Rokelle. By ascertaining that the source of the Quorra or Niger was not more than 1600 feet above the sea, he dispelled the idea that it was connected with the Nile. The further elucidation of the other questions that were then connected with this great river formed the principal object of his next journey, undertaken in 1825 under the auspices of Lord Bathurst. From a letter sent May 10, 1826, from Blad Sidi Mohammed to Consul Warrington at Tripoli we know that he had barely escaped with his life from an attack in which he had received twenty-four wounds. He managed to reach Timbuctoo by August 18th, but shortly afterwards fell a victim to the treachery of his servant. The history of the vain attempt to recover the traveller's journals will be found in the *Quarterly Review*, vol. xlii. (1830). The narrative of his first journey was published in 1825.

LAING, DAVID (1793–1878), a distinguished Scottish antiquary, especially eminent for his bibliographical knowledge, was the son of William Laing, a bookseller in Edinburgh, and was born in that city in 1793. He was brought up to his father's business, and continued for many years in partnership with him. Shortly after the death of the latter, however, a vacancy having occurred in the librarianship of the Signet Library, Laing was elected to that office in 1837, and continued to hold it till the time of his death. In addition to, it is believed, an almost unexampled knowledge of the titles and value of books, Laing possessed an intimate acquaintance with the early literary history of Scotland. His knowledge of Scottish art was also very extensive; and the ecclesiastical history of his native country, particularly during the 16th and 17th centuries, had long been the subject of his profound investigation. It is perhaps to be regretted that with all this knowledge he never produced any large independent work, but confined himself to the editing of the works of others. Of these, the chief are—*Dunbar's Works*, 2 vols., 1834, with a supplement added in 1865; *Robert Baillie's Letters and Journals*, 3 vols., 1841–42; *John Knox's Works*, 6 vols., 1846–64; *Poems and Fables of Robert Henryson*, 1865; *Andrew of Wyntoun's Orygynale Cronykil of Scotland*, 3 vols., 1872–79; *Sir David Lyndsay's Poetical Works*, 3 vols., 1879. Laing was for more than fifty years an active member of the Society of Antiquaries of Scotland, and during that period he contributed upwards of a hundred separate papers to their *Proceedings*. He was also for more than forty years secretary to the Bannatyne Club, many of the publications of which were carefully edited by him, and few of them we believe failed to benefit by his assistance. A complete list of his productions would occupy many pages. His literary activity ended only with his life. He was struck with paralysis when attending to his duties in the Signet Library, and it is touchingly recorded of him that, on awakening out of the fit, he looked about him and asked if a proof of Wyntoun had been sent up from the printers. He died a few days afterwards, on October 18, 1878, at the age of eighty-six years. Perhaps few men who ever lived possessed so much recondite knowledge on subjects connected with Scottish history and literature, and no one could be more ready to communicate whatever he knew to those who were engaged in investigations similar to his own. In 1864 the university of Edinburgh conferred on him the degree of LL.D. In the course of his long life Laing had collected an immense library, a large portion of the books being illustrative of the literature or history of Scotland, and many of them being of extraordinary rarity. It was dispersed by auction in London soon after his death, and the enormous prices obtained for many of the books were such as had hardly ever been known even in the most celebrated of previous book sales. A valuable collection of MSS., chiefly relating to Scotland, was bequeathed by him to the library of Edinburgh university.

LAING, MALCOLM (1762–1818), a Scottish historian, was born at his paternal estate on the Mainland of Orkney in 1762. Having studied at the grammar school of Kirkwall and the university of Edinburgh, he was called to the bar in 1785, but never obtained an extensive practice as advocate. In 1793 he completed the last volume of Henry's *History of Great Britain*, the portion which he wrote being, in its strongly liberal tone, at signal variance with the preceding tenor of the work. In 1800 he published a *History of Scotland from the Accession of James VI. to the Reign of Queen Anne*, a work of considerable research. In a dissertation prefixed to an edition of his *History* published in 1804 he endeavoured to prove the participation of Queen Mary in the murder of Darnley. In the same year he published an edition of the *Historie and Life of King James the Sext.* His only other publication is an edition of the *Poems of Ossian.* For a short period in 1807 Laing represented his native county in parliament. He died in November 1818.

LAI-YANG, a city in the Chinese province of Shan-tung, situated in 37° N. lat. and 120° 55′ E. long., about the middle of the eastern peninsula, on the highway running south from Che-foo to Kin-Kea or Teng-tsi harbour. It is surrounded by well-kept walls of great antiquity, and its main streets are spanned by large pailows or monumental arches, some of which date from the time of the emperor Tai-ting-te of the Yuen dynasty (1324). There are extensive suburbs both in the north and south, and the total population is estimated at 50,000. The so-called Ailanthus silk produced by *Saturnia cynthia* is woven at Lai-yang into a strong fabric; and the manufacture of the peculiar kind of wax obtained from the la-shoo or wax-tree insect is largely carried on in the vicinity.

LAKE. When a stream in its course meets with a depression in the land it flows into it and tends to fill it up to the lip of its lowest exit. Whether it succeeds in doing this or not depends on the climate. In the British Islands, and in most temperate and equatorial regions, the stream would fill the depression and run over, and the surplus water would flow on towards the sea. Such a depression, with its contents of practically stagnant water, constitutes a lake, and its water would be fresh. In warm dry regions, however, such as are frequently met with in tropical latitudes, it might easily happen that the evaporation from the surface of the depression, supposed filled with water, might be greater than the supply from the feeding stream and from rain falling on its surface. The level of the waters in the depression would then stand at such a height that the evaporation from its surface would exactly balance the supply from streams and rain. We should have as the result a lake whose waters would be salt. Lakes of the first kind may be considered as enlargements of rivers, those of the second kind as isolated portions of the ocean; indeed, salt lakes are very frequently called seas, as the Caspian Sea and the Dead Sea. The occurrence of freshwater lakes and salt lakes in the same drainage system is not uncommon. In this case the salt lake forms the termination. Well-known examples of this are Lake Titicaca and the Desguadero in South America, and Lake Tiberias and the Dead Sea on the Jordan.

Distribution of Lakes.—Although there are few countries where lakes are entirely absent, still it requires little study to see that they are much more thickly grouped in some places than in others. Of the larger lakes, for instance, we have the remarkable group in North America, which together form the greatest extent of fresh water in the world. A similar group of immense lakes is found in Central Africa:—Lakes Victoria Nyanza and Albert Nyanza, whose overflow waters go to form the Nile; Lake Tanganyika, at the source of the Congo; and Lake Nyassa, on a tributary to the Zambesi. In Asia the largest fresh-water lake is Lake Baikal, on the upper waters of the Lena. All these freshwater lakes of great size are at the sources of large and important rivers; the salt lakes in which Asia also abounds are at the mouths of large rivers, as the Caspian at the mouth of the Volga, and Aral Sea at the mouth of the Oxus.

Passing from the consideration of these larger lakes, which from their size may be considered inland oceans, and which therefore necessarily occur in small number, we find large numbers of lakes of comparatively small dimensions, and when we consider them attentively we find that they are reducible to a small number of species, and, as in the case of plants and animals, the distribution of these species is regulated chiefly by climate, but also by geological conditions. Perhaps the most important and remarkable species of lakes is that to which the Scottish lakes belong. They are generally characterized by occupying long narrow depressions in the valleys of a mountainous country in the neighbourhood of the sea, and in a temperate climate. On the sea-coast, lakes of this character are found in Norway, Scotland, Newfoundland, Canada, the southern extremity of South America, and the south end of the middle island of New Zealand; somewhat removed from the sea we have the Alpine lakes of Switzerland and Tyrol, and the great Italian lakes, all of which display the same features as those of Scotland or of Norway. In many flat countries lakes are extraordinarily abundant, as for instance in the north part of Russia and Finland, in the southern part of Sweden, in the northern parts of Canada, and on a small scale in the Hebrides.

Lagoons, found on all low sandy coasts, owe their origin to the shifting of the sand under the influence of the wind and tide. They are found at the mouths of large rivers, as on the Baltic and at the mouth of the Garonne.

In volcanic regions lakes are not uncommon, generally of a more or less circular form, and either occupying the site of extinct craters or due to subsidences consequent on volcanic eruptions; such are the Maare of the Eifel in Germany, and many lakes in Italy and in the Azores.

Lakes are not only widely distributed in latitude and longitude, they also occur at all elevations. Indeed, as a certain elevation above the sea produces an effect as regards climate equivalent to a certain increase of latitude, we find lakes existing in the centre of continents, and on high plateaus and mountain ranges, in latitudes where they would be speedily dried up if at the level of the sea. Many of the lakes in Scotland (as Lochs Lomond, Morar, Coruisk), of Norway, of British Columbia, and of southern Chili are raised only by a few feet above the level of the sea, and are separated from it often by only a few hundred yards of land, while in the Cordilleras of South America we have Lake Titicaca 12,500 feet, and in Asia Lake Kokonor 10,500 feet above the sea. Many lakes whose surface is raised high above the level of the sea are so deep that their bottom reaches considerably below that level.

Dimensions of Lakes.—The principal measurements connected with a number of lakes in different parts of the world, presented in the following table, will give a more precise idea of the size of the lakes than could be given by description alone:—

Name of Lake.	Mean Latitude.	Length.	Breadth (Max.).	Depth (Max.).	Height in Feet above the Sea of Surface.	Height in Feet above the Sea of Bottom.	Temperature of Water at Bottom.
		Miles.	Miles.	Feet.			°F.
Superior	47° 45′ N.	350	100	978	627	−351	38·8
Michigan	44° N.	320	80	840	594	−246	...
St Clair	42° 30′ N.	18	22	20	570	+550	...
Erie	42° N.	220	48	204	564	+360	...
Titicaca	16° 30′ S.	90	30	924	12,500	+11,576	54·6
Kokonor	37° N.	91	42	...	10,500	...	...
Baikal	53° N.	330	40	4,080	1,360	−2,720	...
Balkash	46° N.	280	25	238	72	+166	...
Caspian	42° N.	600	50	3,600	−85	−3,685	44·6
Dead Sea	31° 30′ N.	45	10	1,308	−1,272	−2,580	...
Tanganyika	6° S.	330	40	1,000	2,700	...	...
Como	46° N.	48	2·5	1,356	670	−686	...
Geneva	46° 25′ N.	45	8·7	1,092	1,218	+126	41·7 to 43·5
Constance	47° 40′ N.	35	8	394	1,300	+906	39·6
Lomond	56° to 57° 30′ N.	20	4	630	25	−605	41·4 to 42
Morar		11	1·5	1,020	30	−990	40·8 to 41·4
Ness		23	1·3	774	50	−724	41·2 to 42·4
Lochy		10	1	480	93	−387	42 to 44
Katrine		7	0·8	480	364	−116	41·4
Tay		14·5	1	450	390	−60	43·9
Rannoch		9·4	1	378	668	+290	43·9
Ericht		14·5	0·8	330	1,153	+823	44·7
Tummel		2·5	0·5	120	450	+330	45·5
Garry		2·5	0·3	102	1,330	+1,228	53·9

From this table it will be seen that by far the largest continuous sheet of fresh water is the group of North American lakes, and of these Lake Superior is more than double the size of any of the others; this is principally due to its great breadth, as it is very little longer than Lake Michigan. Lake Superior communicates with Lakes Michigan and Huron, which are really branches of one and the same lake, by the St Mary's river, the fall being 49 feet from Superior to Huron. Huron empties itself into Erie by the St Clair river, Lake St Clair, and finally the Detroit river. Lake Erie overflows by the Niagara river and falls into Lake Ontario, whence the water finally is conveyed to the sea by the St Lawrence. The area of the lakes together is in round numbers 100,000 square miles, and, if that of the St Lawrence and its estuary be added, the water area will be about 150,000 square miles, while the whole drainage area is only 537,000 square miles. Hence of the water conveyed by the St Lawrence to the sea, rather more than one-fourth falls on the surface of the water itself. Looking to their great extent, we should have suspected them to be much deeper than is found to be the case. The deepest, Lake Superior, is no deeper than Loch Morar in Inverness-shire. Comparatively shallow, however, as they are, the bottoms of them all, with the exception of Erie, are several hundred feet below the level of the sea. It has been supposed that in former times this chain of lakes formed an arm of the sea similar to the Baltic in Europe, and in support of this view we have the fact of the discovery of marine forms in Lake Michigan.

In Asia Lake Baikal is in every way comparable to the great Canadian lakes as regards size. Its area of over 9000 square miles makes it about equal to Erie in superficial extent, while its enormous depth of over 4000 feet makes the volume of its waters almost equal to that of Lake Superior. Although its surface is 1360 feet above the sea-level, its bottom is 2720 feet below it. A former connexion with the ocean has been claimed for this lake, owing to the fact that seals inhabit its waters. Other large lakes in Asia are mostly salt, and some lie wholly below the level of the sea. Thus the Caspian lies 85 feet below the Black Sea, and the bottom at its greatest depth is 3600 feet deeper. The Dead Sea is over 1300 feet deep, and its surface is 1272 feet below the Mediterranean, so that its bottom is 2580 feet below the level of the sea. In the Caspian seals are found. A former connexion with the Red Sea has been claimed for the Dead Sea, but this is disallowed by Peschel and others. The Jordan valley, with the Sea of Tiberias and the Dead Sea, lie on the line of an extensive fault, and it is claimed that this depression in the surface occurred with the production of the fault. Further evidence in support of the statement that the Dead Sea was never connected with the sea is of a negative character, and consists chiefly in the fact that marine forms have not been found in the waters of the Jordan or of Lake Tiberias, and that silver is absent from the waters of the Dead Sea.

A former connexion with the ocean is claimed for a number of the Swiss and Italian lakes by Dr Forel and Professor Pavesi, and the Norwegian lakes by Loven and Sars, on the ground of the occurrence of marine forms of the crustaceans and other classes. For a summarized account of these researches see Pavesi, *Arch. de Genève*, 1880, iii. 1.

Temperature of Lakes.—The earliest reliable temperature observations in lakes or seas are those of Saussure, and they are to be found in his charming *Voyage dans les Alpes.* He was the first to obtain thoroughly trustworthy observations in the deeper waters of the lakes. He used for this purpose an ordinary thermometer whose bulb was covered over with several thicknesses of cloth and wax, so as to render it very slowly conducting. He was in the habit of leaving it down fourteen hours, and then bringing it up as quickly as possible and immediately reading the temperature. He did not, however, trust to his thermometer not changing its reading while being brought up, but by an elaborate series of experiments he obtained corrections, to be applied when the thermometer had to be drawn through more or less water of higher temperature. His observations are collected in the following table along with those of Jardine in some of the Scottish lakes, at the beginning of the century :—

Name of Lake.	Date.	Temperature of		Depth.	Height above Sea.
		Surface.	Bottom.		
		° F.	° F.	Feet.	Feet.
Geneva	February.	42·1	41·6	1,013	1,230
Neuchâtel	17th July.	73·7	41·4	346	1,304
Bourget	October 1784.	64·0	42·1	256	...
Annecy	14th May 1780.	57·9	42·1	174	1,426
Joux	...	55·6	51·3	85	350
Bienne	...	69·3	44·4	231	1,419
Constance	25th July 1784.	64·6	39·6	394	1,250
Lucerne	28th July.	63·4	40·8	640	1,380
Thun	7th July 1783.	66·2	41·0	373	1,896
Brienz	8th July 1783.	68·0	40·5	533	...
Maggiore	19th July 1783.	78·1	44·1	357	...
Lomond	8th Sept. 1812.	59·5	41·5	600	25
Katrine	7th Sept. 1812.	57·3	41·0	480	364
	3d Sept. 1814.	56·4	41·3	...	...

An exceedingly important and valuable series of observations was made by Fischer and Brunner [1] in the Lake of Thun throughout the course of a whole year (March 1848 to February 1849). They used, after Saussure's method, thermometers protected by non-conducting envelopes, which were pulled up as quickly as possible. The depth of the water where they observed was 540 feet, and they made a series of observations of the temperature at that depth, at the surface, and at eleven intermediate depths, and repeated the series of observations at eight different dates over the year. From these series, which afford the first information of the yearly march of temperature at different depths, we learn that the lake as a whole gains heat till the end of September, then loses it until the month of February, when it begins to warm again, though slowly. The maximum temperature occurs in October at depths from the surface to 70 feet, in November at depths from 70 to 120 feet, in December from 120 to 200 feet, and in February at 500 feet. As the whole yearly variation of the temperature at 200 feet is less than a degree, the epoch at which the greater depths attain their maximum and minimum temperatures cannot be certainly deduced from one year's observations. The minimum temperature of depths from the surface to 80 feet is attained in the month of February, at greater depths in the month of March. During the course of the whole year the temperature at the bottom varied between 40°·7 and 40°·9 Fahr., and in the month of February the whole of the water from the surface to the bottom was between 40°·7 and 41° Fahr.

These and other observations showed that, from depths of 400 feet, the variation of temperature with increasing depth is quite insignificant, so that even though the lake might be 1000 feet deep the temperature at 400 feet is only one or two tenths of a degree different from that of the bottom ; further, on many of the thermometers recently used, it is impossible to distinguish with certainty temperatures differing by less than half a degree, consequently it was not difficult to believe that in all deep lakes there is a considerable stratum of water which remains constantly at the same temperature, all the year and every year, and that in winter this stratum thickens so as often to fill the lake, and gets thinner again in summer. By the improvement of the instruments both of these suppositions have been shown to be erroneous. In summer and in temperate latitudes, however deep the lake may be, its temperature falls as the depth increases, first rapidly and then very slowly, and the bottom temperature observed in any summer depends on the nature of the winter which preceded it, and may vary from year to year by one to two degrees. It was also believed that the deep water of a lake preserved constantly the mean winter temperature or the mean temperature of the six coldest months of the year in the locality. This was deduced from some observations by Sir Robert Christison in Loch Lomond, who found the bottom temperature at Tarbet to be 41°·4 Fahr., agreeing with the mean of the six winter months as observed at Balloch Castle, which, however, is about 15 miles distant. Although the theorem may be accidentally true for Loch Lomond, it has been proved not to hold for other lakes. Thus Simony (*Wien. Sitz. Ber.*, 1875, lxxi. p. 435) gives the following table, comparing the temperature of the bottom water in the Gmünder See with the winter (October to March) air temperature:[2]—

	Winter Period. Mean Temperature.			Summer Period. Mean Temp.	Bottom Temp., Gmünder See.	Date of Observation of Bottom Temperature.
	Oct.–Mar.	Dec.–Feb.				
	° F.	° F.		° F.	° F.	
1867–68	37·5	32·9	1868	64·4	40·5	6th Oct. 1868.
1868–69	40·1	36·8	1869	63·1	40·5	1st Oct. 1869.
1869–70	35·0	29·3	1870	60·8	40·2	26th Sept. 1870.
1871–72	35·2	27·8	1872	62·2	40·0	3d Oct. 1872.
1872–73	41·0	35·0	1873	60·2	40·5	5th Oct. 1873.
1673–74	39·0	32·7	1874	61·9	40·4	25th Sept. 1874.
1874–75	33·8	28·2	...	...	39·1	10th April 1875.

It will be seen that, with the exception of the end of 1872, the mean winter temperature is below that of the bottom water, and generally very markedly so.

During 1877–81 observations have been made by the present writer on the distribution of temperature in lakes forming part of the Caledonian Canal. The monthly mean temperatures at Culloden and at Corran Ferry lighthouse, which cannot differ much in climate from Loch Ness and Loch Lochy respectively, have been supplied by Mr Buchan of the Scottish Meteorological Society. The bottom temperatures are those observed in the deepest part of the lakes, namely, 120 fathoms in Loch Ness, and 80 fathoms in Loch Lochy. The connexion between bottom tempera-

[1] *Mém. Soc. Phys. Genève*, xii. p. 255.

[2] These air temperatures are those of the observatory at Vienna, corrected for difference of level.

ture (as observed in the second week of August) and winter temperature can be judged of from the following table, where the mean temperatures of October to March, and also of November to April, are given :—

	Loch Ness.		Culloden.		Loch Lochy.		Corran.	
	Surface.	Bottom.	Oct. to March.	Nov. to April.	Surface.	Bottom.	Oct. to March.	Nov. to April.
	°	°	°	°	°	°	°	°
1877	53·0	42·4	40·2	40·0	55·0	44·0	42·3	40·8
1878	59·0	42·3	41·6	40·9	61·0	43·7	42·7	42·5
1879	51·4	41·2	37·2	35·8	54·0	42·0	38·9	37·5
1880	57·0	42·4	41·0	40·8	57·6	43·8	42·0	41·9
1881	53·1	41·45	36·1	36·2	54·0	42·25	38·6	38·7

From this table it is apparent that the bottom temperature, even of lakes as deep as Loch Ness, is subject to considerable variation from year to year, that it depends on the temperature of the previous winter, and that it is usually higher than that temperature. The difference between the bottom temperature and the mean winter temperature is greater the lower the winter temperature is. It is further interesting to notice that the mean winter temperature of 1878–79 was about one degree higher than that of 1880–81, yet the bottom temperatures were 0°·25 lower in 1879 than in 1881, and this is no doubt due to the fact that the cold of 1878–79 was more continuous than that of 1880–81, when the actual temperatures observed were much lower. The temperature of the bottom water depends not only on the temperature of the previous winter, and on the depth of the lake; it also depends on the nature of the country where it lies, and especially on its exposure to winds. Winds drive the surface water before them, and if there were no return current it would be heaped up at the further end. The effect is to accumulate surface water at one end, and to draw on deeper water to make up the deficiency at the other end. Hence the prevailing direction of the wind impresses itself on the distribution of temperature in the water; and this is well shown in the distribution of temperature as determined from observations at five stations on the same day in Loch Ness in a summer after a warm winter, and in one after a cold winter. In Scotland, warm weather is associated with southerly and westerly winds, and cold weather with northerly and easterly winds. In the warm years we have accumulation of surface water at the north-eastern end, and of bottom water at the south-western end, producing in summer a higher mean temperature of water at the north-east, and a lower mean temperature of water at the south-west end. In cold years the reverse is observed. Thus in 1879, after a cold winter, the mean temperature of the first 300 feet of water at the south-west end of Loch Ness was 48°·8, and at the north-east end 44°·96, a difference of nearly four degrees. In 1880, after a comparatively mild winter, it was 48°·13 at the south-west end, and 47°·95 at the north-east end, or nearly identical temperatures. Even at stations a few hundred yards from each other, great differences are often observed in the temperatures observed at the same depth, and it is evident that the difference of density so produced must cause a certain amount of circulation. There can be but little doubt that, under the influence of the varying temperature of the seasons, and of the winds, the water of a lake is thoroughly mixed once a year. In lakes which do not consist of a single long trough like Loch Ness, but of several basins as Loch Lomond, the bottom temperature is different in the different basins, even when the depth is the same. Loch Lomond consists of three principal basins of very unequal depth :—the large expanse of water studded with islands at the lower end, the Balloch basin; the middle or Luss basin; and the upper and deepest or Tarbet basin. In the last we have 600 feet of water, in the Luss basin 200 feet, and in the Balloch basin a maximum of 72 feet of water. On 23d September 1876 the bottom temperature in the Tarbet basin was 41°·4, and in the Luss basin 46°·4. Loch Tummel, a much smaller lake, consists of three basins, each of them being from 100 to 120 feet deep, and in them we have bottom temperatures of 46°·3, 46°·9, and 45°·2, the lowest temperature being nearest the outlet.

It might have been expected that the bottom temperature in lakes similar as regards size and depth would be lower at greater elevations and higher nearer the sea-level. This does not, however, hold universally; thus Lochs Tummel and Garry are very similar in size and depth; they are only 12 miles from each other, but Loch Tummel is 450 feet and Loch Garry 1330 feet above the sea; yet at 102 feet in Loch Garry the temperature on the 18th August 1876 was 53°·9, and in Loch Tummel at the same depth on the 16th August 1876 it was 45°·4. The difference of elevation is nearly 900 feet, and, instead of the higher lake holding the colder water, its water is 8°·5 warmer than that of the lower one. Similarly in Loch Ericht, 1153 feet above the sea, the bottom temperature at 324 feet was 44°·7, and in Loch Rannoch, 668 feet above sea, at the same depth it was 44°·0. These examples will suffice to show that many circumstances concur in determining the temperatures of the waters of lakes. There is one factor which is often neglected, namely, the amount of change of water. This depends on the drainage area of its tributary streams, and necessarily varies greatly.

In comparing the bottom temperature in lakes with the mean temperatures of the coldest half of the year, we find that the two approach each other more nearly the higher these temperatures are. When the temperature of the air falls for a lengthened period below the temperature of maximum density of water (39°·2 Fahr.), then the mechanical effect produced is much the same as if the temperature had been raised. For, in virtue of the cooling above, the water will have no tendency to sink; it will rather tend to float as a cold layer on the surface of the warmer and denser water below. Were a lake comparable with a glass of water, that is, were its depth equal to or greater than its length or breadth, it would be possible to realize this ideal condition of things, which, until recently, was supposed to represent what really takes place when a lake is covered with ice, namely, that after the water has all been cooled to a uniform temperature of 39°·2 Fahr. further cooling affects only a small surface layer, which consequently rapidly freezes. If this were the case, we should expect to find the temperature of the water below the ice of a frozen lake increasing rapidly from 32° where it is in contact with the ice to 39°·2 at a short distance from it, and we should expect to find the remainder of the water down to the bottom at the same temperature. In fact, however, the depth of even the deepest lakes bears an insignificant proportion to their superficial dimensions, and temperature observations in summer show that the effective climate, that is, the climate in so far as it is effective for the purpose under consideration, varies much over the surface of even very small lakes. The variations in distribution of temperature produce variations in density which of themselves are sufficient to produce convection currents. Then, as a factor of climate, there are the winds, which are the main mixing agents, and also the movement in the waters caused by the inflow of water at different points and the removal of the excess at one point. The effect of these mechanical agents, winds and currents, is to propagate the air temperature at the surface to a greater depth than would otherwise be the case. At the same time it must be remembered that in seasons of great cold there is rarely much wind. If we reflect, however, on what must take place when there is a large expanse of open water in the middle of a country covered with snow, and exposed to the rigours of a winter night, we see that the air in contact with the surface of the water must get warmed and form an ascending current, its place being taken by fresh air drafted from the cold land surface, which not only cools the water but forces it out towards the middle, thus establishing a circulation consisting in broad lines of a surface movement from the sides to the middle of the lake, and a movement in the opposite direction below the surface. Even if the current of air were not sufficient of itself to produce a surface current in the water, it would do it indirectly. For, as it first strikes the water at the edges, the water there would get cooled most rapidly, and under suitable circumstances would form a fringe of ice; the water so cooled would be lighter than the warmer water farther out, and would have a tendency to flow off towards the middle, or with the current of air. Now, although, when compared with other seasons, there is in a hard frosty winter not much wind, still, even in the calmest weather there is almost always sufficient motion in the atmosphere to enable the meteorologist to state that the wind is from a particular quarter; this will assist the circulation which has just been described as taking place in a calm lake, though it will somewhat distort its effects. It will produce excessive cooling at the side nearest the wind, and, when the lake freezes, it will have a tendency to begin at the windward side.

The extent to which this circulation affects the deeper waters of a lake depends on local circumstances, and generally we may say that the more confined a lake is the more easily will it freeze, and the higher will be the mean temperature of its waters. In the very cold winter 1878–79 the writer was able to make observations on the temperature of the water under the ice in Linlithgow Loch and in Loch Lomond. In the following winter, which, though mild in Scotland, was excessively severe in Switzerland, Dr Forel made observations in the Lakes of Morat and Zürich, confirming the writer's observations of the unexpectedly low temperature of the water. The freezing of so deep a lake as that of Zürich was a fortunate circumstance, because in it the bottom is actually at the temperature of maximum density. The majority of the lakes which freeze are so shallow as to admit of the whole of their water being cooled considerably below the temperature of maximum density.

The distribution of temperature in frozen lakes will be apparent from the table given below. Of the Lakes of Zürich and Morat and Loch Lomond the mean temperatures are in the order of their depth. Linlithgow is altogether peculiar. Its high temperature, which increased steadily all the time it was covered with ice, was due to chemical action amongst the filth which has been allowed to accumulate at its bottom. When the ice broke up the dead fish were taken away in carts.

Dr Forel gives the following particulars about the frozen Swiss lakes. "The Lake of Morat has a surface of 27·4 square kilometres and a maximum depth of 45 metres (147 feet); it is 1425 feet above the sea; and its mean latitude is 49° 56′ N. The ice overspread its whole surface suddenly in the night of the 17th to the 18th December, and it remained frozen till the 8th March. The Lake of Zürich has a superficies of 87·8 square kilometres, a maximum depth of 468 feet and altitude of 1338 feet, and a mean latitude of 47° 16′ N. Its congelation was gradual, and not sudden like that of the Lake of Morat. First the upper part of the lake was covered with ice between Männedorf and Wädensweil. At the end of December, the 28th, the ice covered it entirely, but only for a single day. On the 29th it thawed, and the lake remained partially free of ice until the middle of January. It froze over completely on the 22d January, and on the 25th the ice was 4 inches thick in the centre of the lake." Of the larger Swiss lakes, Morat, Zürich, Zug, Neuchâtel, Constance, and Annecy were frozen in 1880; Thun is known to have been frozen four times, namely, in 1363, 1435, 1685, and 1695; Brienz has only once been frozen, in 1363; Lucerne freezes partially in very severe winters, and Geneva in its western and shallower part, whilst Wallenstadt and Bourget are not known to have ever been frozen.

For further information on the temperature of frozen lakes, see Buchanan, *Nature*, March 6, 1879; Forel, *Arch. de Genève*, 1880, iv. 1; Nichols, *Proc. Boston Soc. of Nat. Hist.*, 1881, xxi. p. 53.

Changes of Level.—As the water supply of lakes depends on the rainfall, and as this varies much with the season, and from year to year, we should expect, and indeed we find, fluctuation of level in all lakes. There are, however, other changes of level which are independent of the water supply, and which resemble tides in their rhythmic periods. They have long been known and observed in Switzerland, and especially on the Lake of Geneva, where they are known by the name of "seiches." The level of the lake is observed to rise slowly during twenty or thirty minutes to a height which varies from a few centimetres to as many decimetres; it then falls again slowly to a corresponding depth, and rises again slowly, and so on. These movements were observed and much studied at the end of last century by Jallabert, Bertrand, and Saussure, and at the beginning of this century they formed the subject of an instructive memoir by Vaucher, who enunciated the following law connecting the seiches with the movements of the barometer. "The amplitude of seiches is small when the atmosphere is at rest; the seiches are greater the more variable is the atmosphere's pressure; they are the greatest when the barometer is falling." Vaucher recognized the existence of seiches in the Lakes of Geneva, Neuchâtel, Zürich, Constance, Annecy, and Lugano, and Dr Forel of Morges, from whose papers, published principally in the *Bibliothèque Universelle et Revue Suisse* during the last five years, the facts regarding the seiches have been taken, has observed them in every lake where he had looked for them. It is in every way likely that they are to be found in all lakes of notable extent and depth. They have been studied principally on the Lake of Geneva, where Dr Forel, at Morges, about the middle of the lake on the north shore, and M. Plantamour, at Sécheron, about a mile from Geneva on the north shore, have had self-registering tide gauges in operation for a number of years. In the writings of the Swiss observers the seiche is the complete movement of rise above and fall below the mean level, the amplitude is the extreme difference of level so produced, and the duration of the seiche is the time in seconds measured from the moment when the water is at the mean level until it is again at the mean level, after having risen to the crest and sunk to the trough of the wave. The amplitude of the seiches is very variable. At the same station and on the same day successive seiches are similar. When the seiches are small they are all small, when they are large they are all large. At the same station and on different days the amplitudes of the seiches may vary enormously. For instance, at Geneva, where the highest seiches have been observed, they are usually of such a size as to be imperceptible without special instruments; yet on the 3d August 1763 Saussure measured seiches of 1·48 metres, and on the 2d and 3d October 1841 the seiches observed by Vénié were as much as 2·15 metres.

They are greater at the extremities than at the middle of lakes, at the head of long gulfs whose sides converge gently than at stations in the middle of a long straight coast, and in shallow as compared with deep lakes or parts of a lake. They also appear to increase with the size of the lake. The duration of the seiches is found to vary considerably, but the mean deduced from a sufficient number of observations is fairly constant at the same locality. Thus, for Morges, Dr Forel has found it to be for the half seiche 315 ± 9 seconds. At different stations, however, on the same lake and on different lakes it varies considerably. Thus on the Lake of Geneva it is, for the complete seiche, 630 seconds at Morges, and 1783 seconds at Veytaux; on Lake Neuchâtel it is 2840 seconds at Yverdon, and 264 at Saint Aubin.

The curves traced by the gauge at Geneva have been subjected to a preliminary harmonic analysis by Professor Soret, and he has decomposed them into two undulations, the one with a period, from crest to crest, of seventy-two minutes, and the other with a period of thirty-five minutes, or a little less than half the larger period. As the amplitudes of the composing curves vary much, there is great variety in the resultant curves. Besides these two principal components, there are others which have not yet been investigated.

With regard to the cause of the phenomenon, Dr Forel attributes the ordinary seiches to local variations of atmospheric pressure, giving an impulse the effect of which would be apparent for a long time as a series of oscillations. The greater seiches, such as those of 1·5 metres, he attributed to earthquake shocks; but, as a very sensible earthquake passed over Switzerland quite recently without leaving the slightest trace on the gauge, he has abandoned this explanation, and is inclined to attribute them to pulsation set agoing by violent downward gusts of wind, especially at the upper end of the lake. M. Plantamour, who has devoted much attention to the same subject, assured the writer, in the summer of 1881, that he was completely at a loss for a satisfactory explanation of them.

Seiches have not been observed on the Scottish lakes, though there is little doubt that they would be found if sought for. There are, however, records of disturbances of some of the lakes, especially in Perthshire, of which the following may be cited as an instance.

A violent disturbance of the level of Loch Tay is reported in the *Statistical Account of Scotland* (1796), xvii. p. 458, to have occurred at Kenmore on 12th September 1784, continuing in a modified degree for four days, and again on 13th July 1794. Kenmore lies at the north-eastern end of the lake, where the river Tay issues from it. It lies at the end of a shallow bay. "At the extremity of this bay the water was observed to retire about 5 yards within its ordinary boundary, and in four or five minutes to flow out again. In this manner it ebbed and flowed successively three or four times during the space of a quarter of an hour, when all at once the water rushed from the east and west in opposite currents, ... rose in the form of a great wave, to the height of 5 feet above the ordinary level, leaving the bottom of the bay dry to the distance of between 90 and 100 yards from its natural boundary. When the opposite currents met they made a clashing noise and foamed; and, the stronger impulse being from the east, the wave after rising to its greatest height, rolled westward, but slowly diminishing as it went, for the space of five minutes, when it wholly disappeared. As the wave subsided it flowed back with some force, and exceeded its original boundary 4 or 5 yards; then it ebbed again about 10 yards, and again returned, and continued to ebb and flow in this manner for the space of two hours, the ebbings succeeding each other, at the distance of about seven minutes, and gradually lessening, till the water settled into its ordinary level. During the whole time that this phenomenon was observed the weather was calm. On the next and four succeeding days an ebbing and flowing was observed nearly about the same time and for the same length of time, but not at all in the same degree as on the first day."

The above is the account given by the Rev. Thomas Fleming, at the time minister of Kenmore, who was an eye witness. It resembles in all essential particulars the descriptions of waves which accompany actual earthquakes, yet in his account he goes on to say—"I have not heard (although I have made particular inquiry) that any motion of the earth was felt in this neighbourhood, or that the agitation of the wave was observed anywhere but about the village of Kenmore." It is well known that there were great seismic movements observed in Perthshire at the time of the Lisbon earthquake, and there is a tradition in the neighbourhood that Loch Lubnaig near Callander was largely increased in extent by the dislocations which took place.

In all lakes there are changes of level corresponding with periods of rain and of drought. They are the more considerable the greater the extent of country draining into them, and the more constrained the outflow. In the great American lakes, which occupy nearly one-third of their drainage area, the fluctuations of level are quite insignificant; in Lake Michigan the U.S. surveyors give as the maximum and minimum yearly range 1·64 and 0·65 feet. In the Lake of Geneva the mean annual oscillation is 5 feet, and the difference between the highest and the lowest waters of this century is 9·3 feet. The most rapid rise has been 3·23 inches (82 mm.) in twenty-four hours. A very remarkable exception to the rule that large freshwater lakes are subject to small variations of level is furnished by Lake Tanganyika in Central Africa. Since its discovery travellers have been much perplexed by the evidence and reports of considerable oscillations of level of uncertain period, and also by the apparent absence of visible outlet, while the freshness of its waters was of itself convincing evidence of the existence of an outlet. By the careful observations of successive explorers the nature of this phenomenon has been fully explained, and is very instructive. It has recently been visited by Captain Hore of the London Missionary Society, and it appears from his reports that the peculiar phenomena observed depend on the fact that the area of country draining into the lake is very limited, so that in the dry seasons the streams running into it dry up altogether, and its outlet gets choked by the rapid growth of vegetation in an equatorial climate. A dam or dyke is thus formed which is not broken down until the waters of the lake have risen to a considerable height. A catastrophe of this kind happened whilst Captain Hore was in the neighbourhood, and he noted the height of the water at different times near his station at Ujiji, and observed it fall 2 feet in two months. It continued to fall until in seventeen months it had fallen over 10 feet. Taking the length of the lake at 330 miles, and the mean breadth at 30 miles, its surface is 9900 square nautical miles. If this surface be reduced 2 feet in sixty days, the water will have to escape at the rate of 137,500 cubic feet per second. The mean rate of discharge of the Danube is 207,000 cubic feet per second. Hence, without taking into account water which would be brought into the lake by tributaries during the two months, we require for outlet a river at least two-thirds of the size of the Danube, and in the Lukuga such a river is found. When Stanley visited it the Lukuga was quite stopped up with dense growth, and no water was issuing; the lake was then rising; when Captain Hore visited it the lake was falling rapidly, and the Lukuga was a rapid river of great volume. One of the chief affluents to the lake was found to be discharging at the rate of 18,750 cubic feet of water per second; a few months later it was dry and the mouth closed with vegetation. During the dry season too the lake, with its 10,000 square miles of surface, is exposed to the evaporating action of the south-east trade wind, and when the supply is so insignificant this must be sufficient of itself to sensibly lower the level. Ordinarily then we might expect the lake to be subject to a yearly ebb and flow corresponding to the periods of drought and rains; and, from what we learn of the great fluctuations of rainfall one year with another, we should expect that during a series of dry years the obstructions to the outflow would gain such a head that the rains of several wet seasons would have to accumulate before forcing a passage. The result would be a tide of a period corresponding to the recurrence of series of wet or dry years. Were the lake situated at or near the level of the ocean, its equatorial position would give it such a preponderance of rain over the whole year as to keep its outlet constantly open; but its actual position, 2700 feet above the sea, produces an alteration in climate, equivalent to an increase of latitude, which would place it in the trade wind region rather than in that of equatorial calms and rains. That such is actually the effect is shown by the range of temperature, which is moderate (59° to 83° Fahr.), and the rainfall (27 to 30 inches), which is almost exactly that of London. The Central African lakes, from their immense size and from their equatorial position, possess a peculiar interest for the physical geographer, and it is to be hoped that before long we shall have sufficient soundings to give a general idea of the size of their basins, and also temperature observations to show the effect of a vertical sun on large bodies of water at a moderate elevation, and removed from the disturbing influence of oceanic circulation.

As might be expected, in salt lakes which have no overflow, the yearly rise and fall is often considerable. In the Great Salt Lake in Utah, the greatest depth of which is 56 feet, changes of level are accompanied by great changes in water surface, and also in saltness of water. In the rainy season the Dead Sea stands 10 or 12 feet higher than in the dry season. The following table shows the chemical composition of the waters of various salt lakes, that of the sea-water in the Suez Canal being added for comparison:—

This table embraces examples of several types of salt lake. In the Kokonor, Aral, and open Caspian seas we have examples of the moderately salt, non-saturated waters. In the Karabugas, a branch gulf of the Caspian, the Urumieh, and the Dead Sea we have examples of saturated waters containing principally chlorides. The Van Sea is an example of the alkaline seas which also occur in Egypt, Hungary, and other countries. Their peculiarity consists in the quantity of carbonate of soda dissolved in their waters, which is collected by the inhabitants for domestic and for commercial purposes. The chemical reader will be struck by the quantity of magnesia salt dissolved in water which contains so much carbonate of soda. The analysis in the table is by Abich, quoted by Schmidt in his interesting "Études Hydrologiques," published in the *Bulletin de l'Académie de St Petersbourg*. Another analysis by De Chancourt, quoted by Bischof, omits all mention of sulphate of magnesia, but inserts the carbonate.

The limits of this article do not admit of the discussion of the many interesting phenomena connected with salt lakes. With regard, however, to a former connexion of the Caspian with the Black Sea, which has been so often suggested, it seems improbable, both on chemical and on physical grounds, that they were ever connected as seas, that is, in the same way as the Black Sea is connected with the Mediterranean; but, if we consider the topography of the Caucasus district, we see that the lowest summit level of the land between the two seas is in the Manytsch valley, 86 feet above the Black Sea. Were the climate of the Caspian to change only very slightly for the moister, its waters might easily rise the 196 feet which would enable it to overflow towards the Mediterranean, while a relapse towards dryness would be followed by the retreat of the waters, which would be then confined as they are now to the basin of the sea. It is important, therefore, to bear in mind that no terrestrial dislocations are required to produce enormous changes in the level of salt lakes; we require only changes of climate, and these very slight. There can be little doubt that, if the climate of the Black Sea extended across the isthmus to the Caspian, the latter would now stand 200 feet higher, would be fresh, and would overflow into the Sea of Azoff.

For other aspects of the subject see GEOLOGY. (J. Y. B.)

LAKE DWELLINGS, as their name implies, are habitations constructed, not on the dry land, but within the margins of lakes or creeks at some distance from the shore. The villages of the Guajiros in the Gulf of Maracaibo are described by Goering as composed of houses with low sloping roofs perched on lofty piles and connected with each other by bridges of planks. Each house consisted of two apartments; the floor was formed of split stems of trees set close together and covered with mats; they were reached from the shore by dug-out canoes poled over the shallow waters; a notched tree trunk served as a ladder; and the piles were so firmly driven that no shakiness was perceptible even when the houses were crowded with people. In such a climate the advantages of dwelling in houses so situated are obvious. The custom is common both in the Gulf of Maracaibo and in the estuaries of the Orinoco and Amazon; indeed the name of the province of Venezuela was given to it from the prevalence of these pile-dwellings along its shores. A similar system prevails in New Guinea. D'Urville describes four such villages in the Bay of Dorei, containing from eight to fifteen blocks or clusters of houses, each block separately built on piles, and consisting of a row of distinct dwellings accommodating a number of families. Cameron describes three villages thus built on piles in Lake Mohrya in Central Africa, the motive here being to prevent surprise by bands of slave-catchers. Similar constructions have been described by travellers, among the Dyaks of Borneo, in Celebes, in the Caroline Islands, on the Gold Coast of Africa, and in other places. Historians have referred to the former existence of the custom in Europe and Asia. Hippocrates, writing in the 5th century B.C., says of the people of the Phasis that their country is hot and marshy and subject to frequent inundations, and that they live in houses of timber and reeds constructed in the midst of the waters, and use boats of a single tree trunk. Herodotus, writing also in the 5th century B.C., describes the people of Lake Prasias as living in houses constructed on platforms supported on piles in the middle of the lake, which are approached from the land by a single narrow bridge. Abulfeda the geographer, writing in the 13th century, notices the fact that part of the Apamæan Lake was then called the Lake of the Christians, because it was inhabited by Christian fishermen who lived on the lake in wooden huts built on piles. Fishermen's huts roughly constructed of branches of trees and supported on piles placed saltire-wise existed in the shallows of the bays on the European side of the Bosphorus not many years ago, and Sir John Lubbock mentions that the Roumelian fishermen on Lake Prasias "still inhabit wooden cottages built over the water, as in the time of Herodotus." The records of the wars in Ireland in the 16th century show that the petty chieftains of that time had their defensive strongholds constructed in the "freshwater lochs" of the country, and there is record evidence of a similar system in the western parts of Scotland. The archæological researches of the past few years have shown that such artificial constructions in lakes were used as defensive dwellings by the Celtic people of post-Roman and mediæval times (see CRANNOGS). Similar researches on the Continent have also established the fact that in pre-historic times nearly all the shallow lakes of Switzerland, and many in the adjoining countries—in Savoy and the north of Italy, in Austria and Hungary, and in Mecklenburg and Pomerania—were peopled, so to speak, by lake-dwelling communities, living in villages constructed on platforms supported by piles, at varying distances from the shores. The principal groups are those in the Lakes of Bourget, Geneva, Neuchatel, Bienne, Zurich, and Constance lying to the north of the Alps, and in the Lakes Maggiore, Varese, Iseo, and Garda lying to the south of that mountain range. Many smaller lakes, however, contain them, and they are also found in peat moors on the sites of ancient lakes now drained or silted up. In some of the larger lakes the number of settlements has been very great. Fifty are enumerated in the Lake of Neuchatel, thirty-two in the Lake of Constance, twenty-four in the Lake of Geneva, and twenty in the Lake of Bienne. Some of these settlements have been of considerable size. The site of the lake dwelling of Wangen, in the Untersee, Lake of Constance, forms a parallelogram more than 700 paces in length by about 120 paces in breadth. The settlement at Morges, which is one of the largest in the Lake of Geneva, is 1200 feet long by 150 feet in breadth. The settlement of Sutz, one of the largest in the Lake of Bienne, extends over an area of 6 English acres, and was connected with the shore by a gangway nearly 100 yards long and about 40 feet wide. The substructure which supported the platforms on which the dwellings were placed was most frequently of piles driven into the bottom of the lake. Less frequently it consisted of a stack of brushwood or fascines built up from the bottom and strengthened by stakes penetrating the mass so as to keep it from spreading. When piles were used they were simply the rough stems of trees of a length proportioned to the depth of the water, sharpened sometimes by fire and at other times chopped to a point by hatchets. On their level tops the beams supporting the platforms were laid and fastened by wooden pins, or inserted in mortices cut in the heads of the piles. In some cases the whole construction was further steadied and strengthened by cross beams, notched into the piles below the supports of the platform. The platform itself was usually composed of rough layers of unbarked stems, but occasionally it was formed more regularly of boards split from larger stems. When the mud was too soft to afford foothold for the piles they were mortised into a framework of tree trunks placed horizontally on the bottom of the lake. On the other hand, when the bottom was rocky so that the piles could not be driven, they were steadied at their bases by being enveloped in a mound of loose stones, deposited around and among them, exactly in the manner in which the foundations of piers and breakwaters are now constructed. In cases where piles have not been used, as at Niederwyl and Wauwyl, the substructure is a mass of fascines or faggots laid parallel and crosswise upon one another with layers of brushwood or of clay and gravel separating the beds of the wooden material, which is steadied and kept in position by upright stakes not driven into the lake bottom,—a few piles here and there being occasionally fixed throughout the mass to serve as guides or stays. At Niederwyl the platform was formed of split boards, many of which were 2 feet broad and 2 or 3 inches in thickness. On these substructures were placed the groups of huts composing the settlement; for the peculiarity of these lake dwellings is that they were pile villages, or clusters of huts occupying a common platform. The huts themselves were quadrilateral in form. The size of each separate dwelling is in some cases marked by boards resting edgeways on the platform, like the skirting boards over the flooring of the rooms in a modern house. The walls, which were supported by posts, or by piles of greater length, were formed of wattle-work, coated with clay. The floors were of clay, and in each floor there was a hearth constructed of flat slabs of stone. The roofs were thatched with bark, straw, reeds, or rushes. As the superstructures are in all cases gone, there is no evidence as to the position and form of the doorways, or the size, number, and position of the windows, if there were any. In some cases the remains of the gangways or bridges connecting the settlements with the shore have been discovered, but in others the village appears to have been practically insular and accessible only by canoes. Several of these single-tree canoes have been found, one of which is 43 feet in length and 4 feet 4 inches in its greatest width. It is impossible to estimate with any degree of certainty the number of separate dwellings of which any of these villages may have consisted, but at Niederwyl they stood almost contiguously on the platform, the space between them not exceeding 3 feet in width. The size of the huts also varied considerably. At Niederwyl they were 20 feet long and 12 feet wide, while at Robenhausen they were about 27 feet long by about 22 feet wide. The character of the relics associated with the sites of the various settlements discloses the fact that in some cases they have been the dwellings of a people using no materials but stone, bone, and wood for their implements, ornaments, and weapons; in others, of a people using bronze as well as stone and bone; and in others again iron and bronze were used. But, though the character of the associated relics is thus changed, there is no corresponding change in the construction and arrangements of the dwellings. The settlement in the Lake of Moosseedorf, near Bern, affords the most perfect example of a lake dwelling of the Stone age. It was a parallelogram 70 feet long by 50 feet wide, supported on piles, and having a gangway built on faggots connecting it with the land. The superstructure had been destroyed by fire. The implements found in the relic bed under it were celts or axe-heads of stone, with their haftings of stag's horn and wood; a flint saw, set in a handle of fir wood and fastened with asphalt; flint flakes and arrow-heads; harpoons of stag's horn with barbs; awls, needles, chisels, fish-hooks, and other implements of bone; a comb of yew wood 5 inches long; and a skate made out of the leg bone of a horse. The pottery consisted chiefly of roughly-made vessels, some of which were of large size, others had holes under the rims for suspension, and many were covered with an encrustation of soot, the result of their use as culinary vessels. Burnt wheat, barley, and linseed, with many varieties of seeds and fruits, were plentifully mingled with the bones of the stag, the ox, the swine, the sheep, and the goat, representing the ordinary food of the inhabitants, while remains of the beaver, the fox, the hare, the dog, the bear, the horse, the elk, and the bison were also found. The settlement of Robenhausen, in the moor which was formerly the bed of the ancient Lake of Pfäffikon, seems to have continued in occupation after the introduction of bronze. The site covers an area of nearly 3 acres, and is estimated to have contained 100,000 piles. In some parts three distinct successions of inhabited platforms have been traced. The first had been destroyed by fire. It is represented at the bottom of the lake by a layer of charcoal mixed with implements of stone and bone, and other relics highly carbonized. The second is represented above the bottom by a series of piles with burnt heads, and in the bottom by a layer of charcoal mixed with corn, apples, cloth, bones, pottery, and implements of stone and bone, separated from the first layer of charcoal by 3 feet of peaty sediment intermixed with relics of the occupation of the platform. The piles of the third settlement do not reach down to the shell marl, but are fixed in the layers representing the first and second settlements. They are formed of split oak trunks, while those of the two first settlements are round stems chiefly of soft wood. The huts of this last settlement appear to have had cattle stalls placed between them, the droppings and litter forming heaps at the lake bottom. The bones of the animals consumed as food at this station were found in such numbers that 5 tons were collected in the construction of a watercourse which crossed the site. Among the wooden objects recovered from the relic beds were tubs, plates, ladles, and spoons, a flail for threshing corn, a last for stretching shoes of hide, celt handles, clubs, long-bows of yew, floats, and implements of fishing, and a dug-out canoe 12 feet long. No spindle-whorls were found, but there were many varieties of cloth, platted and woven, bundles of yarn, and balls of string. Among the tools of bone and stag's horn were awls, needles, harpoons, scraping tools, and haftings for stone axe-heads. The implements of stone were chiefly axe-heads and arrow-heads. Of clay and earthenware there were many varieties of domestic dishes, cups and pipkins, and crucibles or melting pots made of clay and horse dung and still retaining the drossy coating of the melted metal. No bronze objects have yet been found at Robenhausen, although the presence of the crucibles attests the fact of the use of that metal. The settlement of Auvernier in the Lake of Neuchatel is the richest and most considerable station of the Bronze age. It has yielded four bronze swords, ten socketed spear-heads, forty celts or axe heads and sickles, fifty knives, twenty socketed chisels, four hammers and an anvil, sixty rings for the arms and legs, several highly ornate torques or twisted neck rings, and upwards of two hundred hair pins of various sizes up to 16 inches in length, some having spherical heads in which plates of gold were set. Moulds for sickles, lance-heads, and bracelets were found cut in stone or made in baked clay. From four to five hundred vessels of pottery finely made and elegantly shaped are indicated by the fragments recovered from the relic bed at this station. In the settlement at Marin in the Lake of Neuchatel iron takes the place of whatever in the older lake dwellings was made either of stone, bone, or bronze. The swords are well forged, of a peculiarly fibrous iron, and furnished with iron sheaths. The spear-heads are large, sometimes as much as 18½ inches in length, with blades indented by segmental curves. Shield mountings, horse trappings, and personal ornaments such as fibulæ are here made of iron instead of bronze, and Roman and Gallic coins found in the relic bed bring the occupation of the settlement distinctly within the historic period. The antiquity of the earlier settlements of the Stone and Bronze ages is not capable of being deduced from existing evidence. "We may venture to place them," says Dr Keller, "in an age when iron and bronze had been long known, but had not come into our districts in such plenty as to be used for the common purposes of household life, at a time when amber had already taken its place as an ornament and had become an object of traffic." It is now established that the people who erected the lake dwellings in Switzerland were also the people who were spread over the mainland. The forms and the ornamentation of the implements and weapons of stone and bronze which are found in the lake dwellings are the same as those of the implements and weapons in these materials which are found in the soil of the adjacent regions, and both groups of relics must therefore be ascribed to the industry of one and the same people. Whether dwelling on the land or dwelling in the lake, they have exhibited so many indications of capacity, intelligence, industry, and social organization that they cannot be considered as presenting, even in their Stone age, a low condition of culture or civilization. Their axes were made of tough stones, sawn from the block by flint, and ground to the fitting shape. They were fixed by the butt in a socket of stag's horn, mortised into a handle of wood. Their knives and saws of flint were mounted in wooden handles and fixed with asphalt. They made and used an endless variety of bone tools. Their pottery, though roughly finished, is well made, the vessels often of large size and capable of standing the fire as cooking utensils. For domestic dishes they also made wooden tubs, plates, spoons, ladles, and the like. The industries of spinning and weaving were largely practised. They made nets and fishing lines, and used canoes. They practised agriculture, cultivating several varieties of wheat and barley, besides millet and flax. They kept horses, cattle, sheep, goats, and swine. Their clothing was partly of linen and partly of woollen fabrics and the skins of their beasts. Their food was nutritious and varied, their dwellings neither unhealthy nor incommodious. They lived in the security and comfort obtained by social organization, and were apparently intelligent, industrious, and prosperous communities.

The materials for the investigation of this singular phase of prehistoric life were first collected and systematized by the late Dr Ferdinand Keller, who died at Zürich, July 21, 1881, in the eighty-first year of his age. They were submitted in a series of seven successive reports to the Society of Antiquaries of Zürich, of which he was president, and printed in the Society's Transactions, *Mittheilungen der Antiquarischen Gesellschaft in Zürich*, vols. i.-xix., 4to, 1855-76. The substance of these reports has also been issued as a separate work in England, *The Lake Dwellings of Switzerland and other parts of Europe*, by Dr Ferdinand Keller, translated and arranged by John Edward Lee, 2d ed., 2 vols. 8vo, London, 1878. Other works on the same subject are Frédéric Troyon, *Habitations Lacustres des temps anciens et modernes*, 8vo, Lausanne, 1860; E. Desor, *Les Palafittes ou Constructions Lacustres du Lac de Neuchatel*, 8vo, Paris, 1865; E. Desor and L. Favre, *Le Bel Âge du Bronze Lacustre en Suisse*, folio, Paris, 1874; A. Perrin, *Étude préhistorique sur la Savoie specialement a l'époque lacustre (Les Palafittes du Lac de Bourget)*, 4to, Paris, 1870; Ernest Chantre, *Les Palafittes ou Constructions Lacustres du Lac de Paladru*, folio, Chambery, 1871; Bartolomeo Gastaldi, *Lake Habitations and prehistoric Remains in the Turbaries and Marl-beds of Northern and Central Italy*, translated by C. H. Chambers, 8vo, London, 1865; Sir John Lubbock, *Prehistoric Times*, 4th ed., 8vo, London, 1878. (J. AN.)

LAKHIMPUR, or LUCKIMPOOR, a British district in the extreme east of the province of Assam, extending from 26° 51′ to 27° 54′ N. lat., and from 93° 49′ to 96° 4′ E. long. It lies along both banks of the Brahmaputra, which belongs to the district for about 400 miles of its course; and it is bounded N. by the Daphla, Miri, Abar, and Mishmi hills, E. by the Mishmi and Singpho hills, S. by the watershed of the Patkai range and the Lohit branch of the Brahmaputra, and W. by the districts of Darrang and Sibsagar. To the north and north-east the frontier is undefined. The Brahmaputra is navigable for steamers in all seasons as far as Dibrugarh, in the rainy season as far as Sadiya; its navigable tributaries within the district are the Subansiri, Dibru, and Buri Dihing. The greater part of the area (11,500 square miles) is sparsely occupied by independent hill tribes, and only 3200 square miles are directly under British administration. The elephant, rhinoceros, bear, buffalo, wild cattle, and deer are abundant; the capturing of elephants is a Government monopoly worth from £3000 to £4500 annually. Coal and petroleum (both worked for a short time about 1866), building stone, limestone, and ironclay exist in the district; and gold has been washed in the hill streams from time immemorial. Rice was grown on 39,460 acres in 1871. Tea is grown with European capital and under European supervision, and has in recent years made great progress, the plantations in 1874 covering 89,370 acres. Silk cloth is made from the cocoons of the *mugá* worm (*Saturnia assamungis*), which feeds on the *súm* tree; but the manufacture has greatly fallen off. A thousand cocoons yield 6 or 8 oz. of thread, worth 10s. to 11s. per pound. The exports of Lakhimpur are tea, mugá silk, india-rubber, beeswax, ivory, and mustard seed; the imports rice, opium, tobacco, salt, oil, and cotton cloth. The annual fair established by the Government at Sadiya is less of commercial than of political importance.

The population of the settled district in 1871–72 was 121,267, residing in 125 villages, and including 28,388 aborigines, 68,388 semi-Hinduized aborigines, 19,748 caste Hindus, 3826 Mohammedans. The most numerous Hindu caste was the Kolitá (3406), the former priests of the aboriginal kings of Assam; they have now taken to agriculture, and rank as pure Súdras. Of the semi-Hinduized aborigines the most numerous tribe is the Aham, the former rulers of the country (43,942). The hill tribes of the unsettled district are broadly distinguished into a Shan group (Khamtis and Singphos) and an Indo-Chinese group (Mishmis, Abars, Miris, Daphlas, &c.). Most, if not all of them, have sent out little colonies who settle on the borders of the plains. There are no towns in the Lakhimpur district. Dibrugarh, on the Dibru, a few miles above its junction with the Brahmaputra, is the chief civil station, with a population of 3870 in 1872. Lakhimpur figures largely in the annals of Assam as the region where successive invaders from the east first reached the Brahmaputra. The Bara Bhuiyas, originally from the western provinces of India, were driven out by the Chutias (a Shan race), and these in their turn gave place to their more powerful brethren, the Ahams, in the 13th century. The Burmese, who had ruined the native kingdoms, were expelled by the British in 1825; but it was not till 1839 that the country was taken under direct British management.

LALANDE, Joseph Jérôme Lefrançais de (1732–1807), a noted astronomer, was born at Bourg (department of Ain), July 11, 1732. His parents, who were in easy circumstances, sent him to Paris to study the law; but the accident of lodging in the Hôtel Cluny, where Delisle had his observatory, determined his astronomical vocation, and he became the zealous and favoured pupil of both Delisle and Lemonnier. He, however, completed his legal studies, and was on the point of returning to Bourg to practise there as an advocate, when Lemonnier obtained permission to send him, in his own place, to Berlin, for the purpose of making observations on the lunar parallax in concert with those of Lacaille at the Cape of Good Hope. The successful execution of his task procured for him, before he was twenty-one, admission to the Academy of Berlin, and the post of adjunct astronomer to that of Paris. He now devoted himself to the improvement of the planetary theory, publishing in 1759 a corrected edition of Halley's tables, with a history of the celebrated comet whose return in that year he had aided Clairaut to calculate. In 1762, Delisle resigned in his favour the chair of astronomy in the Collége de France, the duties of which were discharged by Lalande with *éclat* during forty-six years. His house became an astronomical seminary, and amongst his pupils were Delambre, Piazzi, Mechain, and his own nephew, Michel Lalande. By his publications in connexion with the transit of 1769 he won great and, in some respects, deserved fame. But his love of notoriety fully equalled his scientific zeal, and earned for him as much ridicule as his impetuous temper did hostility. These faults were partially outweighed by his generosity and benevolence. A strict adherence to hygienic rules long preserved his health, but eventually shortened his life. He died April 4, 1807, of consumption aggravated by systematic exposure to cold.

Although his investigations were conducted with diligence rather than genius, the career of Lalande must be regarded as of eminent service to astronomy. By his talents as a lecturer and writer he gave to the science unexampled popularity; his planetary tables, into which he introduced corrections for mutual perturbations, were the best available up to the end of the last century; and the Lalande prize, instituted by him in 1802 for the chief astronomical performance of each year, still testifies to his enthusiasm for his favourite pursuit. Amongst his voluminous works are *Traité d'Astronomie*, 2 vols. 4to, 1764 (enlarged edition, 4 vols., 1771–81, 3d edition, 3 vols., 1792); *Histoire céleste Française*, 1801, giving the places of 50,000 stars; *Bibliographie astronomique*, 1803, with a history of astronomy from 1781 to 1802; *Astronomie des Dames*, 1785; *Abrégé de Navigation*, 1793; *Voyage d'un François en Italie*, 1769, a valuable record of his travels in 1765–66. He communicated above one hundred and fifty papers to the Paris Academy of Sciences, edited the *Connoissance des Temps*, 1759–1774, and again 1794–1807, and wrote the concluding 2 vols. of the 2d edition of Montucla's *Histoire des Mathématiques*, 1802.

LALITPUR, or Lullitpoor, a British district in the lieutenant-governorship of the North-Western Provinces, India, extending from 24° 9′ to 25° 14′ N. lat., and from 78° 12′ to 79° 2′ E. long., with an area of 1947 square miles. It is bounded N. and W. by the river Betwa, S.W. by the Narayan, S. by the Vindhyachal Gháts and the Ságar (Saugor) district of the Central Provinces, S.E. and E. by Orchha state and the Dhasan. The district is an undulating plain about 1500 feet on an average above the sea-level, in the hill country of Bundelkhand, sloping gradually northwards from the Vindhya range to the Betwa and Jumna. It is drained by several important tributaries of the Jumna, and an immense number of smaller streams; but their rapid and frequently swollen currents, instead of fertilizing, impoverish the land and sweep away embankments and bridges. The general condition of the district is far from prosperous. A large proportion of the area is covered with jungle, and the poor-looking villages are few and far between. Only 366 square miles were under tillage in 1872; the food stuffs (mainly wheat, grain, barley, and millet) are never produced in much greater quantity than is necessary for local consumption, and a bad year results in scarcity, if not famine. As but little is done in the way of irrigation, the spring harvest is a very poor one; and if the rainfall sinks much below its average of 40 inches the autumn harvest is also scanty.

In 1865 the population was 248,146; in 1872 it was only 212,661, while the number of villages had fallen from 750 to 646. About 98 per cent. (207,788) of the inhabitants in 1872 were Hindus—the Brahmans numbering 20,657, Rajputs 20,985, Banias 11,356. The Rajput Bundelas are the most important socially, the Banias commercially. A few Gonds are found in the south, and about 10,000 Sabariyas, a degraded body of savages known to the police throughout India as professional thieves, are scattered throughout the jungle. The district is administered on the non-regulation system by a deputy-commissioner. The only municipality is Lalitpur town (population 8976 in 1872). The Gonds are the earliest known inhabitants of Lalitpur; they have left traces of their ultimate high state of civilization in temples and reservoirs. They were succeeded by the Chandel princes of Máhoba, who in their turn gave place to a number of petty independent rulers. In the 14th century the Bundelas invaded the country, and Lalitpur finally became a part of the state of Chanderi, which continued for the most part practically independent till the beginning of the 19th century, when Sindhia, provoked by raids into Gwalior, sent Colonel Baptiste against Lalitpur, and took the government under his direct control. In 1829 two-thirds of his territory was restored to the Chanderi sovereign. The remainder of the country, which was retained by Sindhia, was in 1844 made over to the British Government. The Bundela chiefs of Lalitpur were among those who most eagerly joined the mutiny, and it was only after a severe struggle that the district was again pacified.

LALLY, Thomas Arthur, Baron De Tollendal, Count de (1702-1766), French general, descended from an old Irish family who emigrated to France along with the Stuarts, was born in Dauphiné in January 1702. His father, colonel in an Irish-French regiment, familiarized him with active service from his boyhood, and he rose step by step in a career distinguished for bravery and conduct till in 1744 he was created a brigadier by Louis XV. on the field of Fontenoy. Previous to this he had been engaged in several plots for the restoration of the Stuarts, and in 1745 he accompanied Charles Edward to Scotland, serving as aide-de-camp at the battle of Falkirk. Escaping in disguise to France, he joined the army of Marshal Saxe in the Low Countries, and for his conduct at the capture of Maestricht in 1748 received the grade of marshal of the camp. When the French in 1756 resolved to fit out an expediton to recover their power in India, Lally was appointed to the chief command. Arriving at Pondicherri in 1758, he alarmed the English by his first successes, and even laid siege to Madras. But he was ill supported by his countrymen, his military chest was empty, and his bravery and zeal were not combined with the qualities necessary for success in Indian administration. Madras was relieved by a British fleet, and the English under Coote assumed the offensive, and inflicted a severe defeat on Lally at Wandiwash. He still made a long and stubborn resistance, but was ultimately besieged in Pondicherri and compelled to surrender in January 1761. Returning to France on parole, he was thrown into prison. Popular indignation at the collapse of French power in India demanded a victim, and the parliament of Paris sentenced him to death on a vague and frivolous accusation. The judicial murder of Lally (9th May 1766) was exposed by Voltaire, and his son Lally-Tollendal obtained in 1778 the formal reversal of the sentence.

LĀMĀISM is partly religious, partly political. Religiously it is the corrupt form of Buddhism prevalent in Tibet and Mongolia. It stands in a relationship to primitive Buddhism similar to that in which Roman Catholicism, so long as the temporal power of the pope was still in existence, stood to primitive Christianity. The ethical and metaphysical ideas most conspicuous in the doctrines of Lāmāism are not confined to the highlands of Central Asia, they are accepted in great measure also in Japan and China. It is the union of these ideas with a hierarchical system, and with the temporal sovereignty of the head of that system in Tibet, which constitutes what is distinctively understood by the term Lāmāism. Lāmāism is hardly calculated to attract much attention for its own sake. Tibetan superstitions and Tibetan politics are alike repugnant to Western minds. But, as so many unfounded beliefs and curious customs have a special value of their own to the student of folklore, so Lāmāism has acquired a special interest to the student of comparative history through the instructive parallel which its history presents to that of the Church of Rome.

The central point of primitive Buddhism was the doctrine of "Arahatship,"—a system of ethical and mental self-culture, in which deliverance was found from all the mysteries and sorrows of life in a change of heart to be reached here on earth. This doctrine seems to have been held very nearly in its original points from the time when it was propounded by Gotama in the 5th century B.C. down to the period in which northern India was invaded and conquered by the Huns at about the commencement of the Christian era. At that time there had arisen a school of Buddhist teachers who called their doctrine the "Great Vehicle." It was not in any contradiction to the older doctrine, which they contemptuously called the "Little Vehicle," but included it all, and was based upon it. The distinguishing characteristic of the newer school was the importance which it attached to "Bodisatship." The older school had taught that Gotama, who had propounded the doctrine of Arahatship, was a Buddha, that only a Buddha is capable of discovering that doctrine, and that a Buddha is a man who by self-denying efforts, continued through many hundreds of different births, has acquired the so-called *Ten Pāramitās* or cardinal virtues in such perfection that he is able, when sin and ignorance have gained the upper hand throughout the world, to save the human race from impending ruin.[1] But until the process of perfection has been completed, until the moment when at last the sage, sitting under the Bo tree, acquires that particular insight or wisdom which is called Enlightenment or Buddhahood, he is still only a Bodisat. And the link of connexion between the various Bodisats in the future Buddha's successive births is not a soul which is transferred from body to body, but the *karma*, or character, which each successive Bodisat inherits from his predecessors in the long chain of existences. Now the older school also held, in the first place, that, when a man had, in this life, attained to Arahatship, his karma would not pass on to any other individual in another life,—or in other words, that after Arahatship there would be no rebirth; and, secondly, that four thousand years after the Buddha had proclaimed the *Dhamma* or doctrine of Arahatship, his teaching would have died away, wickedness and ignorance would have increased in the world, and another Buddha would be required to bring mankind once more to a knowledge of the truth. The leaders of the Great Vehicle urged their followers to seek to attain, not so much to Arahatship, which would involve only their own salvation, but to Bodisatship, by the attainment of which they would be conferring the blessings of the Dhamma upon countless multitudes in the long ages of the future. By thus laying stress upon Bodisatship, rather than upon Arahatship, the new school, though they doubtless merely thought themselves to be carrying the older orthodox doctrines to their logical conclusion, were really changing the central point of Buddhism, and were altering the direction of their mental vision. It was of no avail that they adhered in other respects in the main to the older teaching, that they professed to hold to the same ethical system, that they adhered, except in a few unimportant details, to the old regulations of the order of the Buddist mendicant recluses. The ancient books, still preserved to us in the *Pāli Pitakas*, being mainly occupied with the details of Arahatship, lost their exclusive value in the eyes of those whose attention was being directed to the details of Bodisatship. And the opinion that every leader in their religious circles, every teacher distinguished among them for his sanctity of life, or for his extensive learning, was a Bodisat, who might have and who probably had inherited the karma of some great teacher of old, opened the door to a flood of superstitious fancies.

It is worthy of note that the new school found its earliest professors and its greatest expounders in a part of India which lay outside the districts to which the personal influence of Gotama himself and of his immediate followers had been confined. The home of early Buddhism was round about Kosala and Magadha; in the district, that is to say, north and south of the Ganges between where Allahabad now lies on the west, and Rajgir on the east. The home of the Great Vehicle was, at first, in the countries farther to the north and west. Buddhism arose in countries, subject indeed to Brahman influence, but where the sacred language of the Brāhmans was never more than a learned tongue, and where the exclusive

[1] See, for instance, the *Buddhist Birth Stories*, pp. 19-27 and 53-58.

claims of the Brahmans had never been universally admitted. The Great Vehicle arose in the very stronghold of Brāhmanism, and among a people to whom Sanskrit was a familiar tongue. The new literature therefore, which the new movement called forth, was written, and has been preserved, in Sanskrit,—its principal books of *Dharma*, or doctrine, being the following nine:—(1) *Prajñā-pāramitā*; (2) *Gaṉḏa-vyūha*; (3) *Dasa-bhūmesvara*; (4) *Samādhi-rāja*; (5) *Laṅkāvatāra*; (6) *Saddharma-puṉḏarīka*; (7) *Tathāgata-guhyaka*; (8) *Lalita-vistara*; (9) *Suvarna-prabhāsa.* The date of none of these works is known with any certainty, but it is highly improbable that any one of them is older than the 6th century after the death of Gotama. Copies of all of them were brought to Europe by Mr B. H. Hodgson, and other copies have been received since then; but none of them have as yet been published in Europe (the *Lalita Vistara* has been published by Rājendra Lāl Mitra in Calcutta), and only two have been translated into any European language. These are the *Lalita Vistara*, translated into French, through the Tibetan, by M. Foucaux, and the *Saddharma Puṉḏarīka*, translated into French by M. Eugène Burnouf. The former of these two is a legendary work, partly in verse, on the life of Gotama, the historical Buddha; and the latter, also partly in verse, is devoted to proving the essential identity of the Great and the Little Vehicle and the equal authenticity of both as doctrines enunciated by the master himself.

Of the authors of these nine works, as indeed of all the older Buddhist works with one or two exceptions, nothing has as yet been ascertained. The founder of the system of the Great Vehicle is, however, often referred to under the name of Nagarjuna or Nāgasena, a personage celebrated even in the countries to which the Greater Vehicle has never penetrated as the contemporary and religious instructor of the Yavana king Milinda, and as the answerer of the famous *Questions of Milinda*, a work still preserved in its Pāli form.[1] As Milinda may with all probability be identified with the Greek king Menander, who was one of the followers of Alexander the Great in Bactria, this tradition would imply that the origin of the Great Vehicle must be assigned to as early a date as the 2d century B.C. But the work itself was probably composed at least some centuries afterwards; and it would be hazardous to attach too much importance to any chronological data drawn from it. We must be content at present to settle a certain historical sequence in the principal doctrines of the system which developed into Lāmaism, without pretending to fix any actual dates.

Together with Nāgasena, other early teachers of the Great Vehicle whose names are known to us are Vasumitra or Vasubandhu, Āryadeva, Dharmapāla, and Gunamati—all of whom were looked upon as Bodisats. As the newer school did not venture so far as to claim as Bodisats the disciples stated in the older books to have been the contemporaries of Gotama (they being precisely the persons known as Arahats), they attempted to give the appearance of age to the Bodisat theory by representing the Buddha as being surrounded, not only by his human companions the Arahats, but also by fabulous beings, whom they represented as the Bodisats existing at that time. In the opening words of each Mahāyāna treatise a list is given of such Bodisats, who were beginning, together with the historical Bodisats, to occupy a position in the Buddhist church of those times similar to that occupied by the saints in the corresponding period of the history of Christianity in the Church of Rome. And these lists of fabulous Bodisats have now a distinct historical importance. For they grow in length in the later works; and it is often possible by comparing them one with another to fix, not the date, but the comparative age of the books in which they occur. Thus it is a fair inference to draw from the shortness of the list in the opening words of the *Lalita Vistara*, as compared with that in the first sections of the *Saddharma Puṉḏarīka*, that the latter work is much the younger of the two, a conclusion supported also by other considerations.

Among the Bodisats mentioned in the *Saddharma Puṉḏarīka*, and not mentioned in the *Lalita Vistara*, as attendant on the Buddha are Manju-srī and Avalokitesvara. That these saints were already acknowledged by the followers of the Great Vehicle at the beginning of the 5th century is clear from the fact that Fa Hian, who visited India about that time, says that "men of the Great Vehicle" were then worshipping them at Mathura, not far from Delhi (F. H., chap. xvi.). These were supposed to be celestial beings who, inspired by love of the human race, had taken the so-called Great Resolve to become future Buddhas, and who therefore, very naturally, descended from heaven when the actual Buddha was on earth, to pay reverence to him, and to learn of him. The belief in them probably arose out of the doctrine of the older school, which did not deny the existence of the various creations of Brahmanical mythology and speculation, but allowed of their actual existence as spiritual beings, and only deprived them of all power over the lives of men, and declared them to be temporary beings liable like men to sin and ignorance, and requiring like men the salvation of Arahatship. Among them the later Buddhists seem to have placed their numerous Bodisats; and to have paid especial reverence to Manju-srī as the personification of wisdom, and to Avalokiteswara as the personification of overruling love. The latter indeed occupies in the Mahāyāna very much the position which the old Brahmanical god Brahma, the First Cause of the Brahmanical speculation, had been allowed to retain in primitive Buddhism. The former was afterwards identified with the mythical first Buddhist missionary, who is supposed in the legend to have introduced civilization into Tibet about two hundred and fifty years after the death of the Buddha.

The way was now open to a rapid fall from the simplicity of early Buddhism, in which men's attention was directed to the various parts of the system of self-culture which men could themselves practise, to a belief in a whole pantheon of saints or angels, which appealed more strongly to the half-civilized races among whom the Great Vehicle was now professed. A theory sprang up which was supposed to explain the marvellous powers of the Buddhas by representing them as only the outward appearance, the reflexion, as it were, or emanation, of ethereal Buddhas dwelling in the skies. These were called *Dhyāni Buddhas*, and their number was supposed to be, like that of the Buddhas, innumerable. Only five of them, however, occupied any space in the speculative world in which the ideas of the later Buddhists had now begun to move. But, being Buddhas, they were supposed of course to have their Bodisats; and thus out of the five last Buddhas of the earlier teaching there grew up five mystic trinities, each group consisting of one of these five Buddhas, his prototype in heaven the Dhyāni Buddha, and his celestial Bodisat. Among these hypothetical beings, the creations of a sickly scholasticism, hollow abstractions without life or reality, the particular trinity in which the historical Gotama was assigned a subordinate place naturally occupied the most exalted rank. Amitābha, the Dhyāni-Buddha of this trinity, soon began to fill the largest place in the minds of the new school; and Avalokiteswara, his Bodisat, was looked upon with a reverence somewhat less than his former glory. It is needless to add that, under the overpowering

[1] Edited by Dr V. Trenckner, London, 1880.

influence of these vain imaginations, the earnest moral teachings of Gotama became more and more hid from view. The imaginary saints grew and flourished. Each new creation, each new step in the theory, demanded another, until the whole sky was filled with forgeries of the brain, and the nobler and simpler lessons of the founder of the religion were hidden beneath the glittering stream of metaphysical subtleties.

Still worse results followed on the change of the earlier point of view. The acute minds of the Buddhist pandits, no longer occupied with the practical lessons of Arahatship, turned their attention, as far as it was not engaged upon their hierarchy of mythological beings, to questions of philosophical speculation, which, in the earliest Buddhism, are not only discouraged but forbidden. We find long treatises on the nature of being, idealistic dreams which have as little to do with the Bodisatship that is concerned with the salvation of the world as with the Arahatship that is concerned with the perfect life. Only one lower step was possible, and that was not long in being taken. The animism common alike to the untaught Huns and to their Hindu conquerors, but condemned in early Buddhism, was allowed to revive. As the stronger side of Gotama's teaching was neglected, the debasing belief in rites and ceremonies, and charms and incantations, which had been the especial object of his scorn, began to live again, and to grow vigorously, and to spread like the Bīrana weed warmed by a tropical sun in marsh and muddy soil. As in India, after the expulsion of Buddhism, the degrading worship of Siva and his dusky bride had been incorporated into Brahmanism from the wild and savage devil worship of Āryan and of non-Āryan tribes, so, as pure Buddhism died away in the north, the *Tantra* system, a mixture of magic and witchcraft and sorcery, was incorporated into the corrupted Buddhism.

The founder of this system seems to have been Asanga, an influential monk of Peshāwar, in the Punjab, who lived and wrote the first text-book of the creed, the *Yogāchchāra Bhūmi Śāstra*, about the 6th century of our era. Hwen Tsang, who travelled in the first half of the 7th, found the monastery where Asanga had lived in ruins, and says that he had lived one thousand years after the Buddha.[1] He managed with great dexterity to reconcile the two opposing systems by placing a number of Saivite gods or devils, both male and female, in the inferior heavens of the then prevalent Buddhism, and by representing them as worshippers and supporters of the Buddha and of Avalokitesvara. He thus made it possible for the half-converted and rude tribes to remain Buddhists while they brought offerings, and even bloody offerings, to these more congenial shrines, and while their practical belief had no relation at all to the Truths or the Noble Eightfold Path, but busied itself almost wholly with obtaining magic powers (*Siddhi*), by means of magic phrases (*Dhārani*), and magic circles (*Maṇḍala*). Asanga's happy idea bore but too ample fruit. In his own country and Nepāl the new wine, sweet and luscious to the taste of savages, completely disqualified them from enjoying any purer drink; and now in both countries Saivism is supreme, and Buddhism is even nominally extinct, except in some outlying districts of Nepāl. But this full effect has only been worked out in the lapse of ages; the Tantra literature has also had its growth and its development, and some unhappy scholar of a future age may have to trace its loathsome history. The nauseous taste repelled even the self-sacrificing industry of Burnouf, when he found the later Tantra books to be as immoral as they are absurd. "The pen," he says, "refuses to transcribe doctrines as miserable in respect of form as they are odious and degrading in respect of meaning."[2]

Such had been the decline and fall of Buddhism considered as an ethical system before its introduction into Tibet. The manner in which its order of mendicant recluses, at first founded to afford better opportunities to those who wished to carry out that system in practical life, developed at last into a hierarchical monarchy will best be understood by a sketch of the history of Tibet.

In Tibet as elsewhere the beginnings of the accounts found in the old historians are merely a recapitulation of legends in which popular tradition has explained by miraculous and mythological fancies the origins of its civilization. Its real history commences with Srong Tsan Gampo, who was born a little after 600 A.D., and who is said in the Chinese chronicles to have entered, in 634 after Christ, into diplomatic relationship with Thai Tsung, one of the emperors of the Thung dynasty. He was the founder of the present capital of Tibet, now known as Lhasa; and in the year 622 (the same year as that in which Mohammed fled from Mecca) he began the formal introduction of Buddhism into Tibet. For this purpose he sent the minister Thumi Sambhota, afterwards looked upon as an incarnation of Mañju-srī, to India, there to collect the sacred books, and to learn and translate them. Thumi Sambhota accordingly invented an alphabet for the Tibetan language on the model of the Indian alphabets then in use. And, aided by the king himself, who is represented to have been an industrious student and translator, he wrote the first books by which Buddhism became known in his native land. The most famous of all the works ascribed to him is the *Mani Kambum*, "the Myriad of Precious Words,"—a treatise chiefly on religion, but which also contains an account of the introduction of Buddhism into Tibet, and of the closing part of the life of king Srong Tsan Gampo. He is also very probably the author of another very ancient standard work of Tibetan Buddhism, the *Samatog*, a short digest of Buddhist morality, on which the civil laws of Tibet have been founded. It is said in the *Mani Kambum* to have fallen down from heaven in a casket (Tibetan, *samatog*), and, like the last-mentioned work, is unfortunately only known to us in meagre abstract.

King Srong Tsan Gampo's zeal for Buddhism was shared and supported by his two queens, the one named Bribsun, a princess from Nepāl, the other named Wen Ching, a princess from China. They are related in the chronicles to have brought with them sacred relics, books, and pictures, for whose better preservation and honour two large monasteries were erected, and opened and dedicated with much ceremony. These are the cloisters of La Brang and Ra Mochay, still, though much changed and enlarged, the most famous and sacred abbeys in Tibet, and the glory of Lhasa. In after times the two queens have become semi-divine personages, and are worshipped under the name of the two *Dārā-Eke*, the "glorious mothers," being regarded as incarnations of the wife of Siva, representing respectively two of the qualities which she personifies, divine vengeance and divine love. The former of the two is worshipped by the Mongolians as *Okkin Tengri*, "the Virgin Goddess;" but in Tibet and China the rôle of the divine virgin is filled by *Kwan Yin*, a personification of Avalokitesvara as the heavenly word, who is often represented with a child in her arms. Srong Tsan Gampo has also become a saint, being looked upon as an incarnation of Avalokitesvara; and the description in the ecclesiastical historians of the measures he took for the welfare of his subjects do great credit to their ideal of the perfect Buddhist king. He is

[2] *Introduction*, &c., p. 558.

said to have spent his long reign in the building of reservoirs, bridges, and canals; in the promotion of agriculture, horticulture, and manufactures; in the establishment of schools and colleges; and in the maintenance of justice, and the encouragement of virtue. But the degree of his success must have been slight. For after the death of himself and of his wives Buddhism gradually decayed, and was subjected by succeeding kings to cruel persecutions; and it was not till more than half a century afterwards, under King Kir Song de Tsan, who reigned 740–786, that true religion is acknowledged by the ecclesiastical historians to have become firmly established in the land.

This monarch again sent to India to replace the sacred books that had been lost, and to invite Buddhist pandits to translate them. The most distinguished of those who came were Santa Rakshita, Padma Sambhava, and Kamala Sīla, for whom, and for their companions, the king built a splendid monastery still existing, at Samje, about three days' journey south-east of Lhasa. It was to them that the Tibetans owed the great collection of what are still regarded as their sacred books—the *Kandjur*. It consists of 100 volumes containing no less than 689 works, of which there are two or three complete sets in Europe, one of them in the India Office Library. A detailed analysis of these Scriptures has been published by the celebrated Hungarian scholar Csoma de Körös, whose authoritative work has lately been republished in French with complete indices and very useful notes by M. Léon Feer. These volumes contain about a dozen works of the oldest school of Buddhism, the Hīnayāna, and about 300 works, mostly very short, belonging to the Tantra school. But the great bulk of the collection consists of Mahāyāna books, belonging to all the previously existing varieties of that widely extended Buddhist sect; and, as the Sanskrit originals of many of these writings are now lost without hope of recovery, the Tibetan translations will be of great value, not only for the history of Lāmāism, but also for the history of the later forms of Indian Buddhism.

The last king's second son, Lang Darma, concluded in May 822 a treaty with the then emperor of China (the twelfth of the Thang dynasty), a record of which was engraved on a stone put up in the above mentioned great convent of La Brang, and is still to be seen there.[1] He is described in the church chronicles as an incarnation of the evil spirit, and is said to have tried his best to overthrow religion, and to have succeeded in suppressing Buddhism throughout the greater part of the land. The period from Srong Tsan Gampo down to the death of Lang Darma, who was eventually murdered about 850 A.D., in a civil war, is called in the Buddhist books "the first introduction of religion." It was followed by more than a century of civil disorder and wars, during which the exiled Buddhist monks attempted unsuccessfully again and again to return. Many are the stories of martyrs and confessors who are believed to have lived in these troublous times, and their efforts were at last crowned with success, for in the century commencing with the reign of Bilamgur in 971 there took place "the second introduction of religion" into Tibet, more especially under the guidance of the Pandita Atīsha, who came to Tibet in 1041, and of his famous native pupil and follower Brom Ston. The long period of depression seems not to have been without a beneficial influence on the persecuted Buddhist Church, for these teachers are reported to have placed the Tantra system more in the background, and to have adhered more strongly to the purer forms of the Mahāyāna development of the ancient faith.

[1] Published with facsimile and translation and notes in the *Journal of the Royal Asiatic Society* for 1879–80, vol. xii.

For about three hundred years the Buddhist Church of Tibet was then left in peace, subjecting the country more and more completely to its control, and growing in power and in wealth. During this time it achieved its greatest victory, and underwent the most important change in its character and organization. After the reintroduction of Buddhism into the "kingdom of snow," the ancient dynasty never recovered its power. Its representatives continued for some time to claim the sovereignty; but the country was practically very much in the condition of Germany at about the same time—chieftains of almost independent power ruled from their castles on the hill tops over the adjacent valleys, engaged in petty wars, and conducted plundering expeditions against the neighbouring tenants, whilst the great abbeys were places of refuge for the studious or religious, and their heads were the only rivals to the barons in social state, and in many respects the only protectors and friends of the people. Meanwhile Jenghiz Khān had founded the Mongol empire, and his grandson Kublai Khān, who ruled over the greatest empire which has ever owned the sway of a single man, became a convert to the Buddhism of the Tibetan Lāmas. He granted to the abbot of the Sakya monastery in southern Tibet the title of tributary sovereign of the country, head of the Buddhist Church, and overlord over the numerous barons and abbots, and in return was officially crowned by the abbot as ruler over the extensive domain of the Mongol empire. Thus was the foundation laid at one and the same time of the temporal sovereignty of the Lāmas of Tibet, and of the suzerainty over Tibet of the emperors of China. One of the first acts of the "head of the church" was the printing of a carefully revised edition of the Tibetan Scriptures,—an undertaking which occupied altogether nearly thirty years, and was not completed till 1306.

Under Kublai's successors in China the Buddhist cause flourished greatly, and the Sākya Lāmas extended their power both at home and abroad. The dignity of abbot at Sākya became hereditary, the abbots breaking so far the Buddhist rule of celibacy that they remained married until they had begotten a son and heir. But rather more than half a century afterwards their power was threatened by a formidable rival at home, a Buddhist reformer.

Tsongkapa, the Luther of Tibet, was born about 1357 on the spot where the famous monastery of Kunbum now stands. He very early entered the order, and studied at Sākya, Brigung, and other monasteries. He then spent eight years as a hermit in Takpo in southern Tibet, where the comparatively purer teaching of Atīsha (referred to above) was still prevalent. About 1390 he appeared as a public teacher and reformer in Lhasa itself, and before his death in 1419 there were three huge monasteries there containing 30,000 of his disciples, besides others in other parts of the country. His voluminous works, of which the most famous are the *Sumbun* and the *Lam Nim Tshenpo*, exist in printed Tibetan copies in Europe, but have not as yet been translated or analysed. But the principal lines on which his reformation proceeded are sufficiently well attested. He insisted in the first place on the complete carrying out of the ancient rules of the order as to the celibacy of its members, and as to simplicity in dress. One result of the second of these two reforms was to make it necessary for every monk openly to declare himself either in favour of or against the new views. For Tsongkapa and his followers wore the yellow or orange-coloured garments which had been the distinguishing mark of the order in the lifetime of its founder, and in support of the ancient rules Tsongkapa reinstated the fortnightly rehearsal of the *Pātimokkha* or "disburdenment" in regular assemblies of the order at Lhasa—a practice which had fallen into desuetude. He also restored the custom of the first disciples to hold the so-called *Vassa* or yearly retirement, and the public meeting of the order at its close. In all these respects he was simply following the directions of the Vinaya, or regulations of the order, as established probably in the time of Gotama himself, and as certainly handed down from the earliest times in the piṭakas or sacred books. Further, he set his face against the Tantra system, and against the whole crowd of animistic superstitions which had been allowed to creep into life again among the more ignorant of the monks and the people. He laid stress on the self-culture involved in the practice of the pāramitās or cardinal virtues, and established an annual national fast or week of prayer to be held during the first days of each year. This last institution indeed is not found in the ancient Vinaya, but was almost certainly modelled on the traditional account of the similar assemblies convoked by Asoka and other Buddhist sovereigns in India every fifth year. Laymen as well as monks take part in the proceedings, the details of which are entirely unknown to us except from the accounts of the Catholic missionaries, —Fathers Huc and Gabet,—who describe the principal ceremonial as, in outward appearance, wonderfully like the high mass. In doctrine the great Tibetan teacher, who had no access to the Pāli Piṭakas, adhered in the main to the purer forms of the Mahāyāna school; in questions of church government he took little part, and did not dispute the titular supremacy of the Sākya Lāmas, though in other matters he had raised the standard of revolt. But the effects of his teaching weakened their power. The "orange-hoods," as his followers were called, rapidly gained in numbers and influence, until they so overshadowed the "red-hoods," as the followers of the older sect were called, that in the middle of the 15th century the emperor of China acknowledged the two leaders of the new sect at that time as the titular overlords of the church and tributary rulers over the realm of Tibet. These two leaders were then known as the *Dalai Lāma* and the *Pantshen Lāma*, and were the abbots of the great monasteries at Gedun Dubpa, near Lhasa, and at Krashis Lunpo, in Further Tibet, respectively. Since that time the abbots of these monasteries have continued to exercise the sovereignty over Tibet,—their pretensions being supported, in the few cases in which an attempt has been made to dispute it, by the power of Mongolia and China.

As there has been no further change in the doctrine, and no further reformation in discipline, we may leave the ecclesiastical history of Lāmāism since that date unnoticed, and devote our little remaining space to the consideration of some principal points in the constitution of the Lāmāism of to-day. And first as to the mode of electing successors to the two Great Lāmas. It will have been noticed above that it was an old idea of the northern Buddhists to look upon distinguished members of the order as incarnations of Avalokitesvara, of Mañju-srī, or of Amitābha. These beings were supposed to possess the power, whilst they themselves continued to live in heaven, of appearing also on earth in a *Nirmāna-kāya*, or apparitional body. In the same way the Pantshen Lāma is looked upon as an incarnation, the Nirmāna-kāya, of Amitābha, who had previously appeared in that way under the outward form of Tshonkapa himself; and the Dalai Lāma is looked upon as an incarnation of Avalokitesvara. Theoretically, therefore, the former, as the spiritual successor of the great teacher and also of Amitābha, who occupies the higher place in the mythology of the Great Vehicle, would be superior to the latter, as the spiritual representative of Avalokitesvara. But practically the Dalai Lāma, owing to his position in the capital, has the political supremacy, and is actually called the *Gyalpo Rinpotshe*, "the glorious king,"—his companion being content with the title *Pantshen Rinpotshe*, "the glorious teacher." When either of them dies it is necessary for the other to ascertain in whose body the celestial being whose outward form has been dissolved has been pleased again to incarnate himself. For that purpose the names of all male children born just after the death of the deceased Great Lāma are laid before his survivor. He chooses three out of the whole number; their names are thrown into a golden casket provided for that purpose by a former emperor of China. The Chutuktus, or abbots of the great monasteries, then assemble, and after a week of prayer, the lots are drawn in their presence and in presence of the surviving Great Lāma and of the Chinese political resident. The child whose name is first drawn is the future Great Lāma; the other two receive each of them 500 pieces of silver. The Chutuktus just mentioned correspond in many respects to the Roman cardinals. Like the Great Lāmas, they bear the title of Rinpotshe or Glorious, and are looked upon as incarnations of one or other of the celestial Bodisats of the Great Vehicle mythology. Their number varies from ten to a hundred; and it is uncertain whether the honour is inherent in the abbacy of certain of the greatest cloisters, or whether the Dalai Lāma exercises the right of choosing them. Under these high officials of the Tibetan hierarchy there come the Chubil Khāns, who fill the post of abbot to the lesser monasteries, and are also incarnations. Their number is very large; and there are but few monasteries in Tibet or in Mongolia who do not claim to possess one of these living Buddhas. Besides these mystical persons there are in the Tibetan Church a number of other ranks and degrees, corresponding to the deacon, full priest, dean, and doctor of divinity in the West. At the great yearly festival at Lhasa they make in the cathedral an imposing array, not much less magnificent than that of the clergy in Rome; for the ancient simplicity of dress has quite disappeared in the growing differences of rank, and each division of the spiritual army is distinguished in Tibet, as in the West, by a special uniform. The political authority of the Dalai Lāma is confined to Tibet itself, but he is the acknowledged head also of the Buddhist Church throughout Mongolia and China. He has no supremacy over his co-religionists in Japan, and even in China there are many Buddhists who are not practically under his control or influence.

The principal authorities for the history of Buddhism have already been given at the close of the article BUDDHISM. To these may now be added T. W. Rhys Davids's *Buddhism*, London, 1878; *Buddhist Birth Stories*, London, 1880; *Buddhist Suttas from the Pāli*, Oxford, 1881; and *Hibbert Lectures*, London, 1881; also Bushell, "The Early History of Tibet," in the *Journal of the Royal Asiatic Society*, 1879–80, vol. xii.; Sanang Setsen's *History of the East Mongols* in Mongolian, translated into German by J. Schmidt (*Geschichte der Ost-Mongolen*); "Analyse du Kandjur," by M. Léon Feer, in *Annales du Musée Gaimet*, 1881; Schott, *Ueber den Buddhismus in Hoch-Asien*; Gutzlaff, *Geschichte des Chinesischen Reiches*; Huc and Gabet, *Souvenirs d'un Voyage dans la Tartarie, le Tibet, et la Chine*, Paris, 1858; Pallas's *Sammlung historischer Nachrichten über die Mongolischen Völkerschaften*; and Bābu Sarat Chunder Das's "Contributions on the Religion and History of Tibet," in the *Journal of the Bengal Asiatic Society*, 1881. (T. W. R. D.)

LAMA-MIAU, or DOLANOR, one of the chief cities of Inner Mongolia, is situated 150 miles north of Peking, in a barren sandy plain watered by the Urtingol, a tributary of the Shandugol. The town proper, almost exclusively occupied by Chinese, is about a mile in length by half a mile in breadth, has narrow and dirty streets, and contains a large population for its extent. Unlike the ordinary Chinese town of the same rank, it is not walled. A busy trade is carried on between the Chinese and the Mongolians, who bring in their cattle, sheep, camels, hides, and wool to barter for tea, tobacco, cotton, and silk. At some distance from the Chinese town lies the Mongolian quarter, with two groups of lama temples and villages occupied by 3300 priests. Dr Williamson (*Journeys in North China*) describes the chief temple as a huge oblong building with an interior not unlike a Gothic church. Lama-miau is the seat of a manufactory of bronze idols and other articles of ritual, which find their way to all parts of Mongolia and Tibet. The craftsmen work in their own houses. See Prejevalsky, *Mongolia*, 1876.

LAMARCK, Jean Baptiste Pierre Antoine de Monet, Chevalier de (1744–1829), a celebrated French naturalist, was born 1st August 1744, at Bazantin, a village of Picardy. He was an eleventh child; and his father, lord of the manor and of old family, but of limited means, having already placed three sons in the army, destined this one for the church, and sent him to the Jesuits at Amiens, where he continued till his father's death. After this he would remain with the Jesuits no longer, and, not yet seventeen years of age, started for the seat of war at Bergen-op-Zoom, before which place one of his brothers had already been killed. Mounted on an old horse, with a boy from the village as attendant, and furnished by a lady with a letter of introduction to a colonel, he reached his destination on the evening before a battle. Next morning the colonel found that the new and very diminutive volunteer had posted himself in the front rank of a body of grenadiers, and could not be induced to quit the position. In the battle, the company which he had joined became exposed to the fire of the enemy's artillery, and in the confusion of retreat was forgotten. All the officers and subalterns were killed, and not more than fourteen men were left, when the oldest grenadier seeing there were no more French in sight proposed to the young volunteer so soon become commandant to withdraw his men. This he refused to do without orders. These at last arrived; and for his bravery he was made an officer on the spot, and soon after was named to a lieutenancy.

After the peace, the regiment was sent to Monaco. There it happened that one of his comrades playfully lifted him by the head, and to this it was imputed that he was seized with disease of the glands of the neck, so severe as to necessitate grave surgical interference, and put a stop to his military career.

The courage of Lamarck, so early exhibited, was in future to be shown by the maintenance of his opinions in the absence of any friendly support, and by fortitude amid many adversities; while his activity was to be displayed, not only in manifold speculation, but in copious and varied scientific work. He went to Paris and began the study of medicine, supporting himself by working in a banker's office. He early became interested in meteorology and in physical and chemical speculations of a chimerical kind, but happily threw his main strength into botany, and in 1778 published his *Flore française*, a work in which by a dichotomous system of contrasting characters he enabled the student with facility to determine species. This work, which went through several editions and long kept the field, gained for its author immediate popularity as well as the honour of admission to the Academy of Sciences.

In 1781 and 1782, under the title of botanist to the king, an appointment obtained for him by Buffon, whose son accompanied him, he travelled through various countries of Europe, extending his knowledge of natural history; and on his return he began those elaborate contributions to botany on which his reputation in that science principally rests, namely, the *Dictionnaire de Botanique* and the *Illustrations de Genres*, voluminous works contributed to the *Encyclopédie Méthodique* (1785). In 1793, when he was already forty-nine years of age, in consequence of changes in the organization of the natural history department at the Jardin du Roi, where he had held a botanical appointment since 1788, Lamarck was presented to a zoological chair, and called on to lecture on the *Insecta* and *Vermes* of Linnæus, the animals for which he introduced the term *Invertebrata*, still employed. Thus driven, comparatively late in life, to devote his principal attention to zoology instead of botany, he had the misfortune soon after to suffer from impaired vision; and the malady progressing resulted subsequently in total blindness. Yet his greatest zoological work, the *Histoire Naturelle des Animaux sans Vertèbres*, was published from 1815 to 1822, with the assistance, in the last two volumes, of his eldest daughter and of M. Latreille. A volume of plates of the fossil shells of the neighbourhood of Paris was collected in 1823 from his memoirs in the *Annales des Muséum*. The later years of his blind old age were spent in straitened circumstances and accumulating infirmities, solaced, however, by the devotion of his family, and particularly of his eldest daughter, of whom Cuvier records that she never left the house from the time that he was confined to his room. He died 18th December 1829.

The character of Lamarck as a naturalist is remarkable alike for its excellences and its defects. His excellences were width of scope, fertility of ideas, and a pre-eminent faculty of precise description, arising not only from a singularly terse style, but from a clear insight into both the distinctive features and the resemblances of forms. That part of his zoological work which still finds a large and important place in the science of the present day, and constitutes his solid claim to the highest honour as a zoologist, is to be found in his extensive and detailed labours in the departments of living and fossil *Invertebrata*. His endeavours at classification of the great groups were necessarily defective on account of the imperfect knowledge possessed in his time in regard to many of them, *e.g.*, echinoderms, ascidians, and intestinal worms; yet they are not without interest, particularly on account of the comprehensive attempt to unite in one great division as *Articulata* all those groups that appeared to present a segmented construction. Moreover, Lamarck was the first to distinguish vertebrate from invertebrate animals by the presence of a vertebral column, and among the Invertebrata to found the groups *Crustacea*, *Arachnida*, and *Annelida*. In 1785 (*Hist. de l'Acad.*) he evinced his appreciation of the necessity of natural orders in botany by an attempt at the classification of plants, interesting, though crude and falling immeasurably short of the system which grew in the hands of his intimate friend Jussieu. The problem of taxonomy has never been put more philosophically than he subsequently put it in his *Animaux sans Vertèbres*:—"What arrangement must be given to the general distribution of animals to make it conformable to the order of nature in the production of these beings?"

The most prominent defect in Lamarck must be admitted, quite apart from all consideration of the famous hypothesis which bears his name, to have been want of control in speculation. Doubtless the speculative tendency furnished a powerful incentive to work, but it outran the legitimate deductions from observation, and led him into the production of volumes of worthless chemistry without experimental basis, as well as into spending much time on fruitless meteorological predictions. His *Annuaires Météorologiques* were published yearly from 1800 to 1810, and were not discontinued until after an unnecessarily public and brutal tirade from Napoleon, administered on the occasion of being presented with one of his works on natural history.

To the general reader the name of Lamarck is chiefly interesting on account of his theory of the origin of life and of the diversities of animal forms. The idea, which appears to have been favoured by Buffon before him, that species were not through all time unalterable, and that the more complex might have been developed from pre-existent simpler forms, became with Lamarck a belief or, as he imagined a demonstration. Spontaneous generation, he considered, might be easily conceived as resulting from such agencies as heat and electricity causing in small gelatinous bodies an utricular structure, and inducing a "singular tension," a kind of "éréthisme" or "orgasme"; and, having thus accounted for the first appearance of life, he explained the whole organization of animals and formation of different organs by four laws:—

"1. Life by its proper forces tends continually to increase the volume of every body possessing it, and to enlarge its parts, up to a limit which it brings about.

"2. The production of a new organ in an animal body results from the supervention of a new want (*besoin*) continuing to make itself felt, and a new movement which this want gives birth to and encourages.

"3. The development of organs and their force of action are constantly in ratio to the employment of these organs.

"4. All which has been acquired, laid down, or changed in the organization of individuals in the course of their life is conserved by generation and transmitted to the new individuals which proceed from those which have undergone those changes."

It is the second law which has been principally associated with Lamarck's name, and is often referred to as his hypothesis of the evolution of organs in animals by appetence or longing, although Lamarck does not teach that the animal's desires affect its conformation directly, but that altered wants lead to altered habits, which result in the formation of new organs as well as in modification, growth, or dwindling of those previously existing. Thus, he suggests that, ruminants being pursued by carnivora, their legs have grown slender; and, their legs being only fit for support, while their jaws are weak, they have made attack with the crown of the head, and the determination of fluids thither has led to the growth of horns. So also the stretching of the giraffe's neck to reach the foliage he supposes to have led to its elongation; and the kangaroo, sitting upright to support the young in its pouch, he imagines to have had its fore-limbs dwarfed by disuse, and its hind legs and tail exaggerated by using them in leaping. The length to which he carried such notions can be fairly estimated by the illustration which, long after the publication of his *Philosophie Zoologique*, he selected in the introduction to the *Hist. Nat. des Anim. sans Vert.* "I conceive that a gasteropod mollusc, which, as it crawls along, finds the need of touching the bodies in front of it, makes efforts to touch those bodies with some of the foremost parts of its head, and sends to these every time quantities of nervous fluids, as well as other liquids. I conceive, I say, that it must result from this reiterated afflux towards the points in question that the nerves which abut at these points will, by slow degrees, be extended. Now, as in the same circumstances other fluids of the animal flow also to the same places, and especially nourishing fluids, it must follow that two or more tentacles will appear and develop insensibly in those circumstances on the points referred to."

However absurd this may seem, it must be admitted that, unlimited time having been once granted for organs to be developed in series of generations, the objections to their being formed in the way here imagined are only such as equally apply to the theory of their origin by natural selection. Thus, for example, neither theory considers that it has to deal, not with crude heaps of mere functional organs, but with exquisitely orderly forms, nor accounts for the symmetrical first appearance of parts or for sex; nor, though Lamarck tried hard, has he or any later writer reduced to physical law the rise of consciousness in association with structures which in their physical relations are mere mechanisms capable of reflex actions.

In judging the reasonableness of the second law of Lamarck as compared with more modern and now widely received theories, it must be observed that it is only an extension of his third law; and that third law is a fact. The strengthening of the blacksmith's arm by use is proverbially notorious. It is, therefore, only the sufficiency of the Lamarckian hypothesis to explain the first commencement of new organs which is in question, if evolution by the mere operation of forces acting in the inorganic world be granted; and surely the Darwinian theory is equally helpless to account for the beginnings of a new organ, while it demands as imperatively that every stage in the assumed hereditary development of an organ must have been useful.

Furthermore, to no writer more recent than Lamarck can be attributed the credit of first pointing attention to the repetition of acquired variations in the progeny, or the idea of weaving that fact into a theory of the origin of species. His words are:—"Everything which nature has caused individuals to acquire or lose by the influence of the circumstances to which their race is long exposed, and consequently by the influence of the predominant employment of such organ, or its constant disuse, she preserves by generation to the new individuals proceeding from them, provided that the changes are common to the two sexes, or to those which have produced these new individuals" (*Phil. Zool.*, i. 235). It is interesting to note in this passage that he hesitated to believe that peculiarities could become permanent unless possessed by both parents.

Notwithstanding his attempt to evolve all vital action from the forces at work in the inorganic world, Lamarck made a broad distinction between the "power of life," to which he attributed the production of "a real progression in the composition of the organization of animals," and the modifying effects of external circumstances. The existence of such a progression cannot now be doubted, and constitutes evolution in the only sense in which it is universally admitted. Lamarck, equally with Darwin, teaches the more speculative doctrine that the complex forms are descended from simpler ancestors. In the *modus operandi* by which they hold this to have been accomplished both have admitted the action of a variety of modifying circumstances. Lamarck gave great importance to the influence of new wants acting indirectly by stimulating growth and use. Darwin has given like importance to the effects of accidental variations acting indirectly by giving advantage in the struggle for existence. The speculative writings of Darwin have, however, been interwoven with a vast number of beautiful experiments and observations bearing on his speculations, though by no means proving his theory of evolution; while the speculations of Lamarck lie apart from his wonderful descriptive labours, unrelieved by intermixture with other matters capable of attracting the numerous class who, provided they have new facts set before them, are not careful to limit themselves to the conclusions strictly deducible therefrom. But those who read the *Philosophie Zoologique* will find how many truths often supposed to be far more modern are stated with abundant clearness in its pages. (J. CL.)

LAMARTINE, ALPHONSE MARIE LOUIS DE PRAT DE (1790–1869), poet, historian, and statesman, was born at Mâcon on the 21st of October 1790, and died at Passy on the 1st of March 1869. The family of Lamartine was good, and the title of Prat was taken from an estate in Franche Comté. His father was imprisoned during the Terror, and only released owing to the events of the 9th Thermidor. Subsequently the family returned to the country. Lamartine's early education was received from his mother. He was sent to school at Lyons in 1805, but not being happy there was transferred to the care of the Pères de la Foi at Belley, where he remained until 1809. For some time afterwards he lived at home, reading romantic and poetical literature, but in 1811, being then twenty years old, he set out on his travels for Italy, where he seems to have sojourned for nearly two years. His family having been steady royalists, he entered the Gardes du corps at the return of the Bourbons, and during the Hundred Days he sought refuge first in Switzerland and then at Aix en Savoie, where he fell in love, with abundant results of the poetical kind. After Waterloo he returned to Paris, and mixed a good deal in society. In 1818–19 he revisited Switzerland, Savoy, and Italy, the death of his beloved affording him new subjects for verse. He had now got together a considerable body of poetry, and after some difficulties he got his first book, the *Méditations*, published (1820). It was exceedingly popular, and helped him to make a position. He had left the army for some time, and he now entered the diplomatic service and was appointed secretary to the embassy at Naples. On his way to his post he married at Geneva a young English lady, Marianne Birch, who had both money and beauty (1823), and in the same year his *Nouvelles Méditations* appeared. In 1824 he was transferred from Naples to Florence, where he remained for five years. His *Last Canto of Childe Harold* appeared in 1825, and he had to fight a duel with an Italian officer, Colonel Pepe, in consequence of a phrase in it. The *Harmonies Politiques et Religieuses* appeared in 1829, when he had left Florence. Having refused an appointment at Paris under the Polignac ministry (destined to be fatal to legitimism), he went on a special mission to Prince Leopold of Saxe-Coburg, who was not yet king of the Belgians, but was talked of as king of Greece. The next year he was elected to the Academy. Lamartine was in Switzerland, not in Paris, at the time of the Revolution of July, and, though he put forth a pamphlet on *Rational Policy*, he did not take any active part in politics. In 1832 he set out with his wife and daughter for Palestine, having been unsuccessful in his candidature for a seat in the chamber. His daughter Julia died at Beyrout, and before long he received the news of his election by a constituency (Bergues) in the department of the Nord. He returned through Turkey and Germany, and made his first speech shortly after the beginning of 1834. Thereafter he spoke constantly, and acquired considerable reputation as an orator,—bringing out, moreover, many books in prose and verse. His Eastern travels (*Souvenirs d'Orient*) appeared in 1835, his *Jocelyn* in 1836, his *Chute d'un Ange* in 1838, and his *Recueillements*, the last remarkable volume of his poetry, in 1839. As the reign of Louis Philippe went on, Lamartine, who had previously been a liberal royalist, something after the fashion of Chateaubriand, became more and more democratic in his opinions. He set about his greatest prose work, the *Histoire des Girondins*, which at first appeared periodically, and was published as a whole in 1847. Like many other French histories, it was a pamphlet as well as a chronicle, and the subjects of Lamartine's pen became his models in politics. At the revolution of February Lamartine at once became one of the most important personages in France. He was one of the first to declare for a provisional government, and became a member of it himself, with the post of minister for foreign affairs. He was elected for the new constituent assembly in ten different departments, and was chosen one of the five members of the Executive Committee. For a few months indeed Lamartine, who for nearly sixty years had been a distinguished man of letters, an official of inferior rank in diplomacy, and an eloquent but unpractical speaker in parliament, became one of the foremost men in Europe. His own inexperience in the routine work of government, the utterly unpractical nature of his colleagues and of the constitution which they endeavoured to carry out, and the turbulence of the Parisian mob proved fatal to his chances. During his brief tenure of office Lamartine gave some proofs of statesmanlike ability, notably in his reply to the deputation of United Irishmen who visited him in the hope that the new French democracy would take up the old hatred of the republic against England; and his eloquence was repeatedly called into requisition to pacify the Parisians. But no one can permanently carry on the government of a great country by speeches from the balcony of a house in the capital, and Lamartine found himself in a dilemma. So long as he held aloof from Ledru-Rollin and the more radical of his colleagues, the disunion resulting weakened the Government; as soon as he effected an approximation to them, the middle classes, who more in France than any where else were and are the arbiters of Governments, fell off from him. The quelling of the insurrection of the 15th May was his last successful act. A month later the renewal of active disturbances brought on the fighting of June, and Lamartine's influence was extinguished in favour of Cavaignac. There is hardly another instance on record of so sudden an elevation and so rapid a fall. Before February in 1848 Lamartine was, as has been said, a private person of talent and reputation; after June in the same year he was once more the same, except that his chance of political pre-eminence was gone. He had been tried and found wanting, having neither the virtues nor the vices of his situation. In January 1849, though he was nominated for the presidency, only a few thousand votes were given to him, and three months later he was not even elected to the legislative assembly.

The remaining story of Lamartine's life is somewhat melancholy. He had never been a rich man, nor had he been a saving one, and during his period of popularity and office he had incurred great expenses. He now set to work to repair his fortune by unremitting literary labour. He brought out in the *Presse* a series of *Confidences*, and somewhat later a kind of autobiography, entitled *Raphael*, which treated his own experiences in romantic fashion. He began and finished several historical works of more or less importance, the *History of the Revolution of* 1848, *The History of the Restoration*, *The History of Turkey*, *The History of Russia*, besides a very large number of small biographical and miscellaneous works. In 1858 a subscription was opened for his benefit. Two years afterwards, following the example of Chateaubriand, he supervised an elaborate edition of his own works in forty-one volumes. This occupied five years, and while he was engaged on it his wife died (1863). He was now a man of more than seventy years old; his powers had deserted him, and even if they had not the public taste had entirely changed, and was no longer disposed to welcome or enjoy his sentimental fashion of handling prose and poetry. His efforts had not succeeded in placing him in a position of comfort and independence; and at last, in 1867, the Government of the empire (from which he had perforce stood aloof, though he never considered it necessary to adopt the active protesting attitude of Quinet and Victor Hugo) came forward to his assistance, a vote of twenty thousand pounds being proposed in April of that year for his benefit by M. Émile Ollivier. In no other country than France would this have been anything but creditable to both parties, for Lamartine, both as a distinguished man of letters and as a past servant of the state, had every claim to the bounty of his country. But the bitter party feeling which animated the later years of the reign of Napoleon III. made the grant something of a party matter, and Lamartine was reproached for accepting it by the extreme republicans and irreconcilables. He did not enjoy it long, dying, as has been said, on the 1st of March 1869, two years before the collapse of the empire.

As a statesman Lamartine was placed during his brief tenure of office in a position from which it would have been almost impossible for any man who was not prepared and able to play the dictator to emerge with credit. At no time in history, not even in the great revolution of sixty years earlier, were unpractical crotchets so rife in the heads of men as in 1848, and at no time was there such an absence of what may be called backbone in a nation as then in France. But Lamartine could hardly have guided the ship of state safely even in much calmer weather. Personally he was amiable and even estimable, the chief fault of his character being vanity and an incurable tendency towards theatrical effect, which makes his travels, memoirs, and other personal records as well as his historical works radically untrustworthy. Nor does it appear that he had any settled political ideas. He was first an ardent legitimist, then a liberal royalist, then a constitutionalist of an indefinite type, then a republican; and it does not appear that any of these phases was the result of reasoned conviction, but rather of a vague kind of sentiment and of the contagion of popular and prevalent ideas. In regard to money he was entirely disinterested, never obtaining or seeking any lucrative office. That he was quite so disinterested in the matter of personal vanity and ambition cannot perhaps be safely affirmed. He did good by moderating the revolutionary and destructive ardour of the Parisian populace in 1848; but he had been perhaps more responsible than any other single person for bringing about the events of that year by the vague and frothy republican declamation of his *Histoire des Girondins*. Altogether little more can be said of his political career than that he was the most striking if not the most successful instance of the French system, which has prevailed since the downfall of the first empire, of making literary success a direct road to political eminence.

More must be said of his literary position. Lamartine had the advantage of coming at a time when the literary field, at least in the departments of belles lettres, was almost empty. The feeble school of descriptive writers, epic poets of the extreme decadence, fabulists, and miscellaneous verse-makers which the empire had nourished could satisfy no one, though its members still continued with unceasing fidelity to copy themselves and their models. Madame de Stael was dead; Chateaubriand, though alive, was something of a classic, and had not effected a full revolution. Lamartine did not himself go the complete length of the romantic revival, but he went far in that direction. He availed himself of the reviving interest in legitimism and Catholicism which was represented by Bonald and Joseph de Maistre, of the nature worship of Rousseau and Bernardin de St Pierre, of the sentimentalism of Madame de Stael, of the mediævalism and the romance of Chateaubriand and Scott, of the *maladie du siècle* of Chateaubriand and Byron. Perhaps if his matter be very closely analysed it will be found that he added hardly anything of his own. But if the parts of the mixture were like other things the mixture itself was not. It seemed indeed to the immediate generation so original that tradition has it that the *Méditations* were refused by a publisher because they were in none of the accepted styles. They appeared, as has been said, in 1820, that is to say, when Lamartine was nearly thirty years old. The best of them and the best thing that Lamartine ever did is the famous *Lac*, describing his return to the little mountain tarn of Le Bourget after the death of his mistress, with whom he had visited it in other days. The verse is exquisitely harmonious, the sentiments conventional but refined and delicate, the imagery well chosen and gracefully expressed. There is indeed an unquestionable want of vigour, but to readers of that day the want of vigour was entirely compensated by the presence of freshness and grace. Lamartine's chief misfortune in poetry was that not only was his note a somewhat weak one, but that he could strike but one. The four volumes of the *Méditations*, the *Harmonies*, and the *Recueillements*, which contained the prime of his verse, are perhaps the most monotonous reading to be found anywhere in work of equal bulk by a poet of equal talent. They contain nothing but meditative lyrical pieces, almost any one of which is typical of the whole, though there is of course considerable variation of merit. The two narrative poems which succeeded the early lyrics, *Jocelyn* and the *Chute d'un Ange*, were, according to Lamartine's original plan, parts of a vast "Epic of the Ages," some further fragments of which survive, especially one of not a little merit which was published four years after the author's death in company with some youthful attempts at the classical tragedy and a few miscellanea. *Jocelyn* had at one time more popularity in England than most French verse. *La Chute d'un Ange*, in which the Byronic influence is more obvious than in any other of Lamartine's works, is more ambitious in theme and less regulated by scrupulous conditions of delicacy in handling than most of its author's poetry. It does, however, little more than prove that such audacities were not for him.

As a prose writer Lamartine was, as may be seen from what has been said (and many of his works have not been mentioned), very fertile. His characteristics in his prose fiction and descriptive work are not very different from those of his poetry. He is always and everywhere sentimental, though very frequently, as in his shorter prose tales (*The Stone Mason of St Point*, *Graziella*, &c.), he is graceful as well as sentimental. In his histories, the style being one for which he was radically unfitted, the effect is worse. It has been hinted that Lamartine's personal narratives are doubtfully trustworthy; indeed with regard to his Eastern travels some of the episodes were stigmatized as mere inventions by persons who had every reason to be well informed and none to bear false witness. In his histories proper the special motive for embellishment—falsification would be too rough a word—for the most part disappears, but the habit of inaccuracy remains. Lamartine as an historian belongs exclusively to the rhetorical school as distinguished from the philosophical on the one hand and the documentary on the other.

It is not surprising when these characteristics of Lamartine's work are appreciated to find that his fame has declined with singular rapidity in France. As a poet indeed he had lost his reputation many years before he died. He was entirely eclipsed by the brilliant and vigorous school who succeeded him with Victor Hugo at their head. It is possible that the *Chute d'un Ange* was an effort to compete with them on their own ground; if so, it was an entire failure. Lamartine's power of initiative in poetry was very small, and the range of poetic ground which he could cover strictly limited. He did not attempt the great task of the day, the freeing of the Alexandrine from the restraints imposed upon it, and the devising or reviving of new lyric metres to refresh and invigorate French poetic style. He could only carry the picturesque sentimentalism of Rousseau, Bernardin de St Pierre, and Chateaubriand a little further, and clothe it in language and verse a little less antiquated than that of Chênedollé and Millevoye. He has been said to be a French Cowper, and the parallel holds good in respect of versification and of his relative position to the more daringly innovating school that followed, though not in respect of individual peculiarities. Lamartine in short occupied a kind of half-way house between the 18th century and the Romantic movement, and he never got any further. When a living English critic questioned his importance in conversation with Sainte-Beuve, the answer was, "He is important to *us*," and it was a true answer; but his importance is now chiefly historical, even to Frenchmen.

The already mentioned edition is the most complete one of Lamartine, but there are many issues of his separate works. Since his death, besides the poems already mentioned, some *Mémoires Inédits* of his youth have been published, and also two volumes of correspondence. (G. SA.)

LAMB, CHARLES (1775–1834), an original and delightful English essayist and critic, was born in Crown Office Row, Inner Temple, London, February 10, 1775. His father, John Lamb, a Lincolnshire man, who filled the situation of clerk and servant companion to Mr Salt, one of the benchers of the Inner Temple, was successful in obtaining for Charles, the youngest of three children, a presentation to Christ's Hospital, where the boy remained from his eighth to his fifteenth year (1782–1789). Here he was fortunate enough to have for a schoolfellow the afterwards famous Samuel Taylor Coleridge, his senior by rather more than two years, and a close and tender life-long friendship began which had a singularly great influence on the whole of his after career. When the time came for leaving school, where he had learned some Greek and acquired considerable facility in Latin composition, Lamb, after a brief stay at home (spent, as his school holidays had often been, over old English authors in the library of Mr Salt), was condemned to the labours of the desk,—an "unconquerable impediment" in his speech disqualifying him for a school exhibition, and thus depriving him of the only means by which he could have obtained a university education. For a short time he held a clerkship in the South Sea House under his elder brother John, and in 1792 he entered the accountant's office in the East India House, where during the next three and thirty years the hundred folios of what he used to call his true "works" were produced. A dreadful calamity soon came upon him, which seemed to blight all his prospects in the very morning of life. There was insanity in the family, which in his twenty-first year had led to his own confinement for some weeks in a lunatic asylum; and, a few months afterwards, on the 22d of September 1796, his sister Mary, "worn down to a state of extreme nervous misery by attention to needlework by day and to her mother by night," was suddenly seized with acute mania, in which she stabbed her mother to the heart. The calm self-mastery and loving self-renunciation which Charles Lamb, by constitution excitable, nervous, and timid, displayed at this crisis in his own history and in that of those nearest him, will ever give him an imperishable claim to the reverence and affection of all who are capable of appreciating the heroisms of common life. His sister was of course immediately placed in confinement, and with the speedy return of comparative health came the knowledge of her fatal deed; himself calm and collected, he knew how to speak the words of soothing and comfort. With the help of friends he succeeded in obtaining her release from the life-long restraint to which she would otherwise have been doomed, on the express condition that he himself should undertake the responsibility for her safe keeping. It proved no light charge; for, though no one was capable of affording a more intelligent or affectionate companionship than Mary Lamb during her long periods of health, there was ever present the apprehension of the recurrence of her malady; and, when from time to time the premonitory symptoms had become unmistakable, there was no alternative but her removal, which took place in quietness and tears. How deeply the whole course of Lamb's domestic life must have been affected by his singular loyalty as a brother need not be pointed out; for one thing, it rendered impossible his union with Alice Winterton, whom he appears to have truly loved, and to whom such touching reference was made long afterwards in *Dream Children, a Reverie*.

Lamb's first appearance as an author was made in the year of the great tragedy of his life (1796), when there were published in the volume of *Poems on Various Subjects* by Coleridge four sonnets by "Mr Charles Lamb of the India House." In the following year he also contributed along with Charles Lloyd some pieces in blank verse to Coleridge's new volume of *Poems*. In 1798 he published a short and pathetic prose tale entitled *Rosamund Gray*, and in 1799 he was associated with Coleridge and Southey in the publication of the *Annual Anthology*, to which he had contributed a short religious poem in blank verse entitled "Living without God in the World"; the company in which he was thus found brought upon him the irrelevant and pointless ridicule of Canning and Gillray. His next public appearance was not more fortunate. His *John Woodvil* (1801), a slight dramatic piece written in the style of the earlier Elizabethan period, and containing some genuine poetry and happy delineation of the gentler emotions, but as a whole deficient in plot, vigour, and character, was held up to ridicule by the *Edinburgh Review* as a specimen of the rudest condition of the drama, a work by "a man of the age of Thespis." The dramatic spirit, however, was not thus easily quenched in Lamb. His next effort (1806) was a farce, named *Mr H.*, the point of which lay in the hero's anxiety to conceal his name, "Hogsflesh"; it has recently been put upon the boards with success in America, but in London it did not survive the first night of its appearance. Its author bore the failure with rare equanimity and good humour, and soon struck into new and more successful fields of literary exertion. In 1807 appeared *Tales founded on the Plays of Shakespeare*, written by Charles and Mary Lamb; and in 1808 *Specimens of English Dramatic Poets who lived about the time of Shakespeare*, with short but felicitous critical notes. In the same year Mary Lamb, assisted by her brother, also published *Poetry for Children* and a collection of short school-girl tales under the title *Mrs Leicester's School*; and to the same date belongs the *Adventures of Ulysses*, designed by Lamb as a companion to the *Adventures of Telemachus*. In 1810 began to appear Leigh Hunt's quarterly periodical, *The Reflector*, in which Lamb published much (including the essays on the tragedies of Shakespeare and on Hogarth) that subsequently appeared in the first collective edition of his *Works* (2 vols. 12mo), which appeared in 1818. The establishment of the *London Magazine* in 1820 stimulated him to the production of a series of new essays which rose into instant popularity, and may be said to form the chief corner-stone in the small but classic temple of his fame. The first of these, as it fell out, was a description of the old South Sea House, with which Lamb happened to have associated the name of a "gay light-hearted foreigner" called Elia, who had frequented it in the days of his service there. The pseudonym adopted on this occasion was retained for the subsequent contributions which appeared collectively in a post 8vo volume of *Essays* in 1823. After a brief career of five years the *London Magazine* came to an end; and about the same period Lamb's long connexion with the India House terminated, a pension of about £450 having been assigned to him. The increased leisure, however, for which he had long sighed, did not prove favourable to literary production, which henceforth was limited to a few trifling contributions to the *New Monthly* and other serials. The malady of his sister, which continued to increase with ever shortening intervals of relief, broke in painfully on his lettered ease and comfort; and it is unfortunately impossible to ignore the deteriorating effects of an over-free indulgence in the use of tobacco and alcohol on a temperament such as his. His removal on account of his sister to the quiet of the country, by tending to withdraw him from the stimulating society of the large circle of literary friends who had helped to make his Wednesday evening "at homes" so remarkable, doubtless also tended to intensify his listlessness and helplessness. One of the brightest elements in the closing years of his life was the friendship and companionship of Emma Isola, whom he and his sister had adopted, and whose marriage in 1833 to Mr Moxon, though a source of unselfish joy to Lamb, left him more than ever alone. While living at Edmonton, he was overtaken by an attack of erysipelas brought on by an accidental fall as he was walking on the London road; after a few days' illness he painlessly passed away on December 27, 1834. The sudden death of one so widely known, admired, and beloved as Charles Lamb fell on the public, as well as on his own attached circle, with all the poignancy of a personal calamity and a private grief. His memory wanted no tribute that affection could bestow, and Wordsworth has commemorated in simple and solemn verse the genius, virtues, and fraternal devotion of his early friend.

In depth of thought and splendour of genius Charles Lamb was surpassed by not a few of his contemporaries, but as an essayist he is entitled to a place beside Montaigne, Sir Thomas Browne, Steele, and Addison. He unites many of the characteristics of each of these writers,—refined wit, exquisite humour, a genuine and cordial vein of pleasantry, and heart-touching pathos. His fancy as an essayist is distinguished by great delicacy and tenderness; and even his conceits are imbued with human feeling and passion. He had an extreme and almost exclusive partiality for our earlier prose writers, particularly for Fuller, Browne, and Burton, as well as for the dramatists of Shakespeare's time; and the care with which he studied them is apparent in all he ever wrote. It shines out conspicuously in his style, which has an antique air, and is redolent of the peculiarities of the 17th century. Its quaintness has subjected the author to the charge of affectation, but there is nothing really affected in his writings. His style is not so much an imitation as a reflexion of the older writers; for in spirit he made himself their contemporary. A confirmed habit of studying them in preference to modern literature had made something of their style natural to him; and long experience had rendered it not only easy and familiar but habitual. It was not a masquerade dress he wore, but the costume which showed the man to most advantage. With thought and meaning, often profound, though clothed in simple language, every sentence of his essays is pregnant, and in this respect he bears a strong resemblance to the writers already named. If he had their manner, he possessed their spirit likewise. To some of his essays and specimens we are considerably indebted for the revival of the dramatic writers of the Shakespearian age; for he preceded Gifford and others in wiping the dust of ages from the works of these authors. In his brief comments on each specimen he displays exquisite powers of discrimination; his discernment of the true meaning of his author is almost infallible. As a poet Lamb is not entitled to so high a place as that which can be claimed for the essayist and critic. His dependence on Elizabethan models is here also manifest, but in such a way as to bring into all the greater prominence his native deficiency in "the accomplishment of verse." Yet it is impossible, once having read, ever to forget the tenderness and grace of such verses as those to Hester Savory and on "The Old Familiar Faces," or the quaint humour of "A Farewell to Tobacco." As a letter writer also Lamb is entitled to rank very high.

The *Letters* of Charles Lamb, with a sketch of his life by one of his executors, Sir Thomas Noon Talfourd, appeared in 2 vols. in 1837, and *Final Memorials of Charles Lamb*, by the same hand, were published in 1848. Supplementary to these is the *Memoir* by another personal friend B. W. Procter (Barry Cornwall) published in 1866. See also Fitzgerald's *Charles Lamb, his Friends, his Haunts, and his Books*, 1866; Cradock's *Charles Lamb*, 1867; and Carew Hazlitt's *Mary and Charles Lamb: Poems, Letters, and Remains*, 1874. There have been several complete editions of the *Works* of Lamb; of these the fullest as well as most recent is that of Fitzgerald (*Life, Letters, and Writings of Charles Lamb*, 6 vols., 1870–76).

LAMBALLE, Marie Thérèse Louise de Savoie-Carignan, Princesse de (1749–1792), daughter of Louis Victor of Carignan, was born at Turin, 8th September 1749. In 1767 she was married to Stanislaus, prince of Lamballe, and son of the duke of Penthièvre. After his death in the following year an unsuccessful attempt was made to arrange a marriage between her and Louis XV. She then retired from the court; but, having accidentally made the acquaintance of Marie-Antoinette, she was after the accession of Louis XVI. appointed by the queen superintendent of the royal household, and enjoyed her closest intimacy and friendship. In 1792 she shared for a week her imprisonment in the Temple, but on the 19th August she was transferred to La Force, and, having refused the oath against the monarchy, she was on September 3d delivered over to the fury of the populace, after which her head was placed on a pike and carried before the windows of the imprisoned queen.

See Lescure, *La Princesse de Lamballe*, 1869; and Fassy, *Louise de Savoie-Carignan, Princesse de Lamballe, et la Prison de La Force*, 1868.

LAMBERT, Johann Heinrich (1728–1777), physicist and mathematician, was born at Mulhausen, Alsace, August 29, 1728. He was the son of a tailor; and the slight elementary instruction he obtained at the small free school of his native town was supplemented altogether by his own private reading. Having cultivated a good style of penmanship, he became book-keeper at Montbéliard ironworks, and subsequently (1745) secretary to Professor Iselin, the editor of a newspaper at Basel, who three years later recommended him as private tutor to the family of President A. von Salis of Coire. Coming thus into virtual possession of a good library, Lambert had peculiar opportunities for improving himself in his literary and scientific studies. In 1759, after completing with his pupils a lengthened tour of two years' duration through Göttingen, Utrecht, Paris, Marseilles, and Turin, he resigned his tutorship and settled at Augsburg. Munich, Erlangen, Coire, and Leipsic became for brief successive intervals his home. Finally in 1764 he removed to Berlin, where he received many favours at the hand of Frederick, was elected a member of the Royal Academy of Sciences, and ultimately (1774) undertook the editing of the astronomical almanac. On September 25, 1777, he died of consumption, the natural result of a life spent in excessive application to all kinds of mental labour. Seventeen hours daily were devoted by him to reading and writing; and, as might have been expected in the case of one who wrote so much, many of his numerous publications are of little permanent interest. Not a few, however, are very valuable, and show him to have been a man of original and active mind with a singular facility in applying mathematics to practical questions.

Lambert's most important work, *Pyrometrie* (Berlin, 1779), is a systematic treatise on heat, containing the records and full discussion of many of his own experiments. Worthy of special notice also are *Photometria*, Augsburg, 1760; *Insigniores orbitæ Cometarum proprietates*, Augsburg, 1761; and *Beiträge zum Gebrauche der Mathematik und deren Anwendung*, 4 vols., Berlin, 1765–72.

The *Memoirs* of the Berlin Academy from 1761 to 1784 contain many of his papers, which treat of such subjects as resistance of fluids, magnetism, comets, probabilities, the problem of three bodies, meteorology, &c. In the *Acta Helvetica* (1752–60) and in the *Nova Acta Erudita* (1763–69) several of his contributions appear. In Bode's *Jahrbuch* (1776–80) he discusses nutation, aberration of light, Saturn's rings, and comets; in the *Nova Acta Helvetica* (1787) he has a long paper "Sur le Son des Corps Elastiques"; in Bernoulli and Hindenburg's *Magazin* (1787–88) he treats of the roots of equations and of parallel lines; and in Hindenburg's *Archives* (1798–99) he writes on optics and perspective. Many of these pieces were found among his effects after his death, and published posthumously. Recognized as among the first mathematicians of his day, he was also widely known for the universality and depth of his philological and philosophical knowledge. The most valuable of his logical and philosophical memoirs were published collectively in 2 vols., 1782. See Huber's *Lambert nach seinem Leben und Wirken*.

LAMBERT, John (1619–1694), was born in 1619 at Calton Hall in the parish of Kirkby Malham, in the West Riding of Yorkshire. His family was of ancient lineage, and long settled in the county. He studied at the Inns of Court, but without making the law his profession. In 1640 he married Frances, daughter of Sir William Lister. He was present at the great meeting of the Yorkshire gentry on Heyworth Moor (3d June 1642), and in September was appointed a captain of horse under Lieutenant-Colonel Fairfax. He did good service at the siege of Hull (11th October 1642), at Bradford (5th March 1644), and at the important engagement at Selby (10th April 1644). At Marston Moor (2d July 1644) he commanded part of Sir Thomas Fairfax's cavalry on the right wing. He was sent into York to arrange terms for the surrender of the city, which took place July 16, 1644. When the "New Model" army was formed in the beginning of 1645, Colonel Lambert was appointed commissary-general of the army in the north. He beat the royalists at Keighley and Ferrybridge, and took several strong places. He followed Fairfax's campaign in the west of England in 1646, and was a commissioner with Cromwell and others for the surrender of Oxford in the same year.

When the quarrel between the army and the parliament began, Lambert threw himself warmly into the army's cause. He is said by Clarendon to have assisted Ireton in drawing up the several addresses and remonstrances issued by the army, both men having had some experience in the law, and being "of a subtle and working brain." In August 1647 Lambert was sent as major-general by Fairfax to take charge of the forces in the northern counties. His wise and just managing of affairs in those parts is commended by Whitelocke. He displayed personal courage in suppressing a mutiny among his troops, kept strict discipline, and showed much diligence in hunting down the moss-troopers who infested the moorland country.

When the Scotch army under the marquis of Hamilton invaded England in the summer of 1648, Lambert was obliged to retreat till Cromwell came up from Wales, and joining him destroyed the Scotch army in three days' fighting from Preston to Warrington. Lambert pressed Hamilton with the cavalry, and took him prisoner at Uttoxeter, a few days after the battle. He then marched back into Scotland, where he was left in charge of the troops. In December 1648 he sat down before Pontefract Castle, which held out till March 1649. Lambert was thus absent from London at the time of the violence put upon the parliament by Colonel Pride, and the other measures which led to the king's death.

Cromwell, when appointed to the command of the war in Scotland (26th July 1650), took Lambert with him as major-general. He was wounded at Musselburgh, but was with Cromwell at Dunbar on the 2d of September, when the soldiers begged that Lambert might lead them the next day, and Cromwell willingly gave his consent. He defeated the "Protesters" or "Western Whigs" at Hamilton, on the 1st of December 1650. In the following July he was sent over into Fife to get a position in the rear and flank of the Scotch army near Falkirk, and force them to decisive action by cutting off their supplies from Perth. A battle fought at Inverkeithing, with heavy loss to the Scots, in which Lambert behaved with great gallantry, gave him the position he required, and he improved it by taking Inchgarvie and Burntisland. Charles now (as Lambert had foreseen) made for England. Lambert with the cavalry was ordered to harass his march down the western shires, while Cromwell followed through Yorkshire and the Midlands. In the action at Warrington Bridge Lambert again distinguished himself by his personal courage, and at Worcester also (3d September 1651), where he commanded the forces on the eastern bank of the Severn, and had his horse shot under him. Parliament now conferred on him a grant of lands in Scotland worth £1000 per annum.

In November 1651 he was made a commissioner to settle the affairs of Scotland, and on the death of Ireton he was appointed lord deputy of Ireland in February 1652. He accepted the office with pleasure; but his magnificent preparations offended the Commons, who limited his office to the term of six months. Lambert hereupon resigned the deputyship without entering on its duties.

Notwithstanding this affront Lambert took part with Cromwell in the expulsion of the Rump (20th April 1653) and its council of state. He was joined to the lord-general and two others as additional members of the little parliament of nominees, making up the number to one hundred and forty-four. He presented the act of resignation of that assembly, and was principally concerned in drawing up the address requesting Cromwell to assume the protectorate, and the Instrument of Government, which was the constitution of the Protectoral rule. At the installation of Cromwell he bore a prominent part. In the parliament of 1654, and again in 1656, Lambert (or Lord Lambert as he is now generally called) sat as member for the West Riding of Yorkshire. When the proposal to declare Oliver king was started in parliament (February 1657) he at once declared strongly against it. A hundred officers headed by Fleetwood and Lambert waited on the Protector, and begged him to put a stop to the proceedings. Lambert was not convinced by Cromwell's arguments, and Cromwell and he henceforward never spoke to each other as friends. On his refusal to take the official oath of allegiance to the Protector, Cromwell deprived him of his commissions, giving him, however, a pension of £2000 a year. He retired to his house and garden at Wimbledon, and appeared no more in public during Oliver Cromwell's lifetime.

On the accession of Richard he seems to have expected the first place in the army, but was not unwilling to be second to Fleetwood. The Protector was between two parties—the court party, who wished to hold to the "Petition and Advice," and the army party or Wallingford House party, who, whilst supporting Richard as Protector, wished to put the control of the army into stronger hands. Richard saw that to deliver up the power of the sword was to abdicate, and refused to make Fleetwood general. Lambert was elected for Pontefract in Richard's parliament, and took part with the republican malcontents who soon combined with Wallingford House. Councils of officers were held, which Lambert, though holding no commission, was invited to attend. They determined to stand by the "good old cause" and to demand the dissolution of the parliament as being too full of monarchical and Presbyterian notions —in fact, to put the civil power aside and set up a military government in its stead. The Protector dissolved parliament (22d April 1659). The officers, unable to rule without a parliament, restored the Rump as representing the Commonwealth (7th May 1659). Richard's Protectorate had practically ended with his parliament, and he now laid down the show of royalty. Sir George Booth and Sir Thomas Middleton headed a royalist rising in Cheshire, which Lambert put down after a sharp encounter near Chester. He promoted a petition from his army that Fleetwood might be made lord-general and himself major-general. The republican party in the house took offence. The Commons (12th October 1659) cashiered Lambert, Desborough, and other officers, and retained Fleetwood's commission as chief of a military council of seven, republicans of the old sort. Lenthall, the speaker, was to give his orders to the army. On the next day (13th October) Lambert caused the doors of the House to be shut and the members kept out. On the 26th a "committee of safety" was appointed, of which Lambert was a member. He was also appointed major-general of all the forces in England and Scotland, Fleetwood being general. Lambert was now sent with a large force to meet Monk, who was in command of the English forces in Scotland, and either negotiate with him or force him to terms. Monk, however, declared for the liberty and authority of parliament, and set his army in motion southward. The committee of safety was obeyed no more than the Rump had been. The soldiers themselves cried out for the restoration of parliament, and on the 26th of December the Rump was recalled to restore some appearance of lawful authority.

Meanwhile the bulk of Lambert's army was dissolved by the mere appearance of Lord Fairfax in arms on Marston Moor, and he was kept in suspense by Monk's deceits and delays, till his whole army fell from him, and he came back to town almost alone. Monk marched unopposed to London, and declared for a "free parliament." The "excluded" Presbyterian members were recalled. Lambert was sent to the Tower (3d March 1660), from which he escaped a month later (9th April 1660). He tried to rekindle the civil war in favour of the Commonwealth, but was speedily recaptured, and sent back to the Tower (24th April). On the Restoration he, along with Vane, was exempted from danger of life by an address of both Houses to the king. The next parliament (1662) brought a charge of high treason against them. Vane was beheaded, but Lambert was spared, and remained in custody in the island of Guernsey for the remainder of his life. He died at the age of seventy-five, in 1694.

Lambert would have left a better name in history if he had been a Cavalier. His genial, ardent, and excitable nature, easily raised and easily depressed, was more akin to the royalist than the puritan spirit. Vain and sometimes overbearing, as well as ambitious, he believed that Cromwell could not stand without him, and, when Cromwell was dead, he imagined himself equal to succeed him, and thought that the first place must be his by right. Yet his ambition was less selfish than that of Monk. Lambert is accused of no ill faith, no want of generosity, no cold and calculating policy. Lambert was not merely a soldier. He was an able writer and speaker, and an accomplished negotiator, and took pleasure in quiet and domestic pursuits. He learnt his love of gardening from Lord Fairfax, who was also his master in the art of war. He painted flowers, besides cultivating them, and incurred the blame of Mrs Hutchinson by "dressing his flowers in his garden and working at the needle with his wife and his maids." He made no special profession of religion; but no imputation is cast upon his moral character by his detractors. It has been said that he became a Roman Catholic before his death. (F. W. C.*)

LAMBÈSE, or LAMBESSA, the ancient *Lambæsa* and the *Tazzut* or *Tezzulet* of the natives, is situated in the French province of Constantine in Algeria, about 6 miles east of Batna. The modern village is well known for its great convict establishment (founded about 1850); and the remains of the Roman town, and more especially of the Roman camp, in spite of the wanton vandalism to which they have been more than once subjected since their discovery, are among the most interesting in northern Africa. The ruins of the town are situated on the lower terraces of the Jebel Aures, and consist of triumphal arches, temples, aqueducts, and an immense quantity of ordinary masonry evidently belonging to private houses. To the north and east lie extensive cemeteries with the stones still standing in their original alignments; to the west is a similar area from which, however, the stones have been largely removed for building the modern village. Of the temples the most noteworthy are those to Æsculapius and Health (Salus), and to Isis and Serapis. About two-thirds of a mile from the town on the level ground of the plain of Batna stands the camp. It measures 1640 feet from north to south by 1476 feet from east to west, and in the middle rise the ruins of a prætorium. This noble building is 92 feet long by 66 feet broad and 49 feet high; its southern façade has a splendid peristyle half the height of the wall, consisting of a front row of massive Ionic columns and an engaged row of Corinthian pilasters. The ruins of both city and camp have yielded a rich harvest of inscriptions (Renier edited 1500, and there are 4185 in the *Corpus Inscr. Lat.*, vol. viii.); and, though a very large proportion are epitaphs of the barest kind, the more important pieces supply a fair outline of the history of the place.

Lambæsa was emphatically a military foundation. The camp of the third legion (Legio III. Augusta), to which it owes its origin, appears to have been established between 123 and 129 A.D., in the time of Hadrian, whose address to his soldiers was found inscribed on a pillar in a second camp to the west of the great camp still extant. By 166 mention is made of the decurions of a *vicus*, 10 curiæ of which are known by name; and the vicus became a municipium probably at the time when it was made the capital of the newly founded province of Numidia. The legion was removed by Gordianus, but restored by Valerianus and Gallienus; and its final departure did not take place till after 392. The town soon afterwards declined. It never became the seat of a bishop, and no Christian inscriptions have been found among the ruins.

See Bruce; Peysonnel; L. Renier, *Inscriptions romaines de l'Algérie*, Paris, 1855; Gustav Wilmann, "Die Röm. Lagerstadt Afrikas," in *Commentationes phil. in honorem Th. Mommseni*, Berlin, 1877; Playfair, *Travels in the Footsteps of Bruce*, London, 1877. A ground plan of the ruins is given in *Mém. des Antiq. de France*, tom. xxi.

LAMBETH. See LONDON.

LAMECH, לֶמֶךְ, is a name which appears in each of the antediluvian genealogies, Gen. iv. 16–24 and Gen. v. In the first he is a descendant of Cain, and through his three sons father of the several avocations of early civilization; in the latter he is father of Noah. In each case, though in different senses, he marks the close of the first epoch of the world's history. Since the publication of Buttmann's *Mythologus* it has come to be generally recognized that the two genealogies terminating in Lamech are divergent forms of a single list. The parallelism of the two is not confined to the identical names, Lamech and Enoch. Methuselah (Μαθουσαλα) not Methusael is the true reading of the LXX. in Gen. iv. 18, and there are some textual grounds for thinking that in the same verse Mehujael has displaced an older reading Mahalaleel. Kainan again is closely akin to Cain, and there is also a less close resemblance between Jared and Irad, while Enos (Enosh) and Adam both mean *man*. Thus the two series beginning with Enosh and Adam and ending in Lamech do not vary more than is often the case with different recensions of ancient name lists. See especially Lagarde, *Orientalia*, ii. 33 *sq.* Again it has been pointed out, especially by Wellhausen, *Jahrb. f. D. Theol.*, 1876, p. 400 *sq.*, that Gen. iv. 16–24 is in its original conception quite distinct from the history of the curse of Cain (Gen. iv. 1–15), and offers the history of the beginnings of existing civilization (verse 20 *sq.*), not of a civilization extinguished by the flood; and the continuation of this narrative is plausibly sought in the history of the tower of Babel, according to which the human race entered Babylonia from the east (comp. iv. 16 with xi. 2), whereas the movements of the sons of Noah start from Ararat. On this view we are to suppose that the oldest literary source of the Hebrew history of the origins of our race ignored the flood, and traced the beginnings of city life to a land east of Eden (Nod), which has no place in later geography, and of which Cain was the first settler. Lamech is a descendant of Cain, under whose sons the different special avocations of a very primitive civilization differentiate themselves. The mass of the people are tent dwellers and shepherds, their "father" or the patron of their occupation being Jabal; but the arts are also developed in two branches, the "father" of minstrelsy being Jubal, while the art of metallurgy is traced back to Tubal Cain (LXX. simply Θοβελ). The etymologies of the proper names throw little light on this interesting conception; that of Lamech is quite obscure,[1] and the names of the sons, if they are Semitic, may be all derived from the root יבל, expressing the notion of "offspring." It is indeed conceivable that some of the names are of non-Semitic origin; *túpâl* in Persian and Turkish means bronze, and the nation of Tubal was known to the Hebrews for bronze-work (Ezek. xxvii. 13), which would go well enough with the fact that Kayn in Arabic means a smith. But on the other hand the wives and daughters of Lamech, as well as the other two sons, have names that point naturally to Hebrew roots, so that it is very doubtful how far one is entitled to press these foreign analogies in explaining what is certainly one of the oldest Hebrew traditions.

What we read in Genesis of Lamech and his race seems to be a mere fragment of an older and more copious tradition. He has two wives—Adah (עָדָה, "ornament"?), a name which reappears in Gen. xxxvi. in the genealogy of the Edomites, and Zillah (צִלָּה, "shadow"). Ewald gives to these names a mythological colour by making Adah mean "aurora" (Arabic *ghadât*) in contrast to Zillah, "shadow"; but in that case we should expect the LXX. to transcribe the word by Γαδα not Αδα, as Irad is rendered Γαιδαδ. At the same time the unquestionable occurrence of names of gods in the Edomite genealogy where Adah recurs favours the view that something of the same sort may be found in Gen. iv. 16 *sq.* On the other hand it is certainly important that the sons of Lamech form two brotherhoods (verse 21) divided by their maternal descent. The fathers of pastoral life and minstrelsy stand apart from the father of metallurgy and his sister Naamah. Handicraft especially in metals is generally practised by foreigners among the Semitic nomads, so that Tubal Cain may very well represent another race, such as the non-Semitic people which introduced metallurgy in Chaldæa according to Assyriologists. The name Naamah ("gracious") is so plainly akin to the divine name Naaman (Noʿmân, Adonis) that we can scarcely refuse to compare what is said of her brother with the Phœnician legend in Philo Byblius (Euseb., *Pr. Ev.*, I. x. 9) of two brothers, inventors of iron and iron-working, of whom one named Chrysor was skilled in sayings, incantations, and divination, and was worshipped as a sort of Phœnician Hephæstus. The details of Phœnician legend, however, in this as in other cases, are widely divergent from the Bible story.

The savage "sword song" of Lamech is unique in the Bible, and breathes the true spirit of the desert:—

> Adah and Zillah, hear my voice;
> Ye wives of Lamech, give ear unto my speech.
> I slay a man for a wound,
> A young man for a stroke;
> For Cain's vengeance is sevenfold,
> But Lamech's seventyfold and seven.

In the other form of the genealogy the line of Lamech is dissociated from the guilty Cain and leads up to Noah. This form of the tradition is much more recent, belonging to the Levitical or priestly narrator. Its chief importance is that it shows how inseparably Lamech and his genealogy were connected with the ancestry of the Hebrew race.

LAMEGO, a town in the district of Vizeu in the province of Beira, Portugal, is situated 6 miles south of the Douro, and about 50 miles east of Oporto. As the seat of a bishop, it contains a Gothic cathedral, a part of which is referred to the 14th century. One of the churches was

[1] The conjectures and supposed parallels offered by Ewald (*Geschichte*, i. 382, 391; *Jahrb.* vi. 2) and Movers (i. 476 *sq.*) offer no safe basis for speculation. G. Smith (*Chaldæan Genesis*, ch. xvii.) proposes to identify the name with the Accadian Dumugu and Lamga, "moon."

formerly a Moorish mosque, and, though intrinsically commonplace, enjoyed for a long time an undeserved fame as the meeting place of the cortes said to have been convened in 1143 or 1144 by Alphonso Henriquez, the first king of Portugal, to settle the royal succession and to determine the laws of the country. But within the last forty years it has been pretty clearly demonstrated that no such cortes ever met. To archæologists the ancient bath preserved at Lamego will afford more interest than the old Moorish castle, which crowns the hill on which the city stands. Numbers of swine are reared in the neighbourhood, which furnish the well-known Lisbon hams. The old name of Lamego was Lama or Lamacœni. Under the Moors, who were driven out in 1038 by Ferdinand of Castile, it was a leading city. The population in 1878 was 8383.

LAMENNAIS, Hugues Félicité Robert de (1782–1854), French theologian, philosopher, and political writer, was born at St Malo in Britanny. His father, Pierre Louis Robert, merchant and shipowner, had been ennobled by Louis XVI. because of aid to royal naval armaments and for importing and selling corn at easy prices in a time of public distress. His property of La Mennais, with the feudal prefix De, gave him a new surname. His wife was as noted for her saintly temper as her humane husband for scepticism. The death of his mother and his father's bankruptcy deprived young Lamennais early of regular education. An eccentric uncle got charge of him, and for years the freedom of this uncle's library was all his training. His elder brother Jean, priest, educationist, and author, had taught him the elements of Latin, and by his own further efforts he comprehended Livy at ten. Well read in Rousseau at twelve, he criticized religion so adroitly with the parish priest that he could not be admitted to communion. In 1796 he sent a discourse combating modern philosophy to a provincial academy. He visited Paris with his father next year, where he wrote democratic letters to the newspapers. On his return he joined his brother for study at a house near Dinan called La Chenaie, built by their maternal grandfather. Greek, Latin, Hebrew, modern languages, the church fathers, the controversialists, and historians occupied him. Religious struggle, and an intense melancholy, aided it may be by the *malheureuse passion* which he is said to have suffered from, account for the fact that he was twenty-two before taking his first communion, though in direct preparation for the clerical life.

In 1808 his hand found its proper work. His *Reflexions on the State of the Church during the 18th Century and on the Actual Situation*, published anonymously at Paris, was the first important theological stand made against the materialistic philosophy which had its apotheosis in imperialism. Napoleon's police seized the book as dangerously ideological, with its eager recommendation of religious revival and active clerical organization. It awoke the ultramontane spirit which has played so great a part since in the politics of churches and states. But Lamennais was not yet ready for the contest. Pious exaltation of spirit was his prevailing mood, as is shown by his translation next year of the *Spiritual Guide* of the ascetic Blosius. Indeed, to the end of his life there is recurrence to what may be called poetic religious feeling, one of his latest reliefs from the storms of political struggle being a translation of the Gospels. In 1811 he took the tonsure, but shortly after became teacher of mathematics in the seminary founded by his brother at St Malo. Theological politics had large discussion after the concordat of 1802, by which the Gallican Church was re-established; and the brothers' joint work, *Tradition upon the Institution of Bishops*, which was published a few days after the restoration, condemns the Gallican principle which allowed bishops to be created irrespective of the pope's sanction.

The revival of the Bourbon monarchy drew Lamennais to Paris, and the Hundred Days sent him to exile. The abbé Caron gave him work in his school for French exiles in London; and he also became tutor at the house of Lady Jerningham, whose first impression of him as an imbecile changed into friendship. In 1815 he returned with the abbé to Paris, where his seeming fatuity cost him much misery as a seminarist of St Sulpice; but with Caron's aid, whom he called his spiritual father, he took full sacerdotal ordination next year, though with reluctance, as a letter to his sister shows. He enjoyed much peace with his friend at the Maison des Feuillantes, and finished there the first volume of his great work, the *Essay on Indifference in the Matter of Religion*. Published in 1817, it affected Europe like a spell. Since Bossuet no clergyman wielded such power as he gained at a blow. He denounced toleration, and advocated a Catholic restoration to belief. The right of private judgment, introduced by Descartes and Leibnitz into philosophy and science, by Luther into religion, and by Rousseau and the Encyclopedists into politics and society, had, he contended, terminated in practical atheism and spiritual death. Ecclesiastical authority, founded on the absolute revelation delivered to the Jewish people, but supported by the universal tradition of all nations, he proclaimed to be the sole hope of regenerating the European communities. In 1824 the fourth volume completed the work, and the *Defence* of the same date indicates the violent opposition he met with, not only from his natural enemies, the lovers of personal freedom in thought, science, and politics, sacred or civil, but from the Gallican bishops and monarchists, because he argued that all authority rests in the Holy See, and from his ultramontane friends, because he dared to support the Christian revelation by an analysis of human, or, as they considered, profane tradition.

Meanwhile Lamennais had become journalist on the *Conservateur*, with Chateaubriand, De Bonald, and De Villèle for his fellows in essentially political work. When in 1820 De Villèle became the chief of the ultras, or friends of absolute monarchy, Lamennais, who was not the monarchist they thought him, left the *Conservateur* with other contributors, named "the incorruptibles," and in the *Drapeau Blanc* and in the *Mémorial Catholique* he opposed his previous comrade. His principles compelled him to draw a firm line as to the divine right of even legitimate kings, especially in connexion with church supremacies. In 1823 he was before the tribunals for an article in the *Drapeau Blanc*. He went to Rome in 1824, and Pope Leo. XII., his admirer, offered him the cardinal's hat, which he refused. On his return he published *Religion in its Relations to Civil and Political Order*, the first volume of which was a picture of the religious state of France, and the second an attack on the competence of the assembly of the clergy in 1682 to decree the liberties of the Gallican Church. The law accepting these liberties, Lamennais was summoned before the state courts, and with all France keenly interested was condemned to pay a fine. From this time he broke with the legitimists and the liberals, and Rome became to him the only seat of the social problem. His ideal was a pure theocracy.

But in the *Progress of the Revolution and War against the Church* the element of popular political liberty began to appear, modifying such infallibility of the head of the church as deposing of princes and dispensing with oaths of allegiance taken by their subjects implied. The revolution of 1830 increased his popular leanings, and in the journal *L'Avenir*, which he founded in September with the mottoes "God and Liberty," "The Pope and the People," theories strange to ultramontanism were broached. With Lacordaire, Montalembert, Gerbet, and other disciples, he demanded rights of local administration, enlarged suffrage, universal and equal freedom of conscience, of instruction, of meeting, and of the press. Methods of worship were to be criticized, improved, or abolished, and all in absolute submission to papal spiritual but not temporal authority. The Jesuits and the prelates grew alarmed, and "the modern Savonarola" was denounced to Gregory XVI. On their spiritual obedience the writers of *L'Avenir* were ordered to suspend the journal, which they did (1831), and Lamennais, Lacordaire, and Montalembert set out for Rome to get the papal pardon and blessing. They were not received, and "Catiline departed," to be overtaken by a bitter encyclical letter at Munich from the pope condemning the new doctrines. So interested was Gregory in the questions raised that under an assumed name he published a work of refutation. To his demand of submission Lamennais signed obedience, with a saving clause as to his country and humanity. The iron had entered his soul, and deeply wounded he retired to La Chenaie, the scene of his youthful inquiries and memories. His genius had turned the entire Christian church against him, and those whom he fought for so long, the ultramontanes, were the fiercest of all his opponents. The famous *Words of a Believer* appeared in 1834, and his final rupture with the church took place. "Small in size but immense in its perversity," was the pope's criticism in a new encyclical letter. A tractate of aphorisms, it has the vigour and sacred breathing of a Hebrew prophet.

Henceforth Lamennais is the apostle of the people alone. The *Affairs of Rome and the Ills of the Church and Society* came from old habit of religious discussions rather than from his real mind of 1837, or at most it was but a last word. *Modern Slavery*, *The Book of the People*, *Politics for the People*, two volumes of articles from the journal of the extreme democracy, *Le Monde*, are titles of works which show that he has arrived among the missionaries of liberty, equality, and fraternity, and he soon gets a share of their martyrdom. *The Country and the Government* caused him a year's imprisonment in Ste Pélagie. He struggled through difficulties of lost friendships, limited means, and personal illnesses, faithful to the last to his hardly won dogma of the sovereignty of the people, and, to judge by his contribution to Louis Blanc's *Review of Political Progress*, was ready for something like communism. He was named president of the "Société de la Solidarité republicaine," which counted half a million adherents in fifteen days. The Revolution of 1848 had his sympathies, and he started *Le Peuple Constituant*, but was compelled to stop it on 10th July, complaining that silence was for the poor; but again he was at the head of *La Révolution Democratique et Sociale*, which also succumbed. He managed his own publications; and pamphlets without number, and at intervals volumes of *Mélanges*, kept his influence fresh and his republican aims to the front as much as possible. In the constituent assembly he sat on the left till the *coup d'état* of Napoleon III. in 1851 put an end to all hopes of popular freedom. While deputy he drew up a constitution, but it was rejected as too radical. A translation of Dante chiefly occupied him till his death in the fourth year of the second empire. He refused to be reconciled to the church, and was buried at Père La Chaise without funeral rites, according to his own directions, mourned for by a countless concourse of democratic and other admirers.

During the most difficult time of his republican period he had one resource by which to find solace for his intellect from the noise of daily politics. From 1841 till 1846 he was engaged on the work which will remain longest as evidence of his thinking power and of his clear brilliant style, his *Sketch of a Philosophy*. Of the four volumes, the third, which is an exposition of art as development from the necessities and aspirations of the temple, stands pre-eminent. The rest of the work somewhat answers to the modest title of the book. Some papers which he wished to be published intact after his death were kept back by the religious zeal of his brother and sister, but in 1855 and afterwards till 1859 six volumes appeared under the care of Émile Forgues. Blaize, the nephew of Lamennais, disputed various rights with Forgues, and in his biography of his uncle he questions facts in the account of the life prefixed by the editor to the *Posthumous Works*. But the whole matter is of private rather than public interest, affecting the position of Lamennais in little degree.

The complete works have been published twice at Paris, in 12 volumes, 1836–37, and in 11 volumes by Pagnerre, 1844 *sq.* Neither edition is anything like complete, but that of Pagnerre is the more so. Besides the biographical matter given by Forgues and Blaize as preface—the former to the *Posthumous Works*, the latter to the *Unedited Works*, Sainte-Beuve has Lamennais as one of his skilful *Portraits Contemporains*, Castille has him among the *Portraits politiques au dix-neuvième siècle*, and George Sand's thoughts of "the Breton" can be read in *French Authors at Home*. Robinet, Gerbet, and Regnault may be selected from many others who give personal details. Querard's *Les Supercheries Littéraires Devoilées*, article "La Mennais," will give ample introduction to all that is known of the author's works, and of the works connected with him. (T. SI.)

LAMENTATIONS. Book of. The Old Testament book of Lamentations bears in Hebrew Bibles the superscription אֵיכָה, "Ah how!" the opening word of the first chapter, and also of chaps. ii. and iv. The Talmud, however, and Jewish writers in general call it the book of קִינוֹת, "elegies" or "dirges,"[1] of which the Septuagint title Θρῆνοι and the Latin *Lamentationes* or *Lamenta* are translations. The fuller title *Lamentationes Jeremiæ Prophetæ*, *Lamentations of Jeremiah*, expresses the ancient tradition as to the authorship of the book. It is found in the Syriac and in some MSS. of the LXX., *e.g.*, in ℵ, but not in A and B; and the shorter anonymous form is undoubtedly older.

The dirges which make up the book are five in number, and the first four are alphabetical acrostics,—successive verses in chaps. i., ii., iv., or successive sets of three verses in the case of chap. iii., beginning with successive letters of the alphabet. The last chapter has twenty-two verses, like chaps i., ii., and iv., but is not an acrostic.

It is noteworthy that in chaps. ii., iii., and iv. the letter *Pe* (פ) precedes *'Ayin* (ע), contrary to the ancient and established order common to the Hebrew alphabet with its Greek and Latin derivatives, in which O stands for ע. The sense shows that this irregularity is not due to a transposition of the original order of the verses, while the fact that the same transposition occurs three times makes it plain that the deviation from the common order is not due to want of skill to make the acrostic perfect, but rests on a variation in the order of the alphabet as used by the author. Thus it has not unnaturally been argued by Thenius that chap. i., which takes the alphabet in the common order, must have a different author from chaps ii.–iv.; but it is quite as probable that in chap. i., as Ewald suggests in the 2d ed. of his *Dichter*, p. 326, ver. 16 originally followed ver. 17, and was transposed to reduce the acrostic to the usual form. In the other chapters the sense forbade such transposition.

The subject of the five dirges is not the death of an individual; they refer to a national calamity—the widowhood of Jerusalem and the overthrow of the Judæan state by the Chaldæans. But the examples of Amos v. 1, 2, Jer. ix. 19 [18], Ezek. xix., show that they are not less properly called dirges on that account; the lamentations of Israel over the desolation of Zion, the agonies of the last desperate struggle and the extinction of national existence, appropriately took a form modelled on the death-wail sung by "cunning women" (Jerem. ix. 17) and poets "skilful of lamentation" (Amos v. 16) at the wake (אֵבֶל) of the illustrious dead. Among the Hebrews, as among other primitive peoples, this type of poetry was much cultivated,

[1] This name, as will appear below, is perhaps as old as the book of Chronicles, and is the Hebrew title known to Jerome (*Prol. Gal.*).
